The Role of Management Accounting Methodology in the Forecasting of Regional Economy Development

Yuliya B. Rzhavina, Mari State University, Russia, barievna1@rambler.ru

Mariya V. Sayranova, Mari State University, Russia, vladi986@rambler.ru

Abstract

Modern business conditions require development of existing approaches to the management process. Domestic economy growth towards innovation implies enhancement of its efficiency. There is an increasing necessity for management improvement on every level: micro- (organization, business), meso- (regions, branches of activities) and macro- (country economy). Conceptual framework of management accounting in Russia has its own peculiarities associated first of all with the history of its development, traditions of national accounting school and adjustment of global practices to management tasks. Modern management accounting principles are based both on traditional accounting elements and on particular tools of management accounting subsystems. Management accounting information can be important not only for a particular business entity internally, but also for timely long-ranged decision-making at a higher level of economy management. Thus consolidated theme-based managerial reports will extend the opportunities of analytical procedures of higher-level management bodies for the purpose of regional economy control. The fact that currently all the potential opportunities of management accounting tools at a regional level are not fully used generates the need for further researches within this topic.

Keywords: management accounting, business accounting, tools, forecasting, regional economy.

Introduction

Existing principles and peculiarities of market relations predetermine the development of business environment. In the economic system of every country containing features of market economy business entities are working in a competitive environment under natural scarcity, risks and uncertainty. Modern development of domestic economy towards innovation implies enhancement of its efficiency. Generated amendments of management methodology expect to elaborate new and to improve existing informational flow systems. Such conditions are leading to increase of necessity for management improvement on each level: micro- (organization, business), meso- (regions, branches of activities) and macro- (country economy).

The Method

Management system should ensure efficiency of business processes related to products (works, services) distribution to the ultimate consumer while management should receive full and exact information necessary for decision-making, analysis and control of current processes at different levels. Thus requirements for management information are increasing which is leading to a need to organize some tools contributing to the receipt of timely and full information reflecting the condition of internal and external environment (Rzhavina, Y.B., 2013).

The Research

A lot of foreign and national theorists and practitioners have been always interested in the origin and development of management accounting, its essence and role in the process of operation control. A great number of management accounting definitions can be found in various literature sources of recent years. The main point and the purpose of management accounting is widely described by the famous wording: “production of the information for management purposes” (Sokolov, 1996).

Accounting for the purpose of management, as confirmed by historical evidence, has been developed in line with book-keeping science and practice. For this reason economists of different countries acquire its own understanding and appliance of management accounting. Analysis of accounting evolution from its origin to this day allows for the conclusion that management accounting has appeared as a consequence of traditional accounting weak points (Rzhavina, 2015). Many elements of management accounting were not something new for the domestic economy. For a long time Russia has been stayed an agricultural country with a simple accounting based on the entries of debt and credit (unigraphic recording). By the end of XIX century in line with increase of industrial facilities and development of production accounting within various emerging accounting theories it can be talk of the first reference to management accounting. Russian experience highlights a successful development of industrial book-keeping which has been improved both in industrial activity and in building sector. Extensive use of budget estimates was a prototype of budgeting in its modern sense. Accounting development as a science required involvement of budget planning, forecasting, control and economic analysis to adjust accounting for management purposes (Sokolov & Sokolov, 2006). Modern principles of management accounting are based both on traditional accounting elements established by law (documentation and inventory, assessment and calculation, accounts and double entry, balance consolidation and reporting) and on particular methods of such management accounting subsystems as planning, analysis, control and monitoring (Rzhavina, 2013). Development of informational technologies provides management accounting with an opportunity to use the results of conducted researches on simulated models capable to find solutions for semi-structured tasks (Vahrushina, 2008).

Conceptual framework of management accounting in Russia has its own peculiarities associated first of all with the history of its development, traditions of national accounting school and adjustment of global practices to management tasks (fig. 1) (Rzhavina, 2013).

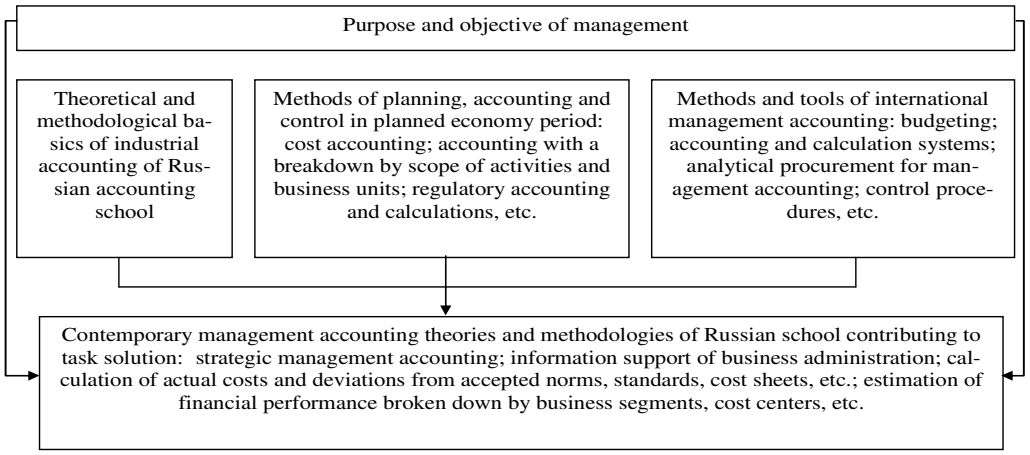

Fig. 1: Contemporary framework of management accounting in Russia

Obviously the development of efficient management accounting system depends not on the improvement of existing accounting tools but on identification of the principal informational needs of management on various levels and looking for appropriate and reasonable solution approaches. All methods of management accounting pursue the same goal – to provide with a real opportunity to select a reasonable management decision based on the comparison of alternatives generating a single organizational system which gives a possibility to find effective and intelligent solutions for retrospective, current and future predictive tasks.

Nowadays there is a great variety of management accounting organization and implementation forms used in domestic practice due to the lots of external functioning factors primarily political, economic and social as well as internal such as organizational and technological. Russian legislation does not cover management accounting. Every business entity considers necessity of implementation of

management accounting system, methods and managerial reporting standards individually (Rzhavina, 2013).

Management accounting information can be important not only for a particular business entity internally, but also for timely long-ranged decision-making at a higher level of economy management. Management accounting methods (devices and tools) used to consolidate management information can also be applicable at a regional level. As an example consolidated theme-based managerial reports of a public nature which do not contain any commercially sensitive information but extend the opportunities of analytical procedures of higher-level management bodies for the purpose of regional economy control. Similarly to accounting (financial) or statistical reporting which is provided to government agencies by every business entity based on regulatory requirements, managerial reports will be received by relevant departments in due time. Essential, supplementary and operational information which is obtained will generate an opportunity for executive authorities to use predictive and analytical tools of regional economic policy more efficiently. The content of managerial reporting, its purposive character, cycling and level of detail depend on its prospective users (Rzhavina, 2015). General scheme of managerial reporting levels of a region which are similar to managerial reporting levels of a business entity is as follows (fig. 2):

Fig. 2: Regional managerial reporting levels

Russia is a heterogeneous country with its specific spatial features, ethnic composition, natural and climate conditions causing the significant difference of economic opportunities and development level between regions. Socio-economic position of every region as a complicated system is influenced by both objective or external factors including macroeconomic conditions, geographic location, sectorial structure, natural resources and subjective or internal factors reflecting the quality of management tools (Nesterova & Osipova, 2014). Nowadays economic development is associated not so much with growth in volumes, but first of all with quality changes. The priority is given not to resource availability but to efficiency of its usage (Tsaregorodtsev & Sayranova, 2015).

All business entities of a region compose a sole object of regulation and development. Renovation of forecasting and planning techniques in all spheres of regional economic policy contributes to correspondence of goals and development objectives between region and particular business entities (Ataeva, 2015). In such case it is possible to apply management accounting techniques based on stated goals and objectives specific for every branch of a region. Therefore particular requirements for management accounting process will depend on specifics of workflows standard for each branch of a region. The point to be emphasized is that implementation of a system approach implying consistent organizational, informational and methodological support with a glance to peculiarities of every existing accounting system is of a great importance.

Conclusion

Currently management accounting tools are not fully implemented at the level of regions and branches due to the lack of theoretical, methodological and instructional researches in this area. Therefore it is necessary to elaborate methodology of accounting management as well as to improve procedural tools considering given specifics. Adjustment of management accounting techniques in terms of forecasting of regional economy evolution will provide with an opportunity to find the most efficient paths for development.

Abstract

The article deals with modern problems of social and economic development of Russia and its regions. The authors pay special attention to the innovative development of industry in Russian regions. They investigate factors, sources and technologies of sustainable growth of the regions, analyze the dynamics of indicators that characterize the place and role of the innovation component in these processes and justify the innovation of management of the economy of Russian regions as the dominant pattern of their development. In this regard, the main focus is on the creation of innovative industrial clusters in the regions, high-tech industries based on breakthrough technologies; the priorities and risks of forecasting the processes of innovation management of the economy of Russian regions are determined; the development of dynamic forecasts and simulation models for the development of sectorial clusters is carried out.

The research is supported by the grant of the Russian Science Foundation № 16-18-10017 "The complex of programs for forecasting the economic development of the region"

Keywords: forecasting, innovatization, risks, modeling.

Introduction

Objective. The aim of the study is to justify priorities and risks of forecasting the innovatization in managing the economy of Russian regions. In that context, the problem of regulating the system of managing the innovative development of enterprises in industrial complex of Russian regions and the rationalization of priorities and risks of these processes acquire special significance. Due to the insufficiency of their theoretical development and under the influence of external and internal disturbances, the regional structure of the industrial system can become unbalanced with pronounced social and economic contradictions. Therefore, this problem remains relevant, and upholds its theoretical and practical significance and prospective viability.

Methodology/Approach and Results

To achieve this goal, a holistic approach and a method of structural and logical decomposition to the study of priorities and risks of forecasting innovation in the management of the economy of Russian regions were used. It made it possible: to justify priorities, to identify the risks of forecasting innovation in managing the economy of Russian regions. The reliability of forecasted priorities and risks of sectorial clusters in the process of forming a model of indicative management of innovative development of enterprises of the industrial complex of Russian regions makes it possible to take proper managerial decisions to ensure their efficiency.

Originality/value

The originality of the research is in presenting the innovation of managing the economy of Russian regions based on justified assessment of priorities and risks as a process of accumulation, preservation, use and development of traditional capacities of innovative management of economic entities in the system of interaction between business, government and society. The article justifies

the need for the development of innovative industrial clusters as the basis for modernizing managerial processes in the regional economy of Russia. It is proved that the forecasting of risks of industrial clusters in the process of forming a model of indicative management of innovative development of enterprises of an industrial complex of Russian regions gives the possibility of taking proper managerial decisions to minimize them and targeted measures to support and stimulate innovative activities.

Theoretic Articulation of the Issue

All economic processes at any level of the economic system can be divided into traditional and innovative ones, which form traditional and innovative spheres of activity, having specific features at various stages of technical, technological, organizational, managerial, socio-economic and institutional development of a particular society. For example, traditional forms dominated in pre-industrial national spatial economic systems and primitive forms of innovative relations are only beginning to form. There prevailed material traditions with mild continuous improvement. Industrial society is characterized by the optimization and rigidity of the process of sustainable transformation of innovative and traditional relations. In this economic system, there is a predominance of orientations to innovative material forms and industrial technologies in its structure. The specific feature of the post-industrial period is a steady demand for intellectual innovations.

World theoretical and practical experience shows that one should take into account what forms, levels and ways of their interaction are preferable for it - routine, innovational or innovative in choosing the priorities in traditionalization and innovatization of the structures of sustainable development of a national economic system at all its levels apart from the criteria and levels of traditionality (basic, carrying fractals) and innovativeness (for different typologies in economic science: breakthrough, basic, improving, supplementing) material and immaterial, intangible benefits). We need to develop fractal properties and/or to create our own innovations, and/or to borrow them from other economic systems. At the same time, the circumstances of traditionalization and innovatization of specific spatial economic systems require clarification of the question of the alternative or complementarity of the main forms of innovation.

The orientation towards innovation, that is, the creation, accumulation, preservation, use and development of one's own breakthrough innovations, implies the partnership of business, government and society, which should support and ensure the development of the research and development sector, as well as the corresponding infrastructure (technology parks, innovative incubators, centers of prototyping and commercialization of technologies, etc.). The choice of the vector of innovative development, which is carried out with the help of technologies borrowed from other national economic systems, requires a different structural budgeting and strategy in this economic space. For example, the positive experience of Japan and South Korea shows that at the first stage of innovation of the structures of development of their national economic systems, the innovative form, that is, the borrowing of foreign technologies, dominated. Later an innovative form, which, at present, is the dominant and priority-oriented one, has balanced it out.

K. Peres revealed the negative consequences of the use of innovative forms of strategizing of the innovatization of spatial patterns of development of national economies in Latin America countries. In the 80-90-ies of the last century outdated technologies of the previous (the fourth) wave of technology were exported to these countries as on to the periphery, while the highly developed countries had already begun the distribution of the next, fifth, wave technology. As a result, with the help of outside funds, Latin American countries managed to create the infrastructure corresponding to the borrowed technologies that at that time was not able to give a full pay-off due to technologies of the fourth wave, which had already become potentially outdated. It all resulted in a debt crisis in this group of countries, Perez C. (2002) and Schumpeter J.A. (1982).

Specific features of Russian economy determine priorities for the innovatization of spatial structures for the development of economic systems at all levels, in all its sectors and spheres. On the one hand, the country has a scientific and productivity base (unlike Japan and South Korea in the middle of the last century) for an innovatization form of development based on its own breakthrough technologies.

On the other hand, there is a significant differentiation and disparity in the levels of innovatization in the spatial structures of the development of regional economic systems and their serious lag behind the level of foreign countries economic development. However, the strategic planning of an innovative form of development based on its own breakthrough technologies throughout Russia is too risky, and the orientation toward borrowed foreign technologies may not give the desired effect, fixing its peripheral position in the processes of innovatization at the mega-level .

It is extremely important to monitor the innovative potential in the field of creating or borrowing new technologies when choosing priorities for the innovatization of spatial structures of the development of the national economic system of Russia. The analysis showed that some regions of Russia could reproduce on their territory a development model based on the creation of breakthrough technologies, the other part of regions can specialize in borrowing already existing technologies. This will contribute to the diversification of the processes of innovatization in the spatial structures of the development of Russia's national economic system, which will reduce the risks in implementing various areas of its innovation policy.

World experience in supporting the innovatization of local structures of the development of national economic systems shows that it turns out to be the most effective at the meso level, on which individual regions and cluster entities are concentrated. The support and stimulation of the innovatization of the structures of their development, depending on their particular characteristics, is carried out both by alternative approaches and by complementary forms and methods that ensure the sustainability of innovatization of local structures for the development of national economic systems.

The problem of sustainability and its solution is based on maximization of the innovative potential of regional structures for the sustainable development of the national economic system. In the light of this, there is a need to define, regulate and maintain regional sustainability that corresponds to the initial assumptions and principles of innovation.

There are various approaches to definition of regional stability of development of an economic system: on the one hand, this category is disclosed as a guarantee for its purposeful movement; on the other hand, regional stability is characterized as the immutability of the trajectory of an economic system, as well as the form of proportionality of social reproduction.

We believe that the fundamental element of the regional stability of structures of national economic system development is their ability to generate innovation and innovative conditions, factors and prerequisites at all levels of the hierarchy of the economic system. We regard regional stability in this respect as a property of the regional economic system to create and maintain such fractal links between the structure-forming elements that support all the necessary parameters of its dynamic renewal at a given level with the purpose of its efficient functioning in a competitive environment.

With that, we note the unity of regional stability and the variability, equilibrium and non-equilibrium of regional structures of dynamic development of an economic system. In that context, the process of innovatization of the structures of regional sustainable development of economic systems is represented by a short-term stable initial criterion for the transition of the regional economy from uncertainty, disequilibrium and unbalance to a state of stable, balanced, conformal and coordinated dynamic development. That particular of all others predetermines the algorithm for the innovatization of regional structures for the sustainable development of economic systems

The Management of the Innovatization of the Industrial Complex of Russian Regions

The problem of regulating the system of management of the innovatization of the industrial complex of Russian regions is now acquiring special significance, since under the influence of external and internal disturbances the structure of the industrial system can become unbalanced with pronounced social and economic contradictions. An example of this is the world economic crisis of 2008, which became a kind of catalyst for the manifestation of negative phenomena in the social and economic life of most Russian regions. In particular, we are talking about a decrease in the level of business

activity, production volumes, profits, real incomes of the population, rising unemployment, increasing debt burden, decreasing liquidity, etc. The macroeconomic indicators presented in Table 1 indicate that the pace of socio-economic development has now sufficiently slowed down.

Table 1: Dynamics of macroeconomic indicators in the Russian Federation for years 2003-2016

The indicator	2003	2004	2005	2006	2007	2008	2009	2010	2015	2016
GDP growth rate, in % vs. to the prior year	107,3	107,2	106,4	108,2	108,5	105,2	92,2	104,3	104,3	103,4
Investment growth rate in % vs. to the prior year	112,5	113,7	110,8	116,7	122,7	109,9	84,3	106	108,3	106,6
Retail sales growth rate, in % vs. to the prior year	108,8	113,3	112,8	114,1	116,1	113,6	94,9	106,4	107	106,3
Profit margin in all the activities, in billion rubles	2 324	3 214	4 556	7 145	7 290	3 985	5 335	7 870	9 725	7 824
Real disposable household income of the population in % vs. to the prior year	115	110,4	112,4	113,5	112,1	102,4	103,1	105,1	101,2	105,8
The number of citizens with substandard income, in % to the total population	20,3	17,6	17,7	15,2	13,3	13,4	13	12,7	12,5	10,9
The unemployment level, in % to economically active population	8,6	8,3	7,7	7,3	6,3	6,5	8,7	7,3	6,5	5,5

Table 1 shows that almost all indicators characterizing the dynamics of development and the growth potential (investment) of Russia in recent years have a pronounced downward trend. In particular, the growth of industrial production following the results of 2016 significantly slowed down and amounted to only 3.4%. In these conditions, an important prerequisite for the development of industrial production is through intensive use of the resource base, the key factor in the development of which is innovatization.

Despite all the negative factors, the innovative scenario for the development of the economy of the Russian regions, developed by the Ministry of Economic Development of the Russian Federation, provides for an increase in the share of the innovation sector to 20% of GDP by 2030. Main problems of innovative industry development in Russian regions, where most of which still remain subsidized, are the following:

- a cut in prices at world commodity and raw materials stock exchanges, which will affect export comings, stability of the budget sector, the structure of domestic demand and inflation;

- the dependence of the balance of payments of Russia and the entire Russian financial system on capital flows and instability of global financial markets will increase;

- the cyclical development of the economy, which is reflected in the changes in the situation and other conditions of operation of industrial enterprises will contribute to crisis phenomena.

In general, only an innovative development scenario, in which the accelerated development of non-commodity sectors and the expansion of the national savings base are expected, in the end will manage to enhance the resistance of Russian regions' economy to possible destabilizing factors. In that context, regional authorities should focus on creating innovative industrial clusters; high-tech industries based on breakthrough technologies; scientific and innovation techno parks, engineering centers and technology transfer centers, design firms, testing laboratories, business incubators.

Their priority development should be based on the strategies of regions, designed for a long-term period. Cluster development programs should carry out a detailed strategic and cluster analysis of the regional economy and involve all stakeholders: government authorities, business, business associations, research and educational institutions, financial institutions.

Clustering As a Prime Organizational and Managerial Form of Innovatization in the Economy of Russian Regions

Clusters are to strengthen the innovative component of sustainable development of regional economies, because:

- regional innovation and industrial clusters are based on the established stable system of distribution of new technologies, knowledge, products, the so-called technological network, which has a joint scientific basis

- cluster enterprises have additional competitive advantages due to the possibility to carry out an internal specialization and standardization, to minimize the costs to introduce innovations;

- an important feature of innovative and industrial clusters is the presence of flexible business structures in their organization - small enterprises that gives the opportunity to form innovative points of economic growth in the region.

- regional industrial clusters are extremely important for the development of small business: they provide small firms with a high degree of specialization in servicing a particular business area, as this facilitates an access to the capital of an industrial enterprise, active exchange of ideas and transfer of knowledge from specialists to entrepreneurs take place;

- clusters provide the authorities with tools for an effective interaction with business, enable them to advance the adoption of organizational and economic decisions in the cluster;

- the staffing of enterprises improves, the infrastructure of research and development appears;

- clusters stimulate labor productivity and the promotion of innovations.

One of the results of successful state indicative management of innovative development of an industrial complex is the increase in the number of small innovative companies. With that, the innovation economy is intends to increase the level of investment attractiveness of a regional system and its image. Small innovative business is developing quite dynamically in the cluster model of spatial organization of region's economy. At present, the cluster approach in ensuring innovative development of industrial enterprises is actively used in many regions of the Russian Federation, namely in the Samara, Kaluga, Yaroslavl, the Tatarstan Republic and the Bashkortostan Republic, St. Petersburg, and others. In return, the intensity of innovation in industrial production determines the strategic positioning of regional industrial systems in general. The Primorsky Region, Magadan, Tomsk, Nizhny Novgorod Regions, the Chuvash Republic, the Sverdlovsk, Samara Regions, the

Republic of Tatarstan, the Orlov and Orenburg Regions occupied the first 10 positions in innovative activity from 2005 to 2016.

By the number of advanced production technologies created and used, it is possible to determine the direction of innovation activity in the regions, which also influences their innovative activity. One can see from Table 2, where the first 15 positions in these indicators are identified, that most organizations use ready-made technologies.

Table 2: Regions - leaders in the number of created and used technological innovations

The number of created technologies		**The number of used technologies (technologies, put into action)**	
Nizhny Novgorod Region	307	Nizhny Novgorod Region	109513
Moscow Region	272	Moscow Region	59099
Sverdlovsk Region	195	Sverdlovsk Region	50748
Samara Region	126	Tula Region	40561
Chelyabinsk Region	120	The Republic of Bashkortostan	29580
Novosibirsk Region	111	Samara Region	26848
Kaluga Region	90	Tyumen Region	25918
Tyumen Region	87	Saratov Region	24439
Voronezh Region	78	Perm Region	24218
Vladimir Region	45	Chelyabinsk Region	21220
Saratov Region	75	Kaluga Region	18763
Krasnoyarsk Region	68	The Udmurt Republic	17975
Belgorod Region	62	Omsk Region	16631
Perm Region	62	The Republic of Tatarstan	14697
Rostov Region	55	Vologda Region	13656

A peculiar feature of the Russian model of innovative development of enterprises in the regional industries is a sufficiently high scope of asymmetry. In particular, in terms of innovation activity, the scope of intra-regional asymmetry was 15.5 in 2016, compared to 25.5 in 2005. Thus, in 2005 the highest level of innovative activity was recorded in the Perm Region (33, 2%), and the lowest in the Amur Region (1.3%). In the year of crisis - 2008 - this ratio decreased to 11.2 (in the Magadan Region - 26.9%, in the Altai Republic - 2.4%). Gradually, in 2009 and 2010 the ratio decreased to 11.1: in 2009 in the Magadan region - 33.3%, in the Sakhalin Region - 3%, in 2010, respectively, 34.3% and 3.1%. In 2016, the scope of asymmetry declined, with the largest value also recorded in the Perm Region (23.2%), the smallest in the Altai Republic (1.5). Consequently, the level of territorial differences, despite the crisis, is gradually decreasing. The 2008-2009 crisis could explain that, when the regions needed to protect their economies by taking innovative decisions in business and industry. Transformation of economic conditions, increasing risks of financial and investment environment contributed to the fact that the positions of many regions have changed. Specifically, regions with a lower level of innovative activity advanced higher in rating (the Magadan Region in 2005 - 6.2%, in 2016 - 34.3%), or, quite the opposite, there is a tendency to decrease activity in some other regions (in 2005 in the Perm Region 33.2%, in the Sakhalin Region - 6.2%, in 2016 - 21.3% and 3.1%, respectively) Postaliuk M and all (2013)

We also note that the level of innovation activity in the industry of the regions should serve as a kind of barometer that correctly sorts out priorities in structural and technological policies, taking into account changes in research and development, the quality of researchers and R & D expenditures, the level of technology of production and labor productivity. Over time, the innovative component of the development of industrial will go up, as the introduction of innovations contributes to the competitive growth and adaptive effectiveness of its development Golichenko O. (2012).

Forecasting risks of innovatization in managing the economy of Russians regions

We note that in order to build a model for forecasting innovation in managing the enterprises in the industrial complex of regions, especially important is to have information about the projected risks in key industries Postaluk M.P. and Vafin A.M. (2015). At the same time, our research considers only internal risks of enterprises of regional industrial clusters, which largely simplifies their forecasting. External risks are rather difficult to forecast, and certain data on them for the future are contained in official government documents. As for the organizational, structural, technological, economic and social risks inherent in individual sector clusters, they are rather inertial, and there are no dramatic changes in the estimated parameters of the above-mentioned risks Glazyev S. and all (2002). This happens because the risks under consideration take place due to the state of the technical and technological level of the industrial potential of sectorial clusters in the regions, formed by their organizational structure, etc.

Forecasting the risks of sectorial clusters in the process of regional management is a difficult task, especially due to the insufficient degree of reliability of economic forecasts in the realities of the Russian economy is not high enough Lurie E.A. (2009).

The appearance of dynamic forecasts, and later on the elaboration of simulation models and territorial industrial meso models made it possible to study and present the trajectories of the development of industrial clusters. In dynamic models the interrelationship between the individual elements of an economic complex of the region and the conditions of their development over time experienced a more detailed examination, but the influence of technological links between the objects of specialization, servicing and auxiliary industries, consumption norms of many local resources and the scale of development of individual elements of the production infrastructure limited it Granberg A.G. (1985).

A cluster model of an economic complex of the region can be built only after the determination of its structure, trajectories of development of individual sectorial clusters and the system as a whole. The beginning of the use of alternative graphs, the development of linear-linguistic models, expert systems is the next stage in the development of forecasting models is the next step in the development of forecasting models Bodrunov S.D. (2013).

In order to forecast the risks of regional industry clusters, within the framework of this study, we have chosen a forecasting method based on autoregressive models of the integrated moving average (ARIMA time series). This method, unlike the regression analysis, for example, does not take into account causal factors, but it makes it possible to reveal tendencies, cycles and other systematic characteristics of statistical time series. It is a very accurate method of short-term (up to two years) forecasting, but with longer terms, its accuracy drops sharply.

ARIMA models rely mainly on the autocorrelation structure of the data. The ARIMA methodology does not provide for any clear model for predicting this time series. Only a general class of models is defined, which describe the time series and make it possible to somehow express the current value of a variable through its previous values. Then the algorithm, substituting the internal parameters, itself selects the most suitable forecasting model. There is a whole hierarchy of Box-Jenkins models. Logically, it looks as follows:

$$AR(p)+MA(q) \rightarrow ARMA(p,q) \rightarrow ARMA(p,q)(P,Q) \rightarrow ARIMA(p,q,r)(P,Q,R) \rightarrow$$

The Box-Jenkins forecasting methodology differs from the most of other methods, because it does not allow any particular structure of the data of the time series, for which the forecast is performed. It uses an iterative approach to the definition of an admissible model among the general class of models. Then the chosen model is compared with the historical data in order to check whether it describes the series accurately. The model is regarded as acceptable if the balances are generally small, distributed randomly, and do not contain useful information. If the given model is not satisfactory, the process is repeated, but already with the use of a new improved model. Such an

iterative procedure goes on until a satisfactory model is found. From that point on, the predetermined model can be used for forecasting purposes.

The risk forecast of regional industry clusters was carried out in the short-term perspective using the Box-Jenkins method. We chose this method not only due to high accuracy of the forecast, but also due to the accepted provision that the risks can be predicted for a longer term only with a high degree of conventionality.

Within the framework of this study, an attempt was made to forecast the risk profile of sectorial clusters of the Republic of Tatarstan, using the example of a petrochemical cluster. To do this, the «Matrixer» program was used, which is intended for data analysis and processing, econometric and statistical calculations. Using this program, it is possible to evaluate the following models (and test hypotheses about them): linear regression, nonlinear regression, binomial logit and probit, and many other models. Therewith, this program works with the following types of objects: matrices, variables (columns of matrices), scalars, rows and models.

According to the results obtained, the organizational, structural, technological, economic and social risks of the petrochemical cluster will decrease in the short-term perspective, but insignificantly (see figures: 1, 2, 3, 4).

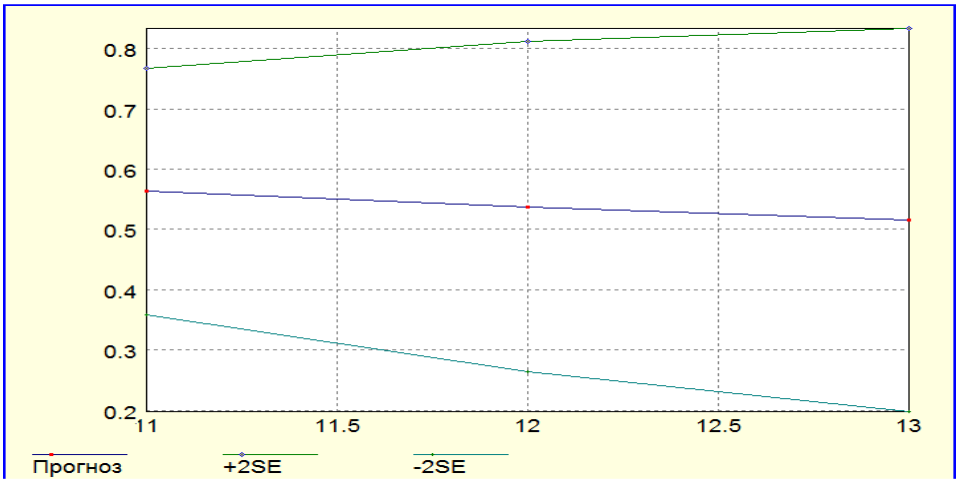

Fig. 1: The forecast of organizational market risks in a petrochemical cluster of the Republic of Tatarstan.

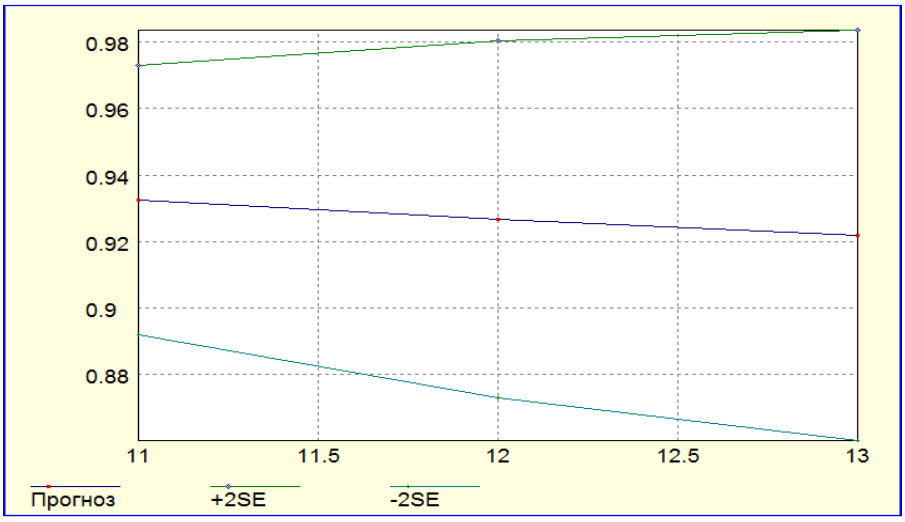

Fig. 2: The forecast of technological risks in a petrochemical cluster of the Republic of Tatarstan

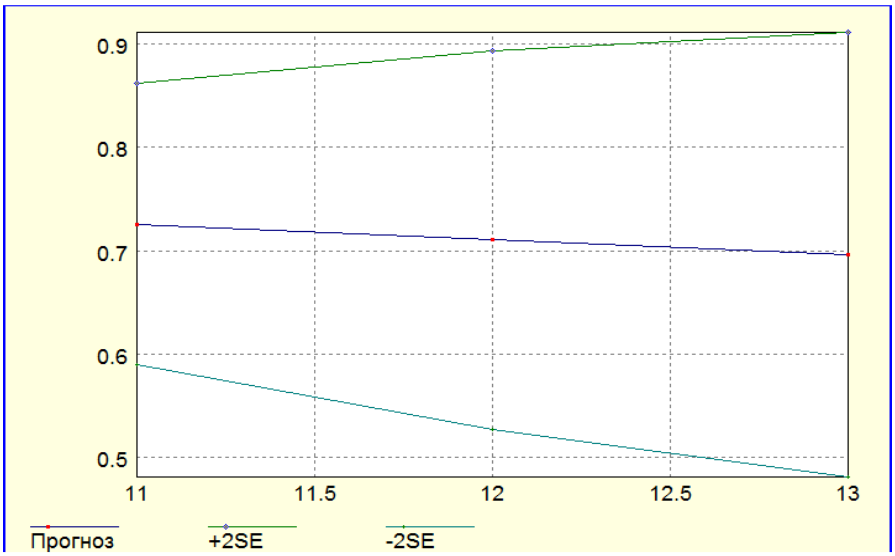

Fig. 3: The forecast of economic risks in a petrochemical cluster of the Republic of Tatarstan

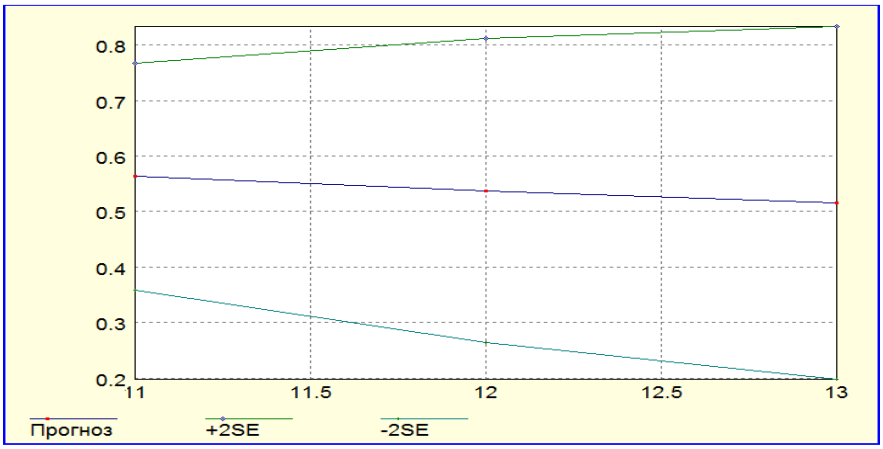

Fig. 4: The forecast of social risks in a petrochemical cluster of the Republic of Tatarstan

When constructing the forecast of the risks of the petrochemical cluster of the Republic of Tatarstan, one of the simplest models of Box-Jenkins was used (1.0.0) - an autoregressive function. The accuracy of the model characterizes the closest proximity of calculated observations to the actual one at the approximation period. We concluded that models with a smaller discrepancy between actual and calculated values reflect better the process under study. To characterize the degree of proximity, the following coefficients were used: the coefficient of determination (the closer to 1, the more accurate is the model); The average relative approximation error (the closer to 0, the more accurate is the model). For all the given parameters, the forecast values correspond to the requirements.

Minor risk reduction, in our opinion, is because this cluster is the most developed, has a good resource development potential, and concentrates sufficiently large investment flows. It is important that many priority projects of the petrochemical cluster of the Republic of Tatarstan have already been implemented, or are under implementation. However, the risk structure does not change. In this case, at the regional level, it is necessary to take measures aimed, first, at reducing technological risks, overcoming the technological and technical backwardness of petrochemical industries.

Conclusions

Forecasting the level of innovation activity in the industry of regions should serve as a kind of barometer that gives the possibility to sort out correctly priorities in structural and technological policies, taking into account changes in research and development, the quality of researchers and R & D expenditures, the level of technical equipment of production and labor productivity. The innovative component of the development of industrial enterprises in future should increase, as the introduction of innovations contributes to the recovery of competitiveness and adaptive effectiveness of its development.

Forecasting the risks of sectorial clusters in the process of forming a model of indicative management of innovative development of enterprises in the industrial complex of the regions, makes possible to take adequate management decisions to minimize the risks and target measures to support and stimulate innovation.

Abstract

The paper deals with testing different strategies - Inertia Weight Strategies, Constriction Factors and Interpersonal Learning – of a Particle Swarm Optimization implemented in a simulation optimizer. The strategies were tested on five different discrete event simulation models reflecting real optimization problems in industrial companies. We specified different objective functions of discrete event simulation models considering the simulated system. We tested different settings of the strategies to reduce bad settings. We replicated optimization experiments with concrete optimization method parameters settings to reduce the randomness of the behaviour of the optimization method strategies. We evaluated the success of finding the optimum by the different PSO strategies according to other optimization methods - Random Search, Downhill Simplex, Hill Climbing, Tabu Search, Local Search, Simulated Annealing, Evolution Strategy, Differential Evolution and Self Organizing Migrating Algorithm.

Keywords: Particle Swarm Optimization, discrete event simulation models, PSO strategies, heuristic optimization methods

Introduction

Simulation optimization is a commonly used problem-solving technique for finding the global/local optimum of the optimized objective function respecting the specified constraints. The equation reflects a process of finding a possible – feasible - solution (suitable settings of decision variables) using experimentation with a discrete event simulation model reflecting the modelled problems. (Volna, 2012), (Weise, 2009)

$$\breve{\mathbf{X}} = \operatorname{argmin}_{\mathbf{X}\in\tilde{X}} F(\mathbf{X}) = \{\breve{\mathbf{X}} \in \tilde{X}: F(\breve{\mathbf{X}}) \leq F(\mathbf{X}) \forall \mathbf{X} \in \tilde{X}\} \quad (1)$$

- $\breve{\mathbf{X}}$ denotes global minimum of the objective function;
- $F(\mathbf{X})$ denotes the objective function value of the candidate solution – the range includes real numbers. The objective function represents the aim of the simulation optimization;
- $\tilde{X}$ denotes the search space.

The objective function represents the quality of the found solution compared to the modelled problem. The objective function/s can reflect company activities i.e. production, logistics, sales, supply, the appropriate use of company resources - employees, machines, materials, etc. The objective function maximization can be converted to function minimization.

Simulated problems are often NP-hard problems, so we use the simulation optimizer using different (heuristic, metaheuristic, etc.) optimization methods to find the optimum of this function. The simulation optimizer automatically varies the input parameters of the discrete event simulation model to find the

suboptimal or the optimal feasible solution of the modelled problem. The simulation optimizer provides the suitable settings for the decision variables of a simulation model.

Particle Swarm Optimization – PSO

The PSO algorithm is a stochastic population-based optimization method proposed by Eberhart and Kennedy in 1995. (Eberhart & Kennedy, 1995)

PSO is a computational method, which optimizes a problem iteratively, trying to improve a candidate solution. PSO is a form of swarm intelligence simulating the behaviour of a biological social system i.e. a flock of birds or a school of fish. (Parrish & Hamner, 1997)

When a swarm looks for food, its individuals will spread in the environment and move around independently. Each individual has a degree of freedom or randomness in its movements, which enables it to find food accumulations. Therefore, eventually, one of them will find something digestible and, being social, announces this to its neighbours. These can then approach the source of food. (Weise, 2009)

Particle Swarm Optimization has been discussed, improved, and refined by many researchers such as (Bonyadi & Michalewicz, 2017), (Cai, et al., 2004) , (Sun, et al., 2012), (Venter & Sobieszczanski-Sobieski, 2003), (Zhan, et al., 2009)

Comparisons with other evolutionary approaches have been provided by Eberhart and Shi. (Eberhart & Shi, 1998)

We use a Box constraint – the search space is limited:

$$\tilde{X}_j = b_j - a_j, a_j \leq b_j \tag{2}$$

$$\tilde{X} = \prod_{j=1}^{n} \tilde{X}_j \tag{3}$$

- j denotes the index of the decision variable of the simulation model;
- $\tilde{X}_j$ denotes the length of the interval of the j-th decision variable;
- a_j denotes the lower bound of the interval of the j-th decision variable;
- b_j denotes the upper bound of the interval of the j-th decision variable;
- n denotes the dimension of the search space.

The swarm of particles (individuals) is generated in the search space. This initial generation of the set of particles usually uses random distribution. To distinguish these particles from each other, the generated particles are placed into a list. Each item can be accessed by its index in this list:

$$p_i = ParticleList[i] \forall i: i = \{0,1,2, \dots, m-1\} \tag{4}$$

- p_i denotes the i-th particle;
- $ParticleList$ denotes the list of particles;
- m denotes the length of the list.

Each particle represents the candidate solution - the individual - in the list of the generated candidate solutions – population – in the context of population-based algorithms. Each particle p has a position $p.X$. This position is the vector of point coordinates of each axes in the n-dimensional search space - the values of each decision variable of the simulation model in our case.

Some optimization algorithms need to access these values, so the element is transformed into a list of values of decision variables (vector of point coordinate in the search space). Decision variables – simulation model input parameters - represent the axes in the search space. These axes are indexed from zero to $n-1$:

$$p.X[j] = x_j \forall j: j = \{0,1,2,\dots,n-1\} \quad (5)$$

- $p.X[j]$ denotes the position of the particle in the n -dimensional search space;
- x_j denotes the point coordinate in the search space.

Particle swarm optimization uses a velocity vector to update the current position of each particle in the swarm.

The position of each particle is updated based on the social behaviour that a population of individuals, the swarm in the case of PSO, adapts to its environment by returning to promising regions that were previously discovered. The process is stochastic in nature and makes use of the memory of each particle as well as the knowledge gained by the swarm as a whole. (Venter & Sobieszczanski-Sobieski, 2003)

The velocity vector $p.V$of the particle p determines in which direction the search will continue. If this vector contains high values of velocity, the search for the optimum has an explorative character. Otherwise - low velocity, the search has an exploitive character.

The positions and velocities of all particles are randomly initialized in the initial phase of the PSO algorithm. The velocity of a particle is updated and then its position in each step. Therefore, each particle has a memory holding its best position $p.X_{best}$. In order to realize the social component, the particle furthermore knows a set of topological neighbours. This set could be defined to contain adjacent particles within a specific perimeter, i.e., all individuals that are no further away from the positon of the particle than a given distance according to a certain distance (Euclidian distance). (Weise, 2009)

For convenience, we assume that the optimization algorithms solve the minimization problem (function maximization can be converted to function minimization).

The following algorithm – see Fig. **1** - contains the following parameters:

- m denotes the number of generated particles;
- n denotes the dimension of the search space;
- $X[j].\mathrm{LowerBound}$ denotes the lower bound of the j-th decision variable;
- $X[j].\mathrm{UpperBound}$ denotes the upper bound of the j-th decision variable;
- $ParticleList$ denotes the list of particles; p denotes the current particle;
- g_{best} denotes the best found global particle from the list of particles (swarm);
- $\mathrm{Rnd}(x.y)$ denotes the function returning a single uniformly distributed random number in interval $[x, y)$;
- $p.X[j]$ denotes the position of the particle – point coordinate of the j-th decision variable;
- $p.X_{best}$ denotes the positon of the best found particle during its existence;
- $p.F_{best}$ denotes the objective function value of the best found particle during its existence (we use the objective function as the fitness function)
- $p.V[j]$ denotes the velocity of the particle of the j-th decision variable.

The algorithm contains functions:

- $\mathrm{CreateList}$ for creating an empty list for placing the particles into it;
- $*.Add$ function is a shortcut for inserting one item at the end of a list.

$particleList, gbest \leftarrow$
$GenerateParticles(m, n, X[j].\text{LowerBound}, X[j].\text{UpperBound}, g_{best})$

Generating the list of particles used in the PSO algorithms

```
1   begin
2     ParticleList ← CreateList(□);//create an empty list
3     for i ← 0 to m − 1 do begin
4         p ← CreateParticle(□); //creating a particle
5         for j ← 0 to n − 1 do begin
6             p.X[j] ← Rnd(X[j].LowerBound, X[j].UpperBound);
7             p.V[j] ← Rnd(−0.1,0.1);
8         end;
9         p.X_best ← p.X;
10        p.F_best ← F(p.X);
11        ParticleList.Add(p); //add current particle to the list of particles
12        if  F(p.X) < g_best.F then do begin //current particle is the best
13            g_best.X ← p.X;
14            g_best.F ← F(p.X);
15        end;
16    end;
17    result ← ParticleList, g_best;
18  end;
```

Inertia Weight Method

The Inertia Weight Method has been published by the authors Shi and Eberhart in several papers. (Shi & Eberhart, 1999), (Eberhart & Shi, 2000), (Eberhart & Shi, 2001)

The following equation describes the velocity of the particle where a new velocity for each particle (potential solution) is calculated. This velocity is based on its previous velocity, the particle's location at which the best objective function value so far has been achieved, and the population global (or local neighbourhood, in the neighbourhood version of the algorithm) location at which the best objective function value so far has been achieved.

$$p.V[j] \leftarrow w \cdot p.V[j] + c_1 \cdot rand(\quad) \cdot (p.X_{best}[j] - p.X[j]) + c_2 \cdot rand(\quad) \cdot (g_{best}.X[j] - p.X[j]) \tag{6}$$

- $p.V[j]$ denotes the velocity of the particle of the j-th decision variable;
- w denotes the weight – parameter reducing the velocity of the particle;
- c_1 denotes cognitive weight;
- c_2 denotes social weight;
- $rand(\quad)$ denotes the function returning a single uniformly distributed random number in interval $[0, 1)$;
- $p.X_{best}[j]$ denotes the positon of the j-th decision variable of the best found particle during its existence;
- $p.X[j]$ denotes the position of the particle – point coordinate of the j-th decision variable;
- $g_{best}.X[j]$ denotes the position of the best global particle from the list of particles– point coordinate of the j-th decision variable.

The following equation updates each particle's position in the solution hyperspace. Two random numbers are independently generated. The use of the inertia weight w, which typically decreases linearly from about 0.9 to 0.4 during a run, has provided improved performance in a number of applications. (Eberhart & Shi, 2000)

$$p.X[j] \leftarrow p.V[j] + p.X[j] \tag{7}$$

The Inertia Weight algorithm contains the other parameters:

- t_{max} denotes the maximum number of iterations;
- v_{max} denotes the maximum velocity of the particle;
- ReduceWeight denotes the parameter of reducing the weight – Boolean;
- $w_{default}$ denotes the default value of the weight;
- w_{reduce} denotes the constant reducing the weight;
- t denotes the number of current iteration;
- $ParticleList$ denotes the list of particles;
- p denotes the current particle;

Fig. 2 Fig. **2** demonstrates the principle of the Inertia Weight method. The algorithm parameters not described in the previous text have the same meaning as in the previous – see Fig. **1**.

$gbest \leftarrow$ InertiaWeight(m,n,X,t_{max},ReduceWeight, $w_{default}, c_1, c_2$)

Inertia Weight pseudocode

```
1   begin
2     g_best ← CreateParticle(□);
3     g_best.F ← Double.MaxValue();
4     for j ← 0 to n − 1 do begin
5       v_min[j] ← −1 * X[j].UpperBound;
6       v_max[j] ← X[j].UpperBound;
7     end;
8     w ← w_default;
9     ParticleList, g_best ←
      GenerateParticles(m, n, X[j].LowerBound, X[j].UpperBound, g_best);
10    t ← 0;
11    while t < t_max do begin
12      if ReduceWeight then do begin
13        w ← w_default − ((w_default − w_default * w_reduce) / t_max) * t;
14        if w < 0 then
15          w ← 0.01;
16      end;
17      for i ← 0 to m − 1 do begin
18        p ← ParticleList[i];
19        for j ← 0 to n − 1 do begin
20          p.V[j] ← w · p.V[j] + c1 · rand(□) · (p.X_best[j] − p.X[j]) + c2 ·
            rand(□) · (g_best.X[j] − p.X[j]);
21          if p.V[j] > v_max[j] then
22            p.V[j] ← v_max[j];
23          else
24            if p.V[j] < v_min[j] then
25              p.V[j] ← v_min[j];
26          p.X[j] ← p.V[j] + p.X[j];
27          if p.X[j] > X[j].UpperBound then
28            p.X[j] ← X[j].UpperBound;
29          else
30            if p.X[j] < X[j].LowerBound then
31              p.X[j] ← X[j].LowerBound;
32        end;
33        if F(p.X) < p.F_best then begin
```

```
34                  p.X_best ← p.X;
35                  p.F_best ← F(p.X);
36              end;
37              if F(p.X) < g_best.F then begin
38                  g_best.X ← p.X;
39                  g_best.F ← F(p.X);
40              end;
41          end;
42          t = t + 1;
43      end;
44      result ← g_best;
45  end;
```

Fig. 2: Inertia Weight Algorithm - Pseudocode

Constriction Factor (Clerc's constriction method)

Work done by Clerc (Clerc, 1999) indicates that use of a constriction factor may be necessary to insure convergence of the particle swarm algorithm. A detailed discussion of the constriction factor is beyond the scope of this paper, but a simplified method of incorporating it appears in the following equation:

$$p.V[j] \leftarrow K \cdot (p.V[j] + c_1 \cdot rand(\quad) \cdot (p.X_{best}[j] - p.X[j]) + c_2 \cdot rand(\quad) \cdot (g_{best}.X[j] - p.X[j])) \tag{8}$$

Where:

- K denotes the constant used for calculating the velocity that is affected by the cognitive and social weights. This parameter is reflected by other parameters:

$$K \leftarrow \frac{2}{\left|2-\varphi-\sqrt{\varphi^2-4\varphi}\right|}, \text{ where } \varphi \leftarrow c_1 + c_2; \tag{9}$$

- φ denotes the parameter used for calculating the constant multiplier K. (Eberhart & Shi, 2000)

Typically, when Clerc's constriction method is used, φ is set to 4.1 and the constant multiplier K is thus 0.729.

In initial experiments and applications, v_{max} was set to 100,000, since it was believed that v_{max} was not necessary when using Clerc's constriction approach. However, from subsequent experiments and applications (Eberhart & Shi, 2000) it was concluded that a better approach to use as a 'rule of thumb' is to limit v_{max} to $X[j].\text{UpperBound}$, the dynamic range of each variable on each dimension, while selecting w, c_1, c_2 according to previous equations. (Eberhart & Shi, 2001)

Fig. **3** demonstrates the principle of the Constriction Factor method. The algorithm parameters not described in the previous text have the same meaning as in the previous algorithms.

$gbest \leftarrow$ ConstrictionFactor(m,n,X,t_{max},ReduceWeight,$w_{default}$,c_1,c_2)

Constriction Factor algorithm - pseudocode

```
1   begin
2     g_best ← CreateParticle(□);
3     g_best.F ← Double.MaxValue();
4     for j ← 0 to n − 1 do begin
5       v_min[j] ← −1 ∗ X[j].UpperBound;
6       v_max[j] ← X[j].UpperBound;
7     end;
8     w ← w_default;
9     ParticleList, g_best ←
      GenerateParticles(m, n, X[j].LowerBound, X[j].UpperBound, g_best);
10    t ← 0;

12    K ← 2 / |2−φ−√(φ²−4φ)|;
13    while t < t_max do begin
14      if ReduceWeight then do begin
15        w ← w_default − ((w_default − w_default * w_reduce) / t_max) ∗ t;
16        if w < 0 then
17          w ← 0.01;
18      end;
19      for i ← 0 to m − 1 do
20        p ← ParticleList[i];
21        for j ← 0 to n − 1 do begin
22          p.V[j] ← K · (w ∗ p.V[j] + c_1 · rand(□) · (p.X_best[j] − p.X[j]) +
            c_2 · rand(□) · (g_best.X[j] − p.X[j]));
23          if p.V[j] > v_max [j] then
24            p.V[j] ← v_max [j] ;
25          else
26            if p.V[j] < −v_max [j] then
27              p.V[j] ← −v_max [j];
28          p.X[j] ← p.V[j] + p.X[j];
29          if p.X[j] > X[j].UpperBound then
30            p.X[j] ← X[j].UpperBound;
31          else do
32            if p.X[j] < X[j].LowerBound then
33              p.X[j] ← X[j].LowerBound;
34        end;
```

```
35            if F(p.X) < p.F_best then begin
36                p.X_best ← p.X;
37                p.F_best ← F(p.X);
38            end;
39            if F(p.X) < g_best.F then begin
40                g_best.X ← p.X;
41                g_best.F ← F(p.X);
42            end;
43        end;
44        t = t + 1;
45    end;
46    result ← g_best;
47  end;
```

Fig. 3: Constriction Factors Algorithm – Pseudocode

Interpersonal Learning PSO (ILPSO)

In the regular PSO, each particle in the swarm has two ways to learn information. Firstly, it learns from itself via its personal best position $p.X_{best}$, which can be considered as information exchanging in an internal environment. Secondly, it learns from the external environment by only using the best previous position $g_{best}.X$ in the entire swarm. However, it is obvious that some potential useful information is ignored because all the particles in the swarm learn from the same exemplar ($g_{best}.X$), which has been discussed in (Liang, et al., 2006). The interaction in regular PSO is "one-way", which means each particle in the swarm just assimilates the best information passively, and its personal best position $p.X_{best}$ will never propagate to other particles if the $p.X_{best}$is not the $g_{best}.X$.

Fig. **4** demonstrates the principle of mixing the indexes of particles to create the pairs used in the Interpersonal Learning PSO algorithm. This algorithm contains other parameters:

- $rndNumber$ denotes a random number – index of the particle, $rndNumber \in \mathbb{N}_0$;
- $rndIndex$ denotes the local variable representing the index of selected particle;
- $rndIndexesList$ denotes the list containing the randomly sorted indexes of particles.

The algorithm parameters not described in the previous text have the same meaning as in the previous algorithms.

$rndIndexesList \leftarrow MixIndexes(m)$

Function mixing the indexes of the particles in the list.

```
1   begin
2     rndIndexesList ← CreateList(⬚);
3     for k ← 0 to m − 1 do
4         rndIndexesList.Add(k);
5     l ← m;
6     while l > 1 do begin
7         l ← l − 1;

Fig. 4: Algorithm of Mixing the Particles Indexes – Pseudocode

ILPSO is a different technique from the basic PSO. The ILPSO algorithm randomly assigns two particles into a pair without repetition for all particles. The particles in the pair affect each other during the specified number of iterations – θ - line 23 in the ILPSO algorithm – see Fig. **5**. The learning centre is constituted through synthesizing their best personal positions – lines 38 and 39. Finally, both particles follow the learning centre to update their velocities and positions – line 52 in the ILPSO algorithm. (Ma, et al., 2015)

Fig. **5** demonstrates the principle of the Interpersonal Learning PSO algorithm. This algorithm contains the other parameters:

- θ denotes the reassigning gap – the number of iterations to reassign the pairs – the interpersonal learning process;
- w_1, w_2 denotes the weight of the first particle in the pair; weight of the second particle in the pair - ratio of particles distances to the learning centre;
- $rndIndexesList$ denotes the list containing the randomly sorted indexes of particles;
- $pairList$ denotes the list of the indexes of each particle in the pair;
- $pair[k]$ denotes the k-th particle in the pair $k \in \{0,1\}$;
- ρ_1 denotes the difference between the objective function values of the first particle in the pair and the objective function value of the best particle found by the whole swarm $g_{best}.F$

$gbest \leftarrow \text{ILPSO}(m,n,X,t_{max},\text{ReduceWeight},w_{default},\theta,c_1,c_2)$

Fig. 5: Interpersonal Learning PSO – Pseudocode

Other Tested Optimization Methods

We tested the Particle Swarm Optimization method against other optimization methods:

- Random Search (Majer, 2003)
- Downhill Simplex (Nelder & Mead, 1964), (Tvrdik, 2004), (Weise, 2009)
- Local Search (Majer, 2003)
- Hill Climbing (Weise, 2009)
- Tabu Search (Monticelli, et al., 2008)
- Simulated Annealing (Monticelli, et al., 2008), (Weise, 2009)
- Differential Evolution (Tvrdik, 2010), (Vincent & Ponnambalam, 2013)
- Evolution Strategy (Marik, et al., 2001), (Tvrdik, 2004), (Miranda, 2008)
- Soma (Zelinka, 2004)

A detailed description of the optimization methods which were implemented in the Simulation Optimizer can be found in (Raska & Ulrych, 2015).

Tested Discrete Event Simulation Models

We specified different objective functions according to the aim of the simulation. The quality of the candidate solution represents its objective function value. This value is calculated from the responses of the simulation model after a finished simulation run. We simulated all feasible candidate solutions of the discrete event simulation model to find the best candidate solution of the search space – the optimum.

Three discrete event simulation models were built in Arena simulation software. A detailed description of these simulation model can be found in (Raska & Ulrych, 2016).

- The manufacturing system and logistics model;
- The assembly line model;
- The penalty model.

Two other discrete event simulation models - the production and control stations model and the transport model - were built in Tecnomatix Plant Simulation software.

The Production and Control Stations Model

Two other discrete event simulation models were built in Tecnomatix Plant simulation software. The Production and Control Stations Model is focused on a production workshop – see Fig. **6**.

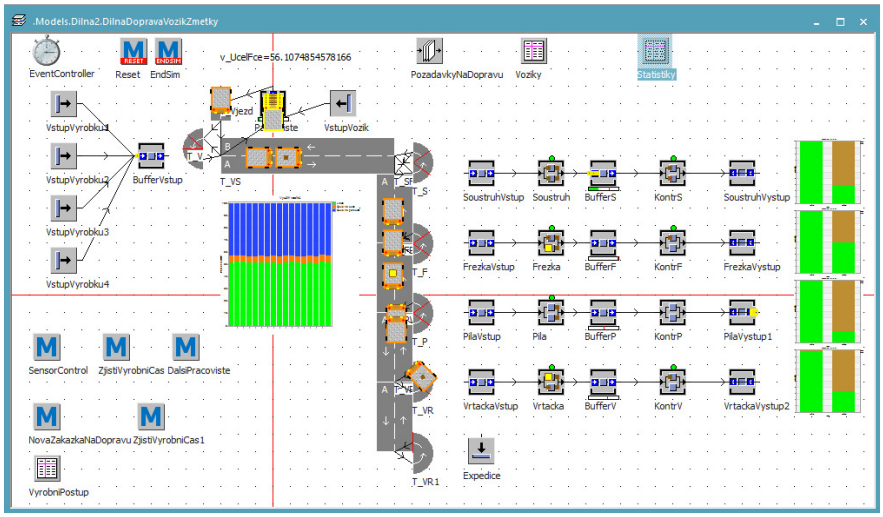

Fig. 6: Production And Control Stations Model – Tecnomatix Plant Discrete Event Simulation Model

The simulation model simulates six different workplaces. Four types of products are processed at the workshop. The time of the arrival of each product at the workshop is specified. The product passes through the workplaces respecting the technological processes. A forklift truck transports the products between workplaces.

The main goal is to determine the number of machines and controllers at individual workplaces according to the number of lift trucks, machines and controller utilization (maximizing production processes).

The objective function:

$$F(\mathbf{X}) = \frac{\text{NumberOfProcessedProducts}}{10} + \sum_{WN=1}^{4} (\text{MachineUtilization} + \text{ControllerUtilization}) \tag{10}$$

The Transport Model

The simulation model describes the transport from the warehouse to production lines by tractors. This model illustrates a situation where supply requirements are gradually collected. The tractor with trailers conveys the parts to production lines from the warehouse at regular intervals. The transports are performed according to the requirements of the production lines. Each tractor has defined places to serve and this list of places does not change during the simulation. All supply requirements arise stochastically. The aim of the simulation study is to find the correct sequence of served places at the production lines. The transport time is shorter than the processing time of the supplied parts at the production / assembly line. The places for unloading the parts are indexed and the tractor has to pass through these places in ascending order – see Fig. **7**.

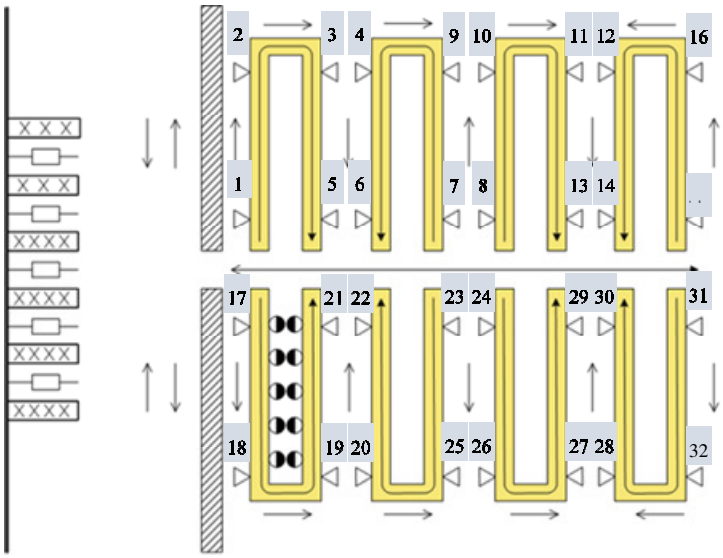

Fig. 7: Diagram of the Transportation Path

The simulation model has eight production lines. Each production line has four places for unloading. Four tractors convey the parts from the warehouse. Each tractor pulls a maximum of four trailers. A trailer can convey a maximum of six different boxes with components. Two hundred different parts are conveyed from the warehouse to the production lines. Each tractor can supply from zero to ten places for unloading. Each tractor exits the warehouse every fifteen minutes.

The objective function reflects the average utilization of tractors with trailers conveying the small and large parts, and the finished product. The objective function also reflects the overall average utilization of the production lines. The average utilization of production lines in the objective function is superior to the average utilization of all types of tractors using the coefficients. The objective function is minimized.

Definitions of the objective functions:

$$F_1(\mathbf{X}) = \sum_{i=1}^{4} DT_i \tag{11}$$

$$F_2(\mathbf{X}) = \frac{\sum_{i=1}^{32} TO_i}{100} \tag{12}$$

$$F_3(\mathbf{X}) = \left(\sum_{i=1}^{200} NT_i\right) * 10000 \tag{13}$$

$$F(\mathbf{X}) = F_1(\mathbf{X}) + F_2(\mathbf{X}) + F_3(\mathbf{X}) \tag{14}$$

Where DT_i denotes the distance travelled of the i-th tractor [m]; TO_i denotes the time over the maximum delivery time of the part at the i-th place for unloading at the production line [sec]; NT_i denotes the number of transport requests to the i-th part to a production line where the part does not have the assigned tractor for the transport [sec]; $F(\mathbf{X})$ denotes the objective function.

Optimization Experiments

We tested all possible solutions inside the defined Search space of the simulation model so we could create an external database containing the settings of the simulation model input parameters and its objective function value for each discrete event simulation model. The simulation optimizer downloads this knowledge database to local computer memory before it performs the simulation runs – increasing the speed of the simulation optimization experiment. The same termination criteria were satisfied for each optimization method. The first termination criterion is the maximum number of simulation runs that can be performed in the optimization for each model. We calculated this maximum number using the information entropy - Shannon Entropy. The number of all possible solutions in the search space is reduced using information entropy. (Borda, 2011)

The reduction coefficient:

$$\delta = \max\{0{,}1 - \beta \cdot log\tilde{X}\}, \delta \in [0{,}1] \tag{15}$$

- $\tilde{X}$ denotes the size of the search space – the number of all possible solutions in the search space;
- β denotes the coefficient of search space reduction.

The maximum number of simulation runs that it is possible to perform in each optimization experiment:

$$\tilde{X}_H = \left\lfloor 2^{\delta \cdot log_2 \tilde{X}} \right\rfloor \tag{16}$$

We could also specify the second termination criterion - the value to reach - because we could specify the global optimum of the objective function using the database of performed simulation experiments. If the optimization algorithm finds a possible solution whose objective function value is within the defined tolerated deviation from the objective function value of the global optimum, the optimization experiment is stopped.

We defined a step and lower and upper boundaries for the parameters of the PSO algorithms and other optimization methods. If the Random Search, Downhill Simplex, Hill Climbing, Tabu Search, Local Search, Simulated Annealing, Evolution Strategy, Differential Evolution or Self Organizing Migrating Algorithm have the same parameters as another optimization method, we set up both parameters with the same boundaries (same step, lower and upper boundaries).

Evaluating Criteria

The first criterion is the function whose output is the standardized scalar value $f_1 \in [0{,}1]$ of not finding the known VTR (value to reach). This value represents the failure of finding the global optimum by the optimization method in a particular series – value minimization. This criterion is expressed by pseudopascal code and shown in Fig. **8**. This criterion contains the parameters:

- X^* denotes the list of found optima in each optimization experiment in the series;
- $\mathbf{X}^*$ denotes the global optimum in the search space; ε denotes the tolerated deviation from the value of the objective function value of global optimum;
- $F(\mathbf{X})$ denotes the objective function value;
- n_{Succ} denotes the counter of successfully finding optimum;
- f_1 denotes the standardised scalar value.

```
1   begin
2     n_Succ ← 0;
3     for i ← 0 to Length(X*) − 1 do
4         if |F(X*[i]) − F(X*)| ≤ ε then
5             n_Succ ← n_Succ + 1 ;
      (*Optimum or acceptable candidate solution
      was found *)
6     result ← (Length(X*) − n_Succ) / Length(X*);
      (*standardization - % share of unsuccessful
      series*)
7   end;
```

Fig. 8: The First Criterion – Finding the Global Optimum or Suboptimum - Pseudopascal Algorithm

If the failure is 100[%] the first criterion equals 1, therefore we try to minimize this criterion. Average Method Success of Finding Optimum can be formulated as follows:

$$f_{1AVG} = \left(1 - \frac{\sum_{i=1}^{s} f_{1_i}}{s}\right) \cdot 100[\%] \tag{17}$$

- i denotes the index of one series;
- f_{1_i} denotes the value of the first criterion (Optimization method success – the best value is zero);
- s denotes the number of performed series.

The following chart – see Fig. **9** - shows the average optimization method success of finding the optimum (suboptimum if its objective function value is in the tolerated deviation from the objective function value of the global optimum).

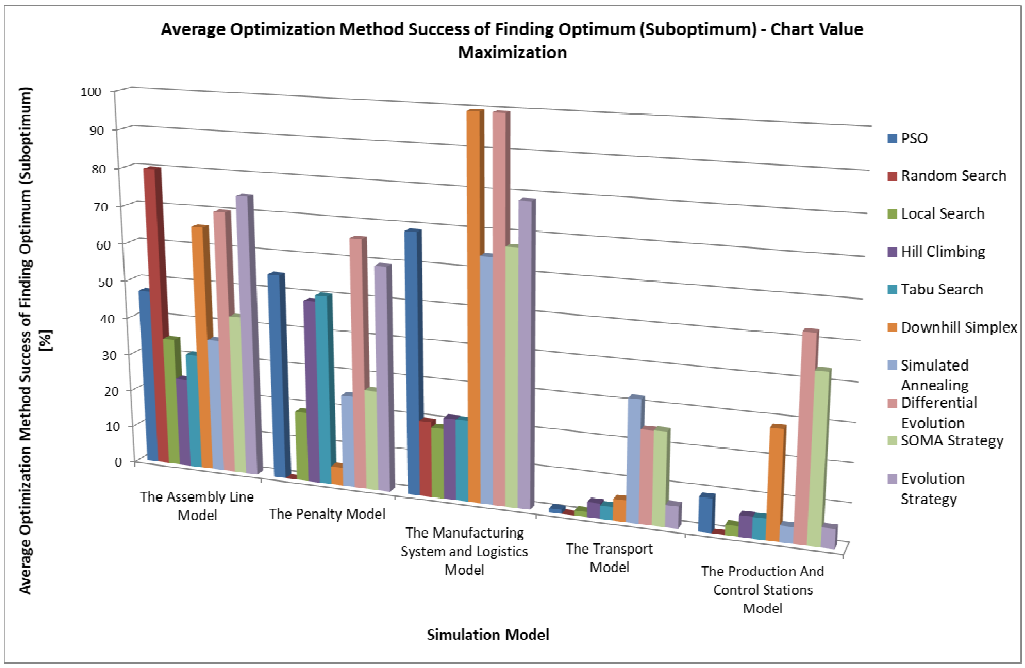

Fig. 9: Average Optimization Method Success of Finding Optimum (Suboptimum) of All Tested Optimization Methods

The following table shows the specifications of the tested discrete event simulation models. This table also contains the maximum number of performed optimization experiments using the Information entropy – reducing the search space.

Table 1: Specifications of the Discrete Event Simulation Models

Discrete Event Simulation Model	$F(\tilde{\mathbf{X}})$	$F(\hat{\mathbf{X}})$	n	$\hat{X}$	$\hat{X}_H$
The Assembly Line Model	7092	22032	2	238	124
The Penalty Model	100.7093	4,6426.34	2	251,001	8,747
The Manufacturing System and Logistics Model	-11.53367	22.64956	3	8,671	1,454
The Transport Model	44,502.25	4.26E+07	8	252,000,000	74,512
The Production And Control Stations Model	2.149858	57.29105	9	259,200,000	74,847

It is obvious that Random selection is not a very effective method for searching for the global optimum. The success of this method strongly depends on the number of simulation experiments. The high success of Random selection in the case of the assembly simulation model causes a small number of possible solutions in the search space of this simulation model. We can assume high average selection strategies success of finding the optimum (suboptimum) if the dimension of the search space of the discrete event simulation model is lower or the objective function surface is simple - The Manufacturing System and Logistics Model; The Assembly Line Model; The Penalty Model. If the objective function surface is hard

– multimodal, planar regions, etc. – the optimization failure rate of the PSO is high i.e. The Production and Control Stations Model.

We can see the high average optimization success of the Differential Evolution. The Downhill Simplex method is another effective method for searching for the global optimum. The PSO is not such an effective optimization method in the case of our tested discrete event simulation models. PSO performed a low number of optimization experiments. This method needs a higher number of experiments to move individual particles in the swarm to the global optimum.

The next figure – Fig. **10** – shows the success of finding the optimum of the tested PSO strategies. The chart contains the series where the best found setting is 100[%] – the global optimum in each optimization experiment was found. The specified tolerance between the best objective function value of the found solution candidate by the PSO and the objective function value of the global optimum in the optimization experiment equals $\varepsilon = 0.0001$. The Constriction Factors strategy is better than the other two tested strategies if the objective function surface is simple. The Interpersonal Learning PSO is more effective than the other tested strategies if the dimension of the search space of the discrete event simulation model is higher.

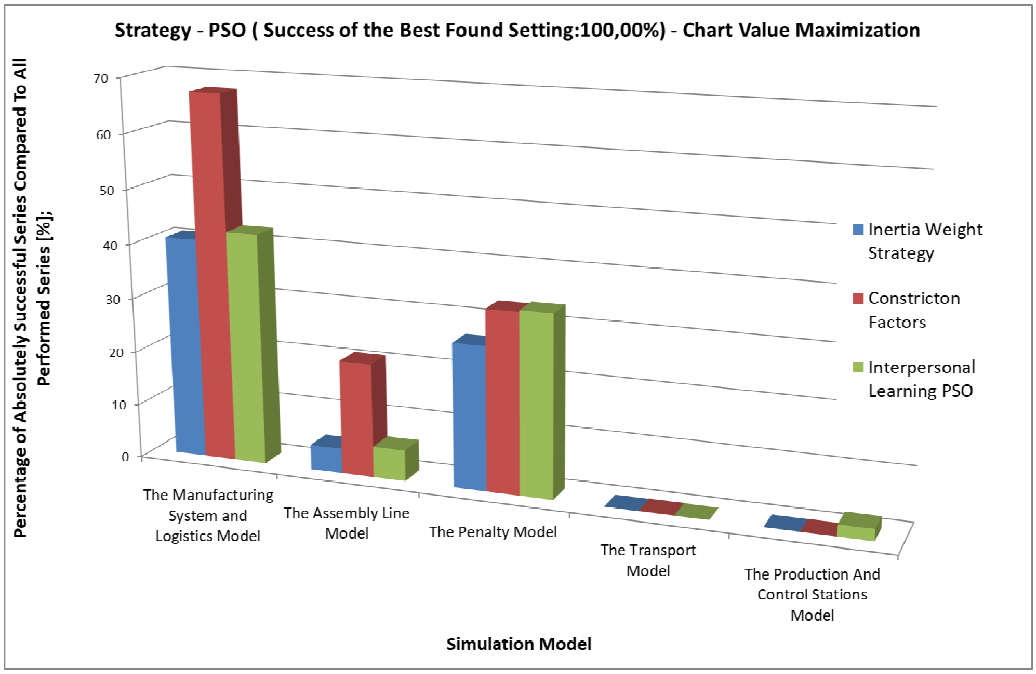

Fig. 10: Success of Finding Optimum of the Different PSO Strategies – the Series Where the Best Found Setting is 100[%]; ε = 0.0001

Conclusion

The goal of the research was to test different settings – series - of the PSO strategies on five discrete event simulation models. We evaluated the success of finding the optimum by different PSO strategies. We deduced that PSO is an effective strategy for the simulation models where the dimension of the search space is small and the objective function landscape is not multimodal. The PSO method was better than the other tested pseudo gradient methods. PSO was not more effective at searching for the global optimum than the other tested metaheuristic optimization methods.

A problem can occur if the objective function landscape is multimodal. The PSO needs a higher number of optimization experiments to converge to the global optimum than the other tested optimization methods.
We confirmed that the success of finding the optimum by the PSO strategies strongly depends on the objective function landscape. Problems occurred when searching for the optimum in the higher dimension of the search space of the discrete event simulation model - the production and control stations model and the transport model.

Abstract

In the XXI-st century we still talk about the evolutionary concept of globalization. In the end, we should understand if it's a phenomenon that ignites research in technologies and evolves towards less developed areas of the world. Also, globalization could derail because of the environment, the social, economic and political spread could be seen as dangerous. These are some of the dilemmas that we have these days and we try to answer them in a clear and simple way during this paper.

Keywords: globalization, capital, growth, global commerce

Introduction

Starting from the premise of this quote, we realize that this process referred to in the last century as "globalization" has its origins from the beginning of civilization, when a man in his desire to know more had to migrate to countries that were rich or in full progress (Bran et al., 2012).

Globalization is a modern term mentioned the first time by Theodorov Levitt in his scientifically research "Globalization and Marketing" in 1980 and is used to describe changes in all companies as a result of events occurring in some part of the globe and the consequences that appeared. It is becoming more visible in societies around the globe, even in less developed countries that they need to handle these complex changes which are ceaseless, especially in countries fully in progress or already developed that seem to flourish in all areas under imminent globalization. (Bran et al., 2012)

People around the world are getting closer than ever, both physically and mentally. Goods and services appearing in a country will be promoted immediately in another one. International transfer and communication are more common and will soon become indispensable. To describe this moment, they use the term globalization. The widespread phenomenon affects economic affairs and exerts a broad influence on society. Growing developing countries is the main cause of globalization and brings them both as opportunities and disadvantages. Globalization is certainly a strong power and important change factor in terms of cultural, economic, political and social progress, inside not only in the USA, but also in the entire world. It can be considered a process by which countries get closer through increased contact, communication and trade in the idea to create a single global system, a New World Order.

Given that globalization is a complex set of processes that affect virtually all aspects of our lives everyday - art, culture, economy, politics, immigration, climate, and healthcare - studies on globalization reveal bluntly a multiplicity of perspectives in humanities, social science and the forms it takes globalization at a higher level, the forces that shape them, their historical origins and their impact on all aspects of life of individuals and communities.

Without doubting it, XVIII and XIX centuries where and still are the most dynamic periods in close connection with the development of historical facts, social contradictions and complexity of social movement, but as the dramatic consequences of processes and phenomena developed in spiritual, political and military context, and in economic and social values, which led to the spread of globalization. We can say that we are in "the century of extremes" in which mankind experienced the most spectacular evolutions, from nothing to almost everything, we managed both to "stop the clock in place" and to meet the highest level of economic and cultural development of civilizations in ages, actually situated the threshold very high today. But it is also the century in which hundreds of millions of people have been victims of wars, revolutions in various fields, and from different ideologies, whether religious, ethnic politics, etc.

Globalization is a concept often used to characterize the current state of the economy worldwide, but is understood by everyone because there is different perception of the events that happened in our lives. Some see it as a complex and complete uniformity, others, on the contrary, that of a diversification in the bad sense of proportion, based on respect for common principles that are imposed. Under this latter aspect, globalization is the almost natural consequence of the increasingly accelerated course imprinted on history, the first Industrial Revolution.

What distinguishes the contemporary phenomenon of globalization from the previous integration processes since its first appearance is: - scale (formerly being regional, current global); - the pace of change is slowly but surely beginning to grow, and now very fast for a period of 40-50 years to support a greater technological progress than before, with immediate and irreversible impact on the conditions of daily life.

With the advent of the Industrial Revolution, globalization has become more prominent, with the discovery of new territories and migratory flows. But the most interesting is the development synchronized with the technological progression by which manual work has been replaced by machines. In this process based on a mechanized worker, it is the most important actor in globalization, and globalization itself has the role of monitoring, control and power of the machine and quality control. The industrial revolution had the effect of increasing production, improving quality of life and human awareness that can hold more capital, more power, which made him sacrifice himself for a full life satisfaction (Bran et al., 2012).

It is only after the end of the Second World War that we can consider the extraordinary momentum of globalization; when the process has actually become a widespread phenomenon (or when the world has become aware of it), an alarming and extremely satisfying growth in rich countries. Now we can think of globalization as a union among nations which aims at reorganizing national borders and transposing them into a single market through which certain transfers can be made: a workforce based on "brain theft" or intellectual theft, then uniformly promotes unloading taxes for the less developed countries that cannot keep the pace. Members that are opulent are setting standard rules that impact not just the poor countries, but also the developed ones too. Lack of capital for environmental protection results in environmental decay, declining population, and high mortality for all beings (Bran et al., 2012).

The chaos we face today stems from the fact that from the development stage of the most important global economic plans, the economic and technological origins ignited mainly from the

United States, and represent that potential differences between all countries to create a so-called race in the pursuit of profit and power (Bran et al., 2012).

Immediately after this expansion of the phenomenon, the cruel reality shows us two clear asymmetric hypotheses: developed countries assimilate the most important benefits (economic efficiency, infrastructure, civilization, somewhat at higher ground), while poorly developed countries seem to regress from all points of view and remain indebted towards developed countries. On the one hand, there is a universally beneficial culture for everyone, and on the other the barricade created by the fact that culture of societies disappears and becomes a show that brings profit, but does not support evolution. Here we can conclude that this concept of globalization is only a façade after hiding the following reason: who owns capital has the profit, who do not hold debt with recovery in sight (Bran et al., 2012).

Objectives declared of globalization are concretized into one: building one governance system for the entire world and a world society with universal rules and thought in unison is utopic, but not impossible. But there is only one question. Who benefits from this transformation going from all national governments into a single world government? Rich countries can afford to go through transitions of this type, but poor countries should be indebted to move through transitions? This paradigm about the global society today that we discuss in this paper has further arguments and grounds based also on common sense.

The Club of Rome – Social Engineering from a Global Perspective

The purpose of this organization is to behave like a global stimulus, regardless of interests and political tendencies, ideological perspectives or existing business. The Club of Rome is composed of influential personalities with a special education in diverse and vast areas and that the main objective is to develop right thinking and healthy progress in regard of globalization and the struggle against globalization by this means should emphasized. This organization includes scientists, that could validate proclaims about the future, senior officials in the international environment business, presidents or former presidents of different states, people from business environments, etc. The Club is contributing to solving alarming global problems, like social, economic, policies, technological, environmental, psychological and even cultural ones; one of the most controversial enigmas that the world has to face, because change must be made at this level, but is also the most difficult to change the most difficult level.

Scientist Bertrand Schneider, Secretary General of the famous Club of Rome, says that the "global horizon" is actually an inclination transposing gradually in the world economy, in politics, in social life and in other areas on which the trend changed enormously its current route towards an information society biased on development.

In the idea that the computerization of this consuming society deepens itself with every aspect that we dissect closer, there are big questions about the way and the efficiency of the current governance at the level of each member state of this "masquerade" and last but not least about the capacity of the final decision makers. We could argue that globalization involves more than interdependency between nation states that nobody knows for sure if they really where biased towards freedom of movement in the direction of the economy, but is in reality an undermined economy, without small degrees of freedom

The following are also very relevant. First of them is the idea of geographically deployment, this phenomenon is not an all-encompassing phenomenon, because there are a lot of very poor and few developing countries who cannot participate in the "welfare" of the world because they cannot even help either. All parts of human existence are included in one, and man unfortunately take all steps that to expand rapidly without regard to long-term consequences.

In conclusion, summarizing all the above, globalization:

1. Is in general the product of dependent developed countries without national borders;
2. Highlights borderless information that speeds up the process of globalization;
3. Comprises the entire economy;
4. Represents universal culture;
5. It represents all kinds of human relationships.

Attitudes and Approaches Regarding Globalization

Globalization is a phenomenon as complex, heterogeneous, that has levels of development and different approaches in all respects, with chaotic changes and unfortunately irreversible processes, which obviously deepens with each event in part, through we cannot define it concretely. Actually, we cannot include a wealth of features in a single definition of just a few lines.

Approaches and attitudes about this process are indeed different and are sometimes located at opposite poles. Although if you look between the lines can be upheld, well-founded arguments that globalization is the antithesis even with itself are encountered, mainly because to the extent that it helps the already prosperous countries to hold the monopoly on global development, equally destabilizing alarmingly underdeveloped areas/economies and moving them to a continuous decline (Bodislav, 2015).

Joachim Wilmeyer states that participation in the creation performance, in fact, is itself entitled to performance, should offer equal opportunities for all, fair financing, equity among human generations in the country, especially to meet basic needs; only after they accept, we can conclude positively that only through globalization we have perfect environmental support in all respects. An interesting thing to note is that if hypothetically globalization would have been used and complied by all countries as a whole, then basic needs would be completed for all citizens of planet Earth.

From the other side of the observing position, UNESCO says that the way globalization pours exclusively negative effects on our social perspectives, relationships are not directly proportional to changes that evolve in market turbulence, but these are the effects of the flawed and even disastrous way in which governments of some countries make themselves felt present in the global mechanism. As shown above, the evolution of this phenomenon highlights that there are several actors from different fields (economy, culture, society, etc.) that attempt to balance the balance in favor of profit, also by disregarding the real interests of individuals (Bran et al, 2012).

In 1966 to better understand globalization, Marshal McLuhan introduced a thinking exercise that very efficiently summarizes planet Earth's human inhabitants: if the global population would be reduced to a single village with only 100 inhabitants and which would be called the global village, it would look something like 70% are illiterate persons, 15% would be have an average intellect and literacy level and other 15% would be developed intellectually and from literate perspective. It is easily to understand on whose side the power is and who dominates the entire "community" (Bran et al., 2014). There are two interesting observations, today 80% of the global population has poor conditions of life and welfare at optimal standards is found for 6% of the global population (Bran et al., 2012).

As we observe these favorable or less favorable attitudes towards the term globalization drive us towards the idea that single entity would be rather trimmed or could make a difference in this case if it represents the state. The state must assimilate the conditions "imposed" or offered under conditions of globalization

and filter them according to its traditions and specific (economic, cultural, social, etc.) and even according to long range interest.

Conclusions

For countries with poor economies the state loses much of its power because it has to concentrate towards development, but the social side brings it down; so, we could state that development is lagging in such countries, and they just have to be addicted to those that thrive. (Bran et al, 2012).

In response to these negative effects felt by most nations there is a set up mechanism and ignites an anti-globalization movement. A first approach on globalization is the internationalization of globalization. From this perspective, the term known as "global" is another term to describe relations between states, and "globalization" means an increase in interdependencies and international exchanges. In this sense, Paul Hirst and Grahame Thompson gave globalization the spin of being flowed mechanism for trade and capital investment among the world (Bran et al, 2012). Obviously, such a type of "globalization" can be identified in large flows between different countries and in terms of population, messages and ideas. Thus, globalization refers to the increasing interaction and interdependence between people from different countries. The second approach identifies globalization with modernization theory or westernization in the form of its role in the spec of being "Americanized". Following this idea, globalization is dynamic, evolving, so to speak having a faster rate than humanity's evolutionary trend. (Bran et al, 2012).

A third approach identifies globalization with universalization. When Reiser and Davies invented the word Globalization in 1940, had in mind "universalization" and heralded a fusion of all the cultures of the world and putting them in one conceptualized and universal culture. In this sense, global means all over the world, and globalization is the spread of different ideas, discoveries in science, but above all it represents universal culture among peoples from all over the world. In short, means "splintering" the nations, mixing and loss of national crops. (Bran, 2012).

The final approach to globalization is that it identifies the process similar with "deterritorialization". Starting from this premise we can say that one of the most well established goals involving a "geographical reconfiguration" is because territorial boundaries are no longer defined at a social space representative of a country, but there is a global space, uniform, featureless single, without taking into account the individual needs of individual recognition.

Globalization is about increasing links between states and societies that are currently taking part in the global system. It describes the process by which events, decisions and activities are carried in a part of the world that has significant consequences for individuals and communities located far from each other (Bran et al., 2012).

One last thing to say in this context, how this phenomenon draws both pro and contra opinions, but the only way we can evaluate the true face of globalization is the discussion of the areas in which it emerges and to draw conclusions in the most objective manner, especially when research is fragmented and offers a small piece of the puzzle.

Abstract

Globalization is a word that is synonym with commerce growth worldwide, which is in favor of increasing scaled production, consumption of goods and services in unseen quantities, beating all standards of the last century. This shaped human kind's activity and decreased the volume of hard labor. Although it is difficult to evaluate the impact of globalization on the environment, this paper tries to show some shades and nuances on the how the phenomenon influences today's life.

Keywords: globalization, deforestation, natural resources, greenhouse effect, CO2 emissions.

Introduction

Globalization is the process through which all people and communities experience economic, social, cultural evolution more frequent by having different experiences that are unified. By definition, the globalization process affects everyone in the whole world, regardless of their development level or on what side of the economic scale they are (Bran, Ioan, 2009).

Questions tied to globalization and its evolutionary environment have gained momentum due to tremendously growth observed in some parts of the world and in other parts regress constantly being registered, but globalization has meant also a change at the very important concept of how we each think of the environment. Many of us see today's environmental issues that are of international interest, not only of national interest, such as protection of rivers that are tributaries of the great Industrial Revolution and also end of the planetary ocean and not least the atmosphere that suffers because of pollution in each state, especially in those that are highly industrial and educating people on environmental protection is considered heritage and issues need to be financed to have their negative externalities reduced. This subject is a global threat because of the cross-border impact and because of the impossibility that only one or a few nations especially rich can solve this great dilemma through a proprietary manner (Bran, Ioan, 2009).

Climate change is one of the main environmental issues, perhaps the worst, because it is impossible to predict exactly how it will develop and what the consequences will be, especially if they are negative. Its causes, however, are known. Climate change comes largely from the greenhouse effect - ie excessive retention of solar energy in the atmosphere due to the accumulation of certain gases, especially CO2. The main sources of CO2 emissions are industrial production, transport and, more indirectly,

deforestation. These three human activities are independent of globalization as a process, but they evolved and accelerated during the 20th century, especially in recent decades.

Globalization – The Promoter of Mass Deforestation

Deforestation is an indirect cause, but perhaps the most serious and significant greenhouse effect, to which we add landslides and many other hazards seen on Earth today. A deforested area reduces the amount of CO2 the plants turn it into oxygen, this translates into an equivalent increase in the volume of CO2 in the atmosphere and thus add to the greenhouse effect. In total, the estimated emissions from deforestation is about 20% released in the atmosphere which has high levels of output. Between 1990 and 2005, the world lost 3% of its forests. Current, about 200 km2 of forest land - twice the size of Paris - disappears every day.

Following the path of environmental issues developed, there are many international non-governmental public and private organizations that are seeking solutions to environmental problems, such as the United Nations Environment Program, Greenpeace and World Watch Institute. A multitude of treaties have been concluded to harmonize government policy on environmental protection. Some environmentalists even proposed creating a "world environmental organization" to coordinate international policies.

In recent years, economic globalization has brought rapid and deep changes in countries around the world, more or less being sustainable through the filters of economic, social and environmental replenishment of resources. In general, there was a trend of decentralizing the government and reducing the role it plays in the daily life of its citizens. In countries that are in development, this change has major implications on forests and on the quality of life on the long run.

Whether it is due to a market economy (based on the consumer and consumption) or required by an economy that is centralized, the management or control of forest lands in usually as task of the public sector through its forest services. In order to stop illicit mass deforestation, public entities decided to privatize forests, by selling or renting them to private firms, NGOs, and so on, but this decision it seems to have been in vain if we look around at the thousands of hectares of forest species that disappear monthly (Bran, Ioan, 2009).

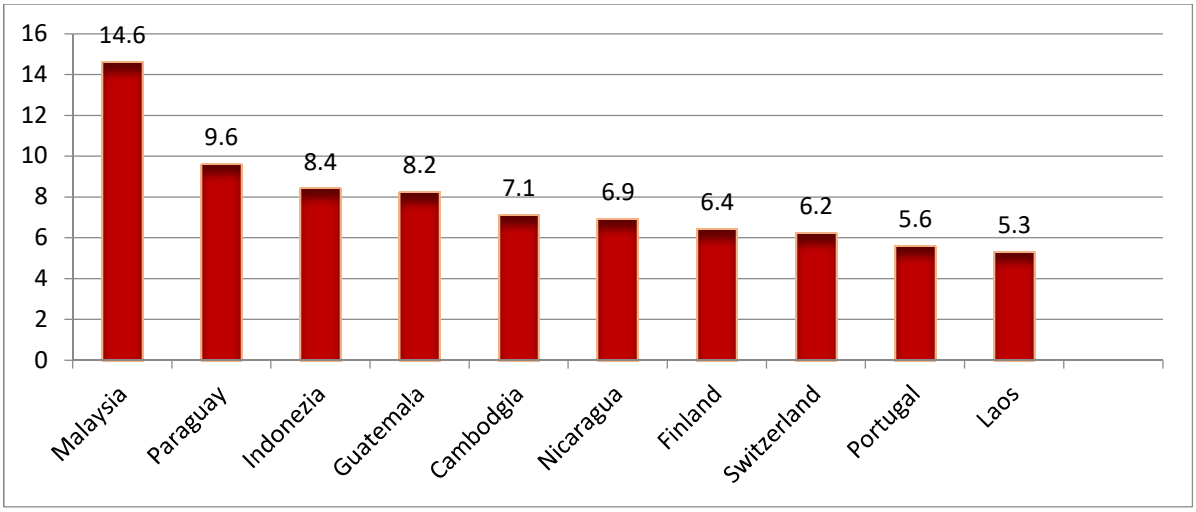

Fig. 1: Top countries with the largest illegal deforestation (% of the country's wooded area)

In this figure, we have the countries with the highest percentage of illegal deforestation in the world, in descending order.

The total loss of forest in Malaysia amounted to 14,4% of the country's forest area from 2000 to 2014. The loss square translates into 47.278 km (18.244 square mille), an area larger than Denmark.

As a critical promoter of globalization, the transport systems have multiplied emissions from road transport (mainly cars and trucks) which are, of course, very large, even more so within the national borders, but especially seen in the economically developing countries in particular. As you know, opening regional areas such as the total elimination of border controls between European countries part of the EU boosted extremely powerful road freight. Despite some recent alternatives to road transport, like lorries transported by train for part of the trip, transnational road transport is still a major source of CO2 emissions.

Globalization = Greenhouse Effect

The greenhouse effect increases the Earth's temperature by capturing the heat in the atmosphere. This keeps the Earth's temperature at a higher level than if the direct heat of the sun was the only source of light. When it reaches the Earth's surface, some of it is absorbed, ie that heats the soil, and then the rest bounces back into space in the form of heat. The greenhouse gases that are in the atmosphere absorb and then redirect some of this heat back to Earth.

The greenhouse effect is a major factor in support for our planet's warmth. In fact, without the greenhouse effect, the average global Earth's temperature would be much lower and life on Earth as we know it would not be possible.

The difference between the actual average temperate on Earth 14°C (57.2°F) and the effective expected solar radiation is -19°C (-2.2°F), and the average temperature that provides power and actual emissions is 33°C.

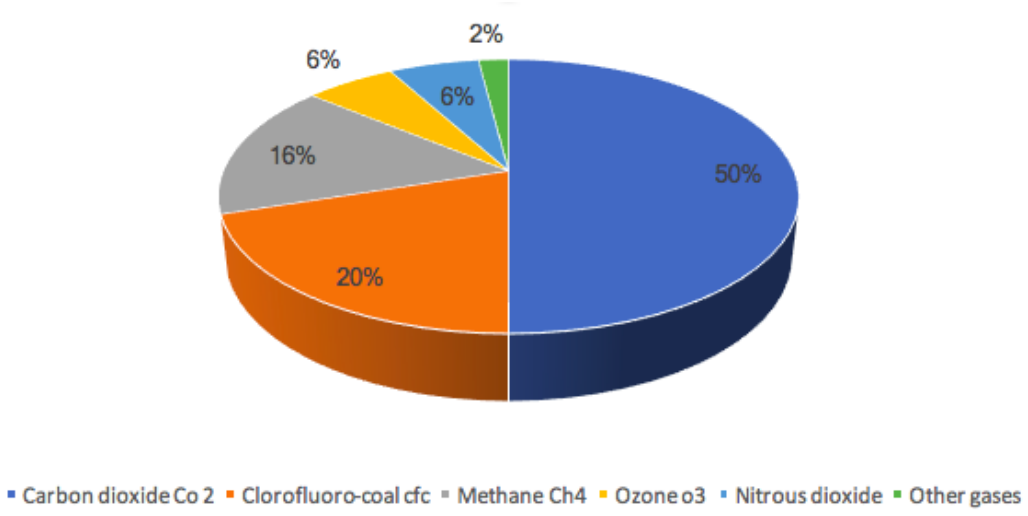

Fig. 2: Types of gas and their contribution in percentage points in 2016 air pollution

Globalization "Indirectly" Promotes CO2 Emissions Related To Industrial Activity

While the Industrial Revolution was a vector for accelerating globalization, buy empowering cross-border trade and transnational investments in turn, and stimulated industrial activity. This is often a major source of GHG (greenhouse gass) emissions, as in the case of electricity, which still largely involves burning coal, oil and its derivatives. Enhanced globalization has then accentuated the greenhouse effect and global warming. Global warming is one of the undesirable effects of globalization which apparently will become a major problem for humanity because it was deliberately not counted for.

For decades, developed countries - the world's pioneers of industrialization - have been the world's largest polluters, responsible for most of GHG emissions. Today, the United States is responsible for about 20% of global emissions and through the Trump administration it stopped being part of the Paris Climate Agreement.

According to statements of IEA - International Energy Agency, in 2016 the carbon dioxide emissions were at its maximum, and the fact is that it's in line with the development of countries across the globe. The prospects for 2017 show that in the first semester, China and the US have fallen as producers of GHG emissions, and in Europe stagnated. According to the agency, the largest decrease was in the US (-3%), ie 160 million tonnes of carbon dioxide (CO2) less than in the previous years, while the economy grew by 1.6%.

Across the EU, carbon dioxide emissions have stagnated in 2016 and in the first half of 2017. This happened in the conditions in which experts say demand for gas increased by 8% and the need for coal fell by 10% percent. Renewable energy has played a significant role, but one quite small. Researchers say the decline was driven by a sharp increase in shale gas supplies and renewable energy sources that replaced coal.

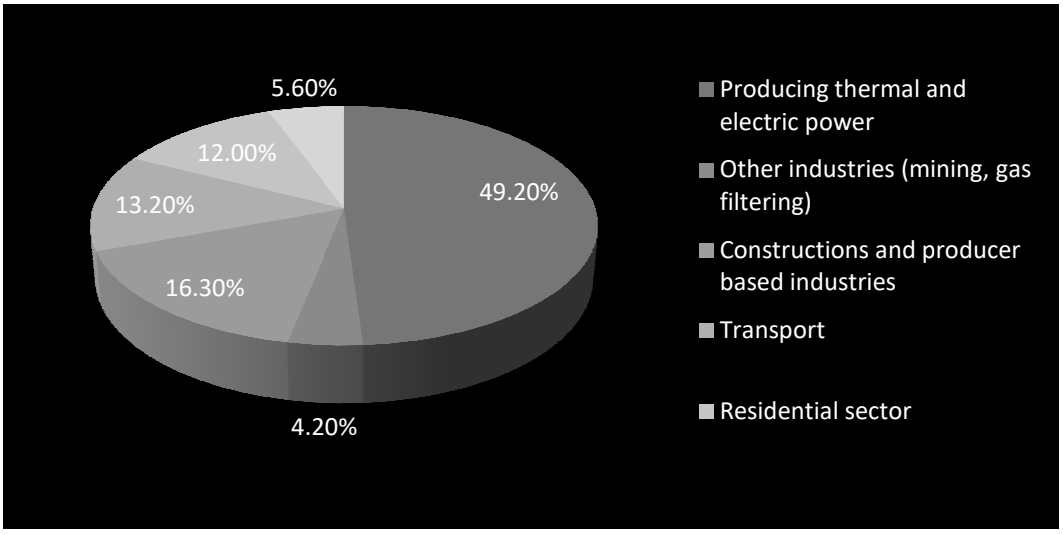

Fig. 3: Share of CO2 emissions by sector in EU

In China, carbon dioxide emissions fell by 1% in 2016 and the pace is kept also for 2017. In the same time the demand for coal decreased, although the economy grew by 6.7%. Experts say the contribution of renewable energy, nuclear energy and natural gas has contributed to this general decrease in emissions.

Globalization and the Behavior of Multinational Companies towards the Environment

There are four categories of multinational corporations:

1. Multinational corporation, decentralized with a strong headquarter;

2. Global corporation that is based on acquiring a cost advantage through centralized production or whenever available and cheaper;

3. International company that has an optimal fiscal headquarter and invests a lot in corporate R & D;

4. Transnational enterprise that combines the three previous approaches and merges into the modern corporation.

Industrial corporations are abundant in terms of technology innovation and capital investment targeted for increasing their production. In the context of globalization, privatization and market liberalization, they are considered to be one of the most important factors in shaping the future of the world. However, these factors have brought not only economic growth, but also a negative effect on the environment.

In an attempt to reduce costs, many multinational corporations have expanded their export activities through subsidiaries established in less polluting, already developed countries. Environmental pollution does not necessarily have to cross a country's borders as a substance, it can also cross the border by a decision taken in a state that leads to environmental consequences in another. Otherwise, the environmental degradation resulting from the subsidiary's activities can often be traced back to the parent company's regulatory orders. Importantly, because multinational corporations are large contributors to the world economy, they enjoy significant political power on the international stage. The predominant position of these corporate giants is not equally balanced with that of victims when they try to make multinational corporations responsible for environmental damage. Most often, the production cost is required to be countered by introducing environmentally unfriendly manufacturing processes and consumables used in production, which slowly but consistently have a consistent environmental footprint.

Ironically, all the elements of the environment still offer us the opportunity to go on clean streets and breathe clean air, in spite of the fact that polluting factors are rapidly multiplying. From multinational companies, to road traffic and people who deliberately deforest and pollute, we all have our part to blame for the environment's decay.

Employees' Training and Development System by Utilizing Competency Model and Wings Method

Katerina Kashi, VŠB – Technical University of Ostrava, Faculty of Economics, Ostrava, Czech Republic, email: katerina.kashi@vsb.cz.

Abstract

Currently, employees' training and development plays an integral part of human resources management; it is necessary for both, the company and its employees. Today, well-educated and trained employees present a significant value for any company. Competency models are more and more used for effective human resource management. Well-designed competency models can be used by the organizations within the human resource management for various activities. The author has used the MCDM methods; AHP helped to scale down the number of measures and helped to determine the most important competencies, which lead to the design of competency model. TOPSIS method has been used to evaluate employees' performance. From a MCDM application point of view the WINGS can be a powerful tool for managers in problems that deal with both importance and relationship among evaluated factors, attributes or alternatives. Using WINGS the managers can combine the weights (importance) derived from AHP or other MCDM method and also their subjective (expert) opinion about the cause and effect of these competencies. By improving those competencies, the overall training and development should improve the employee key competencies.

Keywords: Employees' training and development, competency models, key competencies, WINGS method.

Introduction

The activity of training and development does not represent only to manage some course or training, it is much more. Before the training, it is necessary to take certain steps, to consult proposal of training with employees and at the end of training cycle it is necessary to evaluate it. The process also includes the discussions with supervisors about the training necessity and justification for these training programs and also their financial demands. The most important part of training and development is the person who is being trained. Since, if our employees will be trained and developed towards something they do not really want or need, the training and development will not provide required results.

However, most of the companies exercise the training and development system where the training activities are based on the needs of employees, either based on needed development or according to their development objectives determined at their annual appraisal. According to Novák, Vokoun, Stellner and Vochozka (2016) also the private personnel agencies stress the need for better qualifications and skills.

Main aim of this paper is to identify the training and development needs and activities for middle managers in the automotive industry in the Moravian-Silesian region.

Literature Review

Learning is no longer the transfer of information but it is the creation of knowledge as it is visibly expressed by improvement in business results and innovations. At the beginning of 20th century human resource managers have expressed the opinion that one of the main challenges they have to confront involve issues related to training and development, Boyatzis (2008). Barett, O'Connell (2001) finds that employees are likely to place greater value on training programs that are highly respected by colleagues, supervisors and managers. Companies which are able to create an environment where training is valued and supported by employees will be able to achieve greater commitment outcomes. Training perceived by employees to be effective will likely have a positive impact on job satisfaction and motivation.

Forrest and Peterson (2006) said that training and development objectives are to develop competencies such as technical, human, conceptual and managerial for the furtherance of individual and company's growth. According to Vokoun (2015) the most hampering factors of innovation were among others lack of skilled personnel.

Competency and Competency Models

The introduction of competency based approaches within the corporate environment initiated around 1970 and their development has been rapid since then.
Mirabile (1997, pg. 74) defines competency as "a knowledge, skill, ability, or characteristic associated with high performance on a job, such as problem solving, analytical thinking, or leadership. Some definitions of competency include motives, beliefs and values".According to Berge and Verneil (2002) many organizations are now adopting competency-based models to meet the evolving goals and needs.
Vazirani, 2010 defines competency model as a descriptive tool that identifies the competencies needed to operate in a specific role within a job, occupation, organization or industry. According to Fogg, 1999 a competency model is a behavioral job description that must be defined by each occupational function and each job. Shippman, 2000 states that depending on the work and organizational environment, a group of 7 to 9 total competencies are usually required of a particular job and depicted in a competency model. According to Cooper, 2000 the competency model is a collection of competencies and standards of performance establishing qualifications for a specific job position.

Used Methods

The research presented in this paper is based on two methods, i.e. AHP and WINGS. These methods can be also used in comparison of regions, finance. (Zmeškal, Dluhošová, 2015 or Minarčíková, 2015). Analytic hierarchy process is a framework of logic and problem solving that spans from the spectrum from instant awareness to fully integrated consciousness by organizing perception, judgments and feelings into hierarchy of forces which influence decision results. The method is based on innate human ability to utilize information and experience to estimate relative magnitudes through paired comparison. The hierarchy represents a complex problem in a multilevel structure, where the first level is the goal followed by levels of factors, criteria and subcriteria. It can decompose a complex problem in search of cause-effect explanations in steps which form a linear chain. For detailed description of AHP, see Kashi, Friedrich (2013); Kashi, Franek (2014); Papalová (2015).

Wings Method

The WINGS method (Weighted Influence Non-linear Gauge System) has been published recently (Michnik, 2013) and it is not widely known yet. That's why it will be shortly described, all steps of WINGS procedure during the process of solution of the model (the full description of the method and its theoretical background can be found in (Michnik, 2013). The basic input in WINGS comprises two features of the studied system's components: internal strength of each component and influence that one component exerts on another one.

The following scale for the influence evaluations has been chosen: 0 no influence, 1 low influence, 2 medium influence, 3 high influence, 4 very high influence. Similarly, the evaluations for internal strength (importance) of system components span from no strength (0) to very high (4) with values computed from the initial AHP weights, that were acquired before. The strength (importance) dimension in WINGS can have different meanings, thus it is possible to use AHP estimated priorities converted into WINGS scale. The preferences of importance are a result of Saaty pairwise comparison instead of direct input made by decision makers suggested in the original WINGS procedure as of Michnik (2013). Following description of WINGS is composed of following steps.
All evaluations are inserted into a square matrix **D** called the direct strength-influence matrix. This matrix is a $n \times n$ type with components d_{ij}. Values that represent the strength (importance) of components are inserted on the main diagonal ie. d_{ii}= importance of the component i. Values

representing influences are inserted into the matrix so that $i \neq j$, d_{ij}= influence of the component *i* on the component *j*.
Matrix **D** is then calibrated according to the formula

$$\mathrm{C}=\frac{1}{s}\mathrm{D} \quad (1)$$

where calibrating factor *s* is defined as a sum of all elements of matrix **D,** ie.

$$s=\sum_{i=1}^{n}\sum_{j=1}^{n} d_{ij} \quad (2)$$

The calibration ensures the existence on total strength-influence matrix T defined in (3) if there exist at least two positive elements in the matrix D and both are not in the same row. Opposite situation can be excluded from the analysis, because it does not represent any system. As well as in the DEMATEL it will ensure that the results are stable according to homothetic transformation $d_{ij} \to d_{ij}^{'} = \alpha d_{ij},\ \alpha > 0,$ for $i, j = 1,...,n.$ In the next step the total strength-influence matrix T is calculated:

$$T = C + C^2 + C^3 + ... = \frac{C}{I - C} \quad (3)$$

The way of calibration ensures that the series in above equation converge, and consequently the total strength-influence matrix **T** exists in almost all cases besides some exotic ones that can be excluded from the consideration. Then, for each element in the system the row sum r_i and column sum c_j of the matrix **T** are calculated:

$$r_i = \sum_{j=1}^{n} t_{ij}, \quad c_j = \sum_{i=1}^{n} t_{ij}, \quad (4)$$

where t_{ij} are elements of the matrix **T**. The r_i and c_i represent the total impact and the total receptivity of component. Finally, for each element in the system $r_i + c_i$ and $r_i - c_i$ are calculated. $r_i + c_i$ shows the total engagement of the component in the system; $r_i - c_i$ indicates the net position (role) of the component in the system: its positive sign means the component belongs to the influencing (cause) group, negative sign means that the component belongs to the influenced (result) group. Therefore, we can create a graph XY ($r_i + c_i$ and $r_i - c_i$), that it is called engagement-position map, that together with a numerical output helps with the analysis and discussion.

Results

Based on the results from the research executed by the author in 2014, where employees of one manufacturing company located in the Czech Republic were asked about the satisfaction with the performance appraisal system and the choice of evaluated competencies, the following competencies were mentioned the most often: work with information, problem solving, leadership, change management, effective communication, active listening, negotiating, team cooperation, motivating others, relevant professional knowledge, business knowledge, strategic thinking, analytical thinking, proactivity, creativity, mental agility and emotional resilience. To be able to identify key competencies, one position (the top manager – who is a top manager in the company) was chosen for this illustration. To determine key competencies for top manager, the method AHP was used. Based on the consultation with the company's HR manager, director, and financial manager, these competencies were divided into

the four following groups (criteria): managerial, interpersonal, technical competencies and personal qualities.
Next these competencies were compared in pairs based on modified Saatys scale (1-9 i.e. A - I) and a scale was assigned to each competency group (criteria) and each competency (sub criteria). This evaluation was done by an oral interview, where a table has been printed and the author has interviewed and wrote the results into the table, where the assessors rated each competency based on his/her personal knowledge, experience, etc. The interview has been done with the HR manager, director (direct supervisor of top manager) and one top manager – financial manager. An average scale was calculated from all of the collected data for each competency. Then an evaluation was executed to find out which group of competencies (criteria) has the most value for given position. Next the specific competencies (sub criteria) were arranged in the order of importance.

Sample illustration of the decomposition of competencies for the utilization of AHP is shown in fig. 1.

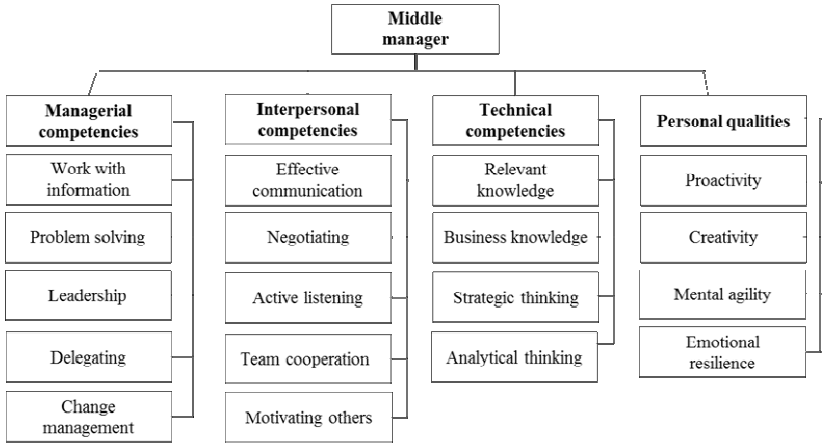

Fig. 1 : Proposal of the decomposition of competencies for the utilization of AHP

The above competencies were pair-wise compared by three experts based on a scale A-I, see Table 1. The author has purposely changed the scale from 1 – 9 to letter scale in order to eliminate rating score with the average number, i.e. 5.

Table 1: Paired comparison matrix for managerial competencies

Managerial	**Work with info**	**Problem solving**	**Leadership**	**Delegating**	**Change manag.**	**Local weight**
Work with info	1	1	7	7	3	0,369
Problem solving	1	1	7	7	5	0,408
Leadership	1/7	1/7	1	1	1/3	0,050
Delegating	1/7	1/7	1	1	1/3	0,050
Change manag.	1/3	1/5	3	3	1	0,123
RI	1,12	CI	0,02			
N	5	**CR=CI/RI**	**0,01**			
λmax 5.1312310						

Then the weights for individual group of competency were calculated based on the formulas. Global weights are shown in Table 2.

Table 2: Global weights for competencies for the position of middle manager

Ranking	Competency	Global weight	Ranking	Competency	Global weight
1	Professional knowledge	18,73%	10	Motivating others	2,77%
2	Analytic thinking	17,59%	11	Creativity	2,38%
3	Proactivity	14,06%	12	Strategic thinking	1,95%
4	Mental agility	9,22%	13	Problem solving	1,66%
5	Team cooperation	9,08%	14	Work with info	1,50%
6	Effective communication	5,94%	15	Negotiating	1,44%
7	Stress resilience	4,69%	16	Change management	0,50%
8	Business knowledge	4,26%	17	Leadership	0,20%
9	Active listening	3,83%	18	Delegating	0,20%

Utilization of WINGS method for the Determination of Necessary Training

The existing WINGS model of interrelationships and influences was used as a starting point and importance measure was added to the matrix as characterized by (1). Then the following sequence of (2) to (4) was used to determine the total strength-influence matrix **T.** Then values of $r_i + c_i$ and $r_i - c_i$ were calculated to draw the engagement-position maps for each of the levels of the model.

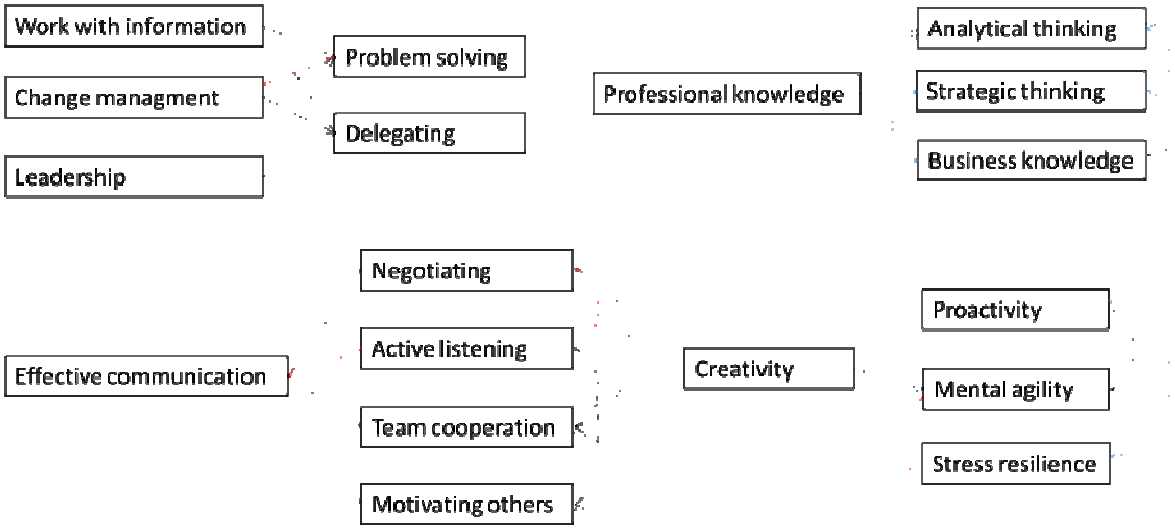

Fig. 2: Interrelation map for managerial competencies

It can be seen that the work with information, change management and leadership have high influence on competencies of problem solving and delegating, we can also see that the problem solving can have an effect of change management competencies as well; looking at the professional knowledge competence, we can identify complex relationship with analytical thinking, strategic thinking and business knowledge, which are interrelated and focusing on them can lead to a mutual improvement. It should be also noticed, that analytic thinking can impact the competency of business knowledge and strategic thinking. However, the effective communication was not identified, using the AHP, for the position of the middle manager as the most important, we can see that it has high influence on other important competencies, i.e. team cooperation, active listening, negotiating and motivating others. Furthermore, there are complex relationships among these competencies as well; this means that further improvement of these individual competencies will lead to the improvement of more than one competency. We can see that one of the identified key competencies, i.e. team cooperation plays an important role also within the interrelationship of the above mentioned competencies. Although, the

creativity was not identified as one of the key competencies, using expert's evaluation with WINGS it was found that it has an influence on more important competencies, such as proactivity, mental agility and stress resilience; it should also be mentioned that the proactivity has a profound influence on the mental agility and stress resilience.

This novel application of the multiple criteria decision making method WINGS is so far the only one focused on competency modeling and HR management. Using WINGS the managers can combine the weights (importance) derived from AHP or other MCDM method and also their subjective (expert) opinion about the cause and effect of these competencies. The results can be illustrated by the position-engagement map, which helps to identify the competencies that should be trained and developed the most, since they do have an impact on the most important competencies. By improving those competencies, the overall training and development should improve the employee key competencies.

Conclusion

Competency models designed by the utilization of AHP, TOPSIS and WINGS can help the human resource management in several areas, such as: planning training and development activities, employee appraisal, hiring new staff and compensation. The paper presented an example that revealed fundamental benefits of MCDM approach towards competency modelling. AHP method helped to scale down the number of measures and helped to determine the most important competencies, which can lead to the achievement of company's strategic goals. Because of the inherently inter-related nature of the attributes, the determination process of priorities can be quite complex.

This insight should help the company's management to concentrate on improving particular competencies that are most influential to the others. The technical competencies were found to be not affecting nor affected by other competencies. When comparing results from the expert evaluation using AHP and WINGS we have to look for an intersection. The most important competency according to prioritization using AHP is professional knowledge followed by analytic thinking. Application of WINGS revealed that these competencies are independent to other competencies and are interrelated only within technical competencies themselves. A training and development plan for middle managers can be developed from these results.

A combination of learning modalities seems particularly well suited for this purpose. Some competencies such as those in interpersonal competencies clusters benefit from face-to-face practice and, optimally, time spent observing other managers can help to improve these competencies.

The competencies are ordered based on importance, the HR department and the employees themselves will know on which competency they need to concentrate the most and also what knowledge/skills have to be improved by the employees the most. In our case the employees should mostly concentrate on improving professional knowledge, analytic thinking, proactivity, mental agility, team cooperation, effective communication and stress resilience, since these competencies are the most preferred by the company for the middle manager position.

The author sees limitation of the presented work in the number of respondents and selection of Moravian-Silesian region. Further research of the utilization of MCDM methods in competency modelling and in the human resources in general could be aimed at a larger number of respondents on different levels of management, the author plans to find out if there are differences in key competencies on various levels of management that is top management, middle and line management and if there are similarities on those positions if managers work in different fields. The study can also be broaden to other positions that can be generalized, i.e. teacher.

Abstract

As stated in our previous works, this paper is part of a larger research aiming to build up econometric models applicable in oil industry that may be useful for managers working in oil industry. Hence, in this paper discuss about models that describe two-dimension motion in homogenous porous environment. In the first part, the article deals with flat radial motion, when is considered an oil well that crosses the entire thickness of the productive wall and the productive layer is horizontal. Then, the paper deals with motion generated by an oil well eccentrically located in a circular contour supply deposit, when the motion generated by an oil well under the conditions mentioned in the first part, the only difference that the oil well is placed eccentric. These models will be useful tools for decision makers to an optimal management of the extraction process in an oil drilling and extraction unit.

Keywords: oil deposits, decline oil production, two-dimension motion, homogenous porous environment

Introduction

Sustained development of production and the increase of its economic efficiency involves as a necessity the rational use and exploitation of material resources and energy [Kula, 1994; Pearce and Turner, 1990]. Therefore, increasing material and energy resource recovery is a major coordinate for economic growth and improvement in economic efficiency.

Despite the fact that oil extraction is achieved in a closed system, which should enable it to avoid or, at least, substantially reduce all forms of pollution, the exploration and exploitation of oil deposits continue to be among the most polluting industrial activities [Bulearcă and Popescu, 2014]. Oil, heavy oil, salt water and various chemicals contamination of land around drilling and extraction oil-wells is, with all its incidentally character, extremely harmful to soil, surface water and groundwater. In this respect, the severity of pollution will depend, of course, on the nature of the pollutant, its quantity and why this pollution occurs [Bulearcă *et al.*, 2016].

As this paper is part of a larger research aiming to build up econometric models applicable in oil industry that may be useful for managers working in oil industry, this article discusses about models that describe two-dimension motion in homogenous porous environment [Avram, 2005; Iordache and Avram, 1995]. Our focus should be placed on three different types of motion: flat radial motion; motion generated by an oil well eccentrically located in a circular contour supply deposit; and motion generated by an oil well in a deposit with linear supply contour (this type of motion, along with bi-dimensional motions in a homogeneous porous medium, will be presented in one of our future work).

Hence, by thorough analysis, we will demonstrate that certain methods used for the final recovery factor increase involve enhancing the natural energy of an oil deposit, as well as helping to improve oil well performance [as presented in our previous research - see Bulearcă *et al.*, 2017], like when applying under-balanced drilling that is instrumental in increasing oil wells productivity by reducing the oil well formation damage [Qamar, 2013; Rehm *et al.,* 2013]. In this respect, oil displacing (washing) by steam, which is a way of increasing the final recovery factor, leads to enhancing the total energy of the system. All these aspects and other related issues on this topic will be further discussed in the next paragraphs.

Flat Radial Motion

To estimate the crude oil production from oil deposits, analytical models have been developed corresponding to different geometric configurations [Costache, 2008; Cretu, 1987; Cretu and Ionescu, 2005]. On the other hand, some models consider oil as an incompressible fluid, and other (more complex) take account of its compressibility. Finally, the motions to be modeled shall be either stationary - independent of time -, or non-stationary.

The following incompressible liquid stationary motions are considered [Hawkins, 1956], characterized by the condition: $dp/dt = 0$, at any point in the motion range and at any time t. Fundamental equations solutions obtained for these motions can be used either to study qualitative certain aspects of non-stationary motions, or to study non-stationary motions through methods that assimilate them with a succession of stationary states.

It is considered an oil well that crosses the entire thickness of the productive wall, receiving fluid through its natural wall, and called *the perfect oil well from the hydrodynamic point of view.* If the productive layer is horizontal with a constant thickness h, and the oil well produces the constant pressure p_c, at a constant pressure p_s of a coaxial cylindrical zone with the outer border of radius r_c, (figure 1), then the radial motion is flat radial stationary, generally speaking.

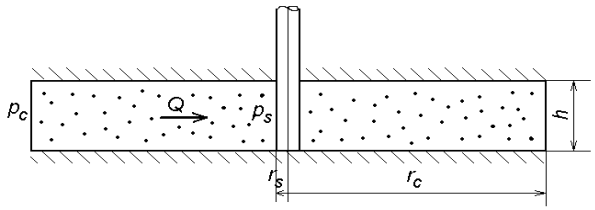

Fig. 1: Configuration of the flat radial motion of a fluid through a homogeneous porous environment

Notation used in figure 1 has the following meanings:

r_s – oil well radius;
r_c – supply radius contour (border);
$_{ps}$ – oil well dynamic pressure at a certain depth (measured from the average depth of perforated interval),
p_c - static pressure of productive layer, called the supply pressure on the perimeter.

Providing the stationary character of the motion generated by the oil well, the condition that the pressure p_c is constant is satisfied if through the outer border radius r_c, which must be permeable and it's named *supply border,* a quantity of fluid equal to that produced by the oil well enters into the drainage area of the oil well.

Given the axial symmetrical character of the motion, it is studied in cylindrical coordinates that, for flat motion, are reduced to polar coordinates *r,* q. Under these conditions, microscopic continuity equation associated with state equation of incompressible liquid is reduced to form:

$$\frac{1}{r}\frac{\mathrm{d}}{\mathrm{d}r}(r v_r)=0 \ , \tag{1}$$

where the radial velocity, which is the only component of the velocity filter, is given by Darcy's law:

$$v=v_r=-\frac{k}{\mu}\frac{\mathrm{d}p}{\mathrm{d}r} \ . \tag{2}$$

From relations (1) and (2) follows the differential motion equation:

$$\frac{\mathrm{d}}{\mathrm{d}r}\left(r\frac{\mathrm{d}p}{\mathrm{d}r}\right)=0 \ , \tag{3}$$

that is successively integrated until leading to the solution:

$$p = a \ln r + b, \tag{4}$$

which is the pressure variation law and is associated with boundary conditions (as shown in figure 1):

$$\begin{cases} \text{for } r = r_s \ , \ p = p_s \ , \\ \text{for } r = r_c \ , \ p = p_c \ . \end{cases} \tag{5}$$

By replacing the conditions (5) into (4) we obtain the equation for the two constants of integration:

$$a=\frac{p_c-p_s}{\ln\frac{r_c}{r_s}} \ , \ b=p_s-\frac{p_c-p_s}{\ln\frac{r_c}{r_s}}\ln r_s=p_c-\frac{p_c-p_s}{\ln\frac{r_c}{r_s}}\ln r_c$$

and pressure variation law (4) becomes:

$$p=p_s+\frac{p_c-p_s}{\ln\frac{r_c}{r_s}}\ln\frac{r}{r_s}=p_c-\frac{p_c-p_s}{\ln\frac{r_c}{r_s}}\ln\frac{r_c}{r} \ . \tag{6}$$

If the pressure derivative d*p*/d*r* is replaced in the Darcy equation, is established the filtration velocity equation:

$$v = -\frac{k}{\mu}\frac{p_c - p_s}{\ln\frac{r_c}{r_s}}\frac{1}{r}, \tag{7}$$

which introduced into the macroscopic continuity equation (8),

$$Q = A|v| \tag{8}$$

where the normal section at filtration velocity at any point has the form of a cylinder of any radius *r*, the area of this section being:

$$A = 2 \square r h, \tag{9}$$

leads to the equation of the incompressible fluid flow volume of the oil well:

$$Q = \frac{2\pi k h(p_c - p_s)}{\mu b_t \ln\frac{r_c}{r_s}}. \tag{10}$$

In the previous equation we have considered an oil well. For the oil flow to be expressed at the surface conditions (at the pressure in the storage tank that is practically equal to atmospheric pressure), in the denominator of equation (10) the oil volume factor b_t was introduced, being defined as the amount of oil at deposit conditions that corresponds to the oil unity volume under surface conditions. Given that, at the deposit pressure, the oil contains a significant amount of dissolved gases, which are separated in the liquid phase prior to its tank storage, volume factor of the oil has a value higher than the unity.

Figure 2 shows the variation graphics of filtration speed and pressure as related to the radius. It is noted that the maximum values of gradients pressure and velocity are recorded in the vicinity of the oil well, which highlights the importance of this area to the oil well production flow.

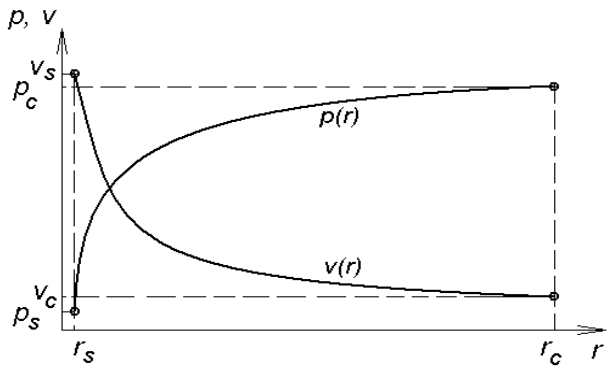

Fig. 2 Graphic of filtration speed and pressure as related to the radius, according to the stationary flat radial motion of a liquid

The ratio between the oil well flow and differential pressure of production is called *the oil well productivity index* and has the expression:

$$I_p = \frac{Q}{p_c - p_s} = \frac{2\pi k h}{\mu b_t \ln \frac{r_c}{r_s}}. \tag{11}$$

Specific productivity index is the ratio between I_p and the thickness h of the productive layer, i.e.:

$$I_{ps} = \frac{I_p}{h} = \frac{Q}{h(p_c - p_s)} = \frac{2\pi k}{\mu b_t \ln \frac{r_c}{r_s}}, \tag{12}$$

while the capacity:

$$C = k\,h \tag{13}$$

is called *the collector oil layer production capacity*. The parameters I_p and I_{ps} directly characterize the performance of the oil extraction well.

From equations (10) and (11) we see that productivity index is the slope $Q\ (p_c - p_s)$, and is called *the indicating diagram* (figure 3). In the area of validity for Darcy's equation upper limited by the critical point *C,* the indicating diagram is the straight line described by the equation (11), while in nonlinear filtering the indicating diagram is a curve with decreasing slope.

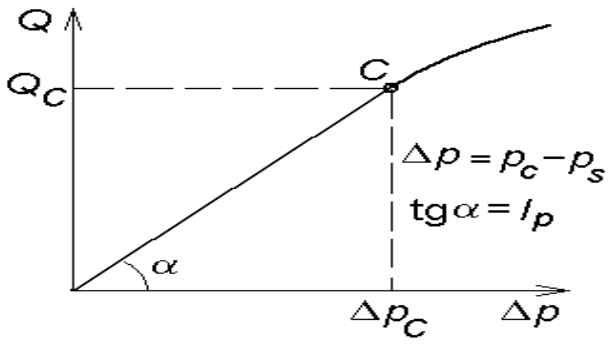

Fig. 3: Graphic of volume flow according to the differential pressure under flat radial motion Of a stationary liquid

One of the main purposes of oil extraction technology is to increase productivity index of each well to the maximum possible values from the economical point of view. This process is known as *stimulation of wells productivity* and can be done through various ways, which can be deduced from the analysis of how each factor in relation (11) should be amended to increase the productivity index.

Increasing the permeability *k* through hydraulic acidizing or cracking and thermal methods for viscosity lowering (as cyclic steam injection in the productive layer) are the main ways to boost productivity oil wells.

By stimulation oil recovery period is reduced as effect of increasing the extraction rate, but not necessarily obtaining an increase of the final recovery factor as well.

Methods to increase the final factor involve the enhancement of the natural energy of a deposit.

Thus, while displacement (washing) crude oil with steam, which is a way of increasing the ultimate recovery factor, leads to increase the total energy of the system, most of the heat supplied to the deposit in the cyclic steam injection (which is a method of stimulating oil wells productivity) is lost during production as a result of thermal conduction towards impermeable layers from the collector's roof and couch, and during heat transport to the surface at the same time with heated fluids produced by the oil well.

Motion Generated By an Oil Well Eccentrically Located In a Circular Contour Supply Deposit

Let's consider the motion generated by an oil well under the conditions mentioned in the previous paragraph, the only difference that the oil well is placed eccentric, at a distance *d* from the center of the circular contour supply of radius r_c.

To study this motion, the method of complex variable functions associated to flat potential motion can be used. In this regard it is noted that if the function is defined as:

$$\varphi = -\frac{k}{\mu} p \ , \tag{14}$$

then, velocity components presented according to Darcy's law as follows:

$$v_x = -\frac{k}{\mu}\frac{\partial p}{\partial x} \ , \ \ v_y = -\frac{k}{\mu}\frac{\partial p}{\partial y} \ , \tag{15}$$

take the form:

$$v_x = \frac{\partial \varphi}{\partial x} \ , \ \ v_y = \frac{\partial \varphi}{\partial y} \ , \tag{16}$$

showing that two-dimensional motion of single-phase incompressible fluids in porous homogeneous environment behaves like a potential move with speed potential *j*. Neglecting the oil well radius r_s related to radius r_c of the supply contour, the oil well can be assimilated to a linear distribution of negative sources.

The complex potential of the motion generated by the oil well in the plane *xOy* in figure 4 is given by:

$$f_1(z) = -\frac{Qb_t}{2\pi h}\ln(z+\delta)\ , \tag{17}$$

where $z = x + iy$, Qy *and* Qb_t are expressed as oil flow at oil deposit conditions (corresponding to flow Q at surface conditions), while complex number z_1 which defines the position of the oil well to the axis system is expressed as:

$$z_1 = x + \square + i\,y = z + \square$$

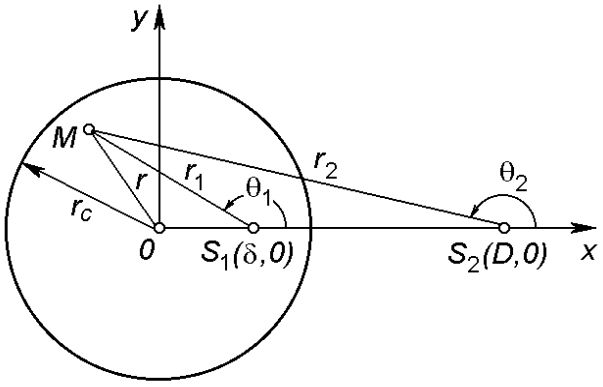

Fig. 4 : The two flat sources equivalent to the motion generated by an oil well eccentrically located

The oil well was considered as a negative flat source, S_1, because it absorbs fluid from the motion, while intensity (flow) flat source is the ratio between flow rate and length h of the linear source.

For the extension of the motion (which takes place, obviously, only within the circle of radius r_c) throughout the plane xOy, a positive source S_2 (considered as an injection well, with intensity (volume flow) + Q) is introduced, symmetric to the circle in point S_2, located from the field motion center at a distance:

$$D = r_c^2 / \delta\ . \tag{18}$$

Thus, the motion generated by the eccentric oil well of an oil deposit can be studied using the model of flat potential motion generated by two sources of opposite sign.

As a result, the complex potential of source S_2 is expressed as:

$$f_2(z) = \frac{Qb_t}{2\pi h}\ln(z+D)\ , \tag{19}$$

and the complex potential of the resulting motion is obtained by summing the complex potential of the two sources as follows:

$$f(z)=-\frac{Qb_t}{2\pi h}\ln(z+\delta)+\frac{Qb_t}{2\pi h}\ln(z+D)=\frac{Qb_t}{2\pi h}\ln\frac{z+D}{z+\delta}\ . \tag{20}$$

Writing that:

$$z_1=z+\delta=r_1e^{i\theta_1}\ ,\ z_2=z+D=r_2e^{i\theta_2}\ ,$$

equation (20) becomes:

$$f(z)=\frac{Q\,b_t}{2\,\pi\,h}\left[\ln\frac{r_2}{r_1}+i(\theta_2-\theta_1)\right]=\varphi+i\,\psi\ , \tag{21}$$

and the real part of the equation becomes:

$$\varphi=\frac{Qb_t}{2\pi h}\ln\frac{r_2}{r_1}+\varphi_0\ , \tag{22}$$

While introduced in (14), gives the pressure equation:

$$p=-\frac{Q\mu b_t}{2\pi k h}\ln\frac{r_2}{r_1}+C\ , \tag{23}$$

where r_1, r_2 are the bipolar coordinates defined in figure 4, and j_0 is the potential value at speed $r = r_s$.

To express the boundary conditions is assumed that the point M in figure 4 is successively owned by the oil well wall and supply contour.

If M belongs to the border of radius r_s, the first boundary condition takes the form:

$$\text{for } r_1=r_s \text{ and } r_2=D-\delta,\ \ p=p_s\ . \tag{24}$$

If M is on the outer border of the oil well area (figure 5), based on the relationship of symmetry to the circle (40) results that triangles OS_1M şi OS_2M are like.

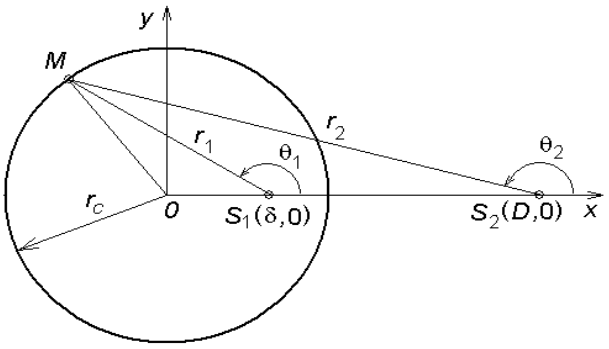

Fig. 5: Illustration of the condition that the point M belongs to the outer border of the eccentric oil well drainage area

We can write the equations expressing the two triangles' side proportionality:

$$\frac{r_c}{\delta}=\frac{D}{r_c}=\frac{r_2}{r_1}$$

and the second boundary condition as follows:

$$\text{la}\frac{r_2}{r_1}=\frac{r_c}{\delta},\ p=p_c\,. \tag{25}$$

Substituting the boundary conditions (24) and (25) in equation (23), the following system of equations is obtained:

$$\begin{cases} p_s=-\dfrac{Q\mu b_t}{2\pi k h}\ln\dfrac{r_c^2-\delta^2}{\delta r_s}+C\ , \\ p_c=-\dfrac{Q\mu b_t}{2\pi k h}\ln\dfrac{r_c}{\delta}+C\ , \end{cases} \tag{26}$$

For constant C and oil well flow rate Q, from equations (26) it then results:

$$C=p_c+\frac{p_c-p_s}{\ln\dfrac{r_c^2-\delta^2}{r_c r_s}}\ln\frac{r_c}{\delta}\ , \tag{27}$$

and

$$Q=\frac{2\pi k h\left(p_c-p_s\right)}{\mu b_t\ln\dfrac{r_c^2-\delta^2}{r_c r_s}}\ . \tag{28}$$

Introducing expressions (27) and (28) into (23), the pressure variation law in bipolar coordinates becomes:

$$p = p_c - \frac{p_c - p_s}{\ln\frac{r_c^2 - \delta^2}{r_c r_s}} \ln\frac{\delta}{r_c}\frac{r_2}{r_1}. \tag{29}$$

Returning to Cartesian coordinates, then multiplying by 2 the numerator and denominator from the right ratio of the equation (29) in order to eliminate radicals, we obtain the equation:

$$p = p_c - \frac{p_c - p_s}{2\ln\frac{r_c^2 - \delta^2}{r_c r_s}} \ln\frac{\delta^2\left[(x+D)^2 + y^2\right]}{r_c^2\left[(x+\delta)^2 + y^2\right]}, \tag{30}$$

expressing the pressure variation law in Cartesian coordinates. Based on this pressure we can now better estimate the production of crude oil from oil deposits; however, several analytical models corresponding to different geometric configurations helping to estimate this production will be presented in our future researches.

Conclusions

In conclusion, the present paper has aimed to build up more econometric models applicable in oil industry that may be useful for managers working in oil industry. Hence, this article dealt about models that describe two-dimension motion in homogenous porous environment. Our focus was placed on three different types of motion.

In the first part, flat radial motion was studied. It was considered an oil well that crosses the entire thickness of the productive wall, receiving fluid through its natural wall, and called the perfect oil-well from the hydrodynamic point of view. For a productive layer horizontal with a constant thickness and an oil well producing at a constant pressure, it was demonstrated that the radial motion is flat radial stationary, generally speaking, but this remains to be discussed in our future researches.

In the second part, the motion generated by an oil well eccentrically located in a circular contour supply deposit was analyzed. We considered the motion generated by an oil well under the conditions mentioned in the previous paragraph, with the only difference that the oil well is placed eccentric, at a certain distance from the centre of the circular contour supply. To study this motion, the method of complex variable functions associated to flat potential motion was used and then introduced in our analysis.

Hence, by thorough analysis, we have demonstrated that certain methods used for the final recovery factor increase involve enhancing the natural energy of an oil deposit as well as helping to improve oil well performance. In this respect, oil displacing (washing) by steam, which is a way of increasing the final recovery factor, leads to enhancing the total energy of the system. All these aspects and other related issues on this topic will be further discussed in the next paragraphs.

At the same time, in the paper we have analyzed that most of the heat supplied to the deposit in the cyclic steam injection process (which is a method for stimulating oil-wells productivity) is lost during the production process as a result of thermal conduction to impermeable layers of both roof and couch collector, as well as through the heat transport to the surface alongside the heated fluids produced by the oil well.

Starting from these findings and to extent the motion range from the upper semi-plane to the entire plane, a fictitious positive source of strength may be introduced, symmetric to the supply contour, and our future researches will take it into consideration. Hence, further analysis on this topic will follow in our next papers to come.

Levels of Business Process Modeling

Hana Tomaskova, Faculty of Informatics and Management, University of Hradec Kralove, Hradec Kralove, Czech Republic, hana.tomaskova@uhk.cz

Abstract

This article deals with introducing the BPMN notation and its use at different levels of modeling. BPMN is currently a highly desirable notation in a corporate environment that serves to understand the company, its structure and its subsequent re-engineering and modeling of business processes.

Keywords: BPMN, Object modeling, Levels of modeling, business process

Introduction

„The Business Process Modeling Notation (BPMN) is a graphical notation that depicts the steps in a business process. BPMN depicts the end to end flow of a business process. The notation has been specifically designed to coordinate the sequence of processes and the messages that flow between different process participants in a related set of activities.“(www.bpmn.org)

BPMN was created by an Object Management Group (OMG) as open and therefore free of charge. Looking at BPMN, at first glance, it allows very much similarity to flowcharts but instead offers much more sophisticated tools to describe and simulate behavior. This is an "event-triggered behavior," a description of the "something happened" mode (Silver, 2009). Another, very significant feature of BPMN is its "business-friendly" orientation. This orientation and processes modeling is very important for the company's business and knowledge (Mohelska & Tomaskova, 2010, Tomaskova, 2009).

Origin and history of BPM

Dumas (Dumas, 2013) derives the business processes management in the natural development of human life in connection with the division of labor. This situation culminated in the second industrial revolution when the individual employee's specialization reached such a level that it was necessary to create a group of experts to manage this work. They were responsible for meeting the goals, optimizing processes and ensuring the effective functioning of the company. One of the drawbacks of this solution was the extensive corporate structure. In the late eighties, the company learned about the Japanese companies management after the confrontation. These studies have found that it is more important to work with the whole process than with its individual tasks.

The previous paragraph is related to BPR - Business Process Redesign or Re-engineering. In spite of certain difficulties associated with poor access to BPR, where businesses attempted to over-radicalize or redesigned activities that were not key to business, it was proven that process-oriented companies were essential to increase efficiency and their customers satisfaction. (Dumas, 2013).

From the information technology development perspective, one of the most important facts was the development of specific systems to support BPM and BPR. These systems include ERP (Enterprise Resource Planning) and WfMSs (Workflow Management Systems). ERP systems are used to manage company data. WfMSs, on the other hand, serve to pass on the work to individual actors based on process models, thus allowing for easier changes implementation in company processes. Another of the features is to analyze business processes and to further develop them into more complex systems known as Business Process Management Systems (BPMSs). These are nowadays used to automate processes.

BPM life cycle

The BPM life cycle can be described as a continuous cyclical repetition of the following phases (Dumas, 2013)

1. Process Identification - Finding a problem, identifying process-related issues, determining process hierarchies, optionally measuring process performance
2. As-is modeling - a model of the current process is created
3. Process analysis - the relationship between the problems and the parts of the process in the as-is model, the determination of the priority to solve individual problems
4. To-be modeling - determines changes leading to problem-solving and their subsequent transformation into a model showing the new form of processes, optionally simulation and measurement of process performance and comparison with the as-is model
5. Implementation of the process - the changes defined in the previous phase are put into practice
6. Monitoring and Process Control - Process performance is measured and data is compared to data already acquired, to identify additional or unresolved errors

Process Identification

In terms of business process modeling, it is important to identify processes that will be modeled and then modified. In most businesses, the analysis of all business processes is not financially and time-consuming. It is often necessary to consider the priority of individual processes and first to focus on improving processes of strategic importance for business. Dumas (Dumas, 2013) emphasizes the need for knowledge of all processes in the company so that the criteria can be determined by the criteria that will be emphasized.

Designation phase

It is necessary to set a specific strategy for the processes selection and in a number of processes, it must be a reasonable compromise so that their change affects the processes improvement but at the same time it is possible to change them.

The next step in the determination phase is to determine the relationships between processes, whether from the hierarchical perspective of superiority and process subordination and from the viewpoint of the workflow of the work when determining the time sequence of the processes. However, realize that it is not the primary goal of strictly recording processes and relationships, but rather understanding all contexts and issues.

Validation phase

Dumas (Dumas, 2013) provides the following criteria, appropriate for verifying the importance degree and attention devoted to the process.

- Importance - relates to the strategic importance of each process and its relation to the strategic goals of society
- Dysfunction - Used to assess process status from the perspective of errors and problems, those with more obstacles deserve more attention
- Feasibility - Assessing obstacles to changing process, or motivation to make changes

Design of processor architecture

Process architecture is a model depicting the relationships between rules in society. It is about establishing a consumer-producer relationship. Process architecture also sets the level of detail capture. Dumas (2013) distinguishes between 3 levels.

- Landscape model - shows only the largest processes with a high degree of abstraction
- Abstract Process Models - shows individual business processes in a more detailed form, but still more abstractly
- Detailed Process Models - This is a description of processes at the level, inputs and outputs, flow, process participants, an example of this model is BPMN

BPMN levels

Bruce Silver in his book (Silver, 2009), divides modeling of business processes into three levels according to the way diagrams are used. These levels are subdivided according to the model purpose and, depending on the diagram detail.

Descriptive modeling is the simplest form of modeling to describe the functioning of an organization in terms of the continuity of activities and responsibilities and the roles of individual organizational units in these processes. In its essence, it is the closest to the classic modeling of flowcharts. For this purpose, only the basic set of BPMN notation elements is used. Here, however, a specific form must be retained so that, in case of an extension to the second or third level, the model can only be specified without major structural changes.

The second level is called an analytical model and its goal is to provide a complete and the complete processes description. The only exception is the removal of the technical details required for "running the model". For technical details, we mean, for example, the structure and type of data and their expression. However, the BPMN specification can not separate technical information from others, the second layer is defined by what is seen in the diagram. The second level of BPMN is focused on business processes and is designed for management and analytics, as it enables it to capture all the details that can then be passed on to the IT department in an easy-to-understand and simple form. Another suitable use of the second level of BPMN is the possibility of simple analysis of the alternative course of business processes.

The third level of BPMN diagrams is primarily focused on developers. It consists in adding all the technical details to the properties of the individual elements and subsequently generating the XML code. This use of BPMN is, however, a novelty from BPMN 2.0.

Conclusion

BPMN has been a very functional notation since introduction. This notation describes the business and its processes. The article presented a brief history of this notation and the basic of business processes modeling. Various levels of modeling and life cycle BPM have been described.

Abstract

E-Learning system acquired in the last decade an increasing number of students. In fact, it represents a flexible educational support for the student; it tunes automatically the studied resources according to the individual personality, needs and knowledge of the connected student; it offers a personalized service by analyzing collected data about the student. However, those students often cat off due to some mismatch with their concerns. In fact, e-Learning systems generally rely on the student's data observed on the e-Learning platform and neglect other sources of information. But, the more information we get, the more we are close to the student and his real expectations. Therefore, we propose, in this paper, the enrichment of the student model by observing his behavior on parallel opened URL(s) to deduce his acquired knowledge and to detect bridge events that require the system intervention for appropriate recommendation to stabilize the student behavior. The main treated issues focus on firstly, what is the useful information to observe in order to detect the real knowledge acquired by the student? Secondly, how this information is used to enrich the student's model?

Keywords: student modeling, data analysis, web personalization, e-Learning.

Introduction

In e-Learning platforms, individual personalization constitutes an essential service to attract the student. In fact, personalization of online platform services, in order to satisfy the implicit and explicit student needs or the student knowledge, has been a subject of many research studies. Eiriniaki and Vazirgiannis (2003) mentioned that web personalization is a process that contains a set of stages; first, the collection of the web data, second the modeling of these data, third the analysis of the collected data, and finally the personalized services are delivered. In this paper, we deal with the collection and the modeling of the web data, which concern the e-Learning platform, in order to detect the real student's gained knowledge as well as the troubles related to the student's learning behavior. The latter is used to provide an instantaneous recommendation to stabilize the student's learning attitude. In an e-Learning platform, the student-modeling phase includes several facets related to the complexity of the student's personality and how the external and internal effects of the learner's individual environment can affect his behavior on the studied course. One considered facet concerns the student's learning style, defined by Jonassen and Grabowski (1993) as the individual skills and preferences like learning materials that affect the learner perception and concentration. Yet, Popescu et al (2010) discussed in detail this subject and defined a tool handling different learning styles like the model of Felder and Silverman (1988). This model subdivides the

learner‘s style on various categories according to research work of Truong (2016), Ciloglugil and Inceoglu (2016), Rani et al (2015). However, it requires that student responds to a long survey in order to detect his style. This is considered as a major inconvenient. So, many works have tried to automate this detection, such case is depicted in the research work of Ahmad et al (2013) and Khribi et al (2013). Another important facet concerns the student’s knowledge is that it aims, on the one hand, to link the domain of the e-Learning application to the gained knowledge; on the other hand, it detects the gap that affects the evolution of the considered knowledge. This is a very important mean that allows an implicit assessment of the learner progression and determines the bridge events that simulate the demotivation of the student about some studied course or concepts. In the next section, we review this facet with details. Other works explored the facet of the student’s behavior and cognitive capability such us Polin and Martin (1992). They mainly analyzed the student’s cognition among his observed behavior and they characterized the student’s ability to learn, to keep attention of the course, etc. Bandura (2001) reported that the student cognition is often discussed in the field of psychology science. Besides, we note that studying the facet of student social interaction is omnipresent in the web personalization process, particularly with the e-Learning platform. It presents a crucial tool to deduce the existent relation between the e-Learning environment and the student’s social behavior as it is proved in the research work of Chu and Chen (2016). We consider that each quoted facet associated with student modeling issue, provides an overview of the observed student interests, needs, and wishes. The combination of them offers a complete mirror of the student and provides a better recommendation of possible resources and courses to the learner. Actually, the connected student to the learning platform leaves a trace of his personality, his interests, his intellectual level, and his social capability in each visited URL. Therefore, in order to be more accurate when modeling the student, we should take into consideration his external web navigation during his connection to the e-Learning platform. It’s like a large picture that can’t be detected from an only camera but it needs more cameras placed in distant places. Especially for student’s knowledge modeling, there are different external sources of information that can be cumulated and analyzed to determine the real level of acquired knowledge about defined concepts in the e-Learning platform. Hence, we propose to integrate the psychology facet and the knowledge facet in our analysis. Besides, we aim to detect the bridge event that simulates the student’s changing learning behavior. This then leads to the recommendation of the appropriate services.
The remainder of the paper is organized as follows: The second section presents the related works to the modeling of student knowledge and student behavior in the field of e-Learning system. The third section describes in detail the information provided by an e-Learning system about the student’s knowledge and the enrichment made by web scrapping on the student’s gained knowledge.

Our contribution is highlighted in the third section. It consists essentially on collecting the all student significant interactions; not only the past exams and tests but also the student interactions on forums. Furthermore, we deal with the emotional side in our analysis. The proposed approach is validated with a simulation of our algorithm to prove its efficiency to deduce the real knowledge gained by the student during its learning process.

Related Work

Since we deal with the student-modeling phase of the web personalization process, particularly modeling the student knowledge, we present, first, the developed models in order to model this knowledge. Then, we quote the proposed approaches that treat student behavior and events.

The Student Knowledge Models

In the context of e-Learning system, the most interesting fact to know is the knowledge of the student and his current as well as future interests about some concepts or knowledge. It is a challenging purpose because the studied subject “learner” can’t judge his knowledge about concepts as expert; moreover he

tends to hide his real knowledge or his misunderstood about something. Therefore, many studies had focused on such issue. In fact, there exist four principle classes; the overlay model, the perturbation model, the ontological model, and the machine learning model.

The overlay model was introduced by De Boeck and Wilson (2004). It consists on representing the student knowledge as a subset of the domain or expert knowledge. The gap of the student knowledge is detected through the difference between the expert's knowledge and the student's gained knowledge as explained by Bontcheva and Wilks(2005). Many tutoring systems have adopted this model such as GUIDON, which was introduced by Clancey (1983). The complexity of the overlay model depends on the granularity of the domain and its composed concepts representations. It supposes that the student knowledge is included in the expert knowledge; nevertheless, the student may have knowledge that experts didn't gain yet. Moreover, the student's behavior could vary from one student to another, as the reasoning process varies, so the logic of reasoning of an expert can't be the only path that leads to success. Besides, the overlay model ignores the cognition of the student and his needs according to his accumulated knowledge. Another developed approach manages the evolution of student's knowledge with a graph where the nodes correspond to the student's knowledge evolution rules and the edges represent the relationship showing the transition between connected nodes such as generalization. Thanks to the dynamic aspect of the graph, this approach offers an easy monitoring of the student's knowledge evolution, but the proposed graph has a static states.

The perturbation model as explained by Surjono and Maltby (2003), Baschera and Gross (2010) presents an amelioration of the overlay model since it considers the incorrect reasoning of the student to analyze the reasoning behind wrong answers and to understand the misconception of the student's behaving. A "bug" library supports such mission, is deduced from experimentations. However, new bugs and new misconceptions are not considered in this library.

Cheung et al (2010) explored the ontological model. The latter ensures the reuse of information organized in a semantic way as the knowledge of the domain. However, such model is closely related to the defined domain of the e-Learning application, also it ignores the cognition and the emotional states of the student.

Machine learning has been adopted as a model that dynamically observes the student and deduces if he is able to resolve certain problem, if the knowledge has been mastered, and if there is a lack in student understanding. The most known approaches that handle this model are the Latent Factor Model (LFM) based on Item Response theory introduced by Boeck and Wilson (2004) and the Bayesian Tracing Knowledge (BTK) introduced by Albert et al (1995). Indeed, the LFM deduces, from a group of student, the latent ability of each student to solve the problem and the latent difficulty of each problem. It doesn't treat the evolution of skills or student's knowledge through time. The BTK considers the evolution of knowledge in time but it doesn't make distinction between the student and the problem. To overcome those limits, Khajah et al (2014) suggested to combining the two models. The combination seems interesting as it insures the evolution of the individual knowledge in time taking into account the difference between student and problem. The limitation of this approach consists in collecting the student ability only from tests as well as neglecting the psychological effect on that model. Yet, there are other sources as questions and responses on forums that provide a certain level of mastered knowledge or a deficiency in certain knowledge. In addition, the passed tests don't often reveal the real level of knowledge gained by the student. In fact, there are many factors that affect the student's response especially on exams such as the track, the fear, and the lack of confidence. So, it is very interesting to be able to quantify the level of knowledge taking into account those factors. Besides, the observation windows used for tracking the student is very limited. We believe that the knowledge of the student is also built from external forums and external professional networks.

In this paper, we deal with computing the knowledge of the student accumulated from his internal and external web navigation. In fact, we believe that exploring the student's activity on the Web, such as

asking a question or answering a question, provide for the e-learning system a correct and clear vision about the actual knowledge gained by the student and the real incomprehension or blockage that the student suffers from. This improves the prediction of the student's intensions and preferences. So we can offer a stable and efficient learning process.

Mastered Concepts

Many research works have adopted the facet of student's mastered concept in the student's model in order to predict the student response facing a certain problem such as the Bayesian tracing knowledge or the Latent factor model. The latter takes into consideration the student's ability and the problem complexity. Indeed, for measuring the gained knowledge, it is important to consider all conditions that can influence the student response as emotions or problem difficulty. Besides, the connection that exists between concepts as well as the included set of Learning Objects in each concept constitutes a key factor that should be included to draw image of gained Learning Objects and so concepts and so determines his level of knowledge. In other words, it is essential to consider the concepts, concepts' domains, access hierarchies, exams and difficulties related to concepts, emotion of student, significance of response, and pertinence of questions. These factors contribute to enrich our Bayesian network model to provide the probability that Learning Objects/concepts are acquired by the student. So, we treat, in this section, the main information that should be analyzed to deduce the student's gained level of knowledge. This knowledge is detected according to different sources of information detection; knowledge obtained from an internal source, the e-Learning system in our case, called internal knowledge, and those obtained from external sources, the student web browsing, called external knowledge.

Internal Knowledge

In an e-Learning system, the domain of the application is represented as a set of concepts I, every course (F) includes a subset of concepts to handle. Besides, every concept is a set of Learning Objects and every Learning Object k_j is a set of term as:

$$C_i = \{k_j, j = 1..l\}, l \leq |k| \\ k_j = \{t_n, n = 1..f\} f \leq |t| \quad (1)$$

-Here C_i represents the *i* th concept in the course F and k_j represents the *j* th learning object on the concept C_i

A course F is represented as follows

$$F_j = \{C_h, h = 1..M\}, M \leq |C| \quad (2)$$

- With M number of concepts included in course F_j

The student can write a question on the forum of the e-Learning platform; every question is also related to a subset of terms that describe one or more concepts difficulties. So, a proposed question, x, at the moment, t, from the student, u, is represented as follows:

$$Q(t, x, u) = \{te_b, b = 1..B\}, B < |te| \quad (3)$$

Similarly, the response, x', produced at the moment, t', by the student, u, is presented as:

$$R(t', x', u) = \{te'_c, c = 1..C\}, C \leq |te'| \quad (4)$$

The student can also pass a test composed with large set of words related to a subset of Learning Objects included in concepts, generally, concepts related to each test and Learning Objects are indicated. So, the passed test, p, by the student, u, begins at time, t, and finishes at time, t', can be represented as follows:

$$test(t,t',u,p)=\{k_d, d=1..D\}, D<|k| \quad (5)$$

All concepts are organized in an oriented graph. The graph nodes represent the concepts and the edges represent the existence relation between those concepts. For instance, when the i th concept Ci is connected to the j th concept Cj, the edge is depicted from Ci to Cj, this means that before learning the concept Cj the student should imperatively gained the knowledge about the concept Ci. If there is a double connection between two concepts, the two concepts can be gathered because each concept can be related to the other. The following figure illustrates our example of the domain representation. Every set of concepts that has been surrounded represents a possible combination of those concepts in one course or one exam.

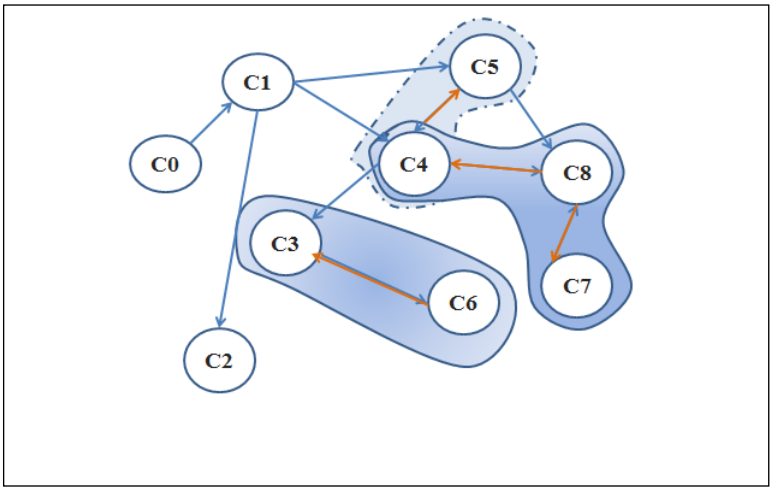

Fig.1: The relation between internal concepts

In order to be able to measure the degree of gained knowledge from each concept visited by the student, we deal with, firstly, the student's response and student's questions as well as the mark accumulated by the student during exams. We aim also to interpret the emotion of the student during exams to be able to judge the obtained mark since student emotion could influence the exam circumstances.

A. Deducing concepts and Learning Objects related to questions or responses

The first challenge is to be able to extract the concept and the Learning Object mentioned on each question and response. Computing the similarity between one asked question and one Learning Object is not an easy step; in fact, the same Learning object can be expressed with different sets of words such as "data visualization" and "how to plot m observation in two dimensional figure?". Applying a Jaccard coefficient leads to "0" similarities. So, we are facing a Natural Language Processing problem. The majority of researches that deal with such a problem employ one of the three following methods as knowledge based method, adopted by Radinsky et al (2011) as well as Gabrilovich, and Markovitch (2007) or corpus based method, adopted by Cilibrasi and Vitanyi (2007) or a combination of those

methods, introduced by Li et al (2003). In this paper, we deal with a corpus based method and more precisely with a supervised method. This is justified by the fact that we want to obtain an accurate classification of each asked question or given response related to the Learning Object existing in the e-Learning platform. In order to collect the needed corpus for the training data, we use Stack Overflow. This latter offers the possibility to obtain a large training data thanks to the stack exchange API. By querying the API, we obtain for each Learning Object between 1000 and 1500 questions, as well as Answers. Then, we consider the use of Recurrent Convolutional Neural Network RCNN, introduced by Lai et al (2015). After that, we compare its performance to the performance of Convolutional Neural Network CNN when applied to our data. CNN is introduced in the research work of Kim (2014). We conclude after experiments, as shown in Fig.2, that the RCNN outperforms the CNN. Therefore, we opt for the use of RCNN in order to obtain a more accurate classification task.

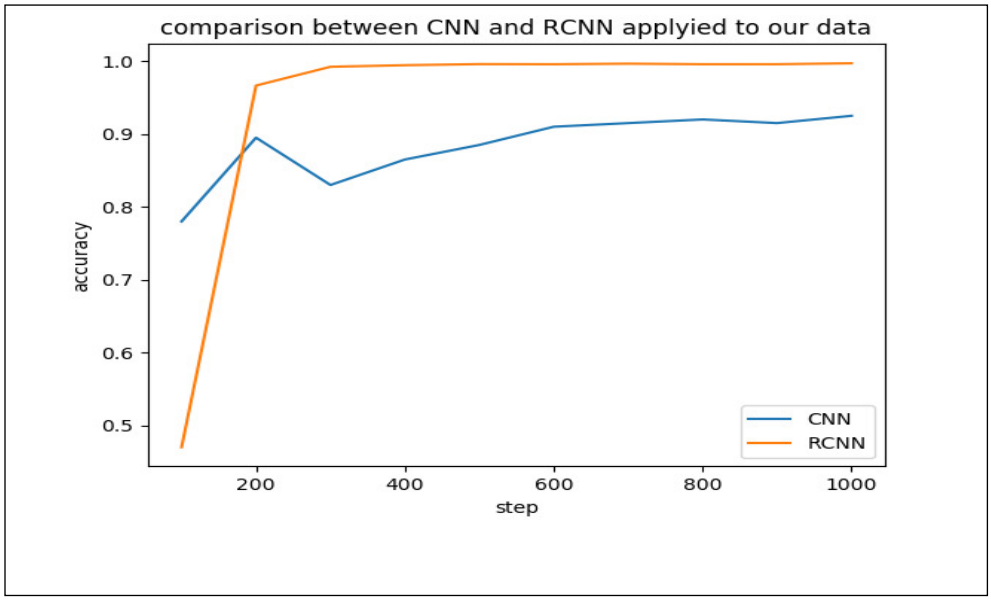

Fig.2: comparison between RNN and RCNN performance on our data

B. Question and test difficulties

It is very important to measure the concepts difficulties in tests, exams, or questions in order to be able to quantify the gained level of knowledge taking into account the student's response among the test's difficulty as well as the degree of student's question difficulty. This is useful to understand how the student has learned this concept (in depth or superficially). There are many definition of concept difficulty. The first definition, mentioned by Crocker and Algina (1986), considers that concept difficulty is the number of learner who answered the concept correctly divided by the total number of learner. This probability is generally given by teacher. The second definition, introduced by Kardan and Bahrani (2014), is based on the student's annotation (implicit feedback) when reading exams to determine the concept difficulty relying on term frequencies for every concept. We note that the first one proposes a general difficulty level and the second one proposes an individual difficulty level tracked from annotation. Therefore, we propose to combine the two definitions. We assume that measuring the difficulty of one concept figured in one test should take into account the general difficulty of this concept under all students as well as the individual probability that student has learnt this concept. The following equation resumes this computation:

$$concept_diff(C_i) = \frac{P(nb_rightAnswer(C_i))}{P(nb_allAnswer(C_i))} \times (1 - P(gained_ant(C_i))) \times \sum_{t \in C_i} d(t)$$
$$P(gained_ant(C_i)) = \prod_{k \in nb(C)/C_k < C_i} P(gained(C_k)$$
$$d(t) = (1 - \tanh(f(t) + 1/3) \quad (6)$$

-nb_rightAnswer represents number of right answers realized by the student;

-nb_allAnswer represents the number of all existent answers delivered students whose accomplish the test. Where P(gained_ant(Ci)) is the probability of student's gained concepts that should be mastered before the concept Ci . d(t) is the difficulty rating of term t and f(t) is the frequency of tem t. The first fraction in the concept_diff(C_i) is experimentally deduced.

C. Measuring emotions behind exams and questions

In order to measure student's emotions when answering questions or exams, we suggest using the RCNN [22] for this classification problem. Indeed, emotions are classified into five defined classes as: <confused, confident, ignoring, stressed, nothing>. The entire student's annotation, before or when responding a question, is kept and labeled manually to be used as a training data. We note that emotion is a number accorded to each detected feeling when the student passes an exam, this number is deduced according to the probability of the emotion to influence the learner's marks such as confused= 0.5 , confident=1.5, ignoring=0, stressed=1.5, nothing=1.

D. Level of gained knowledge

In order to measure the pertinence of a question written by the concerned student on the concept, we compute the emotional feeling of the students who respond to question. This can be determined through RCNN as explained before, classifying responses on question as <interesting, not interesting, nothing>; we note that nb_interest represents number of persons that express a certain interest to the question or vote for the question $Q(C_i)$ and nb_notInterest is the number of persons that express a disinterest to the question or consulted the question without any reaction .

$$pertinenceQ(C_i) = \frac{nb_interest - nb_notInterest}{nb_total} \quad (7)$$

Moreover, the pertinence of an answer is computed by dividing the number of time the response is viewed under the number of time the most viewed response is consulted. So, we summarize the form of the obtained and treated data to determine the level of gained knowledge as follows:

- Data related to exam: Concept, emotion, mark, difficulty, and time.
- Data related to question: Degree of evocation of concept, pertinence, and time. Generally, an asked question by the student reveals that he is confused about some concept, he misunderstands a thing related to a concept, or he ignores something related to a concept. In parallel, the pertinence of a question reveals that the student is learning in depth the concept and shows a certain level of concentration.
- Data related to response: Degree of evocation of concept, pertinence, and time. Generally, the response indicates an increase of level of knowledge when it is pertinent.

In order to build a full image of the learner gained knowledge about a certain concept after passing an exam or a test, we can compute the probability to gain a concept as explained in the Fig.3.The graph

(8)

illustrates the logic behind computing the gained knowledge in one concept. Precisely, it represents the structure of our Bayesian network given by the equation (8).

$$P(gained_C) = P(gained_k_{exam} \mid x,y,z,t) \cup P(gained_k_{response} \mid p,t' < t)$$
$$-P(gained_k_{exam} \mid x,y,z,t) \cap P(gained_k_{reponse} \mid p,t' < t)$$
$$-P(unkoun_k_{question} \notin k_{exam} \mid p',t'' < t)$$

With:

- k_{exam} represents the learning object figured in the exam, $k_{question}$ represents the learning object figured in the question, and $k_{response}$ represents the learning object figured in the response;

- x, y, z, and t are respectively emotion, difficulty, mark and time of passed exam; t' represents the time of posted response and t'' represents time of posted question.

- p and p' represent respectively pertinence of question and response.

- α, β, δ are the degree of evocation of the learning object k included in the concept among exam, question, and response.

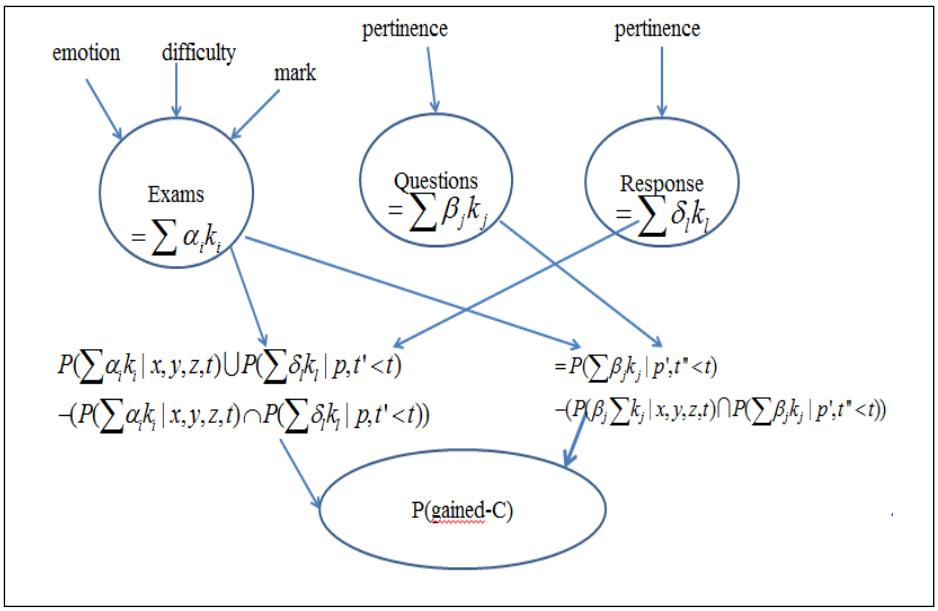

Fig.3: Level of gained knowledge in the concept C after passing an exam

We note that when combining the knowledge detected from m questions, the result is subdivided into m. So, we compute the mean of the computed knowledge from different student's actions and regarding to the same Learning Object.

External knowledge

Generally, the student opens several URL(s) in parallel to the e-Learning platform. He can consult in parallel his social networks to discuss with his friends the learned courses. He can use some known forums to ask about a misunderstood concept or to consult some responses about a certain question related to a certain concept. There are several forums like stack overflow, development.com, github, etc. Scraping student's behavior via these external URL(s) and especially forums could enhance the student's model. The scraping process should be automatically carried out according to a given filter. In our case, filter is a dataset of word corresponding to vocabulary related to the thematic of learning. However, this process presents some difficulties like performing data in short time or scraping data from a dynamic HTML structure. Indeed, the majority of web pages supports HTML format, which can be scrapped through the student's web browser to identify important URL(s) related to the learning topic. These URLs are used to capture student's concerns and interests about a particular subject. We notice that most websites have some Meta data stored in Meta tags of the HTML format; this meta data represents the description of the web page. Therefore, we extract the description of a webpage by parsing meta tags. Then, we compute the difference between the description of the concerned webpage and our defined filter. So, first, we extract information about opened URL(s) by means of the student's web browser. Then, we identify the following types of opened URLs:

- URLs that correspond to forums: Forum web pages are treated by using a method of text mining in order to understand the student's issues under the proposed questions and answers. For instance, in the case of Stack Overflow, the frameworks frequently used by student in computer science area could be detected.
- URLs of professional networks like LinkedIn. We analyze those URL(s) to extract the student's skills and to draw the graph of professional friends.

We explore those two types of URL(s) and we deal with data provided by web scraping according to a defined filter. We believe that the student's skills extracted from forums and professional networks can affect the student's model in the e-Learning context. It provides a better understanding of the gained student's knowledge and it indicates the encountered difficulties during the learning process. Moreover, the asked concepts in the extern platforms or forums can be related to other courses attended in another e-Learning platform, the recognition of these courses could be useful to recommend other courses for the student from our e-Learning platform. In our solution, we deal with Stack overflow. Through this forum, the student can ask a question, respond to a question and vote for a question or response, the vote can be negative. We propose to take advantage of the performed actions and determine if the contribution of the student is important. So, this can explain how the student is concentrated about one concept integrated in the question and it can inform us about the level of gained knowledge that concerns a certain Learning Object related to a certain concept. We are based on the combination between neo4j and Stack Overflow to implement our idea. Indeed, neo4j is capable to convert the Stack Overflow data in a huge graph that can be queried at any time to pursue the student's behavior on such forum. The information scraped from Stack Overflow is used to add the effective score for the learning object. We measure the score of each question and each response according to the tagged items in the corresponding question as follows:

$$ScoreQ_i = \frac{vote(Q_i) \times \sum_{j \in Q(i)} \alpha_j k_j}{totalviewed(Q_i)} \quad (9)$$

$$Score(R_{i,l}) = \frac{vote(R_{i,l}) \times \sum_{j \in R(k,i)} \beta_j k_j}{totalviewed(R_{i,l})}$$

Where:

-$ScoreQ_i$ corresponds to the score of the knowledge included in the question$i$. It describes how deeply the student is concerned about some concept.

-$ScoreR_{i,l}$ corresponds to the score of gained knowledge, detected in the response l related to the question$i$.

We are interested only on the Learning Objects or concepts included in the domain of the e-Learning platform, so that our problem is maintained as a classification problem. After that, we integrate the Learning Object and its computed score in our defined model in Fig.3. Indeed, the score represents the pertinence of the question or response related to this detected learning object. Following this logic, we accumulate an accurate image of the level of knowledge acquired by the concerned student.

A. Scenario and experiments

In this section, we present a simple simulation of our proposed approach in order to obtain more accurate information about the student's accumulated knowledge. We consider a student that learns from Dataquest. We choose the following parameters:

-Concept: Python foundation and programming concept,

-Learning Object: Exploration of Data Visualization, Learn how to explore data by creating and interpreting data graphics using matplotlib and pandas.

-Test on such concept: for each test the mark "x" is converted as 1 x>15, to 0.5 if 10<x<15, to 0 if x<10, the considered student obtains 1.

-Asked questions after tests: "data plotting in boxes with python: I have an array d[0:100] which is defined in boxes (or cells) whose center are stored in these two arrays x[0:100] y[0:100]and whose size is h[0:100]I wish I could plot an image showing boxes/cells colored according to the value of the array defined in each of them. It seems and histogram but it is not. Do you have any idea where to start?. The same query is asked on the e-Learning platform. It has 10 votes and 14 comments from different persons in the stack overflow platform and four interests and one disinterest in the e-Learning platform. Applying the previous cited algorism we obtain:

Table1: simple scenario explanation

	Internally	Externally
classification	Exploration of Data Visualization	Exploration of Data Visualization
pertinence	0,33333	0,714
Level of gained Knowledge(LO)	[(0,33333+0,714)/2]x1=0,5325→0,5	

We note that every score corresponding to the computed Knowledge "x" about a certain Learning Object is converted to 0 if x<0.4, to 0.5 if 0.4<=x<0.8, to 1 if x>=0.8.

Table2: A comparison between students' accumulated knowledge in the e-learning platform and those accumulated through our approach

	LO(1)		LO(2)		LO(3)		LO(4)		Agree
	B	A	B	A	B	A	B	A	
Student1	1	0.5	1	1	0.5	1	1	1	4A 2B
Student2	1	1	1	1	0.5	0	0.5	1	3A 3B
Student3	0.5	1	0.5	1	0.5	0	0.5	0	3A 1B

After exposing three students to the observation process of their external and internal navigation, we made a survey as each student is provided with two lists of its accumulated Knowledge. The first list (B) corresponds to the each student knowledge according to the passed tests. The second list (A) corresponds to the student knowledge regarding to our accumulated knowledge. This latter is related to the student's internal and external navigation. The result is shown on the table 2. In fact, we obtain for the first student four agrees about the A knowledge and two agrees about the B knowledge. We have for the second student agrees about three A and three B, and finally the third student agrees present three A and one B. We note that our process increases the performance of the learning process by tuning the knowledge level for each learning object according to all information kept from the learner learning process during his connection to the e-learning platform

Conclusion

This paper proposed a novel use of the student interaction on parallel open forums in order to better full fit the model of the student and more precisely construct a clear picture about the student gained knowledge. For that, we use Bayesian Network and we take into consideration emotion as well as question and response scraped in parallel opened URL(s). The fact of scraping from parallel URL(s) significant data is very challenging, yet we limit our focus on data correlated semantically to the domain of the e-Learning platform. This can be enlarged to encompass other learning objective but the process of identifying the Learning Objects in the scraped URL(s) should be automatically done.

Box-ing Happiness

Feyza Aglargoz, Anadolu University, Eskisehir, Turkey, feyzak@anadolu.edu.tr

Feyyaz Kaya, Anadolu University, Eskisehir, Turkey, feyyazkaya@gmail.com

Abstract

This ongoing research aims to explore the consumer behavior and psychology behind the subscription box business models and the motivations of buying and sharing this experience in social media. The study tries to explore meanings of unboxing videos, not just merely observe. This exploratory research focuses on the subscription box business model which has become extremely popular among shoppers and are widely used by many companies. There are not enough overall statistics about subscription box industry but between 2013-2016, subscriptions have increased 3000% (Chang, 2016). The most popular subscription box companies are Birchbox, Ipsy, Mac & Mia, FabFitFun, The Year of Wellness, GlossyBox, BeautyArmy, Le Tote Box, Box of Style and Dollar Shave Club (Boyd, 2016). Content is generally created based on customer's preferences. There are so different subscription box models in a wide range of categories (women, men, beauty, food, moms, babies, kids, drinks, fitness, eco, crafts, pets, artisan etc.). However, the industry has become so saturated that new entries are starting monthly subscription boxes for more specific categories like niche boxes and luxury boxes (Ray, 2015).

Social media plays an important role in the diffusion of subscription box business models. Particularly, YouTube videos on subscription boxes are conspicuously increasing. So, in this study unboxing videos in YouTube will be used. Main research method of the study is interpretive video analysis (videography). Today, there is an explosive diffusion of privately produced videos using the Internet as a favorite medium of distribution. This has also opened new ways for the social sciences to produce and present data. The dissemination of video as a technology has now allowed many more social scientists to use it because it is not only relatively cheap, reliable, and available but due to its widespread private use, video has become less and less obtrusive. Knoblauch and Tuma (2011:416) consider videography to be a specific form of focused ethnography since the use of video has important consequences for the focusing process. Ethnography helps to determine exactly where, when and who is to be recorded on video. This exploratory research will contribute to a developing understanding of a new consumption phenomenon, subscription-based e-commerce. This research also contributes to consumer behavior by adopting ethnography on videos. Analyzing videos can bring valuable insights to consumer behavior study.

Innovation of the Economies of European Union Countries in 2009-2016

PhD. Anna Kowalska, Wroclaw University of Economics, Wroclaw, Poland
anna.kowalska@ue.wroc.pl

Abstract

The impact of innovation on the competitiveness of economies is one of the priorities of modern economic policy. Economists' views on the innovativeness of economies and the factors that influence the building or weakening of international position of each country have led to the creation of various rankings published by scientific institutes. These rankings not only determine the innovation of the individual countries, but also the factors that incite or discourage countries from doing innovative activities. The aim of this article is to present the results of a comparative analysis of changes in the innovativeness of the economies of the European Union over a period of 7 years. The analysis used the results of the Summary Innovation Index (SII) used in the European Innovation Scoreboard (EIS).

Keywords: innovation, economy, European Union, competitiveness

Introduction

The innovation of the economy is "the ability and motivation of entrepreneurs to conduct scientific research to improve and develop production, to seek new solutions, ideas and concepts" [Grodzka, Zygierewicz 2008]. The introduction of innovation can be carried out at different levels. Innovative actions by businesses, industries, regions or whole economies in the form of new products, technology improvements or increased efficiency will increase their competitiveness vis-à-vis other countries [Firlej, Kowalska, Piwowar 2017].

The impact of technological progress and innovation on economic growth has long been supported by economic theory [Solow 1957; Arrow 1962]. Economic empirical research also confirms this. They indicate that acceleration of economic growth is possible thanks to an increase in productivity dynamics [Khan, Luintel 2006; Leeuwen, Klomp 2006] and this provides investment in research and development as well as innovation [Cameron 1996; Bailey 2003]. At present, with limited labor and environmental resources and declining income from investment in physical and human capital, long-term economic growth can only be achieved by improving the efficiency of the use of these inputs.

The European Union to reduce the technological gap that separates the European Union from the United States and Japan has developed the Europe 2020 Strategy. This strategy was adopted by the European Commission in March 2010 and its priorities are to increase the innovation and thus competitiveness of the Community.

Purpose, Scope and Methodology of Research

The aim of the article is to evaluate the innovativeness of the economies of the European Union by means of synthetic indicators and to show the changes that took place in this regard in years 2009-2016. The analysis covered 28 countries belonging to the European Union.

The European Innovation Scoreboard (EIS) reports and the Summary Innovation Index (SII) have been used to analyze the innovations of individual economies in the European Union. The SII, in some reports

called European, was introduced by the European Commission and the University of Maastricht in 2001 as a unified system for examining the degree of innovation in European countries. This index was created to identify and analyze instruments impacting socio-economic cohesion policy when assessing the living standards of EU citizens [Tarnowska 2013]. The level of innovation was calculated using the international innovation research program – Community Innovation Survey, Eurostat and the OECD data.

Over the years, the methodology for measuring this index has changed. At present, the SII consists of 27 indicators, thematically divided into ten dimensions. Each dimension describes another area of the country's innovation. They were collected in four related groups:

1. framework conditions of the 3 most important areas known: human resources (new doctorate graduates, population completed tertiary education. lifelong learning), attractive research systems (international scientific co-publications, scientific publications among top 10% most cited, foreign doctorate students) and innovation-friendly environment (broadband penetration, opportunity-driven entrepreneurship);
2. investments, consisting of two areas: finance and suport (R&D expenditure in the public sector, venture capital investments) and firm investments (R&D expenditure in the business sector, non-R&D innovation expenditure, enterprises providing ICT training);
3. innovation activities, which included 3 areas: innovators (SMEs with product or process innovations, SMEs with marketing or organisational innovations, SMEs innovating in-house), linkages (innovative SMEs collaborating with others, public-private co-publications, private co-funding of public R&D expenditures) and intellectual assets (PCT patent applications, trademark applications, design applications);
4. impacts on specific projects in terms of innovation ie. employment impacts (employment in knowledge-intensive activities, employment fast-growing firms innovative sectors) and economic effects (medium & high tech product exports, knowledge-intensive services exports, sales of new-to-market and new-to-firm innovations), [more: EIS, Methodology Report, 2017]

The standared deviation ($S(x)$) was compared to the mean (arithmetic mean) as a measure of the variance between the states analysed [Olszańska 2012].

The results have been sorted in order to identify the European Union countries that stand out in terms of the largest and smallest levels of the phenomenon over the period under consideration. The number of groups separated in a given year depends on the variability of the phenomenon under investigation. For clarity, in some figures and in tables were used the country abbreviations as shown in table 1.

Tab. 1: Symbols of countries

Symbol	Country	Symbol	Country	Symbol	Country	Symbol	Country
BE	Belgium	EL	Greece	LT	Lithuania	PT	Portugal
BG	Bulgaria	FR	France	LU	Luxembourg	RO	Romania
CZ	Czech Republic	HR	Croatia	HU	Hungary	SI	Slovenia
DK	Denmark	IT	Italy	MT	Malta	SK	Slovakia
DE	Germany	CY	Cyprus	NL	Netherlands	FI	Finland
EE	Estonia	ES	Spain	AT	Austria	SE	Sweden
IE	Ireland	LV	Latvia	PL	Poland	UK	United Kingdom

Source: own study.

The scale of 0-1 was adopted for the SII index (where 1 stands for the highest achievable level of innovation). Depending on the distance separating the countries from the average innovation index of the

community countries, they were divided into four groups, depending on the % level of the innovation compared to the EU average:

1. "innovation leaders" (over 120%);
2. "following the leaders" (90-120%);
3. "moderate innovators" (50 - 90%);
4. "weak innovators" (below 50%).

Research Results

The value of the Summary Innovation Index for individual European Union countries varies (fig.1). Innovation leaders among the economies of the European Union are the Scandinavian countries, including Sweden, which has the highest value of SII. Countries such as Sweden, Denmark, Finland, but also the Netherlands, Great Britain, Germany, Austria, Luxemburg and Belgium in 2016 are also among the innovation leaders. These are countries which Summary Innovation Index accounted for more than 20% of the value of the average European Union index. When analysing innovation leaders, it can be seen that only the countries of the old European Union belong to this group.

In 2016 only three countries, ie. Ireland, France and Slovenia, were included in the group of so-called innovation supporters. The SII value for these countries was between 90 and 120% of the EU average. The most numerous group (as many as 14 countries in the European Union) found themselves in the so-called moderate innovators group. Among the countries the weakest in terms of innovation was (value below 50% of the EU average) Bulgaria and Romania.

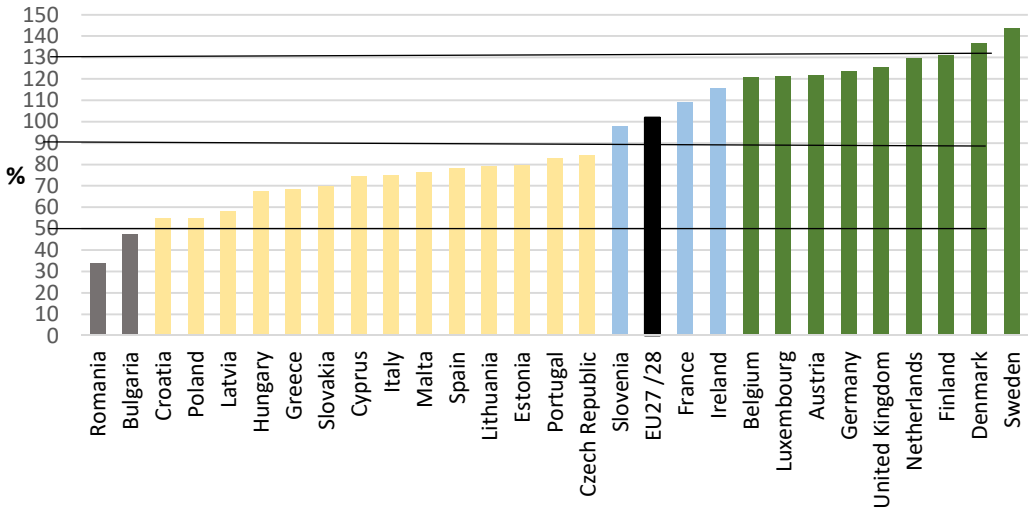

Fig. 1: Performance of EU Member States' innovation systems in 2016 [%]

Source: own study based on EIS

Analysis of the SII index in 2016 compared to 2009 showed significant changes in its values (fig.2). The states were divided into 4 groups because of the dynamics of change over seven years. Group 1 included countries whose SII increased in the analysed period, ie. Sweden, Denmark, Finland, United Kingdom, Netherlands, Austria and Belgium as well as so-called supporters of innovation: Ireland and France. The biggest increase in the index over the past 7 years has been observed in the UK. This allowed UK move

from so-called supporters of innovation to the leaders. This transition was also the case of Austria, the Netherlands and Belgium.

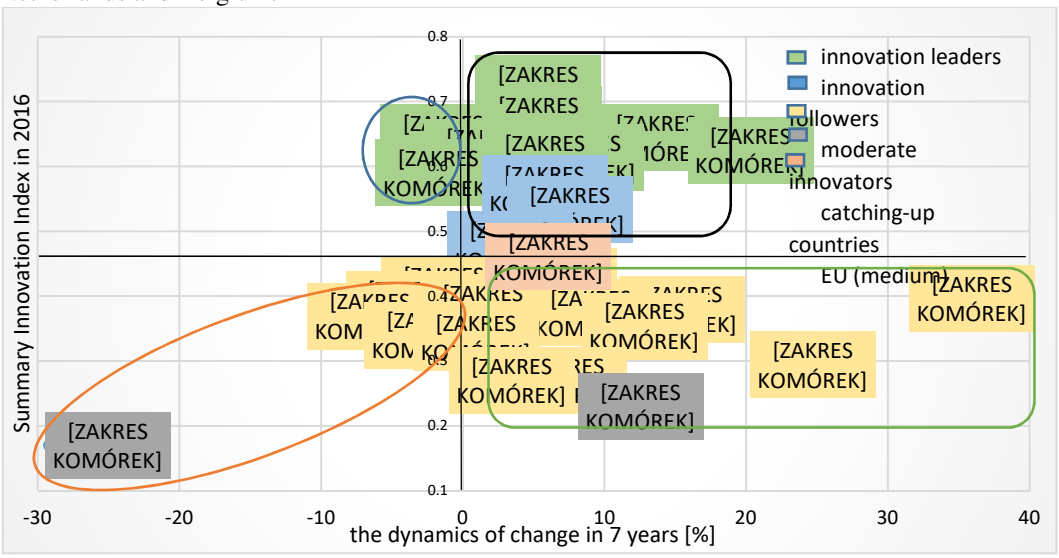

Fig. 2: SII index in 2016 and dynamics of change in 7 years [%] in EU countries

Source: own study based on EIS

In 2009 and 2016 only three countries, ie. Ireland, France and Slovenia, were included in the group of so-called innovation supporters. Another group of countries were those whose Summary Innovation Index declined but remained above the EU average. These countries included so-called innovation leaders ie. Finland, Germany and Luxembourg. The third group was composed of countries that, despite having the value of the index below the EU average, showed a rise in its value during the period considered. These countries are working to increase their competitiveness. These are the Czech Republic, Latvia, Malta, Lithuania, Slovakia, Croatia, Italy and Bulgaria, which, despite being in the group so-called weak innovators showed a positive change in the index over the period considered. In this group, a significant increase in innovation is evident in Latvia (almost 40%) and Lithuania (up by more than 20%). Such a significant increase in the innovation index allowed these countries to move to the so-called moderate innovators group. The fourth group is the countries whose Summary Innovation Index has declined within 7 years. Cyprus, Portugal, Estonia, Spain, Hungary, Greece and Romania belong to the so-called weak innovators. Cyprus (a drop of 10%) and Romania (a drop of almost 30%) showed that the value of the index, despite its low value, have decreased in the past seven years. Among the analysed countries were two, ie. Slovenia and Poland, whose index value did not change.

While analysing the SII of countries calculated previously, five groups of countries with similar levels of innovation were identified using the arithmetic mean and the standard deviation (table 2). Over the past three years, there is seen even greater disparity between countries in terms of innovation (from 2 to -3).

Throughout the period analysed, the highest index of innovation, falling within the range of two standard deviations from the mean, was recorded in Sweden and Denmark. In the second group of countries where the average index of innovation was above the EU average, but lower than in the group of leaders, were: Netherlands, United Kingdom, Germany, Austria, Luxembourg, Belgium, Ireland and France. This group joined Finland, which fell out of the so-called leaders group. In these countries, the SII was above the EU average by one standard deviation. Another group of countries in which the average index of innovation was less than one standard deviation throughout the analyzed period was Slovenia, the Czech Republic, Portugal, Estonia, Spain, Italy, Cyprus and Malta. The fourth group of countries in which the average index of innovation was in the analysed period two standard deviations below the EU average (-2) are

Latvia, Poland, Croatia and Bulgaria. The countries still included in this group were Slovakia, Greece, Hungary and Lithuania, which only in 2016 jumped to the supporters of innovation. In the last fifth group was Romania whose the SII in the last three years examined was three standard deviations below the EU average (-3).

Tab. 2: Diversification of innovation in EU countries according to SII in the years 2009÷2016

Country	2009	2010	2011	2012	2013	2014	2015	2016
Sweden	2	2	2	2	2	2	2	2

Source: own study based on EIS

The analysis of innovation data of economies conducted by 4 groups of dimensions showed not only large differences in innovation levels across countries but also significant changes over seven years (table 3).

The leader of innovation, as previously mention, was Sweden. Its Summary Innovation Index in the period considered was the highest among the surveyed counties and placed Sweden first in front of Denmark and Finland. The weakest quotations of the synthetic indicator showed Romania, Bulgaria and Poland.

Source: own study based on EIS

In spite of the high Swedish quotas for the SII, the deterioration in the value of indicators in particular group is evident. In the case of Sweden, the drop in the value of the indicators was achieved for three of the four group ie. investments and innovation activities (by 6% each) and impacts (by 2%). On the other hand, there was an increase in the rate for the framework conditions by 6%. The significant increase in the framework conditions was observed in Luxembourg (by 16%), Denmark, Malta and the Netherlands (by 13%). The fall in the value of the indicator in this group was noted by only two countries: Slovenia (by 9%) and Slovakia (2%). In the case of Bulgaria, however, its value has not changed. The biggest drop in the value of indicators after seven years was recorded in: Cyprus – in the group of investments (by 20%); Estonia – in case of innovation activities (by 23%) and in Croatia – an impacts (by 13%). On the other hand, the largest increase in the value of the indicator was noted in the group of investments in Latvia (by 26%), innovation activities in Malta (by 14%) and in an impacts in Great Britain (by 15%). Such a significant increase in the value of the index by the United Kingdom has given it first position in this area with an index of 0.84 points, thus diminishing Germany, Italy and Luxembourg. In the case of

two countries, ie. the Netherlands and Italy, the value of indicators has increased in all four groups. Very poor results were obtained by Romania. Over the past seven years, in three of the four groups, indicators have decreased, despite their earlier low values. A slight increase (by 1% to 0.24 points) was noted for the framework conditions.

The dimensions that influenced the value of SII obtained by individual countries were also analysed. Among the dimensions influencing the framework conditions of the countries that achieved the highest value of this indicator in 2016 was the innovation-friendly environment (fig. 5). Such countries were Denmark (1 point), Sweden (0.94 points) and Finland (0.87 points). The lowest values for innovation-friendly environment were recorded in Cyprus (0.23 points), Croatia (0.21 points) and Greece (0.15 points). In the case of Sweden and Finland, the value of this ratio increased respectively by 6% and 15% in 2009, while Denmark remained at the same level. In the case of Austria, the drop in value was the greatest (by 22%). It also decreased significantly in the case of Slovenia (by 16%) and Belgium (by 14%), and increased in case of Malta (by 22%), Poland (17%) and Lithuania (15%).

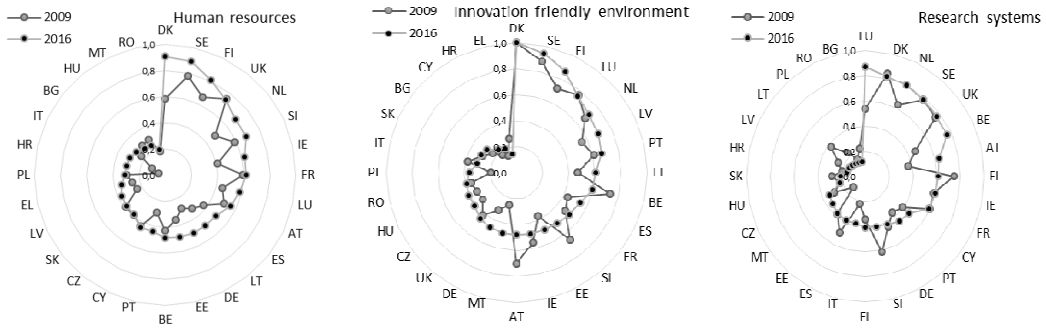

Fig. 5: Dimensions belonging to the framework conditions group in EU countries in 2009 and 2016

Source: own study based on EIS

Significant increase of indicators occurred in human resources dimension. In Belgium was the largest (by 33%). Second was Romania (by 26%). In turn, in the research systems dimension the highest value of the index in 2016 were recorded in Luxembourg. The 33% increase in the index allowed this country to take the first place in this group. Belgium (33%) and Malta (22%) also recorded significant gains. Latvia and Slovenia recorded the biggest drop, accordingly by 23% and 22%.

In the group of investments (fig. 6), the high values of the indicator for the finance and support dimensions recorded Estonia (70 points) right behind Finland (0.72 points). In 2016, the increase in this indicator compared to 2009 was the highest in Estonia (by 29%) and in Slovakia (by 34%). In this dimensions, as many as 18 countries recorded a drop in this indicator over the period considered. The largest was in sequence in Ireland (by 29%), Luxembourg (by 26%), Belgium and Bulgaria (by 22%) and Romania (by 20%).

In the case of the dimensions of firm investments, the highest indicators value were obtained in 2016: Germany (0.73 points, growth by 15%), Sweden (0.70, growth by 7%) and Austria (0.69 points, growth by 14%). The largest increase in the indicator in this dimensions was recorded by Latvia (by 24%). The weakest results in this dimensions took place in 2016: in Cyprus (0.20 points, compared to 2009 drop by 38%), in Lithuania (0.18 points, drop by 10 points), and in Romania (0.05 points, drop by 16%). Significant decrease in addition to Cyprus was recorded by Slovakia (by 22%).

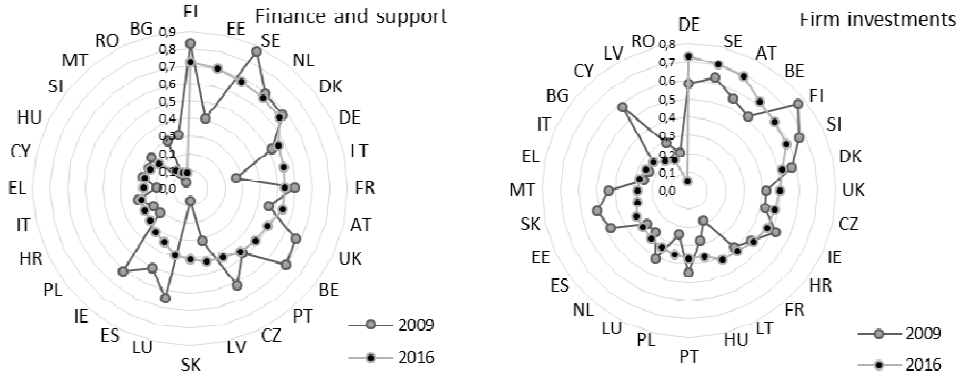

Fig. 6: Dimensions belonging to the group of investments in EU countries in 2009 and 2016
Source: own study based on EIS

Another group of the SII is innovation activities (fig. 7). One of the three dimensions in this group is innovation. In their case, over the past 7 years, the indexes have been declining in as many as 20 countries of the European Union. The biggest drop, as much as 65%, was recorded in Estonia, but also significant in: Denmark (by 24% and changed position in this dimensions from 1 to 3), Spain (by 22%) and Cyprus (by 20%). The Netherlands, Great Britain and Latvia recorded significant increases, accordingly by 18% and two times 16% .

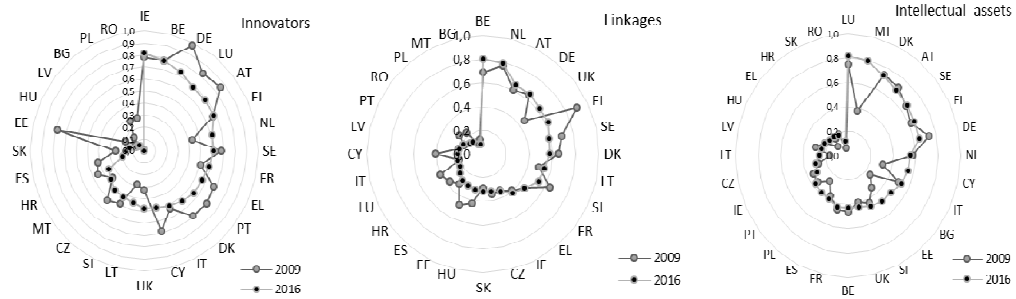

Fig.7: Dimensions belonging to the group of innovation activities in EU countries in 2009 and 2016
Source: own study based on EIS

In the linkages dimensions in 2016 compared to 2009 value of indicators also decreased in the majority of EU countries. The biggest decline was recorded in Finland, where the index fell by 28%. This caused Finland to fall from leader position to 6th place in the ranking. Significant drops of 19% were also recorded by Luxembourg and Cyprus. The biggest increase in the linkages index in 2016 can boast only the United Kingdom. The other countries, if they had an indicators increase in this dimensions, it oscillated within limits 1-5%.

The last dimensions in this group is the intellectual assets. For this factor, the highest rates in 2016 compared to 2009 were recorded in Malta, Luxembourg and Denmark. The highest increase was noticed in Malta (42%). Cyprus and Bulgaria also recorded significant growth in this dimensions (each 24%). The largest drop in the discussed dimension (at 9%) was obtained by Germany. The lowest value of the indicator in 2016 was achieved by Romania (despite the increase in the value of this index by 6% compared to 2009).
The last group affecting the SII is the impacts, which comprise two dimensions (fig. 8).

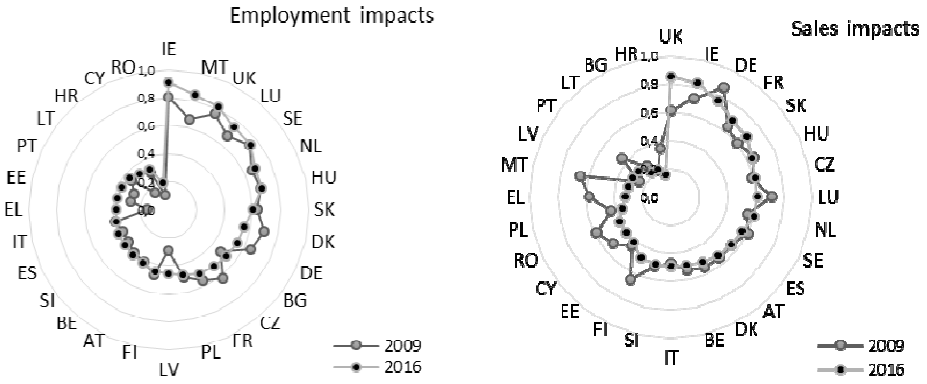

Fig. 8: Dimensions belonging to the group of impact in EU countries in 2009 and 2016
Source: own study based on EIS

In the employment dimensions, most EU countries recorded an increase in the value of this indicator. The leaders in this dimensions in 2016 were Ireland (0.91 points), Malta (0.84 points) and the United Kingdom (0.81 points). Romania has the lowest value (0.20 points), although there was a significant increase in the indicator in this dimension (9%). However, significantly higher values of the index were obtained by Greece (by 22%), Malta (by 18%), Lithuania and Croatia (by 17%). The value of this indicator in Denmark (14%), Germany and the Czech Republic (by 11%) declined the most. For the second dimensions of impacts, the highest values in 2016 were recorded by the United Kingdom (0.86 points) followed by Ireland (0.83 points). In the case of Great Britain, the highest increase in this indicator was observed (24%). This caused this country to move from the 8th to the 1th position. Most of the countries in this dimensions between 2009 and 2016 recorded a decline in these indicators. The biggest drops were in Malta (35%) and in Greece (25%). The lowest indicator in this dimensions was noticed in Croatia (0.20 points), which fell in the ranking from 25th to 28th place.

Conclusion

The article analyses changes in innovation of the economies of the European Union. On the basis of the comparison of indicators contained in the reports of the European Innovation Scoreboard (EIS) it can be stated that the countries of the community are very different in terms of innovation.
Summing up the results of the analyzes, it must be stated that the gap between the new and old EU Member States is large and in some cases still growing. In 2016, the position of the most developed countries has mostly strengthened further, while the countries of the new European Union, beside the significant increase in Lithuania, Latvia and Slovakia, have not significantly changed their position and in some cases even worsened.

At present, economic development largely depends on intangible factors related to knowledge. Skilful dissemination and application of knowledge ensures a better use of material resources available in a given country. Diffusion of innovation results in a competitive advantage, as demonstrated by indicators obtained by developed countries. Nevertheless, to make innovative solutions, you must have adequate financial resources. This is especially visible in the countries of the new European Union, ie Lithuania and Latvia. For these countries, the European Union's contribution to the improvement of both the synthetic index and the majority of indices in particular areas and categories has increased over the past 7 years.

Poor indexes in most countries of the new European Union as well as in countries experiencing the economic crisis, ie. Greece and Spain, indicate that they need to develop strategies for increasing the innovativeness of economies on the international stage. Certainly, the right strategy and the domination of their attributes by each country will allow for a longer period of time to reduce or even offset the distance between the two groups of countries.

Why Banks Adopt Mobile Banking?

Ceylan Onay, Boğaziçi University, Department of MIS, Istanbul, Turkey
ceylano@boun.edu.tr
Yasemin Ezgi Öztaş, Master student, Boğaziçi University, Department of MIS, Istanbul, Turkey
yaseminezgii@gmail.com

Abstract

Majority of literature on electronic banking has focused on internet banking adoption either by banks or by customers. Mobile banking differs from internet banking because it is available free of location and hence enables access to financial services anytime anywhere. However, why banks adopt mobile over and above internet banking has been neglected so far. This paper investigates the determinants of mobile banking adoption from banks' perspective. Using a sample of 14 retail banks from Turkey, we show that banks are more likely to adopt mobile banking to increase their deposits, profitability, market share and for better risk management of their loan portfolio.

Keywords Mobile banking, Banks, Financial Services, Technology, Turkey

Introduction

Financial institutions are profit-seeking enterprises that try to maximize revenues and reduce their cost of production simultaneously. However, competition in financial services is fiercer than ever due to information technologies that bring increased transparency, lower switching costs and higher disintermediation (Claessens , S., Dobos, G., Klingebiel, D., Laeven, L., 2013; Claessens, S., Glaessner, T., Klingebiel, D., 2001). We see disappearance of boundaries between banks and ICT companies, new start-ups that enable peer-to-peer lending, new payment infrastructures such as blockchain technology that challenge the value proposition banks deliver. Compared to banks these new financial services providers are much less regulated and far more flexible. These developments point out too much higher competition for not only retaining the existing customer base but also for protecting the margins. As margins decrease, banks profitability decrease. Banks are challenged to create new revenue sources such as service fees and commissions (Adizes, 2013). Hence, importance of creating value-added services that leverage information technology becomes even more important. (Wonglimpiyarat, 2014)

Mobile banking represents the next step of financial institutions towards providing new services to customers and seizing technological opportunities in terms of new business models (Riquelme & Rios, 2010). Mobile banking not only enables banks offering new and customized products and services but also enables customers to interact with their banks regardless of time or location, and to access details of their banking and financial transactions whenever and wherever necessary. Mobility is the most noteworthy difference of mobile from internet banking (Laukkanen, 2007; Suoranta, 2004). Furthermore, mobile banking enables access to financial services particularly for the unbanked segments in emerging economies bringing opportunities to expand banks customer base (Klein, 2011; Bose, 2016) . It naturally adds up that mobile-based financial services may increase a financial institution's asset growth, which is crucial in an increasingly competitive environment.

Research shows that customers have become less willing to visit traditional branches, less loyal, more receptive to new electronic channels and more sophisticated in demanding better service quality including

24 hour service availability (Coelho & Easingwood, 2003). Customers value compatibility, perceived usefulness, and attitude in their decision to adopt mobile banking (Shaikh & Karjaluoto, 2015). Customers perceive mobile banking as a competitive advantage (Koenig-Lewis, Hanmer-Lloyd, & Ward, 2010) and banks use mobile banking to build relationships with customers to retain and develop their customer base. (Veronika & Nikolay, 2015). Thakur (2014) shows that satisfaction from mobile banking in fact increases customer loyalty. Considering the fast penetration of smartphones in both developed and developing economies, mobile banking has become an important distribution channel for banks.

From a competition point of view banks who invest in IT increase productivity, decrease operating expenses, increase profitability and market share (Chang-Soo & Davidson, 2004). Transactions carried out via mobile are more cost-effective for both banks and consumers than branch-based transactions, involving less time and fewer people (Laukkanen & Lauronen, 2005). In this regard, mobile banking gives financial institutions an opportunity to lower their operating expenses, increase productivity and profitability. Previous research shows that banks increase profitability once they adopt internet banking. Hernando & Nieto, (2007); DeYoung, (2007); Ciciretti, Hasan, & Zazzara, (2009) and Onay and Ozsoz (2012) show that internet banking allows banks to focus on more labour intensive functions at branches. What does mobile banking add to this equation? Why and when banks adopt mobile is the question we address in this paper.

To our knowledge, this is the first study to explore the factors that affect financial institutions' decisions to adopt mobile banking particularly in an emerging economy. Penetration of mobile banking has been fast (Ratten, 2011) and new technology penetrates even faster in emerging economies due to leapfrog effect (Claessens, Glaessner, & Klingebiel, 2001). Literature reveals that many research on electronic banking has focused on Internet banking, whereas research focusing on mobile banking is relatively less and receives underrated attention (Suoranta & Mattila, 2004 ; Laukkanen & Pasanen, 2008; Puschel, Mazzon, & Hernandez, 2010).

In our paper, we follow a similar strategy to Furst, Lang, & Nolle, (2002); Singh, (2007); Dandapani, (2017), and Hernández-Murillo, (2010) who investigate internet banking adoption by banks and try to identify the factors that contribute to the adoption of mobile banking services by financial institutions in Turkey. Adoption of Mobile banking in Turkey began in the second half of the 2000's and penetrated thoroughly. Customers who have logged into mobile banking at least once in last three months has increased from 445k to 19million in the past 5 years. As of 2017 of the 33 retail banks in Turkey, more than half offer mobile banking according to the Banks Association of Turkey. The transition to mobile was a sequential process for all the banks in our sample as they first adopted internet banking channel, which was then followed by the adoption decision for mobile. In this regard, we are able to analyse what particularly drives mobile banking adoption for banks.

Information Technologies can be used by banks to support and enhance relationships with their customers through cross-selling of customized products and innovative services and by making the business process flexible and customer-driven. Information availability through apps/browsers and customer opinions may boost demand for niche products (Anderson, 2006). Furthermore, a bank's product mix can affect the adoption of technological innovations as information technology may help create more customized products/services (Hannan & McDowell, 1984; Dandapani, 2017). Banks can monitor customer payment behaviour, update campaigns and deliver relevant offerings via mobile. Accordingly, Information Technology not only enables customized offerings but also enables better risk management. While Dow Jr., (2007) discuss that banks would be less likely to invest in new technology when delinquent loans increase; Cadena & Schoar, (2011) show that SMS/application reminders have a comparable impact on the repayment behaviour of borrowers. Competition also challenges banks to innovate. Barbosa & Salazar, (2015) show that banks with more market share offer a more diverse set of products and services. Accordingly, we hypothesize that banks are more likely to adopt mobile banking in an attempt to increase deposits, profitability and market share and to manage loans and non-performing loans more efficiently.

Data and Research Methodology

Our dataset is collected from the year-end consolidated aggregate income statements and balance sheets compiled by the Banks Association of Turkey (2016) and adjusted for inflation using the Consumer Price Index (CPI) published by the World Bank (WDI, April 2016). The banks in our sample offered a similar package of Mobile banking products, services, and transactional capabilities at the time of adoption: 1) Information inquiries, 2) Account balance checking and maintenance, 3) Fund transfers, 4) Automatic Bill and Credit Card Payments, 5) Savings and investments transactions, 6) Retail and commercial banking transactions, and 7) Online trading. Our main dependent variable is mobile banking adoption dummy coded as one when the bank adopts a transactional mobile banking and zero otherwise. All unbounded explanatory variables are winsorized at the 1% level at both tails.

In our identification strategy, we first estimate OLS firm FE model and then replicate our main findings with probit and logit models with firm fixed effects for robustness. Using a sample of 14 retail banks over a period of 21 years from 1994 to 2015, we show that the level of deposits, loans, profitability and market share drives banks in adopting mobile over and above internet banking channel (Table 1).[1] We interpret our results according to column 11; the logistic regression estimation.

Findings and Discussion

We find that mobile banking services are more likely adopted when deposits to assets ratio decrease and when loans to assets ratio increase. This confirms our proposition that banks use mobile banking as a means of attracting new customers beyond the reach of its physical and internet branches as well as managing its assets more efficiently with more monitoring of customer behaviour data. We also show that banks are more likely to adopt mobile banking when profitability falls. This is contrary to findings of Furst, Lang, & Nolle, (2002); Singh, (2007); Dandapani, (2017), and Hernández-Murillo, (2010) who show that profitable banks adopt internet banking. We find that banks rely on mobile banking to increase profitability possibly via delivering more customized products/services and expanding their customer base via mobile. We also find a significant positive coefficient for market share indicating that banks are more likely to adopt mobile banking when their market share increases. This is also contrary to what has been documented for internet banking adoption Dandapani, Lawrence, & Rodriguez, (2016) and shows that mobile banking is also perceived as a way of increasing customer satisfaction and loyalty beyond increasing customer base. These results are robust to alternative estimations controlling for internet adoption by banks and crisis dummies.

Table 1 Regression Analysis - Estimations in columns 2-9 are OLS Firm Fixed Effects, while column 10 presents the results of Probit and column 11 presents the results of Logit estimation. Mobile dummy equals one when bank adopts transactional mobile banking and zero otherwise. Depositta is the ratio of total deposits to total assets. Loansta is the ratio of total loans to total assets. Nonperfta is the ratio of total non-performing loans to total loans. Roa is the return on assets. Market Share is the ratio of total asset of a bank to total assets of all banks within a given year. Internet dummy equals one when the bank adopts transactional internet banking and zero otherwise. Crisis dummy takes a value of one if there is a systemic banking crisis and zero otherwise. First row reports the estimated coefficients and second row gives the robust std. errors clustered at the firm level in italics. *** p<0.01, ** p<0.05, * p<0.1

Abstract

The paper includes a research on possibilities of earnings quality assessment and putting the results into the relationship with the most widely used traditional financial ratios as a return on assets, profit margin or total assets turnover ratio. The concept of the earnings quality measurement techniques represents relatively new, and an under-research field. The most significant researches are the one conducted by DeAngelo (1986), Jones (1991), Dechow and Dichev (2002) in which authors develop models for measuring discretionary and non-discretionary accruals that represent an earnings quality proxies. The purpose of those models is to detect levels of management choices that affect the financial result of the company. The conducted research gives results on modified Jones (1991) model by using the sample of large Croatian companies for a nine-year period. Next to determining the level of discretionary accruals, the paper includes correlation results between the accruals proxies and traditional financial indicators. The most significant part of the paper includes results about the differences between accruals level in the 'loss' and 'profit' companies. The obtained results show that there are more management choices (manipulations) in the 'loss' observations, and that 'profit' observations are more affected by business conditions (non-discretionary accruals).

Key words: earnings quality, discretionary accruals, non-discretionary accruals, cash flow

1. Introduction

Earnings quality, which is "the aggregate result of the application of various accounting treatments, estimates, and assumptions that are made by management", according existing literature, is one of several attributes of reported income that is widely considered to be desirable characteristics of a firm's reported earnings (Salerno, 2014, p. 255). The goals of decision-makers unquestionably determine the definition of earnings quality. According to Dechow, et al (2010, p. 344) "the quality of earnings is a function of the firm's fundamental performance". According to Dichev et al (2013), high-quality earnings are "sustainable and repeatable; specific characteristics include consistent reporting choices, backing by actual cash flows, and absence of one-time items and long-term estimates" (Dichev, et al, 2013, p. 1).

Most frequently used earnings quality proxies are earnings persistence, predictability, smoothness, timeliness, value relevance, loss avoidance, investor responsiveness magnitude of accruals, income-increasing accruals, absolute value of discretionary or abnormal accruals and the extent to which accruals map into past and future cash flows, volatility, conditional conservatism (Dechow, et al., 2010, p. 344, Dichev, et al, 2012, p. 1, Francis et al, 2004, p. 967, Perotti and Wagenhofer, 2014).

Francis et al (2004) characterize accrual quality, persistence, predictability and smoothness as accounting-based attributes because they are typically measured using accounting information only, while value relevance, timeliness, and conservatism characterize as market-based because proxies for these constructs are typically based on relations between market data and accounting data. In accordance with conducted research in which Francis et al. (2004) examined the relation between the

cost of equity capital and abovementioned attributes of earnings, the largest cost of equity effects is observed for the accounting-based attributes, in particular, accrual quality. (Francis et al, 2004, p. 967)

Perotti and Wagenhofer (2014) examine how commonly used earnings quality measures fulfill a key objective of financial reporting by predicting that firms with higher earnings quality will be less mispriced than other firms. According to their research, "accruals measures generate the largest spread in absolute excess returns, followed by smoothness and market-based measures. These results lend support to the widespread use of accruals measures as overall measures of earnings quality in literature" (Perotti and Wagenhofer, 2014, p. 545).

Many modes are developed with the objective to assess earnings quality. An early research stage resulted in less complex models that have been modified and improved over time. Recent researches focus on an assessment of non-discretionary and discretionary accruals as a proxy for assessing earnings quality by using information, not only from the balance sheet, but also from the cash flows statement. There is no clear consensus between researches which discretionary accruals model gives the best results.

2. Literature review

Accruals "modify the timing of reported earnings; therefore use of discretionary accruals enables the manager to transfer earnings between periods" (Healy, 1985, 89). Discretionary (abnormal or unexpected) accruals often serve as a proxy for earnings management, and are in focus of many developed expectations models (e.g. Healy model, 1985; DeAngelo model, 1986; Jones model, 1991; Modified Jones model, 1995; Dechow and Dichev model, 2005; Francis et al model, 2005).

According to Healy (1985), managers observe a cash flow from operations and non-discretionary accruals at the close of each year and select discretionary accounting procedures and accruals to maximize their expected benefit from bonuses (Healy, 1985, p. 89). Within the model, the discretionary accruals sum to zero over the managers' employment horizon with the firm (Healy, 1985, p. 89). "It is assumed that every firm having discretionary accruals other than zero applies profit management, every firm having discretionary accruals below zero operates in the direction of increasing profits and every firm having discretionary accruals above zero operates in the direction of decreasing profits" (Aren, 2003, cited in Yurt and Ergun, 2015, p. 41). In his research, Healy found that there is a close linkage between accruals and managers' income-reporting incentives under their bonus contracts (Healy, 1985, p. 106). "Holthausen, Larcker, and Sloan (1995) just like Healy found evidence, consistent with the hypothesis that managers manipulate earnings downwards when their bonuses are at their maximum" (Yurt and Ergun, 2015, p. 42).

DeAngelo's (1986) model uses prior period's total accruals as a measure of normal (non-discretionary) accruals and defines abnormal (discretionary) total accrual as the difference between current total accruals and normal total accruals (Jones, 1991, p. 207). Both Healy (1985) and DeAngelo (1986) models assume that the non-discretionary accruals are constant in the examined period (Yurt and Ergun, 2015, p. 43).

Jones (1991) model focuses on discretionary accruals as a measure of managers' earnings manipulations, but unlike previous models, he takes into account changes in non-discretionary accruals caused by changes in economic conditions (Jones, 1991, p. 223). According to results "managers decrease earnings through earnings management during import relief investigations" (Jones, 1991, p. 194).

Dechow et al (1995) modified the Jones model to eliminate the conjectured tendency to measure discretionary accruals with an error when discretion is exercised over revenues (Dechow, 1995, p. 199). In the Jones model, revenues are used to control the economic environment of a company, but

reported revenues to some extent may be affected by managers' attempts to decrease reported earnings (Jones, 1991, p. 211-212) because of which Dechow et al. in a modified version of the model implicitly assumes that all changes in credit sales in the event period result from earnings management (Dechow, 1995, p. 199). This improved version of the Jones model is named Modified Jones model and it is widely used by researchers.

Unlike previous models, which are focused on estimating abnormal accruals (Yurt and Ergun, 2015, p. 43), Dechow and Dichev (2002) put forward a new approach to measure accruals and earnings quality. They define accruals quality "as the extent to which working capital accruals map into operating cash flow realizations, where a poor match signifies low accrual quality" (Dechow and Dichev, 2002, p. 36). According to the new model, precise estimates imply a good match between current accruals and past, present, or future cash flow realizations (Dechow and Dichev, 2002, p. 53). Dechow and Dichev find that both earnings and accruals volatility are good proxies for measuring low accruals and earnings quality (Dechow and Dichev, 2002, p. 54).

Jones et al (2008) evaluate the ability of 10 measures derived from the extant discretionary accruals models to detect the existence of a fraudulent event that overstated earnings, the extent of fraudulent earnings, and voluntarily earnings restatements. They find that only the accrual estimation errors estimated from Dechow and Dichev 2002 and McNichols 2002 modification of Dechow and Dichev have predictive power for both fraud and non-fraudulent restatements of earnings. (Jones, Krishnan and Melendrez, 2008, p. 529)

To estimate abnormal accruals, Cheng et al (2012) evaluated the performance of the modified Jones model, modified Jones model with operating cash flows, and modified Jones model with return on assets. They recommend that researchers use the industry-specific modified Jones model with return on assets model to estimate abnormal accruals when investigating earnings management since the model remains the best one from the perspective of abnormal accrual mispricing (Cheng et al, 2012, p. 1).

Francis et al (2005) investigate the relation between the accruals quality and costs of debt and equity capital. In their study, accruals quality is used as a proxy for information risk, and accruals quality metric is based on Dechow and Dichev's (2002) model and following McNichols (2002) discussion of this model, they also include the change in revenues and property, plant and equipment as additional explanatory variables (Francis et al., 2005, 296). According to their research "lower-quality accruals are associated with higher costs of debt, smaller price multiples on earnings, and larger equity betas." (Francis et al, 2005, p. 323).

There are several studies that investigate the linkage between debt financing and earnings quality. Ghosh and Moon (2010), using accruals quality as a proxy for earnings quality, where earnings quality refers to the ability of earnings to predict future cash flows, determine non-monotonic relation between debt and earnings quality. In accordance with their study, the relationship is positive at low levels of debt and negative at high debt levels (Ghosh and Moon, 2010, p. 538). Similarly, Valipour and Moradbeygi (2011) find a positive and significant relationship between low levels of debt financing and earnings quality, and according to their study, "firms aggressively use accruals to manage earnings to avoid covenant violations and reduce the cost of financing" (Valipour and Moradbeygi, 2011, p. 155).

Šodan (2015) investigates whether the extent to which fair value disclosed in the financial statements is related to the earnings quality measures in the eastern European countries over 2002-2011. He formed an aggregate earnings quality measure that is based on the six most commonly used earnings quality proxies (persistence, predictability, smoothness, accruals quality, value relevance and conservatism). According to preliminary empirical findings, "both firms and banks with increased exposure to fair value accounting in financial reporting have lower level of aggregate earnings quality". (Šodan, 2015, p. 1769)

Salerno (2014) analysed the impact that quality of reported earnings has on the accuracy of financial analysts' earnings forecasts. He used two measurements of forecast accuracy. "For both measurements of accuracy the results show that higher earnings quality is associated with improved forecast accuracy." (Salerno, 2014, p. 255)

The accruals and earnings quality are a research field that has been covered by many papers during the last decade. In that period numerous approaches to measure accruals are developed. As Ohlson (2014) pointed out in his work, "while accruals can be misleading, on average accruals provide useful information as indicators of future cash flows and earnings that go beyond the information in current cash earnings". (Ohlson, 2014, p. 80.)

3. Research question, research design and methodology

The objective of this paper is to determine the level of abnormal accruals in Croatian large companies. Results will be used to assess the linkage between earnings quality proxies and traditional financial indicators and ratios in analysed companies. Accruals proxy can be used to compare management choices and potential manipulations in companies that operate with profit compared to companies that generate losses. Related to that, the research includes analysis of differences between results within the profitable and non-profitable observations. Considering the review of the objectives, it is possible to develop a research hypotheses:

H1: There exists a significant correlation between discretionary and non-discretionary accruals, and traditional financial indicators and ratios.

H2: It is possible to detect a significant difference in earnings quality between 'profit' and 'loss' companies.

As it was emphasized earlier in the paper, the Jones model is focused on total accruals as a measure of earnings management (Jones, 1991, p. 206). "Total accruals are calculated as the change in noncash working capital before income taxes payable less total depreciation expense. The change in noncash working capital before taxes is defined as the change in current assets other than cash and short-term investments less current liabilities other than current maturities of long-term liabilities and income taxes payable." (Jones, 1991, p. 207). The model used in the research represents the Jones model with certain modifications. Due to the lack of an available data the total accruals model does not include current maturities of long-term debt, and tax payable includes all tax liabilities, and not only income taxes. Next to that, deferred costs are included as a part of current assets, and deferred revenues as a part of current liabilities. All variables are scaled by total assets. Total accruals are calculated by using the following equation:

$$\frac{ACC_t}{TA_{t-1}} = \left(\frac{\Delta CA_t^{t-1}}{TA_{t-1}} + \frac{\Delta AVR_t^{t-1}}{TA_{t-1}} - \frac{\Delta Cash_t^{t-1}}{TA_{t-1}}\right) - \left(\frac{\Delta CL_t^{t-1}}{TA_{t-1}} + \frac{\Delta PVR_t^{t-1}}{TA_{t-1}} - \frac{\Delta TP_t^{t-1}}{TA_{t-1}}\right) - \frac{Dep_t}{TA_{t-1}}$$

where:

ACC_t = total accruals in year t for company i
TA_{t-1} = total assets in year t-1
ΔCA_t = change in current assets between year t and t-1
ΔAVR_t = change in deferred costs between year t and t-1
$\Delta Cash_t$ = change in cash between year t and t-1
ΔCL_t = change in current liabilities between year t and t-1
ΔPVR_t = change in deferred revenues between year t and t-1
ΔTP_t = change in tax payable between year t and t-1
Dep_t = depreciation and amortization costs in year t

The total accruals (ACC_t) represent a difference between changes in non-cash current assets and change in current liabilities other than the tax payables decreased for depreciation and amortization

costs. As previous researches highlight (DeAngelo, 1986; Jones, 1991; Dechow and Dichev, 2002) the total accruals include a change in a discretionary and non-discretionary accruals. The same authors affirm that the change in non-discretionary accruals is approximately zero, so the change in total accruals reflects the change in a discretionary accruals. The total accruals are determined as follows:

$$\frac{ACC_{it}}{TA_{it-1}} = \alpha_i \frac{1}{TA_{it-1}} + \beta_{1i} \frac{\Delta TR_{it}^{it-1}}{TA_{it-1}} + \beta_{2i} \frac{NonCA_{it}}{TA_{it-1}} + \varepsilon_{it}$$

where:

ACC_{it} = total accruals in year t for company i
TA_{it-1} = total assets in year t-1
ΔTR_{it} = change in total revenues between year t and t-1
$NonCA_{it}$ = non-current assets in year t
ε_{it} = error term in year t for firm i
i = 1,….,N = company index
t = 1,…,Ti = year index

The second model is used as a proxy in order to absorb the noise resulting from the change in a business condition where the non-current assets represent investments, and change in revenues scaled by total assets represents growth of business activities of the company. The prediction error (residual) in the model represents the level of discretionary accruals at the observation point.

In order to meet the research objective, we used traditional financial ratios that are considered as the most important in evaluating financial position and business performance. The financial position is evaluated by using an equity-to-assets ratio and a total assets turnover ratio. The business performance is evaluated by using a return on assets, return on equity and profit margin. The chosen financial ratios are computed in accordance with the formulas provided by Žager, K., Mamić Sačer, Sever Mališ, Ježovita & Žager L. (2017).

The conducted research includes an earnings quality analysis of Croatian large companies that prepared and disclosed their annual financial statements for 2016 (327 companies were classified as large). According to the Croatian Accounting Law, large companies are those that meet two of three criteria: total assets >150 million HRK, total income >300 million HRK, average employees' number >250 (Official Gazette, No 78/2015). Those criteria are harmonized with Directive 2013/34/EU of the European Parliament and of the Council of 26 June 2013 on the annual financial statements, consolidated financial statements and related reports of certain types of undertakings. Because the data on cash flows in Croatia are available only from 2008, the time framework covered by the research is a nine-year period. The next limitation included in the research is a companies' size. The analysis includes only companies that are classified as large within all observed years (2008-2016). That limitation reduced the number of observed companies from 327 to 208 companies (1664 observations).

4. Research results

Table 1 shows descriptive statistics of the total accruals, residuals (prediction error), and predicted values. According to Jones (1991) predictions based on the estimated regression coefficient from the used regression equation are considered as a non-discretionary accruals, and belonging residuals (prediction errors) are considered as a discretionary accruals (Jones, 1991, p. 217).

Table 1: Descriptive statistics

ACC: Total accruals RES: Residuals SRes: Standardized Residual PV: Predicted Value SPV: Standardized Predicted Value					
Source: authors' calculation					

The total accruals in the regression model are dependent and change in total revenues and value of non-current assets, all scaled by total assets, are considered as independent variables. The results of the regression model (Table 2) show no auto-correlation problem (Durbin-Watson is 2.069) but an important limitation of the model is very low R^2 and adjusted R^2 by which every independent variable in the model explains only 3.7 % of the variations in the dependent variable. Nevertheless, the model is considered significant (p-value is 0.000).

Table 2: ANOVA table of multiple regression model

Model		Sum of Squares	df	Mean Square	F	Sig.
1	Regression	1.436	3	.479	21.271	.000[b]
	Residual	37.367	1660	.023		
	Total	38.804	1663			
a. Dependent Variable: Total accruals scaled by total assets						
b. Predictors: (Constant), Scaled non-current assets, Scaled change in total revenues, 1/TA(t-1)						
Source: authors' calculations						

The most important results of the model are residuals that represent discretionary accruals. Dechow and Dichev (2002) consider a standard deviation of the residuals a measurement of the earnings quality. The authors underline that lower standard deviation represents higher earnings quality. Jones (1991) highlighted that is necessary to calculate standardized residuals and standardized prediction values to obtain accruals proxies. The regression model, which is a result of this research, shows that non-discretionary accruals do not equal zero, and that the total accruals cannot be considered as only discretionary accruals. Next to that, we concluded that the discretionary accruals (residuals) have a higher standard deviation compared to the non-discretionary accruals (predicted values). Results show that changes in total accruals are mainly the outcome of a discretionary accruals.

In order to test the first research hypothesis, a correlation statistic is used. Pearson's correlation matrix (Table 3) shows the linkage between observed variables included in the earnings quality model and chosen financial indicators and ratios. Total accruals are statistically significant related to almost all variables. The correlation matrix shows significant but low strength between total accruals and non-discretionary accruals. On the other side, the total accruals are statistically significant and highly, almost perfectly, related to the standardized residuals.

As expected, cash flow changes are negatively related to the total accruals, i.e. if the total accruals increase the cash flow from operating activities decreases. Consequently, it can be concluded that a

higher accruals level leads to lower cash flows. Related to that, a net income and EBIT changes are positively related to the total accruals. Altogether, lead us to the conclusion that there exists a difference between accrual and cash basis in presenting financial information and results, and consequently accrual basis represent potential for management choices.

The total accruals are significantly linked to the business performance ratios as the economy and the profitability ratio. Higher accruals result in a higher total economy ratio, return on assets, return on equity and profit margin. Contrary to that, the financial position ratios, as an equity-to-assets ratio and total turnover ratio, are not statistically significant related to total accruals.

KOUI: total assets turnover ratio									
Source: authors' calculations									

Both accruals proxies, discretionary and non-discretionary, are related to the equity-to-assets ratio. The correlation is significant but low. Predicted values (non-discretionary accruals) are statistically significant related to changes in net income and EBIT. Respecting the obtained results of the conducted analysis, we accept the first research hypothesis that there exists a statistically significant correlation between discretionary and non-discretionary accruals, and traditional financial indicators and ratios.

The next research phase includes assessing earnings quality respecting the business performance measured by net income and traditional financial ratios. For the research purposes a dummy variable is included in the research. The dummy variable represents a category variable that divides observations into two groups, 'loss' companies (0), and 'profit' companies (1).

Table 4: Results of Mann-Whitney test for detecting changes in 'loss' and 'profit' companies for observed variables

	Net Income	Cash flow from operating activities	Return on Assets	Total accruals	Discretionary Accruals	Non-discretionary Accruals
Mann-Whitney U	.000	153326.000	29859.000	187756.000	203089.000	164400.000
Wilcoxon W	63903.000	214401.000	93762.000	251659.000	266992.000	228303.000

a. Grouping Variable: Category ('profit' companies = 1; 'loss' companies = 0)						
Source: authors' calculations						

Respecting the fact that the observed data is not normally distributed, the difference between the two categories is tested by using non-parametric Mann-Whitney test (Table 4). Obtained results show a significant difference respecting grouping variable, i.e. 'profit' vs. 'loss' companies (p-value is 0.000).

Table 5: Descriptive statistics for observed variables respecting category variable

	'loss' companies			'profit' companies		
	Mean	Standard Deviation	Median	Mean	Standard Deviation	Median
NI	-89,264,362	160,492,204	-29,008,989	68,135,865	190,154,693	17,678,015
CFt	62,237,317	336,253,626	9,688,515	107,169,557	337,965,897	41,089,280
ROA	-.04368	.11737	-.00861	.07894	.26508	.05206

SPV	-.30879	.78454	-.31627	.08434	1.03556	.04080

NI: Net Income
CF: Cash flow from operating activities
ROA: Return on Assets
ROE: Return on Equity
MP: Profit Margin
ACC: Total Accruals
SRES: Standardized residuals (discretionary accruals)
SPV: Standardized predicted value (non-discretionary accruals)

Source: authors' calculations

As expected, the 'loss' companies have negative mean and median values of net income, and for the 'profit' companies observed indicators are positive (Table 5). It is interesting to notice that both categories have a positive cash flow from operating activities, but the value of the cash flow on average is significantly higher in 'profit' companies compared to 'loss' companies. The results of the chosen financial indicators confirm the existence of differences between observed categories. All observed financial ratios of 'loss' companies have the negative median, and for 'profit' companies median is positive. The negative median for return on assets and profit margin of the 'loss' companies tells us that at least 50 % of observation had higher reported loss than interest expenses.

The most important part of the research is to analyze the difference between earnings quality in 'loss' and 'profit' companies. "The standard deviation of a series of systematically large positive residuals may very well be low, indicating that there is little inference problem. Accruals quality therefore is consistent with the view that high-mean, low-variance firms have good (not poor) earnings quality." (Francis, Olsson and Schipper, 2008, p. 297) The results of Mann-Whitney test show the significant difference between two categories tested for total accruals, standardized residuals (discretionary accruals), and standardized predicted values (non-discretionary accruals). 'Loss' companies show a lower quality of the total and discretionary accruals. "Abnormal accruals as a measure of earnings quality is based on the view that accruals which are not well explained by accounting fundamentals (fixed assets and revenues) are an inverse measure of earnings quality. The abnormal accruals measure is typically estimated using some version of the Jones (1991) approach." (Francis, Olsson and Schipper, 2008, p. 298) Conflicting results are obtained for a non-discretionary part of total accruals where 'loss' companies result in higher quality than 'profit' companies. It can be concluded that 'profit' companies are more affected by business conditions than 'loss' companies. "Abnormal accruals are traditionally viewed as capturing management's financial reporting decisions (or discretion)." (Francis, Olsson and Schipper, 2008, p. 298) The higher standard deviation of discretionary accruals leads us to the conclusion that the financial result of 'loss' companies is more affected by management choices than in 'profit' companies. Taking into account obtained results of conducted analysis the second research hypothesis can be accepted, i.e. it is possible to detect a significant difference in earnings quality between 'profit' and 'loss' companies.

5. Conclusion

The paper includes research about the earnings quality of Croatian large companies for the period from 2008 to 2016. The purpose of earnings quality models is to detect levels of management choices that affect the financial result of the company. The research is conducted by using appropriate statistical tools as multiple regression model, correlation analysis, non-parametric tests. Limitation of the research is the lack of an available data due to the content and structure of the financial statementns, and much important than that, there is no availabe data on cash flows for periods before 2007. The conducted research gives results on modified Jones (1991) and Dechow and Dichev (2002) models. Obtained results show that there exists a significant correlation between accruals measurements and traditional financial indicators and ratios. The research resulted in finding a statistically significant difference in discretionary and non-discretionary accruals between 'loss' and

'profit' companies where 'loss' companies are more affected by management choices, and 'profit' companies are more affected by business conditions. Future researches could be directed to the analysis of specific accounting policies and estimates that affects financial position and business performance of companies.

Acknowledgment

The paper is a result of a project entitled "The Role and Significance of the Analytical Procedures in the Earnings Quality Evaluation" which is financed by the University of Zagreb as a short-term research support for 2017.

Abstract

Growing process maturity of Polish organizations, causes a growing demand for information technology to meet business expectations. The answer to these needs is Business Process Management. This article brings together the functionality of Business Process Management systems and the benefits of their implementation. Tools are compared according to certain criteria developed by the authors. Both open source and commercial tool are concerned.

Keywords: Busiess Process Management, tools, frameworks, comparison, open source, commercial

Introduction

In the era of growing process maturity of Polish organizations, there is also a growing demand for information technology to meet business expectations. IT tools should support business and keep up with its ongoing development as mentioned in Gawin et al (2013), Jasiulewicz-Kaczmarek et al (2016, 2018), Piotrowski (2007), Drejewicz (2012) and Baeyens (2017). Businesses are increasingly empowered to increase employee productivity and improve information management to increase competitiveness, reduce costs and adapt to dynamic market and legal situations.

The answer to these needs are the Business Process Management (BPM) systems. They allow you to map business processes as workflow diagrams, automate tasks and improve their execution parameters. The essence of process automation is the transfer of control from humans to IT systems.
.
Progressive globalization and the widespread development of the IT industry are contributing to the increasing availability of process management tools. The business software market is filled with modern and sophisticated solutions, so the choice of the right tool is becoming more and more difficult and raises a lot of questions and doubts among potential customers. Larger companies must organize tenders to collect comparable values for choosing the right system.

This article brings together the functionality of Business Process Management systems and the benefits of their implementation. Tools are compared according to certain criteria developed by the authors.

The BPM market in Poland has been growing at about the same pace as in other countries in Central and Eastern Europe, with initial systems being reminiscent of Document Management Systems (DMS) and projects focused on improving processes from the business logic point of view as described in Object Management Group (2017). Then, with the development of IT technology, the companies' vision of the BPM benefits focused on seeking financial and temporary savings as part of the optimization of their internal processes. In the public sector, however, the focus was on implementing ISO standards. Currently, the Polish market follows trends from Western Europe and the United States, where BPM implementation projects focus on operational risk management.

The market sectors in Poland, where BPM systems are the most popular are:

- banking,
- telecommunications,
- energy,
- public administration,
- insurance industry.

The above sectors are mainly composed of large companies employing over 200 employees and corporations with many complex business processes requiring automation. The most common areas in organizations that implement BPM tools are:

- customer service,
- administration,
- accounting.

These are areas where interactions with customers (internal and external) as well as work flow must be under strict control.

Analysis of process modeling capabilities

In order to compare their process modeling capabilities, each of the analyzed tools had been investigated to find a set of potential functional features that BPM tools can offer. The first analyzed feature is the ability to graphically model processes. The graphical environment in each tool can vary a lot from very modest to very sophisticated and eye-catching graphics. The next feature to check will be the presence of a process engine responsible for implementing and running the modeled processes. Some of the applications described offer not only the BPMN notation, which is currently standard in business process modeling, but also allow modeling using other notations like, for example, Unified Modeling Language (UML). If a framework offers its own notation, then this fact will also be noticed. In addition to the ability to draw a diagram, it will be shown whether these tools offer model validation. Flexible tools should offer the ability to export and import models created with other tools using MS Visio or XPDL. The data modeling context, which includes all the data required for a process, will also be analyzed. Process data like on-screen forms, documents, attachments, document repositories, or any external sources of information that may be required for execute the process at every possible stage will be considered. Another assessment criteria concerns the business rules, both defining and enforcing. A business rule is a rule that defines or constrains some aspect of business and always resolves to either true or false. Business rules are intended to assert business structure or to control or influence the behavior of the business. A useful option or extension of the BPMN diagram is the ability to simulate the process. Simulation is used to trace the process flow, find bottlenecks, and test the continuity of the process. More advanced tools also allow you to estimate the time and costs of processes, which may help you in forecasting your budget, but will not replace Business Intelligence. The last element analyzed is whether the framework is provided with ready-to-modify template processes.

According to Activiti (2017), Github Activity (2017), Bonita (2017), Github Bonitasoft (2017), Github: jBPM (2017), Documentation jBPM (2017), Camunda (2017), Github: Camunda (2017), Orchestra code (2017), Orchestra User Guide (2017), OW2 Orchestra (2017), Yaoqiang (2017), Code Yaoqiang (2017), Table 1 shows the results of the analysis of open source tools covering the above-described scope of features.

Tab. 1 Process modeling capabilities – open source tools

	Activiti BPM	**Bonita BPM**	**jBPM**	**Camunda BPM**	**Orchestra**	**Yaoqiang BPMN Editor**
Graphical modeling	YES	YES	YES	YES	YES	YES
Built-in process engine	YES	YES	YES	YES	YES	NO
Supported notations						
BPMN	YES	YES	YES	YES	YES	YES
BPEL	NO	NO	NO	NO	YES	NO
UML	NO	NO	NO	NO	NO	NO
Own	NO	NO	NO	NO	NO	NO
Model validation	YES	YES	YES	YES	YES	YES
Model import	YES	YES	YES	YES	YES	YES
Model export	YES	YES	YES	YES	YES	YES
Data modeling	YES	YES	YES	YES	NO	NO
Forms	YES	YES	YES	YES	NO	NO
Document repository	YES	YES	NO	YES	NO	NO
Business rules	NO	YES	YES	YES	NO	NO
Process simulation						
Process flow animation	NO	YES	YES	NO	NO	YES
Time/Cost estimation	NO	YES	YES	NO	NO	NO
Process templates	NO	YES	NO	NO	NO	YES
YES	9	13	11	10	7	7
NO	7	3	5	6	9	9

Based on the table above, all of the open source tools analyzed have a graphical interface that enables modeling using the BPMN notation, validation of modeled processes, as well as options for importing and exporting process models. The process engine that enables them to be implemented in enterprises is available in almost every application except the Yaoqiang BPMN Editor, which is used exclusively for modeling. Only Orchestra allows you to map the BPMN process to BPEL, while the rest of the analyzed applications only support BPMN.
Based on the above results, Bonita BPM not only provides an easy-to-read graphical and user-friendly interface, but it is also a fully-featured solution for complex process modeling.

According to Aurea BPM (2017), Bizagi (2017), IBM Blueworks (2017), iGrafx (2017), K2 blackpearl (2017), Oracle BPM (2017), Table 2 summarizes the results of the process modeling capability analysis for commercial tools and is subjected to the same evaluation criteria as the open source tools.

Tab. 2 Process modeling capabilities – commercial tools

	Aurea BPM	**Bizagi BPM Suite**	**IBM Blueworks Live**	**iGrafx FlowCharter**	**K2 blackpearl**	**Oracle BPM Suite**
Graphical modeling	YES	YES	YES	YES	YES	YES
Built-in process engine	YES	YES	YES	NO	YES	YES
Supported notations						
BPMN	YES	YES	YES	YES	YES	YES
BPEL	NO	NO	NO	YES	NO	YES
UML	NO	NO	NO	YES	NO	NO
Own	NO	NO	NO	NO	NO	NO
Model validation	YES	YES	YES	YES	YES	YES
Model import	YES	YES	YES	YES	YES	YES
Model export	YES	YES	YES	YES	YES	YES
Data modeling	YES	YES	YES	NO	YES	YES
Forms	YES	YES	YES	NO	YES	YES
Document repository	YES	NO	YES	YES	YES	YES
Business rules	YES	YES	YES	NO	YES	YES
Process simulation						
Process flow animation	YES	YES	YES	NO	NO	YES
Time/Cost estimation	YES	YES	NO	NO	NO	YES
Process templates	NO	NO	YES	YES	YES	YES
YES	12	11	12	9	11	14
NO	4	5	4	7	5	2

By analyzing the above table, it can be seen how small differences in their capabilities appear among commercial tools. All analyzed tools have a graphical environment for process modeling in BPMN notation, and also allow you to import and export modeled processes. Except for iGrafx FlowCharter, all standard tools are equipped with a model validator that can capture potential errors in the process. Similarly, screen forms support, the ability to model data and bind them to process elements, and the ability to model and execute business rules are present in all evaluated tools. The only tool out there that is suitable only for modeling is the iGrafx FlowCharter. It does not have a process engine, but includes the UML modeling feature and converts modeled processes into BPEL.
The differences in modeling capabilities between the analyzed commercial solutions are negligible. The tool with the best process modeling capabilities seems to be the Oracle BPM Suite, but the Aurea BPM competes with all the features but the ready-made diagram templates.

Analysis of end-user interface and business analyst interface

This section analyzes the interfaces available to end users of the application and to business analysts. Access options have been defined that reflect the various forms of work on the systems under consideration. The first will be web browser access for process modeling, task management, or process monitoring. The four most popular browsers are: Internet Explorer (Edge), Mozilla Firefox, Google Chrome and Opera. The next criterion is to check whether the system can work in the cloud and whether it has a mobile application or desktop application. It will show on which operating systems you can use the tool, and whether it is a cross-platform application that is independent of the operating system. The comparison will also take into account the language versions of the tool and whether the application has a

Polish version. The final element will be the interface for developers i.e. plugins for popular development environments, such as Eclipse or Microsoft Visual Studio.
According to Activiti (2017), Github Activity (2017), Bonita (2017), Github Bonitasoft (2017), Github: jBPM (2017), Documentation jBPM (2017), Camunda (2017), Github: Camunda (2017), Orchestra code (2017), Orchestra User Guide (2017), OW2 Orchestra (2017), Yaoqiang (2017), Code Yaoqiang (2017), Table 3 below shows the results of the analysis of open source tools that indicate the available user interfaces.

Tab. 3 Available user interfaces – open source tools

	Activiti BPM	**Bonita BPM**	**jBPM**	**Camunda BPM**	**Orchestra**	**Yaoqiang BPMN Editor**
Web browser interface:	YES	YES	YES	YES	YES	NO
Internet Explorer	YES	YES	YES	YES	YES	NO
Mozilla Firefox	YES	YES	YES	YES	YES	NO
Google Chrome	YES	YES	YES	YES	YES	NO
Opera	YES	YES	YES	YES	YES	NO
Cloud/SaaS	NO	NO	NO	NO	NO	NO
Desktop application	YES	YES	NO	YES	NO	YES
Operating systems						
Windows	YES	YES	YES	YES	YES	YES
Linux	YES	YES	YES	YES	YES	YES
Unix	YES	NO	YES	YES	YES	NO
Mac OS	YES	YES	YES	YES	YES	YES
Multi-platform application	YES	NO	YES	YES	YES	NO
Mobile application	NO	YES	NO	NO	NO	NO
Polish version	NO	NO	NO	NO	NO	NO
Plug-ins	YES	YES	YES	YES	YES	YES
YES	8	7	7	8	7	5
NO	3	4	4	3	4	6

By analyzing the above table, you can see that the poorest tool is the Yaoqiang BPMN Editor again - it's a desktop application, it does not require installation, and it is available in three versions for Windows, Linux and Mac. The remaining five tools offer access via all considered web browsers. None of the tools offer a Cloud or SaaS (Software as a Service) model, which may be understandable for community-driven solutions. The vast majority of solutions are cross-platform applications that have one version regardless of the operating system on which they are deployed. The distinctive tool is Bonita BPM, which is the only one with a dedicated mobile application.

Among the open source tools, the largest range of interfaces have Alfresco and Camunda BPM, but these are minor differences compared to the Bonita BPM, jBPM, and Orchestra, that took the second place.
According to Aurea BPM (2017), Bizagi (2017), IBM Blueworks (2017), iGrafx (2017), K2 blackpearl (2017), Oracle BPM (2017), Table 4 below summarizes the results of analysis of available user interfaces for commercial tools and is subjected to the same evaluation criteria as the open source tools.

Tab. 4 Available user interfaces – commercial tools

	Aurea BPM	**Bizagi BPM Suite**	**IBM Blueworks Live**	**iGrafx FlowCharter**	**K2 blackpearl**	**Oracle BPM Suite**
Web browser interface:	YES	YES	YES	NO	YES	YES
Internet Explorer	YES	YES	YES	NO	YES	YES
Mozilla Firefox	YES	YES	YES	NO	YES	YES
Google Chrome	YES	YES	YES	NO	YES	YES
Opera	YES	YES	YES	NO	YES	YES
Cloud/SaaS	YES	YES	YES	NO	YES	YES
Desktop application	NO	NO	NO	YES	YES	YES
Operating systems						
Windows	YES	YES	YES	YES	YES	YES
Linux	YES	YES	YES	NO	NO	YES
Unix	YES	YES	YES	NO	NO	YES
Mac OS	YES	NO	YES	NO	NO	YES
Multi-platform application	YES	NO	YES	NO	NO	YES
Mobile application	YES	YES	YES	NO	YES	YES
Polish version	YES	YES	NO	YES	NO	NO
Plug-ins	NO	NO	NO	NO	YES	YES
YES	9	7	8	3	6	10
NO	2	4	3	8	5	1

From the table above, most commercial tools offer web browser access and cloud computing, with the exception of the iGrafx solution, which only works with a desktop application running on Microsoft Windows. Also K2 Blackpearl and Oracle BPM Suite offer a desktop application. All applications support MS Windows operating system, while it is the only supported operating system for the K2 Blackpearl. The Linux and Unix OSs are supported by four tools: Aurea BPM, Bizagi BPM Suiute, IBM Blueworks Live and Oracle BPM Suite. Bizagi does not support Apple Mac OS and does not offer a cross-platform application-independent system.

Process monitoring capabilities analysis

One of the key elements of business process management is the ability to monitor them. It is called the Business Activity Monitoring (BAM). They continuously gather information about Key Performance Indicators (KPIs). This section outlines the capabilities of BAM tools delivered with the analyzed BPM systems.

A set of four predefined reports will be analyzed. Potentially reports should show process execution statistics (such as execution time or iteration amount), allow review of executed processes, provide detailed data about individual activities in the process, and provide a view of process participant statistics. It will be investigated whether the tools have the ability to define their own reports using the wizard. When creating your own reports, it will be helpful to define your own KPIs for the process. Next, it will be verified whether the tools enable working with data from external sources together with with process flow data. Next, you will be able to compare the capabilities of defining dashboards, drawing charts, and data operations (filtering, selection, and multi-layered data collapsing and expanding). It will be determined which tools have the ability to define system notifications when the indicator reaches a limit value. At the end, data import and export capabilities will be investigated.

According to Activiti (2017), Github Activity (2017), Bonita (2017), Github Bonitasoft (2017), Github: jBPM (2017), Documentation jBPM (2017), Camunda (2017), Github: Camunda (2017), Orchestra code (2017), Orchestra User Guide (2017), OW2 Orchestra (2017), Yaoqiang (2017), Code Yaoqiang (2017), Table 5 below summarizes the results of the analysis of business process monitoring capabilities for open source tools.

Tab. 5 Business process monitoring capabilities – open source tools

	Activiti BPM	**Bonita BPM**	**jBPM**	**Camunda BPM**	**Orchestra**	**Yaoqiang BPMN Editor**
BAM	NO	YES	YES	NO	NO	NO
Predefined reports:	NO	YES	YES	NO	NO	NO
Process execution statistics	NO	YES	YES	NO	NO	NO
Process review	NO	YES	YES	NO	NO	NO
Process activity statistics	NO	YES	YES	NO	NO	NO
Process participants statistics	NO	YES	YES	NO	NO	NO
Report wizard	NO	NO	YES	NO	NO	NO
KPI	NO	YES	YES	NO	NO	NO
External data	NO	YES	YES	NO	NO	NO
Management dashboards	NO	YES	YES	NO	NO	NO
Charts	NO	YES	YES	NO	NO	NO
Data manipulation:						
Filtering	NO	YES	YES	NO	NO	NO
Selecting	NO	YES	YES	NO	NO	NO
Multidimensional	NO	NO	YES	NO	NO	NO
Alert system	NO	NO	NO	NO	NO	NO
Data export	NO	YES	YES	NO	NO	NO
Printing to file	NO	YES	YES	NO	NO	NO
YES	0	14	16	0	0	0
NO	17	3	1	17	17	17

As you can see in the table above, BAM is not an open source domain for process management tools - only two of them offer this functionality. The jBPM, which offers a rich, built-in BAM module, is the best in the list. A set of predefined reports fulfills the criteria. It has a graphical report generator that allows you to create reports for business users. It supports process KPIs and allows you to create new indicators. The other solution, Bonita BPM, does not have a built-in report wizard, but is integrated with another open source tool that has such a wizard. Although because it is another project, it was not included in the list. The Bonita BPM reports do not have a multidimensional construction, which prevents aggregation and drilling up/down of data.

According to Aurea BPM (2017), Bizagi (2017), IBM Blueworks (2017), iGrafx (2017), K2 blackpearl (2017), Oracle BPM (2017), Table 6 summarizes the results of the analysis of the business process monitoring capabilities for commercial tools, and is subjected to the same evaluation criteria as the open source tools.

Tab. 6 Business process monitoring capabilities – commercial tools

	Aurea BPM	**Bizagi BPM Suite**	**IBM Blueworks Live**	**iGrafx FlowCharter**	**K2 blackpearl**	**Oracle BPM Suite**
BAM	YES	YES	NO	NO	YES	YES
Predefined reports:	YES	YES	YES	NO	YES	YES
Process execution statistics	YES	YES	YES	NO	YES	YES
Process review	YES	YES	YES	NO	YES	YES
Process activity statistics	YES	YES	YES	NO	YES	YES
Process participants statistics	YES	YES	YES	NO	YES	YES
Report wizard	YES	YES	NO	NO	YES	YES
KPI	YES	YES	NO	NO	NO	YES
External data	YES	NO	NO	NO	NO	YES
Management dashboards	YES	YES	NO	NO	YES	YES
Charts	YES	YES	YES	NO	YES	YES
Data manipulation:						
Filtering	YES	YES	YES	NO	YES	YES
Selecting	YES	YES	NO	NO	YES	YES
Multidimensional	YES	YES	NO	NO	YES	YES
Alert system	YES	YES	NO	NO	YES	YES
Data export	YES	YES	YES	NO	YES	YES
Printing to file	YES	YES	NO	NO	YES	YES
YES	17	16	8	0	15	17
NO	0	1	9	17	2	0

By analyzing this table, you can see that the IBM Blueworks Live and iGrafx FlowCharter tools do not provide common process monitoring modules. The IBM tool has a set of predefined statistics, which, using graphs with the ability to navigate through predefined filters, covers the scope of the report. Graph data can be exported to MS Excel. The other four tools, depending on the requirements of the enterprise, can meet the needs of process monitoring reports. Bizagi BPM Suite and K2 Blackpearl tools do not offer reports that include data imported from external systems. The other two systems, Aurea BPM and Oracle BPM, meet the complex scope of business process monitoring. It should be borne in mind that while Oracle fully supports BAM with its own resources, Aurea BPM is supported by an external analytical tool OEM (Original Equipment Manufacturer), which sells it under its own brand as a BAM module.

Analysis of integration possibilities

The tools that are used to implement the process management system should allow integration with existing infrastructure in the enterprise. Such integration enables full automation of business processes. In the first place, you will be able to integrate with the two popular tools: Sharepoint and Outlook and their ability to be used as client applications. Next, the capabilities of external access to process engines will be examined, as well as the capability of API or Web Service integration. Finally, you will be able to see which applications allow you to integrate processes with database objects.
According to Activiti (2017), Github Activity (2017), Bonita (2017), Github Bonitasoft (2017), Github: jBPM (2017), Documentation jBPM (2017), Camunda (2017), Github: Camunda (2017), Orchestra code (2017), Orchestra User Guide (2017), OW2 Orchestra (2017), Yaoqiang (2017), Code Yaoqiang (2017), Table 7 below summarizes the results of the analysis of the ability to integrate BPM tools with existing enterprise infrastructure for commercial tools.

Tab. 7 Integration capabilities – open source tools

	Activiti BPM	**Bonita BPM**	**jBPM**	**Camunda BPM**	**Orchestra**	**Yaoqiang BPMN Editor**
MS SharePoint	NO	YES	NO	NO	NO	NO
MS Outlook	NO	NO	NO	NO	NO	NO
API/Web Service – engine	YES	YES	YES	YES	YES	NO
API/Web Service – modeler	YES	YES	YES	YES	YES	YES
Database objects	YES	YES	YES	YES	YES	NO
YES	3	4	3	3	3	1
NO	2	1	2	2	2	4

By analyzing the results from Table 7, you can see a certain standard for open source software. All have APIs or Web Services to communicate with other software. This allows, for example, to run specific processes or remodel them using external software. The exception is, of course, Yaoqiang BPMN Editor which does not have its own engine nor external database access. None of the tools support integration with the popular MS Outlook e-mail program. Only Bonita BPM supports integration with the Sharepoint application platform.

According to Aurea BPM (2017), Bizagi (2017), IBM Blueworks (2017), iGrafx (2017), K2 blackpearl (2017), Oracle BPM (2017), Table 8 shows the results of the analysis of the integration capabilities of commercial tools, and they were subjected to the same criteria for evaluation as open source tools.

Tab. 8 Integration capabilities – commercial tools

	Aurea BPM	**Bizagi BPM Suite**	**IBM Blueworks Live**	**iGrafx FlowCharter**	**K2 blackpearl**	**Oracle BPM Suite**
MS SharePoint	NO	YES	NO	YES	YES	YES
MS Outlook	NO	NO	NO	YES	YES	YES
API/Web Service – engine	YES	YES	YES	NO	YES	YES
API/Web Service – modeler	YES	YES	YES	NO	YES	YES
Database objects	YES	YES	NO	NO	YES	YES
YES	3	4	2	2	5	5
NO	2	1	3	3	0	0

The data in Table 8 show that the analyzed commercial tools are mostly adapted to integrate with existing systems in enterprises. Four of them (Bizagi BPM Suite, iGrafx Flowcharter, K2 Blackpearl, Oracle BPM Suite) support integration with Sharepoint platform, three of which integrate with MS Outlook. Due to its purpose, iGrafx FlowCharter does not provide programming interfaces to communicate with external software. Systems K2 and Oracle in the above table meet the full scope of the tested integration possibilities.

Conclusions

By analyzing the statements in this article, you will notice that some of the tools are used exclusively to create process models and draw process diagrams. On the other hand, the rest can be a complete set of tools for implementing enterprise process management systems.
Table 9 summarizes the results of the previous four areas of analysis. The first column shows the tools tested, while the next four columns show all the criteria met, and then in the "Sum" column they are added together. A total of 49 properties were verified, as referred to in the last column showing the percentage of all the features for the tool. The tools are divided into commercial and open source.

Tab. 9 Analysis summary

		Process modeling capabilities	GUI	Process monitoring capabilities	Integration possibilities	SUM	% features fulfilled
open source	Activiti BPM	9	8	0	3	20	41%
	Bonita BPM	13	7	14	4	38	78%
	jBPM	11	7	16	3	37	76%
	Camunda BPM	10	8	0	3	21	43%
	Orchestra	7	7	0	3	17	35%
	Yaoqiang BPMN Editor	7	5	0	1	13	27%
commercial	Aurea BPM	12	9	17	3	41	84%
	Bizagi BPM Suite	11	7	16	4	38	78%
	IBM Blueworks Live	12	8	0	2	22	45%
	iGrafx FlowCharter	9	3	0	2	14	29%
	K2 blackpearl	11	6	15	5	37	76%
	Oracle BPM Suite	14	10	17	5	46	94%

The above analysis summary table clearly indicates that only two open source tools fulfill more than 75% of the analyzed features, Bonita BPM and jBPM deserve attention in this segment. Among the commercial tools, the most fulfilled features has the Oracle BPM Suite with the result of 94%. It should be noted that aside from the worldwide software giant, the Aurea BPM, which covers 84% of the measured range of functions, is exceptionally well presented. The other two commercial tools that fulfill more than 75% of the surveyed features are Bizagi BPM Suite and K2 blackpearl.

Ensuring Stability of the Territorial Subject of the Russian Federation in the Conditions of Unstable Economy

Marina V. Kazakovtseva, Mari State University, Yoshkar-Ola, Russia, marina290576@mail.ru

Firdaus Z. Gumarova, Mari State University, Yoshkar-Ola, Russia, gumarovaf@mail.ru

Elena Y. Yuricheva, Mari State University, Yoshkar-Ola, Russia, roman1135@yandex.ru

Abstract

Financial stability of territorial subjects of the Russian Federation in many respects depends on economic activity in the region. In the conditions of insufficient budget financing attraction of foreign investments by regions has to become one of sources of growth of enterprise activity.

Keywords: financial stability of the region, foreign investments, investment potential of the region.

Introduction

Balance and stability of the budgetary system on a long-term basis are the most important prerequisites of ensuring macroeconomic stability that promotes formation of basic conditions for economic growth, investment development and increase in competitiveness of the Russian financial and economic system.
Despite active work of federal organs of the power on improvement of the interbudgetary relations, it should be noted today that the operating system not fully solves a problem of financial stability of territorial subjects of the Russian Federation.

Investment Appeal of the Region as Base for Ensuring Financial Stability of the Budget of the Subject

The first six months of the current 2017 say that the income of budgets of regions of Russia continues to grow at rather high rates. Total amount tax and non-tax and the income for this period grew approximately more than by 20% in comparison with the corresponding period of last year. It demonstrates that the profitable base of subjects of Russia gradually began to grow. Deficiency of regional budgets made more than by 2,5 times smaller volume, than for the corresponding period of last year.

It testifies to efficiency of the events for optimization of expenses held by regions, mobilization of profitable sources.

At the same time it is necessary to recognize that own income for execution of the account powers assigned to regions only most economically developed regions have. Stability of modern budgetary system of regions in many respects has to be defined by efficiency of average or long-term strategy of regional policy of the Russian Federation.

Financial stability of the region is one of the key factors defining investment appeal of the region. At everything it is important to note it, as financial stability of regions directly depends on investment activity in the region, on its investment appeal both for Russian, and for foreign investors. Increase in budget revenues can be reached thanks to increase in a taxable basis due to placement on platforms of the region of new competitive productions (Ayupov, Kazakovtseva, 2014).

In the conditions of globalization use of foreign investments is the objective need caused by system of participation of national economy in the international labor division and a capital modulation in branch, free for business.

The important role of direct foreign investments as a factor of economic growth is confirmed with experience of the countries which showed high dynamism and realized essential structural transformations in the last decades: People's Republic of China, India, Brazil, South Korea, etc.

In Russia demand for investments, not important, foreign or Russian, is huge. The Russian regions took a big step over the past few years in the development plan for appeal of investment climate. The world community is deeply impressed that Russia in 5 years rose from the 120th place to the 41st place in the rating of Doing Business (Butenko, 2017). Respectively the international investors could not but pay to it attention.

Investment appeal of the region is defined as set of the factors influencing expediency, efficiency and level of risks of investment investments in the territory of this region. Let's consider distribution of the Russian regions according to the rating of investment appeal.

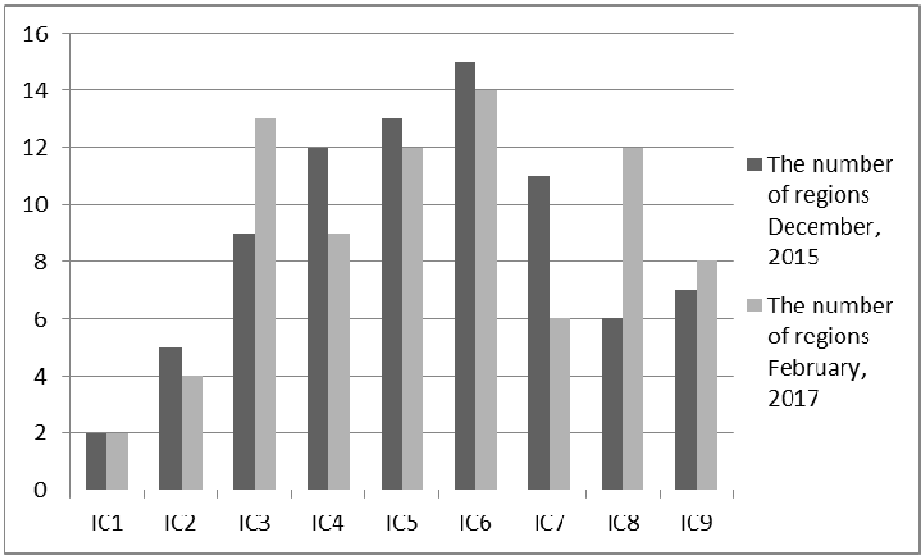

Fig. 1: Distribution of regions on groups of rating

If in 2015 19 regions worsened in a year the positions in rating, and 10 regions – improved, then in 2017 already 21 regions worsened the positions in rating, and improved only 6 regions. In 2017 the number of regions in group of leaders with "high" investment appeal – with 16 to 19 increased.

Results of rating of investment appeal of regions are confirmed by statistics of distribution of the direct foreign investments arriving in: 88% of receipts of direct foreign investments were the share of group of regions with "high" investment appeal while regions with "moderate" in total could attract only 2% of direct foreign investments.

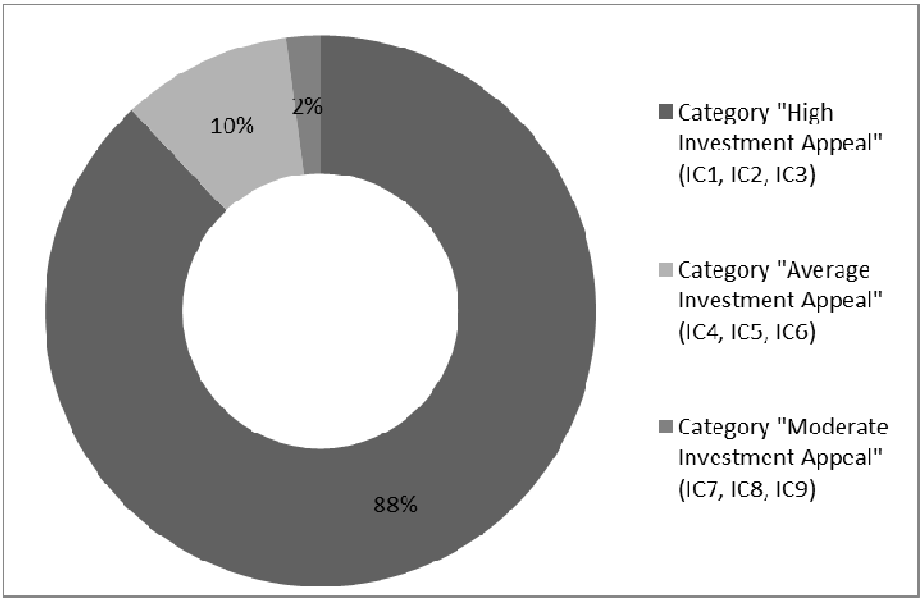

Fig. 2: Distribution of direct foreign investments

Investment appeal of the region consists of several factors, each of which can be estimated by means of selection of indicators for it. In the rating of National Rating Agency seven factors of regional investment appeal are considered:

1) Security of the region with natural resources and quality of the environment in the region.
2) Region manpower.
3) Regional infrastructure.
4) Domestic market of the region.
5) Production potential of regional economy.
6) Institutional environment and socio-political stability.
7) Financial stability of the regional budget and enterprises of the region.

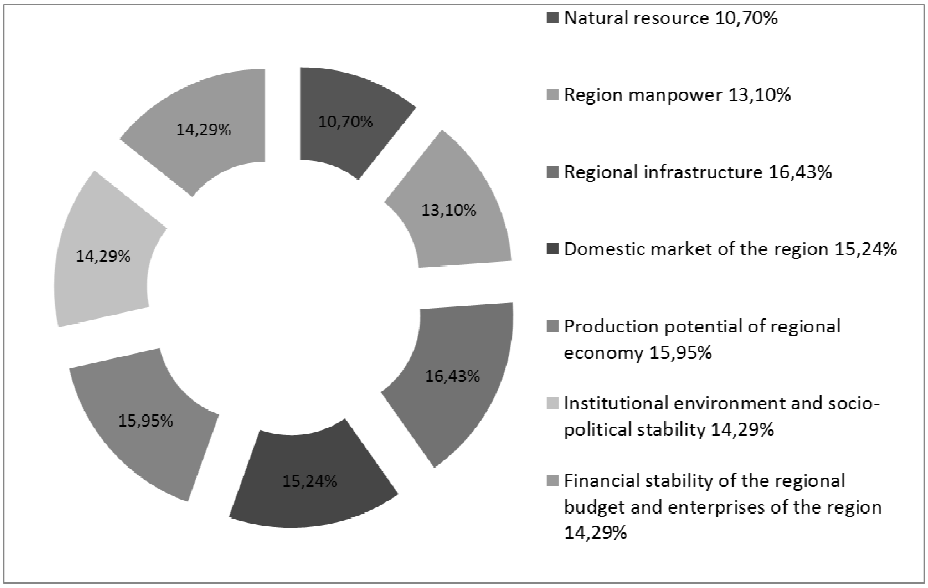

Fig. 3: Factors of investment appeal of regions

Financial stability of the region both its level of investment appeal the interconnected and complementary indicators: high level of financial stability of the region provides appeal of the region to investors and, on the other hand, the high level of investment activity in the region will provide financial stability of the regional budget due to growth of a taxable basis. The indicator of financial stability of the regional budget for an assessment of investment appeal is defined on the basis of indicators: amount of tax revenues, balance of the budget, level of a regional central government debt.

The rating of investment appeal of regions developed in Russia was already among the best world practices, other countries which thought of how to improve investment climate address his developers. Nevertheless in Russia this practice can be developed through models of regions, through road maps, advance to these target models. We consider what to the Russian regions is on what to work from the global point of view.

Actions for Attraction of the Russian and Foreign Investments into Regions of Russia

Now average profitability from investments becomes lower that leads to the fact that short-term financial investments already become less interesting. And world business the community is convinced that now, in Russia for three years it is senseless to invest.

Respectively it is necessary to pass to attraction of strategic investments when the investor comes seriously and for a long time. Various state support is especially necessary for such strategic investments.

Not to attract the strategic investor without existence of qualitative human resources, it is necessary that universities that people professionally grew were near and developed.

Now Russia loses the competition for the foreign capitals to Asian and Latin American developing states which markets are more attractive to investors (Byshok and Dorofeyeva, 2011).

At the beginning of 2014 in connection with a geopolitical situation around annexation of the Crimea, in the foreign exchange market in Russia large-scale investment crisis as a result of which the foreign capitals almost completely ceased to come to domestic economy began panic.

Following the results of 2014 the volume of direct investments in real sector of the Russian economy was reduced by 3,5 times. In 2015 the annual balance of direct foreign investments was reduced by 71% concerning the level of 2014. Do not want to invest the capitals in domestic economy not only foreign investors, but also the Russian oligarchs to whose share from 60 to 70% of total inflow of the foreign capital inflowing to Russia from offshore jurisdictions (almost all direct investments arriving from the Republic of Cyprus from the Bahamas fall and from the British Virgin Islands, have the Russian origin). Large-scale also decrease in attraction of the foreign credits and loans was same.

Despite aspiration of the federal center to alignment of quality of investment climate in regions of Russia, regions of Russia are still characterized by essential differentiation on the level of investment appeal. The non-uniform institutional environment and various administrative approaches lead to uneven distribution of investments between regions. The best regions continue to increase the investment appeal (so, base for economic development), and outsiders – "fail" stronger, the gap between the successful and lagging behind regions becomes even more (Devyatlovsky, 2012).

In 2016 the volume of direct foreign investments to regions considerably exceeded indicators of 2015, however the main volume of foreign investments (82%) falls to the share of 19 regions with high investment appeal.

At the same time on the following territorial subjects of the Russian Federation: Mordovia, Mari El, Ivanovo, Kostroma and Kirov regions in 2016 lowered rating estimates of investment appeal. In all

listed regions the macroeconomic situation remains adverse: investments fall or do not grow, infrastructure and institutional development lags behind the average Russian level, the income of regional budgets does not cover expenses, there is a growth of a debt load.

The volume of direct foreign investments to the Republic of Mari El in 2013 made 10 mln. dollars, in 2014 –6 mln. dollars, in 2016 – only 1,3 mln. dollars. In the next Chuvash Republic for the same period the volume of direct foreign investments made 163 mln. dollars in 2013 and 54 mln. dollars in 2014. On inflow of direct foreign investments per capita the Republic of Mari El shows in rating among territorial subjects of the Russian Federation one of the worst indicators.

Low level of foreign investments in these regions can be written off, of course, for the general macroeconomic instability in Russia, the imposed sanctions and low investment appeal of the country in general. However, experience of a number of regions (The Republic of Tatarstan, the Kaluga, Ulyanovsk, Belgorod regions) shows that to attract foreign investors quite really.

Activization of inflow of foreign investments into the Russian economy requires creation of favorable investment climate. Criterion of appeal of national economy to foreign investors is risk level of an entrepreneurial activity and profitability of investment projects.

Foreign investors, first of all, are interested in the economic capacity of the region, in capacious sales market of the made production, in high solvency of the population of the region. Respectively, the main indicator of investment appeal is the volume of a gross regional product, than above its level, especially the region is attractive to potential investors. On world statistics, the most attractive branches for attraction of foreign investments are the processing industry, trade, mining. The anti-Russian sanctions imposed in 2014 limit investment into financial sector and fuel branch that increases appeal of the alternative directions of investment, such as telecommunications, pharmaceutics, agricultural production and processing of agricultural products.

Possible forms of cooperation with foreign investors are various: crediting, leasing, creation of cooperation management enterprises or completely with the foreign capital, the conclusion of concession agreements, creation in the territory of the region of free economic zones.

Weak points of the Republic of Mari El are production, institutional, infrastructure spheres of action of economy. Outside the country very few people know about Mari El – the republic is poorly presented at the international economic forums, the mechanism of representations abroad does not work. The region is obliged to tell about the progress, advantages of a business environment, concrete achievements more. However participation in itself in the international forums does not give any guarantee of an indication of interest of foreign investors to the republic as the absolute information openness is important. Important not only how many investments now in the region, parallel improvement of the reached business climate is important. If not to improve business climate, investments will be even less.

Recently the tendency was outlined in Russia that investments flow from resource and export investments into investments into technologies, into services that means existence of the human capital.

Attraction, deduction, development of the human capital, in turn, requires qualitative and available health care, education, the comfortable urban environment.

If million-plus cities have more opportunities of attraction of investments into high technologies, telecommunications, then in the small cities and in the rural zone development of agricultural IT technologies is possible. The agricultural industry in Russia very well develops recently, not only grows, but also technologization. Attraction of foreign investments into agrarian sector (poultry farming, pig-breeding, processing of meat and a bird) is most urgent for the Republic of Mari El. More than 20% of internal regional product of the Republic of Mari El are occupied by agrarian sector. In recent years in Mari El in this branch steady growth rate of production and the largest

volume of investment investments is observed – the region takes leading places among regions of Russia on production of meat of the cattle and a bird per capita (Kazakovtseva, Gumarova, Tsaregorodtsev, 2015).

Today in the conditions of the imposed anti-Russian sanctions and reciprocal restriction of deliveries of agricultural production from Europe the Russian producers are forced to change constantly suppliers, to increase purchases in the countries of America. Such logistic shoulder increases both terms and cost, complicates quality control process. As a result, many European producers state intentions about localization of production in Russia. It, first of all, belongs to producers of seed material, incubatory egg. Localization of this production will allow to reduce product cost approximately for a third. In Russia this production will be demanded by both large-scale enterprises and small farmers. The Russian regions focused to a large extent on agricultural industry have an excellent possibility of involvement of the European investors on the platforms.

For attraction of investment projects in the region the body or the company (agencies on attraction of investments, corporation) which will be engaged in holding the foreign presentations of investment potential of the subject, participation in trade and economic missions, the international actions has to be created, to promote development of projects of public-private partnership, establishment of international cooperation, to participate in creation of necessary infrastructure and other actions for improvement of quality of investment climate in the subject (Kapustina, Lipkova L. and Falchenko, 2016).

In the Republic of Mari El since 2013 the Autonomous nonprofit organization "Agency of Investment Development of the Republic of Mari El" which tasks is implementation of above-mentioned actions works. The Investment portal of the Republic of Mari El is created. In 2015 on the basis of the Agency of investment development of the Republic of Mari El the Regional Integrated Center which purpose is ensuring granting the integrated package of services directed to business internationalization, and also increase in efficiency and competitiveness of business in the interregional and international markets is created. For formation of favorable investment climate the Investment strategy of the Republic of Mari El within which execution in 2016 by the Regional integrated center together with the Ministry of Economic Development of the Republic of Mari El held business missions of businessmen of the Republic of Mari El in Germany, the Netherlands, Finland, Sweden, Austria, Slovakia, Italy for the presentation of economic investment potential of the Republic of Mari El is accepted.

However the reached level of the saved-up investments, especially foreign, testifies to insufficiency of ongoing efforts.

One of actions for attracting investors to the region is creation of platforms for placement on them the industrial enterprises – industrial parks. In 2013 the Government of Mari El made the decision on creation of the industrial park, however because of insufficiency of budgetary funds realization of actions for creation of the industrial park is still not begun.

A special role is played also by subjective criteria of investment appeal of the region to which it is possible to refer: level of bureaucratic barriers, political stability, qualification of the population, respecting the rule of law and law and order, professionalism and sequence of regional administration.

Summary

All given actions for improvement of investment potential and attraction of the foreign capital have long-term strategic character. At the correct statement they are capable to help regions with the solution of structural and branch problems of economy with smaller state investment expenses and in much shorter terms. Improvement of investment potential of the region creates conditions for attraction of the foreign capital and, further, leads to a steady financial condition of the region (Kazakovtseva, 2012).

In the conditions of budgetary deficiency of the regional budget, fall of the real income of the population one of the main criteria of managerial effectiveness of the territorial subject of the Russian Federation will be ability to attract long-term Russian or foreign investors. It will allow to create new and qualitative jobs, will increase tax revenues, will provide growth of regional economy, financial stability of the region and will increase the general level of quality of life in the region.

Abstract

The article is devoted to the issues of making an administrative decision on the basis of accounting (financial) accounting data. A practical mechanism for evaluating the investment project from the position of management accounting is proposed. Documentary support of the risk management of the investment project for risk management has been developed. A methodology for estimating profit taking into account risk is proposed.

Keywords: risk, accounting, decision, project.

The research was carried out with the financial support of the RFFI and the Government of the Republic of Mari El oblast in the framework of the scientific project No. 16-12-12001 (a) "Development of accounting and analytical support for risk management and risk reflection in the accounting (financial) statements of commercial organizations of the Republic of Mari El in crisis management ".

Introduction

Currently, the activities of each organization are carried out under conditions of constant uncertainty. The consequence of market uncertainty is the occurrence of risks. Risk is, first of all, the probability of loss of resources, non-receipt of certain incomes and unforeseen expenses in the economic activity of the enterprise. Any enterprise risks, since it cannot rule out the occurrence of undesirable situations. But there is the possibility of reducing their occurrence and the occurrence of damage.

Hence, there is a desire to create such a mechanism that would promote the best way to take risks into account when implementing the goals set by the company. In this case, this mechanism is considered to be risk management or risk management. Risk management is a system for identifying, assessing and managing the risks faced by a business entity. The information of the accounting reporting facilitates the adoption of significant management decisions. According to the requirements of the legislation, events that have occurred and events that are likely to occur are recorded in the accounting. Since the purpose of accounting is to inform interested users, the analysis should be based on an assessment of the consequences of all possible significant risks.

Project Analysis

A well-organized system of internal information about the costs of an enterprise is an important and crucial condition for the effective management of the organization. The fact of adopting one decision is only an integral part of the effective decision-making process. Decisions should be effective. This means that the department of management accounting, risk management should be more widely involved in the decision-making process. This problem is raised in their research by such scientists as

Bethge (2000), Stafievskaya (2015), Tolstova (2009), Laikov (2009), Sokolov (2000), Khokhlov (2007).

The need for methodological developments in the convergence of management accounting and risk management is said in their research by scientists such as Sarycheva and Shvetsov (2015).

In the research, professor Mizikovsky (2004) says that each enterprise is subject to a number of risks that must be taken into account. For example, let's take the current commercial enterprise «Alfa», specializing in repair and construction works, whose plans are to launch an investment project - the production of construction materials for their own needs and for sale in order to obtain profit. To realize this goal, equipment for 800000 rubles is needed, the list of which is given in Table 1.

Table 1: necessary equipment for the opening of production of building materials at the Company "Alfa"

The equipment	Cost, thousand rubles.
Machine	600
Tool	100
Security system	100
Total:	800

To produce 1000 pieces of building materials, circulating assets amounting to 9220 thousand rubles are required (Table 2).

Table 2: requirements for working capital

Types of working capital.	Consumption	Price, rubles.	Cost, thousand rubles.
Raw materials and materials: - raw materials A, kg. - raw materials B, kg	 1000 220	 3 220	 3 0,220
Electricity, thousand kW/h	1	6	6
Total:	–	–	9,220

To start production at the «Alfa» plant, the cost of raw materials and materials will be realized in the amount of 3220 thousand rubles. The cost of electricity will be 6 thousand rubles.

For further calculation, you need to know the number and average monthly salary. The monthly wage bill is 36000 rubles (Table 3).

Table 3: number and average monthly salary at the enterprise "Alfa"

Position	Number of persons	Salaries, rubles	Amount, rubles
Worker for work on equipment	**2**	**18000**	**36000**

The cost of production was determined in the amount of 917250 rubles (Table 4).

Table 4: costs of construction materials production enterprise "Alfa"

Indicators	Cost, rubles
1. Raw materials	3220
2. Labor costs	36000
3. Payroll taxes	10800
4. Equipment purchase costs	800000
5. Total direct costs	850020
6. Expenses for maintenance and operation of equipment	25000
7. General production expenses	17000
8. General running costs	25500
9. Total indirect costs:	67500
TOTAL:	917520

For the implementation of the project, a decision was made to attract investment resources in the form of own funds for the amount of 950 thousand rubles, which covers the costs of production of construction materials.
The expected payback period characterizes the ratio of money flows and investments. Simple payback period is 3.5 months, i.e. 114 days. Discounted payback period, taking into account the real rate of comparison of 13% per annum, is 1 year and 11 months, i.e. 1 year and 357 days from the beginning of the project.

Define the risk-free discount rate by the formula:
r = (1 + n-1) * (1 + n-2) * (1 + n-3) -1
Where n1 is the real interest rate;
n2 - the rate of inflation;
n3 - is the probability of risk.

Define the variables:
n1 - 8.52% (for 2017);
n2 - 8.7%;
n3 - do not count.
r = (1 + 0.0885) * (1 + 0.087) - 1 = 1.0852 * 1.087-1 = 0.18

The next indicator of the effectiveness of the investment project is the net present value of the project (NPV). With a discount rate of 18% and a planning interval up to 2018

NPV = (950:1,18)+(950:1,36)+(950:1,54) = 805+699+617= 2121 thousand rubles.

Thus, this calculation of net present value indicates the profitability of the project (because NPV> 0). The internal rate of return on the project (IRR), i.e. the conditional income rate for the project without inflation is 39%. It is twice the discount rate, which is equal to 18%, which confirms the effectiveness of this investment project.

The breakeven point analyzes the lower limit of the profit of the investment project. In this case, it is equal (in 2017) (9900*5480) : (9900-3241) = 7849 thousand rubles. Therefore, it is necessary to render services 5280: (1500 -3341) = 450 services per year. The safety factor at the end of 2017 will be ((9900-7849): 9900)*100% = 20.72% consequently, the company "Alfa" will have a significant profit.

The profitability index (PI) was 1.57

PI = 150000:950000=1,57

The index of profitableness exceeds one.

Thus, on the one hand, we can say that the project under analysis for the enterprise is profitable. On the other hand, we must take into account the risks, since without taking them into account; the enterprise can expect a negative outcome.

We accept the profitability index of this project, since it is above unity. According to calculations, net income in 2017 will amount to 1256 thousand rubles and will reach in 2019 1,584 thousand rubles (Table 5).

Table 5: financial result of the project at the «Alfa» plant for 2017-2019

№	Indicators	2017 year	2018 year	2019 year
1.	Revenue from sales without value added tax, thousand rubles.	10000	11000	12000
2.	Cost of services, thousand rubles.	7500	8250	9000
3.	Gross profit from sales, thousand rubles.	2500	2750	3000
4.	Expenses related to core business, thousand rubles.	950	1000	1050
5.	Profit (loss) from sales, thousand rubles.	1550	1750	1950
6	Other income, thousand rubles.	100	110	120
7	Other expenses, thousand rubles.	80	85	90
8	Balance sheet profit, thousand rubles.	1570	1775	1980
9	Profit tax, thousand rubles.	314	355	396
10	Net profit, thousand rubles.	1256	1420	1584

In 2019 the company "Alfa" plans to increase the volume of services (Table 6).

Table 6: calculation of cash flow, thousand rubles

Indicators	The value of the indicator by years of project implementation		
	2017 year	2018 year	2019 year
1. Operating activities			
1.1. Revenue from sales without value added tax, thousand rubles.	10000	11000	12000
1.2. Expenses for rendering services	8450	9250	10050
1.3. Profit before tax	1570	1775	1980
1.4. Taxes and fees	314	355	396
1.5. Projected net profit	1256	1420	1584
2. Equity	950	–	–

Thus, a simple payback period is 3.5 months, the discounted payback period is 1 year and 11 months; The net present value of the project is 2,548 rubles; The internal rate of return of the project is 39%; Index of profitability - 1,20; Break-even point in monetary terms is equal to 3617 thousand rubles. Based on the calculated data, it is possible to give a positive assessment to the developed investment project.

Investing in this project, having the most favorable calculations, we should not forget that until the time of obtaining the required revenue from its implementation, there remains a risk that must be taken into account. For this purpose, in our opinion, it is necessary to open an off-balance sheet 040 "Risks". In the debit of the account, the actual risk is supposed to be reflected, in the credit of the account - income received to reduce the actual risk. The difference between the assessment of actual risk and income received is a "recognized" risk at the balance sheet date. The basis for the

maintenance of this account is the proposed primary document "The card of the off-balance sheet investment risk" (Fig. 1).

Type of risk *Investment risk*
Risk assessment:__*917520*_____ date:____*02.02.2017*_____
Accounting account _ Debit account 040, *Actual risk 917520*

Index	Date	Base	Amount, rubles
Proceeds from the project	*25.02.2017*	*Agreement No. 324 of February 23, 2017*	*122100*
…..			
Account credit 040:			*122100*

Recognized risk:*795420 руб. (917520-122100) date:__25.02.2017*_____
Recognized risk:_____ *date:*_____

Fig. 1 : The off-balance sheet of investment risk

The card is a cumulative register that allows you to obtain operational information about investment risks at the balance sheet date for risk managers. The card indicates the type of risk, the reason for the occurrence, the full assessment and the amount of recognized risk for the formation of the reserve. Practical significance is that the accountant takes timely and documented risk and creates a reserve to maintain the company's stable financial position. As a rule, risk is considered from two positions: probability of an event, or through its consequence, namely damage. If we estimate profit as an effect of the subject, then in the model of its calculation, we must take into account the risks, namely:

$$Pks = C\ Ke \sum_{i=1}^{i=n} - f\ x - F + Dr - Rr$$

Pks – profit of a commercial entity (net of tax) in conditions of uncertainty and risks.
C – Unit price
Ke – Number of units sold
f – Price per unit of the j - th factor of production
x - Total number of j-th factor of production used in the production process
n – Number of factors of production
F – Fixed payments
Dr – Incomes connected with the consequence of risk
Rr – Expenses related to the consequence of risk

Obtaining the result determines the following set of costs:

- Expenses for the reproduction of fixed and circulating funds;
- Marketing costs;
- Costs incurred by the subject within the framework of the implemented decision in a risk environment.
-

The proposed methodology differs from the typical one in that profit is determined taking into account the risk.

Since today the economic risk is not an object of accounting, but is analyzed in the system of risk management, then its investigation is possible if it is ensured:

- Description of economic risks associated with the activities of the commercial organization;
- It is possible to calculate the impact of economic risks on accounting objects;
- Reflection in the accounting (financial) reporting of information on economic risks and their consequences;

- Availability of analytical accounting tools for the purpose of assessing economic risks (correlation-regression method, variance analysis).
-

This aspect is possible on the basis of the development of methodological provisions that would ensure the interaction of the risk management system and accounting based on the exchange of information on risks, the development of precisely the analytical functions of accounting. Risk management in case of recognition of the presence of risks, must take decisions related to their minimization. In this case, the accounting system should reflect this information about the risks.

Abstract

The relevance of the stated topic is conditioned by the need to manage the quality of the training of primary school teachers implementing inclusive education technologies in general education organizations. The purpose of the article is to determine the model for managing the training of pedagogical personnel for the implementation of inclusive education in primary school. Research methods for this problem are analysis and synthesis, comparison and generalization of the results of other studies, questionnaires of employers-leaders of general education organizations, allowing systematically and comprehensively study the quality process of training pedagogical personnel of the primary education system for work in conditions of inclusion. The article presents the results of the assessment of the quality of the pedagogical staff in primary school for the implementation of inclusive education, and the model of training is described. The materials of the article are of practical value for specialists of professional educational organizations engaged in the training of personnel for inclusive education.

Keywords: management of training of pedagogical personnel, model of management of teachers` training, vocational training, inclusive education, primary school teacher, children with disabilities.

Introduction

Training of teachers is one of the priority areas of vocational education in Russia. The "National doctrine of education of the Russian Federation" (2000) affirms the leading role of the teacher in achieving the goals of education, pays great attention to the training of pedagogical personnel, to the involvement talented professionals in the education system. At the state level, priorities are set for managing the training of teachers in accordance with the demands and needs of society. The current request of the society at the moment is the introduction of inclusive education in the educational activities of general education organizations. The Law on education of the Russian Federation (2012, p. 27 article 2) focuses on the implementation of inclusive education, that can provide equal access to education for all students regardless of diversity, special educational needs and individual capabilities. It should be borne in mind that inclusive education is realized, first of all, in the interests of persons with disabilities who need to develop a special educational route, which is determined by specific educational needs. In this regard, the country needs highly qualified pedagogical staff capable of implementing inclusive education.

With the enactment of the Federal state educational standard of primary General education (2013), the issues of the realization of the right to education for students with disabilities became widely discussed. Since

2016, inclusive education has been introduced throughout the primary school. For children of this category, adapted basic educational programs for primary general education are being developed. In this regard, the tasks of training teachers for the implementation of inclusive education in primary school are put on the forefront. For primary school teachers who have rich teaching experience, courses of improvement of qualification on the implementation of inclusive education. Universities that have implemented training in the specialty 44.03.01 – pedagogical education –introduce disciplines that help the preparation of future educators for inclusion in the variable part of the federal state educational standard.

Materials and Methods

T. A. Vlasova, B. S. Gershunsky, N. I. Konyukhov, N. N. Malofeev, M. S. Pevzner, B. T. Puzanov, I. A. Sikorsky, and others devoted their researches to the study of professional training of teachers for work with children with disabilities in different historical periods. Methodological issues of teachers` training for work in conditions of inclusive education, measures to increase personal and professional readiness for work in conditions of inclusive education are presented by works of G.V. Novikova and Ts. Boyko (2015). N.V. Ryabova and O.I. Karpunina (2016) consider the problems of staffing of the education system, the solution of which the authors see in the retraining and upgrading of the pedagogical staff providing the educational process, the psychological and pedagogical support of subjects of education and the socio-cultural integration of persons with disabilities into modern society. The problem of competence-oriented improvement of professional skill of specialists in the field of designing an inclusive educational environment is discussed in the works of G.N. Podchalamova and TA. Zubareva (2012). Modern trends in the professional training of specialists in the inclusive sphere are attracted by T.V. Timokhina (2016), who describes options for training specialists to work with children with disabilities on the basis of primary, secondary and higher professional education in the areas of training: adaptive physical education, correctional pedagogy in primary education, junior nurse for caring for patients , special pre-school education, special defectology education, etc.

One way or another, the works of the above authors deal with the structuring and systematization of training for the implementation of inclusive education in general education organizations, but there is no talk of managing this process. In our opinion, it is necessary to raise the issues of managing the training of pedagogical personnel for the implementation of inclusive education. For our part, we propose a model for managing the training of pedagogical personnel for the implementation of inclusive education in primary schools.

Results

The preparation of pedagogical staff for the implementation of inclusive education in the primary school in the Republic of Mari El is carried out both by professional educational organizations, as well as by the institutions of advanced training and retraining of educators. If we pay attention to the programs they implement, then each structure makes its own contribution to the training of pedagogical personnel. State budget professional educational institution of the of the Mari El Republic "Orshanskiy Multidisciplinary College named by I.K. Glushkov" specialty 44.02.01 – Pre-school education – realizes the program"Organization of corrective-developing work with children with speech development deficiencies ". The Federal Budgetary Educational Institution of Higher Education "Mari State University" prepares specialists for the bachelor's system in the directions of 44.03.03. Special (defectological) education (Logopedics), 44.03.03 Special (defectological) education (Pre-school defectology), 44.03.01 Pedagogical education (Primary education), 04/04/01 Special (defectological education) (psychological and pedagogical support of persons with disabilities). The Mari Institute of Education is engaged in the development of skills in the field of inclusive education under the program "Content of Corrective and Developing Work with Primary School Students in the Conditions of Introducing the Federal State Educational Standard". Within the retraining courses for pedagogical staff, the Federal Budget Educational Institution of Higher Education "Mari State University" at the Department of primary and

general education realizes the program "Logopedic technologies in the professional activity of the teacher of educational organizations, implementing the Federal state educational standard of primary education"

In order to analyze and systematize the training of the teaching staff of the Mari El Republic in the field of inclusive education, we have compiled a table (Table 1)

Table 1: System of training teachers for inclusive education in the Republic of Mari El.

Educational organization	**Level of training**	**Realized direction of preparation**	**Educational programs**
State budget professional educational institution of the of the Mari El Republic "Orshanskiy Multidisciplinary College named by I.K. Glushkov"	Specialty of secondary vocational education	44.02.01Pre-primary education	Curriculum Program "Organization of corrective-developing work with children with speech development deficiencies "
Federal Budget Educational Institution of Higher Education "Mari State University"	Bachelor's program	44.03.03. Special (defectological) education	The curriculum program "Speech therapy"
		44.03.03. Special (defectological) education	Curriculum Programs "Preschool Defectology"
		44.03.01 Pedagogical Education (Primary Education)	Fundamentals of special pedagogy and psychology; Logopedic work in primary school; Federal state educational standard for children with disabilities in conditions of inclusive education; Methods of correction of developmental disabilities and social adaptation of younger schoolchildren
	Master's Courses	44.04.01 Special (defectological education)	Curriculum "Psychological and pedagogical support of persons with disabilities"
	Professional Retraining Courses	Logopedic support of training for persons with disabilities	Curriculum Programs "Logopedic Support for the Education of Persons with

			Disabilities"
	Teacher training courses	Training of primary school teachers in the field of inclusive education	The curriculum "Logopedic technologies in the professional work of the teacher of educational organizations implementing the Federal State Educational Standard of Basic General Education"
The Mari Institute of Education	Teacher training courses	Training of primary school teachers in the field of inclusive education	Curriculum Programs "The content of correctional and developing work with primary school students in the conditions of the introduction of the federal state educational standard"

To determine the optimal model for training teachers for the implementation of inclusive education and assessing the quality of training, a focus group survey was conducted. For this purpose the questionnaire was composed, which was based on the requirements of the teacher's professional standard (2009), reflecting the specifics of work in elementary school. . Below is the text of the questionnaire on assessing the level of the teacher's readiness for the implementation of inclusive education in primary school.

Questionnaires assessing the level of the teacher's readiness to implement inclusive education in primary school.

(Instruction: "Dear colleagues, evaluate the quality of the work of primary school teachers who have been trained in programs for the implementation of inclusive education." Each indicator is scored on a 100-point scale. Please note that 75-100 points is a high level of readiness to implement educational and educational activity, 60-74 points, sufficient level of training, 36-59 points - average level of training, 0-35 points - low ").

In the organization of pedagogical activity the teacher of primary classes:
1. takes into account the peculiarity of the social situation of the development of the first-grader in connection with the transition of the leading activity from the game one to the educational one, purposefully forms the social position of the pupil in children.

2. Provides the development of the ability to learn (universal learning activities), to the level necessary for training in the main school

3. Uses special approaches to teaching, in order to include in the educational process all students: with special needs in education; gifted pupils, pupils for whom the Russian language is not native; students with disabilities

4. he Is able to build educational work taking into account the cultural differences of children, gender and age and individual characteristics

5. he is ready to accept different children, regardless of their real educational possibilities, peculiarities in their behavior, mental and physical health. He is able to provide them with professional help.

6. he is able in the course of observation to identify different problems of children associated with the peculiarities of their development.

7. Ready for interaction with other specialists within the framework of the psychological-medical-pedagogical consultation.

8. Can read the documentation of specialists (psychologists, defectologists, speech therapists).
9. he is able to make together with other specialists a program for the individual development of the child.

10. He has special methods that allow him to carry out correctional and developing work.

11.he is able to monitor the dynamics of the child's development.

12. Is able to protect those who are not accepted in the children's collective.

13. he is able to develop and implement individual development programs (including: adapted basic general education programs, special educational development programs), taking into account the personal and age characteristics of students.

14. he owns psychological and pedagogical technologies (inclusive) necessary for working with various students: gifted children, socially vulnerable children who have fallen into difficult life situations, migrant children, orphans, children with special educational needs (autistic, with a deficit syndrome attention and hyperactivity), children with disabilities, children with behavioral deviations, children with addiction.

15. understands the mechanisms of the formation of violations existing in the child, uses special means and methods of correction in the pedagogical process.

The survey involved 98 heads of educational organizations and deputy heads on educational work of primary school. They evaluated the quality of training of specialists who received training in programs for the implementation of inclusive education, in compliance with the indicators of the professional standard. Then the average score was calculated, which corresponded to the following levels of training quality: 75-100 points - high level of readiness for inclusive education, 60-74 points sufficient level of preparation, 36-59 points - average level of preparation, 0-35 points - low.

In the course of analyzing the results of the questionnaire, we obtained the following data:
- The high level of preparation for the implementation of inclusive education (75-91 points) was shown by graduates of the Bachelor's Degree in the direction of 44.03.01 Pedagogical education (primary education) passed professional retraining courses "Logopedic support for the education of persons with disabilities".

- High indicators were noted among the graduates of the training area on March 44, 2003. special (defectological) education, but, as was noted by the respondents, they have difficulties in constructing the learning process, that is, they lack the knowledge of teaching methods in primary school.

- Sufficient level of preparation for the implementation of inclusive education (74-65 points) was noted among teachers who received education in the direction of 44.03.01 Pedagogical education (primary education), who received additional knowledge of inclusion in the course of studying the subjects of the variable part of the bachelor's educational program (the basis of special pedagogy and psychology, logopedic work in primary school, the federal state educational standard for children with disabilities in

the context of inclusive education; a method of correcting the developmental disability and social adaptation of younger schoolchildren).

- Sufficient level of preparation for the implementation of inclusive education (72-68 points) was noted among primary school teachers who have experience and passed courses of continuing education for primary school teachers in the field of inclusive education.

When assessing teachers who have experience in primary school but who have not received instruction in inclusive education, the average level of readiness was noted about 48-52 points, which is acceptable for the implementation of inclusive education. But, as a rule, these specialists have difficulties in compiling adapted educational programs and individual development routes for a child with disabilities.

Thus, the level of readiness of primary school teachers to implement programs of inclusive education varies in the parameters from 91 to 48 points, which indicates the imbalance of the training system. The solution to this problem may be the opening at the university a new direction of training 44.03.05 - pedagogical education with two profiles: primary education; psychology and pedagogy of inclusive education. The model of training primary school teachers for the implementation of inclusive education can be structured as follows: basic training is conducted in the direction of 44.03.05 - pedagogical education in two profiles: primary education; psychology and pedagogy of inclusive education, for beginners and graduate students who have not been educated in the field of inclusion, retraining courses "Logopedic support for the education of persons with disabilities" may be organized, for primary school teachers with educational experience may be organized training courses in the field of inclusive education.

Table 2: The model for managing the training of pedagogical personnel for the implementation of inclusive education in primary school

The level of training	**Specificity of training**
Higher pedagogical education (bachelor's degree)	44.03.05 teacher education in two profiles: elementary education; psychology and pedagogy of inclusive education.
Professional retraining for specialists with pedagogical education and pedagogical training areas 44.03.01	Courses "Speech therapy support education of persons with disabilities"
Refresher courses for teachers who have educational and work experience	Courses under the program "the Content of correctional-developing work with pupils of initial classes in the conditions of introduction of Federal state educational standard"

Conclusion

Thus, the system of teachers` training for the implementation of inclusive education goes through the stages of its formation. The most successful training of pedagogical staff in the field of inclusive education in the primary school should be based on the integration of basic training with two profiles, professional retraining and advanced training courses for teachers with extensive experience. The management of the training of pedagogical personnel is able to streamline the existing experience and

build an organic practical-oriented model for improving the quality of inclusive education of primary school teachers.

Adaptive System of Mathematical Training of Students: Structure and Comparative Analysis

Vera I. Toktarova, Mari State University, Yoshkar-Ola, Russian Federation, toktarova@yandex.ru

Abstract

This article considers the issues connected with pedagogical design of mathematical training of students of the higher educational institutions. It gives the definition of the adaptive system of mathematical training of students and considers different methodological approaches to the interpretation of adaptation as cross-disciplinary characteristics. Conceptual and functional structure of educational system is presented. There is a comparative analysis of mathematical training of students in traditional and adaptive educational systems.

Keywords: mathematical training, adaptive system, adaptation, educational process, university, students.

Introduction

Rapid development of multi-level education, widespread introduction of electronic and mobile educational programmes and standards implies the availability and provision of a wide range of alternatives, among which the students can make a choice based on their own abilities and competencies, as well as needs of the labour market.

Personal orientation of mathematical training of HEI students contributes to the rethinking of didactic techniques used in higher school, especially in conditions of functioning of HEI electronic information and educational environment (Fedorova and Toktarova, 2016). The content of modern mathematical education shall be directed to the development of student's professional and personal skills; educational technologies shall be based on the mechanisms of adaptation to students' individual characteristics; the learning strategy shall take into account student's internal motivation and the targets of training and shall be based on non-linear technology.

Legal framework of adaptation mechanisms was reflected in the Federal Act On Education in the Russian Federation (The Law, 2012) where one of the main features of state policy and legal regulation of relations in educational sphere is the freedom to choose education according to aptitudes and needs of a person, creation of conditions for self-fulfillment of every individual, and independent development of his or her abilities, including the right to choose the form of getting education, forms of education, institution providing educational activities, and direction of education. At the same time, Federal State Educational Standards should provide the variability of educational programmes content of the appropriate level of education, the possibility of developing educational programmes of different difficulty levels and directions taking into account educational needs and abilities of students.

Adaptation as a Cross-Disciplinary Characteristic

A productive study of adaptation phenomenon is possible only at the interdisciplinary level, which will allow to use efficiently the principles of a variety of approaches as a theoretical and methodological basis for the design of an adaptive system of mathematical training of students in higher educational institutions:

– *social and philosophical approach* is the adoption by a student of social goals and a system of values, recognition of the importance of studying mathematics, development of mathematical literacy and his or her culture, and building-up of an intelligent professional capable of self-organization and self-training, being ready and adapting to the constant changes in society and looking for solutions to the challenges in the new environment through the development of diverse forms of thinking;

– *medical and biological approach* where a student is considered to be a developing system capable of self-organization by means of inner resources and relationships with the external environment. In this case, the resources are physical and mental health, which can help to avoid the effects of fatigue and overloading in the process of studying mathematics and other subjects;

– *technical and cybernetic approach* is reflected in a combination of conditions ensuring a wide application in the educational process of information and communication technologies and electronic information and educational environment, including the means of building individual learning paths, interactive support of problems solution, and provision of personal statistics of learning progress which allows controlling and correcting the level of knowledge, skills, and abilities of a student at any stage of mathematical training;

– *psychological and pedagogical approach* reflects the dependence of adaptation processes on individual characteristics and abilities of a person, offers opportunities to increase the efficiency of students to study at the univerrsity, ensures continuity in the continuous system 'school-university', adapting of a student to new technologies, tools and methods of learning, facilitates the acquisition of skills of individual work, organization of mathematical activities in the electronic information and educational environment providing the functions of adapting to individual features and abilities of students.

Adaptation is an inherent characteristic of an individual, which has a direct impact on the degree of his or her inclusion in social relations and, as a consequence, in the educational process. When considering a student as a subject of study, the adaptation characteristics defined by different subject areas should be taken into account: the most important condition for the successful adaptation is the optimal combination of adaptive and adapting activities which vary depending on specific situations. Taking into account the fact that learning is a purposeful process of interaction between a teacher and students, it can be assumed that the key condition of successful adaptive learning is the mutual adapting activities of a teacher and adaptive activities of students.

The Structure of the Adaptive System of Education

The adaptive model of mathematical training of students is based on the idea of prioritizing the development of the student. In the process of its design, scientific knowledge is primarily considered as a means of personal development and then as an object of study. The purpose of mathematical training is to develop and correct aptitude for learning as a cognitive capability; subject-subject relationships; personal characteristics of the subject of study (Toktarova, 2017).

At the same time *the adaptive system of mathematical training of HEI students* is an open dynamic system which:
– includes a set of interrelated components – subjects of education;
– is oriented to meet the professional, personal, and social needs of students in mathematics, skill, abilities, and competencies;
– is characterized by adapting to the specific conditions of the learning process, depending on students' individual characteristics and necessary criteria for perfecting and improving the quality of education.

From the point of view of management theory, the adaptive system of training is characterized by adapting to the specific conditions of the learning process, depending on particular necessary criteria for perfecting and improving the quality of education. In respect to school education T.I. Shamova, P.I. Tretyakov, and N.P. Kapustin (2002) define the adaptive system of training as a 'flexible system of arranging learning sessions taking into account individual characteristics of students. In the system under consideration, the relationship between the teachers and the students is fundamental, at the same time, the feedback is a backbone factor (Figure 1).

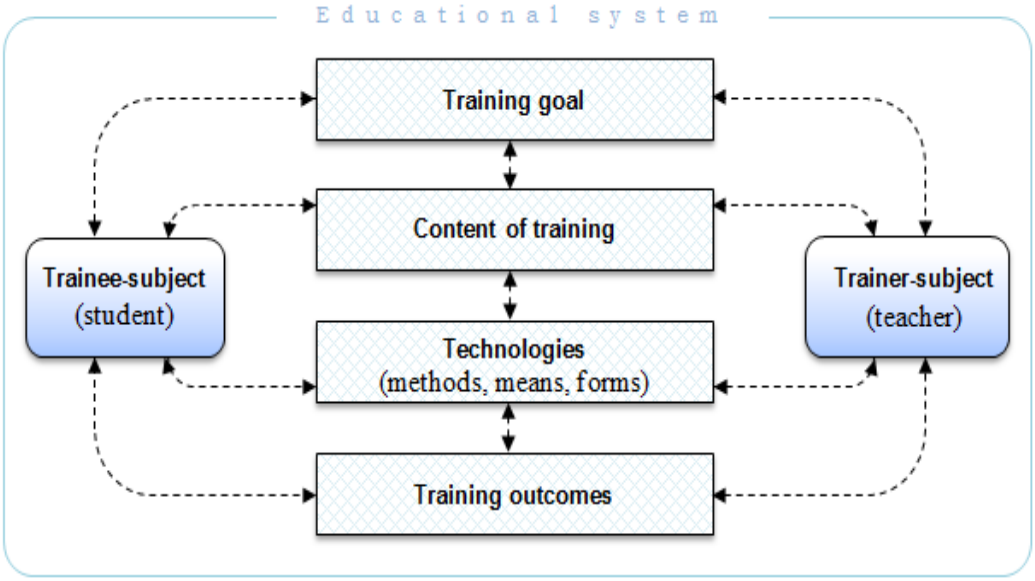

Figure 1: The structure of educational system.

When considering the functional components of a system, it is necessary to pay attention to the subsystem of technologies for training arrangement that play a special role in the process of providing adaptive learning. Each of the components of this subsystem has a high quality of adaptation depending on the intended objectives and training conditions.

Building of the mathematics teaching process for students in the adaptive system provides an opportunity to build mental activities of every student in accordance with their individual characteristics and preset requirements, which is achieved by clear definition of the purpose and stages of activity, methods and tools, content of education and educational technologies (Table 1).

Table 1: Comparative characteristic of mathematical training of students in different educational systems

Name of indicator	Traditional system of mathematical training of HEI students	Adaptive system of mathematical training of students
Purpose of training	Training of specialists with fundamental knowledge and competences in their profession / major	Training of specialists with fundamental knowledge and competences in their profession / major capable to develop and educate themselves
Orientation ('vector') of training	From the knowledge system to the object of training. Mathematical knowledge as an object of study.	From the subject of training to the content of knowledge and learning technologies. Mathematical knowledge as a tool for the development of a student's personality and as an object of study
Conditions of training	The educational process aims at creating similar conditions for all students	Students are subjects of the learning process, they determine an individual path in the process of training.
Principles of training	The learning process consists of interiorization of normative activities	Identification of personal learning style based on the diagnostics of a student's personal qualities
Taking into account the subjective experience of a student	The training process is primarily connected with an informational function independent of the subjective experience of the student	Diagnostics of the subjective experience and the prior foundation of knowledge determines the content of the student's mathematical training
Determination of the amount of knowledge	There is the same level of knowledge for all students and the relevant training material is selected	There is an adjusted amount of knowledge designed for each student based on his or her abilities, motives, opportunities, interests, etc.
Creation of a path for learning the training materials	The teacher consistently assignes the topics for the training material	The topics are consistent with the student's cognitive characteristics
Teacher's role (trainer)	There is a teacher's (trainer's) authoritarianism	Learning is seen as a process of development (self-development) of a student taking into account his or her abilities. The teacher acts as a tutor (assistant) most of all
The nature of an interaction of the participants in	A student as an object of study. Teacher's activities are aimed at regulating the student's activities	A student is an active subject of the learning process and is linked to the teacher by the joint activity

the learning process		
Orientation to training forms	Orientation to teamwork and frontal work	Orientation to individual work, independent exploration, and personal discoveries
Teaching methods	Reproductive teaching methods. The work is limited to 'coaching' of students to solve the tasks of one type, another type, etc.	Identification of student's learning style which serves as a basis for definition of the learning strategy, selection of appropriate teaching methods
Content of education	Invariant character of the content. The mathematics course predominantly provides for training and learning tasks; tasks for recognition and proof	Variability, flexibility of content within the standard. A student chooses the type of tasks to solve: training, learning, searching, problem-solving, creative; for recognition, construction, proof, research, conversion
Professional orientation of the mathematical content of education	Development of a system of mathematical knowledge for students to be used in further professional activities	Selection of mathematical tasks and study examples depending on the future career of the learner
Control	Strict system of supervision by the teacher	Application of various forms of control and self-monitoring, including continuous pedagogical monitoring

Thus, today, the strategic direction to improve the quality of the mathematical training of HEI students is defined by us as a conversion of the learning process into an adaptive system in which student's personality is at the centre of constant attention, is a backbone factor of training, is aimed at all-round development, and training activities are characterized by cognitive and developing skills.

The Value of Library Services Depending On Individual Determinants

Simona Pichová and Denisa Chlebounová
University of Pardubice, Faculty of Economics and Administration, Pardubice, Czech Republic
simona.pichova@upce.cz, denisa.chlebounova@upce.cz

Abstract

Importance of libraries is indispensable in the educational society, both with regard to the availability of public services and information for society as a whole, but also as a cultural and educational way. The value of libraries can be expressed through elicitation approaches of willingness to accept compensation and willingness to pay, which will be presented based on the obtained primary data from research in the Czech Republic. The data will be further compared to individual indicators of education with regard to the quality of human capital. The work will be a correlation and regression analysis of the data from which it will be possible to draw conclusions as to whether and to what extent the library services affect the level of education in society.

Keywords: libraries, WTP values, WTA values, contingent valuation

Introduction

Libraries are an important part of each developed country's culture. In the Czech Republic, even before, the law was in force, which made the creation of a separate municipality conditional upon the establishment of a library in that municipality. Public libraries running municipalities and cities currently have more than five thousand units in the Czech Republic and have more than 64 million library units with the library. The borrowed books were more than 60 million in 2015, which in the same year corresponds to 5.69 borrowings per inhabitant (according to date from Czech Statistical Office, 2016). Visitors go to libraries primarily for the purpose of lending books, but today the library functions as cultural, educational and community centers. Libraries also fulfill the principle of equality as a function of their ability to access and use their services regardless of gender, age, nationality, political or religious affiliation, and thus prevent social exclusion (Directive IFLA/UNESCO, 1994). Their services, thanks to a large number of libraries, are easily accessible to everyone, enabling the dissemination of information and fostering the growth of education in society.

Consumption of library services is made possible by the system of public services provided and is therefore covered by public budgets. The cost of providing them can be directly determined from the individual budgets of regions, towns and municipalities. However, their benefits to society are not directly measurable and difficult to express (Stejskal et al., 2013). One option is a contingent valuation method that works with elicitation approaches to willingness to pay (WTP) and willingness to accept (WTA) compensation. In the Czech Republic, under the guidance of the Municipal Library of Prague, research was carried out on these issues in cooperation with the University of Pardubice and the Matěj Bel University in Banská Bystrica. Thanks to this project, which was funded by the Ministry of Culture of the Czech Republic in 2013-2016, primary data is available which has enabled further research.

Theoretical Background and Previous Research

The most important part of the analyses is the determination of the benefit value that the contingent valuation method deals with. The principle of CV consists in assigning the relevant values to individual goods and services by the consumer, because the consumer himself can best define the perceived value of

a good or service. In the case of public services where there is no market price for a service, it is an expression of individual consumer preferences, for example through willingness to pay for public service consumption. The second option is to determine the amount of money consumers would be willing to accept as a deterioration in the quality of life if the service was not provided to them and would compensate for them. This method should help answer the question whether the service should be a public service, ie to be financed from public sources, and to what extent public resources should be represented to finance the cost of producing this service if the conditions of the Pareto Efficiency are to be met (Hanemann, 1991). For financial evaluation of non-market benefits resulting from the activities of public libraries, it is appropriate to use this method.

Determining the subjective value of consumed goods is possible only by questionnaire survey or controlled interview. Obtaining these data is technically very demanding because individual consumers have to understand the questions posed enough and must be able to express the value of their consumption in relation to, for example, their retirement, the value of their time or the comparison of the cost of other goods. In practice, approaches based on the consumer's willingness to pay have proved to be useful in determining the value of consumed goods (Knetsch, Sinden, 1984; Luzar, Cosse, 1998; Horowitz, McConnell, 2002). The WTP approach addresses the value of services according to individual preferences and determines the value the consumer is willing to spend on obtaining the service. Elicitation techniques for WTP issues have undergone significant developments, but there are still no unified practices that would be mainstreamed. Elicitation always depends on the individual's individual preference, on the various current factors, and on the question of the payment mechanism offered. So the survey maker can negatively or positively influence WTP results (Mitchell, Carson, 2013). The WTA approach expresses the value of the service on the basis of willingness to accept the denial of service consumption. It is the minimum amount of money the consumer is willing to accept for denial of a particular service or for what value he / she is willing to accept with a certain negative phenomenon (pollution, misuse).

The beginnings of the appraisal of public service valuation procedures have taken place on cultural (public) services and can be linked to a research conducted in the USA (North Carolina) between 1999 and 2002. The research concerned and evaluated the experiences of Blue Ridge Parkway visitors many views and scenic corners). Here, CVs have also been used, as researchers have used WTP's approaches to rewarding the benefits the park brings to its visitors. A pioneering study on the analysis of the benefits of public libraries was carried out in 1999 in St. Louis Public Library (USA). In 2004, further breakthrough studies were carried out in the field of library valuation in London in the United Kingdom and the United States, namely in Florida (Aabø, 2007). The first study, which brought a high-quality and scientifically widely accepted methodology, was a study of the economic benefits and returns of public investment in public libraries in the state of Florida (USA). Research has provided data to donors who have found effectiveness in returning public investment, total consumer perceptions, and the social benefits of libraries. Further studies on contingent valuation of library services are shown in Table 1. It is also possible to determine the ratio between the WTP and WTA values.

Table 1: The ratios between WTA and WTP elicitation approaches according to selected studies

Authors	Country	WTA	WTP	WTA:WTP
Holt, 1999	USA	136 mil. USD	15 mil. USD	9,0 : 1,0
Pung et al., 2004	Great Britain	273 GBP	116 GBP	4,9 : 1,0
Aabø, 2004	Norway	2000 NOK	400 NOK	5,0 : 1,0
Sociores, 2013	Czech Republic	1797,61 CZK	595,72 CZK	3,0 : 1,0

Source: own processing according to Holt (1999), Pung et al. (2004), Aabø (2004), Sociores (2013)

The values show that the value of accepting the compensation for the library service is several times higher than the willingness to pay for the service. At the same time, it is necessary to draw attention to the fact that the resulting WTP values are the result of more detailed inquiries, as the surveys are more focused on this value, while the WTA remains slightly omitted, and its values are, as a rule, devoted to just one question.

Data and Methods

The data was obtained through a questionnaire survey in 2012 for users of the Municipal Library of Prague. In the framework of the questionnaire survey, 11 397 Municipal Library of Prague readers were contacted, of which 2 227 were respondents (return of 20 %). However, the incomplete answers appeared from the results, which were removed for the accuracy of the analysis. The data analysis file after reviewing and editing included 1 429 records. The value of the benefits of library services through the WTP and WTA approaches will be further analyzed.

Subsequent data processing will be performed by statistical methods: correlation and regression analysis. The correlation analysis is used to determine the extent to which the individual properties interact. The Spearman's correlation coefficient will be performed in the article (Kubanová, 2008):

$$R_S = 1 - \frac{6}{\mathrm{n}\,.\,(n^2-1)} \sum_{i=1}^{n} (R_i - Q_i)^2$$

Regression analysis is used to describe the dependence of two or more numerical variables. It is a mathematical model that is expressed by a regression function. In the paper, a multiple linear regression model will be constructed in which the number of selected independent variables is expanded and the problem of how the values of the random variable Y depend on the independent variables xi, i = 1, 2,.. k. The multiple regression model has the form (Kubanová, 2008):

$Y_i = \beta_0 + \beta_1\ \beta_{i1} + \beta_2\ \beta_{i2} + \cdots + \beta_k\ \beta_{ik} + \varepsilon_i.$

Hypothesis and Data Analysis

The values that respondents attribute to library services in terms of (a) how much they are willing to pay (WTP) or (b) what amounts they are willing to accept for compensation if they are not able to use the service (WTA) are considerably subjective. The aim of the hypothesis is to demonstrate whether there is a correlation between the individual variables and WTP and WTA values. Thus, whether and to what extent variables have an effect on the value (a) of the willingness to pay and (b) the willingness to accept compensation for the library services for the consumer.

H1: The perceived value of the consumer of a library service depends on:

H1a: age of the consumer (age),

H1b: gender of the consumer (gender),

H1c: education of the consumer (education).

H1d: value of money saved by the library user (saved),

H1e: number of books borrowed per month (number of books),

H1f: net monthly household income (income),

H1g: frequency of library visits (frequency).

Within the established hypothesis, a correlation analysis (Spearman's correlation coefficient) was performed, the results of which are shown in Table 2. The correlation coefficient may take values within the interval <-1; 1>, with the value 0 indicating that the relationship between the variables is not, and the closer the resulting value is closer to the value 1, there is a greater dependence between the variables under consideration. The correlation coefficient was determined for confidence intervals of 99 %, 95 % and 90 %.

Table 2: Impact of selected variables on WTA and WTP

Determinants	**WTA**	**WTP**
Age	- 0,191***	- 0,002
Gender	- 0,005	0,035
Education	0,004	0,089***
Saved	0,040	0,080***
Number of books	0,027	0,119***
Income	0,099***	0,181***
Frequency	0,080***	0,091***

*Note: statistically significant values that are significant: *** at a confidence interval of 99 %; ** at a confidence interval of 95 %, * at a confidence interval of 90 %.*

Source: own processing

From the resulting correlation coefficients, it can be seen that WTP has a larger number of indicators than WTA. Statistically significant for the WTA value are the variable household income and library attendance frequency. Determining the WTP value affects both the amount of money saved and the number of books borrowed by respondents per month, as well as the household income and the frequency of library visits. Statistical dependence has been confirmed for some variables. The correlation coefficient is low and it can be assumed that these variables have little effect on WTA and WTP. The dependency of variables will be verified by regression analysis.

Regression models will be input to variables that have been flagged as statistically significant in the previous analysis, with WTA and WTP being tracked separately. For analysis, a multiple linear regression model will be used, which will be processed in Statistics, ver. 10. The resulting value of the determinant coefficient for the following statistically significant indicators is as follows:

- determination coefficient for WTA: 0,021156;

- determination coefficient for WTP: 0,0562322.

The results conclude that these variables, which are statistically significant, explain the model only from a small percentage. In the case of WTA, the model of the variables is influenced by only 2 %, and in the case of WTP access, the value is affected by statistically significant variables only from 5.6 %. There is a relationship that the more explanatory variables, the stronger the dependence of the variables, there is also the reason why the value of the coefficient of determination is higher for WTP (5 statistically significant indicators) than for the WTA (3 statistically significant indicators).

Conclusion

The correlation analysis showed statistically significant influence of variables on both WTA and WTP values. Further data exploration was done using a regression analysis, however, which found very little influence of these variables on WTA and WTP values. The variables examined do not significantly affect the value of WTA and WTP. The analysis also found that significant variables from the correlation analysis to the WTP value are based on positive values and hence there is a dependence: with the one variable growing, the other variable also increases. When income such as income, number of borrowed books, level of education, amount of money saved, and frequency of library visits increase, then the willingness of people to pay higher amounts for library services increases. The positive values of the correlation coefficient for the variable income and the frequency of the library visits are based on WTA values. If people have a higher income or are going to the library more often, then they would require a higher amount of compensation for not using the reader's card. At the same time, the variable age was found to be the only negative value of the correlation coefficient for WTA. If there are younger people, they require higher compensation for the library (the necessary literature for study, lower incomes during studies) may be justified. The analysis revealed that the variables examined, which originate from and affects the immediate surroundings of respondents, do not affect the expression of value for library services.

Discussion

The analysis has shown that individual variables that act on the immediate surroundings of the individual do not affect respondents in determining WTP and WTA value for library services. Due to the lack of dependency between variables, the WTP and WTA can only explain manipulative techniques in a questionnaire survey, which is, however, excluded by the Sociores Professional Proquest, as well as a verification pilot study. The analysis has shown that the surrounding influences do not affect the determination of the value of WTP and WTA, the effect of the subjective component of each individual

on particular values will be crucial. In order to find out, it is necessary to question the respondents in the form of questionnaire surveys. The research also brings new questions and suggestions that can be deal with in future research on the subject.

Work Reform in Indonesia: An agenda for greater efficiency

Laurencia S. Krismadewi, University of Economics, Prague, Czech Republic,
krismadewi.laurencia@gmail.com

Abstract

Purpose: The aim of the present work is to study the effects of labour market, in a study of a concept of flexibility in referring to the firm's ability to institute some changes and read environmental changes socioeconomic through on-labour markets. The background of the study identifies some highlights, i.e. the determination of mobility of labour, migration, wage, improve the ability of labour, barriers to entry and exit, and flexible working. It is shown that labour market flexibility may not produce unidirectional effects on productivity and employment. **Design/methodology/approach:** We relied on a variety of methods to obtain understanding through the sources that we encountered from qualitative of practitioners in top management and quantitative data of 100 employees in Indonesia. The prevalent complementary data sources included organizational records and journals. **Findings:** This study generally found that the flexibility and outsourcing weighed the positive and significant effect on the labour market. We combine labour market flexibility and outsourcing when the labour market is set by prompting national governments to implement a variety of programs that would make labour markets flexible. **Originality/value:** The paper fulfils an identified utility to study critically discusses the implications of labour flexibility on the international management of human resources.

Keywords:flexibility,labour,outsourcing,efficiency.

Introduction

International competition more over the speed of technological change increase has been an increasing demand for greater labour flexibility (Vincente-Lorente & Suarez-Gonzalez 2007). The intense competition has been a reinforcing stimulus of non-standard forms of employment such as outsourcing, temporary, part-time or informal employment. Consequently, appearing the assumption that these labour market flexibilities giving alternative for the rising unemployment (Flau and Mittelstadt, 2010).

Indonesia boasts the largest economy in the Association of Southeast Asian Nations (ASEAN), and the 16th largest worldwide. As a growing country which is the most populous country inhabitants are second in the world, Indonesia provides a rich context for research with a great opportunity for researchers to experiment and to test theories, models, and ideas. Therefore, the strong point of Indonesia that explain about the foreign investments with increasing of the recent macroeconomic growth, the diverse natural resources, young, large and burgeoning population, political stability (relative), prudent fiscal management, strategic location in relation to the giant economies of China and India, low labour costs.

In the point of view of population growth about two million population of Indonesia available to work yearly, that becoming a very big challenge for the Government of Indonesia in stimulating the creation of new jobs in the various sectors. The unemployment reduction movement is a concept of flexible labour markets such as outsourcing and contract workers in Indonesia moreover outsourcing has become prevalent in all areas of industries. As job creation efforts, the Indonesian government to implement Unemployment Reduction Movement (GPP). The development program is to create employment opportunities more widely in the program such as the program of job training and productivity. The expectation of these programs is to improve

the competitiveness and competence of human resources. Highlight for selected economies in ASEAN in table 1 presents the form of multiple structural dimensions of Indonesia economy that it shows the competitiveness trends that underline the evolution of the overall the performance which can be compared to its peers.

Note: Myanmar is not included in the GCI 2016 -2017 Report

Indonesia (41st) drops four places as it is overtaken by a few countries. Despite many reforms to its business environment, its performance remains one of the contrasts: the country ranks 10th for market size, 30th in the macroeconomic environment pillar—in spite of the protracted commodity bust—and 31st for innovation. It performs well in terms of financial development (42nd, up seven). Nevertheless, Indonesia ranks a low 100th in the health and basic education pillar (down 20), and 108th in the labour market efficiency (World Economic Forum, 2017). The three most problematic factors in Indonesia linked to labour inadequately educated workforce, poor work ethic in the national labour force, and policy instability. These all present current data derive the indicators of the competitiveness trends in Indonesia economy along with the obstacles that will face in competitive market. Especially in a global market which is growing quickly as today, about countries need a flexible labour market to encourage the economy (Rajeev, 2009). However, to a greater extent flexible labour market need to ensure that the ongoing structural transformation process practises the creation of quality jobs. The greater labour flexibility will increase the ability of a nation to allocate its resources efficiently and improve purpose of the technology for the economic development of that nation. Therefore, to increase the labour market flexibility through innovation revamping that refers to employment issues such as staff wages, the ease of which companies can hire and fire employees, length of probation periods and power of unions. These flexible markets, which favour workers' rights can lead to lower unemployment and higher labour productivity. It will be important attention to Indonesia toward competitiveness challenges e.g. ASEAN Economic community has been open for the following 7 (seven) kinds of jobs are (1) Engineering Services, (2) Nursing Services, (3) Architecture, (4) Land Surveying, (5) Medical Practices, (6) Dental Practices, (7) Accountancy, (8) Tourism. These suggest faced serious challenges on labour markets in Indonesia that goods, services, including worker will flow from countries that have high efficiency and productivity into countries that have low efficiency and productivity. Unquestionably, what we intend to do in this paper subsist to analyse the functioning of the labour market flexibility. Accordingly, focus on labour market trends accordingly investigate how the flexibility of labour in Indonesia.

1. Literature Review

1.1. The concept of labour market flexibility

The reference of labour market flexibility namely the ability and willingness of labour to respond to changes in market conditions, including changes in the labour demand and the wage rate that connected with labour market regulations and institutions. Concerning how labour markets function adjust supply to demand in the central of supply-side of the macro-economy that acts as an essential aspect of labour market flexibility. The demand for labour adjusts constantly to changes in national income and the business cycle that will change as a result of large-scale and deep-seated changes to the structure of an economy that often brought about by changing technology or through globalisation. According to Eamets and Paas (2007), the extent of state institutions and trade unions in labour market regulation distinguish between the levels of labour flexibility in macro-level flexibility. The covers of institutional flexibility consist labour market regulations, labour policy, trade union activities and labour taxes. Meanwhile, in micro-level flexibility consist worker flows, job flows and working time flexibility (Messina, 2007). In essence, this refers to the firm's ability to institute some changes in its working patterns, including setting wages, hiring employees on contracts, firing them and changing the working hours (Conley 2008). A commonly held view is that labour market flexibility is an essential ingredient for progress for a long time as unequivocally good, helping address the wider problems of unemployment (Rowley 2013). Labour market flexibilities have created a knowledge-intensive economy where least of the workers obtain involved in knowledge-intensive work also benefit from high wages attached to those jobs (Schuler & Jackson 2005). Moreover, the types of labour market flexibility have as occupational flexibility is the ability of workers to move in different types of job, mostly related to available skills, reduces levels of structural unemployment; geographical flexibility is the ability of workers to receipts advantage of job availability in different areas, depending on quality of transport as well as housing market, reduces regional disparities, increases productive efficiency; wage flexibility is the ability of firms to adjust wages in response to changes in supply and demand, restricted by trade union power including another collective bargaining, commonly a key side to keeping unemployment down in extreme recession; contractual flexibility that happened in varied industries, workers inhabit now offered jobs in six or three months or constantly on month-to-month contracts, makes firms further willing to take on new workers – easily discarded if they don't work out. Related to issues of labour market flexibility, there are factors that affect labour market flexibility (Howell,2011:189):

- Remuneration

Wages that is a key element of labour market flexibility to adjust to bring about equilibrium between demand also supply, including relative wage flexibility which relates to the adjustment of wage rates between sectors of an economy, or between regions, however, real wage flexibility will adjust to economic shocks.The determination of wage levels national does not reflect local conditions including labour not conform to changes in the condition local who created inflexibility wages relatively. Including for incentives or the generous unemployment benefits may reduce labour market flexibility.

- Skills and training subsidies can improve labour mobility. Multi-skilled workers may be able to adjust their working patterns or workloads to suit changing demand conditions.
- Proportion amount of part-time or temporary work. The labour market is more flexible when there is a larger proportion of part-time work relative to full-time work or temporary contracts. For flexibility work hour that firm has the ability to offer a flexible working environment as well as flexible working patterns.
- Hiring or firing. The firms will have greater freedom to hire workers when demand increases, conversely when firing, the demand for labour decreases. The excessive legislation to limit the ability of firms to hire or fire will reduce flexibility.

- Information. The better information about job vacancies, or to opportunities for promotion make workers can respond more effectively to changes in the requirements of firms.
- Mobility namely the willingness also able to move from one job to another, geographical mobility, be that as it may, industrial mobility that moving between industries. In case of geographical mobility, the extent of migration allowing or encouraging labour to migrate between countries that will increase the degree of labour market flexibility in the recipient country.
- Entry or exit barriers. The entry barriers such as the requirement for excessive qualifications (racial, gender, disability or age discrimination), or due to trade union restrictive practices, further exit barriers such as lengthy contracts or notice periods of labour will become less flexible.

Atkinson's model identifies four main flexibilities sought by companies:

- The functional ability describes the firm's ability to match the skills of employees with tasks by dismantling the traditional rigidities between different occupational groups through outsourcing and offshoring of services (Kalleberg, 2003).
- External numerical flexibility involves adjustment of the labour force from the external market and through relaxed hiring and firing regulations including temporary employment (Leighton, 2003).
- Internal numerical flexibility involves adjustment of schedules or working hours and comprises mainly of part-time jobs (Wilton 2013).
- Financial/wage flexibility involves the wage differences with the aim of ensuring that the employment cost reflects the supply and demand of labour mainly of individual performance wages, assessment based pay and rate-for- the job systems (Wilton 2013).

In Atkinson's model describes how companies respond to the increased need for flexibility. The highly skilled workers are core group with firm-specific capabilities that contains a unique resource. The first peripheral group have possessed skills which are not firm-specific and hence the firm may rely on the external market to fill such posts namely functional and numerical flexibility (Wilton 2013). The second peripheral group consist of workers under atypical forms of employment that providing both the temporal and numerical flexibility.

1.2. Measure of labour market flexibility

The OECD's Employment Protection Legislation ("EPL")[16] index measure the labour market flexibility which is available from the OECD (Organisation for Economic Cooperation and Development) and G20 countries. The index measures the procedures involved in hiring workers on either fixed-term or temporary contracts and the procedures and costs involved in dismissing individuals and groups of workers. Based on statutory laws, collective bargaining agreements, case law, contributions from OECD member countries, and experts' advice for each country. There three main areas in 21 basic items: (1) Individual dismissal of workers with regular contracts (category EPR) measures three aspects of dismissal protection: (i) procedural inconveniences of the dismissal process faced by employers, such as notification and consultation requirements; (ii) length of notice periods and conditions of severance pay; and (iii) difficulty of dismissal, such as the circumstances under which a dismissal possible, and repercussions for the employer if an unfair dismissal is discovered; (2) Additional costs for collective dismissals (category EPC) measures the extra costs faced by employers when they dismiss several workers simultaneously, over and above the costs applicable for individual dismissals; (3) Regulation of temporary contracts (category EPT) measures regulations for fixed-term and temporary work contracts in terms of job type and duration, requirements for such workers to receive equal pay and working conditions of permanent employees, and regulations for the setup and operations of work agencies.

1.3. Implication of outsourcing on labour market flexibility

Labour market flexibility seems to have had tremendous impacts on the business world. Whereas these atypical forms of unemployment may not be new, the tactics and strategies employed in some countries are. However, there remains a dilemma with regard to creating a flexible workforce. Neoliberal economists hold to the view that labour market flexibility plays an important role in economic progress and is key to overcoming the turbulent effects of economic instability (Wilton 2013).

Changes in the labour market have led to the rise and growth in demand for flexible labour arrangements, such as part-time jobs, temporary contracts, labour hires and outsourcing among many others. Outsourcing has become a popular way to reduce company costs and gain other competitive advantages. In an ever-changing environment characterized by expanding intense globalization, nonstandard work arrangements and intense competition, outsourcing human resource functions not only seems logical but also a necessity (Kock, Wallo, Nilsson, & Hoglund, 2012) (Cooke, Shen, & Mcbride, 2005) state that outsourcing is often associated with specialized services, suppliers created extent economics, flexibility of organization, risk move and learning from external professionals. Governments are thus under pressure to minimize the regulation of business practices in response to the changing nature of the labour market. But at the same time, they must strike a balance between economic responsiveness and employee protection (Pagano, 2005). This can be seen with the long battle over the rights for workers working under atypical forms of employment such as temporary contracts, a key characteristic of the labour market flexibility.

Flexi-work as a factor of labour market flexibility arrangements is seen to further widen the wage gap, that impact of labour market flexibilities on income inequality. The studies by Blanchard & Landlier (2002) and Giesecke & Gross (2004)7 have argued that there is no upward mobility for atypical forms of employment; studies by Gregg & Wadsworth (2010) have found these labour market flexibilities as widening income inequality. Flexible working arrangements, such as outsourcing involve contracting out services by the management, which implies engaging 'labour without obligation' (Hall 2013). In return, workers implicated in outsourcing tend to feel a little obligation. There is a host of other issues of concern associated with non-standard employment such as low pay, lack of promotion, lack of employer pension schemes and even lack of sick pay provision (McGovern et al 2004). The study has been observed by Kalleberg et al. (2003) in the US, indicating the potentially harmful effects of labour market flexibility on the labour market.

2. Overview of Labour Market Trend in Indonesia

In ASEAN's performance in a global context, Indonesia, Singapore, Malaysia, and the Philippines have more services-based workforces, Malaysia has the region's largest share of the workforce in the industry, while Vietnam and Thailand have a more agriculture-heavy labour market. Nearly 40% of the overall workforce in ASEAN is occupied in agriculture, an equal number (41%) is engaged in the services sector while 19% are involved in the industry. Across the region economic and developmental indicators have improved steadily over the past decade that will presented in labour market condition ASEAN (see table 2).

Table 2: Labour market conditions in ASEAN

Country	Level finding skilled employees (7=easiest, 1=hardest)	Average monthly wage (US$)	Workers in vulnerable employment (%)	Incidence of child labour (%)
Cambodia	3.4	121	64	18.3
Indonesia	4.3	174	36	6.9
Lao PDR	3.1	119	83	10.1
Malaysia	5.3	609	22	-
Myanmar	2.4	-	89	-
Philippines	4.4	206	42	11.1
Singapore	4.8	3547	9	-
Thailand	3.8	357	56	8.3
Vietnam	3.4	181	63	6.9

Source: Asian Development Bank, 2016.

Note: "Workers in vulnerable employment" refers to the number of unpaid family workers and informal sector "own-account workers" as a share of total employment.

Over the years the Indonesia's labour market has continued to expand with the number of employed growing while unemployment rate has been steadily declining. However, the declining unemployment rate masks the overall employment situation in the country. More than 50 percent of the workers are still engaged in informal employment. Labour Market Outlook of Indonesia reveals that in 2016, the Indonesian labour force had reached 127.6 million with an overall total unemployment rate of 5.5 percent or equal to 7 million people who are without work. Owing to its rapid growth, the services sector became the key source of employment, creating 14.2 million jobs in the last decade. The industry sector, with its modest performance, contributed only 7.1 million new jobs, including 4.4 million jobs in manufacturing. The agriculture sector lost 900,000 jobs in the last decade. Most new jobs were generated in urban areas. The majority of jobs created use short-term contracting arrangements or are in the informal sector. Employment quality is a major issue, and compliance with existing labour regulations is very low. Youth unemployment, skills shortages, and skills mismatches are also persistent challenges. Gains in labour productivity have been slow, and a multifaceted approach for accelerating labour productivity is required to support growth in higher value-added activities**.**

2.1. Employment Trends

The economic challenges confronting Indonesia at present remain modest compared to those facing many emerging economies and other commodity-exporting countries. Indonesian financial markets also appear to be in good shape compared to many other countries. The labour market situation is more problematic. Since mid-2014 there has been much media attention and political discussion about job losses in the manufacturing sector. There have been closures of a few high profile multinational enterprises and warnings about mounting pressures in export markets.

The official labour market data compiled by the Indonesian statistical office (Badan Pusat Statistik, BPS) would suggest that aggregate labour demand weakened somewhat. Over the year to February 2016 the aggregate employment level declined by roughly 200,000. Employment contracted in agriculture and manufacturing year-on-year, with shifts between urban and rural labour markets helping to moderate job losses. Employment levels in the service sector remained static. The unemployment rate remains moderate at 5.5 %, partly because of a decline in labour force participation. Indonesia's labour markets have been characterised by a considerable degree

of turbulence and structural change. Labour markets are extremely flexible in Indonesia. Most of the poor are "unskilled" workers in rural areas. These workers are helped by a development strategy that favours rapidly expanding demand for labour and allows labour to reap the maximum rewards the market will bear. Public sector employment, however, is not a viable tool to increase the long-term standard of living of workers. Following Harrod's definition of the natural growth rate, potential labour productivity growth is potential growth less the growth rate of the labour force. Because labour market data in many developing economies in Asia are unreliable, working-age population, which is the population aged 15–64, is used as a proxy for the labour force. These data are filtered using appropriate statistical techniques to purge short-term variability, which is caused largely by transitory migration flows. The competitiveness trend of labour market efficiency ASEAN countries' economies that described in two indicators i.e. flexibility and effect use talent (see Figure 1 and 2).

The regular employees tend to have shorter periods of job tenure than other workers. Job tenure for own account workers, employers assisted by temporary and unpaid workers, employers of permanent workers, and regular employees. The regular employees tend to have shorter job tenure than do other workers. In addition, youth, women and those with lower levels of educational attainment also tend to have shorter job tenure in comparison to the average. This would suggest that these groups are more likely to work on short-term contracts than on permanent contracts, due to segmentation in the labour market. Each year a large number of jobs are created and destroyed, with workers being hired or separating from their employer. Incentives for short-term contract, the scale of the informal economy, changes to labour market regulations, and dismissal regulations tend to influence worker reallocation rates.

Indonesia ranked number five in the attractiveness of its outsourced business potential behind India, China, Malaysia and Brazil. In Indonesia, outsourcing has only been implemented on a small scale, but it provides significant opportunities to secure work from overseas. The key is therefore for responsible bodies such as the relevant ambassador and chamber of commerce officials to seek out work that can be carried out in Indonesia such as within data input, information technology and administrative processes. The demand that outsourced workers' rights should be protected is fair and justified. It is true that the perception of outsourcing by many Indonesians is negative as the government has not been forthcoming in

implementing outsourcing regulations. The number of job opportunities compared to the amount of labour available is also limited which is coupled with a lack of qualified workers so the bargaining position of workers is weak.

In Indonesia, merely one in three of workers captured in the sample completed secondary schooling or any post-secondary education. In contrast, the Philippines workforce exhibits higher educational attainment: nearly three in five are secondary school graduates or have post-secondary schooling. Moreover, across the five countries, only in the Philippines does high-skill employment as a manager, professional or technician exceed 20 percent. In Indonesia, the share is only around 9 to 10 percent, among the three countries with available information on the job experience, workers in Indonesia, on average, tend to have more experience working with the same employer (see Table 3).

Unless otherwise indicated by a superscripted note, "value" refers to percentage rates for the corresponding age group. The following exceptions apply: 1 / Survey response on a 1–7 scale (1 = worst score, 7 = best score) - 2 / Data on a normalized 0.090 - to 1.000-scale (0.090 = best score, 1.000 = worst score) - 3 / Data from –2.33 (worst score) to 2.21 (best score)

2.2. Earnings and governance trends

The Indonesian labour market is generally open and flexible, although there are significant restrictions on the use of contract workers. Recent significant increases in the minimum wage for many provinces have

made unskilled and semi-skilled labour costlier. In the bellwether Jakarta area, following a 44 percent increase in 2012, the minimum wage was raised again from IDR 3.1 million (USD $229.6) in 2015 to IDR 3.3 million (USD $244.4) at the end of 2016. Under the new wage setting policy adopted as part of the October economic stimulus package, annual minimum wage increases will be indexed directly to inflation and GDP growth. Previously, minimum wage adjustments were subject to negotiations between local governments, industry, and unions, and the changes varied widely from year to year and from region to region. With the new sector-based calculation, in Jakarta, the new minimum wage in the electronics sector was 30 percent higher or IDR 4.0 million (USD $296.3), while in West Java, the minimum wage in the automotive sector was set at IDR 4.1 million (USD $303.7). In 2015, Indonesia's monthly average minimum wage stood at US$123, higher than its competitors in manufacturing countries such as Vietnam ($118), Bangladesh ($68) and India ($77). The new minimum wage policy, which calculates annual wage hikes based on the inflation rate and economic growth, guarantees that workers' wages will increase every year.

Another challenge facing the labour market in Indonesia is workers' productivity, which has been cited by businesses as one of the key determinants when selecting a location to invest in. Vietnam, Indonesia's main competitor attributed 38 percent of its GDP growth between 1990 and 2013 to labour productivity growth. Indonesia's competitiveness becomes even more questionable when productivity stagnates and the discrepancy between wage and skill levels widens over time. In January 2014, Indonesia launched a national insurance plan. In October 2011, the Indonesian government passed a revised Social Security Law, which took effect in January 2014, in which all formal sector workers must participate. Subject to a wage ceiling, employers' must contribute an amount equal to 4 percent of workers' salaries to this plan. In July 2015, Indonesia established the Social Security Organizing Body of Employment (BPJS-Employment), a national agency to support workers in the event of work accident, death, retirement, or old age.

Indonesia's large domestic market, growth prospects, natural resource endowment and abundance of low-cost labour makes it a potentially attractive foreign direct investment (FDI) destination (Hornberger, 2011). FDI has a positive effect on economic growth and employment, because it decreases the shortage of capital accumulation and increases the productivity. One of the most important factors attracting FDI in recent trend is qualification of labour, besides low wages or better wage differentials between investors and host country. FDI inflows have picked up substantially over the past few years in Indonesia (see Table 4).

Tab.4: Flow of FDI in Indonesia

Economic Sector	2012	2013	2014	2015	2016	Trend

2.3. Employment quality trends

Unemployment decreased slightly to 5.5 percent in October 2016. Unemployment tends to be higher than the national average among young people. Indonesian labour is relatively low-cost by world standards, but lack of adequate skills training and complicated labour laws combine to make an Indonesia's competitiveness lag behind other Asian competitors. Investors frequently cite high severance payments to dismissed employees, restrictions on outsourcing and contract workers, and limitations on expatriate workers as significant obstacles to new investment in Indonesia. In October 2015, the Ministry of Labour issued a revised regulation No.35/2015 on the Procedures of Hiring Foreign Workers to lighten requirements for companies to bring foreign employees. The new regulation eliminates the provision that required companies to hire 10 local staff for every foreign worker hired and dropped the requirement of work permits for foreigners who participate in seminars, speeches, workshops, board meetings, and training. The new regulation still prohibits local companies from hiring foreign employees as commissioners. Employers also note that the skill base provided by the education system is lower than that of neighbouring countries, and successive Labour Ministers have listed improved vocational training as a top priority.

The projected, as well as Indonesia's working-age population will increase steadily until 2030. To take full advantage of this demographic dividend, further investment is needed in education and training that will help the economy make the transition to activities that add more value. Longer term, changes are required to improve the quality and relevance of education and training, and to address skill shortages and mismatches in the labour market. Table 5 highlights that in 2010 half the population lived in urban areas, and with the increasing pace of urbanization it is expected that an additional 85 million people will be living in urban areas by 2035. This shift will have profound implications for the labour market. In particular, rural labour force participation tends to be higher than urban labour force participation, and urban unemployment tends to be higher than rural unemployment. If these trends continue, there is a risk of lower labour force participation and higher unemployment in the years to come.

Table 5: Population projections for urban and rural areas, 2010-2035

Variable	2010	2015	2020	2025	2030	2035
Number of people (millions)						
Urban	118.8	136.2	153.7	170.9	187.9	203.6
Rural	119.7	119.3	117.4	113.9	108.5	102.1
Total	238.5	255.5	271.1	284.8	296.4	305.7
Percentage of the population (%)						
Urban	50%	53%	57%	60%	63%	67%
Rural	50%	47%	43%	40%	37%	33%

Source: BPS Indonesia population projection, 2010-2035, Jakarta

Demographic shifts will also influence the labour market. The workers that are entering the labour market today are better educated and have greater capacity for adopting new technology than the average worker of today. However, the share of younger groups (aged 15-29) in the working age population is projected to decline from 40% to 34% between 2010 and 2035, entailing an increase in the mature age population (Jones, 2013). As the labour force matures, the demographic gains from a younger and better educated workforce will dissipate.

2.4. Competitiveness and business climate

One of the keys to economic development through structural change is the promotion of a competitive, innovative and dynamic. The challenges facing Indonesia are illustrated by global

competitiveness rankings (Figure 3) i.e. labour market efficiency, primary education outcomes, technological readiness, and infrastructure.

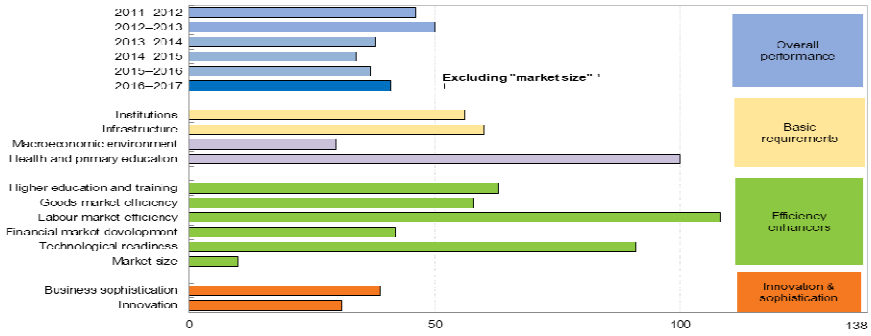

Fig.3. Indonesia's global competitiveness rankings, aggregate and subcomponents
Source: World Economic Forum, Global Competitiveness Report 2016-2017

3. Conceptual Framework, Methodology and Findings

3.1. Conceptual Framework

How do the perceptions about labour market flexibility can be influenced the economic growth in Indonesia? Two indicators in flexibility market, which are labour market, mechanism and innovation, are very important to make sure that the employees are allocated for the most effective utilization in a country's economy. A very simplified depiction of this conceptual framework is illustrated in Figure 4 below. Understanding how the functioning of the labour market flexibility in Indonesia.

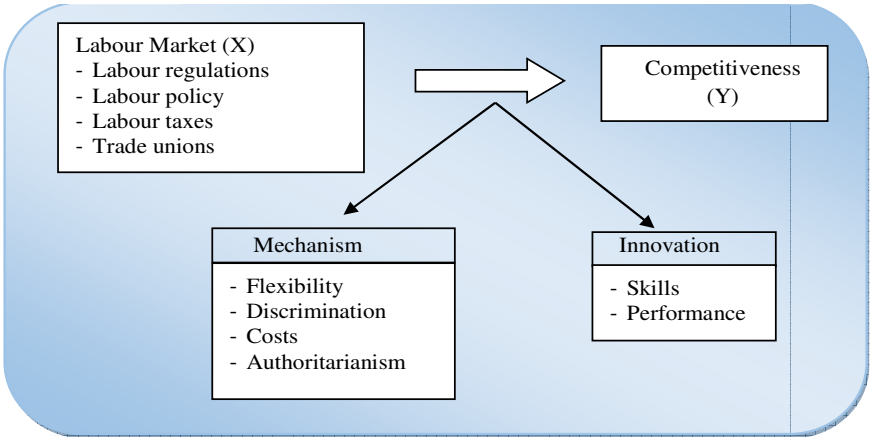

Fig. 4. Framework of report

The report pays particular attention to the function of the mechanism and innovative step that workers need to be equipped with to be employable and support firms' competitiveness and productivity.

3.2. Methodology and Findings

The evidence presented in this study is based on both quantitative and qualitative research methods. Qualitative and quantitative are an appropriate choice when seeking to gain a deeper understanding of an actual phenomenon from the involved participant's perspective (Yin, 2011). The samples of this study are workers in Indonesia through random sampling from the variety of industries. Data statement has been taken from the samples through questionnaires from the period January 2017 to

June 2017. Data analysis was performed using Statistical Packages of the Social Science (SPSS). Multiple regression analysis was utilized to determine the relationship between the independent variables and the dependent variable. It is based on variety of publicly collected data on labour market flexibility which are identified where appropriate in the text and table 6 and 7.

Table 6: Analysis of Multiple Linear Regressions

Independent Variable	Regression Coefficient	Beta	t-value	Sig
(Constant)	15.976		4.676	0.000
Flexibility	0.295	0.334	4.435	0.000
Innovation	0.251	0.314	4.297	0.000
R	0.447			
R Square	0.542			
F	31.82			
Sig F	0.000			

Source: Author calculations based on quantitative data.

Table 6 depicted that the number R obtained 0.447 and it explained the correlation between variables of flexibility and innovation affect on competitiveness is 0.447, that denoted a strong relationship. The value of R squared of 0.521 means contribution percentage of the flexibility and innovation affect on innovation amounted to 54.2%, whilst the remaining 45.8 % is influenced by other variables not included in this research model. The significant value of F with $\alpha = 5\%$ it can be concluded that flexibility and innovation simultaneously have a significant effect on competitiveness.

Tab. 7: Dimension correlation of labour market flexibility on innovation

Dimension	Indicators	Average of indicators	Average of dimensions	Average of variables
Mobility of labour	Willingness	4.33	4.39	4.12
	Ability	4.44		
Migration	Allowing	4.42	4.50	
	Encouraging	4.57		
Wage flexibility	Adjustment of wage rates	4.01	4.15	
	Real wage	4.28		
Rates of pay	Local	3.35	3.72	
	National	4.09		
Making work pay	Reward	4.64	4.58	
	Compensation	4.52		
Improve ability of labour	Skills	4.36	4.25	
	Training	4.13		
Barriers to entry and exit	Requirement	4.02	4.06	
	Agreement	4.10		
Ability to hire and fire	Freedom to hire	3.89	3.51	
	Freedom to fire	3.12		
Information	Vacancies	4.21	4.27	
	Promotion	4.32		
Flexible working	Environment	3.72	3.76	
	Patterns	3.80		
The amount of time	Part-time	4.13	3.12	
	Full-time	4.10		
Innovation relationship	Accumulation of skills	4.41	3.42	3.27
	Innovative performance	4.43		

Source: Author calculations based on quantitative data

Table 7 depicted that the average value of variable flexibility is 4.12, while the variable of innovation is 3.27. It indicates that flexible of labour market is good enough, while the innovation is still lacking. The average value of dimension of flexibility has lowest value is 3.12 by the amount time of time working. That indicates the labour market is more flexible when there is a larger proportion of part-time work relative to full-time work. Flexibility also improves when temporary contracts can be used. In dimension of flexibility that making work pay has the highest average is 4.58. For making work pay, if the reward gap between work and non-work is too small, there may be little incentive to work. Hence, excessively generous unemployment benefits may reduce labour market flexibility. The amount of tax paid from wages (the tax wedge) can also affect flexibility via its effect on incentives. In secondary data as a reference, a few econometric studies of the impact of minimum wages did not find a significant negative impact on minimum wages on overall employment. However, the upward adjustments of minimum wages were found to change the composition of employment. The rise in minimum wages adversely affected employment in smaller enterprises, but employment expanded in larger firms. The adverse employment impact was great for female, young and less educated workers, while the employment prospects of white-collar workers were enhanced by increases in minimum wages.

In the proposed qualitative, the use of unstructured in-depth interviews helped in gathering information during the data collection phase of the study. The unstructured interviews contained open-ended questions designed to provoke the disclosure of the relevant information necessary to answer the study's research questions. The qualitative analysis of the activities and implications of labour flexibility and talent utilization efficiency, including managers from various industries and department; and a review of a wide range of written material on the various intermediaries, including program documents, web-based descriptive material, and secondary descriptions of the organizations, and is presented in table 8 and 9.

Table 8: Primary and Sub-Themes Recorded from Practitioner Interviews

Primary themes	Sub-themes related to primary theme
reason to outsourced	The company focus on core activity that companies could do outsource for non-core work, e.g. production (packaging and helper), labour supply (office boy or catering).
Proportion	The proportion of females less than 30 percent that is distinguishing employees based on the type of work for outsourcing needs.
length of contract	The employment contract managed by the vendor that separated with the company. There are one-year contract and two-year contract.
recruitment	outsourced (contract) employee The contract is a company to company that every month company could request the vendors about how many employees that they need for a specific function or a certain position. The most important is the targets are achieved. For the labour supply employees like office boy, catering; the supervision is under the company, however, for the business outsourcing employees, the supervision is under the vendor. permanent employee The standard procedure in recruitment system, i.e. screening- interviews-medical check-up-offering post-salary-hire.

termination	outsourced (contract) employee the process is company to company if the contract end, the outsourced employee could change the vendors, therefore the employees are mostly same but need to move to new vendors permanent employee based on Law No. 13 of 2003 on the "Manpower Law" contains specific provisions on termination of employment the Employee can also give a voluntary written resignation to the Employer, for example, when the Employee wants to move to another company. The resignation process that is initiated by the Employee is not too complicated. The Employee will usually give a written resignation to the Employer 30 days prior to his/her resignation becoming effective. the entitlement of Employees who voluntarily (and properly) resign from employment to receive both service period recognition pays and compensation based on written or unwritten policies of the Manpower Department
incentives /bonus	outsourced (contract) employee the vendors decide to give the bonus to the outsourced employees, it is purely the profit of ndors that year permanent employee monthly incentive, mostly are received by sales people or merchandisers the company gives the bonus yearly; usually it is the combination between individual performance and business performance.
managing its employees	outsourced (contract) employee every month the company needs to adjust by order how to ensure the vendor will follow the company procedures and regulations, e.g. the audit and investigation of outsourced employees then company found that they were not paid based on the minimum wage permanent employee use work completion system in every area will input the data of the employees; how many days they worked, if they have an incentive or not, etc. Those would be the basis of the company copayment will have managed every month. the challenge is the generation that varies with the company; gen Y, gen X, and gen Z. the movement is very slow as high

	bureaucracy and quite centralized until the national office
demand of outsourced employees recruited into permanent employees	there is no demand – company avoided the same job for outsourced employees and permanent employees and have to divide work locations for outsourced employees and own employees
rules and information regarding the rights an obligation that obtain from the company	The company decided to choose company A, B, or C as the partner companies who provide the labour supply and made sure that they follow the Indonesian labour law on how they treat employees.
industrial relation	the outsourcing system regulations from the government is sometimes still in the "grey" area every 30 outsourced employees in one location, there must be one "coordinator" is owned by the company and they will report the working condition of outsourced employees to company that's responsible for these things and dealing with the company.
engagement	outsourced employee the outsourced employees as part of the company's engagement survey that focus more about productivity permanent employee the company has to make the right measurement and commitment to internal employees to make achievable standards

Source: Author's description based on qualitative data

Tab.10: Quantifying the 21 basis measures of employment protection strictness in Indonesia

A. Individual dismissals of workers with regular contracts

No	Items	Descriptions
1.	Notification procedures in the case of individual dismissal of a worker with a regular contract	The employer must negotiate with the worker or his/her trade union about an intended dismissal. If there is no agreement, the employer must receive permission to terminate the employment contract from the institution for the settlement of industrial relations disputes.
2.	Delay involved before notice can start	The employer and the worker or his/her trade union should attempt to resolve the dispute about termination within 30 days. If negotiations fail, one or both parties can file the dispute with the local manpower office, which will offer both parties the opportunity to settle the dispute through conciliation. If there is no agreement, the dispute is decided by the Industrial Relations Court, which should give a verdict within 50 days of the dispute being filed. If the first ruling is appealed to the Supreme Court, these delays are increased by another 60 days. Calculation (for EPL indicators): average of appealed and not appealed cases.
3.	Length of notice period at	There is no notice period as dismissal must be approved

	different tenure durations (a)	by the institution for the settlement of industrial relations disputes.
4.	Severance pay at different tenure durations (a)	Dismissed workers are entitled to severance pay equal to one month's wages for each completed year of service plus one additional month up to a maximum of nine months' pay and a reward-for-service payment equal to two months' pay for the first completed three years of service plus an additional one month's pay for each three completed years of service thereafter. In addition, the worker is entitled to compensation for housing, medical and hospitalization (which is deemed to be 15 percent of the severance pay and/or service pay to which the employee is entitled; cf. Art. 156(3) Manpower Act N. 13, 2003). However, this compensation is also paid in the case of resignation (and therefore it is not included in the calculation for EPL indicators - Art.162 Manpower Act N. 13, 2003) Calculation (for EPL indicators): 9 months: 1 month; 4 years: 5+2 months; 20 years: 9+7 months.
5.	Definition of unfair dismissal (b)	Fair: the worker has reached retirement age; grave wrongdoing by the workers (stealing, giving false information, drunkenness, indecency, gambling, violence, breaking the law, careless or intentional damage, leaking business secrets); violating provisions specified in the work agreement, the enterprise's rules and regulations or the enterprise's collective agreement (but dismissal can only take place in this case after giving three warnings each 6 months apart); in the event of a change in the status of the enterprise, merger, fusion or change in the ownership of the enterprise where workers are not willing to continue their employment; where the enterprise (or a division thereof) has to be closed down due to continual losses suffered for two continuous years (in this case ordinary severance pay is doubled) or force majeure; if the enterprise goes bankrupt; if the worker has been absent from work for at least five days without submitting a written reason to the employer and the employer has asked twice for a written reason. Unfair: absence from work due to illness, fulfilling obligations to the State, practicing religion, marriage, pregnancy or breastfeeding; union membership or carrying out union duties with the permission of the employer; reporting a crime by the employer; discrimination on the grounds of religion, political orientation, ethnicity, colour, race, sex, physical condition or marital status; disability due to an industrial illness or work accident.
6.	Length of trial period (c)	Maximum of three months. There is no trial period allowed for fixed-term contracts.
7.	Compensation following unfair dismissal (d)	The employer is obliged to pay all the wages and entitlements which the affected worker should have received.
8.	Reinstatement option for the	If the termination of employment takes place for reasons

	employee following unfair dismissal (b)	other than those allowed, it will be declared null and void and the employer shall be obliged to re-employ the affected worker.
9.	Maximum time period after dismissal up to which an unfair dismissal claim can be made (e)	Any worker whose employment is terminated without the decision of the institute for the settlement of industrial disputes and does not accept the termination can file a lawsuit to the institute for the settlement of industrial disputes within a one-year period after termination.

B. Temporary employment

No	Items	Descriptions
10.	Valid cases for use of standard fixed term contracts	A work agreement for a specified period of time can only be made for a certain job, which, because of the type and nature of the job, will finish in a specified period of time, that is: (a) Work to be performed and completed at one go or work which is temporary by nature; (b) Work whose completion is estimated at a period of time which is not too long and no longer than 3 years; (c) Seasonal work; or (d) Work that is related to a new product, a new [type of] activity or an additional product that is still in the experimental stage or tryout phase. A work agreement for a specified period of time cannot be made for jobs that are permanent by nature.
11.	Maximum number of successive standard FTCs (initial contract plus renewals and/or prolongations)	One extension possible.
12.	Maximum cumulated duration of successive standard FTCs	A work agreement for a specified period of time may be made for a period of no longer than two years and may only be extended once for another period that is not longer than 1 year.
13.	Types of work for which temporary work agency (TWA) employment is legal	In principle, temporary agency workers must not be used by employers to carry out their enterprises' main activities or activities that are directly related to production processes, except for auxiliary service activities or activities that are indirectly related to production processes. In practice, however, the limitation is so general that temporary agency workers are widely used in many different situations.
14.	Are there restrictions on the number of renewals and/or prolongations of TWA assignments? (f)	Temporary work agency workers are employed either on contracts of unlimited duration or fixed-term contracts. No limit for renewal of assignments.
15.	Maximum cumulated duration of TWA assignments (f)	Temporary work agency workers are employed either on contracts of unlimited duration or fixed-term contracts. No limit for assignments. But, in practice, long duration of subsequent fixed-term assignments increases the probability that contract workers successfully claim to become permanent employees of the user company.
16.	Does the set-up of a TWA require authorisation or reporting obligations?	Temporary work agencies shall take the form of a legal entity business with license from a government agency responsible for labour/ manpower affairs.
17.	Do regulations ensure equal	In principle yes but in practice this is rarely the case.

	treatment of regular workers and agency workers at the user firm?	Calculation (for EPL indicators): average of Yes and No.

C. Additional regulations for collective dismissals

No	Items	Descriptions
18.	Definition of collective dismissal (b)	There are no special regulations or additional costs for collective dismissals.
19.	Additional notification requirements in cases of collective dismissal (g)	There are no special regulations or additional costs for collective dismissals.
20.	Additional delays involved in cases of collective dismissal (h)	There are no special regulations or additional costs for collective dismissals.
21.	Other special costs to employers in case of collective dismissals (i)	There are no special regulations or additional costs for collective dismissals.

Source: OECD EPL Database

4. Conclusion

Labour market flexibility such as part-time jobs, temporary contract, outsourcing, labour hire and contracting out to have significant impacts on the labour market. Flexible labour arrangements, such as outsourcing, not simply a cost-cutting exercise, however, there is also an imperative need to strike a balance between economic responsiveness and employee protection (Autor, 2007). The device of strategies needs to take into consideration both the benefits of flexible arrangements and its implications on the labour market.

From the results of the study, there are three important points that are important and worthy of attention in labour market flexibility in Indonesia that is in need of innovation that is remuneration and conditions, information exchange, regulatory requirements for participation. A more flexible labour market needs to ensure that the ongoing structural transformation process does create quality jobs. The score from the Variable of Dependency on Professional Management Practice in Indonesia is also low, which means management in Indonesia has not professional yet. The scores for Indonesia's Capacity to retain or attract talented human resources are also low. Similarly, the female participation in the workforce is also still low. For current incentive systems in the labour market tend to discourage stable employment and career progression. There is the review from labour law provisions for short-term contracting, worker dismissal, severance payment and unemployment insurance in the light of the need to accelerate the skills formation and foster productivity gains. Over the long run, the role of government in the labour market is to formulate and enforce appropriate protective legislation, especially regarding worker safety, environmental protection, and prevention of abusive child labour practices and allow the labour union movement to develop in healthy and productive ways that allow labour to bargain on an equitable basis.

The studies of ILO having shown that there is a positive relationship between labour market policies and employment tenure that labour markets in Europe and Japan are quite stable, as indicated by the surprising resilience of long-term jobs, reflected in long average tenures and contributing to more productivity. Thus, the objective of the labour market policies and employment, should be to realize the right of every citizen to work or to (re-) integrate into the labour market, the right to a free choice of employment, as well as the right to decent conditions of work, and protection against unemployment and underemployment that will be the challenge for policymakers: To develop innovative policies that can better manage labour market changes from an economic and social point of view. The important point also

that labour market must have the flexibility to shift workers from one economic activity to other economic activity quickly and at low cost as well as to allow fluctuations in wages based on labour productivity without causing heavy social disruptions. Efficient labour market must also ensure strong and clear incentives for employees and promote meritocracy in workplaces. Together, these factors have positive effects on the employee's performance and the country's attractiveness to develop talents which are important elements in the growing labour market from time to time.

Abstract

The boom of technology and the emergence of the Internet had led quite quickly to the existence of an online environment where people are spending more and more of their time. Smart devices allow them to access websites and social networks from anywhere at any time as long there's an internet connection. The purpose of this research was to explore the contribution of social media platforms to improve the marketing operations in small businesses. Thus, this study presents some of the results of a questionnaire-based research conducted in the first part of 2017, aiming to reveal the perspective of managers from small companies on adopting and utilizing e-marketing tools towards small businesses promoting process through sales and advertising activities. From the multitude of social media platforms, few are preferred by the companies to strengthen their online presence. Also, the article describes the latest Facebook features used to promote a product or a service on the market, especially for small companies. These findings aim to constitute as baseline for further investigation through research theories and practices for digital marketing development. Finally, limitations and future research directions are discussed.

Keywords: e-marketing, social media, online business, small businesses

Introduction

The appearance of Web 2.0 platform moved people from a position of passive users to active participants, and Web 2.0 enabled them to interact with other users and other businesses. Soon, social networks also appeared. *Myspace* opened this road, followed by *Facebook*. Malerba (2010) found that social networking sites such as *Facebook, Twitter, LinkedIn*, and *YouTube* represent a huge opportunity for services firms because these are more dynamic in exploiting opportunities using knowledge intensively. Hang (2014) observed that for many companies these social networks opened new doors and offered the opportunity to promote products and services in a new world. Web cookies became another informational source in the digital marketing industry, allowing data gathering on behaviour and browsing habits of internet users.

In 2015, the number of online searches over a mobile device exceeded the volume of desktop users, conforming to Google's current information cited by Today's. If people get the same access to information by using smart mobile devices instead of a home pc, then they tend to utilize more these portable devices that can be carried anywhere. In 2016 was estimated that 20% to 35% of all commercial orders were placed online using a smart mobile device. However, selling is just one side of the desired outcome, with the return of customers on same platform or website being just as important. In some cases, such as real estate or health care projects, it is very important to establish a contact with a customer through the contact form. Between 15 to 25% of contacts are made through a mobile device.

There are considerable gaps in our common understanding of the digital marketing and its role in small businesses development. The existing research has focused primarily on social media as e-marketing and advertising support for small businesses. This interaction has received relatively little research attention, creating a gap regarding this subject in specialized literature. The purpose of this study is to

systematically investigate how digital interactive media stimulates managers from small businesses to improve the bottom-line performance in real life, given the theoretical positive relation between the two into small businesses operations.

This article is proposing an analysis of online promotion platforms - especially *Facebook*, as being the most widespread social networking and describing the steps a small company should follow to promote its business in the online environment. This environment is used by most people because it is facile and easy to use anytime, anywhere by anyone who has a smart device with a valid Internet connection. More and more small companies adapted their websites by changing resolution and structure to be correctly displayed onto mobile device used by customers to access them. The questionnaire proposed in this paper has the role to establish the preferred channels adopted by small companies to reach their goals which mainly consists in the business prosperity on all levels.

The current paper will first provide a theoretical background and a brief discussion of the subject investigated in this study. Next, we present the research method employed in this study, followed by the analysis result and main findings. Finally, managerial implications, limitations, future directions and conclusions are discussed.

Theoretical background

In a world where more than 170 million people regularly use social networks, the success of a business consists in creating brand awareness in the online environment and promoting it through digital marketing by keeping up-to-date with developments in this domain. Nowadays, there are numerous researches in the field of digital marketing with the desire to find innovative ways to bring higher turnover and brand stability to the existing online market. This can be done by targeting consumers and meeting their requirements so that they do not just feel like a number but a real person.

The authors of this paper, Carvalhosa et al (2017) present a platform that enables them to analyse and optimize the information received from a municipality. They say that an organization can evolve by using tools for e-Government and techniques created especially for the digital marketing to satisfy the current customers and attract new ones. The process of adopting an optimum method is not an easy one and it presumes certain steps.

Semenov and his team of researchers (2017) outline how should the marketing activity of an enterprise be analysed in the context of digital marketing communications by using an algorithm. Its role is to increase the performance of an enterprise on all its levels from an economic point of view.

Stephen and Andrew (2016) study the consumer's behaviour in fields like social media. They defined five key points like the level of digital culture of a person, his / her reactions to digital advertising, how does this virtual environment affects a consumer, the transfer of information through word of mouth and the mobile environments. There are presented some directions that can be followed to improve customer's experience fold to their necessities and personality.

Signori et. al. (2016) reveal the outcomes of a study on the role of digital marketing for brand awareness in the online environment by creating a social impact with positive notes for the company's image. This study is realized by taking into consideration the activity of different actors, the construction of the ecosystem and the exchanges made between them. The innovative part is given by the new perspective of digital marketing that is different from the traditional one and it is concentrated on the social impact of present technologies.

In the case of online presence, it is important that the site has a well-optimized landing page, as stated by visitors who do not access it from the desktop.

In another article, Mooney (2016) presents an application that brings together the balance of business, the technology that should be adopted and the insight of user's needs. Their opinion must be taken in consideration always to satisfy their requirements and to ensure their loyalty.

The online environment has begun to be used to promote a business all over the world. This trend is due to the increase number of Internet users at a global scale and the advantages offered by this environment, which are mainly represented by the low costs and higher flexibility compared to other offline media means. At the same time, another advantage is the ease with which a company may reach its target audience using social media promotion channel.

An advertiser must consider three major aspects that can turn into benefits according to Nita (2010). First, the user's desired action is easy to accomplish, from accessing a form or viewing the contact data when navigating. Redundancy is not useful. Then, when it comes to online stores, the need for an account to place an order is not the most appropriate feature on mobile devices, because the waiting time and the steps that follow should be as short or as few as possible. Finally, the information needs to be well structured and easy to navigate on a small screen - like the most used by mobile devices. Images that occupy significant space are avoided, as is a video player that loads heavy content. To increase readability of a text, there can be used "Read more" buttons or choose a shorter one. The most important thing is the concise information.

According to a Google analysis, searches made on mobile by Internet users will exceed those made on the computer in 2017. It is an important moment for entrepreneurs who choose to make their online marketing strategy and determine for which device should prepare their website to make it more efficient at the target audience. The figure 1 will illustrate the percentage of the user's smart devices growing number.

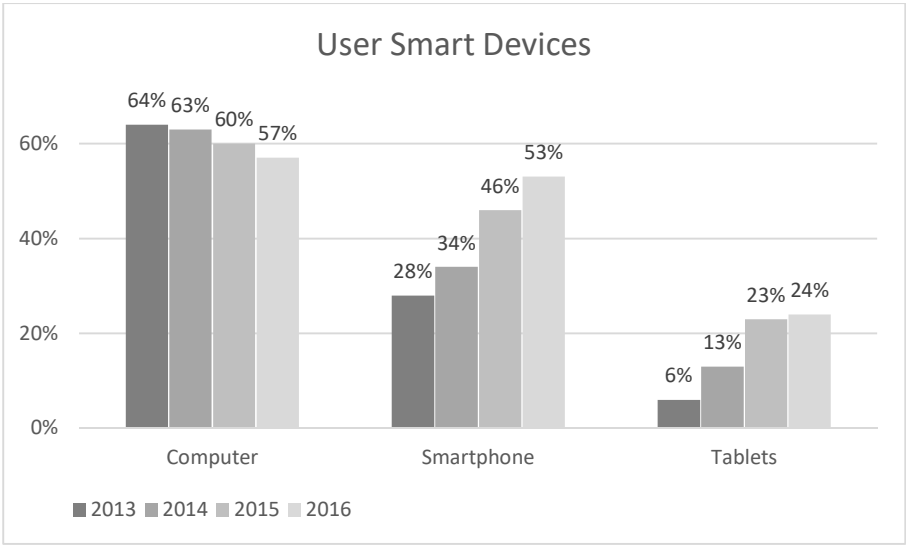

Fig.1 The increase usage of smart devices to access the Internet (source: adapted from L. Pârvu, newsletter, 13.10.2016, accessed 24 March 2017)

Facebook. This social network helps a company to interact with consumers by creating the opportunity to have a closer relationship with them. On Facebook, promotion campaigns can be run to engage consumers, and make a brand more and more valuable. Small markets can also be studied on Facebook. Consumers can be asked to indicate their sources of information for choosing the desired product. The promotion strategy can be adapted to their behaviour.

Twitter. This is another social network that helps to promote a business. Unlike Facebook, messages posted on Twitter must have other features. These should be as short as possible and may refer, among other things, to launching a new product, announcing the opening of a new store, announcing the winner of a competition organized by the company, announcement of winning a prize by the company at an advertising event, posting news related to the company's field of activity, posting links to direct fans to a clip in which a product or event organized by the company takes place, designing an exclusive campaign on this social network.

Blogs. Blogs are another important channel of promotion today. For example, a company operating on a certain market might be able to promote their products to blogs where products from the same area are being discussed. A company representative with a nickname may enter discussions with members of that community and try to direct their attention to the products of the company he represents. At the same time, those discussions remain posted on the blog and can be viewed by other people who are interested in buying that type of products. The major advantage of such discussions is that they show credibility to those who visualize them.

LinkedIn. Promoting on this network of professional profiles should not just be limited to creating employee profiles on LinkedIn, but also to enrol in professional groups related to the field in which the company operates. At the same time, employees must initiate and participate actively in the discussions that take place in those groups and try in a subtle way to promote the products or services offered by the company they represent.

Web directories and article directories. A method for better positioning your site in organic search results generated by Google's search engine is, among other things, enrolling in web directories and articles. Thus, a company's site will give credibility to Google's search engine, helping you in the long run to better rank in the organic results area.

Google AdWords. This program helps a company promote and sell the online store products they own. It is an effective way to get quick results by providing a competitive product offer, choosing relevant keywords for the company's products, and compiling persuasive ads that contain benefits and call-to-action messages. This will differentiate company's competitors and convince consumers to choose its products to the detriment of competitors. By using this program, a site may appear in the paid ad area on the right side of the Google search engine, on the first page of the results.

Regardless of size, the performance of an organization is directly related to the efficiency of its processes. Thus, the competitive advantage, as well as the strengthening of the market position, depends on the enterprise's effort regarding continuous improvement of business processes (Thakkar et al, 2008, Halley et al., 1997, Quayle, 2000). In this context, the use of digital technology generates major opportunities for SMEs facilitating product visibility and increasing attractiveness for new customers. Thus, according to the data collected by the National Institute of Statistics, SMEs in Romania often confront with problems in promotion process, due to lack of sufficient funds or lack of specialized personnel with specific knowledge of this domain.

Research methodology

To meet the research objectives, we developed a quantitative empirical study to investigate the impact of digital interactive media on the promoting process of small businesses. The methodology applied was a structured questionnaire and a procedure stratified sample with proportional allocation. The method used during the primary research is the survey and the tool – the questionnaire. We used a cross-sectional survey for data collection. A multi-item method was used to form the questionnaires.

Table 1: Composition of sample

Variable	Frequency	Percentage
Firm size (number of employees):		
Less than 9 employees	18	60
Between 9 and 20 employees	8	27
More than 20 employees	4	13
Firm age (number of years since foundation):		
Less than 3 years	16	53
Between 3 and 8 years	9	30
More than 8 years	5	17
Gender (respondents):		
Female	13	43
Male	17	57

The respondents of the pilot sample were 30 small companies from IT field. The authors intend to expand the research to other medium companies from all type of fields. The respondents were asked to indicate the extent to which they use the digital interactive media by social networking sites in promoting processes especially in small businesses. The respondents hold various job titles and have more than 2 years of experience with marketing activities. The response rate was 90 percent and resulted in 30 valid questionnaires (N=30). Among the valid respondents, 57 percent of the respondents were males and 43 percent of the respondents were women. Most of the small businesses have ranged from 1 to 15 years. The data were assessed for the extent of missing values. The missing values were completely at random and the means substitution method was used the replace them. The composition of the sample is presented in Table 1.

Analysis and results

As outlined in the present research, the top three social media channels that are preferred by small companies to be used for marketing promotion include Facebook - 79%, LinkedIn - 71% and Twitter - 60%. Detailed results are presented in Figure 2.

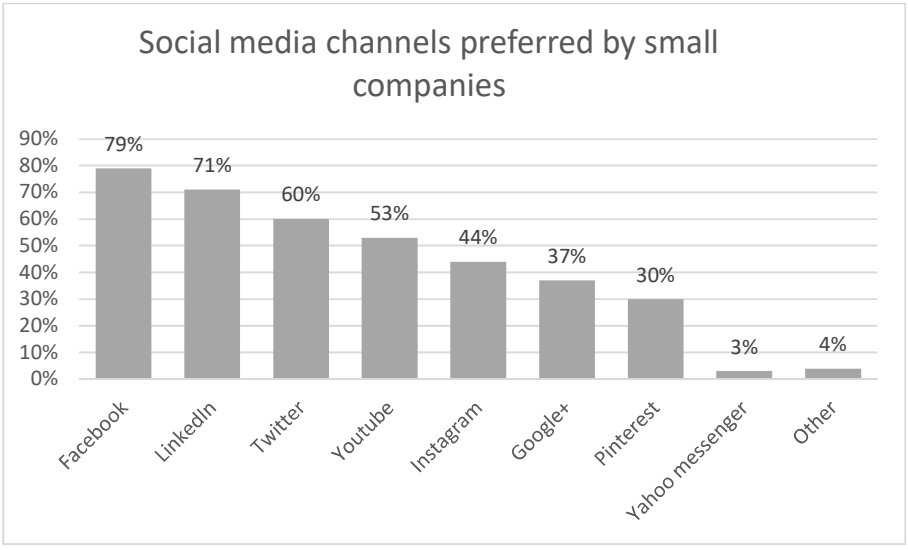

Fig. 2 Social media channels preferred by small business

The information disseminated by companies attribute in proportion of 82% to company's goods and services, 66% on general information about the company, and 58% about campaigns, promotions, direct or indirect sales. Job offers appear on social media to just 41% of companies

Whether of organic or paid usage, at some point a company will send users to their website and if it does not offer a great mobile experience, the company will lose them. In addition, images are slightly different on the mobile versus big screens of desktop computers, and a company should consider first the mobile users. Currently, there are two main ways to reach people on Facebook: *organic approach* - people simply see the posts on a page, and *promote* - pay for a particular post to be displayed to people. Although theoretically people can be reached and not pay (organic), this promotion method no longer works for 98% of business types. The 2% of businesses that can reach thousands or millions of people for free are those that have native viral content.

The key to effective Facebook use to promote business comes from customer understanding, how the platform works and testing the creative part. Facebook promotion can be displayed only to people who visited a certain site. Better yet, a company can show ads to people who have seen a certain page on the site. The outcomes of the questionnaire revealed that 83% of companies marketing departments concentrate their focus on building proper e-marketing campaigns and pages for their companies.

It is known that before a firm starts creating the campaign itself, it should define the target audience. Small businesses can use different tools to create the new audience, once the pixel is installed, can be done from Ad accounts and the All Tools section of the Audiences. Finding new customers can be done through the feature Lookalike Audience. More than 50% of companies queried by this research are using this option.

If a company has an e-commerce website for example, and it had collected hundreds or thousands of email addresses from customers so far, the department in charge of promoting the company can upload them to Facebook and Facebook will search for profiles associated with those email addresses. This way a greater number of people can be found, who resemble original customers in interests or behaviour. According to the present research a percentage of 64% of the questioned companies use this feature for the promoting process.

Similar to the way Lookalike Audience is created above, Facebook can be "asked" to find more people who resemble those who have seen specific pages on the company's site (service / goods page, for example). According to the study this is one of the best strategies deployed in the last year due to access to a large database. Facebook does a great job of identifying what they have in common with those who have bought from the company and thus can identify new potential customers.

Discussion and conclusions

Our exploratory study is a response to the demand for improvement in promoting process of small businesses and extends the stream of research to digital media. Small businesses must proactively develop their capabilities using IT to make their web presence more visible. Companies can use various systems to capture, store, analyse the data to extract value and generate market for their offerings. The findings confirm that digital media provide strong support for improving the business performance of small businesses.

One of the key insights provided by this study is how managers can use digital media in all stages of business process especially in promoting activities. Our findings indicate that some digital media contribute to faster time to market or faster to offering adoption on the market. Small businesses have been exploring the Internet for many years and, increasingly in last years, the social media for promotion. If, a few years ago, social networks, blogs, and microblogging services were jammed by marketing directors, largely because of the limited public and its lack of relevance for their business, the data now looks quite different.
Both the rank of the companies interested in advertising in this environment and the budgets spent on it has grown. The total amounts are no longer hundreds of millions of euros worldwide, as it was before

2008, but rather 4.26 billion euros this year, according to eMarketer Research Company, 70% above the level in 2010. Facebook is mainly responsible, however, for the impressive outlook and evolution of the market.

Digital mobility and connectivity are increasingly important in personal life, but also in business. Based on behaviours, we find that users carry over all mobile devices with them, check them frequently, and often use multiple mobile devices at the same time.

Digital media in business context for small companies is a key factor due to the increasing number of users who search a company on the internet and prefer to conduct their different actions and activities on the online environment by using a smart mobile device. Since business players are increasingly discovering the benefits for their own company through the use of digital marketing, this paper analyse the extent to which Romanian firms are moving in this direction and the proper tools for this target.

The main objective of the present paper consists in identifying the main channels preferred by small companies in Romania for online promotion. A future direction of this research is to extend beyond analysis of the current tools and gain actual insight of their perspective regarding the benefits of social media in performance improvement.

This study has several limitations, which can be addressed in future research. First, for each firm included in sample, a single respondent was the source of information. We suggest that the future research should use multiple sources of survey data. Second, our research is based on cross-sectional data. Furthermore, digital media tools adoption can be regarded as a dynamic process. Consequently, a longitudinal study may extend our research on mediating the effects of the relationship between digital media and promoting process. Thus, future research will be needed to investigate changes in patterns and factors. Digital media could have impact on the operating efficiency or quality provided by firms especially in service industry. We believe that this is a promising research area and our study offers an important first step in this direction.

Abstract

The purpose of this study is to analyse students' acceptance of Internet of Thing (IoT) in higher education. Student performance is important in the evaluation the education quality in higher education institutions, but there is little research to explore the role of IoT services on teaching and learning processes. Previous research has demonstrated that IoT technology can promote online collaborative and interactive learning. This study is a cross sectional survey and it focuses on Romania. In spite of these findings, relatively little work has been conducted on whether IoT technology influence the higher education systems and students' academic performance. Thus, we explore students' attitudes towards the use of IoT tools in their learning or social activities, what kind of IoT tools the students prefer and if there is a significant difference in attitudes of students who are employed and who are not. We have used the regression analysis to investigate the acceptance of this technology in learning and teaching processes. Empirical data were collected through a survey of 86 students from University Politehnica of Bucharest, Romania. We used this analysis to test the proposed hypotheses. The findings reveal that student's perceptions about IoT services highlight the fact that there is a lack of regulation and privacy concerns. The analysis results indicate that IoT technology has significant positive effect on student performance. The students' acceptance of IoT technology in higher education depends on perceived usefulness and perceived ease of use. The results of this study support previous research and provide additional information about IoT services. The study is a cross sectional survey and it focuses on Romania. However, the results may be common to other countries and universities. These findings require further investigation in future research on theories, and practices for academic leadership development. Finally, limitations and future research directions are discussed.

Keywords: Internet of Thing, higher education, learning, teaching.

Introduction

The Internet of Things (IoT) or the Internet of Everything (IoE) brings together students, faculty members, data, teaching and learning processes, and smart, connected devices to create new dynamic capabilities and value by collaboration, interactivity, and cooperation. Education is one of many other areas of our lives that the IoT will transfer such as energy, transportation, homes, cities, and healthcare. Universities must become more flexible, agile in order to attract the best and brightest students in highly competitive education market. Kowatsch and Maass (2012) maintain that IoT offers many possibilities for research, teaching and learning and it plays a disruptive role in higher education. This technology can reduce the operating costs of universities and improve the ability to analyse big data regarding students' requirements. Thus, this technology is a catalyst that helps students develops the skills needed to successes in the education market.

Wessel and Christensen (2012) said that the internet is an infrastructure which provides the terminals for end users, while the IoT provides the interconnection of smart objects. Many students hadn't heard of the IoT and this situation may be a barrier to adoption of this technology in higher education institutions. According to Andersson and Matsson (2015) IoT adoption and usage has been analysed from the industry's point of view and it has obtained a lot of attention in healthcare, transportation, smart cities smart home and so on. However, except for the some studies, little is known about how students and faculty members accept this technology in higher education. Lack of awareness is a barrier to adoption for IoT devices. Education is an important factor to improve this situation.

This study purpose is twofold. First, we aim to analyse the influence of IoT usage in higher education. A students' performance is impacted by study, social habits, their passions, and effectiveness of teaching and learning processes. For example, professor can grade tests online and collect data on their students to better adapt the courses according to their capabilities and preferences. And, second, we study the antecedents which have an impact on student's acceptance and usage in higher education. And their possible mediating role in IoT services usage. Thus, this paper will provide new insights into the influence of each variable in the use of IoT services in higher education.

Next follows a literature review and hypotheses development. Then a section of this paper is dedicated to test our research model and hypotheses on data collected form respondents. Next, we present our research methodology, which is followed by our empirical analysis results. The paper concludes with a discussion of our findings, the theoretical and practical contribution of our study, and future research directions.

Theoretical background and hypotheses

This paper analyses the decision to adopt IoT services in higher education context. So, we must review research into adoption model and how smartphone, tablet and their collection of applications need to meet students' needs. Education can be improved significantly through access to better education materials and resources. Students' preferences and needs must be understood accurately. Teaching is not separate from learning because it will affect the way in which students learn. Teachers need to have a realistic understanding of student's capacity to learn to improve and accelerate the learning process because students vary in the level of abstraction that they can handle study time more effectively.

Universities have different devices such as vending machine, refrigerators, lab equipment, lighting systems, heating systems that can be connected to internet. Smart devices create opportunities for interaction, collaboration among students and professors and they can reduce operating cost by increasing energy efficiency by attaching smart sensors to monitor electricity use in university. Kuo, Walker, Schroder, and Belland (2014) said that limited interaction may affect students' satisfaction without the utilization of appropriate technologies in fully online learning settings. This approach is a fundamental change in the way teachers and students interact and how they meet new learning experiences.

The Technology Acceptance Model (TAM) is based on the Theory of Reasoned Action (TRA) and the Theory of Planned Behaviour (TPB). According of this model, attitudes may affect behaviour intention, which in turn has a high influence on the students' acceptance of IoT applications. Davis (1989) appreciates that perceived usefulness of IoT applications has positively influenced the behavioural intention to use. Davis, Bagozzi and Warshaw (1989) have developed the technology adoption, presented in Figure 1. The original TAM model developed by Davis defines perceived usefulness as the prospective student's subjective probability that using IoT applications will improve his or her academic performance in higher education. Davis (1993) thinks that perceived usefulness is a major determinant of use behaviour and intention. Trevino and Webster (1992) tested that users are willing to adopt new

technology is an antecedent to perceived ease of use. Also, perceived ease of use has been found to influence behavioural intention to use indirectly through perceived usefulness.

Davis defined the perceived usefulness as being the degree to an individual believes that using the system will help him/her attain gain in job performance. He also explained the degree of ease associated with the use of the system. Attitude toward using is the individual's positive or negative feeling about performing the target behaviour. Various studies have demonstrated how usefulness is directly related to attitude, as well as the intention of use.

The Internet of Thing refers to the possibility of smart objects to connect to the internet and to send and receive data. Smart sensors can easily be attached to every object to send its data wirelessly or via electric lines to a network hub. Bagheri and Naghighi (2015) thinks that this technologies offers different value propositions such as access to learning resources customise curricula, lower costs, personalised learning, enhanced safety and collaboration. Wessel and Christensen (2012) said that personalized learning process to enable students to determine the pace at which they learn. Student can view and lecture video presentations of their courses or other materials form wherever they are.

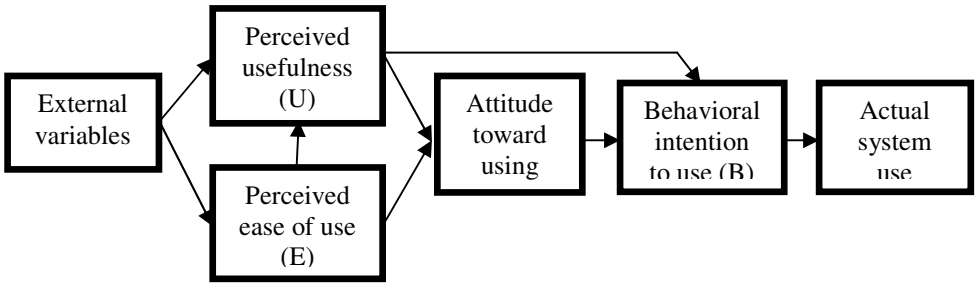

Fig.1. Technology acceptance model

The IoT hardware requires operating systems and communication protocols and the ability of smart connected objects to be identifiable, to communicate and to interact with each other or through a central control unit. Its architecture included different integration layers to combine and integrate information acquired from smart devices. A lot of students use laptops and mobile smart devices into their learning process. Advantage of mobile technology to meet students' needs by offering of tailored educational context. Wessel and Christensen (2012) said that predictive analytics can be used to attract most reputed and talented faculty members, eliminate errors through automated data acquisition or understand academic problems early and take corrective action. Our prediction is supported by previous research in which IoT based architectures can help students and explained how students become co-creators of knowledge, using the IoT services to capture more value of improved learning ecosystem. The technologies which universities use are increasingly cloud-based. These technologies make learning more engaging and relevant. As a result, we propose the following hypotheses:

Hypothesis 1*: Perceived usefulness will positively affect the intentions to use IoT applications in higher education*

Hypothesis 2*: Perceived ease of use will positively affect the intentions to use IoT applications in higher education*

Hypothesis 3*: Perceived ease of use will positively affect the perceived usefulness of IoT applications in higher education*

Hypothesis 4*: Students' attitude towards technology will positively affect the perceived usefulness of IoT applications in higher education*

Hypothesis 5*: Students' attitude towards technology will positively affect the perceived ease of use of IoT applications in higher education*

Hypothesis 6*: Perceived risk will positively affect the perceived usefulness of IoT applications in higher education*

Hypothesis 7*: Perceived risk will positively affect the perceived ease of use of IoT applications in higher education*

Hypothesis 8*: Perceived value will positively affect the perceived usefulness of IoT applications in higher education*

To reduce the variance caused by other factors, we controlled for the age and gender of respondents. Relationships among the constructs were empirically tested as follows. The conceptual framework is shown in Figure 2.

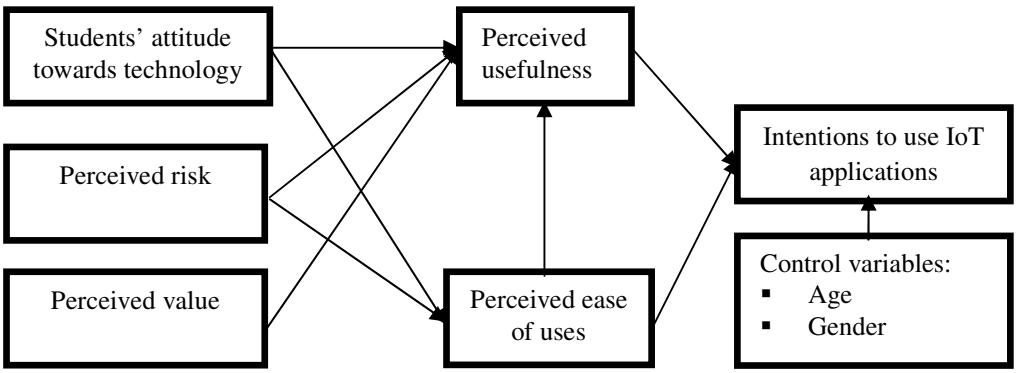

Fig.2. Proposed research model

Method

Research Design

In order to meet the research objectives and to test the proposed hypotheses, we developed a quantitative empirical study of the mediating effects of perceived ease of uses and perceived usefulness on the relationships between external variables and intention to use IoT applications. This study used cross-sectional survey data. The relationships proposed in the conceptual model were estimated through hierarchical regression analysis.

Data were collected from a sample of engineering students (86 students) were recruited from University Politehnica of Bucharest (UPB), during April 2017. This university is the largest and the oldest technical university in Romania. About 64 percent of the respondents were males and 36 percent of the respondents were fameless. The age of the respondents ranged from 22 to 25 (SD=1.86 years). The average age was

24.2 years. The response rate was 86 percent and resulted in 75 valid questionnaires (N=75). The data were assessed for the extent of missing values. The missing values were completely at random and the means substitution method was used the replace them. All of the items were also measured on a 7-point scale ranging from 1 (strongly disagree) to 7 (strongly agree).

Variable Measurement

When possible, construct measures were created based on previously validated survey instrument. In addition, individual measures were averaged to obtain a simple value for each construct. *Intention to use (IU)* (dependent variable) was developed by Venkatesh and Bala (2008) and adapted for this study and it was measured using 3 items: "I intend to use IoT services to improve my academic performance (IU1)"; "I think that IoT services would provide access to learning resources (IU2)"; "I would use the IoT services in the next few months (IU3)". *Perceived usefulness (PU)* developed by Pikkarainen et al. (2004) and adapted for this study and it was measured using 3 items: "I usually use smart devices into my learning process (PU1)"; "Using IoT technology could increase the efficiency of teaching process (PU2)"; "Using IoT technology could increase my collaboration with students and faculty members (PU3)". *Ease of use (EU)* was developed by Cabanillas et al. (2013) and adapted for this study and it was measured using 3 items: "Interaction with the IoT technology is clear and understandable (EU1)"; "I think it is easy to get IoT services in higher education institutions (EU2)"; "In general, the IoT services are easy to use (EU3)". *Perceived value (PV)* was measured using 2 items: "I like to use IoT services in teaching and learning processes because only in this way I can meet my needs and interests (PV1)"; "I believe that IoT services would be useful for accelerate the learning process (PV2)". *Perceived risk (PR)* was measured using 3 items adapted from (Benlian and Hess, 2011): "I believe the security of my data and applications are not guaranteed when using IoT services (PR1)", "The privacy in IoT services is not assured (PR2)", and "IoT services performance and reliability are not guaranteed (PR3)". *Students' attitude towards technology (STT)* was measured using 3 items: "I believe that technology enhances my learning experience (STT1)", "I look forward to that job that requires me to use IoT technology (STT2)" and "I believe that technology gives me the opportunity to acquire new knowledge and increase my satisfaction (STT3)".

Following previous studies, we controlled for respondent age and gender that were not of direct interest for testing our hypotheses but could be theoretically related to the intentions to use IoT applications and might provide reasonable alternative explanations for our findings. We expect that age has a greater impact on intentions to use IoT services because they have digital skills to use the IT tools. Student age was operationalized as the logarithm of the number of years in order to normalize the data. Gender, as dummy variable, was included to control for the specific impact on the intentions to use IoT applications in higher education. We coded male respondents as 0 and female as 1.

Analysis and results

We have tested all of the hypotheses together within a single model. All measurements of the constructs are based upon the respondent's perceptions. Because measures for the dependent and independent variables were taken from the same questionnaire, we performed Harman's one-factor test to see whether one factor accounted for the majority of variance in the data. Therefore, we entered all items used in the questionnaire into an unrotated exploratory factor analysis. The first factor accounted for 28.3 % of the variance. Since a single factor did not emerge and one-factor did not account for most of the variance, this suggested that common method bias was not a serious concern in our data set.

Table 1 presents the descriptive statistics, correlations for all variables used in this research and reliabilities among all variables. We can see that no bivariate correlation is greater than 0.8 and there is little threat of common methods in our data. The highest correlation coefficient is equal to 0.354. The correlation analysis shows that most coefficients are low (well under 0.4), which minimizes concern with multicollinearity issues in our analysis. Many indicators showed a significant positive correlation. Correlation greater than or equal to 0.248 are significant at $p<0.05$. Correlation greater than or equal to 0.312 are significantly at $p<0.01$.

Table 1: Descriptive statistics and reliabilities of the variables

Variables	M	SD	IU	PU	EU	PV	PR	STT	Gender
IU	5.83	1.27	(.809)						
PU	5.22	.87	.312**	(.906)					
EU	4.47	.54	.269*	.022	(.743)				
PV	6.78	.51	.003	.354**	.015	(.823)			
PR	4.87	.8	.260*	.318**	.262*	.031	(.895)		
STT	5.84	1.23	.248*	.321**	.175	.024	,151	(.783)	
Gender	.59	.49	.1	.065	.004	.123	.192	.048	-
Age	3.12	.09	.09	.224	.043	.061	.118	.181	.183

*Note: N=75; *p <0.05 correlation is significant at the 0.05 level (2-tailed); **p<0.01 correlation is significant at the 0.01 level (2-tailed)*

Data was analyzed with SPSS 20.0 software with maximum - likelihood estimation. Cronbach's alpha was used to determine the internal consistency of items in each scale. Statistical procedures were used to establish the reliability and validity of the measures with all items. We applied the Cronbach's alpha indicator to measure the scales' reliability. Reliability of the factors was measured using Cronbach's alpha for each construct and was found to be greater than the recommended minimum of 0.7 indicating high reliability (Hair et al. 1995). The Cronbach's alphas ranged between 0.906 (for perceived usefulness) and 0.743 (for perceived ease of use). Cronbach's alpha coefficients for internal consistency reliabilities appear in parentheses along the diagonal.

Hypothesis testing

The model was analysed using hierarchical linear regression with intentions to use IoT applications as the dependent variable. We have included in the model as control variables age in years and gender as male and female. The results are shown in Table 2. In Model 1 was included only control variables against intentions to use IoT applications, and no significance are shown. Model 2 examines perceived usefulness, perceived ease of uses, perceived value, perceived risk and students' attitude towards technology as the independent variables. The R Square is 0.411, that is, this model explaining 41.1% of the variance of dependent variable.

Table 2: Hierarchical multiple regression (dependent variable – IU)

Explanatory variables	**Model 1**		**Model 2**	
	β	t	β	t
Gender	.12	1.015	.094	.788
Age	-.116	-.985	-.103	-.846
Perceived usefulness (PU)	-		.56	3.244
Perceived ease of uses (EU)	-		.651	4.212
Perceived value (PV)	-		.089	.722
Perceived risk (PR)	-		.214	1.833
Students' attitude towards technology (STT)	-		-.97	3.236
R	.151		.411	
R Square	.023		.169	
Standard error of the estimate	1.27		1.22	
R Square Change	.023		.169	
F Change	.842		1.952	

The variables students' attitude towards technology and perceived ease of uses of IoT services has a key role in the explanation of intentions to use IoT applications in higher education. The most appropriate model that was found significant is 2. As predicted, we found that perceived usefulness of IoT services had a significant positive influence on the intentions to use IoT applications in higher education (β=0.56, $p<0.01$). The perceived ease of uses of IoT services had a significant effect on the intentions to use IoT applications in higher education (β=0.651, $p<0.01$). These results support Hypotheses 1 and 2. However, Hypothesis 3 was not supported because the coefficient for the interaction term was not significant and perceived value does not have a significant moderating effect. This result confirms that the IoT technology is not known in higher education institutions. Hypothesis 4 what it is refers to the influence of students' attitude towards technology on the perceived usefulness of IoT was supported (the correlation between these variables was .321, $p<0.01$). Hypothesis 5 was not supported because the correlation coefficient between these variables was not significant. Hypothesis 6 was not supported because the correlation coefficient (0.048) is not statistically significant. Hypothesis 7 was supported because the correlation coefficient is statistically significant (.262). Hypothesis 8 was supported because the correlation coefficient between these variables is statistically significant (.354).

Conclusion

The results of this study highlight the way in which the IoT services influence the intentions to use IoT applications and improve the students' performance. We found that the relationship between perceived value, perceived risk, and students' attitude towards technology on the intentions to use IoT services in higher education are mediating by effect of processes perceived usefulness and perceived ease of uses of IoT technology. The results highlight that perceived value and perceived usefulness was positively related to intentions to use IoT services in higher education.

The study presents a number of limitations, among which the perceptions of the students were surveyed and it would be helpful to examine the perceptions of the faculty members. Also, an interaction between students' perception and their cognitive learning strategy could influence the behavioural intention to use social media and digital computing devices in higher education institutions. In addition, the data in this study was collected by using a cross-sectional survey. A longitudinal design might be a good solution to

investigate the adoption and use of social media in higher education. Such future research should be based on more longitudinal methods to capture adoption's time dependency effect.

Finally, the sample size of this study was modest and the results need to be replicated and extended in both public and private universities with caution. As regards the sample, a larger sample would reduce the influence of random variation. Future research using larger samples should aim to examine the robustness of our findings, preferably by simultaneously testing them

Abstract

This article describes the basic points of view on data collection in smart environments using intelligent sensors. The Smart Cities are used as the example environment for open the questions and tasks, some principles and techniques are described. In the conclusion, the next steps of future work in research on participating universities in this field are introduced.

Keywords: Smart Cities, IoT, intelligent sensors, smart systems

Introduction

Smart systems represent a new phenomenon of the current time. The one of the most developing area of this field is oriented on Smart Cities. The idea of smart or intelligent city brings many new questions and tasks for scientists, engineers, and designers. These questions should be answered and the tasks should be solved in very short time using the overall knowledge from many fields of physics, informatics or everyday life of people as the users and as the integral parts of such smart environment.

This article should open basic points of view on the smart environment, smart systems and intelligent sensors, and define the frame for the next research realized in cooperation of professionals of several participating departments of universities.

Smart Cities and Urban IoT

The definition of the "Smart City" term is not yet precisely specified, but there is a general notion of its meaning by Zanella et al (2014), Schaffers et al (2011), and Cuff et al (2008). It is a concept to make a better use of the public resources, increasing the quality of the services offered to the citizens, while reducing the operational costs of the public administrations. It specifies a new term “Urban IoT” that brings many benefits in the optimization and management of traditional public services, i.e. transport and parking, street lighting, surveillance and maintenance of public areas, etc. Different types of data, collected by a pervasive urban IoT, are available, that also stimulate the creation of new services upon those provided by the IoT.

Smart Structures

The "Smart Structures" are defined by the level of its sophistication as mentioned by Apurval et al (2017) based on first study by Rogers (1990). The relationship between these structures can be seen in the Fig. 1.

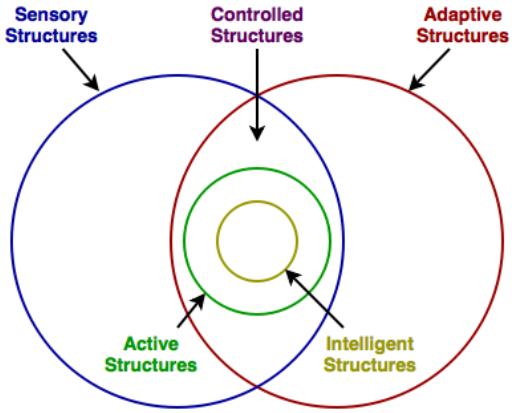

Fig. 1: Smart Structures relationship by Rogers (1990).

The brief descriptions of the levels with examples follow:

- **Sensory Structures** possess sensors that enable the determination or monitoring of system states or characteristics, i.e. temperature sensors.
- **Adaptive Structures** possess actuators that enable the alteration of system states or controlled manner, i.e. road signal switches.
- **Controlled Structures** result from the intersection of the sensory and the adaptive structures that possess both sensors and actuators integrated in the purpose of controlling the system states or characteristics, i.e. simple thermostatic controllers.
- **Active Structures** possess both sensors and actuators that are highly integrated into the structure and exhibit structural functionality in addition to control functionality, i.e. free parking places counters with front display showing the free places count.
- **Intelligent Structures** are basically active structures possessing highly integrated control logic and electronics that provides the cognitive element of distributed or hierarchic control architecture, i.e. intelligent city routing systems providing ability to find the route automatically.

Smart Materials

There are many of "Smart Materials" to be used as the base for sensor designs. The materials belong to one of two types, active or passive. While the passive material doesn't have an inherent capability to transduce energy, the active materials have an ability to modify their shape or some properties under the applied electric, thermal or magnetic fields, also they have an inherent capacity to transduce energy as described by Fairweather's thesis (1998). These materials, i.e., are used for sensor designs by Apurval et al (2017):

- **Optical fibers** – When the fibers are exposed to the influence of the strain, temperature, electrical and/or magnetic fields, pressure, and other conditions, the signal change (polarization, phase, intensity or frequency) can be measured.
- **Piezo-Electric materials** – When the material is in the influence of mechanical stress, it generates measurable electrical charge; when it is exposed to electrical field, its dimension changes can be measured.
- **Electro-Rheological (ER) fluids** – When the fluids are exposed to electrical field, its viscosity changes and can be measured.
- **Magnetostrictive materials** – When the material is in the influence of magnetic field, its dimension changes in relation to the process of internal magnetic domains structure modifications.

- **Shape Memory Alloys (SMAs)** – These alloys recover their normal shape under given condition, it means the deformations comes back to the original state.

Urban IoT

The Internet of Things technologies used to collect and provide data across the smart cities forms a new "Urban IoT" infrastructure. It should can integrate different technologies across the given communication lines to transfer data and commands. The typical design of that infrastructure by Zanella et al (2014) can be seen in the Fig. 2.

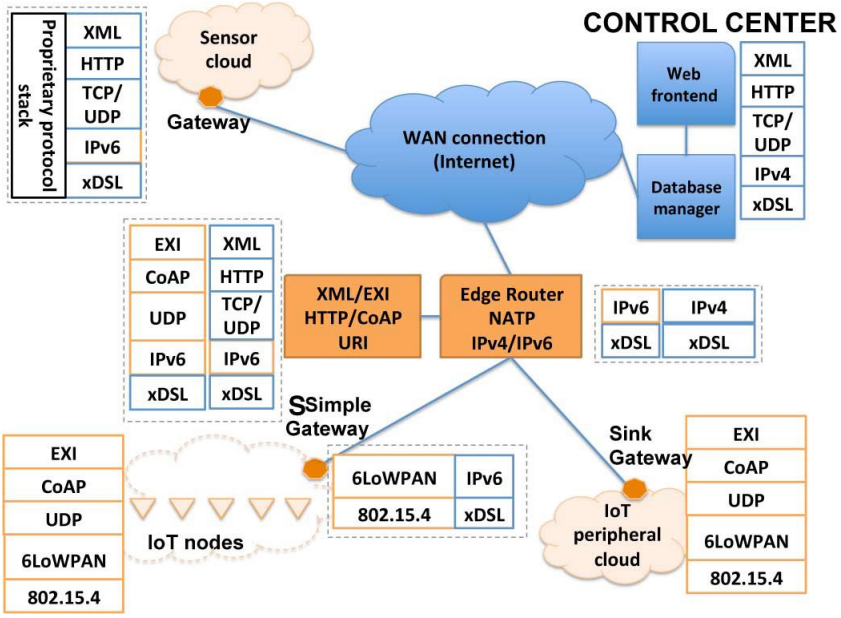

Fig. 2: Conceptual representation of an Urban IoT based on the web service approach by Zanella et al (2014).

The design of Urban IoT services requires to deploy a new protocol layers depending on the different sensor and communication technologies. The main effort is oriented on link layer of the simplified ISO/OSI model like four-layer TCP/IP stack. The higher layers of the network node stack correspond to the commonly used protocols and services, to be simply integrated in the given client's protocols and standards, typically web services.

Sensors and Communication

The technologies of data collection for Smart Cities opens wide field for using of intelligent sensors. In relation to Urban IoT design, there is important question how to collect the data and how to transfer the data from the sensor to the core of the system for evaluation and presentation to the citizens with minimal effort and minimal costs. It leads to using of simple and low consumption equipment forming the sensor itself, and the well-known and verified communication technologies and infrastructures to save the development costs.

Intelligent Sensors and Data Collection

Today, there are many different products on the market that provide the necessary service to be used as intelligent sensors. Typically, it consists of a microcontroller unit or simple microcontroller board with interfaces for analog sensing or digital communication with one or more sensors, and the sensors itself. This unit must communicate with the sensors as the first, and the other communication provides the data to the core of the system. The communication with the sensors depends on the sensor technology, in contrast with the communication with the system core that depends on the technology of the system elements interconnection.

Analog sensors need to be connected using A/D converter that typically comes as the part of used microcontroller unit. It is necessary to provide some procedures of measurements and function to convert the measured values to usable data. In this case, the intelligence of the sensors is given by the programming of the microcontroller unit.

Digital sensors contain their own basic intelligence providing the evaluation of the measured values into the form of digital data. In addition, they can be controlled by a microcontroller unit that can set an additional measurement parameters (scale, resolution, thresholds, etc.). When using the digital sensors, the designer doesn't need to know the details of the sensor physical technology well.

The data collection features depend on the requirements of the given system. The possible scenarios are these:

- **Periodical sensing** is used for the continuous collecting, when the system must provide short term or long-term progress description of the controlled feature.
- **Sensing on demand** provides the measurement depending on an event or an external request.

Connection in Smart Environment

In the smart environment, there is more types of connection that will be described separately. Today's trends and technologies brings a new look on the human interaction with the smart systems. This interaction can be described as a connection too, because it has very similar features to other connection types in the smart environment.

Connecting with People. This is the basic connection type that provides direct interaction with the system by administrators or common users in general. It is typically realized by Human Interface Devices (HIDs). The HIDs can have a form of common equipment or specialized application. Personal computers play main role used as HIDs, but their importance is diminishing. In opposite, the importance is higher with on the portable devices like tablets or smartphones. In the special environment of smart houses, there are smart human interfaces dedicated for this role, i.e. personal access system with biometric readers.

Connecting with Objects. The system should manage many elements, which are used as the execution objects. These objects also provide some information about their state as the feedback for the controlling system. The connection can have wired form, when the location of the object does not change, or can have wireless form, if the object changes its location often or the wired connection cannot be realized in relation to some limits.

Connecting Digital with Physical. A very special task is the realization of connection between physical sensor (typically measuring some non-electric physical quantity) and digital equipment that processes measured raw data and provides the connection to smart system, when playing the role of object (see previous paragraph). The bridging from physical to digital is typically the most demanding on designer efforts, although many converters are available on the market.

Conclusion and Future Work

The world of intelligent sensors is very diverse and miscellaneous, smart systems are developing very quickly now-a-days. The near future can bring these technologies in the everyday life of cities and their citizens.

The design of such systems needs to use cooperation of many technics and technologies with many intelligent structures and equipment. The next task for the designers and developers is to adapt used standards and customs, and specify new ones. This is the future work to hold the possible compatibility and flexibility of data collection, processing and evaluating in the smart environment.

Analysis of the Stability of Clustering Structures Based on the MCDM Methods

Roman Guliak, VŠB – TU Ostrava, Ostrava, Czech Republic; O. M. Beketov National University of Urban Economy in Kharkiv, Kharkiv, Ukraine. e-mail: roman.guliak@vsb.cz;

Abstract

The measurement of regional development and the clustering of regions are the problem of high importance, especially in the context of EU Regional policy. Properly defined a lagging cluster of regions is the main recipient of the Structural and Cohesion Funds. Traditional clustering methods fail to rank regions what makes these methods not applicable for the problem of recipients' determination. In the current measurement practice MCDM methods are considered to be a suitable ranking tool. Meanwhile MCDM methods are not meant to cluster the alternatives considering similarities between all alternatives within the cluster in terms of all criteria. The quasi-clustering can be done, which is based on the consideration of distances to the etalon established by MCDM methods. In this research the stability analysis has been suggested as a tool to validate the number of quasi-clusters, to identify the most stable structure and to define the most suitable MCDM method for the clustering. Two MCDM methods were chosen to measure the regional development, in particular VIKOR and Hellwig's. By the stability analysis the VIKOR method was defined as the most suitable for clustering. Clustering Stability analysis was applied for the 35 NUTS 2 regions from Visegrad group.

Keywords: regional development, MCDM, stability of clusters, Hellwig's, VIKOR

JEL Classification: C44, R15

Introduction

The measurement of regional development is the basic step for the realization of EU Regional policy with the subsequent distribution of Structural and Cohesion Funds. The last one requires the determination of lagging regions which is in current practice predominantly based on the GDP indicator. This indicator is not able to reflect properly the standards of living. Thus, it drives the search for the alternative ways of the lagging regions determination based on more essential indicators describing the regional development and well-being of the society.

In this paper we favor the application of Multi-Criteria Decision Making (further – MCDM) methods, but not traditional clustering ones. It is explained first of all because of the ranking power of the MCDM methods. Pure clusters, obtained by the traditional clustering methods, without knowing their aggregated level of development are of low interest in the context of EU Regional policy. Moreover in case of more than 5 criteria the interpretation of clusters is very challenging task. Due to this, the priority is given to the application of the MCDM methods able to conduct the multi-dimensional measurement of the regional level.

After the literature analysis we can sort out three groups of different approaches. The representatives from the first group (Snieška, Bruneckienė, 2009; Huggins, Thompson, 2010; Annoni, Dijsktra, 2013; Gábor, Ottaviano, 2015) prefer the simple linear way of criteria aggregation coming mostly from American school based on the multi-attribute value functions and multi-attribute utility theory (MAUT) (Keeney, Raiffa, 1976). The second group (Oliva, Miguel, 2005; Fernandez, Navarro, 2013, Guliak[b], 2017) is concentrated on the application of methods from outranking family. The most widely used methods are ELECTRE and PROMETHEE (Roy, 1968; Brans et al., 1984). Another principally different approach (Ramík, Hančlová, 2012; Charles, Zegarra, 2014; Guliak[a], 2017) originates from the Data Envelopment Analysis (DEA) – nonparametric method introduced by

Charnes, Cooper, and Rhodes (1978). The key concept of this approach is the technical efficiency being calculated following the input-output criteria division.

All listed MCDM methods are targeted on the ranking problem. However, there is another not less important clustering problem making a regional measurement complete. Having observed such a wide variety of MCDM methods applied, the question arises whether final utility values produced by the certain MCDM method are able to reflect in the best way the true clustering structure of the alternatives being evaluated. To the extent of our knowledge in the economic and management literature there is no research shedding the light on this question. Therefore the aim of this paper is to suggest the approach to the stability analysis of clustering structures produced by different MCDM. This analysis will provide the decision maker with the knowledge which MCDM method solves better the clustering task.

The remaining part of the paper is organized as follows. Section 2 describes the MCDM methods applied for the measurement of regional development. The following section presents the stability approach to the analysis of clustering structures. Section 4 presents the results of the application of MCDM methods. The last section gives the conclusions.

MCDM Methods Applied

Below we describe two selected MCDM methods, namely Hellwig's and VIKOR. Both of them are related to the distant based methods, with the same methodological basis steamed from Multi-Attribute Utility Value Theory (MAVT). Their utility functions measure the distance to the artificially created ideal point (etalon).

The mentioned methods are based on the distance function but differentiate in the dealing with the ideal point. The Hellwig's method measures the difference to the positive ideal point, while compromise VIKOR method pays attention to the mutual concession between a maximum utility of the majority and a minimum individual regret of the opponent. In other words, the VIKOR method considering just "closeness" to the positive ideal solution is influenced by the minimum of individual regret and suitable for the decision makers aimed at the maximum profit and risk avoidance. Meantime applying the Hellwig's method a decision-maker will prefer profit maximization following risk loving strategy.

Let us suppose that MCDM problem can be described by *m* alternatives $(A_1, A_2, ..., A_m)$ presenting the NUTS 2 regions and *n* criteria $(C_1, C_2, ..., C_n)$ characterizing the performance of the regions. Performance matrix $X = [x_{ij}]_{m \times n}$ shows all values assigned to the alternatives relating to an each criterion. The weights of criteria have been denoted by $W = [w_1, w_2, ..., w_n]$ under the condition of $\sum_{j=1}^{n} w_j = 1$.

The Helwig's method, named after Polish scholar, is aimed at the measurement of the degree of regional development and detecting homogenous groups (Harman, H.H., 1976; Hellwig, Z., 1968; Pluta W., 1977). The steps of introduced method are following.

Step 1: form an initial matrix of data and to normalize it:

$$Z_{ij} = (x_{ij} - \bar{x}_j) / S_j, \tag{1}$$

Step 2: determine an etalon E_o $(Z_{01} \ldots Z_{0n})$ in accord to the min-max criterion;

Step 3: calculate the distances from the etalon:

$$c_{io} = \left[\sum_{j=1}^{n} (z_{ij} - z_{oj})^2 \right]^{1/2}, \tag{2}$$

Step 4: calculate the upper limits C_o (critical distance) of the options using:

$$c_0 = \bar{c}_0 + 2S_0, \tag{3}$$

$$\bar{c}_0 = \frac{1}{m}\sum_{i=1}^{m} c_{i0}, \tag{4}$$

$$S_o = \left[\frac{1}{m}\sum_{i=1}^{m}(c_{io} - \bar{c}_o)^2\right]^{\frac{1}{2}}. \tag{5}$$

Step 5: to calculate the development score (d_i) of the options using:

$$d_i = 1 - \frac{c_{i0}}{c_0}. \tag{6}$$

where: x_{ij} – j^{th} attribute of the i^{th} region, $i = 1,2, \ldots, m$ (number of regions);
$j = 1, 2, \ldots, n$ (number of attributes);
z_{oj} – normalized coordinate of the etalon;
Z_{ik} – normalized value of k^{th} variable in the i^{th} region;
S_o – standard deviation of the distances.

The VIKOR (VlseKriterijumska Optimizacija I Kompromisno Resenje) method is a compromise ranking method developed by Opricovic (1998). Its role is to find multi- criteria raking index based on particular measure of closeness to the ideal solution, providing a maximum group utility of the majority and a minimum of the individual regret of the opponent (Opricovic, Tzeng, 2004). The mathematical procedure of VIKOR has the four main steps.

Step 1: to determine the best (desired) f_j^*, and the worst (tolerable) f_j^- values of all criterion functions:

$$f_j^* = \left\{(\max_i \; f_{ij} \,\middle|\, j \in C^{benefit}), (\min_i \; f_{ij} \,\middle|\, j \in C^{cost})\right\} = \left\{f_j^* \,\middle|\, j = 1,2,...,n\right\} \tag{7}$$

$$f_j^- = \left\{(\min_i \; f_{ij} \,\middle|\, j \in C^{benefit}), (\max_i \; f_{ij} \,\middle|\, j \in C^{cost})\right\} = \left\{f_j^- \,\middle|\, j = 1,2,...,n\right\} \tag{8}$$

Step 2: to calculate the maximum utility of the majority (min S_i) and a minimum individual regret of the opponent (min R_i) from the L_p - metric:

$$L_{p,i} = \left\{\sum_{j=1}^{n}\left[w_j(f_j^* - f_{ij})/(f_j^* - f_j^-)\right]^p\right\}^{1/p}, \tag{9}$$

$$1 \le p \le \infty,\ i = 1,2,...,m,$$

$$S_i = \sum_{j=1}^{n} w_j(f_j^* - f_{ij})/(f_j^* - f_j^-), i = 1,2,...,m \tag{10}$$

$$R_i = \max_j[w_j(f_j^* - f_{ij})/(f_j^* - f_j^-)], i = 1,2,...,m. \tag{11}$$

Both S_i and R_i are measured from 0 to 1, when 0 means that it reached the best level.
Step 3: to compute the best and the worst values:

$$S^* = \min S_i,\ S^- = \max S_i, i = 1,2,...,m$$

$$R^* = \min R_i,\ R^- = \max R_i, i = 1,2,...,m.$$

Step 4: to determine the value Q_i representing the compromise solution, integrated by the maximum utility of the majority (S_i) and minimum individual regret of the opponent (R_i) as the base for an agreement established by mutual concessions:

$$Q_i = v\left[\frac{S_i - S^*}{S^- - S^*}\right] + (1-v)\left[\frac{R_i - R^*}{R^- - R^*}\right], i = 1,2,...,m. \tag{12}$$

where v is the balance parameter following the strategy of maximum group utility (if v >0.5) or the strategy supporting negative individual regret (v <0.5). In this research the equal importance is given to the both strategies and v =0.5.

All the presented methods deal with the external weights, which in the current research are calculated by objective Entropy method (Zanakis et al., 1998).

Approach to stability analysis of clustering structures

To start the discussion about clustering based on MCDM methods, one should mention that while MCDM methods construct an ideal point or etalon from the alternatives' attributes expressed in the best way, the clustering methods have nothing to do with that. On the contrary they pay maximum attention to the attributes of each alternative and measure the distance between alternatives to find the similarities for the cluster identification. MCDM methods in turn measure the distance to the purely etalon producing the corresponding vector of final scores. It means that MCDM do not pay explicitly (considering each attribute separately) attention to the neighbours with respect to the distance to them. The distance between neighbours is accounted indirectly by means of the distances to the etalon. Such way of similarities measurement can be called as quasi-clustering, what per se has the rights to exist and requires some additional analysis suggested below.

Let us define the main characteristics of the suggested stability analysis:
– firstly, it is based on the one input variable (utility value), presenting the distance to the etalon;
– secondly, the way how clusters are defined is the hierarchical agglomerative one, because all clusters consist of mergers of previously formed clusters and the clustering process begins with as many clusters as there are alternatives and ends with a single cluster;
– thirdly, to measure the similarities between alternatives we use the single linkage method or "neighbor joining" calculating the differences between utility values.
For example, an *i*-th alternative is declared to be closer (more similar) to *j*-th than to observation *k*-th if $D(i; j) < D(i;k)$. The linkage method has been chosen because relying on the vector of ranked utility values it will easy deal with non-elliptical shapes of clusters, will be sensitive to outliers and will produce elongated clusters (not spherical).

Therefore, considering the sets of alternatives $A = \{a_i | i = \overline{1,n}\}$, clusters $C = \{c_k | k = \overline{1,f}\}$, $f \le n$ and MCDM methods $M = \{m_p | p = \overline{1,l}\}$, the task for the clusterization is to find the optimal number of clusters $k_p^z \le n$ at the *z*-th step related to the *p*-th MCDM method. The algorithm of controlled merging process is the following:

1. Initialization. To start by assigning each item to each own cluster so as $k = n$.
2. Iteration. If $d(i + j, k) < d_z$ merge two clusters, which are the most similar until n=1.
3. Selection. To choose the most appropriate MCDM method (M*) for the clustering, defined at *z*-th step by the *p*-th MCDM method such as $m^* = \{ S_z^p \to \min \}$.

where d_z^* – is the minimal univariate discretion value or minimal similarity threshold at the *z*-th step measured as:

$$d_z = \frac{z}{n-1}; \tag{13}$$

S_z^p – in-Stability index related to *z* clusters and to the *p*-th method:

$$S_z^p = d_z^* \times \frac{k_z^p}{n} \text{ or} \tag{14}$$

$$S_z^p, \% = \frac{\max S_z^p - \min S_h^p}{\min S_h^p} \times 100\%. \tag{15}$$

k_z^p – is the number of clusters extracted at the the *z*-th step by the *p*-th MCDM method;

z, h – steps of clustering with corresponding minimal univariate discretion values d_z, d_h.

The described algorithm is based on the assumption that each region represents its own cluster if utility values are uniformly distributed. In this case there are no more or less similar alternatives merging into a cluster. As a result according to the algorithm we define the minimal in-stability index

representing the clustering structure with the strongest similarities within and the strongest dissimilarities between clusters. Such a structure is considered to be the most representative and points out at the p-th MCDM method as the most appropriate for the clustering.

Measurement of Regional Development within the Visegrad Group

The initial 9 essential indicators describing the economic, social and innovative aspects (table 1) are used for the measurement of performance of 35 NUTS 2 regions from Visegrad group. The entire indicators are benefit ones apart the UN, which is the cost one.

Table 1: Indicators describing the performance of regions from Visegrad group, 2013 year

#	Abbrev.	Indicators
1	*DI*	Disposable Income (net) of households by NUTS 2 regions, in purchasing power standard based on final consumption per inhabitant, PPS/inhab.
2	*ER*	Employment Rates by sex, age (from 15 to 64 years) and NUTS 2 regions, %.
3	*TE*	Tertiary Education (levels 5-8), %.
4	*UN*	Total Unemployment (%), %.
5	*PROD*	Regional productivity measured as the ratio between Gross Value Added at basic prices and the number of the persons employed, euro/pers.
6	*GFC*	Gross Fixed Capital formation by NUTS 2 regions, euro/per.
7	*TRD*	Total intramural R&D expenditure (GERD) by sectors of performance and NUTS 2 regions (Percentage of gross domestic product (GDP), %.
8	*JVR*	Job Vacancy Rate activities (except activities of households as employers and as own use producers; activities of extra-territorial organizations and bodies), %.
9	*BRD*	Total intramural R&D expenditure by business enterprise sector, %.

From table 3 we have derived the correlation between the GDP criterion and utility values generated by the MCDM methods. Based on the correlation from table 4 we can state that MCDM methods produce quite similar utility values as the correlation between them is 0.91. Besides, one should notice, that despite the fact of the methods similarity, VIKOR method correlates better with GDP criteria. Nevertheless, the difference between GDP and utility values is quite essential, as the correlation is less than 0.76.

Table 4: Utility values of the NUTS 2 regions

	GDP	*Hellwig's*	*VIKOR*
GDP	1		
Hellwig's	0,695	1	
VIKOR	0,763	0,911	1

After the preliminary statistical analysis the stability algorithm is implemented to utility values according to the formulae 13-15. As a result all stability statistics describing the clustering process are gathered in table 5. According to the selection step from the algorithm the minimal instability index is being chosen. The minimum 0 % of instability is identified on several steps and within both methods. The most interesting however is that clustering structure which has the minimal instability with the largest number of clusters. Thus, we are inclined to choose the 3 clusters structure produced by the VIKOR method at the 2-nd step of stability analysis.

Table 5: Stability statistics

Criteria		Steps of stability analysis											
		1	2	3	4	5	6	7	8	9	10	11	12

The transformation of clusters can be presented at the tree-like diagram (dendogram) recording the sequences of merges or splits at a certain step with the corresponding distance represented by the discretion value. In the dendogram (table 6), the rows are associated with the items and the columns are associated with levels (steps) of clustering, allowed by the controlled merging process.

Table 6: Dendogram based on the VIKOR method

Regions	Value score	Steps of analysis / # clusters

Having applied stability analysis to the utility values, we obtained the dendogram showing clustering structures at different steps. From the dendograms we can visually decide about the clusters' durability attributed to the method with long-lasting clusters. From table 6 we can observe that the most durable VIKOR based structure includes 2 clusters and lasts for 9 steps. Compare to all other

clustering structures originated from Hellwig's method, this is the most stable and has the in-stabilty index 0 %. This structure has the most similarities within and dissimilarities between clusters.

However, the priority can be given to another as well 0 % instable structure including 3 clusters. The final decision, in case when instability indices are equal, depends on the interpretability of the clusters and the problem specificities. Any way, one solid decision is made about VIKOR's appropriateness for the clustering problem. The VIKOR method is considered as the most suitable for the clustering due to its high clusters durability lasting 12 steps and the lowest instability index.

Conclusions

The MCDM methods were incorporated into the clustering problem and used as the distance measurement foundation. Measuring the distance to the etalon MCDM methods are able to provide just quasi-clustering, because the similarities between alternatives are not measured directly. Nevertheless quasi-clustering appears to be advantageous especially when all alternatives have to be ranked and there are many (more than 3) criteria essentially complicating the interpretation of clusters extracted by the traditional clustering methods.

To choose the most appropriate clustering structure and the MCDM method for this purpose is the important task especially in the context of EU Regional policy. The amount of Structural and Cohesion funds assigned to the lagging regions depends on the clustering and ranking results. Different MCDM methods would produce different distribution of utility values making the impact on the way how the alternatives are clustered. The algorithm for the stability analysis has been suggested to select the most appropriate MCDM method for the clustering problem.

The main idea of the suggested stability analysis is to control the merging process by the calibrating the uniform discretion value at each step. The uniform discretion value works as the benchmark for the similarity measurement. The minimal degree of clusters instability is a key indicator for the clusters validation and the method selection.

After all, according to the instability index we have selected VIKOR method as the most suitable for the clusters identification. Correspondingly the 3 clusters structure produced by this method is characterized by the highest similarities within cluster and highest dissimilarities between clusters.

Abstract

In modern industry, we are slowly reaching the limit where performance, productivity, efficiency may be increased by better organization of systems and continuous improvement of production processes. Undoubtedly, the human factor, including the intellectual capital and reorganization of the management processes, make unused potential in this regard. The purpose of this article is to identify the changes taking place in the area of organizational management in response to the assumptions and defined development trends of Industry 4.0. The idea called Management 3.0 constitute the future of modern management. Creation of complex adaptive management systems will become a requirement for the efficient organization and efficient functioning of intelligent Industry 4.0 enterprises.

Keywords: Management 3.0, Industry 4.0, complexity, engineer of the future, soft skills.

Introduction

Issues shaping functional conditions of today's enterprises indicate the need of a permanent development of concepts and management theories in response to the ongoing of market transformation processes. Management is a tangible and distinctive instrument of action for every organization (Drucker, 2010). Among the most important management conditions for the 21st century are: (1) the globalization of economic activity, (2) dissemination of information technology, (3) formation of a post-industrial society, (4) increase in the importance of knowledge and skills, (5) conditions of continuous change, (6) increase of society aspirations (employees, customers, contractors), (7) economical state influence. Facing these economic changes, it is clear that far-reaching changes in business conduct and the management of various organizations are necessary. For more than a dozen years the source of success has been seen in the construction of a knowledge-based economy. It is assumed that in the circumstances of permanent uncertainty, only knowledge may constitute a competitive advantage and that the business's success lies in a unique way of acquiring, processing and creating knowledge. Continuous market changes, the emergence of new technologies, new products, new competitors require from modern companies to undertake new activities, forcing new ways of looking at the 21st century organization's effective management adapted to today's economic reality, new challenges and industrial conditions.

The pursuit of open innovation and continuous learning and technological improvement is related to the provision of appropriate infrastructure and adequate competence preparation. Thorough transformations in the emerging market' countries is also required in business models, especially in the resource management. In Poland, the main resources still comprise: work, capital and raw materials, but according to the fourth industrial revolution's concept these should be: data, knowledge and organization. In modern industry, we are slowly reaching the limit where performance, productivity, efficiency may increase by systems' better organization and continuous improvement of production processes. Undoubtedly, the human factor, including intellectual capital and reorganization of management processes, constitute an unused potential in this regard.

The purpose of this article is to identify changes taking place in the area of organization's management in response to the assumptions and defined development trends of Industry 4.0. The idea called Management 3.0 is going to become the future of modern management. Nonetheless, questions loom: what principles should be addressed facing the fourth industrial revolution, what transformations are expected by manufacturers in this area and, in long term, relating to trust-based management strategy; so called 'empowerment', is industrial engineer 4.0 already an average managerial level?

Fourth Industrial Revolution

From a manufacturer's perspective, contemporary market is a dynamic structure continually governed by the laws of demand and supply. Over the past few years, the conditions of running a business have changed significantly, particularly in areas where information technologies, rapid information exchange and new forms of interaction with customers are of increased importance. Production batches and shelf-life of products have shrunk considerably, and at the same time the diversity and complexity of products have increased. Customers have become more demanding, in many areas changing into prosumers, whereas manufacturers have been forced to accept new ground rules, as mass customization of products and services has become more profitable than mass production.

Production processes are one of the most important areas in the business activity in the world economy. According to analyses, companies capable of implementing innovative manufacturing techniques using existing infrastructure and traditional developed markets enjoy an additional competitive advantage. Such an approach is characteristic of the intensive phase of economic globalization, which will dominate the current (extensive) one over the next decade (Zawadzka, 2007). This stimulates attempts to create novel forms of production organization in accordance with evolutionary progress in automated manufacturing systems, reaching as far as self-regulating automated manufacturing cells and self-transforming automated manufacturing systems, as presented in (Afentakis, 1986; Banaszak, Muszyński, 1991).

Faced with the dynamically growing complexity of manufacturing systems, classic flexible manufacturing systems (FMS) are incapable of meeting the demands of modern civilization. This leads to decreasing human control over manufactured systems, which in the discussed area manifests as their low tolerance to disruptions. Increasing this tolerance, without resorting to engaging a human in each case, along with an increase in the system complexity control without losing its functionality, is the goal of solutions proposed within intelligent production systems (IPS) and digital manufacturing.

Another industrial revolution, termed Industry 4.0, is already underway (cf. Fig. 1). Its main objective is to increase global competitiveness by increasing the quality of products and decreasing manufacturing costs. Smart factory and smart services solutions will offer higher flexibility of actions and more effective allocation of resources, paving the way for agile manufacturing and scalable logistics solutions. Computer networks will be integrated with unified capabilities and real-time information exchange. The online control of processes requires building a suitable interface between the human, machines and technological devices, defined by their mutual interdependence. In the 21st century, the increasing complexity of systems becomes a concern requiring sophisticated solutions. According to analyses, the number of robots in Europe has doubled over the last decade, with the robots becoming more intelligent and flexible. According to Gartner Inc., the world's leading IT research and advisory company, until 2020 over 20 billion devices will be able to communicate with each other, which in the global economy will correspond to an added value of ca. 1.9 trillion USD (Gartner, 2017).

Evolutionary changes observed in the industry in the 21st century progress from electronic IT industrialization to next-generation (also known as intelligent) manufacturing systems (NGMS). The new generation of manufacturing, known as Industry 4.0, heads in the direction of designing manufacturing systems that integrate information processing with matter processing. This direction can be termed matter digitalization, and its assumptions are implemented in smart factories controlled by cyber-physical systems (CPS) in an environment known as the Internet of Things (IoT).

The term digital production refers to the integrated use of automatic systems, processes and tools by design and manufacturing companies to provide customers with products as soon as possible and with the minimum engagement of operators (Andrews, 2012).

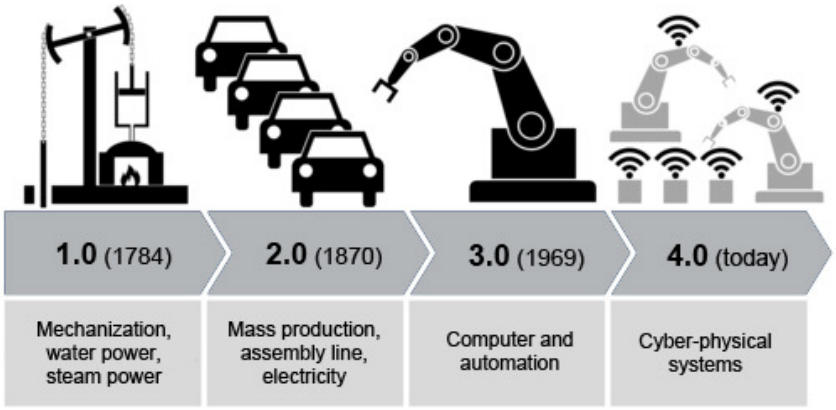

Fig. 1: Industry development stages

Digital modeling of matter processing allows to transform material goods, integrated based on information, within a computer-aided manufacturing organization system. In other words, material goods following digitalization increasingly become digital goods (Badurek, 2014). From the perspective of IT, this megatrend of civilization manifests as virtualization (Canetta, 2011). Nevertheless, the origin of Industry 4.0 is influenced by the cyclical development of economy and the occurrence of crises, where more risk has to be taken and new technological solutions need to be sought to sustain the increase in productivity of companies. This can no longer be achieved solely by the computerization of the industry using methods typical of the Industry 3.0 paradigm (i.e., electronic-IT industrialization) characteristic of the second half of the 20th century.

In the future, the gradual transformation of flexible manufacturing systems through the use of CPS into increasingly intelligent systems will allow to couple virtual and physical systems, culminating in a new level of integrated intelligence, characterized by the interaction and coordination of computing and physical processes in real time. According to Plattform Industrie 4.0 (2013) this will have a significant impact on creating values, business models, secondary (subordinate) services, and work organization, which in turn will force modern manufacturing companies to undertake actions with regard to: (1) horizontal integration by means of value networks, (2) comprehensive digital integration of engineering in the entire value chain, as well as (3) vertical integration and network integration of manufacturing systems.

Industry 4.0 poses both a chance and a threat for the industry. In reality, traditional business enterprises face new challenges that will change the existing rules of productivity and competition. Enterprises must proceed to remove the barriers between information and physical structures. Interdisciplinary thinking, both in technical and social areas, is key in the continuous process of learning and cooperation with a significant impact on individual professional roles. These transformations force entrepreneurs to reorganize their management processes accordingly, as well as to redefine the role of engineers by bestowing them with a managerial character.

Management 3.0 in Industry 4.0

The evolution of management theory can be described as a successive transformation of basic paradigms into respectively proposed concepts, beginning with hierarchy, through models, ending with its complexity (cf. Table 1). In today's market economy, the problem of system complexity precludes the use of Newton's linear solutions, which are characterized by trying to dismantle the problem first, analyze it then well and finally choose the 'best' solution, which often leads to local optimization, system's slowdown, and creation of rules which are often rejected by people. Such deterministic

approach to the industrial enterprise's management and human beings is only short-term and relatively limited, and has also particular significant limitations, as it effectively abolishes motivation, creativity, innovation and employee autonomy.

Systems thinking, self-organizing teams, creativity and people's and/or teams' innovation, delegation of authority and responsibility are the foundations of modern management.

Table 1: From Management 1.0 to 3.0

Management 1.0	Management 2.0	Management 3.0
Hierarchies	Models	Complexity
- issuing and controlling commands (command and control), - hierarchy, information flow and top-down management decisions, - the most popular way of managing, - still used today in the rigid organizational structures.	- response to Management 1.0 weaknesses, - implementation of processes and their improvements, - Business Process Reengineering, Total Quality Management, etc., - self-learning organization, - still top-down management (hierarchy), - inherits most problems from Management 1.0.	- an idea based on the complex adaptive systems theory, - an organization seen as a network of links between its participants, - self-organizing network, - assumes that all models (Management 2.0) may be useful but not always effective, - management focused on people and their relationships, not on processes and models, - empowerment of people, - indication of the boundaries in which the team is to move (alignment) instead of strict control, - shortening the feedback cycle time.

Source: elaboration based on (Pieprzyca, 2016)

The Management 3.0 approach is a proposal for a complete system where people can work more effectively with as few factors as possible, which would limit their performance and creativity, and at the same time, with clear established rules. It replaces traditional management concepts associated with hierarchical organizational structures, supplemented by emerging and disappearing concepts such as the Balanced Scorecard, TQM, etc. (Stawicki, Skowroński, 2013). The said Management 3.0 responds to the problem of maladjustment of the management system, particularly at the middle and high level of the organization for agility and self-organization practices. This concept is based on several assumptions described by Jurgen Appelo (2016) regarding to agile leadership. The author proposes a coherent, six-pillar system that would solve this problem (cf. Fig. 2). He presents it with a bit of a wink with the use of an amoeba-like creature called Martie, at the same time, distancing himself from rigid models, so often found in the management literature. His tentacles show the main pillars of Management 3.0 concept. There are no more important or less important tentacles, and their size, as in the case of pseudopods, varies according to needs and situations. Pure adaptive system.

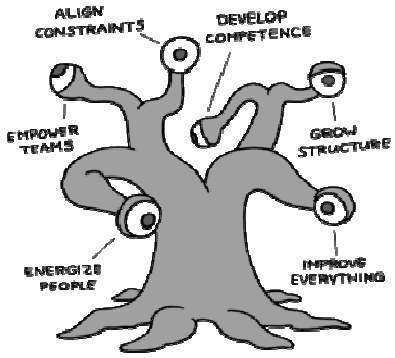

Fig. 2: Martie as the main assumptions of Management 3.0 according to J. Appelo
Source: (Appelo, 2016)

At the outset of the discussion, there is a paradigm that says that every organization is treated as a network of employees' connections and channels of communication, although its organizational structure continues to be formally hierarchical. Additionally, social complexity indicates that management refers to people and relationships between them, rather than corporate divisions and profits. So it can be said that Management 3.0 is not so much a concept of human management as the leadership of teams working in networked organizations, in which people and relations between them count most. This is the concept of taking care of people forming a complex adaptive system, rather than a mechanism composed of easily replaceable elements (Stawicki, Skowroński, 2013).

One of the basic assumptions of agile leadership pointed out by J. Appelo (2016) is a different approach, to the existing ones, to motivate people, hiding under the motto energize people, and oriented, in its essence, on internal motivation. Because people are the most important part of an organization, allowing them to be active, creative and motivated is the key task of the manager. In practice this means that the manager should understand the basic inner desires of people such as status, authority, curiosity, or relationships with others, try to recognize them in the members of his team and lead them accordingly. The agile management distances itself from the traditional methods referring to the legendary 'stick and carrot' and external motivational systems.

Empowering teams are another element of agile leadership, based on the assumption that teams can and can self-organize. The manager's task is to delegate decision-making powers to them and to create an ambience of confidence in their decisions and actions within established areas. This simplifies the decision-making path as well as facilitates the functioning of teams in a complex organizational community while encouraging team members' proactive attitudes. It is important that the manager himself also understands that delegating responsibility and decision-making power raises his or her status in the company rather than lowers it.

At the same time, the boundaries and directions of self-organizing teams should be defined. Align constraints are the third element of the model that answers the question of how to make the effects of the self-organizing system work according to assumed goals and intentions, without resorting to micro-management, temporary suspension of self-organization and other actions, withdrawing the company a few steps behind on the road to become an environment, which is truly supporting the creativity.

The fourth component of the Management 3.0 model is the employee's competence development with the introduction of the culture of the team's continuous competence improvement as well as processes at all levels of the organization. It is a trivial fact that self-organizing teams are not able to achieve their goals if team members have not got appropriate skills.

The last two components of the model are to create an adaptive and scalable organizational structure (grow structure) and continuous improvement (improve everything), understood as skillful management and change stimulation. In a complex environment, an ideal, balanced motivation system, competence development and self-organization does not exist. The main task of the manager is to behold, to draw conclusions, to correct, to change and to experiment. In today's world, the only thing that is certain is change, and a skilful implementation of it is becoming a standard competence for both managers and engineers. The agile manager understands and allows teams to experiment in a safe environment, stimulate development and effectively introduce required changes (Stawicki, Skowroński, 2013).

Industrial engineers 4.0 as knowledge workmen

The most important task for the 21st century companies is to increase the productivity of the most valuable asset in who is commonly identified as the knowledge worker (Drucker, 2010). In addition to the management level, in industrial enterprises, engineers, regarded as professionals, experts in their fields, play a key role in creating added value.

Karl E. Sveiby (1997) proposes to divide the organization's employees into four categories: (1) professionals, (2) managers, (3) supporting staff, and (4) leaders. He assumes that modern

organizations should mainly consist of professionals who generate enterprise's value, and leaders whose one of tasks is an appropriate professionals' management. Other groups of employees should support the work of professionals and leaders. Such an organization, aimed at generating added value through the use of knowledge, has a chance to succeed in today's difficult socio-economic conditions. (Beyer, 2012). Professionals are made up of specialists and experts. They are characterized by very high professional competence, intelligence and creativity. They are generally characterized by a high level of expertise, education, and experience that successfully translate into creation, dissemination and practical use of knowledge (Davenport, 2007). It is precisely this group that modern engineers must be epitomized with as they are increasingly attributed with their organizational skills and managerial competences.

There is no doubt that in the age of reproducibility, which is now assured by machine, which are currently replacing the human, the necessity to perform routine activities will decrease in favor of creative skills. An engineer should be able to process and analyze a large amount of data from multiple sources, evaluate the information validity, its credibility, and draw relevant conclusions. This will be helped by his ability to gain access to this information, including electronic media and Big Data tools (Stoch, Gracel, 2017).

The need for quick adaptation to changes in the modern world implies the need to rid the traditional concept of professional qualifications to the term 'competence'. The need for the research of new areas of competence, characterizes the engineers of the future. A growing demand for effective and efficient engineers with managerial qualifications is being beheld. At the same time, due to the enormous importance of the ability to communicate easily, solve conflicts or deal with non-standard situations, for proper modern organizations' functioning, there is a need for a new kind of competence, resulting not so much from the technical knowledge acquired during shaping of the technical education, but the ability to function in a team, the ability to build enterprises' intellectual capital. In order to implement new organizational or technological solutions, an adequate level of so-called absorption capacity is necessary – dependent mainly on knowledge, attitudes and employees' skills.

The Astor Academy representatives, using a personality profile (ThomasPPA), have created interesting profiles of the engineer's personality before the era of Industry 4.0, naming him a 3.0 engineer, and the engineer of the future (engineer 4.0). As a result of the analysis two diametrically different attitudes emerged. Engineer 3.0 is a logical, analytical and systematic person who follows the procedures. He has an innate need to perform his tasks properly and focuses on issues rather than people. He is able to work with people but in a team he knows. He does not like changes and new issues. He works calmly, prudent from the beginning to the end, and has the ability to bring things to an end. He is very attentive, polite, organized, predictable and methodical. Engineer 4.0 is an open and active person who loves diversity both in terms of human relations and tasks. He has the ability to impart the others with very technical, detailed information with enthusiasm and optimism, which arouses positive feelings among the audience, regarding the ideas that he shares. He attaches great importance to detail and strives for perfection. He ensures high quality of work and compliance with norms. He obeys rules and procedures (Stoch, Gracel, 2017).

Certainly, the features which distinguish these two profiles (two people) are: speed, openness to change and flexibility towards them. Engineer 4.0, besides invariably essential technical competences, must be aware of the importance of soft competences and the ability to integrate them skillfully. It is followed by greater interdisciplinarity and openness to the broadening horizons of knowledge in various disciplines. The productivity growth can be seen both: in the increase of automation and the computer system implementation as well as in the building of effective teams oriented on better goal achievement (Bittel, 1994). It seems that among the engineers, the ability of teamwork, independence in work organization and decision-making will be gaining importance. In Polish reality, appreciation of the importance of the co-workers' potential and their real empowerment is still a fundamental challenge for the 21st century management.

Conclusion

In-depth research is required in order to define the determinants of effective management of manufacturing companies according to the fourth industrial revolution assumptions and the progressive civilizational transformations, referred to as the 'third wave' embodying the information (technology) society. According to Alvin Toffler (Toffler, Toffler, 1995), the history of mankind is headed to the age of knowledge and information. At present, agricultural, industrial and the 'third' so-called post-industrial civilizations, overlap and the direction of the transition is being slowly developed. Increasingly, new technologies are being used, less energy-consuming, based on renewable energy resources – solar, water, and chemical. It is conducive to the reconstruction of the destroyed natural environment and to the establishment of the concept of sustainable development. High-tech industries like: computer, oceanic, cosmic, or biological, where human knowledge becomes a very important resource dominate high-developed economies. Simultaneously, new possibilities for interpersonal communication emerge – the flow of information is getting faster, bigger amount of and more diversified information is being transferred, which is essential for the development of these industries and promotes their dissemination. In such a complex economic reality, it is becoming increasingly important to make more and more decisions, thereby the scope of delegation of responsibilities must grow, heading towards the idea of empowerment, what directs changes in the attitudes of Industry 4.0 engineers. In this respect Management 3.0 assumptions seem to be justified. The question of management tools, such as: methods, techniques, tools, that enable successful implementation in an industrial environment remain an open one.

Industrial enterprises may certainly be presenting a new type of organization, but the production activities of these forward-looking companies are completely different from those of classical economics. It will no longer be a closed factory that uses only resources like work, capital, and raw materials, but new organizations which will create collaborative networks, effectively exploiting and multiplying resources such as data, knowledge, and organization. Contemporary industrial enterprises, heading in the direction of knowledge-based organizations should be characterized as follows (Mikuła, Pietruszka-Ortyl, Potocki, 2007): (1) appropriate structure of resources and investments in intangible resources, (2) knowledge management, (3) building relationships with the environment, (4) appropriate organizational structure, (5) appropriate organizational culture, (6) change of roles and working areas of employees. The development of intellectual capital in this type of industrial enterprise primarily involves investing in the development of its individual components, inter alia by: (1) investment in employees' education, (2) protection of intellectual property rights, (3) investment in new information and telecommunication technologies, (4) increase in R&D investment, (5) application of cooperation development programs.

Undoubtedly, the creation of complex adaptive management systems is a requirement for an efficient organization and productive operation of intelligent Industry 4.0 enterprises. The idea of Management 3.0, which is based on the principles of: energize people, empower teams, align constraints, develop competence, grow structure, improve everything is a forward-thinking concept, ridding from rigid models and hierarchies for a nimble management approach to complex production systems.

Abstract

In modern conditions the agroindustrial branch represents the multifactorial complex integrated social and economic system which comprises agrarian formations of various ways of agricultural production.
The purpose of the article is the consideration of tendencies of formation, author's emphasis, justification of contemporary ways of agricultural production management in the Russian Federation, identification of the key reasons of support of the main ones. At the present stage of agricultural production development in Russia it is possible to allocate the following ways of agricultural production management: corporate, individual, state, family, homeownership.
Pinpointed are the current shortcomings of priority state support of the corporate way and the current positive aspects of state support of the family way of agricultural production. Problems of justification of support by types of way in the Russian agrarian economy sector are obvious and demand more responsible approach of public authorities to creation of conditions for sustainable development of all forms of economic management and equal approach to economic support of both large agricultural organizations (corporate way) and small forms of agrarian business (family way) which farms are. At the moment support of the latter way is mostly declarative.

Keywords: agriculture, ways of agricultural production management, organizational and economic mechanism of management, state support.

JEL Classification Codes: O 13, F-14, Q 18, R 38

Statement of the Problem

Throughout the development of history, the agrarian economy sector was represented by its characteristic forms of management. In modern conditions, the agroindustrial sector represents a multifactorial, complex integrated social and economic system. It comprises agrarian formations in various organizational and legal forms of ownership, having a variety of needs for different resources. A key feature of agriculture reform in the Russian Federation after the collapse of the USSR has been the transition from collective farming units (collective farms and state farms) in the countryside to the formation of a mixed agrarian economy with comprehensive organizational and legal forms of agriculture (societies, partnerships, peasant (farmer) farming units, state unitary enterprises.

The urgency of the problem chosen for the study is predetermined by the task of analyzing the existing organizational ways of agriculture and choosing the most optimal one in the context of a reduction in state funding for this sector.

1 The publication was prepared within the framework of the scientific project No. 16-32-00030, supported by Russian Humanitarian Science Foundation

Analysis of Recent Research and Publications

The choice of the desirable type of farming, taking into account the interests of the entrepreneur and the state, was of interest to many scientists.

Vainshtein A.L., Lopatin I.D. in their work "Optimum sizes of the agricultural enterprise" [1], as well as Ritter K., Chayanov A. (Ritter, Tschajanoff, 1923) "Peasant economy course" [2] touched upon this topic, but could not give it proper attention.

Taking as a premise his own understanding of the specifics of peasant farms, A.V. Chayanov made a significant contribution to the interpretation of the processes of their differentiation and proposed a typology of farming ways in the early twentieth century, which includes six types of farming units: 1) capitalist, 2) semi-labor, 3) well-off family-labor, 4) poor family-labor, 5) semi-proletarian, 6) proletarian [3].

At the present stage, according to Dürr J. (Dürr, 2016), the role of agriculture in economic development, promoting small farmers against large-scale agriculture, have been and remain at the center of a long and controversial discussion [4].

At the same time, another researcher, K. Iliopoulos (Iliopoulos, 2013), discloses the issues of agricultural production management way from the point of view of the possibility of obtaining state support in the EU countries by non-traditional agricultural cooperatives [5].

Earlier we conducted a study [6,7,8,9], which indirectly touched upon the indicated topic and demonstrated that a unified economy, a mathematical model, which should be different for different ways of agricultural production, is an effective means of optimal planning of expanding the volume of effective production of agricultural products.

Despite the large amount of works in this field of research, typification and selection of the most promising way in the field of agricultural production remains of current interest.

Purpose of the Article

The purpose of the article is to review the trends in formation of, the author's emphasis of, the rationale for the current ways of agricultural production in the Russian Federation, and the identification of key reasons for supporting the main ones.

Main Results of the Study

The problem of choosing the optimal ratio of the size and type of agricultural production, is now very acute for Russia and is not fully assessed, either by the peasants themselves or by the country's leadership. However, as a matter of fact, the system of correlation of large-scale agricultural producers and small farms that is being formed in this period lays such foundations as food security, territorial organization, social equality, and the harmonious development of the country's territory as a whole.

The choice of this or that organizational and legal form is predetermined by the following factors:

- the aim of the agricultural business which is the basis for its management (the large-scale production, small-scale production, self-employment), that is, consumer or entrepreneurial approach with the selling of the surplus;
- the level of property responsibility of the founders, owners of the organizational and legal form;
- the legal criteria governing the management of enterprises of various organizational and legal forms (vertically integrated holding, horizontally integrated holding, society, peasant (farmer) farming unit);

- the fundamental approach to agricultural production management, based on family (small-scale production, self-employment with the involvement of relatives and possibly outsiders) or collective (large-scale) forms of labor organization.

At the present stage of agricultural production development in Russia it is possible to single out the following ways of managing agricultural production: corporate, individual, state, family, homeownership. We will dwell on each of them in more detail.

The corporate way is diversified large-scale agricultural agroindustrial holdings (investment companies) that have a branching network of subsidiaries that are not limited by the presence in one region, having a diverse specialization, at the head of which there is a parent company. The main goal, like in any large-scale business, is to maximize profit with reduced interest in the social development of the territories. This type of enterprise includes such enterprises as AIH Miratorg, OJSC Group Cherkizovo, OJSC Efco, etc.

The individual way is medium-sized farms, designed for commodity production of agricultural products that do not have a branching network (and are represented by local farms), limited by the presence in one or two districts of the region, having a narrow specialization.

The state way is a few farms of agroindustrial production preserved after the collapse of the USSR. This type includes such agricultural enterprises in agrarian educational institutions as training and experimental farms.

The family way is mostly represented by peasant farms, based on the involvement of family members, limited use of hired labor (only for seasonal work), the owner himself performs the main work, independently manages the production process, adopts and implements all decisions on production management. An important distinctive feature is the accommodation directly on the farm with the family. The predominant progressive thought of development is the well-being of the farming unit and of the territory as a stronghold of existence, the aim of large-scale commodity production is developed to a lesser degree than in other ways, while maintaining the development of agriculture in the given territory. This type includes a limited liability company, large farms, large personal subsidiary plots.

The homeownership way is represented by activities that mostly are not related to entrepreneurship, but are aimed at the production of agricultural products for one's own needs, with possible selling of surpluses, thus it is not a commodity production. In this way the availability of land resources is minimal, labor resources are represented by family members and in rare cases hired workers are employed. This type includes personal subsidiary plots, small farms.

Here we would like to note that profit is not the main task of economic activity of such agricultural production ways as the family way and the homeownership way. They are more focused on the development of the family.

However, with proper development of production activities, state support and the emerging synergetic effect, in the family way family-collective values will be combined with the goal of increasing production and reaching the level of large-scale production. That will ensure sustainable development of rural areas as an indispensable condition for preserving labor resources, population density and harmonious distribution of the country's population.

Table 1: The main indicators of agricultural development in the Russian Federation, in terms of

farm categories

Name of key figure	2000	2005	2010	2011	2012	2013	2014	2014 in % to 2000
Agricultural organizations								
Number of cattle, thousand heads	16509	11064	9256	9165	9060	8800	8523	52
Number of pigs, thousand heads	8518	7317	10815	11430	13679	14705	15588	1.8 times
Total area under crops, thousand hectares	74192	60472	56104	56643	55665	56096	55285	75
Peasant (farmer) farming units, including individual entrepreneurs								
Number of cattle, thousand heads	543	932	1476	1693	1931	2049	2145	3.9 times
Number of pigs, thousand heads	403	566	798	666	559	463	422	105
Total area under crops, thousand hectares	6501	11942	15601	16531	17155	18575	19727	3.3 times
Farming units of the population								
Number of cattle, thousand heads	10468	9629	9236	9253	8939	8715	8596	82
Number of pigs, thousand heads	6903	5929	5605	5162	4578	3913	3536	51
Total area under crops, thousand hectares	3977	3423	3482	3488	3505	3386	3513	88

Source: calculated by the authors on the basis of data from the Federal State Statistics Service of the Russian Federation

The identification of features in the production of agricultural products by farm category always causes genuine economic interest. Each farming unit category has its own characteristics and advantages in the production of agricultural products. For example, the farming units of the population have the smallest share in the production of grain and milk, but at the same time they have the highest yield and productivity for the five-year period. The major financial infusions into dairy farming through investment companies could not push it from stagnation, did not stop the fall in the number of cows [10]. And the farming sector, with minimal state support, has been showing steady growth of the livestock all these years: by 3.9 times in 15 years.

In 2014 peasant (farmer) farms in Russia, including individual entrepreneurs, produced agricultural products at current prices in the amount of 422.7 billion rubles. Compared to 2013, the volume of gross output (in comparable prices) increased by 11.2%, including in plant production by 12.3%, in livestock breeding by 7.5%. For comparison: in agricultural organizations, production in 2014 increased by 6.8%, and in farming units of population decreased by 3.2%.

The dynamics of the growth in the number of farms in the Russian Federation looked like this: 1991 - 49,013; 1995 - 280,112; 2000 - 261,100; 2014 - about 200 thousand, even less farms conducting agricultural activities. Russian farming is still developing in an unstable and not always cost-effective way. There is a clear tendency towards a decrease in the number of Russian peasant (farmer) farms, not only because of their enlargement.

In foreign countries this historically traditional form of farm management has evolved from a semi-natural farming unit to large and medium-sized commodity production [11]. The development of

family farming in Europe received significant state support after World War II. In the former Soviet republics farming units, like in Russia, have developed since 1990. In all countries there is a multi-structured multi-way agriculture, while state support for farms, in particular family farms, continues.

The State Program for the Development of Agriculture and Regulation of Agricultural Products, Raw Materials and Food Markets for 2013-2020 in the Russian Federation includes a special subprogram "Support of Small Forms of Management", the subprogramme's resources were provided in the following areas: support for beginning farmers; development of family livestock farms on the basis of peasant (farmer) farms; ownership registration of land plots by peasant (farmer) farms; state support for small business loans.

We can look at the example of a typical agrarian region of the Russian Federation - the Kursk region, and the promising indicators of the development of small forms of management on the land, which are laid down in the Subprogram "Development of agriculture, food and processing industries in the Kursk region for 2014-2020" [12]. The planned number of peasant farms created with the help of state support, envisioned in the program under consideration, is 53 units by 2015, which is almost 4 % from the number of peasant farms registered in 2014 (1339 units). The area of land plots that are registered into the ownership by peasant (farmer) farms, including individual entrepreneurs, for the program's period is 9.2 thousand hectares, which is only 3.6 % of the total land area provided for farmers at the end of 2014 (262.7 thousand hectares). It is obvious that the implementation of the program under consideration does not help to solve the problem connected with the development of small and medium-sized forms of management on the land.

The current target subprogram of agricultural development in the Kursk region for 2014-2020 does not provide for the distribution of resources according to the areas of their use, nor does it reflect the consideration of state support from the federal budget, which in turn creates difficulties associated with the use of indicative indicators of this program as a tool for program-target regulation of innovative development of regional agriculture in order to increase the level of food security.

The abovementioned example of one of the regional programs, on the whole, reveals the essence of the federal program which is mostly declarative: the indicators for the growth and improvement of agriculture efficiency, designed in the subprogram under consideration, have no economic feasibility, are not supported by any forecasting or analytical economic planning calculations; the text of the program, subprograms and appendices does not contain a justified agreement on the resource potential, distribution of agricultural products and production balances, schemes and descriptions of the location of agricultural production in the country.

The problems of support feasibility by ways of agricultural production in the agrarian economy sector are obvious and require a more responsible approach of government authorities to creating conditions for sustainable development of all forms of management and an equal approach to economic support of both large agricultural organizations (corporate way) and small forms of agrarian entrepreneurship (family way) which farms are.

With intensive development of the family way, the country receives additional volumes of quality food and, which is no less important, the stability of the social and economic development of rural areas increases. Today in the Russian Federation a trend is forming for the concentration of large-scale agricultural production in comfortable rural settlements, but there remain a large number of small villages and villages whose population is dying out, and there is no purpose of supporting such villages and the local population, as large investment companies (supported by the state) are not interested in this.

The policy of agricultural development of the Russian Federation in fact focuses on the implementation and support of investment projects (ranges from 17.5 billion US dollars to 350 billion US dollars), designed to attract significant private and public investment. In most Russian regions more than half of the subsidies fall on a single borrower. In the Chechen Republic all subsidies are allocated to one limited liability company, in the Primorsky Territory 99% of the subsidies fell on one Moscow agricultural holding [13]. And the direct consequence of this is an extremely low dynamics

of agricultural production growth, a chronic disadvantage of the village. The village continues to lose human capital at a rapid pace.

We will highlight the existing shortcomings of priority state support of the corporate way:

- the economic model of management in rural areas is destroyed, which leads to depopulation of the territtorry;
- the cost of large-scale investments is overestimated (corruptness), as a result there is a long payback period or sunk costs of projects and high debt load of the industry;
- the quality of the products is reduced (improper ration of animal feeding, use of antibiotics, veterinary drugs). As a result, often unsalutary products are produced;
- the ecological balance in rural areas is destroyed;
- the struggle between farmers and large businesses for the rental of shares of rural residents, as a consequence there is the growth of latifundia.

At the same time, we will note the existing positive aspects of state support of the family way of agricultural production:

- high quality of products produced among other things through organic farming;
- environmental safety of production itself and habitat;
- flexibility and low cost of investment;
- involving the local population in the business and ensuring its integration with existing businesses;
- preservation of the rural population of the working population of the country.

The family way of management today is not just agricultural business, it is a form of social organization of rural areas. The farmer should become a key figure of the rural economy in raising the level of the social life of the village. It is also important to have a real program for the development of peasant (farmer) farms.

Conclusions

Agroindustrial production has a tendency to move from simple to complex, from small to large. This is typical both for technology and the organization of production, the means of labor used, the size of the functioning enterprises, and for the systems of economic management.

In the current conditions of management in the agrarian sector, when the globalization of the economy inevitably leads to a process of increased intensification, industrialization, enlargement of production, on one hand, and increased competition and, consequently, the need for increased efficiency of production activity on the other hand, the state, as the regulator of agricultural development has a difficult task to choose the support of any given way. The choice of differentiating each of them predetermines the growth of agricultural production or the preservation and increase of the rural population itself employed in rural areas.

The simplest solution of the first task is to support the corporate way of farming, which to a greater extent has been implemented in the territory of the Russian Federation, with the formal declaration of the second task.

However, if the state seriously took care of increasing the volume of production of agricultural products by supporting the family way, then by rebuilding roads, power lines, assisting in construction, acquiring equipment, seeds, animals, etc., it would be possible indeed to introduce additional areas of agricultural land into the agrarian production and, on the basis of private ownership of land and new motivational factors for work, to bring a considerable share from the farming sector (family way) into the total volume of agricultural production of raw materials and foodstuffs in the country.

Multistructure in the Russian agrarian economy sector is impossible without the diversity of organizational and legal forms of management. Peasant farms are the main structure of small and medium-sized agricultural businesses and have the right to their positive development.

The activities of family farms are important for the preservation of rural settlements and rural areas. The catastrophic processes of extinction of villages can be stopped - first of all by creating economic conditions for profitable management in a considerable number of rural families, which would allow both to feed the family and to provide extended reproduction.

The task of the state today is to create economic conditions and remove barriers that impede the sustainable development of peasant farms as small agricultural business entities.

In most countries the family way develops in conditions of cooperation, which is not present in modern Russia. Not everything that exists now in this sector in foreign countries can be applied in Russia in a mirror manner, but much is not only possible but also necessary to introduce into the development of the family way in the agrarian sphere in the Russian Federation.

Unethical Leader's Identity: a Simple Model and its Methodological Application

Marian Stančík
Institute of Management at Faculty of Management, Comenius University in Bratislava
Odbojárov, Bratislava, Slovakia
marian.stancik@fm.uniba.sk

Abstract

Since a leader can hide unethical actions and/or pretend ethical communication, an ethically positive self-image of an unethical leader can be intentionally achieved in the eyes of followers. This conference paper presents a simple model of unethical leader's identity (consisting of moral actions, communication and values) and its complementary potential for further research in the field of unethical (as well as ethical) leadership.

Keywords: Unethical leader's identity, ideology-based research approach, unethical leadership

Introduction

Many known authors, diverse empirical frameworks (see: Theoretical background) and popular conceptualizations (Padilla et al., 2007; Thoroughgood et al., 2012) are available, nevertheless (un-)ethical leadership stays a social phenomenon with a variety of conceptually different definitions.

But, how can anybody tell who is actually an unethical leader, if environmental factors like e.g. national culture (Ferencikova et al., 2016; Scholtens and Dam, 2007), individual factors like e.g. moral awareness (Rest, 1986) or individual development (Rest and Narvaez, 1991), as well as diverse situational factors e.g. information availability (Akerlof and Dickens, 1982) or salience of moral norms (Nye and Forsyth, 1984) and a whole spectrum of conflicts due to economic rationality play important roles besides? And, how to deal with observed paradoxes, when an ethical leader at work behaves unethically in private (Riggio et al., 2010)? Or, how to address a phenomenon when a direct leader is reported more cynically, but the one at the top of the hierarchy, personally unknown to the follower, is reported positively (Lord and Maher, 1991)?

The herein suggested theory bases on the Leader-Member-Exchange theory (Graen and Uhl-Bien, 1995) abbr. LMX which introduced the importance of a dyadic leader-follower relationship and the Implicit Leadership Theory (Rush et al., 1977) abbr. ILT which introduced the importance of follower's perception. But, opposite to recent trends in the field of (un-)ethical leadership, the suggested theory is derived from the author's working thesis *"consequences of an unethical leadership do not need to appear immediately"*.

To overcome the matter of time-dependent information processing, let us suggest moving object of research from its tangible area of a leader-follower dyad (any behavior, traits and characteristics) to its intangible but still descriptive and measurable area (cognition based on moral values and ideology) which is independent on the matter of leader's observable behavior and/or follower's perception. Hence, an alternative approach to study a well-known topic of (un-)ethical leadership attempts to uncover details which have not been considered so far.

Theoretical Background

To address the scientific chances and challenges of the research presented in this paper, let us first outline the situation using a selective analysis of four frameworks previously developed to measure ethical leadership (abbr. ELp).

The first analyzed tool to measure ELp is called Ethical Leadership Scale (Brown et al., 2005). Abbr. ELS bases on a social learning perspective. Brown et al. divert from a classical philosophical point of view "how leaders ought to behave" and propose a descriptive behavioral approach to measure ELp. According to social learning (or also cognitive) theory (Bandura, 1971), one's behavior can be acquired by observing and imitating others. Hence, Brown et al. build up a correspondent model to measure ELp through the follower's perception accordingly. The first comment that catches the reader's attention is when the authors discuss limits of this approach due to perceptual biases behind the self-other-agreement; one knows that leaders are almost certain to rate themselves favorably on the ethical dimension of leadership. Another comment that catches attention is the discussion on the levels of management; the extent of hierarchical distance from leader to follower plays an important role since the substance for a personal relationship disappears but the matter of an image-based relationship increases. Let us for now note that these two observations are important for further conceptualization because leader's formal power (thus hierarchical position in logical extent too) and his own perspective-taking (as a crucial precondition for an ethical leadership) correlate negatively (Galinsky et al., 2006; in Pink, 2012, p. 70)

The second analyzed tool to measure ELp is called Leadership Virtues Questionnaire (Riggio et al., 2010). Abbr. LVQ bases on four cardinal virtues (originally mentioned it texts written by Aristotle). Riggio et al. distinguish their work by pointing out the social learning approach limits of ELS. They mention the fact that leaders develop their own ethical leadership behavior by emulating admired, ethical leader role models; but, due to ethical relativism, leaders hence might get easily misguided. Let us here note that this is one of many reasons due to which unconscious leader's behavior plays an important role and thereby any methodology based on measuring tangible behavior must deal with the same troubles when interpreting results. Therefore, as a solution, authors propose to refocus the object of measurement at leader's traits and characteristics because characterological elements are independent of leader's behavior. Let us again mention two interesting limits that catch the reader's attention. Authors of LVQ discuss that the correlation with follower's moral identity, empowerment and organizational identification were better scrutinized longitudinally or experimentally than measured at the same time as the follower's perception of leader's virtues; ethical leadership impact is thus questionable since followers e.g. might not be morally capable of recognizing leader's virtues. While the second limit towards LVQ predictability roots in the fundamental emphasis of social psychology; one knows that the power of the situation overrides characterological factors. Again, let us for now note that these two observations are important for further conceptualization since the difference between intended and effectuated moral behavior is as old as humanity per se can remember and carries over.

The third analyzed tool to measure ELp is called Ethical Leadership at Work questionnaire (Kalshoven et al., 2011). Abbr. ELW bases on a multi-dimensional measurement whose authors critique ELS and LVQ as unidimensional tools that are too simple to measure the complex topic ELp. Therefore, Kalshoven et al. developed a complex set of dimensions to measure and evaluate leadership in terms of ethics and thus contribute to overcoming deficits of previous tools. No matter how complex and comprehensive this model is, let us note that it relies on measuring leader's behavior according to follower's perception and thus have empirical limits in common with many other behavioral frameworks. One comment that catch the reader's attention is the discussion about its predictability towards cultural environment; e.g. the importance of "power sharing" dimension might vary based on the well-known cultural "power distance" dimension. Hence, let us note that this reflection is important for further conceptualization; Since the interdependency of the ethical and the cultural systems is tricky for any social research application (e.g. Scholtens and Dam, 2007), its separation on the other side is a doctrine for an organizational anthropology in cross-cultural environment (Hofstede and Hofstede, 2006).

The forth analyzed tool to measure ELp is called an Improved Measure of Ethical Leadership (Yukl et al., 2013). Abbr. ELQ integrates Leader-Member-Exchange model (known as LMX) and puts work unit performance into focus. In comparison to previously analyzed approaches, the ELQ authors consider leader's individual moral balance of competing goals when influencing work unit performance; ethical leadership might have unethical consequences and, vice versa, e.g. unethical leadership towards individuals might have ethical consequences towards an organization etc. The reader's attention catches the discussion in terms of managerial effectiveness; being an ethical leader is not only commendable but also effective. Even though Yukl et al. count with the importance of leader-follower relationship, let us here note that they do not distinguish nor discuss the correlation of formal (positional at work) and informal (personal as friends) level of their dyad. Since formal and informal relationships coexist in practice all the time everywhere, let us note that this is a very important dimensionality especially in terms of chances for an unethical leader's behavior (e.g. corruption in public sector).

To sum up the analysis of four selected frameworks let us point out that neither applying the recommended 360-degree approach nor the self-other agreement correlation of any of these tools would in the future provide comprehensive answers to the questions introduced in this paper. No matter how many times mentioned in diverse studies, none of the known theoretical frameworks nor research approaches conceptualize the phenomenon of "ethically behaving leaders on workplace behave unethically in private life and/or vice versa" as an integrated as well as interdependent model. Hence, there is a chance for a new model and methodology that is to be presented in the following chapters.

Materials

According to Hunter, all reviewed materials related to unethical leadership have at least one similarity: complexity. And, as he also notes, at least one common need for further investigation: identity (Hunter, 2012). Let us therefore focus on identity closely and suppose that simplification is a strategy to deal with troubles of a current field of research.

The first instrument to build up a comprehensive model of an unethical leader's identity is a definitional analysis of unethical leadership. Known authors like to describe leadership with adjectives e.g. narcissistic, toxic, destructive, dark, dysfunctional, psychopathic, self-serving, despotic or even tyrannical. According to an extensive conceptualization of current theoretical trends by Lašaková and Remišová, "unethical leadership is a process of intentional or unintentional, passive or active, and recurrent influencing that harms others, being it individuals, organizations and/or society as a whole." Authors also define the following preconditions for an unethical leader: a) leader acts badly (lacks certain ethical virtues and engages in unethical acts), b) leader allows bad acts to happen, c) leader is ethically silent (does not voice the importance of ethics at a workplace), d) leader is absent (avoids contact with others or absents it at all), e) leader is self-centered, self-protective and self-serving, f) leader lacks respect to rules and g) leader is professionally incompetent (Lašáková et al., 2016; Lašáková and Remišová, 2015).

The second instrument to build up a measurable model of unethical leader's identity is an applicational analysis of ethical ideologies. According to the fundamental Theory of Ethical Positions (Forsyth, 1980) there are 4 ethical ideologies (or also called Ethical Position) derived from a 2x2 matrix. This concept is defined by dimensions of "ethical relativism" and "ethical idealism" (see: Table 1) and can be evaluated by using Ethics Position Questionnaire (abbr. EPQ).

Table 1: Adapted from the Taxonomy of Ethical Ideologies (Forsyth, 1980)

	Low Relativism	**High Relativism**
High Idealism	Absolutists: Principled idealists who believe people should act in ways that are consistent with moral rules, for doing so will in most cases yield the best outcomes for all concerned.	Situationalists: Idealistic conceptualists who favor securing the best possible consequences for all concerned even if doing so will violate traditional rules that define what is right and what is wrong.
Low Idealism	Exceptionalists: Principled pragmatists who endorse moral rules as guidance for actions, but admit that following rules will not necessarily generate the best consequences for all concerned.	Subjectivists: Pragmatic relativists who base their ethical choices on personal considerations, such as individualized values, moral emotions, or an idiosyncratic moral philosophy.

According to Forsyth, ethical relativism is interpreted as "while some personal moral codes emphasize the importance of universal ethical rules … others maintain a posture of relativism that skeptically rejects universal principles" (Forsyth, 1980). Based on this interpretation, let us suppose that *breaking, bending or respecting rules* in general refers to *one's own belief about the frequency of behaving in line with social norms as well as legal rules*. Further, the meaning of ethical idealism is interpreted by Forsyth as "while a fundamental concern for the welfare of others lies at the heart of some individuals' moral codes, others do not emphasize such humanitarian ideals; the former assume that we should avoid harming others, while the latter assume harm will sometimes be necessary to produce good" (Forsyth, 1980). Based on this interpretation, let us suppose that *caring less/more about others* in general refers to *one's own belief about the quality of behaving towards others or at the expense of others.*

Based on the argumentation above, let us further defined **unethical leader** (abbr. ULr) as *a leader who a) breaks/bends rules/norms more than a follower expects and/or b) cares about a follower less that a follower expects of him.* Regardless of this simplification, let us note that such a definition of ULr is in line with all preconditions of ULr by Lašaková and Remišová and, at the same time, in line with Forsyth's Theory of Ethical Positions; while the follower's expectation is thereby anchored to his own experience with ULp and thus grounded to the social learning theory (Bandura, 1971).

To conclude in other words, *an ULr is and/or behaves more subjectivistic than a follower expects of him*. And, since the meaning of "ethical" excludes "unethical" and vice versa, let us analogically suggest that *an ELr is and/or behaves more absolutistic that a follower expects of him*.

Results

Based on two selected instruments and one definition, let us now suggest that the "Who is an unethical leader" question can be answered with the help of a simple model of an (un-)ethical leader's identity.

Firstly, to deal with diverse terminologies and frameworks used by behaviorists, let us suggest that *one's moral behavior can be understood in detail through his moral actions (abbr. a) and communication (abbr. c); while one's moral values (abbr. v) can be understood in detail through his Ethical Position.* Where the *moral decision making is understood as a process from an intended to an effectuated behavior.*

Secondly, based on the suggestions above, let us define an auxiliary model of one's identity flowingly: **one's identity** *consists of actions (abbr. -a), communications (abbr. -c) and own values (abbr. -v) in the way as they are perceived by one's self or by others*. And let us note, that such a definition is in line with basic ontological assumptions for social research.

Finally, let us induce and thereby define **(un-)ethical leader's identity** *as a set of (un-)ethical actions (abbr. -ra), (un-)ethical communication (abbr. -rc) and (un-)ethical values (abbr. -rv) a leader recognized of himself (or, also, consciously holds) as well as a follower so far perceived of his leader*. Thus defined, there are 6 independent parameters to consider.

So, how is a follower actually going to perceive a leader? In respect to the model of unethical leader's identity the following picture appears (see: Figure 1 and related discussion).

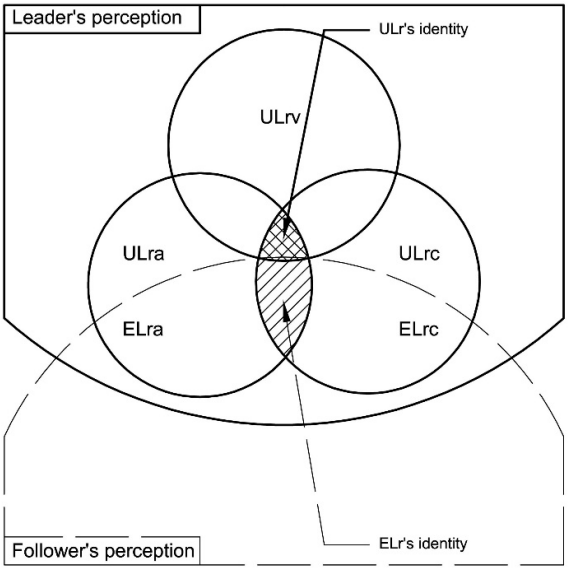

Figure 1: Ethical vs. unethical leader's identity (source: own production)

Discussion

Now, to test this model out, let us firstly remind that (1st premise) *the consequences of ULp do not exist until recognized by followers*, secondly that (2nd premise) *the leader's action can be hidden and/or communication pretended*, while thirdly (3rd premise) *the leader's value system is a moderator between his own actions and outside communication*.

Although a leader might behave unethically because he is unconscious of the consequences his behavior produces and/or is not aware of the follower's moral expectations, the first and second research premises imply that the *meaning of „is" relates to one's values, neither to actions nor communication.* Going back to the definitions of an (un-)ethical leader, one can assume that *if a follower perceives an ethical leader's behavior, it does not automatically mean that the same leader „is" ethical indeed.* And vice versa.

Supposing that a follower does not know a leader personally (see: Figure 1), the application of the first and second research premises explains why *the moral values a leader holds of him and the moral values a follower holds of his leader do not technically need/have to be the same values.* Going back to the definition of an unethical leader's identity, an *ULr might be able (intentionally) to achieve a positive (ethical) image of himself at the level of the follower's perception.* But the follower might never know.

Hence, the vagueness of antecedents and consequences related to unethical leadership might be rooted in (intentionally) shifted perceptions of a dyadic reality; *the leader's Ethical Position according to the follower's perception is not/does not have to be the same as an Ethical Position a leader holds in real.*

No matter if such a shift in Ethical Positions is a product of legal rights and duties varying across the hierarchy, status of social groups or only individual interests. No matter if this vertical, in terms of social structures, shift in ethical ideologies is a personality antecedent for a successful rat racing or a consequence of national and/or organizational cultural dependencies. Let us for sake of this paper deduce (in relative terms) that *ULr holds a subjectivistic moral ideology, while ELr holds an absolutistic moral ideology* per se.

Although the measurability and result interpretation foresee its own limits, a further development of this model and related research methodology is open to integration with e.g. the theory of Cognitive Dissonance (Festinger, 1962) which could allow a more complex scientific and empirical application in the future. In terms of practical application, this simple (un-)ethical leader's identity model foresees a usefulness wherever any form of management and communication take place e.g. in the field of human resource management, political marketing strategies, cultural and organizational anthropology, negotiation and conflict-solving styles etc. Finally, this paper is a partial work towards understanding Slovak business culture and author's further research is therefore intended to achieve its unique conceptualization.

Besides that, once so openly defined for any other application, future research might take different directions. In terms of theoretical conceptualization, the new theoretical definitions of *a naive follower (the one who believes his leader is more ethical than he is in real)* and *a distrustful follower (the one who believes his leader is more unethical than he is in real)* need to be alternatively stipulated and, thereby, their coerced coexistence related to the model of (un-)ethical leader's identity is to be underlined. In terms of methodological development of an ideology-based approach of (un-)ethical leadership, the original EPQ must be adjusted to reflect the leader-follower dyad as technically as possible. In terms of philosophical groundwork, the bias for the result interpretation must be defined at front: Is one's state of mind (matter of subjective perception e.g. ethical consequences) an antecedent or a consequence of a state of reality (matter of objective fact e.g. cultural standard as a reference point)? And, since these two main ontologies are interdependent, how do they interfere with each other in practice?

Conclusion

The conference paper proposes a simple model of unethical leader's identity, in terms of moral actions, communication and vales, and its complementary potential for further research on ethical and unethical leadership.

The suggested theory and research approach propose to divert from researching follower's perception of leader's behavior in terms of ethics; it suggests researching follower's cognition based on own experience with leadership style over time which is independent on the matter of leader's observable behavior and/or follower's perception in the current situation and/or moment of time.

Discussing its methodological application, a variety of possible interpretations can be conducted. According to the definition of one's identity, an unethical leader has two "scientific faces" to be researched separately; one for himself and another for his followers. But, opposite to other methodologies, these two faces are clearly interconnected and, thus, a descriptive, causal, nomological, comprehensive, cross-culturally applicable, integrated and still measurable grounded theory to solve some empirical dilemmas e.g. self-other-agreement is herein offered for discussion.
Hence, an ideology-based approach to researching (un-)ethical leadership is proposed. Let us hope that the idea behind this conference paper helps the scientific community to understand observable (un-)ethical paradoxes at the individual level of leader-follower dyad and many irrational phenomena observed at the organizational, institutional or even public-government level too.

Abstract

The aim of this study is to investigate the relationship between well-being initiatives and employees' perceptions of well-being initiatives in different organizational contexts. We conducted a cross-context analysis of well-being initiatives in three companies operating in different sectors. Findings highlight that organizational contexts (organizational culture, organizational structure and work processes) shape management's strategic intentions about the well-being initiatives offered (i.e., the criteria used to configure the well-being packages), and the intentions that employees attribute to management's decision to offer a given configuration of well-being packages. We contribute to the process-based research of HRM and to the well-being literature by theorizing on the interplay between employers' strategic intentions and employees' attributions of intentions.

Keywords: HR practices effectiveness; organizational well-being initiatives, employee perceptions, organizational context, process-based HRM

Introduction

Well-being is a popular notion in today's society, a virtue as much desired and promoted as contested and debated (Sointu, 2005). Among well-being topics, health and well-being in the workplace have become popular topics, achieving, in the last 50 years, growing impact in mainstream media, practitioner-oriented magazines and scholarly journals alike (Cooper and Cartwright, 1994; Danna and Griffin, 1999; Grant et al., 2007; Huppert and So, 2013; Smith et al., 1995; Sointu, 2005; Diener et al, 1999; Keyes, Schmotkin, and Ryff, 2002; Seligman, 2011). Leaders and managers are enhancing employee well-being in various ways, from professional development and employee recognition practices to healthcare benefits and free employee assistance initiatives, with the belief that these can provide a wide range of competitive advantages for the organization, such as higher employee performance on the job, higher capacity to attract and retain employees and higher recognition of the organization in its external environment (Danna and Griffin, 1999; Gant et al., 2007; Hartwell et al., 1996; Grawitch et al., 2006; Rynes et al., 2002; Sointu, 2005). While most competitive advantages deriving from well-being initiatives are associated to conditions that are internal to the organization (i.e., organizational performance and climate, employee commitment, retention, engagement, etc.), others have increasingly concerned organizational image with respect to external stakeholder such as customers, public press or potential employees. As a consequence, organizations that foster employee well-being are increasingly acknowledged by societal awards, such as Fortune magazine's annual list of the "Best Companies to Work For" and are recognized by current and prospective employees as desirable places to work.

However, well-being has been everything but a straightforward concept, both in research and in the societal sphere. It is widely acknowledged that conceptualisations and experiences of well-being are ambiguous or even contrasting, according to the different institutional settings in which they are produced (Sointu, 2005). Recent studies have identified considerable cultural ambivalence about how to implement work–life balance initiatives, and whom these must ultimately benefit. Questions are raised regarding the feasibility of benefiting different types of workers and organizations at the same time as well as about the possibility of reconciling competing interests between employees and employers. For instance, studies have highlighted the tensions in implementing initiatives that ultimately truly benefit both employers and employees, and have suggested the difficulties of reconciling multiple stakeholder agendas and identifying a common good nexus (Kossek et al., 2006; 2009). The ambiguous and contested nature of well-being is explained in part by the tendency of employers and employees to turn well-being into an increasingly broad, overarching concept which entails multiple dimensions, from health, spirituality, job satisfaction and up to work-life balance, such that, taken together, these can provide an indicator of the life satisfaction of "the whole person" (Warr, 1990; Jamison and O'Mara, 1991; Forgeard et al. 2011). Paradoxically, the wider the concept becomes, the more opportunities it offers for organizations and employees to draw on it differently, according to interests at hand (Kossek et al., 2009). However, relatively little research has explored how well-being initiatives -as proposed by highly different organizations and as experienced by multiple types of employees- are shaped by organizational settings.

In line with emerging research, we argue that to truly understand the underlying causes of well-being, as promoted by organizations and as perceived by employees, one must understand the context in which well-being initiatives are co-produced (Allen et al., 2013; Kossek et al., 2009; Ollier-Malaterre, 2009). From such standpoint, an increasing number of studies have suggested that organizational and institutional contexts impact the well-being initiatives that organizations decide to offer to their employees (Allen, 2001; Goodstein, 1994; Milliken et al., 1998; Ollier-Malaterre et al., 2013; Powell et al., 2009). Other studies have investigated employees' perceptions of well-being initiatives (Eby et al., 2005; Rhoades and Eisenberger, 2002; Shore and Shore, 1995; Thompson et al., 1999). As far as the first aspect is concerned, studies have identified a range of meso-level variables at the organizational level: organizational sector, setting and structure, demographic composition of organization, HR practices and initiatives, well-being culture, work groups and supervisor support (see Den Dulk et al., 2012; Goodstein, 1994) that impact the type of well-being initiatives being offered at the organizational level. Accordingly, organizations make both implicit and explicit choices regarding the adoption of certain practices and procedures as to reward and support certain employee behaviours. Organizational factors (i.e., structural and cultural) have been said to significantly shape the strategy that organizations adopt concerning well-being initiatives (see Allen, 2001; Ollier-Malaterre et al., 2013). Yet currently we have a limited understanding about this phenomenon and how it contributes to shape employees' perception of well-being initiatives.

As concerning employees' perceptions of well-being initiatives, various studies have highlighted that while a company might decide to make certain well-being initiatives available, not all employees may choose to take advantage of them, and not in all cases these will have a positive effect on employees' job satisfaction and affective commitment to the organization (Allen et al., 2013; Bardoel and DeCieri, 2006; Ollier-Malaterre, 2009; 2010; Thompson et al., 1999). In some cases, well-being initiatives may be administered in ways that limit employees' control over how, when and where they work. An insistent and universal promotion of employee initiatives outside the organization might upset employees if they perceive these are used by organizations to promote their own interests and image (Ollier-Malaterre, 2010). Employees may also discount available initiatives when implementation is not perceived in line with formally stated initiatives or when they are applied unequally or discretionally by managers and supervisors (Kelly and Kalev, 2006; Kossek et al., 2005; Lambert and Waxman, 2005; Shanock and Eisenberger, 2006). However, few studies have looked at both sides of the coin so far.

To understand the processes underlying these contrasts, Ollier-Malaterre (2010) calls for renewed attention to employees' awareness, need, use and judgment of organizational initiatives, and suggests that these aspects might develop in a relational space, at the interface between personal factors, organizational environment and institutional environment. From such perspective, how well-being

initiatives are proposed, on the one hand, and how they are perceived and used, on the other, are mutually-constitutive, and shaped by the culture and institutional frame in which the work environment is situated.

Research objectives

We suggest that adopting a relational perspective in which well-being initiative perceptions are a result of negotiated interactions with others (Ollier-Malaterre, 2010), can contribute to reducing this gap. To give an example, previous studies have overlooked whether employees' perception of organizational initiatives as genuine or legitimating, as enablers of their own needs or as constrainers, are related to their perception of the type of organization for which they work (see Allen et al., 2013; Friedman and Lobel, 2003; Grawitch et al., 2006; Kelly and Kalev, 2006). For instance, working in a large private company specialized in tangible goods production in which male employees are predominant might determine HR managers to offer different well-being initiatives than a public company specialized in intangible goods delivery in which women employers are the majority. The first may decide to invest more in development and health and safety initiatives, while the second might decide to give prevalence to work-life balance initiatives. In turn, how employees in the two companies will perceive the initiatives might depend on their understanding of the organization for which they work, and the sector in which it operates. Yet so far few studies have looked symmetrically at both employer and employee perspectives, considering the interests of one in relation to those of the other, and investigating the relation between availability, voluntary or involuntary use, and reports of perceived control among employees and employers (Thompson and Prottas, 2006).

We suggest that a perspective that takes into consideration the characteristics of the organizational setting, and the way they are perceived by employers and employees alike, may significantly contribute to advancing the argument (Kelly et al., 2011). Accordingly, organisations' well-being initiatives and their effect on employees must be considered within the context in which the organization operates (Kelly and Kalev, 2006). Organizational factors such as structure and culture represent further considerations that must be taken into account when trying to investigate employee's perception of the well-being practices they are exposed to.

Consequently, our research question is:

How do organizational characteristics influence organizations' employee well-being initiatives and the perceptions of the employees regarding availability and propensity to use?

Context and Methods

In our study we perform a qualitative cross-context analysis of well-being initiatives in three organizations active in different sectors – mechatronic industry, insurance services and knowledge intensive services – to investigate the relationship between organization contexts, well-being initiatives (in our study labeled as "well-being packages") and employee perceptions of well-being initiatives. Sait Industries is a leader in the design and creation of advanced mechatronic systems for power transmission in agricultural and industrial machines. Sait has more than 1500 employees, six production plants across two continents. Royal Insurance is a leading global insurance company with franchised offices in 60 countries which count about 80.000 employees. Franchises are highly standardized environments and heavily regulated by the parent company as far as locations, workspace layout, functional divisions inside the franchises, work hours and interaction with clients are concerned. Project Consulting is a consulting knowledge intensive firm specialized in the design of data warehouse management, business intelligence, big data analytics and performance management. It was founded in 2001 by a group of university researchers who made of IT research applied to business the strength of their company. Project Consulting is currently traversing a phase of intensive expansion; it employs 130 people, a number which has doubled over the last 5 years. Project Consulting has won several prestigious international awards.

Our data collection consisted in semi-structured interviews with top management, HR managers and employees in each organization, for a total of 70 fully-recorded, fully-transcribed interviews. •

We collected and analyzed our data following the grounded theory approach to build a grounded model (Corbin and Strauss, 2008; Strauss and Corbin, 1990). During the first phases of development of the grounded model, we open-coded for recurrent first order concepts, which we then grouped to create second order themes and finally, aggregate theoretical dimensions. As a final step of our coding, we identified relationships between second order themes and aggregate theoretical dimensions in order to build a grounded model that is represented in figure 1.

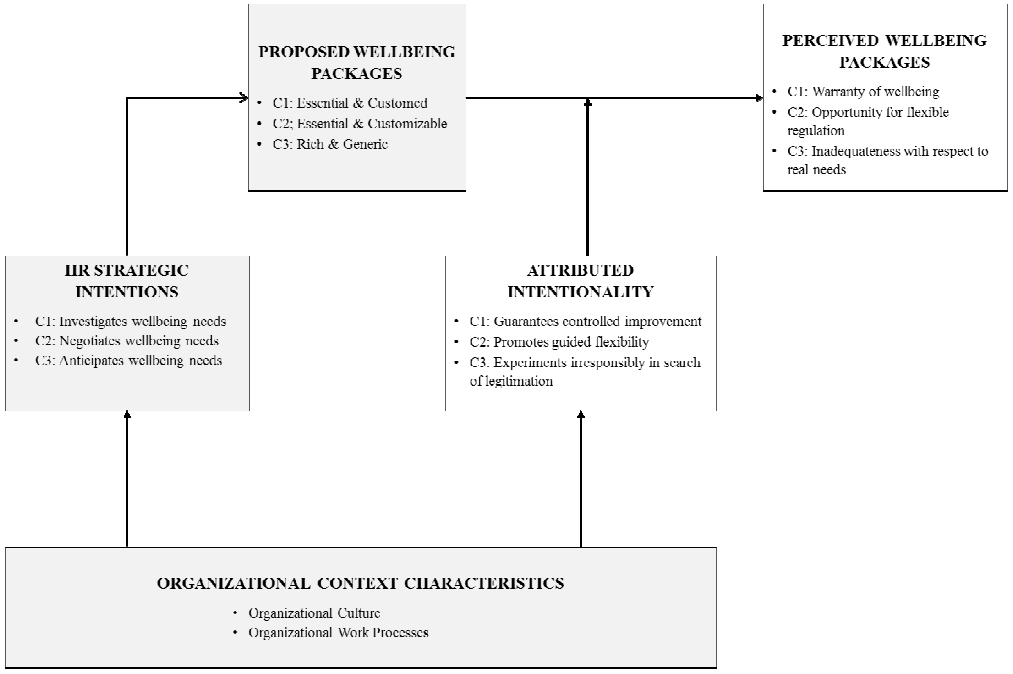

Fig.1. A grounded model of the interplay between well-being initiatives as offered by organizations and as perceived by employees. A cross-case study of three organizational settings (Case 1: Sait Industries (C1); Case 2: Royal Insurance (C2); Case 3: Project Consulting (C3).

Findings

Our findings show that organizational settings (organizational culture and work processes) significantly shape organizations' HR strategic intentionality- how HR managers gathered and used information about employees' well-being demands to craft their company's well-being initiative. We also find that employees interpret their organizations' well-being package by drawing on the broader understanding about the goals and intentions of the organizations for which they work.

In particular, the context characteristics in which the three organizations operated differed in terms of organizational culture, structure and processes. Accordingly, Sait's main goal was to strive for excellence by providing customers with innovative products and efficient services, and by using technological innovation to contribute to the balanced and sustainable growth of the planet. Strong know-how, high quality products, reliability, innovation and efficiency were mentioned by our informants and in documents among Sait's main values and distinctive features. A great attention to safety, health and hygiene were also frequently mentioned by our informants. In terms of organization

of work processes, Sait has a weak/functional matrix organization which combines coordination mechanisms based on rules and procedures with management by exceptions. For instance, functions that ensure operational efficiency and require more frequent or direct contact are located within the same open space. Cross-functional teams called "sites" are created to deal with complex projects inside the organization. A project manager supervises the team, assigning them macro-tasks while leaving micro-tasks for each team member to perform independently. Work processes both in offices and on the production floor are regulated by highly explicit rules and formalized procedures aligned with the total improvement perspective.

Royal Insurance's culture is deeply rooted in the customer-centric culture of the parent organization. As indicated by our informants, the parent company's customer-centric culture pushes the top management of the single franchises to organize and direct all work processes to reflect great attention to customer needs, including customer service hours and logistics or types of services being offered. To give an example, in line with the company slogan "Customer must feel at home", the franchise we studied had recently moved at the ground floor of a central building that offered better accessibility to customers with ambulation problems. We also found out that even the fragrance inside franchised offices was chosen by the parent company after a study of customers' preferences. As our informants explained, Royal aims at actively improving the quality of life of customers and employees alike. A "circular approach" to employee and customer satisfaction was frequently mentioned. Accordingly, Royal Insurance is committed to enhancing employees' happiness and attachment to the work environment because they expect this will also translate in greater customer satisfaction.

In terms of organization of work processes, Royal Insurance has a divisional (i.e., multi-focused) organizational structure based on the standardization and coordination of activities across franchised offices. Like Sait, it entails highly structured rules and procedures, and a clear hierarchical line in which general directives are communicated to managers using a top down logic. Once general directives are distributed, the members of each franchise, and then of each department within the franchise, decide autonomously how to achieve assigned objectives.

Project's culture is best described by dynamism. The company's rapid expansion is driven by the ambitious mission to design solutions for every individual, company and industry, by using cutting-edge technology, solid data analytics and expert teams ready to assist data-supported decisions. To do that, the company places high attention to its clients, aiming to anticipate their needs and exceed their expectations. The company slogan "Advancing knowledge for better decisions making" (internal document source) is used equally inside the company, with clients and in the interaction with external stakeholders. The distinctive features of the company culture are the drive to exceed expectations through a mix of "best decision competencies" -i.e., strong internal know-how, creativity, dynamism and innovation. In terms of organization of work processes, Project Consulting is a project-based company organized around temporary and highly fluid project teams. Employees are usually part of macro-teams from which they are continuously selected and assigned to smaller scope teams. Usually project teams are constituted by professionals at different career stages with different skills and expertise, to ensure complementarity and foster innovation processes. The company's work processes reflect the high speed and high flexibility that characterize the market of knowledge-intensive companies. Individuals' cooperative behaviors are an important ingredient of a team's success. The work environment is relatively unstructured, with few formal rules and procedures to follow, especially when consultants are on site. Individuals are given high levels of autonomy inside projects, based on their professional expertise.

In these three different organizational contexts, we found three types of strategic intentions: a strategy based on well-being needs investigation, in the case of Sait Industries, a strategy based on well-being needs negotiation, in the case of Royal Insurance, and a strategy based on anticipation of well-being needs, in the case of Project Consulting.

These HR strategic initiatives related to different "proposed well-being packages" as follows.

Sait's strategic intention to investigate well-being needs led to a package consisting of essential and customized well-being initiatives; Royal Insurance's strategic intention to negotiate well-being needs let to the setup of a well-being package with essential and customizable features, while the anticipatory strategy of Project Consulting led to the creation of a rich but generic offer of well-being benefits.

We also found that employees perceive well-being packages more or less positively (as warranty of well-being, in the case of Sait Industries, as opportunity for flexible regulation, in the case of Royal Insurance, or as inadequate with respect of real needs, in the case of Project Consulting), according to whether organizations investigated, negotiated or anticipated their well-being needs. Such relationship was influenced by the intentions that employees attributed to their organizations' well-being offer. In the case of Sait Industries, employees saw well-being packages as a way for HR to guarantee controlled improvement of the organization as a whole; In Royal Insurance, the well-being packages were seen as the way through which HR promoted guided flexibility of the work force. By contrast, in Project Consulting, employees interpreted the well-being packages as a corporate tool to experiment irresponsibly in search of internal and external legitimation. We also found that the intentionality that employees attributed to the well-being initiatives of their organizations was considerably shaped by their understanding of the organizational context.

We thus identify two significant factors that explain the degree of fit between well-being packages offered by organizations and employee perceptions:

1) HR strategic intentions - organizations' attributions about what employees might need in terms of well-being.

2) Employee's attributed intentionality - employees' attributions about the intentions with which organizations offer well-being initiatives.

We thus found that the well-being initiatives offered by the three organization were significantly influenced by the contexts in which they operated. Specifically, organizational contexts shaped management's strategic intentions regarding employees' well-being initiatives, on the one hand, and how employees made sense of such intentions (attributed intentions), on the other hand. In turn, attributed intentions shaped employees' perceptions of the well-being packages they were offered.

Discussion and Implications

We aim at contributing to theory and to managerial implications in several ways. First, with this study we propose a renewed attention to how employers and employees co-construct well-being initiatives in well-being context. We show that since cultural and structural features of organizations vary widely across industries, they can have profound implications for the interrelationships between well-being initiatives as proposed by employers and as received by employees. From such perspective, we bring to the fore the system of mutual attributions that surround well-being initiatives –i.e., organizations' and employee's intentionality attributions as far as well-being is concerned. We draw attention to the risks associated to anticipating well-being needs. Perceived initiatives discretion may make sense from the perspective of management, especially when accompanied by the intention to surprise employees by anticipating their needs, but it clearly contradicts employees' goal of increasing control over how, when and where they work and conduct their life in general. When organizations take a "Let's give it a try" approach, employees may resist their offers because they attribute such organizations hidden or auto-referential intentions, that are distant from their real wellbeing needs. Our findings are coherent with the studies showing that whenever employees feel constrained by adventurous HRM initiatives, they may not feel in control and, as a consequence, they may define the organization as unjust, untrustworthy or unreliable (Blair-Loy and Wharton, 2002; Hayman,2009; Kossek et al. 2006). It thus become important to understand whether well-being initiatives are perceived as "real" initiatives –i.e., authentic interest for employee's well-being or as façade initiatives –i.e., tools for "appearing" by obtaining legitimation inside and outside the organization (see also the discussion by Kelly and Kalev, 2006). From such standpoint, the role of management in facilitating the alignment between organizations' intentions and

attributed intentionality may constitute a further research direction to further understand the dynamics of alignment/misalignment (Ahuja et al., 2007; Bertolotti et al., 2004; Kossek et al., 2011; Thompson and Prottas, 2006;). Second, we contribute to the discussion on the role of well-being initiatives availability versus use, underlining the trade-offs between rich well-being packages which provide employees with multiple experiential opportunities and more customized packages which provide greater control (Allen et al., 2013; Chua and Iyengar, 2006; Iyengar and Lepper, 2000; Lapierre and Allen, 2012). Third, we draw attention to how the context in which organizations operate, their mission, goals and HR strategies might lead to unintended consequences as far as employee reception of well-being initiatives is concerned. We claim that the context characteristics in which the three organizations operated differed in terms of the following variables: organizational culture, organizational structure and organization of work processes. Different organizational characteristics contributed to shaping different HR strategic intentions, which were interpreted differently by employees that were seriously conditioned in their interpretation of well-being packages by the understanding they had of the organizational setting in which they were inserted.

The limited understanding about how people use elements from their environments to make sense about another's intention draws the case for a dynamic and contextualized analysis of people's understanding of their mutual roles. Yet, context has received only limited attention so far, and has been prevalently treated as contingency rather than as an active part of a shared intentionality process. The same problem is reflected in the HRM process-based literature which has given limited attention to the antecedents of the relationship between HR initiatives and employee perceptions (Bowen and Ostroff, 2004). By discussing employee oriented versus company oriented attributions, Nishii and colleagues (2008) and Chen and Wang (2014) make a step further but they do not delve into what determines employees to choose an attribution over another. From such standpoint, not only our perspective brings a more nuanced understanding of the well-being challenges people face in different work settings, but also initiates a discussion about the types of solutions that may be most appropriate for settings with different characteristics.

A Review of Bitcoin Literature

Ceylan Onay, Boğaziçi University, Istanbul, Turkey, ceylano@boun.edu.tr

Serhat Serhatlı, Hepsiburada.com, Istanbul, Turkey, serhat.serhatli@hepsiburada.com

Abstract

The purpose of this paper is to review the literature on Bitcoin and Blockchain technology in the past 6 years, during which it has become a global interest to both scholars and practitioners as an alternative to fiat currencies and payment systems. A content analysis is conducted to examine the development and evolution of bitcoin over time to reveal possible trends and changes. Reviewing 143 academic papers, we find that the most dominant research themes were economic and regulatory dimensions of Bitcoin.

Keywords: bitcoin, crypto currency, blockchain, digital economy

Introduction

Digital economy has taken a new turn with the emergence of bitcoin, which is a currency that is produced, stored and transferred digitally. When the first bitcoin transaction has taken place in 2009, little was known about what it was and how it would be used. Over years, Bitcoin has gained momentum rapidly. In a research survey conducted by PwC (2014), nearly half of the U.S. public was aware of Bitcoin and in an interview with Erik Schatzker of Bloomberg's "Street Smart," Bill Gates commented on Bitcoin as: "Bitcoin is better than currency in that you don't have to be physically in the same place and of course for large transactions currency can get pretty inconvenient."

Beyond being a technological innovation, Bitcoin has challenged how we define a currency. It is convertible to fiat currencies such as USD and Euros because it can fulfill three basic functions of money which are being a medium of exchange, a unit of account, and store of value. Yet, there is ongoing debate of viability of it as a currency as it is a decentralized system, where there is no central bank/authority behind it. In this regard, anyone with sufficient computational power could mine (produce) Bitcoin. Once easily mined at PCs, now it can be mined with excessive computing power due to the increase in the transaction volumes. In the Bitcoin network, each transaction has to be verified by six independent miners and this verification needs to be done all the way back to the first transaction in the Blockchain. Yet, this process means that it becomes more secure with each transaction.

Blockchain is essentially a public ledger technology on which cryptocurrencies such as Bitcoin is used. It challenges how we store and share information anonymously in many sectors ranging from health to financial services. It provides both transparency and security at the same time. Bitcoin works peer to peer for transferring money without any fees, challenging the value proposition of banks. PwC (2014) suggest that "Bitcoin becomes new payment system because it has no transaction fee and decentralized peer to peer payment system can be shielded from fluctuations caused by local government politics and their influence on central banks." In this regard, Bitcoin is becoming an open source monetary system solving the double spending problem and security issues via encryption.

In summary, Bitcoin is an electronic currency that's based on a collaboratively maintained ledger. People transfer money by sending messages to maintainers describing where and how much money should move. Maintainers make sure that the messages are from the true account owners by checking digital signatures. And finally, the maintainers reach consensus with each other through a math-based voting process. Six years ago, Bitcoin was just an innovation in information technology but now it is used to buy goods and services and has become an investment on its own. In this paper, content

analysis is conducted to examine what research fields were studied so far and how these topics changed over time.

Research Methodology

2.1 Content Analysis

There has been a remarkable increase in Bitcoin research over the past six years, and it continues to increase as it disrupts the financial services industry. Accordingly, the content of articles that are published in scholarly journals can give an idea about the change in research and themes about Bitcoin. This study provides a content analysis of research articles, which were published over six years, to understand the evolution of Bitcoin. According to Weber (1990) "Content analysis is a research method that uses a set of procedures to make valid inferences from text" and it is particularly used in social sciences to make trend analysis ((Nasir, 2005; Bayramusta and Nasir, 2016). The purpose of this study is; to set light on the progress of Bitcoin in academic research.

Figure 1 shows the content analysis process. The process starts with sample selection, where the articles are identified. In the second stage, the unit of analysis is chosen, which is followed by determination of the theme categories by coders in the third stage. In the fourth stage, from the category schemes judges select the final categories and a reliability analysis is made in the fifth stage to reveal the level of agreement between the judges. Last stage presents the analysis of collected data.

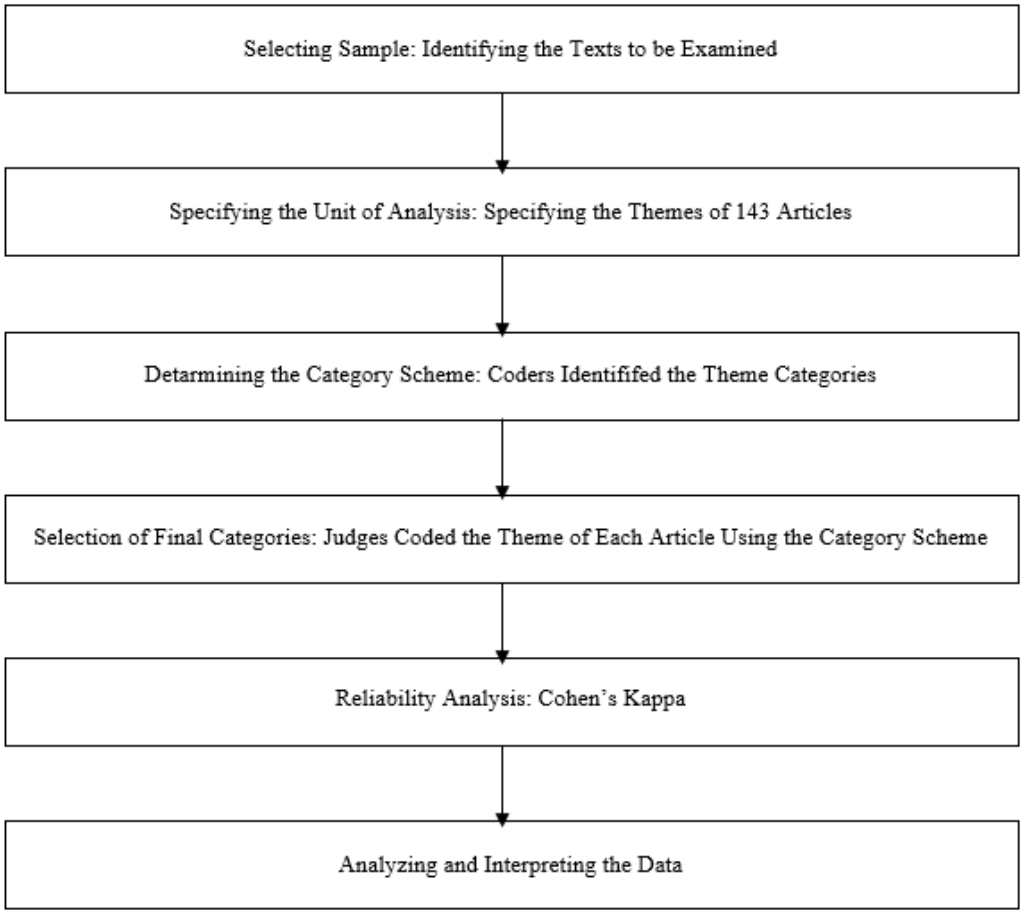

Fig. 1: Phases of content analysis.

2.2 Selecting Sample

The sample of the study consists of 143 academic articles published over the past six years from 2011 to 2016. The databases scanned through the library search facilities include ABI/INFORM complete, Ebsco, Emerald and Proquest, which include journals with different disciplines. The study sample consisted of articles from scholarly reviewed journals, which contain any of the "bitcoin", “Blockchain”, "crypto currencies", "crypto currency”, "digital currencies" or "digital currency" phrases in the title were included in the sample.

2.3 Specifying the unit of analysis

All articles from selected sample were consolidated in a table according to their database, title, author, year, journal and abstract. “Theme” of the articles is chosen as the unit of analysis to classify the papers and title and abstract of all 143 articles were reviewed by researchers to determine the main research topic of the articles.

2.4 Determining the category scheme

Two Ph.D. candidates, who have been studying both in the department of Management Information Systems and working at IT industry, were selected as coders to analyse list of themes and come up with categories. Initially they were trained by 10 randomly selected themes to ensure making classification process more reliable. As a result of training conflicts between coders were discussed and resolved. After training was completed, coders were asked to group 143 themes into small number of broader categories independently. Coders were free in determining categories and had no restriction in number of them while creating. Both coders generated seven categories each. Ultimately, a total of 16 categories were generated from 143 themes by 2 coders (Table 1)

Table 1 : Generated categories by coders.

Coder 1	Coder 2
• *Analysis of bitcoin transaction data and network*	• *Regulations & Legal Issues*
• *Application of Bitcoin on Various Context*	• *Privacy*
• *Evaluation of Bitcoin*	• *Technical Issues*
• *Evolution, Characteristics and Usage of Bitcoin*	• *Market Dynamics*
• *Examining Price of Bitcoin and Its Effects*	• *Financial Literacy*
• *Regulatory and Governmental Issues of Bitcoin*	• *Digital Economy*
• *Risks of Bitcoin* • *Security and Privacy Issues of Bitcoin* • *Tax-related issues in Bitcoin*	• *Security*

2.5 Selection of final categories

All the 16 categories which were collected from coders were evaluated by researchers and 6 mutually exclusive and exhaustive final categories are selected;

1. ″Economic dimension of Bitcoin" category: Analysing Bitcoin’s impact on (i) economic development, (ii) creation of alternative monetary, payment, and financial systems and (iii) its adoption by users
2. "Application of Bitcoin technology in a different sector" category: Usage/modification of bitcoin technology infrastructure, Blockchain, in different sectors such as health industry.
3. "Security dimension of Bitcoin" category: security, privacy, anonymity, cryptography, certification, protocols and validation issues of bitcoin technology.

4. "Price and risk dimension of Bitcoin" category: Evaluation of investing and trading bitcoin as a currency, valuation and risks of bitcoin such as speculation and price bubbles, crisis, inflation risk, usage of bitcoin in risk management
5. "Regulatory and legal dimension of Bitcoin" category: legal framework and compliance issues such as lack of regulation, fraud, criminal activity, taxes, money laundering and financial regulation.
6. "Technical dimension of Bitcoin" category: architectural design of Bitcoin in technical manner.

2.6 Reliability analysis

In order to measure reliability of categories, three judges with doctorate degrees in management information systems were assigned to make reliability assessment. They were asked to assign each of the 143 themes to final categories, which were selected in the last stage.

Even though, there are many ways to measure reliability, one way is to look pairwise percentage of agreement among judges in assigning same themes to the same categories (Table 2).

Table 2 : The percentage agreement of judges

Judges	Number of Matching (out of 143)	Percentage
A and B	*110*	*77 %*
A and C	*103*	*72 %*
B and C	*114*	*80 %*

However, Grayson and Rust (2001) mentioned that "simply using percentage agreement between judges is not so good because some agreement is sure to occur, if only by chance, and the fewer the number of categories, the more random agreement is likely to occur, thus making the relaibility appear better than really is" Therefore Cohen's K is also calculated for robustness according to the directions in the study by Grayson and Rust (2001).

$$K = \frac{p_a - p_c}{1 - p_c}$$

Where p_a is the proportion of agreed on judgments $\left(p_a = \frac{(n_{11} + n_{22} + \cdots + n_{77})}{n_{++}}\right)$; p_c is the proportion of agreements one would expect by chance $\left(p_c = \frac{(e_{11} + e_{22} + \cdots + e_{77})}{n_{++}}\right)$ and $\left(e_{ii} = (\frac{n_{i+}}{n_{++}})\ x\ (\frac{n_{+i}}{n_{++}})\ x\ n_{++}\right)$

We find Judge A and B are in agreement with 0.71 kappa score, judge A and C are in agreement with 0.66 kappa score and judge B and C are in agreement with 0.75 kappa score. According to Landis and Koch (1977), we find substantial agreement between our judges.

Research findings

The number of articles over six years is illustrated in Figure 2. At the beginning, only 2 articles were published respectively in years 2011 and 2012. Next year as bitcoin becomes more popular number of papers published climb up to 12 articles. There has been almost four-fold increase from 2013 to 2014 as the total number of articles reached to 40. After a slight short fall in 2015 with 34 articles, research on bitcoin accelerated dramatically with more interest on Blockchain technology and reached 55 papers in 2016.

3.1 Theme analysis

The result of the theme analysis is shown in Figure 3. The pie chart shows the percentage distribution of all 143 articles by themes. It is seen that, "Economic dimension of Bitcoin" (30%) and "Regulatory and legal dimension of Bitcoin" (22%) have been the dominant themes over six years. The third most studied theme is "Price and risk dimension of Bitcoin" (19%) followed by "Security and privacy dimension of Bitcoin" (16%) theme. Finally, "Application of Bitcoin technology in a

different sector" (9%) and "Technical dimension of Bitcoin" (4%) are the least attention-grabbing themes in the literature.

Social Sustainable Supply Chain Practices and Impacts on Companies Performance: an Exploratory Study on Portuguese Manufacturing Industries

Luisa Alexandra Pinto, Prince Sultan University – College of Business Administration, Saudi Arabia - lpinto@psu.edu.sa / Polytechnic Institute of Viseu - School of Technology and Management of Lamego, Portugal - lpinto@estgl.ipv.pt

Abstract

As the role of businesses in contemporary society is changing, sustainable supply chain management has emerged as an important organisational approach to reducing environmental and social risks. Many companies' actions are under pressure from a number of stakeholders, among others customers, media, governments and investors to implement sustainable practices. So far, sustainable practices in the supply chain have focused largely on the environmental side of sustainability in comparison to the social side. Social standards in supply chains such as labour rights and worker safety are rather difficult to ensure because they are detached from the final product and hence demand monitoring for each step in the production process. This research aims at studying the internal and external social sustainable practices of eight Portuguese companies and the relationship with economic and social performance. First, the author identifies the different social practices based on the literature available It then builds on the data collected from interviews with eight Portuguese industrial companies that consisted of 22 semi-structured interviews with general managers, procurement and environmental/safety managers. Secondary data was collected from reports, websites and the companies' internal documentation. Sectors included glass, automotive, drink, wood-based panels, furniture and cork. The results indicate that the companies' performance is positively affected by the implementation of social practices into the supply chain, namely internal social practices. The paper is of use to supply chain managers, policymakers to understand the internal and external social practices used by the organisations and how they influence performance. Further, the findings could act as a key tool for managers seeking to implement socially sustainable supply chain management practices.

Keywords: social practices, supply chain, sustainability, performance.

Introduction

One of the problems of humanity is that, while man is capable of understanding the problems that he faces, he fails when it comes to planning effective solutions. This failing is due, in part, to an inability to understand that the whole is larger than its parts and that changing one of the elements always implies a change in the other elements of the system (Meadows et al., 1972). The 21stcentury is marked by a heightened urgency to respond to pressing global challenges. These include climate change, water and food insecurity, ecological degradation, and poverty, which are most pronounced in undeveloped countries but come together at the global level.

The concept of Sustainable Development (SD) has been defined in many ways, but the most frequently quoted definition is from *Our Common Future*, also known as the Brundtland Report (1987), where Sustainable Development is defined as "the development that meets the needs of the present without

compromising the ability of future generations to meet their own needs…". SD was introduced into the political agenda by the United Nations Conference on Environment and Development held in Rio de Janeiro in 1992. The turning point for SD was in 2015, with the adoption of the Addis Ababa Action Agenda on Financing for Development, the 2030 Agenda and its associated Sustainable Development Goals, and the Paris climate conference (COP21) in December 2015, where 195 countries adopted the first-ever universal, legally binding global climate deal. The agreement sets out a global action plan to put the world on track to avoid dangerous climate change by limiting global warming to well below 2°C. SD represents a critical element that can only be achieved through a balance between the objectives of economic prosperity, ideals of environmental protection and guarantees of social equality, in accordance with the triple bottom line (TBL) perspective (Elkington, 1998). Furthermore, the focus on sustainable development must be in implementation.

Corporations are key actors for successfully implementing sustainability because of their impact on the environmental matrices of soil, water, and air as well as on the world's resources, their leading role in society (through moulding lifestyles), and their global reach. Sustainability in supply chains refers to traditional financial and operational performances and, simultaneously, to the social and environmental dimensions of business activities, as prominently conceptualised by the TBL approach (Gunasekaran et al., 2004; Dyllick & Hockerts, 2002).

The Sustainable Supply Chain Management (SSCM) agenda uses the term TBL to include all types of values, topics and processes that organisations should adopt. Besides economic objectives, this also covers environmental and social aspects, to minimise any possible damage that results from their activities, and helping create long-term economic, social and environmental value. The idea is to balance the needs of people, the planet and the company's profits to create long-term shareholder value (Elkington, 1998).Effective management of the supply chain is an essential strategy for success in global markets. The possibilities afforded by the concept of Supply Chain Management (SCM) are being explored and applied by companies to increase their growth, and helping develop agile supply chains that can bring products to market more quickly and cheaply (Gunasekaran et al., 2007).

Organisations are confronted on a daily basis with pressures from the media, non-governmental organisations (NGO), the surrounding communities and requirements imposed by environmental legislation. In addition, consumers demand more transparency and responsibility for the conditions under which their products are produced and distributed, and they demand more respect for the environment and human rights. This obliges companies to rethink the ways in which they do business, as they become more conscious of their responsibility to guarantee the long-term future ofmankind (Hay et al., 2005; Kleindorfer et al., 2005; Sarkis et al., 2011).

Sustainable companies have to ensure the production of their products without causing environmental damage while at the same time complying with social standards. Choosing to ignore this problem means they face a significant risk to their reputation and brand, having to justify their choice of suppliers to the media and confront NGO criticisms (Seuring, 2004; Lawrence, 2002). There are a number of NGOs that dedicate their work to highlighting inhumane working conditions, especially in less developed countries. Their work helps uncover strategies used by companies based in developed countries to profit from these unfair working conditions. To reduce costs, companies transfer a large part of their processes which add value to suppliers based in countries with lower cost bases. These companies put their image and reputation at risk due to the poor working conditions (Beske et al., 2008; Cheung et al., 2009; Reuter et

al., 2010). Consumer boycotts of specific products or services and the attention of the media illustrate this type of risk to a company's reputation (Locke, 2003; Teuscher et al., 2006).

SSCM covers numerous areas of environmental and social responsibility, such as the prevention of child labour and forced labour, the substitution of toxic substances in manufacturing processes, the excessive consumption of energy and material and the protection of biodiversity. To be able to manage all these areas, companies employ universally accepted guidelines or standards, such as international standards for certifying management systems covering quality, the environment, occupational health and safety, social or Global Reporting Initiative (GRI) directives (Beske et al., 2008;Bai & Sarkis, 2010; Gold et al., 2010; Koplin et al., 2007; Seuring & Müller, 2008; Wittstruck & Teuteberg, 2011).

The literature reviews available covering SSCM show the growing interest in thistheme, which is still dominated by the research into environmental practices in the supply chain, particularly the relationship between economic and environmental performance. Despite the growing number of papers, the latest literature reviews reveal that the research of social issues in sustainable supply chain management is still scarce and there is a call for more specific research in the field (Carter & Easton, 2011; Carter & Rogers, 2008; Hoejmose & Adrien-Kirby, 2012; Longoni et al., 2014: Pagell& Wu, 2009; Zorziniet al.,2015; Seuring, 2013; Tajbakhsh & Hassini, 2015).

In this research, theoretical contributions are three-fold. One will be to identify the internal and external social practices carried out by eight different companies representing different industries and their position and strategy to address social issues in the supply chain. Second, the level of the implemented practices in eight different manufacturing set-ups. Third, to analyse how the social practices influence the economic and social performance. Therefore, our primary objectives for this research are:

- To identify internal and external social sustainability practices on focal companies' supply chain.
- To analyse the level of social sustainability implementation on the eight manufacturing companies.
- To determine the similarities and differences in their approach to sustainability.
- To analyse how the social practices impact on the organisations' economic and social performance.

The structure of this article is organised as follows. After introducing the topic, the literature is reviewed to identify the socially sustainable practices implemented by different organisations. In section three, the methodology of the study is introduced. The findings and results of the empirical data analysis are presented in section four. Section five includes a summary of the findings, conclusions and future research directions.

Literature Review

A failure to correctly comply with social practices can have serious repercussions for a company's competitiveness and economic performance as well as its reputation and image in the marketplace (Schaltegger & Wagner, 2006).

Due to a failure to implement social practices in their activities, several companies have seen their public image deteriorate. These failures result in judicial proceedings and the loss of current and potential

customers, which represents large costs for the companies involved. Several examples include Nike, who lost hundreds of thousands of dollars in sales following accusations of having purchased from suppliers using child labour. The largest manufacturer of electronic components for computers in the world, producers of the iMac, iPod, iPad and the iPhone for Apple, Foxconn Technology Group, were accused of dozens of labour law violations in their factories in China, including excessive working hours, not paying salaries, and salaries that did not cover minimum living standards.In 2006, Walmart was accusedofa number of unions and community groups of obliging workers to work more hours than contracted, denying payment of overtime, rest periods and lunch breaks. In 2013, Nestle removed pasta meals from shelves in Italy and Spain and suspended deliveries of all processed products containing meat from German suppliers, because it was found that those pasta meals contained horsemeat. In the same year, in Bangladesh, the second largest textile exporter in the world, a building housing various factories collapsed causing the death of 1,229 workers and wounding more than 2,500 people. The image of numerous internationally recognised brand names was affected – including H&M, Benetton, and Mango. More recently, in 2016, factories in Turkey were found using Syrian refugee children working on clothes for Marks and Spencer and the online retailer Asos. Adult refugees were also found working illegally on Zara and Mango jeans. These examples show that all members of the supply chain (namely suppliers) need to incorporate and comply with social criteria and the focal companies are responsible for managing their supply chains.

The companies that are part of global supply chains face a high level of complexity; deal with a large number of suppliers, face constantly increasing customer expectations and different legal requirements for controlling social and environmental aspects. The pressures to effectively manage supplier relationships and the demand for ecologically correct and socially responsible products and services have increased worldwide. All these pressures from the different stakeholders present a significant challenge to company managers, encouraging them to integrate sustainable practices into their supply chains (Carter & Jennings, 2004; Geffen & Rothenberg, 2000; Porter & Kramer, 2006).

As stated in the introduction, a significant body of literature reviews SSCM from the TBL perspective. Gimenez et al. (2012) analysed the impact of environmental and social practices on the environmental, social and economic performance. Caniato et al. (2011) looked at a set of sustainable management practices in the supply chain and performance indicators to understand the relationships between these elements and their impact on the supply chain. Pullman et al. (2009) analysed the environmental and social practices in the supply chain and their impact on environmental performance, quality and costs in the food products sector. Yakovleva et al. (2009) studied economic, environmental and social performance in the supply chain for the food products industry. Using statistical data together with specialist opinions, they constructed a general sustainability index for the food products supply chain, using three sustainability dimensions (economic, environmental and social) to measure the sustainability of the supply chain. De Brito et al. (2008) analysed how companies in the textile sector supply chain can improve their economic, environmental and social performance by implementing a set of environmental and social practices.

Despite the growing number of papers, the latest literature reviews reveal that the research of social issues in supply chain is still scarce, and there is a call for more specific research in the field specially in the relationship between social practices and performance (Carter & Easton, 2011; Carter & Rogers, 2008; Hoejmose & Adrien-Kirby, 2012; Longoni et al., 2014; Pagell & Wu, 2009; Seuring, 2003; Tajbakhsh & Hassini, 2015; Zorzini et al., 2015).

Most of the studies on the social dimension of the TBL and the buying firms' performance (e.g., Akamp and Müller, 2013; Ciliberti et al., 2008; Das et al. 2008; de Brito et al., 2008; Hollos et al., 2012; Gallear et al. 2012; Gimenez et al. 2012; Klassen and Vereecke, 2012; Pagell and Gobeli, 2008; Pullman et al. 2009)have centred their attention on internal or external practices. The following studies have considered the impact of internal practices on different dimensions of the firm. Das et al. (2008) analysed how employee's safety affects operational outcomes, particularly product quality. Similarly, Pagell and Gobeli (2009) focused on the firm's operational performance and examined how it was impacted by managers' attitudes and experiences towards sustainability. De Brito et al. (2008) explored how firms in the fashion supply chain could improve their economic, environmental and social levels. Pullman et al. (2009) analysed the impact of environmental and social programs on the firm's environmental, quality and cost performances. Klassen and Vereeke (2012) developed a framework based on case studies in which they explored the role of external practices on achieving economic improvements. Stiller and Gold (2014) illustrate various SSCM practices in a focal company may use for enhancing social standards in international supply chains. Mani et al. (2015) found that the major social issues in the manufacturing supply chain in India are child labour, bonded labour, education, wages, housing, philanthropy and ethics. Another study by Awaysheh and Klassen (2010) identified four dimensions of supplier socially responsible practices: supplier human rights, supplier labour practices, supplier codes of conduct, and supplier social audits. They emphasise that an increasing number of tiers in a supply chain wouldincrease the use of supplier labour practices, codes of conduct, and social audits.

All these studies focus on either internal or external social practices. We found three papers that combined both internal and external social practices in their analysis, namely Ciliberti et al. (2008), Gallear et al.(2012) and Gimenez et al. (2012). Ciliberti et al. (2008), to achieve a socially responsible management of the supply chain, they classified the set of internal and external practices. Gallear et al. (2012) found that a firm's financial performance is affected by its internal awareness of sustainability issues, the monitoring of the firm's sustainability performance, and the sharing of best practices with suppliers. Finally, Gimenez et al. (2012) analysed the impact of internal and external programs on environmental, social and economic performances.

Although few recent reviews on the social dimension of SSCM and performance are currently available, further research in this field is needed, especially to cover the implementation of internal and external social practices and their relationship with economic and social performance. To this end, the next section seeks to identify the internal and external social practices implemented by companies in the supply chain, both upstream and downstream, the associated indicators used, and the impact of socially sustainable practices on the focal companies economic and social performance.

2.1. Social Practices

To ensure that the supply chain is socially responsible, companies need to adopt internal and external social practices into the supply chain, considering the internal and external environment of the organisation (Pullman et al. 2009, Tate et al. 2010; Gauthier, 2005).

Given the wide-ranging impacts of social questions, there are significant challenges and pressures that companies must confront to be able to systematically treat these issues. There are a series of social aspects to be considered that are related to questions that go beyond the more traditional areas of human rights and salaries. These include, among others, subjects related to health and safety in the workplace,

the contribution of the company to the community, the impact of gaining access to natural resources, health information and education, and other diverse socioeconomic questions.

The approaches that are more widely recognised are related to international human rights standards included in the Universal Declaration of Human Rights and the conventions of the International Labour Organisation. These include questions related to child labour, freedom of association, working hours, health and safety. Besides this, a growing number of NGOs started to develop directives covering commercial operations. Amnesty International laid down a set of principles covering the relationship between business and human rights. Social Accountability International implemented a standard for Social Responsibility (SA 8000) covering human and social questions in the workplace. The Fair Labour Association has a workplace code of conduct. The Ethical Trade Initiative drew-up an ethical work code, and the GRI created an international report on corporate social responsibility and sustainability, highlighting the importance of considering the workplace and human rights, as well as the socioeconomic development of the community in general and society. These approaches are concerned not only with the practices of one particular company but are also interested in the supply chain members for the whole product lifecycle. Thus, an improvement in the social dimension requires the development and maintenance of commercial practices which are just and fair for the workers and the communities in the supply chain. According to Wood (1991), the social issues in the supply chain should be spread across three stages of the supply chain: in-house operations, suppliers, customers, and the external stakeholders which includes society, and NGO's.

According to Elkington (2004), the questions relating to the internal environment of the organisation are linked to human resources practices. These may include the recognition, appreciation and encouragement of workforce skills with appropriate human resources policies; practices of equality, development and well-being; the creation and maintenance of an environment which is participative and open to worker development; fair pay; adequate working conditions; and training and adaptation programmes. In other words, a set of practices designed to bolster skills and competencies and consequently improve worker satisfaction (Daily & Huang 2001; Gauthier, 2005; Gimenez et al., 2012; Walker & Jones, 2012). The internal social practices refer to employment practices such as gender balance, discrimination, opportunities for career advancement, and occupational health and safety in the workplace.

The external environment of the organisation refers to the relationship with the local communities and society in general. The objective here is to guarantee thequality of life for the population and a good relationship with the different stakeholders. This relationship should be managed using democratic and ethical decision-making processes, showing responsibility for the products and services offered, considering the impact on both customers and the wider community who support the negative externalities created in the process (Pullman et al., 2009). External social practices go beyond the limits of the focal company, extending to the members of the supply chain (such as suppliers and customers), and to the relations with other stakeholders (such as local communities). In a bid to make supply chains more socially responsible, many companies are implementing codes of conduct for their suppliers as an integral part of evaluative and collaborative tools (Amaeshi et al., 2008; Andersen & Skjoett-Larsen, 2008; Mont & Leire, 2008). External social practices consider the relationship with stakeholders, as is the case with suppliers and customers, as well as local communities and NGOs.

Authors described the social sustainability in the supply chain in various forms. Krause (1999) described how socially responsible suppliers could be acquired and be enacted by socially responsible supplier development. Purchasing social responsibility (PSR) and its impact on supplier and buyer performance

was studied and proved that social practices have positive impacts on organisational performance (Carter and Jennings, 2000, 2002; Carter and Easton, 2011). Other studies explored what enables social sustainability in the supply chain, ethical supplier development and its impact on corporate social performance, and how social dimensions can be effectively used in supplier selection and evaluation (Lu et al., 2012; Mani et al., 2014).

A wide range of standards and codes of conduct exist for companies to contemplate. They contain recommendations regarding the implementation of environmental and social practices with associated indicators, including their respective metrics (e.g., GRI, Fair Labour Association Guides, Dow Jones Sustainability Index). This variety also reflects the fact that the social practices of sustainability are difficult to measure. Issues related to the downstream supply chain were explored more than issues related to suppliers and in-house operations of the manufacturing plants (Mani et al., 2015).Through this research, we attempt to identify various internal and external social practices in the supply chain and the impacts of the different social practices in economic and social performance.

Based on the literature, the social practices and social performance indicators used in this study are:

- Internal social practices
    - *Internal social management* (e.g. commitment by top management, interfunctional cooperation for social improvements, ethical codes and codes of conduct, SA 8000 certification).
    - *Employment practices* (e.g. gender balance and equality of opportunities, flexible working regimes, career progression opportunities, training and education, opportunities for career development, satisfaction, flexible working hours, rotation of workers).
    - *Health and safety practices* (e.g. number of workplace accidents, absenteeism, health and safety training, safety procedures).

- External social practices
    - *Social collaboration with customers* (e.g. customer health and safety, labelling of products and services, customer privacy, consumer education).
    - *Social collaboration with suppliers* (e.g. codes of conduct, health and security in the workplace, supplier evaluation).
    - *Collaboration with the community* (e.g. support for teaching institutions, support for community projects, grants and donations, partnerships).

2.2. Economic and Social Performance

A performance measurement system is defined as the ability that companies have to attract and retain clients in a market that is increasingly competitive (Neely, 1999). Measuring performance is fundamental for any organisation to manage its activities and operations, while at the same time being an important pre-requisite for an improvement process (Sink & Tuttle, 1989). According to Hervani et al. (2005), performance measurement allows, for example, the efficiency and effectiveness of an existing system to be determined or alternative systems compared. Lambert (2008) sees the lack of adequate measurements as potentially compromising customer satisfaction, having consequences for organisational performance and increasing the probability that opportunities for improving supply chain performance are wasted. Performance measurement is crucial to improving the management of the supply chain (Wong, 2009).

Neely et al. (1999) defend the idea that performance evaluation systems are a set of metrics that measure the effectiveness and efficiency of an organisation. The indicators, or performance measures, should be defined so as to monitor the effort that the organisations put into the different company activities designed to achieve sustainable development. Crucially, they should then be evaluated in comparison with the competition.

Measuring sustainable performance is much more complex than measuring the traditional economic performance for three reasons: (i) There is a need to add two additional dimensions to classic economic performance: social and environmental performance (Epstein & Roy, 2003); (ii) performance is not measured only in terms of customer expectations, but also in terms of the expectations of the different stakeholders in the organisation (Freeman, 2005); (iii) there is a need for transparency in the information exchanged between the different upstream members of the supply chain, even though these are normally outside the control of the focal company (Amaeshi et al., 2008).

The expectation is that implementing social practices will lead to an improvement in the associated indicators, namely those relating to the satisfaction and motivation of the workforce, improvements in the safety conditions in the workplace and number of workplace accidents. Previous research, while not being directly related to the study of internal and external social practices (Cagliano et al., 2010; Gimenez et al., 2012; Pullman et al., 2009), found that companies should recognise, value and involve human resources with practices and policies that promote equality, career progression and equal opportunities, leading to increased motivation and satisfaction among employees. Cagliano et al. (2010) concluded that training is a key factor for improving social and environmental performance, and the incentives are positively related to social performance. In other words, social practices, when they are not applied as part of a wider initiative, do not contribute to performance improvements. Gimenez et al. (2012) provide evidence that implementing social practices such as improvements in health and safety conditions, improve the social reputation. Pullman et al. (2009) found that the implementation of social practices in the food industry helps improve product quality. Drawing on the indicators found in the different studies cited in the literature review, the indicators used in this research are:

- Economic performance, which aims to quantify the impact of the implemented social practices on the focal firm, regarding sales, and Earnings Before Interest, Taxes, Depreciation and Amortization (EBITDA);
- Social performance, which aims to analyse the impact of social practices implementation in the focal firm, in terms of number of injuries, number of working hours lost due to illness, the accident frequency and severity index, absenteeism rate, overall staff turnover rate and training.

Methodology

This study adopted a qualitative approach, using a case study approach which was chosen as the most appropriate research method to describe and explore new phenomena applicable to sustainable practices in the private sector. Suggestions for the number of cases to use in multiple case study research vary, but Eisenhart (1989) suggests eight cases as the maximum that a person can mentally process. Yin (2009) and others are more circumspect in regards to hard numbers and suggest that data should be collected until theoretical saturation. In operations and supply chain management research there are numerous examples of multiple case study research using from three to 11 cases (Pagell, 2009; Walker, 2012).

The research sample is composed of eight companies. Those companies were chosen based ontheir location, production plants in Portugal, and company size as medium and large companies have more resources to implement environmental and social practices (González-Benito & González-Benito, 2006), the supply chain structure, the commitment to sustainability dimensions (economic, environmental and social), and having third party certification and/or recognition (e.g., OHSAS 18001, ISO 9001, ISO 14000, PEFC, GRI). The attitude of transparency that characterises their activities is described in their websites, social reports, newspaper articles, and business press.

Case studies have been developedby means of interviews conducted on the basis of a semi-structured protocol that was developedon the basis of the reviewed literature. The use of protocols is advocated to enhance the reliability of case studies (Eisenhart 1989; 19 Yin, 2009). Twenty-two (22) semi-structured face-to-face interviews were conducted with at least one senior manager in each organisation. Each interview lasted about 60-90 minutes and was conducted on site. For six companies, the respondents were the General Manager, Purchasing and the Environmental, Health and Safety Manager and in some cases other roles, the Human Resource Manager. All interviews were taped, recorded and transcribed, and participants reviewed a draft case study report. To encourage openness of response from interviewees, the company names were made anonymous.

To enhance the validity and reliability of the study, triangulation with secondary data sources was conducted (Yin, 2009). Secondary data was collected from reports and websites, including annual reports, sustainable reports, environmental, safety and social policies, code of conducts, newspaper articles and confidential internal procedures provided by the sampled companies.

Table 1 shows the main features of the selected companies.

Table 1: Characteristics of the Sample

Company	Industry	Annual Turnover	Number of employees	Number of interviews	Role of interviews
C1	Glass	95 ME	350	3	General Manager Environmental, Health & Safety Coordinator Purchasing Manager
C2	Cork	318 ME	927	4	General Manager Environmental, Health & Safety Coordinator Purchasing Manager Human Resources Manager
C3	Automotive components	84.4 ME	348	4	General Manager Integrated Systems Manager Purchasing Manager Public Relations Manager
C4	Wood-based panels	1.321 ME	177	3	General Manager Environmental, Health & Safety Manager Purchasing Manager
C5	Office and commercial furniture	8.62ME	122	1	Quality, Environmental, Health & Safety Manager
C6	Automotive	216ME	190	3	General Manager

	assemblage				Human Resources Manager Purchasing Manager
C7	Drink	498 ME	1500	1	Environmental,, Health & Safety Sustainable Manager
C8	Automotive textile	44 ME	182	3	General Manager Environmental, Health & Safety Manager Purchasing Manager

Analysis and Discussion of the Results

Social sustainability in the supply chain is how a corporation addresses external and internalsocial practices in the upstream and downstream supply chain. This section presents the similarities and differences between the eight companies with regard to their internal and external social sustainable initiatives across the supply chain, the performance indicators used, and the relationship between the social practices and economic, and social performance.

Internal Social Practices

The results are summarised to compare the extent internal social practices of the companiesare implemented, as detailed in Table 2.

Table 2: Level of implementation of internal social practices

Internal social practices	Companies							
	C1	C2	C3	C4	C5	C6	C7	C8
Internal social management								
Commitment by top management to social practices	I	I	I	I	I	I	I	I
Interfunctional cooperation for social improvements	I	I	I	I	I	I	I	I
Ethical codes and codes of conduct	I	I	L	I	L	I	I	L
Employment policies	I	I	I	I	L	I	I	L
Health and safety	I	I	I	I	I	I	I	I

I – Implementation of practices; L – Limited implementation of practices; N – No implementation of practices.

Table 2 shows that the top management's commitment to social practices is high in all the companies. They defined the vision, mission and strategy according to the different certified management systems and integrated management policy regarding quality environmental and social policies (e.g. ISO 9001, ISO 14001, ISO 22001, OSHAS18001, SA 8001) and third party certification depending on the activity sector (HACCP, FSC - Forest Stewardship Council) certification, and SYSTECODE (quality assurance system for the cork industry).

Companies C3, C5 and C8 do not publish a sustainability report according to GRI guidelines, while the others do. This signifies their commitment to the three dimensions of sustainable development (economic,

environmental and social).Company C3 does not publish a sustainability report but publishes an environmental and safety report. This company is looking to become SA 8000 certified and, the purpose is to publish sustainability reports in the near future. Companies C2 and C6 have specific plans for sustainability, reflecting the more direct commitment and involvement of top management to the issue of sustainability and social practices. Company C1 is the only one certified according to the social responsibility standards (SA 8000). All companies in the study define annual objectives covering interfunctional cooperation for social improvements. This ensures the involvement of those that are responsible for the different departments by using different management methodologies. Indicators, goals and action plans are set out to achieve established objectives. Indicators, goals and action plans are set out to achieve established objectives and are monitored on a daily and/or monthly basis, with either monthly or quarterly analysis. Social indicators are definedwith human resources, environment and safety department managers.

Regarding the ethical codes and codes of conduct, companies C1 and C4 have ethics codes and codes of conduct which are applicable to all employees. C1 is the only company that has a code of conduct applicable to all suppliers, while C4's code is applicable only to their tier one suppliers and service providers. The ethics code of C7 covers the relationships between the organisation and the main stakeholders in the organisation: customers, employees, suppliers, competitors and the community.

Companies C3 and C8 do not have an ethics code or code of conduct, but they subscribe to a set of values based on a number of ethical and honesty principles. Thisguides all employees and all those engaged in commercial relationships. Company C5 has a code of conduct for its workers described in the welcome guide that is given to all employees.

Employment policies in all companies are considered very important. Workers are considered the most important resource to achieve the main goals of the organisation. The involvement and active participation of the workers in the identification and resolution of problems related to environmental and social issues are reflected in the large number of activities and projects that target worker awareness in this area to help involve and motivate the workers. Some of the companies in this study show more evidence of worker involvement than others. Company C2 has specific projects and plans for retaining critical skills, helping to ensure the sustainability of the business. Company C8 involves its employees in a variety of activities such as Kaizen, Jishuken, and Quality Control Circles, and by encouraging the creation of working groups that cover different areas. All the companies except companies C4, C5 and C8 developed numerous internal activities that involve workers and community to stimulate the team spirit and solidarity, such as the collection of food products; books and waste oil; blood donation; commemoration of Environment Day, Safety Day, and International Women's Day, among others. Other companies invested in more general projects to encourage organisational culture and identity. This was the case with companies C2 and C6, where activities seek to stimulate interdepartmental knowledge. Two of the companies (C2 and C4) make particular use of Idea Management Systems. For all the companies in the group, these systems seek to identify innovative ideas and measures for improving management, procedures and processes. Furthermore, for all business units and employees, rewards are available for those who come up with the best ideas and suggestions.

Companies consider communication and transparency to be fundamental. A variety of different means of communication are being used to improve the relationship between workers and management. Examples include meetings, a company portal, or the publication of newsletters. C6 has an internal television

channel where employees are kept up to date with the different activities of the company in different areas.

All the sampled companies consider training a priority initiative. It helps encourage changes in attitudes and behaviour. To this end, all companies invest heavily in the training of their employees, including workplace environment and safety. All companies use education to improve the performance of their employees, giving them the opportunity and time to improve their qualifications. The companies undertake an evaluation of the satisfaction and performance of their employees. Some of the companies use performance related pay, which may be linked to individual or global goals.

Health and safety practices were found to have a high level of compliance, even though some of the companies did not have a certified health and safety management system. A variety of actions were implemented to avoid workplace accidents and work-related diseases.

4.2. External Social Practices

To identify the external social practices and analyse the companies' level of implementation, the data was collated and summarised, as shown in Table 3.

Table 3: Level of implementation of external social practices

External social practices	Companies							
	C1	**C2**	**C3**	**C4**	**C5**	**C6**	**C7**	**C8**
Social collaboration with the community	I	I	I	N	N	I	I	N
Social collaboration with suppliers	I	L	L	L	L	L	L	L
Social collaboration with customers	L	I	L	I	L	L	I	L

I – Implementation of practices; L – Limited implementation of practices; N – No implementation of practices.

Looking at external social practices, particularly *social collaboration with the community*, five of the eight companies were involved in social activities within the community. These activities seek to raise awareness among employees of the need to adopt social behaviours and extend to the implementation of activities for and with the community. Suchactivities include collecting food products and clothing; collecting school books; financial donations; voluntary activities in the local community; visits to educational establishments; and partnerships with non-profit organisations.

The relationship with the community is also implemented at a more academic level. Collaborative ventures are common with schools and universities, leading to study visits, placements and research work. Competitions are also used to encourage innovation in partnership with different associations. Companies collaborate with non-profit organisations on projects, which, as stated by the employees, consist of school visits that help develop an entrepreneurial spirit in children and young people. Companies C2, C3 and C6 carry out charity work with a diverse range of non-profit associations.

The company employees take part in colloquia and conferences to share best practice. In all companies, apart from C5 and C7, interaction occurs with associations linked to the area of social sustainability,

including WBCSD, BCSD Portugal, EPIS, GRACE, the Global Compact Network Portugal and the United Nations Global Compact.

C2 and C8 have non-profit foundations designed to promote solidarity and stimulate community initiatives of an ethical, religious, cultural and civil nature, besides the dimension of social and cultural support. They focus on support for children and needy young people in the company's home region, following their progress in school and creating opportunities for developing successful life projects. One of the foundations awards prizes to employees that complete any year of schooling/training in the educational system, also paying fees and textbooks to the orphans of employees and paying out bonuses for births and marriages.

Social collaboration with the suppliers is based on the interaction with the corporations and suppliers. Here the different elements join together in planning activities related to social questions to prevent and resolve social problems.

C1 was found to have a code of conduct applied to all suppliers, tier one and below, whileC4's code is applicable only to tier one suppliers. All companies have rigid regulations for service providers, requiring a series of documents of a social, safety and environmental nature, which is not the case for product suppliers. It should be stated that the majority of supplier companies have certified management systems in one or more of the following areas: quality, environment, health and safety in the workplace, and social responsibility. In turn, the first level supplier companies assure that their suppliers comply with the legislation and standards.

Social questions start with the selection of suppliers and the respective auditing. Most of the suppliers studied are from the European Union, where legislation is very demanding, and the social conduct rules must be upheld. These social conduct rules are based on fundamental human rights found in conventions and international treaties, namely the Universal Declaration of Human Rights from the United Nations and the International Labour Organisation. The companies have an image to preserve and as such do not wish to be associated with companies that use child labour, forced labour, or slavery. None of the companies studied jointly develop activities with their suppliers to meet social objectives.

Social collaboration with customers makes supply chains more socially responsible. Thisis based on democratic and ethical decision making, and taking responsibility for the impacts created by the company's products and services for both customers and the wider community (which are affected by negative externalities from other citizens consumption). Some of the areas of action noted by customers were the traceability of products, packaging integrity, product labelling, health and safety of customers, responsible marketing, education and customer privacy. The sampled companies guaranteed their customers quality products by defining requirements and technical specifications which are subject to rigorous quality control and legislative compliance within the company's sector of activity.

These measures ensure the health and safety of the customers and end-consumers by controlling raw materials, components and packaging.

Some of the companies are more forthright about their commitments in this area. This is the case of C7 which runs responsible marketing campaigns based on commitments with associations in the sector, amid other activities such as improvements in nutritional information, including recommended daily intake on the label of the products or bringing out new products with a low glycaemia level. Company C4 commits

itself to supplying its customers and end-consumers sufficient and reliable information regarding the nature, origin, proper use and disposal of products. Companies C2 and C3 measure their carbon footprint. In the case of C2, the company's activity is shown to benefit the planet in terms of greenhouse gas emissions by absorbing more CO_2 than it emits.

All the companies are united in their effort and dedication towards the question of sustainability. These companies do not consider sustainability to be just a legal obligation, but they believe that besides making profits, they have to work to achieve benefits for all interested parties, society and the surrounding environment.

4.3. Performance

The common performance indicators used by companies in this research to measure economic and social performance are:

- Economic indicators: sales and EBITDA (Earnings Before Interest, Taxes, Depreciation, and Amortization),
- Social indicators: number of accidents, number of working hours lost due to illness, accident frequency index, accident severity index, absenteeism rate, overall staff turnover rate, training hours per employee, age profile, breakdown by gender.

In relation to the social indicators, the number of accidents and the frequency index are monitored by all companies in the study. Six companies monitor the severity index, and five companies monitor the number of working days lost. Four companies monitor the incidence rate and the number of working hours lost due to illness.

Only three companies monitored the indicator covering workplace-related illnesses. As with the environmental indicators, C3 stands out by using a BSC for health and safety, with the indicators of accidents and workplace-related illness; working conditions; supply chain and stakeholders; and emergencies and continuous improvement. Only one company monitors workplace incidents by using the same analytical method for accidents.

Out of all the indicators used to measure external social practices, the customer satisfaction rate is one of the indicators used by all of the companies to measure collaboration with customers. Those companies that measure collaboration with the community use the number of activities carried out, and, more generically, the result obtained from those activities. As regards social collaboration with suppliers, the indicators used for measuring this practice are related to supplier evaluation.

To study the relationship between the implementation of social practices and the economic and social performance, a comparative analysis of the data for the eight companies was carried out. To collect evidence of this relationship, the different interviewees were questioned regarding the particular relationship that respondents felt existed between the implementation of social practices and performance.

While certain trade-offs are considered part of the relationship between implementing social practices and economic performance, three companies found that social practices generate a positive effect on economic performance, increasing motivation, satisfaction and pride among employees, with consequent effects on the product quality, productivity and profitability for the company. However, differing

opinions exist in two of the companies, referring to difficulties in establishing a positive relationship between internal social practices and performance.

According to the interviews given, the relationship between social practices and environmental performance (where this relationship was found to exist) is positive. For most companies, this is a relationship that is hard to verify, although the existence of environmental and social awareness by the employees does lead to a reduction in risk.

Generally speaking, all companies were found to be unanimous in their opinion that there is a positive relationship between implementing practices of health and safety and social performance. This positive relationship is enhanced by drops in absenteeism, the number of accidents and their severity, as well as costs associated with overtime – all factors which understandably have considerable economic impacts. It is without adoubt that a win-win relationship exists between internal social practices and social performance with effects on economic performance.

External social practices, namely those focused on the community, do not have a positive relationship with economic performance. However, the objective is not to achieve an increase in performance. These practices are related to the culture of the organisation, with a set of intrinsic principles and values which have repercussions on reputation and image in the marketplace. In other words, besides the internal impacts, the external impacts are reflected in recognition of companies by the wider community, such as with awards, partnerships being forged with NGOs and participation in different research projects with different stakeholders.

Conclusion and Future Research

The main goal of this research was to analyse social practices and their relationship with economic and social performance. To this end, a literature review was carried out to identify the internal and external social practices and the associated performance indicators. Using eight medium and large Portuguese companies, the most common practices used by the companies were identified, along with the economic and social key performance indicators. Furthermore, the relationship between social practices and performance was analysed.

The study found that the actions of companies cannot be dissociated from access to the resources that support their activities and the ways in which they organise their processes and implement social practices for continuous improvement of their businesses.

All companies employ the widespread use of social practices, namely internal practices. Applicationis based on certified management systems (reflecting internationally recognised standards) and interfunctional cooperation that are enshrined in annually defined objectives covering the different departmental managers using diverse management methodologies.

All, except C5 and C8, embrace external social practices, developing actions in the community designed to increase employee awareness of the importance of adopting sustainable behaviours. The companies guarantee to their customers a quality product by defining the technical requirements that are subject to rigorous quality control and the legislation in the sector. Some companies are more forthright about their behaviour in this area, using responsible marketing campaigns which vary depending on the size of the

company and the resources available. Nevertheless, the absence of joint decisions to reduce the environmental impact,with no joint plans implemented to anticipate and resolve environmental problems, leads us to conclude that the implementation of such practices is limited.

It is worth noting that the commitment to social practices varies according to the strategy and size of the company, the financial resources and the needs and demands of the customers. The observed diversity increases when considering training and awareness projects involving employees and the levels of social collaboration with the community, suppliers and customers.

Overall, drawing on the experience of the eight sampled companies, it can be concluded that implementing social practices has a positive impact on the social performance of the company. Differing opinions were foundin relation to the impact on economic performance. However, when a relationship was found to exist, most interviewees thought it positive. These results can help the professionals to understand how to implement social practices and identify the impact that each practice has on performance. It can also help companies to decide which social practices should be implemented, considering their relative social and economic impact.

As with any other study, there are some recognisable limitations which can hopefully be improved upon with future studies. In particular, while the sample includes companies from different sectors of the economy, it is based on a sample of eight case studies. This limits the possibilities for generalising the results to other contexts.

One of the paths for future work relates to the possibility of generalising the conclusions to other contexts. This can be done by replicating the research using other companies in other sectors or by applying the methodology to small and medium-sized companies from other sectors of the Portuguese economy. Another suggestion for carrying out future work would be the use of longitudinal case studies. This approach would help analyse the implementation and structural dimensions of social practices and economic and social performance over time. This technique benefits the analysis by providing a more comprehensive view of the phenomenon, especially as sustainable management of the supply chain is an emerging area, and the attitudes and behaviours can change significantly between the short and long-term.

Acknowledgment

The author thanks Polytechnic Institute of Viseu and CI&DETS of Portugal for funding this project. The authors wish to express their gratitude to the companies and individuals who agreed to participate in the study.

Abstract

The purpose of this study is to identify the nature of challenges single women experience in attempts to advancing in their professional careers in India. It examines the impact of 'Single Women Stigma' through their personal, professional and societal engagements on their career expectations and advancement. The present study adopted a qualitative descriptive approach because it aimed at investigating the experiences of single working women. Data was collected from in-depth interviews conducted with 21 Single Indian working women. This study draws from Bandura's (2001) social cognitive theory as the theoretical framework. The findings suggest that there are a number of social, organizational and personal attitudinal barriers which hinder the advancement of single women at workplace. Social and organizational stereotypes, gender discrimination, work-life balance issues, single means 'available' (assumptions men have about single women) and lack of opportunity for growth are amongst the most prominent challenges at workplace and in social context. The paper provides insight to the unheard voice of Indian Single Women; the challenges and barriers to their career advancement. The attempt has been made to address the gaps in the literature related to "Single working women" and their career advancement. The implications are discussed and the recommendations to address the needs of this category of employees are provided.

Keywords: Career advancement, Single women, Self-efficacy, Indian Cultural Society.

1. Introduction

The status of women has been subject to great changes over the past millennium. The role and participation of women in the workforce has attracted a great deal of research attention globally (Wertheimer, 1981; Morrison & Glinow, 1990; Matsui *et al.,*1995; Nelson & Burke, 2000; Hayes, 2004; Cheung & Halpern, 2010; Enid Kiaye & Singh,2013; Dezső *et al.,* 2016; Madsen *et al.,* 2017) and particularly in India (Sharma, 1990; Gupta *et al.,* 1998; Budhwar *et al.,* 2005; Singh & Hoge, 2010; Desai *et al.,* 2011; Sahni 2016). However, little work has been done on Single working woman which is a new Universal Sociological Phenomenon of this century. The traditional Indian society from its collectivist cultural perspective presents a common patriarchal social understanding. This positions the bread earner role with the male member of a family, be it father, husband or a son. The woman therefore within the context of this cultural understanding tended to have their identities and roles being constructed from these traditional assumptions (Dalton 1992).

However, as part of the shrinking world of globalization, the Indian society has over the years been experiencing social changes that continuously redefine roles and identities for both males and female members of the society. These changes have informed increasing roles for the female folks. Female members of the families are increasingly stepping out of the house to work, either to earn money to support self, family members or for the sake of maintaining self-respect and dignity that work provides. The increasing engagement of these women in the workforce also comes with its challenges, especially

with the single women of the group which may impede the realization of their career expectations and goals. To quantify the current contribution of the female working force to the Indian economy.

Previous research suggest limited studies on the challenges of single women (Lewis and Borders 1995) and therefore there is a need to further engage in understanding the challenges these category of employees face within different perspectives and experiences at work and careers (Dalton 1992, Kaslow 1992).

The purpose of this study is to identify the nature of challenges single women experience in attempts to advancing in their professional careers in India. It examines the impact of this 'Single Women Identity' through their personal, professional and societal engagements on their career expectations and advancement. This study draws from Bandura's (2001) social cognitive theory as the theoretical framework.

Therefore the present study examines the nature of the challenges through the three questions; what organizational factors impact on Indian single women career advancement? what societal factors impact on their career advancement? And what personal factors impact on their career advancement?

Through the adoption of in-depth interview technique and the general inductive, the study examines both personal and socio-structural issues that impact on career advancement of the study population. The 'single women identity' in the context of this study is inclusive of women who do not describe themselves as being in any formal relationship.

This section has introduced the research background. Section two discusses the review of literature followed by section three which is methodology adopted in the research. Section four highlights the findings of the study and section five are discussion and conclusion.

2. Literature Review

Women are becoming important part of labour force all over the world. They represent almost fifty percent of the population; however, their participation in the workforce is not equal to men in many countries (International Labor Organization, 2014). Especially in India, women participation is small but increasing gradually with passage of time. As more and more women understand their contribution in the economy they are coming forward despite of several challenges.

However, reaching higher positions in management has never been easy for women. Women in high management positions were nearly invisible from the 1970s till 1990s and still it is difficult to find a good number of women in higher positions (Helfat *et al.,* 2006; Laff, 2006). Because of the multiple challenges and barriers at work place female leadership is still disproportionately small in nearly all sectors (Paustian-Underdahl *et al.,* 2014; Srinivasan *et al.,* 2013). However, in modern India women have held high offices including that of the President, Prime Minister, Chief Minister, Union Minister, Governor and leadership positions in corporate world as well. Therefore there is no dearth of women role models in politics or the corporate world (for example, Indra Nooyi, CEO of Pepsico, Chanda Kochhar, the managing director and chief executive officer of ICICI Bank and Mazumdar-Shaw, one of the most famous and inspiring women entrepreneurs are just few to name). The academic research on single women working in India is a recent trend and this is an under researched area.

The misconception and debates whether women perform as well on jobs as men has been addressed by many past studies. The recent studies reveal that there is no male-female difference in learning, problem solving ability or analytical skills and both genders performs equally on leadership positions (Zell *et al.,* 2015; Paustian-Underdahl *et al.,* 2014). Moreover, studies have shown that women scored slightly higher than men on performance measures (Allendorfer *et al.,* 2012). However, studies reveal that women earn less money than men for the same work.

The challenges and opportunities for working women are relatively different than men which can be seen in many ways. They receive fewer challenging assignments and face manager's biasness in providing

development opportunities, which leads to lower moral in women who restrict their managerial aspirations (Hoobler *et al.,* 2014). Moreover, past studies suggest that the societal beliefs and expectations from women create a barrier in their career (Kulkarni, 2002; Budhwar *et al.,* 2005; Vasavada, 2012). Single working women face even more complex environment not only at work place but also in the society. According to Singh (2001), the two categories of Single are; those who are single due to 'circumstance' and the other who are single by 'choice'. The later is a growing phenomenon in India. While studies suggest that women who opt not to marry by choice are rather happier than the married women (Azmawati *et al.,* 2015).

There have been studies on female work role conflicts. Sidani & Hakim (2011) addressing the work family conflicts of white collar single women in a developing country (Arab) context reported low job satisfaction as these women were under paid and had lower upward mobility. Hess & Bourgeois (2010) in their research conducted three studies to access the stereo types regarding men's and women's emotional expressivity and self-perception of their emotional behavior. Studies also suggest a persistent and universal gap between men's and women's earnings (Damast, 2012; Lips, 2013). On the contrary, Gino *et al.,* (2015) found in their study based on number of research and over 4000 participants that women have a higher number of life goals but plays negative outcomes with high power positions therefore, perceives power as less desirable. However, studies on single working women have been limited (Houseknecht *et al.,* 1987; Misra, *et al.,* 2007; Sandberg, 2013).

Review of literature suggests that there have been many studies conducted on working women in India as well in other parts of the world. However, little attention has been paid to the new Universal Sociological Phenomenon of Single women and their challenges at work and in personal life. Therefore, the present paper would address this small but significantly growing portion of Indian workforce and will give insight to the career advancement challenges of single women and also try to close the gap.

Context of Study: India

India has a complex culture with its diverse religions and languages and different opinions and beliefs concerning role and treatment of women at work and in society (Littrell & Bertsch 2013). It is also the second most populous country in the world where 48.5% of the population is represented by women. Women have equal participation in higher education. However, the labour force participation rate for women is not equal to men. The status of women in Indian society has undergone many changes over past decades (Sharma and Mukherjee, 2012). Indian society is typically characterized with stereotyping the role women plays, women is seen as only as house wife and a mother who takes care of all household work (Haq, 2013). The prime responsibility of earning money has always been with the men. When women enters workforce she is expected to perform dual responsibilities and therefore face double challenges that she must both adhere to social expectations as a housewife and, also work as an effective employee (Naqvi, 2011). Moreover, the changing global work environment has impacted India as well, there is a demand of high commitment from employees (Sahni 2016).

In the context of economic liberalization, there has been an increase in employment opportunities for women, but women still face various challenges at workplace (Khandelwal, 2002). Past studies suggest that the societal beliefs and expectations from women create a barrier in their career (Kulkarni, 2002; Budhwar *et al.,* 2005; Vasavada, 2012). However, the trend is changing and India has witnessed a social change. Women employment has now been a widely accepted phenomenon in present Indian society. The perception of society towards working women; be it single or married largely depends on the background of people. For example educated people are having a change in their perception and attitude but some conservative section of the Indian society still do not consider it good for an unmarried girl to go out and work. There is need for change in the way society or people from different backgrounds treat women and the perception they have for working women. As stated by Rawat (2014), impact on social transformation will take place only when the concept of patriarchy is shaken and conditions supporting women empowerment.

3. Methodology

To understand and analyze the challenges in career advancement, the qualitative method was more appropriate for this study. Qualitative research permits researchers to "develop concepts, insights, and understanding from patterns in the data rather than collecting data to assess preconceived models, hypotheses, or theories" (Taylor & Bogdan, 1998, p. 7). A phenomenological qualitative approach has been employed in study with in-depth interviews conducted with Indian women who are single (who do not describe themselves as being in any formal relationship). The study examines the impact of this 'Single Women Identity' through their personal, professional and societal engagements on their career expectations and advancement. This study draws from Bandura's (2001) social cognitive theory as the theoretical framework.

To explore this social phenomenon, data was collected through telephonic interviews from a sample of 21 single women employed in different sectors like banks, universities, government offices and private companies. A convenience sampling was followed given the difficulty of reaching single women. The interviews were 60-70 minutes long and were conducted in English. The interviews were conducted between May 2017 and July 2017.The interview questions had open-ended questions which allowed the interviewees to express their feelings and discuss the challenges that hold them back. The researcher incorporated narrative inquiry techniques.

To maintain the confidentiality of participants, alphabets are used in reporting the findings. The interview transcripts were reviewed for any inaccuracies. Patterns were analyzed after collecting information from participants through open-ended questions. Using a thematic approach, themes related to career advancement challenges were identified after coding and recoding. Content analysis was performed to identify frequent and recurring themes.

A descriptive profile of participants is reflected in Table 1 below. Twenty one participants were chosen for the study. They were diverse in age groups and employment sectors. There was only one woman below the age of 30 years, the age of other participants ranged from 30 to 48. All the participants were employed in cross-sectors, with wide-ranging affiliations in education, banking, private companies and government agencies. The educational background of the participants was also diverse; four participants had earned a Doctoral degree, seven had Master's degree, eight had a Bachelor's degree while one participant was Diploma holder. Twelve participants were from the category of never-married; seven were separated or divorced while two were widow.

Table 1: Brief profile of participants

Name	Age	Status	Education level	Employment
A	38	Unmarried	Doctoral degree	Professor
B	32	Divorced	Bachelor's degree	School teacher
C	36	Unmarried	Bachelor's degree	Banker
D	35	Separated	Master's degree	Software engineer
E	42	Divorced	Master's degree	Private company
F	31	Unmarried	Bachelor's degree	Banker
G	29	Divorced	Master's degree	Software engineer
H	36	Unmarried	Master's degree	Software engineer
I	30	Unmarried	Diploma	Government
J	38	Unmarried	Bachelor's degree	Private company
K	31	Unmarried	Bachelor's degree	Software engineer
L	38	Divorced	Doctoral degree	Professor
M	41	Widow	Bachelor's degree	Banker
N	28	Unmarried	Master's degree	Private company
O	34	Unmarried	Bachelor's degree	School teacher

P	33	Separated	Bachelor's degree	Government
Q	39	Unmarried	Doctoral degree	Professor
R	45	Unmarried	Diploma (Technical)	Private company
S	39	Separated	Master's degree	Government
T	48	Widow	Doctoral degree	Professor
U	41	Unmarried	Master's degree	Banker

4. Findings

This qualitative study examined the experiences of twenty one working women who are not in any formal relationship therefore called 'single'. The findings of study suggest a varied number of issues and challenges as perceived by single women at work and in society at large. The main themes derived from the stories are; social stereotypes and prejudices, gender discrimination, work-life balance issues, single means 'available', lack of opportunity for growth and lack of mentoring. The findings of the study are presented in three parts: organizational factors, societal factors and personal factors, that impact on their career advancement.

The participants in this study provided valuable insights. Investigating the workplace challenges and barriers faced by single women in India, it was found that most of the participants had experienced discrimination at workplace. However, only five participants reported that their marital status does not affect their career advancement. But these women do face many barriers in workplace because they are women. The rich descriptions of the experiences of single women at work and in the social context are provided below.

Organizational Factors

Women are increasingly participating in the labor force in India. The concern here is not only their meager participation; however, they must be given equal opportunity to reach higher positions in the organization. One of the prominent theme which emerged from the interviews is 'gender inequality and discrimination' at workplace. Gender inequality connotes to unequal treatment or perceptions of individuals based on gender (Wood, 2009). This is directly related to lack of opportunity for growth and lack of mentoring for women in general, at workplace. The constraints present in the organization were obvious from the participant's responses. Gender inequality was observed in the response provided by the participants. For example:

(H) In my 10 years long career, I have never received equal increments as my male counterparts, no matter we are equally qualified, skilled and efficient. It is disappointing to note that every year my increment is less than other colleagues who are men. Although I tried to talk to my boss but my efforts go futile.

For single women, in particular, there are no family-friendly policies existing on ground, however, all organizations claim to have flexible work arrangements. It becomes a hindrance for single women who are taking care of the parents and whole family. Many issues were related to work-life balance, as stated by one of the participants:

(J) I am the one who is expected to stay back in the house whenever my parents fall sick, and unfortunately that is the time when my boss calls me to attend a meeting on urgent basis. Being a daughter, I can't leave my old parents on their own and I have to say 'no' to my work during this critical time. I wish my company had some kind of support may be elderly care etc. to help me focus on my work.

Another theme which was common among all the participants is single means you are "available''. This theme has its roots in the social stereotypes and prejudices but experienced in the workplace by most of the single women. The participants mentioned that the male colleagues start taking women who are not married as available for them to date. This is disturbing the single women both psychologically and making them insecure at work. Here is the quote form one of the interviewees which represents the feeling all single women:

(R) I have experienced this early in my career and I see the new girls facing the same in my as well as other companies. I am talking about the perception of men for unmarried women or single women, I don't know what makes them think that if we are not married there is something wrong in our character and we can hang out with them after office till late hours. I mean there's no harm in making friends but it's their scorching eyes which tell the truth-what they want from a female. This is disgusting and I've been handling such situations very carefully because sometimes it's your boss. You need to handle these conditions with great care.

Social factors

In the Indian society, it is difficult to lead a normal life if you choose to be 'single' or even if circumstances forced you to be 'single'. For women, the social pressure to get married and settle has always been there from ages. However, the traditional stereotypical views towards single career women are slowly changing and they are getting acceptance at least in the urban areas of India. The social and family commitment and responsibilities pose a great challenge to single women aspiring to progress and continue in their careers. The social restrictions limit women's advancement at work. For example, one of the participants described the type of constraints:

(T) Life has not been easy for anyone but for me it's a bit more difficult because I carry a tag of being single. The society in which we live does not accept the freedom of any women easily. When my husband died and I started working, my in-laws had an objection but my parents gave me full support to become independent. We have all types of people with all types of prejudices towards single women working in private sector.

There are single women who received a great support from their families and society at large. The following statement is representative:

(B) I am now Single by my choice. I really owe this freedom to my parents. They don't mind my staying with them after my divorce rather they welcomed me with open arms. Our culture used to be not so friendly for women who work for their financial freedom, but I have seen a lot of change in the thinking of people.

The change in the society can be attributed to the socioeconomic level of the given family and the level of education.

As many people have set prejudices in mind like women should take care of house and men are there to earn for them and feed them. One of the respondents said:

(D) In India the environment for working women and non-working women are totally different. Women who stay at home are not exposed so much to the outside world. When they see me going out and also taking tuitions at home where students of all ages come to my place…it's a cultural shock for them.

The finding suggests that being single and working in private sector raises questions in the society. However, the statements reveal that this social prejudice is changing by time. For working women the social prejudices still remain a barrier for career advancement for majority of single working women.

Personal Factors

One of the common themes was the single women's commitment to personal and family responsibilities over work. Women are said to be more emotional and responsible but this might become one of the constraints in their career advancement. Moreover, single women are challenged to cope with stress and sometimes it leads to distress. However, the advancement in technology has supported women in a big way. For example, the automated washing machines and dishwashers are great time savers. Furthermore, use of internet and access to work email has helped women employees who have flexible work arrangement in their organization.

From humane perspective, when one does not have proper emotional support and lacks the balance between personal life and professional life she tends to become weak. But having a good support network helps her in all ups and downs of life. For example, one of the participant's states:

(L) I am a single working mother and for me it's not easy to raise two children alone. However, I have my parent's support but I do not like asking for money from them for any good reason. I do overtime every single day to earn little extra for my school going children. There was a time when I thought of just ending all the problems by ending my life but then I saw my kids. I was under depression for two years and it affected my work to a great extent.

Despite of numerous barriers at work and challenges posed by society, the single women had shown a different level of self-reliance leading to self efficacy. They all were contended with the choices they made in their life. In the words of few participants:

(A)I don't want the world to be with me, I am concerned about only two or three people who are important to me. I am a kind of person who would like to adjust to any type of environment. I am basically an independent person. I am contended in my life.

(P) I cannot change the whole world but I can change myself. I feel hurt whenever I am in situation where people pass bad comments on my marital status I see these people as sick…they have some kind of disease so I am not bothered about their treatment. I just pray for them to get better. I don't react, ignore and I forgive them

(M) There are many problems in life, but one should never under-estimate herself. Women needs to be independent (Single or married) and not rely on anyone else.

These quotes suggest that Single women in India have been facing varied types of challenges in their personal as well professional lives. The organizational constraints and challenges are seen on day to day basis at their workplace (for example, discrimination, stereotype, lack of opportunity for growth) yet the self confidence and self efficacy of single working women is commendable.

The findings reveal the unheard stories of the single women, the constraints present at all levels explain that even in advanced setting people still live with the stereotypes in organization and in society; however, these stereotypes and prejudices takes ages to be broken. A single working woman is a category of employees which demand at least equal rights and opportunities.

5. Discussion And Conclusion

The findings from the sample of participants clearly emphasize the several types of challenges and barriers single women face in the workplace. These barriers serve as strong impediment in their career advancement. These barriers, specially the social factors are present not only in India but around the world (Berg-Cross *et al.,* 2004). The study answers three questions being: what organizational factors impact on Indian single women career advancement? what societal factors impact on their career advancement? and what personal factors impact on their career advancement?

Under organizational factors, the important themes which emerged are 'gender inequality and discrimination' at workplace, single means "available', lack of opportunity for growth and lack of mentoring for women in general. The social factors are equally important and they either undermine the career advancement of women or support them in their career. The main challenges as perceived by single women are; traditional stereotypes associated with single women, social and family commitment and responsibilities. There are other personal factors that add on to this list of challenges. Importantly, stress and distress, lack of emotional support and imbalance between personal life and professional life emerged as main themes under personal factors.

The women are now better educated, well trained and well equipped with self confidence. However, there was clear differentiation leading to discrimination based on the marital status at workplace. For single women the main concern is the quality of work they do and how does being single or married affect the output of their work. Moreover, the single women do not see 'singlehood' as a problem for anyone. In the present modern society, the identity of women should not be wrapped up in marriage. Some of the advantages of single hood as mentioned by the interviewees are; more time to work on yourself; freedom to travel on your choice; ability and freedom to take decision for my life etc.

Indian culture is a perfect example of a combination of both extremes; family pressurizes to get married and close family members becoming matchmakers in all your family occasions just to get you married. On the other hand, in India the family becomes the support system for single women (by choice or by circumstances), they welcome her with open arms. But when it comes to society or social settings, all single women become the talk of the town. However, this trend is changing gradually. People have started respecting single mothers and single working women as well. The contextual supports play key roles in the career advancement of single women.

The twenty first century single working women in India, despite of all odds enjoys the financial freedom, personal freedom and freedom from a unsuitable partner. Although all three factors; Organizational, Social and Personal factors impedes the upward mobility of single women in organizations, Organizational factors were the most common among single women which hinders their career advancement. However, a steady improvement is seen in thinking and perception the society at large has for single working women. The prejudices and stereotypes are still prevalent at many workplaces.

The study has provided a unique investigation of the social phenomenon of single working women and it has explored three different types of factors that prevent her from reaching higher positions in her career. The paper documents the story of unheard Indian Single working women. The constraints to their career advancement are present at all levels; personal, organizational and social. However, the self efficacy and commitment shown by these single women drives them at the workplace. These women have their coping efficacy that makes them stronger and prepare them for the coming challenges.

Moreover, the study has depicted the role of social cognitive systems in India and how salient stereotype limits the single women's growth in organizations. The findings have significant implications for practitioners, human resource departments, academic researchers and many other stakeholders. Few interventions are suggested; organizations should encourage the single professional women and shed the prejudices that men are superior to women (studies have shown there is no difference in the capabilities of men and women). By having more women friendly workplace policies considering contextual factors of Indian society, will help not only the single women employees but lead to organizational effectiveness through committed employees. Cultural and societal interventions are also needed to support them. Creating a positive image of single working women through media can be one of the interventions. The academic researchers might learn from the findings the unique workplace challenges that impede the career advancements of single working women in the contextual framework of India. The organizations can follow The United Nations Development Programme (UNDP) 'GENDER EQUITY SEAL", the new auditable standard and certification system to promote fair treatment of men and women in the workplace. Private sector can play an exemplary role by implementing the best practices nondiscrimination statements and written policies in wages, training and access to opportunities. In total the six critical areas addressed are; Gender-based pay gaps, women's roles in decision-making, work-life balance, women's access to jobs in more dynamic and traditionally male-dominated sectors of the economy, ending workplace sexual harassment and using non-sexist communication. Proper implementation could serve a promising future for all categories of employees.

6. Limitations And Future Research

The present study had some limitations. The limited amount of research available on single working women in India restricted the literature review. The sample size was small but adequate. It was difficult to reach out to the single women and moreover to get consent from women to participate in this study. In addition, the area of study was limited to metropolitan cities of India. Therefore, the future researchers can consider an empirical investigation including B or C class cities as well in the study. In addition, a comparative analysis of career advancement of single women in private and public sector can be one of the future research areas. The studies can consider bringing successful Role models (especially those working for key corporations) for advocacy. They can speak quote and publish for themselves as well thus increase the informal documentation around this important subject).

Debates on Needs vs. Resources: The Limited Character of Natural Resources

Abstract

Most natural resources that are used in production are non-renewable. When they become depleted they are lost for future use. Does it follow that the limited availability of natural resources will at some time in the future constrain economic growth as many environmentalists believe? While classical economists have shared the belief in limits to growth, the distinctive feature of modern neoclassical economics is its optimism about the availability of natural resources. After demonstrating the major role natural resources play in all economies worldwide (in the first part), we revealed the national and international character of natural resources (in the second part), with special focus on the international trade with resources and goods that may alleviate temporary shortages in supplying with raw materials and energy resources of any economy. In the end, the paper dealt with the old controversy between unlimited needs (of economies and of population) and the limited resources (especially of non-renewable natural resources), as their availability is questioned more and more in the present days. Special focus was placed on natural resources scarcity as this is the most pregnant element showing the limitations natural resources must face today. To better understand this issue, an econometric model was given to demonstrate the strong link between the actual stock of natural resources, on one hand, and the increase in exploitable stock due to the geological and soil improvement activity, as well as the raw material and energy production, on the other hand. In the end, some arguments were given to strengthen the need for sustainable development and environmental protection as the sole way to deal with inter-generational allocation of natural resources, which is, in fact, the basis of sustainability.

Keywords: natural resources, availability, scarcity, resource substitution, sustainability.

Introduction

In order to move the entire world economic gear, on average of approximately 3 tons of active minerals per year per world inhabitant are taken from the Earth's crust. Depending on actual consumption, determined by the level of development, pollution is more than 3 tones in the case of an African, but more than 30 tones in the case of a North American.

Approximately 1.2 billion people consume annually four-fifths of the energy produced in the world, and more than 3 billion people use only one-fifth. The ecological balance is in danger not only because of the huge takeover of minerals, but also because of the emanations and discharges of pollutants.

Technology responds: new energies, new materials, new specific consumption, and new processing processes.

And these are just some of the problems of the world we live in. At their center – natural resources with their availability, needs, capitalization and use, subject of the next paragraphs.

The Role of Natural Resources In The Economy

Natural resources [1] occupy a central place in national wealth and of social reproduction as a whole; they constitute both the substance and material conditions, and the virtual driving force necessary for the development of the production of material goods (consumer goods and means of production), as well as the extension of the service system. All economic activities have as their starting point and, ultimately, they are based on the existence of natural resources.

Natural resources are used as sources of raw materials to make goods and also to provide energy [2]. Making goods and producing energy consumes large quantities of resources extracted from the Earth. These resources are removed from the ground by mining. Mining includes digging ore out of the Earth which is refined to produce metals. It also includes drilling for liquids under the Earth. Most people think immediately of oil and petroleum resources; natural gas is removed from the Earth, too.

Natural resources are difficult to define precisely, particularly in the context of international trade. Most people have an intuitive idea of what natural resources are, but “common sense” definitions cannot be relied upon since they eventually run into problems when dealing with ambiguous cases. For example, crude oil and wood are clearly natural resources, but it is less obvious how intermediate and final goods made from these products should be classified.

For the purposes of this paper we should agree with defining natural resources as “stocks of materials that exist in the natural environment that are both scarce and economically useful in production or consumption, either in their raw state or after a minimal amount of processing” (WTO, 2010a). Another way of expressing the idea that natural resources must be scarce and economically useful is that they must command a positive price in markets and can be used either as inputs in production or directly as a source of utility to consumers.

As noted earlier, natural resources falling under this definition typically share a number of key features, including exhaustibility, uneven distribution across countries, negative externalities consequences in other areas, dominance within national economies and price volatility. We now examine each of these features and illustrate them with some concrete examples.

Under these conditions, any act of social production can be regarded as an "entry-exit". The available for "entry" - and what, in the long run, is ordered to be introduced into the social production process - is, in general, resource. "Exit" is the result, which is obtained in the process, and from which a part is consumed definitively for the maintenance and perpetuation of the human factor - the driving force and the purpose of the productive act - and another part is preserved for its reintroduction into the circuit, becoming thus a resource for the development of social production.

In other words, resources are a dynamic, ever changing element. Their scope is not limited to natural resources only, which objectively have given determinations; even in their case, what is at one particular moment considered to be natural endowment, actually bears the imprint of the relative character of the assessment depending on the degree of knowledge and exploitation and valorization technologies at that time.

With regard to mineral resources that are nonrenewable, it is quite difficult to establish with certainty the number of years of exploitation of existing reserves until their complete depletion. If, however, the amount of mineral reserves grouped into safe, probable and possible categories is calculated, this is done by specialists not in order to show that over a number of years the resources of the globe will be

completely depleted or not. These quantities and their exploitation time horizons show the degree of knowledge of the reserves at a given time (allowed both by the size of the funds allocated for geological research and exploration, and by the practical interest that exists in this regard in allocating funds for those extractive industries to increase both current and immediate future production), as well as the technical and economic possibilities of their exploitation.

The extent of knowledge, as a result of geological research, improvement of exploitation and extraction technologies, increases the exploitable reserves of natural resources. Also, new mineral resources are drawn upon the economic circuit, thus enriching their range, while some of them can substitute the classic ones, especially those that have become too expensive.

Considering all this, it is more correct to appreciate that the evolution of the world economy, as a whole, as well as the national constituent economies, will be influenced not so much by the physical limits of resources under the conditions of a normal demographic evolution, but especially by the economies and technological advances (Thorvaldur *et.al.,* 1999). In this respect, the extraction costs of the various minerals become decisive, because of shifting to the use of mineral ores with a lower content and with a growing degree of impurities, at higher exploitation depths and in increasingly difficult conditions. Also a significant influence will have the evolution of research and the application of new technologies that make possible the substitution of classical resources with new ones, as well as saving resources by reducing specific consumption, by recycling them, etc. All these issues are reflected in the production costs and the level of economic efficiency of extracting the useful elements.

Finally, the human factor, the "consumer" of endowment with natural resources that are transformed with the help of economic resources [3], is the main resource of the production act. Without the human factor, this act itself would not exist. The creative work of man is the one that transforms natural endowment into resources; it is the only one that gives birth to the technical and economic resources and, in the process of labor, socially by itself, quantitatively and qualitatively creates and enriches social and economic resources.

Through the present study, the analysis aims at a limited objective: to make a global-world and national-particular “inventory” of natural resources - often referred to in the economic literature as production factors - without penetrating deep and deep neither in the dialectics of the production process itself, nor in the dynamics of the union of the three major categories of resources, nor in the gearing of the "entry-exit" correlations, although the approach permanently pursues the essential link between quantitative and qualitative endowment with resources (seen as "inputs") and economic performances (seen as "outputs").

As a result, numerous and widely important studies and works have drawn attention, especially over the last five decades, on global issues of natural resources (Meadows *et.al.,* 1972; Iancu, 1972; Ayres, 1978; Kula, 1994; Sneddon *et.al.,* 2006; etc.). By new, bold and interesting approaches, they have "shocked" and, precisely by such means, have achieved their purpose: the warnings launched have been received; global problems have penetrated into general consciousness, the dangers and threats stemming from their failure to resolve have been better understood and, as such, the requirement to solve these problems has been imposed.

Many approaches related to natural resources use have emanated from the industrialized world's perimeter, and few of them have projected global issues in light of the vision of this world. There have been trends, whether directly or indirectly, explicitly or implicitly, the problems of the industrialized world to be generalized and "globalized", whether or not the problems of the less developed world have been "forgotten" (van der Ploeg, F., 2011).

Insignificant activities have in fact been made in these approaches to address the global problems of mankind and less developed world, and even weaker have been the attempts to understand the serious and

pressing problems of this world, from catching and emphasizing their global-world impact and to enhance, if not the priority, at least the urgency of their settlement, through extensive international efforts (Warner, 2015).

National and International Character of Natural Resources

The resource problem is multidimensional, its determinations, coordinates and implications being natural, geographic, economic, technical, historical, social, political and ecological. It also proves to have a national and, at the same time, international character, as seen before.

The national character derives from the very objective reality of the national states, which makes the resources to exist, in fact, in geographic, historical and politically constituted-delimited spaces. Each such space has a certain endowment with natural, demographic, technical-economic and social-economic resources, and their allocation, the process of social production itself, takes place in this space, in specific coordinates.

In other words, at the social-national level, it takes place the exploitation of the natural resources stock, the reproduction of the human factor, the formation and distribution of the technical-economic resources, the creation and valorization of the social-economic ones. In each national economic-political-social complex there is, therefore, a specific combination of different categories of resources, which determines differences in their allocation, management, distribution and use in the content of social production itself (Alais, 1971).

Thus, from a global point of view, the situation is highly heterogeneous. The current heterogeneity derives not only from the inherent differences determined by, generically speaking, the "size" of the states and, therefore, the amount of available natural resources, but also from the discrepancies in the degree of the valorization and the efficiency of their use.

The international character of the resource problem is closely related to the heterogeneity mentioned, in both its aspects. The needs-resources report is not the same in the different national spaces, which makes the union, within each of them, of natural and economic resources with the demographic (the human factor), and thus the valorization of the resources as a whole (through the social production process), to be accomplished through relations with other national spaces (Ohlin, 1967). The different natural resources are objective unevenly distributed globally and the possibilities for reciprocal substitution are reduced; needs are, however, general, so there is no alternative to international exchanges with such resources (Bulearca, 1995).

At the same time, if their exploitation takes place in national spaces, the constraints of exploitation are global, because the environment is unique as only a certain takeover of resources may occur regardless of where this takeover takes place (due to the global, limited natural endowment) and only a certain deterioration under the influence of polluting effects may arise regardless of where such effects are generated. The very large and growing diversity of technical and economic resources gives a pronounced international character on the natural resources issue.

Under the circumstances of this diversity, it becomes technically impossible and economically ineffective that in every national space, the entire assortment of technologies and products that constitute links (and therefore resources) in the current production gear complex to be conceived and created; as it would not be possible in every national area to create and make available the full amount of financial resources claimed in such a case. Thus, a certain specialization - and consequently a wide international cooperation - in the sphere of technical and economic resources is objectively claimed. At the same time, consideration should be given to the need and usefulness of international exchanges of experience, in the field of resources, for organizing and managing the micro and macroeconomic processes.

Experience itself proves that the current asymmetry in the world in terms of levels of endowment with technical and economic resources (which causes serious discrepancies in the degree of capitalization of natural resources and human productive potential, as well as in the standard of living and civilization) is closely related to a certain kind of international relations. Organizing international relations is therefore an integral part of the resource issue. The process of allocating, capitalizing and distributing resources - which has, and will preserve, predominantly and decisively a national character - tends to, at the same time, take on an increasingly profound international character, in the context of increasing interdependencies between different national spaces.

Hence, worth noting that countries' differing natural resource endowments – and their uneven geographical distribution – play a critically important part in explaining international trade. Traditional trade theory emphasizes that differences in factor endowments prompt countries to specialize, and to export certain goods or services where they have a comparative advantage. This process allows for a more efficient allocation of resources, which in turn leads to an increase in global social welfare – the "gains from trade" (WTO, 2010b).

Studying the problems of primary resources and highlighting their relationship with the specialization of national economies and the structure of international economic exchanges made possible and necessary to develop ***the theory of endowment with factors***, synthesized in the so-called 'Heckscher-Ohlin theorem' [4]. Relative differences in countries' resource endowments are keys to the standard version of the Heckscher-Ohlin theory of international trade, according to which nations tend to specialize in industries and export products and services that require the use of relatively abundant and inexpensive production factors (natural resources). Conversely, nations tend to import goods and services that require large inputs of relatively scarce and expensive production factors (Heckscher, 1919; Ohlin, 1967). According to this theory, there is an organic link between the endowments with production factors (with primary factors, in particular) and the profile of the national economy.

Hence, endowments of immobile and scarce natural resources may form a source of comparative advantage that guides the pattern of international trade. Consistent with this theory, Leamer (1984) finds that the relative abundance of oil leads to net exports of crude oil and that coal and mineral abundance leads to net exports of raw materials. Trefler (1995) finds similar results with respect to trade in resource-intensive goods.

The Heckscher-Ohlin theory has been modified and extended by introducing other factors besides resource endowments, such as transportation costs, economies of scale and government policy, (WTO, 2010a) that also influence comparative advantage. For example, distance from world markets can be a decisive factor when the natural resource in question is bulky, such as natural gas, and when transportation costs are high. Complementary inputs, such as technology, capital and skilled labour, are also significant when a natural resource sector is characterized by difficult or technically complex extraction processes.

Variables such as education, infrastructure and institutions have also been observed to affect sectoral patterns of natural resources trade (Lederman and Xu, 2007). Only when these other determinants of comparative advantage are in place will a resource-abundant country tend to export resources to countries with a relative abundance in capital and skilled labour and import capital-intensive goods in return (Leamer, 1995). In short, natural resource endowments may represent a necessary but not sufficient condition for the production and export of resources or resource-intensive goods (Feenstra, 2004).

The existence of these two categories of resources - primary and qualitative - and especially the rapid increase in the role of non-material qualitative ones in "contemporary" national economies provided further clarifications and even changes in the old sense of the theory of endowment with factors, in the

following sense: as the development of national economies develops, their profile and structure is increasingly released from dependence on the endowment with natural primary production factors (Johnson, 1968; Vernon, 1970). The structure of the economy remains tightly linked to its own raw material and energy base, only as long as the national economy is at a low level of development.

Based on technical progress, with the expansion and upgrading of the economy's structure and, above all, of the industry's structure, the link with its own energy and raw materials base, in its traditional meaning, weakens (and this is good), in particular, due to three reasons (Sachs and Warner, 1995). Firstly, is the creation of new industrial branches and diversification of production incorporating an increasing volume of highly qualified work and research activities, proliferation of technical and scientific progress in the national economy, resulting in a reduction in the consumption of natural resources per unit of added value. Secondly, is the development of foreign trade relations, which creates availability of foreign currency means of payment for resource imports and the expansion of international cooperation relations on direct, production and technical-scientific investment in the field of energy resources and raw materials. Thirdly, is the widespread resource substitution of raw materials and energy resources with new synthetic and artificial resources, as well as the use of alternative resources (IMF, 2017).

Under these circumstances is required that the national fund of available resources to be known and put to good use by a rational trend in each country, according to its inalienable right to permanently and entirely dispose of national natural resources in the interest of developing its own economy (Tinbergen, 1977; Hartwick, 1977; Bravo-Ortega and de Gregorio, 2005). The current world trade system helps support substantial inequalities in the distribution of the use of natural resources. This raised (Ecobescu, 1981; Brown *et.al.,* 2015) and still raises important questions for global justice.

Therefore, ***the effectiveness*** (the fundamental economic criterion) and ***the equity*** (the fundamental social and ecological criterion), the two main objectives which must govern this process at national level and whose simultaneous implementation is of particular importance and complexity, must be both pursued internationally. In this respect, worth noting that the world economy today uses around 30% fewer resources to produce one Euro or Dollar of GDP than 30 years ago; however, overall resource use is still increasing, but resource efficiency has improved steadily globally. Anyhow, as we consume growing amounts of products and services, this upward trend is more than outweighed by the overall growth of our economies (Brekke and Howarth, 2002).

In order to create a more sustainable and equitable world, regions with high levels of per-capita resource use will need to sharply decrease their resource use in absolute terms. This reduction in resource use in richer regions will give poorer regions the chance to increase their resource use as they overcome poverty and increase their quality of life (Graham *et.al.,* 2017). This principle is already well established in the global debate on climate targets, and it needs to be extended to the area of resource use. Short-term actions can get rich countries on the right track. These include implementing policy measures that increase the prices of natural resources and reward resource-efficient behavior, exploiting resource efficiency within companies, increasing recycling and informing consumers about their options to reduce the use of natural resources (Wackernagel and Rees, 1996).

As a result, more fundamental questions about economics, development and resources need to be addressed in the medium term. Most significantly, how can new models of development to be created in industrialized countries that focus on well-being instead on increased production and consumption? This will require rethinking the role of economic growth and the links between resource use, quality of life and happiness. Therefore, whether economic growth can be sustained in a finite natural world is one of the earliest and most enduring questions in economic literature.

The limited character of natural resources, the need for their sustainable use

Anything that is dug out of the ground cannot be put back; that is why anything that is removed from the ground is considered limited and will ultimately run out. This means that when the supply of the resource runs out there will be no more. The Earth forms natural resources very, very slowly and it takes a very, very long time. The resources that are easiest to dig out are used up first. This includes the minerals in high concentrations and those that are near the surface. Once these are used up, it is necessary to look for more. These resources are harder to obtain and in lower concentration. This makes them more expensive to obtain, so goods cost more. And, as we stated before, eventually the resources will run out.

Natural resources, including materials, water, energy and fertile land, are the basis for our life on Earth. However, humanity's rapidly growing consumption of these resources is causing severe damage. Our climate is changing; fresh water reserves, fish stocks and forests are shrinking; fertile land is being destroyed and species are becoming extinct (Johnson, 2002). In order to continue to thrive on this planet, our lifestyles will need to become more sustainable, so that we are able to protect our natural resource base and the fragile eco-systems on our planet (Howarth, 2012).

Humans today extract and use around 50% more natural resources than only 30 years ago, at about 60 billion tones of raw materials a year. Increasing resource extraction doesn't just lead to environmental problems, but is often also linked to social problems such as human rights violations and poor working conditions. These negative environmental and social impacts are most strongly felt in African, Latin American and Asian countries with low environmental and social standards (Axelrod *et.al.,* 2011). People in rich countries consume up to 10 times more natural resources than those in the poorest countries. On average, an inhabitant of North America consumes around 90 kg of resources each day. In Europe, consumption is around 45 kg per day, while in Africa people consume only around 10 kg per day (SERI, 2009).

Even with unprecedented growth in human population and resource consumption, humans have been quite adept at finding solutions to the problem of scarce natural resources, particularly in response to signals of increased scarcity (Barnett and Morse, 1963; Barnett, 1979; Smith, 1979; Stiglitz, 1979). Because environmental resources are not generally traded on markets, however, scarcity signals for these resources may be inadequate, and appropriate policy responses are difficult to implement and manage. In the debate over the economic scarcity of natural resources, one significant change in recent years has been a greater focus on the ecosystem services and the resource amenities yielded by natural environments (Krautkraemer, 2005). The general conclusion at this point is that technological progress has ameliorated the scarcity of natural resource commodities; but resource amenities have become scarcer, and it is unlikely that technology alone can remedy that.

Starting from these evidences, although its influence on current research on the economics of sustainability is mainly historical (Neumayer, 2004), the legacy of *The Limits to Growth* study (Meadows *et.al.,* 1972) continues to have very considerable implications for environmental policy, in part because of the powerful appeal of the study's "apocalypse-or-renewal" rhetorical framing in the context of the contemporary sustainability movement (Meadows, 1992). In debates over climate change, for example, environmentalists (Victor, 2011) sometimes argue that, because the production and consumption of market goods and services is the proximate cause of greenhouse gas emissions, stabilizing climate will require some curtailment or even the reversal of economic growth.

In response, critics argue that, because economic growth is fundamental to the improvement of human welfare (Howarth, 2012), policies that negatively affect economic growth are unworkable and undesirable (Lomborg, 2001). This contextualization of the issue has led to policy gridlock grounded in an underlying ideological disagreement.

In traditional approaches, natural resources as well as the population appear to be exogenous variables of the economic and social system, which in the short run usually does not pose the real prospect of each resource. In reality, the evolution of primary, population and quality resources is in close interdependence with the evolution of the economic and social system (Stiglitz, 1974). Hence, in dynamic studies, and especially in long-term projections, the resource subsystem must be integrated into the economic system, and at the same time it is necessary to analyze both the evolution of the structure and the mutual influences of the change of the component elements of the system.

The economy and human society, as a whole, long-term development will depend on the availability of factors, represented, first of all, by the natural resources, comprised, in turn, in a very complicated network of relations with the demographic, technological, ecological and biological factors. For modeling these relationships, it is important to identify and define the conceptual apparatus with which we shall operate.

Therefore, worth noting that in most of the papers, a large part of the conceptual and methodological apparatus was closely related to solving the problems of optimal allocation of resources (Kantorovici, 1966), in which the limitation of the production factors appears to be relative in both the static and the dynamic vision. Indeed, resources appear to be deficient in their relationship to the growing need to meet more and more needs in production or consumption (Bulearca, 1993).

As noticed earlier, natural resources can be thought of as natural capital assets, distinct from physical and human capital in that they are not created by human activity (WTO, 2010a). Natural capital may be a potentially important input in a country's "production function", but is important to distinguish between natural resources as factors of production and natural resources as goods that can be traded internationally. For instance, minerals, oil, and various other materials can be extracted and enter into trade. However, other resources may form the economic basis for various sectors of the domestic economy, and therefore are only involved in trade in an indirect way (Josling *et. al.*, 2009). For example, climate and scenery can be exported through tourism. Similarly, agricultural land, which is the archetypal "fixed, immobile" natural resource, can be exported through agricultural commodities grown on that land. Hence, at a fundamental level, natural resources are often a reason for trade rather than tradable goods in their own right.

Hence, the general links between the economic results, on one hand, and the natural resources (interpreted as flows and stocks) and the other primary resources, on the other hand, can be more clearly identified using mathematical relationships and symbols. Thus, we may say that the labor force $L_0(t)$, the production resources $K_0(t)$ and the natural resources $R_0(t)$ are used as primary resources to achieve the final goods and services production $Y(t)$:

$$Y(t) = f\left[L_o(t), K_o(t), R_o(t), t\right].$$

The natural resources $R_0(t)$, represented by the flow of raw materials and primary energy that are used in the production process, are also obtained from the stock of material resources as a result of the mining, forestry and agricultural exploitation activity, and the use of the wealth of waters, etc., for which is required to allocate labor and fixed capital resources. Taking into account the so-called stock of natural resources existing in period t, noted as $S(t)$, as well as the $L_1(t)$ labor force and the fixed capital $K_1(t)$ available, the production of raw materials and energy $R_0(t)$ is given by the relationship:

$$R_o(t) = f\left[L_1(t), K_1(t), S(t), t\right].$$

The more the resource is extracted, the more difficult and more expensive it becomes to extract that resource from the nature. That is why stock *S* is a superior limit that can be reached in the given technological and economic conditions. But the stock has a dynamic character. It can be increased over time: in the case of non-renewable resources, through prospecting and geological research, by adding to the known and exploitable reserves category those new identified and studied resources; and, in the case of renewable resources, through natural processes (rain, wind, solar radiation) and by improving and protecting soil and forests, planting new forests, and researches to create the technologies needed to exploit the natural potential.

The increase in the stock of resources *G(t),* as a result of human activity, requires an appropriate volume of labor $L_2(t)$ and capital or fixed capital $K_2(t)$:

$$G(t) = f\left[L_2(t), K_2(t), S(t), t\right].$$

Taking into account the initial stock of resources (S_0), the increase in exploitable stock due to the geological and soil improvement activity *G(t)*, as well as the raw material and energy production *R(t)*, which leads to the stock resource shortage, the stock of resources at the end of the period *t* can be expressed by the relationship:

$$S(t) = S_0 + \int_0^t \left[G(\tau) - R(\tau) d\tau\right],$$

or in terms of a discrete time model:

$$S(t) = S(t-1) + G(t) - R(t).$$

This simplified model illustrates the linkages between variables and the way to allocate labor and fixed capital resources for the production of raw materials and primary energy, geological activity and improvements needed to increase the stock of resources that make possible to maintain the flow of raw materials and energy required to achieve the increase in final output of goods and services.

In order to stimulate the tendency to promote the consumption of renewable and/or renewable resources and to blur the consumption of non-renewable ones, E. Dolan (1969) proposed the use of a calculation and analysis tool for the evolution of resource expenditures, which he calls the gross national cost (GNC) and subdivides it into two categories: type I, the GNC fraction produced with renewable and recoverable resources; and type II, the GNC fraction produced with depleting and non-recoverable resources. From the point of view of economic management and conservation of natural resources, the issue is to maximize the type I fraction (produced with renewable and recoverable resources) and to minimize the type II fraction (obtained with depleting and non-recoverable resources).

In principle, economic and demographic growth leads to increased consumption of natural resources. Taking into account that natural resources are limited, as earlier demonstrated, it is necessary to know their volume in order to determine the duration of their use until full exhaustion, in the case of non-renewable resources, or their decrease per capita, beyond the level of subsistence, in the case of renewable resources. But these problems shall be thoroughly studied in some of our future works.

Conclusions and Recommendations

Natural resources are indispensable for the functioning of modern economies, and for achieving and maintaining high standards of living in all countries. They are primary inputs in the production of all manufactured goods (e.g. ores and other minerals). Also, they provide the energy needed to transport people and goods from place to place, to light our cities, and to heat our homes and places of work (fuels). They are also a potentially unending source of valuable materials and a habitat for wildlife and plant species (forests, oceans). Finally, in the case of water, they are necessary for sustaining all life on the planet. It is no exaggeration to say that the way the world manages its natural resources will go a long way towards determining the sustainability of the global economy.

Because of the limited character of natural resources, until recently, the economic analysis as a whole, and especially the one on optimization, has been dominated by the concept of resource scarcity (Krautkraemer, 2005). A large part of the conceptual and methodological apparatus was closely linked to solving problems regarding the allocation of resources at micro and macroeconomic level. In this context, the limit of the production factors appears to be relative in both static and dynamic view. Indeed, goods appear to be deficient in the ratio in which these goods are found in the production process, thus appears the need of combining them both quantitatively and qualitatively in the process of their use. They appear to be deficient because the necessary production factors are not available without limit during the production process.

The theory of optimal allocation of resources means a combination of production factors in such a way that, taking into account some restrictions given by the temporal deficiency of some resources, a maximum effect is achieved. Given a large number of technological factors and variants, their efficient use is being pursued, as well as the substitution of deficient resources with other non-fiscal ones. In this respect, conservation of natural resources is also another very important issue. The modern economies should always look for alternative sources of materials. This includes substitution of materials and recycling.

In general, as regarding processes in their dynamics, results that production factors are reproducing in increasing quantities. However, in the process of using the resources, their deficiency is maintained in a relative way (among resources), becoming virtually oscillating over time, precisely because of the intervention with different intensities of technical progress, direct action of man, economic mechanism, and so on. The scarcity of resources in relation to the needs of society is gradually diminishing, based on economic development and increasing the contribution of technical progress to economic growth (Neumayer, 2000).

The scarcity of resources should be highlighted in the economy with prices: the more these resources are deficient, the higher their prices are. Indeed, prices have to express, on one hand, the amount of living and materialized labor costs and, on the other hand, the current and prospective market situation (supply and demand), the status of natural resources, and so on. While trade in natural resources will almost certainly continue to grow in the future, improved international cooperation and domestic regulation should be able to contribute to efficiency gains, the elimination of the adverse consequences of extracting and using natural resources, and perhaps increased stability in the market prices of these goods (Araujo *et.al.,* 2013).

However, the above interpretations have become insufficient for a better understanding of the new issue in the real world. Therefore, it is necessary to address the resource problem in close connection with the evolution of the environment and its factors, with the new economic, social and technological processes of perspective, which take place not only on a national scale, but also on the world stage (Chasek *et.al.,* 2010). Anyhow, even if we look at things in general, the same traditional image is perpetuated, according to which the essential natural resources ensuring biological and economic life are free goods and that man lives in an unlimited space (De Man, 2016). Then, natural resources would be gifts of nature.

Developing industries and technologies, population growth, etc. have begun to increasingly use the environment, so that they have become an additional production factor, and pollution has become a more evolved element in the field of natural environment boundaries. It is necessary for man to change his behavior in relation to nature: from violence and foolishness, he has to be a protector and collaborator of the natural environment or, as Boulding says (1966), to find his place in a system ecologically cyclical that is capable of continuous reproduction of the material form. Anyhow, these issues will be largely addressed in our future work dealing with the estimative speculations and the *"Spaceship Earth"* concept introduced by Boulding a few decades ago [5].

Indicating the number of years of exploiting the reserves until their full depletion, when forecasting economic developments is made, and hence concluding that economic growth should be slowed down or stopped arises not only as an unjustified thing, naive in terms of economic reasoning. All of this, however, should not prompt us to a contemplative or passivity in terms of the impact that resources have on economic growth (van der Ploeg and Venables, 2011). On the contrary, they require the intensification of geological research, the rational management of resources, increased research and technological efforts for the transition to the exploitation of resources with lower content of useful substances and, in particular, the search for new efficient substitution resources or satisfying a larger range of needs.

At this time it is recognized the insufficient study of the relations and of the economic requirements for prevention or recovery of environmental factors, negative effects as well as the lack of a system of economical evaluations of natural resources sufficiently cohesive, comprehensive, efficient and theoretically substantiated, a system to be used for saving the limited natural resources and preserving the environmental factors (Laitos and Zellmer, 2015). Moreover, is the right time to evaluate mineral resources of the subsoil so that such assessments to be used as effective tools in the broad action of rationalizing the extraction and use in production of all natural resources, which is closely correlated with the requirements of economic growth in the future.

The evaluation of natural resources is of a not only theoretical importance, but also of practical importance, for the elimination of waste in the economic processes (production and consumption), for the rational exploitation thereof, and so on. The fact that, in general, the specific consumption of raw materials and energy resources is even higher (Darmstadter, 2002), that the recovery factor of many mineral resources is very small, that there is a great waste in the whole economic circuit precisely to those resources which in the future will become more and more scarce is because prices are set only on the basis of value - current work, and that the specific factors determining the current and prospective situation of these resources are not sufficiently taken into account.

All the above mentioned issues are useful elements in the realization of the economic policy in the field of resources. Carefully used, these elements can indeed help rationalize the consumption of natural resources and preserve environmental factors for a better common future. Moreover, sustainability cannot be developed and imposed on a community, small or large scale. Success depends on the participation and implementation by the community (Buffie *et.al.,* 2012). Community members must be the driving force for the sustainable quality of life for all members, now and for the future generations. Because sustainability is a dynamic concept rather than a static state, it requires decision makers to be flexible and willing to modify their approaches according to changes in the environment (including the diminishing of the actual stock of natural resources), human needs and desires, or technological advances. This means that actions that contribute to sustainability today, either in perception or in reality, may be deemed detrimental tomorrow if the context changes.

The intellectual and political debate about natural resources has seen public attitudes and expert opinion alternate between optimism and pessimism about whether precious natural resources will continue to be available for future generations (Perman *et.al.,* 2003). Growing concern for the environment, combined

with the steady rise in natural resource prices in recent years, has once again brought these issues to the forefront of public consciousness.

Endnotes

[1] There are two basic conditions for a substance or feature to be classified as ***a natural resource*****.** First, the resource must exist naturally in the environment; that is, not synthetically produced by human beings, such as in a laboratory or factory. Crude oil, timber, deer, and sailfish fit that requirement, whereas genetically engineered bacteria or computers do not. A naturally occurring commodity typically is classified as a natural resource when it is extracted or purified from its natural state rather than being created. Second, the resource must be able to be exploited by humans to directly satisfy a need or want. Copper, tuna, and air fulfill such a requirement (with air supplying a need, as a condition for life), whereas an infectious parasiteor mosquito does not (although the parasite or mosquito may provide an indirect benefit as part of nature, such as part of food chains).

Some authorities hold that for a substance or feature to be classified as a natural resource, it must offer potential or actual economic value, creating wealth. This was an original definition provided in the 6th edition of *Black's Law Dictionary* (1990): *"any material in its native state which when extracted has economic value"*. Others do not limit the term to those resources having economic product value, but also include supplying a non-economic value. Resources such as oil, coal, wood, water power, and arable land clearly can be seen as providing potential economic value. These are considered natural resources by all parties. The second, broader concept also includes such features as climate and trees planted in a park. While not considered to have any direct economic value, they do provide important non-economic values. A climate may be seen as part of one's enjoyment of nature and tourism, while trees in a park provide aesthetic values.

This distinction is reflected in the two divergent definitions of natural resource found in the 7th edition of *Black's Law Dictionary* (1999): (1) *"any material from nature having potential economic value or providing for the sustenance of life";* and (2) *"environmental features that serve a community's well-being or recreational interests, such as parks"* (Swarts, 2013).

[2] ***A natural resource industry*** is one in which the primary activity involves extraction and/or purification of the natural resource, instead of creation of the commodity. Examples of natural resource industries include crude oil extraction and processing, fishing, and forestry. Agriculture is not considered a natural resource industry (Swarts, 2013).

[3] Within resources, a growing weight and importance are those whose origin is directly the process of production and social activity itself; created by man, they increasingly condition their productive potential. They are of particular complexity and diversity, but their common specificity delimits them from the other two major categories of resources: natural, on one hand, and human, on the other. Therefore, the term they are called - ***economic resources*** - must be interpreted not in a narrow sense, but in its broad sense of maximum generality. Some of the economic resources represent work and accumulated experience - technical-economic resources, equipment, scientific knowledge, technologies, financial-investment means; others are the framework within which the productive-social activity is carried out, namely the existing economic and social organization, depending on the dynamics of the historical-social evolution and the accumulated experience - the social-economic resources related to the system of production relations and the organizational and management structures (Samuelson and Nordhouse, 2009).

[4] The Heckscher–Ohlin theorem is one of the four critical theorems of the Heckscher–Ohlin model. It states that a country will export goods that use its abundant factors intensively, and import goods that use its scarce factors intensively. In the two-factor case, it states: "A capital-abundant country will export the

capital-intensive good, while the labor-abundant country will export the labor-intensive good." The critical assumption of the Heckscher–Ohlin model is that the two countries are identical, except for the difference in resource endowments. This also implies that the aggregate preferences are the same. The relative abundance in capital will cause the capital-abundant country to produce the capital-intensive good cheaper than the labor-abundant country and vice versa.

Initially, when the countries are not trading: the price of the capital-intensive good in the capital-abundant country will be bid down relative to the price of the good in the other country, the price of the labor-intensive good in the labor-abundant country will be bid down relative to the price of the good in the other country. Once trade is allowed, profit-seeking firms will move their products to the markets that have (temporary) higher price. As a result: the capital-abundant country will export the capital-intensive good, the labor-abundant country will export the labor-intensive good.

The Leontief paradox, presented by Wassily Leontief in 1951 (Leontief, 1951), found that the U.S. (the most capital-abundant country in the world by any criterion) exported labor-intensive commodities and imported capital-intensive commodities, in apparent contradiction with the Heckscher–Ohlin theorem. However, if labor is separated into two distinct factors, skilled labor and unskilled labor, the Heckscher–Ohlin theorem is more accurate. The U.S. tends to export skilled-labor-intensive goods, and tends to import unskilled-labor-intensive goods (Miberg, 1996).

[5] Kenneth Boulding is widely regarded as one of the 'founding fathers' of ecological economics. In his classic paper written in 1966, Kenneth Boulding discusses a change in orientation that is required if mankind is to achieve a perpetually sustainable economy. Boulding concludes his paper by considering the extent to which the price mechanism, used in a way to put prices on external diseconomies, can deal with the transition to "*Spaceship Earth"*. He accepts the need for market-based incentive schemes to correct such diseconomies, but argues that these instruments can only deal with a small proportion of the matters which he raises.

The Evolution of Sport and Tourism Policies In Romania before and after 1989

Katalin Gál, Ph.D, assistant professor, Partium Christian University, Oradea, Romania,
katalin.gal@gmail.com

Tünde Gál, Ph.D student, The Bucharest University of Economic Studies, Bucharest, Romania,
tunde.gal@gmail.com

Abstract

The objective of this paper is to link tourism and sport policies, through the lens of the Romanian paradox: on the one hand increasing statistics referring to the economical embeddedness of sport and tourism, but poor measurable social and cultural impact of both phenomenon, on the other hand a global pressure trough international entities and European Union's long term strategies in policy making – all these have been encouraging to investigate the evolution of tourism and sport policy making in Romania before and after the year 1989, marking the fall of the communist regime. The study, based on a narrative approach, aims to present a short synthesis of the main tourism theory critiques an analysis of how tourism and sport tourism theories and policies are linked to each other in the Romanian context. Briefly reviewing the pre-1989 states in this paper, using a theoretical analytical approach, we undertake to examine also the post-1989 institutional and public policy structures responsible in formulating tourism strategies in Romania. At the intersection, we also keep track of when and in what context these strategies are targeting the sport as a part of tourism. The result of the analysis is a summary study aimed to capture the tourism-related public policy representations in Romania, all in a wider context.

Keywords: public policy, sport tourism, institutional frame, education, research based policy

Introduction

According to the World Travel and Tourism Council (WTTC) the total contribution of tourism to GDP in Romania was 5.2% in 2016, the total contribution to employment was 6.2% for the same year, and the visitor exports 2.8%, forecasted 9.1% for 2017 as stated in the WTTC's 2017 Economic Impact Report. These are just some emphasized statistics for highlighting the economical impact of the tourism sector. The main motivation of this study is to analyze the evolution of tourism and sport strategies and policies in Romania before and after 1989 in the context of the manifest signs and effects of the economical importance and the latent motivation of tourism. Following this logic we would like to answer the question: where is the Romanian decision- and policy making positioned in the global tourism-judgment, how the communist heritage effects the present decision-making, in what scale are EU-funding focused and used to fulfill the objectives and strategies.

The analysis applies a narrative logic and the structure of the study is based on a short overview of tourism theories – focused on critiques of the mainstream approaches, followed by a screening of what meant the public policy in tourism and sport in Romania before and after 1989: analyzing separately the early 90's, the early 2000's, the before and after EU-accession period, and finally the new faces of policy-making in Romania. The conclusion of this study is focusing on the formulation of the main critical aspects regarding tourism and sport policy-making in Romania, highlighting the importance of all manifest and latent factors of the tourism sector.

Short Overview of Tourism Theories Critique and the Theoretical Frame of the Analysis

The theoretical and analytical vision of the current study is embedded in the social scientific fact that the phenomenon around us in different societies/economies and cultures are multi-dimensional and cannot be treated/analyzed exhaustively with a single cause-effect model. According to this quasi-axiom, our

theoretical overview is based on Franklin and Crang (2001) tourism and travel theory critique, in which the authors highlight the dilemmas with existing tourism theories regarding the growing tourism-based research objects, the perception of tourism and the education and study of tourism. The authors also mention that the research objective of the tourism as science has grown and the researcher community connected to this extended area is relatively new. The consequence is that the academic society is faced with a quantitative expansion of scientific works and points of views, but these scientific achievements are dominated by case studies and policy-making documents. The second critique is closely linked to the first one presented and discusses about the problem of the fetishized tourism as a *thing*, *a product*, *a behavior* – which highlights the temptation of the scientific sphere to treat tourism as a particularly economic "thing" (Franklin and Crang, 2001). The authors highlight the importance of linking the social and cultural practices also to the scientific tourism perceptions. The third problematic issue in making tourism theory represents the way tourism is framed for study: the authors identified an obsession of taxonomies and classification, and also highlight a problematic way of analyzing the object of the tourism, the tourist as an over-rationalized economical actor. We can also complete this observation – in the context of Romania – that in the logic, how tourism is represented in the educational offer of the accredited higher education institutions is significantly economy-centered.

The authors' conclusion is that the tourism in not a specialist consumer product or mode of consumption, so the new approaches in modern tourism studies have to reflect the growing significance of the tourism as a cultural laboratory, where the individual tourist is functioning as a "piece" of a global cultural and economical interactional network (Franklin and Crang, 2001).

Based on the above lined up critiques, we have to link the tourism theory to the public policy responses, including not just tourism itself as a sector, but also aspects of sport-tourism. Weed (2008) in an article focusing on the examination of the UK's sport and tourism policy, explains the importance of cross-sectoral liaison between responsible policy entities (respectively sport and tourism public bodies and academic sphere research). The problem is that the well-working developed links between pubic bodies and/or research bodies are isolated and ad-hoc – focused more on priority events and related representations, not on a comprehensive, research-based policy making exercise. In this context Weed (2008) underlines the separate development of different "culture" in the two sectors. It is highlighted also that the "tradition" of public support is manifested in different ways in tourism and sport. While tourism appears in public representation as private sector, sport as public one, actually both having its own policy "department" with different level of the responsibility for policy development bodies.

The literature is relatively weak referring to the sport and tourism policy process, the theoretic goal being to understand the public policy responses to the sport-tourism link (Weed, 2008). Houlihen (1997) in his book about a comparative analysis about public policy making patterns in sport in five different countries highlights that comparison in the public policy analysis has to be done between policy sectors, between responses to a range of issues or between countries. In our analysis the 'between country' approach is unreasonable, but the analysis model of Houlihen on sport public policy and Hall and Jenkins's (1995) analysis model on tourism – integrated by Weed (2008) in his analysis on UK's sport and tourism policy gives us a useful theoretical frame to create those analytical aspects which will help us to follow up the Romanian situation.

The Analytical Frame of the Study

The logic of the analysis follows the outlined theoretical framework. Based on tourism theory critique and some aspects of Weeds' (2008) adopted model in UK's analysis, in case of Romania the presented periods will succeed the following topics: the structure of the policy communities for sport and tourism (the levels of organization, regional specificity, resources and funding, communication and influence); most important strategic policy documents (strategy initiatives, policy development; education and research (the scientific background of delivered experts and research documents, relationship between science and policy making).

The applied analytical vision and methodology is based on the tourism concept as a social, cultural and economic phenomenon, the approach is narrative historical: the study describes the main legislative

regulations and institutional background, presents the main strategically objectives of the policy documents, overlooks the change of position of the education and research during the communist period and after 1989.

Tourism and Sport Policy in Romania Before 1989

In order to analyze the period after 1989 in Romania, it is important to have an overview of the 'heritage' Romania faced after the regime change regarding institutions, political culture, policy making etc. in the context of tourism and sport. The 'story' begins with the nationalization of economic, commercial, and banks societies, road transportation decided on 11 June 1948 and carried out during the years 1949-1950, which determined the transition to state property of the existing touristic units. A part of these units maintained their original functions and once in state ownership, were assigned either to the PMR (Romanian Workers' Party) household or to the ministries and other central and local state administration institutions, or creative unions, being conducted and organized under the provisions of Decree no. 199 of 1949, like other economic units. There was thus a national network of state-owned and cooperative tourist units, consisting of hotels, restaurants, cottages, villas, rest homes, children's and student's camps, sanatoriums and balneo-therapeutic treatment accommodations. Under the strict control exercised over the entire Romanian society, it was set up a well working system of normative acts intended to provide the legal basis of the operation of touristic establishments. At the same time, recreational touristic initiatives were presented as great successes of the new regime, although in reality they were based on buildings, equipment and facilities confiscated from private owners. There were added, especially after 1955, a series of new tourist capacities built in the areas with high touristic potential, like the coastal and mountain areas and in the surroundings of mineral springs.

Until 1989 the institutional background designed to offer the management of tourism at the national level suffered several changes, and under the influence of state propaganda can be identified periods when the tourism and sport policy has been intersected. Initially the national coordination of establishment, organization and operation of the touristic units were provided by the General Confederation of Labor and by The Association of Physical Culture and Sport from RPR (Romanian People's Republic) through the Regional Tourism and Travel Services and Travel and Excursion Offices (that were constituted at the level of institutions and economic units). This inefficient bureaucratic structure has been changed several times. As a first step, the National Carpathian Tourism Office was set up as a state-owned economic enterprise, subordinated to the Ministry of Foreign Trade having in subordination all economic units with tourism profile in Romania. In 1959, in view of improving the functioning of the tourism activity, it was decided that National Carpathian Tourism Office extends its activity by taking over the whole material basis of tourism infrastructure and also the task of organizing domestic tourism activities. At the same time this Office was removed from the tutelage of the Ministry of Foreign Trade and transferred to the subordination of to the Union of Physical Culture and Sports. This was the first institutional interaction between tourism and sport, but in the practical activity, the tourist units have not benefited from this institutional arrangement, the Union of Physical Culture and Sports having other interests and goals, related to the promotion of sport not the organization of domestic or international tourism. In 1968, the establishment of the Youth Tourism Bureau was authorized as a specialized central body with legal personality, stimulating and facilitating tourism among all categories. Finally, in December 1970, was decided the founding of the Ministry of Tourism, with the task of implementing party and state policy in tourism industry in Romania by taking over and subordinating the National Tourism Office and each unit of its composition. So, after the nationalization an entire institutional and legislative background was built, in the field of tourism, with effect until 1989 on the establishment, organization and operation of units (Rădulescu and Stănculescu, 2012).

The education in tourism is another interesting and important critical aspect of the before 1989 situation in Romania. The whole nationalized and centralized educational system was assigned to the principles of the planned economy; the industrialization of the country and economic planning has redrawn the whole structure of the education – including higher education. The disastrous economic planning, focusing the human and material investments towards heavy industry, have had an impact on the Romanian higher education. The other dramatic change of the Ceausescu era consisted in the tendency to cut the university centers' autonomy, which had two important outputs: liquidation of some higher

education institutions and centralization of the remaining under the aegis of supervision of some university centrums.

The faulty five-year plan based economy caused substantial changes in the nomenclature of specializations, and together with legislative interventions, the Romanian higher education became rigid, with relatively small range of specializations – dominated by technical ones. The communist education policies – on higher and public education – the forced industrialization of the country, based on five year planned economy concept caused many discrepancies in the labour market, surpluses and deficits in some sectoral, professional, territorial areas, over-occupation and hidden unemployment of the labor force (Sora, 2011).

As the tourism sector operated under state propaganda, there was no specialized tertiary education, the secondary education system provided the domestic tourism with (more or less) skilled workforce, the higher education sector only after the change of regime started a professionalization process. The only positive aspect we have to highlight is the consolidated secondary education sector – but unfortunately it cannot be traced back to a conscious education policy, it is more related to increasing birth rate, the unmanageable economic plans, and was not effective, so the only thing that matters in this education sector is that it existed.

Regarding sport policies before 1989 the basic axiom is that the sport movement was inseparable from nation and state in Romania – as in the case of other states that had direct control over the society and the private life of the individual. Sport has been declared an important state policy in Romania, although it has also important health dimensions, the role of sport has been well appreciated by the politicians of the 20th century, its potential for transmitting national values and the propaganda message has transformed simple competitions into means of promoting political ideology and have absolutely nothing to do with tourism. As the Physical Education and Sport Law from 1967 provides: “Physical Education and Sport in the Socialist Republic of Romania are activities of national interest” – and transferred the operative authority to the National Council for Physical Education and Sport and for the unions of national institutions and state companies (Bărbulescu, 2010). This sport life organization model encompassed the whole life of the Romanian population, organizing amateur, professional and folk-sporting activities as well. The developed mechanisms for the practice of sport administered and funded by the state ceased after 1989, which greatly influenced the development of public policies since 1989 - its effects are reflected in the following subsection in detail.

Tourism and Sport Policy in Romania After 1989

The ten years after 1989 brought a general instability inside the political, economical, social and technological environment in Romania, spreading also in the tourism sector, causing a lack of coherent development strategy (Stănciulescu and Micu, 2009). This period also remarks the start of the privatization processes of numerous state companies, including the tourism industry as well. In 1998, the National Institute for Research and Development in Tourism was set up, and in the same year the Governmental Decision nr. 972/1998 was elaborated regarding the organization and functioning of the National Tourism Authority (NTA) as a specialized body of the central public administration, with legal personality, subordinated to the Government, which develops, applies, monitors and evaluates the Government's policy in the field of tourism. Despite all this, in the first two decades during the post-communist period, Romania has relied more on touristic "myths", rather than concrete measures; among the options of foreign visitors, the mountain, seaside and spa - Romania's touristic strengths - have registered a continuous decline after 1990 (Neacşu, Neguţ, and Vlăsceanu, 2014). Even though up to the year 2000 in all government programmes, tourism and agriculture have been considered high priority development areas, tourism faced with a lack of facilities and governmental subventions essential for promotion and maintenance (Stănciulescu and Micu, 2009).

The year 2001 marks a change, as Romania started to put into practice an aggressive promotion for its touristic products and this brought to an increased number of tourists. Romania launched its first promotional campaign at international level with the declared scope of improving its image abroad and attracting foreign tourists, entitled „Romania, simply surprising". As well it was present at numerous

trades and annual exhibitions promoting the country. As regards the sporting and educational strategies, the communist heritage was brought forward until the early 2000s without any significant strategic document for a change. During the years 2003-2006 the national programme "Construction of sport halls" had a positive effect not only on the local and regional level by providing proper sporting infrastructure for educational purposes and performance sport, but in recent years attracted multiple high level international competitions in various sports in the country, having a positive impact on tourism and the image of the country.

The European Commission (EC) and tourism stakeholders have recognized the important role that tourism plays in the development of European regions, against industrial and rural decline, or supporting urban regeneration, as well as the need to turn toward more sustainable and friendly practices and policies (EC, 2006). In this context, the year 2007 marks Romania's accession in the European Union (EU), dragging along the benefit of the membership: taking over EU strategies, good practices, the possibility of accessing structural funds. As the Romanian tourism sector has suffered from the absence of an overall policy to drive and direct the sector before entering the EU, in 2007 the Romanian National Tourism Master Plan for 2007-2026 was elaborated by international experts, covering the twenty year timeframe from 2007 to 2026, incorporating a six year action programme for 2007-2013. The plan was meant to be an umbrella policy including various plans and strategies to optimize the sector's contribution to the national economy. As regard to the intersection of sport and tourism policies, the master plan had a separate section targeting the development of the "activity tourism", such as winter sports, golf, hiking, equestrianism, hunting and fishing among the other important touristic areas, but as many other recommendations, were not fully exploited up to this moment. The document underlines also the weaknesses of the actual situation, as tourism, being one of the most competitive economic activities in the world, requires professionalism, commitment, organization and an effective human resource development strategy (MDRP, 2007). Hospitality service skills, both professional and behavioral, were adjudged as still under-developed, also the improvement of service attitude and mentality was pointed of urgent attention (MDRP, 2007). The level of competence in the hospitality and tourism industry was also rated as low, due to the lack of performance standards, the lack of adequate and up-to-date occupational standards, and the lack of adequate education and training standards. It was also highlighted that the NTA did not have a clear market development strategy based on full and deep understanding of market characteristics and trends (MDRP, 2007). As well, in a panorama of European tourism published by Eurostat (Eurostat, 2008) the situation of the Romanian tourism was summarized as follows: "Tourism in Romania is not yet well developed and depends heavily on domestic demand. International tourism flows in the country are still low, and mainly for business purposes."

Connecting sport and tourism, the development of mountain tourism could be considered both an opportunity and a priority for action-taking. The Romanian Carpathians are the largest massif on the continent inside the same border perimeter. The potential of these mountains is supported by the large variety of their natural features, like the 13 national parks and 13 national reserves, which cover around 7% of the country's surface and host wooden areas, natural lakes and pollution-free rivers. Despite the progress of the last few decades, the visibility of this tourism branch is still a work in progress. Even though the Carpathians host an extensive area of hundreds of kilometers of ski slopes brought up to European standards, the technical and material foundation is undergoing a process of modernization, together with the still underdeveloped transport infrastructure. Another key sector linking sport with tourism is ecotourism, and in 2009 the first National Strategy for the Development of Ecotourism in Romania was elaborated, which underlined the possibilities of utilization of ecotourism resources worldwide and in Romania, but drew attention that not only the programmes and information available are incomplete, but also the specific access infrastructure is lacking in the country.

As regard to the investment programmes in tourism, at the beginning of 2010, the Government decided upon a list of tourism investment projects and programmes, which facilitated the financing of tourism investment projects as well as the completion of the ongoing investment objectives. Unfortunately the funding has been interrupted after 2013, leaving important facilities undone in the handling of the local authorities. Due to the increase in the number of tourists and the amount spent per day, in 2015 the Government identified new investments in tourism, and decided to spend about 3 million EUR on

tourism promotion (INCDT, 2016), and some funds were also unblocked to finalize ongoing investments interrupted in 2013.

In 2016, experts within the National Authority for Tourism have developed "Vision for the Development and Marketing 2020", a programme document that defines the objectives and actions necessary to transform Romania into a competitive tourist destination, "adapted to the requirements of one of the most dynamic and markets in the world" (NTA, 2016). The strategy is the starting point for outlining some development areas based on quality, by implementing a quality certification system within tourist destinations and by improving the training and qualification of human resources. The overall objective is "to stimulate the interest of potential tourists to spend their holidays in tourist areas in the country, by increasing Romania's reputation as a quality tourist destination, by increasing the attractiveness of key forms of tourism and by developing sustainable tourism as an engine for local and national economic growth" (NTA, 2016), most of the objectives being almost identical with those, already mentioned ten years ago in the master plan for 2007-2026.

During an analysis of tourism policies over time it is important to mention that both before and after the EU accession, the tourism, as government objective, belonged to many different ministries, encumbering the formulation and implementation of objectives and strategies over time. Before EU accession tourism belonged to the Ministry of Transport, Construction and Tourism. In 2007, it was delegated to the Ministry for Small and Medium Enterprises, Trade, Tourism and Free Professions. Starting from December 2008, it had separate government body, the Ministry of Tourism, until 2009 December, when it was transferred to the Ministry of Regional Development and Tourism. Afterwards it was part of the Ministry of Economy, Commerce and Tourism until December 2015, then part of Ministry of Economy, Trade and Business Environment. From January 2017 has again its own governing body as the Ministry of Tourism.

Although Romania has a complex touristic potential - favoured by a diverse natural landscape and an old and authentic cultural component - supported by unique elements, at a European level we cannot overcome the "passive and subsistence tourism" phase offering mostly accommodation and potential attractions (Neacşu, Neguţ and Vlăsceanu, 2014). Still up to this date, according to the World Economic Forums' Travel and Competitiveness Report 2017, Romania is on the last place among the members of the EU. According to WTTC, Romania "is one of the world least intensive tourism countries, ranking 163 out of 185 countries in terms of contribution to GDP (WTTC, 2017)."

As regards the sport policies, the first National Sport Strategy was elaborated recently, for the years 2016-2032 highlighting that the interconnection between sport and tourism can be exploited both as a way of attracting people to practice sports (active tourism) but also as spectators, in both ways being a potential source of income for the sport industry. The number of mass-sport events have been soaring in the last decade, but this is mostly due to a global trend in developed countries and not as part of any strategy. Due to the destinational characteristics of Romania, the still low prices in the tourism sector compared to Western European countries, it has high potential in attracting sport tourists to the country from all over the world. Today sport and tourism are among the developed world's, most sought after leisure experiences (Brant and Adair, 2014). But establishing an appropriate tourist offer implies a significant effort on the part of the state, materialized in investments used in the consolidation of infrastructure elements. The state also assumes its role as protector of the tourism industry, through fiscal policy and credit policy for investors. Tourism worldwide is no longer just a complementary economic activity, but it has become a real "social phenomenon". Over a billion people travel for tourist purposes on Earth and they generate more than 1 000 billion dollars in revenue and these numbers show the current dimension of this phenomenon. Romania receives less than half of a percent of both, remaining tributary to a touristic system stuck in the past offering simple accommodation and potential beauties (Neacşu, Neguţ, and Vlăsceanu, 2014).

Conclusions

Tourism industry is one of the most dynamic sectors of the global economy, and for countries with significant touristic resources, like Romania, should be a key sector in the national economy through

appropriate strategies to exploit the existing resources. Tourism is also an important way of promoting the image of a country. But as it is apparent from above, the present tourism and sport public policy, and its incoherent intersections are highly influenced by the communistic heritage in Romania. The before 1989 built up models, the institutional and managerial structures has been affected for a long time the Romanian policy making mentality and exercise, the education development, strategies and the financial dimensions of the implementation.

The post-communistic era represents a rigid takeover of the previous systems' logic, only the serious and unsustainable discrepancies has been removed, in the context of the economical and social change tourism and sport did not represent a high priority. The educational system in that time represents disadvantages in the context of the specializations. The two post-communist decades are characterized by correlation and synchronization with world higher education and another type of communication and relationship between education and the economic and social environment. There was a need for a radical change in sense of decoupling from the communist regime. The changes in Romanian higher education are observable in the evolution of the number of specializations, the curriculum, the acquired skills and qualifications. In the case of tourism and sport specializations is particularly valid, because decade-old system-handicaps had to be corrected.

The modern policy making strategies and concrete intervention programs has been highly influenced by the European Union and other international forums' main strategies and objectives in the pre-accession and post-accession period. This fact somehow set a course for the Romanian policy-making, which process was very suggestible by the political interests at all time. The result is, that as the economical of the tourism and sport potential grew, the institutional and political importance also grew for this sectors. Tourism is essential to nations' competitiveness, and so tourism ranks high among European Union preoccupations, but it is a responsibility for each member state – including Romania – to design and to put in practice effective policies in this respect.

Abstract

This paper studies the possibility of using cash-flow-based ratios to improve the completeness and reliability of assessment of the company's solvency and financial stability. These indicators are more informative and reliable for internal users and potential investors and creditors. The two indicators: cash-flow liquidity ratio (CFLR) and cash interest coverage ratio (CICR) – are compared with the conventional ratios for the assessment of solvency - current liquidity ratio (CLR) and interest coverage ratio (ICR). This study explores the financial statements of 12 Russian companies engaged in the provision of airport services during the period between 2011 and 2014. Using the correlation analysis we compared the pairs of conventional liquidity ratios and cash-flow-based ratios. Current liquidity ratio and cash flow liquidity ratio proved to be loosely correlated. Strong correlation was revealed between interest coverage ratio and cash interest coverage ratio. The study showed that using cash interest coverage ratio provides a more accurate representation of the company's financial stability. This ratio can also be used to adjust the company's credit rating.

Keywords: solvency, cash flow, analysis, airport industry companies

Introduction

In the innovative economy environment, companies should decide if they are able to make prompt management decisions and ensure financial stability. Reaching the adequate level of solvency by the company results in the ability to promptly and fully meet its payment obligations. This is relevant both to the company and its partners and shareholders. And so, the quality of solvency management is one of the priorities. Both owners and managers and external users rely on the company's state analysis. An insufficient-solvency company may face a risk of losing both own resources and borrowings. This makes it unattractive for other business entities.

The concept of solvency is related to the concept of liquidity as the ability of an organization "...to convert its assets into cash and fulfill its current liabilities only in cash" (Sorokina E.M., 2012) or "…to have enough assets to cover its liabilities" (https://www.thebalance.com).

There is a wide range of solvency assessment methods used by various parties for specific purposes. It sometimes results in a conflict of interests between stakeholders, managers, and shareholders (Heejung

Yeo, 2016). Thus, clear reliable criteria for assessing solvency must be determined. Regardless of multiple approaches to assessing solvency, the most common practice in contemporary financial analysis is ratio analysis.

Literature Review

The solvency assessment methodology used in Russian practice is reflected in the works of V.V. Kovalev (Kovalev V.V., 2002), A.D. Sheremet and R.S. Sayfulina (Sheremet A.D. and Sayfulina R.S., 2006), N.P. Lyubushin and N.E. Babicheva (Lyubushin N.P. and Babicheva N.E., 2006). In world practice issues of solvency assessment using cash flow figures were considered by such researchers as Van Horne J.C. (Van Horne J.C. and Wachowicz J.M., 1992), L.A. Berntine (Bernstein, L.A. and Wild John J., 2000), Silviu C.V. Chiriac (Silviu C.V. Chiriac, 2015), Heejung Yeo (Yeo H., 2016), Keefe M. O'Connor (Keefe M. O'Connor and Yaghoubi M., 2016). In practice cash flow figures are used for different purposes. For example, the use of its figures in assessing of companies bankruptcy probability increases the significance of the results (Almamy J., et al., 2016, Fawzia N.S., et al., 2017). In addition, the cash flow sensitivities of financially healthy and weak firms are positively correlated with the severity of liquidity crises (Drobetz Wolfgang, et al., 2017). Other authors used cash flows to manage liquidity risk in certain business sectors (Oral C. and Akkaya G.C., 2015), as well as to maximize the future value of the firm (Gajek L. and Kucinski L., 2016).

The difference between the methods lies mainly in the composition of the indicators or approaches to evaluation. Mostly, relative ratios are used, with prioritizing liquidity ratios. However, we suppose that cash-flow-based ratios can be used as additional ratios to describe the company's solvency. Such ratio data are used by various analytical systems in the context of the solvency analysis. For example, the professional market and company analysis system "SPARK" which is widely used in Russia is one of the largest databases of financial and statistical information about companies in various industries, including the provision of interest coverage ratio (ICR) data.

ICR describes the ability of a company to fulfill its interest payment obligations. This ratio shows the probability of the company's default, which is extremely important for describing the level of solvency. The minimum value of the ratio is 1, which describes the company's ability to make interest payments at its own discretion and in full.

Note that interpreting the results with the ratio approach is an important stage in assessing the company's solvency and making financial management decisions. The higher the accuracy and reliability of the ratios used in the analysis, the more valid the conclusions about the company's financial state. Assessing these ratios is associated with a number of immediate problems concerning the limited efficacy of the assessment (Tsyrkunova T.A., 2011, Yeo H., 2016). Firstly, when comparing the estimated ratio values with the normative values, a greater emphasis is put on the value changes rather than the determination of the optimum ratio values. Secondly, there is insufficient accuracy and reliability of the initial information provision in the analysis of the company's financial state. The abstract character of the statement ratios is not able to provide information that will describe the level of its solvency and liquidity (Laskina L.Yu., Vlasova M.S., 2013). This primarily includes accounting earnings and profit. There is an increasingly low representation of data due to ratio manipulation by top managers in order to sugarcoat the real state of the company (Yeo H., 2016). In addition, asset valuation and accounting with the accrual method have some nuances.

The solution of the first issue lies in accounting, when evaluating "... the particular business environment of an economic entity" (Tsyrkunova T.A., 2011) and industry practices of ratio comparison and solvency analysis.

The second issue can be addressed by using cash-flow data in addition to the key ratios. Cash mediates all of the company's financial relations, while variable receipts and payments may result in a decrease in liquidity as a factor of solvency support.

"Cash Flow Statement" data are more difficult to manipulate due to the efficacy of the cash flow indicators. Therefore, cash flow data underlie a number of ratios to describe the company's financial state more fully and reliably (Cheremushkin S., 2007). For example, the "cash flow to debt ratio" is used as a predictor of financial insolvency, and to assess the credit standing of the company. "Capital expenditure ratio" shows the company's ability to finance future growth due to its operating activities. This ratio is used to assess the ability to pay debts and dividends. "Cash return on assets ratio" refers to the ability of the company's assets to generate cash. It is used to verify the conformity of accounting of return real cash flow.

The use of cash flow data in the calculation of cash ratios deals with the most liquid part of current assets - cash and cash equivalents. It also gives a representation of the company's future financial state. Thus, cash flows are advisable to use for liquidity assessment and adjustment of the conventional financial analysis ratios (Giacomino D.E., Mielke D.E., 1993, Kirkham R., 2012).

In terms of the short-term solvency analysis, some researchers suggest comparing such ratios as cash flow liquidity ratio (CFLR) and current liquidity ratio (CLR), as well as cash interest coverage ratio (CICR) and interest coverage ratio (ICR) (Table 1).

Table 1: The comparison of the liquidity of traditional and cash flow coefficients

Traditional ratios		**Cash flow ratios**	
Coefficient	Formula	Coefficient	Formula
Current liquidity ratio, CLR	$CLR = \frac{CA}{CL}$	Cash flow liquidity ratio, CFLR	$CFLR = \frac{CF}{CL}$
Interest coverage ratio, ICR	$CLR = \frac{EBIT}{TIP}$	Cash interest coverage ratio, CICR	$CLR = \frac{CF + TIP + T}{TIP}$

Where: CA – Current Assets; CL – Current Liabilities; CF – Net operating cash flow; EBIT – Earnings before interest and tax; TIP – Total interest Payable in the given period; T – Taxes.

Source: Giacomino D.E., Mielke D.E., 1993; Kirkham R., 2012

Notwithstanding the practice of estimating cash ratios, there are no data on the correlation degree between the above ratio pairs.

Research Method

To justify the possibility of using cash ratios, this paper studies the degree of correlation between cash ratios and conventional ratios in the solvency analysis. This article compares such cash ratios as CFLR and CICR. The object of the study is the data on Russian companies engaged in the provision of airport services.

Data Analysis

Airport industry is one of the key elements in the development of the world economy. The state and growth of such industries "considerably determine the competitiveness of the country's economy" (Orlova T.S., et al., 2013). There is the Federal Target Program "Russian Transport System Development (2010-2020)" which considers the transport system as "... a necessary condition for the implementation of the innovative model of economic growth ...", with "... the development of the land-based aviation infrastructure" being one of the priorities (Varaksa A.M., 2015, Decision of the Russia government No. 848, 2001).

This kind of attention to the Russian airport industry is due to the long period of reduction in the number of airports. According to the Federal Agency for Air Transport (FAAT), there are 297 airports in Russia (Federal air transport Agency, 2017). Experts (Stroganova V.I., 2010, Eremin V.L., et al., 2011) say that it's almost four times less than the 1990-s data (Fig. 1).

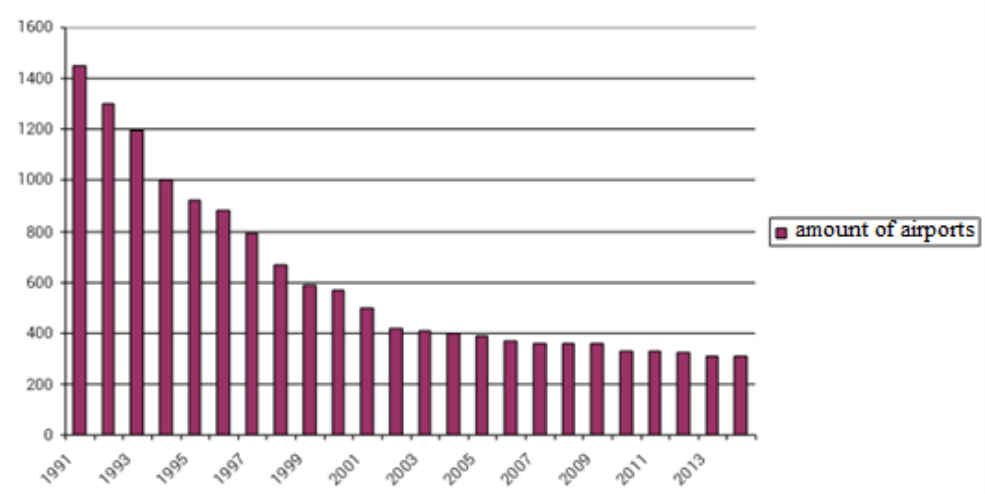

Fig. 1: the dynamics of airports amount in Russia

Source: Federal air transport Agency: https//www.m.favt.ru

Such behavior has particularly affected regions where transport support is less sufficient than in the western part of Russia. Such districts as the Siberian district and the Far Eastern district require extensive aviation infrastructure as the most appropriate mode of transportation in the country and abroad.

A reducing number of airports is accompanied by an increasing number of customer passengers, which results in depreciation of fixed assets. In 2011, this indicator ranged from 40% to 80% (Business Aviation Portal, 2017).

The situation as it has developed is holding back "... transit capacity building and realization, ... the development of the united economic area of the country" (Decision of the Russia government No. 848, 2001). To reverse the situation, heavy financial investments are required (Kramorenko M.I., Varaksa A.M., 2015). Thus, for the most part of airports, development investing means either heavy borrowing or searching for external investors. In both cases, airport companies need to maintain their solvency and stable financial position.

For this study, we selected 12 Russian airport companies located in five federal districts of Russia. Data for the analysis were taken for the period 2011-2014. The list of the companies is given in Table. 2.

Table 2: Sample composition

Airport	Airport
OJSC "Airport Anapa"	JSC "Airport Tolmachevo"
JSC "International Airport Irkutsk"	JSC "Airport Uliyanovsk"
JSC "Kazan" International Airport"	OJSC "International Airport Vladivostok"
PJSC "Khabarovsky Airport"	International Airport JSC "Vnukovo-Invest"
JSC "Omsk Airport"	PJSC "International Airport Volgograd"
OJSC "Airport Pobedilovo"	JSC "Yakutsky Airport"

Source: compiled by the authors

Table 3 calculates the ratio pairs: Current liquidity ratio (CLR) and Cash flow liquidity ratio (CFLR) according to the information provided by the companies in the financial statements for 2011-2014 (Corporate Information Distribution Center, 2017). In addition, Interest coverage ratio (ICR) and Cash interest coverage ratio (CICR) are compared.

Table 3: The comparison of the CLR and the CFLR in airports businesses

Company	2011		2012		2013		2014	
	CLR	CFLR	CLR	CFLR	CLR	CFLR	CLR	CFLR
OJSC "Airport Anapa"	21,88	5,91	1,78	-0,04	5,27	0,78	4,88	0,51
JSC "International Airport Irkutsk"					1,36	1,37	1,78	1,07
JSC "Kazan" International Airport"	0,72	-0,17	1,08	-0,05	0,79	0,06	1,88	-1,28
PJSC "Khabarovsky Airport"	1,19	0,72	1,78	0,49	2,57	0,36	2,23	0,05
JSC "Omsk Airport"	0,69	1,26	1,03	0,99	1,46	1,63	2,07	1,88
OJSC "Airport Pobedilovo"	0,70	-1,35	0,73	-2,38	0,20	-0,54	1,54	-3,30
JSC "Airport Tolmachevo"	1,43	1,12	1,10	0,85	1,62	1,46	3,86	2,85
JSC "Airport Uliyanovsk"	0,99	0,39	0,30	0,70	10,45	-1,04	0,70	0,21
OJSC "International Airport Vladivostok"	12,29	8,10	0,96	0,64	0,61	0,18	0,21	0,18
International Airport JSC "Vnukovo-Invest"	8,62	0,79	18,17	3,40	9,50	0,90	9,54	-0,13
PJSC "International Airport Volgograd"	1,52	0,17	2,17	1,48	3,17	1,96	4,06	2,43
JSC "Yakutsky Airport"	0,88	0,43	1,30	0,68	1,72	0,57	1,71	1,62

Only a few of the represented airport companies have transport-industry average (from 1.2) current liquidity ratios (Federal service for state statistics of Russia, 2017). This indicates the need of the companies to mobilize the available working capital to fulfill their short-term obligations. Moreover, problems with payments on short-term obligations are more likely to be faced by regional airports (particularly, airports of the Volga and Far Eastern Federal Districts).

Results

In contrast to the conventional Current liquidity ratio (CLR), Cash flow liquidity ratio (CFLR) is smaller for almost all of the companies. This suggests that in actual practice companies raise insufficient (or critically low) amounts of cash.

However, in most cases both of the analyzed ratios show synchronism in changing their values (Fig. 2).

Fig. 2: The dynamics of the CLR and the CFR of "Vnukovo airport"

On the other hand, we observe an alternative scenario: an increase in the value of one ratio is associated with the opposite change in the other (Fig. 3).

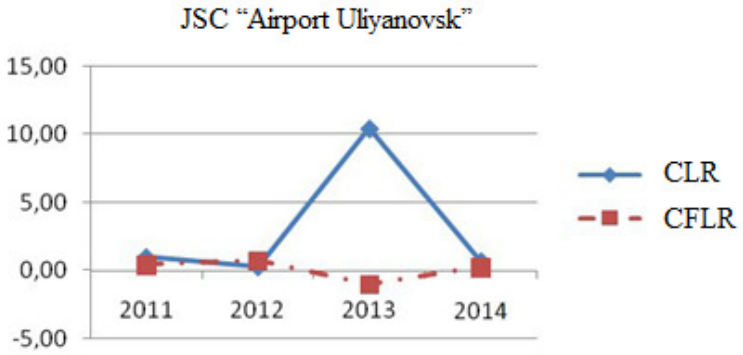

Fig. 3:The dynamics of the CLR and the CFR of "Ulyanovsk airport"

Once we found the "atypical" behavior of the ratios, we conducted a correlation analysis using Pearson's linear correlation coefficients and Spearman's rank correlation coefficients to interrelate the trends. Spearman's correlation between current liquidity ratio and cash flow ratio is 0.4097, indicating a positive but loose correlation between the two ratios.

The same procedure for calculating correlation coefficients was applied to the other pair of ratios: Interest coverage ratio (ICR) - Cash interest coverage ratio (CICR) (Table 4).

Table 4: The comparison of the ICR and the CICR in airport businesses

Company	2011		2012		2013		2014	
	ICR	CICR	ICR	CICR	ICR	CICR	ICR	CICR
OJSC "Airport Anapa"*			20,60	1,13	5,28	13,35	3,51	9,03

JSC "Kazan" International Airport"	1,94	-2,60	11,05	0,20	13,82	6,03	25,49	-225,07
JSC "Khabarovsk Airport"	45,45	51,42	5,87	6,43	6,17	5,20	6,55	2,22
JSC "Omsk Airport"	7,42	17,95	28,63	39,02	48,36	74,01	1 875,41	2 145,95
OJSC "Airport Pobedilovo"	8,18	-7,37	-17,61	-13,85	-8,06	-7,99	12,20	-4,54
JSC "Airport Tolmachevo"	3,15	5,03	7,78	8,64	6,74	5,87	7,19	7,08
JSC "Airport Uliyanovsk"	16,35	97,35	359,59	3 267,59	1,23	-0,42	1,20	1,76
OJSC "International Airport Vladivostok"	6,73	7,05	11,97	12,43	0,73	6,27	-17,38	8,53
International Airport JSC "Vnukovo-Invest"	2,74	3,50	1,05	3,21	1,09	1,56	0,87	0,92
PJSC "International Airport Volgograd"*	16,65	7,33	43,65	76,71				
JSC "Yakutsk Airport"*	34,60	52,96	4 487	10 278				

*Note: a number of companies carried out their economic activities with no interest payments during these years, which made impossible the calculation of ratios.

Source: Authoring

Interest coverage ratio values for airport companies exceed the average of 4.25 for another infrastructure industry – transportation (Laskina L.Yu., 2012). According to CICR values, the following trend can be revealed: the smallest ratio values are attributed to small regional companies (OJSC "Airport Pobedilovo") or those with reduced operating profit (International Airport JSC "Vnukovo-Invest"). It is the companies that encountered the greatest interest payment difficulties.

The calculated CICR values exceed the conventional ICR values in most of the companies, with the same behavior during the investigated period (Figure 4).

Fig. 4: The dynamics of the ICR and the CICR of "Vnukovo airoport"

Note that atypical cases are observed with respect to the direction of changes in these values. For example, the investigated ratio values of OJSC "International Airport Vladivostok" in the last year of the analyzed period varied differently – from 0.73 to -17.38 for ICR and from 6.27 to 8.53 for CICR (Fig. 5).

Fig. 5: The dynamics of the ICR and the CICR of the airport "Vladivostok"

In order to obtain more reliable data on the intensity and behavior of correlation between interest coverage ratio and cash interest coverage ratio, a correlation analysis was conducted. According to the Chaddock scale, this pair of ratios under study is highly correlated. An additional analysis with calculating Spearman's rank correlation coefficient also shows high correlation between interest coverage ratio and cash interest coverage ratio. The rank correlation coefficient is 0,627.

Conclusion

Thus, the study showed that correlation between current liquidity ratio and cash flow liquidity ratio is loose. It would be more informative and reliable for both internal users and potential investors and creditors to use in the analysis the cash ratio from the other pair - interest coverage ratio and conventional interest coverage ratio. Due to the strong correlation, we can suggest a broader use of the cash interest coverage ratio in analyzing the financial state of companies.

Based on the results of calculations, it can be concluded that using cash interest coverage ratio in addition to interest coverage ratio in assessing a company's solvency may provide a broader and deeper understanding of the company's financial stability; moreover, it should be taken into account in determining the company's credit rating. Credit rating adjustment according to international standards will ensure more efficient assessment of investment attractiveness of companies.

Bait & Switch: Corporate Makeover or Destroyer

Benson Nwaorgu
Okan University, Turkey. benlykesu@gmail.com

Abstract

This paper examines the recent upcoming controversy surrounding advertising called "Bait and Switch". The topic has gained notoriety worldwide, in both international court systems and in media. Current research unveils various flavors of Bait and Switch tactics, thereby defining the phenomenon in general and legal context. The current research explains the defining criteria for the tactics to be considered as lawful and discusses the conditions where bait and switch tactic is considered a Turkey shootout instead of a fair sport. The article furthers by sharing the offer types excluding fallacious tactics. The article establishes the legality of this practice, exploring the lawful aspects Bait and Switch (BnS) distinguishing it from a fraud by elucidating its implementation in retail market, sales and departmental store market, and also its value in the sight of court of law. The article put a special focus on how BnS strategies are used by small and medium Enterprises (SME) to drive sales. I have given a detailed description of the model and its effect on the equilibrium. It also reviews the policies and guidelines of Federal Trade Commission (FTC) regarding Bait and Switch.
The later part of the paper discusses the research questionnaire conducted by offline survey. The subjects participating in the survey were people belonging to different income groups. Low income groups never shifted to substituted product owing to their financial limitations. High income group on contrary showed much more flexibility in shifting towards the substituted product.

Keywords: Bait and Switch, Deceptive; FTC; Advertising

Introduction

In general context, Bait and switch is type of advertising technique where a marketer advertises a very attractive price / term that is really a teaser rate which is just meant to attract customers. Once the prospective customer comes to the store to enquire about the advertisement, the product is either not available ("the bait") and in response the advertiser sells the customer a much more expensive product ("the switch"). However, BnS in Legal context is generally considered as a fraudulent or deceptive sales practice in which customer is attracted by advertisement of a low-priced item but then is encouraged to purchase a higher priced one. This term has become a part of scam as it is considered illegal and looked upon as dishonest way of selling goods. The bait and switch has gained most popularity in the mortgage sector, where the providers advertise unbelievably low rates for which vast range of applicants couldn't qualify and forcing the customers to settled at their rates

Two situations are given to explain how BnS occurs in real life example. In this case study peter wants to buy the refrigerator mentioned in advertisement. In situation one the seller baits peter by misrepresenting the product, by saying the refrigerator he is looking for has limited storage and is not suitable for consumers with large storage requirements. Seller pushes peter by diverting his attention from his desired product to the switch, the alternative refrigerator. He Baits peter by offering the product at nearly same price with better features and peter agrees the buy.
In the second situation seller, instead of comparing the refrigerator, says the running out of stock for that model and instead offer another refrigerator with for higher price for same features and carve peter's intention to buy the product which he agrees to buy later.

So, in this case study either the seller pitches the product with some major limitations and then offer the alternative product to buy, or the seller shows the out of stock for the product and pushes the seller to buy the desired product.

"Bait & Switch is also known as form of *Internet Trolling*, which attracts the internet users into watching certain things or entering certain websites with the use of misleading icons and links.

Its main aim is to promote purchases of substituted goods which are available at higher price and making customers satisfied with the available stocks as an alternative for the inconvenience caused due to unavailability of showcased products and reckoning on a seemingly partial recovery of sunk costs expended trying to obtain bait.

These types of scams are common in newspapers as well. The Bait and Switch is alluring for the customers who want to save money. Thus, they end up getting trapped and paying more amount of money as the company assures and convinces them that they are receiving a much better deal. Some customers don't realize that they are victims of bait and switch because this typically doesn't involve selling of phony or non-functional products. But these tactics are frequently used by retail stores & departmental stores which proves to be a blessing for sellers as it increases their sales and along with higher rating of products.

Distinguishing Bns Tactics from Non Bns Tactics

It is important to consider the tactics which are beyond of the circle of BnS, the same way its important to highlight the BnS tactics. It is also unethical t allegedly blame someone for a practice that does not come under BnS and this unnecessary blame game can counter back large legal implications on the consumers.
Pricing error is one concrete example of non BnS tactics and these are most commonly found especially in online searches. The advertiser will list the product A at $500 where its actual price is $5000. This is just a pricing error a consumer should also act rationale while choosing the offers as it is clear that the retail stores won't lose their hundreds and thousands of dollars for honoring this offer.

The other example is the ***availability of limited product stocks*****,** where an offer is proposed only for particular quantity of products or it might state that the offer is for first 10/15 customers only. Expiry of the offer brings the customers to pay the usual prices. This technique which is an exciting marketing stunt, of course, is not bait and Switch until and unless the advertiser mentions the details of the offer. It is like a loss leader, who brings people to the store in hope of large number of savings but end up with no product available in offer.

The advertisers use ***impressive and smooth wording*** to catch up the sight of customers which could sometimes convey wrong meaning or context about the offer to the consumers. There may be shift in perception in minds of consumer and the advertiser behind the idea of offer, but the offer cannot be considered as bait and Switch.

Legality of Bait and Switch

Fraudulent & deceptive forms of bait and switch are intrinsic concerns for law. This practice is crime & considered as fraudulent sales tactics and it is punishable offense under **Lanham Act**. In countries like United States, consumers can file a lawsuit against the advertiser for false marketing. Consumer laws hold this fraudulent business as liable for trademark infringement and the business might also be liable for damages. Consumer laws take this practice as fraudulent because the manufacturer advertises the products that are not meant for sale but the laws doesn't state that the consumer would get the same product they desire for.

As there are two sides of coin, some common advertising or marketing practices on other side of coin prove to be lawful by using traditional bait and switch. Lawful bait and switch occurs in abundance. Virtually every flavor of retail environment, in which consumers enters either physically or virtually, is designed to steer & route consumers to switch to buying more things or a more profitable item.

DELL, for example, has been sued over bait and switch charges by a California law firm for charging the computer giants with systematically deceiving their customers. Another example is of Luxury fashion company named Michael Kors which sued warehouse retailer Costco Wholesale Corp. in federal court over an alleged "bait and switch "advertisement. Kors accuse Costco of false advertising & unfair competition under Federal Lanham Act & New York Common Law.

Review of Federal Trade Commission (Ftc)

Federal Trade Commission defines Bait and switch as "an alluring but insincere offer to sell a product or service which the advertiser in truth does not intend or want to sell. Its purpose is to switch consumers from buying the advertised merchandise, to sell something else, usually at higher price or on basis more advantageous to the advertiser."

According to Federal Trade Commission (FTC), Bait and Switch is considered as fraudulent act as it meets the legal criteria of deception as stated in Section 5 of FTC Act. Thus, Federal Trade Commission prohibit the practice which is punishable on persuasion. While FTC has enforced the laws and deterred scams to a great degree, bait and Switch still remains a stubborn problem that could never disappear from the marketer's bags of tricks. Despite established laws over BnS, the tactic is found lawful in the sight of some marketers while most of the sales team avoid the use of this tactic which has been declared as unlawful by Federal Trade commission. Federal Statue and the State Regulation authority have also voted against this infamous doctrine.

Guidelines of FTC

FTC has issued guidelines to declare the criteria of Bait and switch explaining about what is "bait and switch" advertising and what isn't. where FTC emphasizes that "bait and switch" deals with a disingenuous advertisement. These guidelines are helpful in distinguishing the marketing strategy as bait and switch. According to FTC, if the seller has the ability to sell you the "bait" but talks you into buying something else. That's not "bait and switch." Similarly, If the seller runs out of the "bait" but the advertisement specifies limited quantities, that's also not "bait and switch."

However, If the seller does not intend to sell you the "bait," and disparages the bait or its warranty, credit terms, availability of service, repairs or parts then it's probably the "bait and switch":

similarly employs compensation methods that discourage or penalize sales people for selling the bait. Or Refusal to take orders for the bait refusal to make delivery of the bait within a reasonable time period is also considered as Bait and switch. If the seller shows you a broken or defective product that is also highlighted as BnS. Failure to meet anticipated demand for the bait without disclosing the bait's limited availability in the advertisement also comes under the definition of bait and switch.

Description of Model

Consider a good refrigerator that is for sale. If all the refrigerator's attributes were known, it would appeal to different individuals in different ways. For example, a single door is less likely to be valued highly by a family of four living in Antalya than it is valued by a single man who lives in Ankara. Similarly, a double-sided door refrigerator may have higher value to the family of four than to the single man. Let's

assume index of individuals by some vector of characteristics, x. In this case x might relate to family size and income.

Consider that there are two types of commodities: The first one that comes in two varieties, A and B. The second is a generic good that has price equal to one. Consumers are endowed with wealth W. Cars A and B cost P_A and P_B, respectively. If the consumer buys a type A refrigerator, then he has W - P_A left to spend on the generic good. If the consumer buys a type B, then he has W - P_B left to spend on the generic good. If the consumer buys neither A nor B, then he has W left to spend on the generic good. Thus, in the absence of search costs, utility is given by

$M(x, W - P_A)$ if A is consumed

$N(x, W - P_B)$ if B is consumed

R (X, W) if neither A nor B is consumed. (1)

Now suppose that the consumer must bear cost k to search for the commodity. Under these circumstances, utility is given by

$M(x, W - P_A - k)$ if A is consumed

$N(x, W - P_B - k)$ if B is consumed

R (x, W) if neither A nor B is consumed; no search occurs

R (x, W - k) if neither A nor B is consumed; search occurs. (1')

If a consumer searches and buys A, his utility is $M(x, W - P_A - k)$ and, analogously $N(x, W - P_B - k)$ if he buys B. If he chooses not to search, he avoids cost k and receives utility R (x, W). If he searches and then chooses not to buy, he receives utility R(x, W - k), because the search cost reduces his resources available for the generic good.

Let y be the proportion of firms that produce A and 1 - y the proportion that produce B. For simplicity, it is assumed that a potential customer gets a message from one and only one seller. The message identifies the location of the store and affirms that it has refrigerators to sell. It also declares the type of refrigerator that is for sale. After having received the message, the consumer can decide to "shop," that is, to inspect the good or to stay home. If he does not shop, then all his wealth is spent on the generic good. The consumer's type is un-known to the producer, primarily because the seller does not know the identity of the consumer that his advertisement reaches.

A firm that sells A can either advertise truthfully that it has A for sale at price P_A or advertise falsely that it has B for sale at price P_B. The second strategy is bait and switch. A bait-and-switch strategy is defined as advertising one good but offering another to the buyer after he has already borne the search costs and has come to inspect the product. The truth-telling situation requires a separating equilibrium in which A wants to advertise A and B wants to advertise B. A bait-and-switch equilibrium is defined as a pooling equilibrium in which both sellers advertise that they have B.

Defining a bait-and-switch equilibrium as a pooling equilibrium conforms to common usage of the term "bait and switch." In the bait-and-switch equilibrium, all sellers announce that they have the low-priced good for sale. The announcement merely identifies the location of the automobile showroom and lets the shopper know that there is some positive probability that the advertised good is actually for sale. Buyers

understand that some sellers engage in bait and switch. The shopper arrives at the showroom and learns the identity of the actual refrigerator for sale. If the car is in fact a B, he judges the advertisement to have been truthful. If the car is actually an A, he views the seller as having engaged in bait and switch; this seller has lied about the identity of the good. Even though buyers know that some sellers engage in deceptive advertising, the dishonest behavior by those sellers is exactly what is commonly called bait and switch.

To begin, let us provide conditions under which a separating equilibrium exists. In such equilibrium, sellers of A advertise A, sellers of B advertise B, and buyers shop for a car on the basis of it is announced characteristics. If firms tell the truth, then a consumer who sees an ad announcing that A is for sale at P_A will shop for and buy A if

$$M(x, W - P_A-k)>R(x, W) \quad (2)$$

Similarly, a consumer who sees an advertisement announcing that B is for sale at P_B will shop for and buy B if

$$N (x, W-P_B-k)>R (x, W). \quad (3)$$

When condition (2) holds, the consumer's utility is higher by buying the refrigerator at price P_A and bearing search costs k than by not shopping at all and saving search costs. When (3) holds, the consumer is better off by shopping and buying B than by not shopping at all and saving search costs.
For a separating equilibrium to exist, a seller of A must not want to move to a bait-and-switch strategy. That is, given that consumers expect truthful advertising, the seller of A must not want to advertise falsely that he has B for sale. Since we are interested in bait and switch, we now derive the condition under which a truthful advertising, separating equilibrium will not exist.
Suppose that a seller of A advertises B. Consumers, who initially assume truthful advertising, come to inspect the good if holds. When the customer arrives at A's showroom, he learns that the refrigerator is type A and not B. At that point, the consumer buys the refrigerator if

$$M(x,W-PA-k)>R(x,W-k) \quad (4)$$

After the consumer has borne search costs k, he can either decide to buy A at price PA and receive utility M(x, W - PA- k) or refuse to buy A and receive utility R (x, W - k). Since search costs have already been borne, the utility from not buying A is only R(x, W - k), not R(x, W). A sale of A by a seller who adopts a bait-and-switch strategy occurs only when both conditions (3) and (4) hold. Since the seller of A falsely advertises B, condition (3) must be met for a potential customer to shop. But since A is actually for sale, condition (4) must be met for a customer to buy. Define λ_B as the proportion of individuals with x such that conditions (3) and (4) hold. Then λ_B is the probability that a randomly drawn customer will buy A if a seller deviates to a bait-and-switch strategy, given that buyers expect truthful advertising. Similarly, define λ_T as the proportion of individuals with x such that condition (2) holds. Thus λ_T is the probability that a randomly drawn customer will buy A if seller A advertises truthfully, given truthful advertising by others. Finally, define λ_3 as the proportion of the population who satisfy condition (3), that is, the proportion who would shop for (and buy) B. Since some who will shop for B will not buy A once in the store, $\lambda_3 \geq \lambda_B$.

There are customers who will search for a car thinking that it is a B who would not have shopped at all had they known that only an A was available. Advertising B brings in these customers.

(' Conversely, a seller of B would not want to advertise falsely that he had an A. But A can always be redefined as B, and as will be shown below, if sellers of A want to bait and switch, sellers of B want to advertise truthfully. Therefore, the conditions for only one seller are relevant.)

Once there, some will buy because (4), the condition for buying after search has already been done, is weaker than (2), the condition for shopping and buying an A before search costs are sunk. But there is a cost to advertising B when only A is available. Some who would have bought A are not interested in B. There are likely to be individuals of type x such that (2) holds but (3) does not. Advertising B keeps those potential buyers away. This is the cost of bait and switch.

Normalize the rent per unit of A sold to be one. Then the expected rent to A from advertising truthfully is simply λ_T per potential customer. Analogously, the expected rent from bait and switch is XB per potential customer. A truthful advertising equilibrium exists when $\lambda_T > \lambda_B$ and when the analogous condition holds for sellers of B. Then sellers want to advertise truthfully, and buyers base their shopping decisions on the announced good. Conversely, if $\lambda_T < \lambda_B$, a seller of A will want to deviate from the truthful advertising equilibrium and will engage in a bait-and-switch strategy.

Research Methodology

Current research is focused on consumer behavior and explores the opportunities presented to consumer. Second part of research also focuses on finding the probability and conditions when they prefer to switch, and under what circumstances do they prefer to avoid the substituted products.

Subjects

To reach to the answer, an offline survey was conducted in which 150 people of different income groups were given a questionnaire form. This was followed by Face to face interview along with questionnaire filling.
The consumers of smartphone industry are our major subjects, located in Berlin. The consumers of smartphone industry are chosen because of frequent utilization of this advertising tactics in PC/smartphone industry by producing a product that is way below the market price and then bait with another product. Recent consumer reviews have also opened this dimension of BnS strategies by sales person on marts and huge stores.

Groups

People were divided in 3 income groups and each group was containing 50 people. The reviews of people were asked regarding the online shopping, types of frauds or problems they come across any many such questions.

Results and Discussion

Both high and middle income group were familiar to online shopping and the response rate was 100 % in comparison to 20% of Low income group people. 80% of the lower income group never shopped online. All the people among higher, middle, and lower income groups had come across attractive advertisement which had drawn their attention. On asking the availability of products 20% of higher income group nodded in a yes, however both middle income and lower income group never found the advertised product, and all the income group accepted being the victim to Bait and switch tactic.

Higher income group, did take up the substituted products offered as a switch all the time, and only 50% of middle income group took the switch (alternative product). However, lower income group never considered to buy the switch, owing to their financial limitation. Higher income groups continued purchasing from such vendors where 80% of the middle-income group and 100% of lower income group

had stopped purchasing from such vendors. This was the reason 100% of the lower income group in the study stopped buying online products considering it mostly risky, when 20% of the middle-income group had stopped buying, where this group found shopping online risky sometimes. This on contrary to High income group continue to buy online, where according to them was not risky as all. The responses stated were recorded and thus are analyzed and presented in chart.

After the interview, it was observed that once low income group people experience a fraud they do not tend to change their minds as they fear the loss of their money. The people of this income group never switched to the substitute as the substitute was always available at higher price and that moved out of their budgets. In contrast the change of the product does affect high income group. Due to more of income or savings available with them they mostly tend to change their minds and switch to the substitute product.

QUESTIONS	HIGH INCOME GROUPS	MIDDLE INCOME GROUP	LOW INCOME GROUPS
Have you done online shopping?	Yes	Yes	Only 20%
Do you come across some attractive offers while shopping?	Yes	Yes	Yes
Are the offered products always available?	20% of time	Never	Never
Have you ever been victim to Bait and Switch?	Yes	Yes	Yes
Do you always take up the substituted product given to you at higher prices??	Yes	Only 50% members tend to switch)	No (Seems to be out of budget)
Have you ever taken any legal action against such fraudulent practice??	No	No	No
After coming across such instance have you stopped buying from such vendors?	No	80% members have stopped	Yes
Have you stopped online shopping?	No	Yes-20%	Yes – 100%
Do you think online shopping is risky?	No	Sometimes	Mostly

Conclusion

Bait and Switch is mostly being used as fraudulent practice to deceive the consumers. This paper concentrated on understanding the proper meaning of the BnS concept and how the concept works to attain proper equilibrium in the economy. It also reflected, how the customers are affected and under what circumstance they always tend to substitute the product. This practice occurs only when there are potential customers for a good other than the one seller has available. In summary, bait and switch is more of economic destroyer owing to its misleading nature upon customer arrival. Use of this strategy to attract the consumers to increase their earnings is merely to mislead the customers to buy the desired product, which is an unethical practice, punishable under the FTC act.

Thus, it is advisable for the businesses to avoid pursuing such malpractices, and not to follow fraudulent techniques to improve businesses. It is highly recommended to make use of ethical advertising strategies, which can increase the sales by the use of search engine optimization (SEO), banner advertisements, social media marketing, Google AdSense, e-mail advertising etc.

Drivers and Specificity of Eco-Innovation in Poland – The Latest Research Results

Adam Ryszko, Silesian University of Technology, Gliwice, Poland, adam.ryszko@polsl.pl

Abstract

The paper presents theoretical considerations and results of empirical research on the drivers and specificity of eco-innovation activity in companies in Poland. The diversity of the drivers and the results of eco-innovation activity are pointed out. An analysis is performed of the latest eco-innovation statistics obtained from the Community Innovation Survey 2008 and 2014 carried out in Poland. In addition, the findings of own research are presented, focusing in particular on the relationships between the importance that the surveyed companies attach to selected eco-innovation drivers and the specific results of technological eco-innovation activity. The results of multiple regression analyses made it possible to identify pivotal drivers of both the product and the process eco-innovation speed, number and quality.

Keywords: eco-innovation, technological eco-innovation, eco-innovation drivers, eco-innovation specificity

Introduction

Sustainable development is embedded in the triple bottom line concept. It requires integration of environmental, economic and social performance, which is perceived as a crucial contemporary challenge that companies need to face in their business activity. Eco-innovation plays an essential role in achieving sustainable development and supports these goals, aiming to develop new solutions (i.e. products, services, processes, methods) in a way that benefits the environment. It might be considered as the process of development and adoption of environmentally friendly products, services or processes (from the processual point of view) and as the output (i.e. goal or result) of the eco-innovative process which can be achieved by companies.

According to the Eco-Innovation Scoreboard, Poland is among the countries catching up in eco-innovation. Still, its overall eco-innovation performance is one of the worst in the European Union (EIO Database, 2017). Eco-innovation activity is undertaken by companies in Poland extremely rarely (GUS, 2015). It is therefore essential that the specificity of eco-innovation activity and the drivers accelerating the uptake of eco-innovation are thoroughly investigated. Unfortunately, until now there has been a gap in such analyses with regard to companies in Poland.

For this reason, this paper presents a literature review and an empirical analysis performed in particular with a view to:

- presenting the specificity of eco-innovation activity in companies in Poland,
- identifying eco-innovation drivers in companies in Poland,
- investigating the relationships between the importance attached by companies in Poland to selected eco-innovation drivers and the specific results of eco-innovative activity.

Theoretical Framework

Defining eco-innovation is not a simple task although several attempts have been made in the literature (Carrillo-Hermosilla et al., 2010). According to Kemp and Pearson (2008), eco-innovation is the production, assimilation or exploitation of a product, production process, service, management or business method that is novel to the organization (developing or adopting it) and which results,

throughout its life cycle, in a reduction of environmental risk, pollution and other negative impacts of resources use (including energy use) compared to relevant alternatives. The European Commission defines eco-innovation as any form of innovation resulting in or aiming at significant and demonstrable progress towards the goal of sustainable development, through reducing impacts on the environment, enhancing resilience to environmental pressures, or achieving a more efficient and responsible use of natural resources (European Commission, 2011). The Eco-Innovation Observatory defines eco-innovation as the introduction of any new or significantly improved product (good or service), process, organizational change or marketing solution that reduces the use of natural resources(including materials, energy, water and land) and decreases the release of harmful substances across the whole life-cycle (EIO, 2012a). There is also definition of technological eco-innovations that is based on the general understanding of technological innovations as defined in the Oslo Manual (OECD, 2005) which distinguishes product and process innovations. Thus, technological eco-innovations, *i.e*., product and process eco-innovations, as specific kind of technological innovations consist of new or significantly improved products and processes to avoid or reduce environmental burden (Ziegler and Nogareda, 2009).

Despite differences in wording, all definitions of eco-innovation embrace the environmental component and reflect the two main consequences of eco-innovation: fewer adverse effects on the environment and more efficient use of resources. However, while eco-innovation can be realized in many forms (e.g., product, process, organizational and/or marketing methods), the effect of a diminishing environmental burden is not the primary reason for the deployment of eco-innovation (Hojnik and Ruzzier, 2016).

The studies on eco-innovation drivers commonly adopt general innovation theory (Rehfeld et al., 2007). This means considering technology push (supply side) and market pull (demands side) factors. The research studies in this area also comprise regulatory and institutional frameworks (De Marchi, 2012; Horbach, 2008; Rennings, 2000). In fact, Horbach (2008) enlarged the general innovation theory and proposed the term “environmental innovation theory”, encompassing demand side, supply side, institutional and political determinants of eco-innovation. Other studies (Horbach et al., 2012; Triguero et al., 2013) adopted this theoretical background in exploration of eco-innovation drivers. The research on eco-innovation drivers is also based on other theoretical backgrounds. It includes, most of all, institutional and neo-institutional theory (De Marchi, 2012; Li, 2014), resource-based theory (Chen, 2008; Yarahmadi & Higgins, 2012), and stakeholder theory (Oxborrow and Brindley, 2013; Weng, 2015).

The decision to create and diffuse eco-innovation is influenced by evolving set of factors. Horbach et al. (2012) indicate four groups of the main drivers of eco-innovation: the technology push (supply side), the market pull (demand side), the regulation/policy factors (institutional and political influences) and the firm-specific (internal) factors. Supply side consists of technological capabilities, path dependency and market characteristics. Demand side comprises expected market demand and social awareness of the need for cleaner production, environmental consciousness and preference for environmentally friendly products. Institutional and political influences relates to environmental policy (incentive based instruments or regulatory approaches) and to institutional structure (e.g. political opportunities of environmentally oriented groups, organization of information flow, existence of innovation networks) (Horbach, 2008). Firm specific factors are related to “green capabilities” that play an important role from the perspective of a resource-based view of a firm.

Furthermore, drivers of eco-innovation can be classified as internal or external factors (Del Río González, 2009; Del Río González et al., 2016; Horbach, 2008; Horbach et al., 2012). According to Del Río (2009), internal factors refer to the existence of internal preconditions and features of the company, which facilitate its involvement in environmental technological change. On the other side, external factors stem from the incentives and stimulus derived from a wide range of factors and actors that exert pressures to which company responds. Therefore, Bossle et al. (2016) point out internal factors (i.e. cost savings, adoption of certification, environmental capability, environmental managerial concern, human resources, environmental leadership and culture) that companies can manage in order to adopt eco-innovation and external factors (i.e. regulatory pressures, normative

pressures, market demands, changes in technology) over which companies have little or no control. With regard to internal capabilities which might facilitate an eco-innovative approach, top level management commitment, technological competency, financial and human resources are highly relevant. In addition, Chen et al. (2012) indicate the following internal origins of eco-innovations: environmental leadership, environmental culture and environmental capability.

Based on a thorough overview of emerging literature on eco-innovation drivers, Hojnik and Ruzzier (2016) make the following interesting observations:

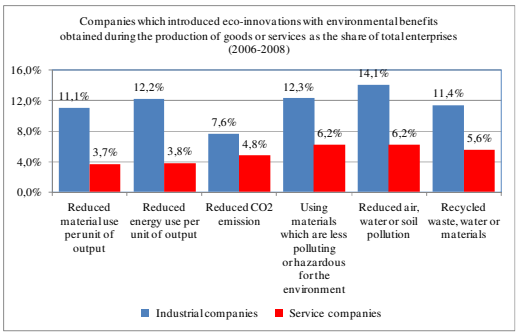
- regulations and market pull factors constitute the most commonly and frequently reported determinants triggering eco-innovation,
- different factors trigger different eco-innovation types, i.e. product eco-innovations are driven most frequently by market pull factors and regulations, process eco-innovations are determined mainly by regulations and the Environmental Management System, and organizational eco-innovations are driven by regulations, technology push factors and market pull factors,
- regulations, market pull factors and the company size constitute important drivers of eco-innovation in both its generation stages (i.e. development/innovation stage and the adoption/diffusion stage), while collaboration with external partners seems to drive eco-innovation primarily in the development/innovation stage, and in turn coercive pressures, normative pressures and mimetic pressures spur eco-innovation in the adoption/diffusion stage. Nevertheless, most studies identify the technology push factors and technological and green capabilities of companies as facilitators of eco-innovation in the innovation/development stage, while in others they also work as facilitators of eco-innovation in the adoption/diffusion stage.

The further part of this paper presents results of the latest research on the specificity and drivers of eco-innovation in companies in Poland. The results are based on public statistics data and on the Author's own findings.

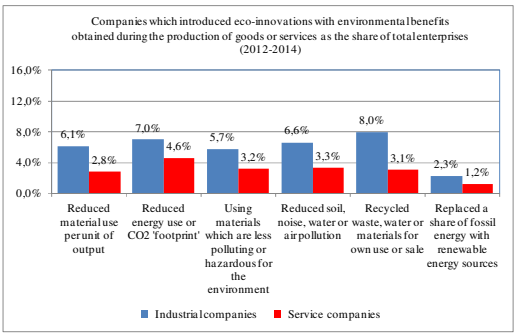
Eco-Innovation Activity and Drivers in Companies in Poland – Results from Public Innovation Surveys and Statistics

Two comprehensive analyses of eco-innovations in Poland have been performed so far. They focused on the response to the Community Innovation Survey 2008 (CIS 2008), covering the years 2006–2008, and the Community Innovation Survey 2014 (CIS 2014), covering the years 2012–2014. The scope of the two surveys differed slightly and different approaches were adopted to the aggregation of data and presentation of results. Although this makes it difficult to compare them directly and unequivocally, some essential conclusions can be drawn from them.

The CIS 2008 showed that in the years 2006-2008 eco-innovations had been introduced in 26.5% of industrial companies and in 16.1% of the service sector enterprises. Large companies (with 250+ employees) were the most innovative. Eco-innovations were introduced in 57.5% and 35% of them in industry and in the service sector, respectively, whereas in small businesses (10-49 employees) the percentage totalled only 21.7% and 14.6%.



The analyses made a distinction between eco-innovations with environmental benefits obtained during the production of goods or services and those offering environmental benefits obtained during the consumption or use of a product or service by the end user. Eco-innovations with environmental benefits obtained during the production of goods or services were implemented by almost a quarter of the industrial companies and by 13.4% of the service sector enterprises. Eco-innovations with environmental benefits obtained during the consumption or use of a product or service by the end user were implemented by 17.8% of the industrial companies and by 11.4% of the service sector enterprises. The main advantages gained due to the implementation of eco-innovations during the production of goods or services were as follows: reduced air, water or soil pollution (14.1% of



industrial companies and 6.2% of those from the service sector) and use of materials which are less polluting or hazardous for the environment (12.3% and 6.2%, respectively). The most common advantage in eco-innovations with environmental benefits obtained during the consumption or use of a product or service by the end user was reduced air, water or soil pollution (12.2% of the total of industrial companies and 7.2% in the service sector).

The CIS 2014 results indicate that the level of eco-innovations introduced in companies in Poland in the years 2012-2014 was significantly lower compared to the period of 2006-2008. In the years 2012-2014, process eco-innovations, product eco-innovations, organizational eco-innovations and marketing eco-innovations were implemented only in 4.1%, 3.9%, 1.6% and 0.7% of industrial companies, respectively. The service sector companies performed even worse: only 1.7% of them implemented product eco-innovations, 0.9% – process eco-innovations, 0.9% – organizational eco-innovations and 0.4% – marketing eco-innovations.

The main advantages gained due to the implementation of eco-innovations during the production of goods or services in industrial companies in the years 2012-2014 were as follows: recycled waste, water or materials for own use or sale (8.0%), reduced energy consumption or CO_2 footprint (7.0%) and reduced soil, noise, water or air pollution (6.6%). In the service sector, the respondents pointed to the following main advantages: reduced energy consumption or CO_2 footprint (4.6%), reduced soil, noise, water or air pollution (3.3%), and use of materials which are less polluting or hazardous for the environment (3.2%). Considering the company size, it can be observed that all types of environmental benefits were gained first and foremost by large entities operating in industry and in the service sector (companies with 250+ employees). The benefits obtained during the production of goods or services were definitely most often indicated by large industrial companies. They concern in particular: reduced energy consumption or CO_2 footprint (25.4%), recycled waste, water or materials for own use or sale (23.3%) and reduced soil, noise, water or air pollution (23.0%). With regard to eco-innovations with environmental benefits during the consumption or use of a product or service, the most frequent advantage, both in industrial and the service sector entities, was reduced energy consumption or CO_2 footprint (5.9% of industrial companies and 4.8% the service sector enterprises). The environmental benefit obtained during the use of a product or service which was indicated by the respondents the least often was facilitated recycling of a product after use (4.4% and 2.9% of companies from industry and from the service sector, respectively).

Detailed results concerning the benefits gained due to implementation of eco-innovations during the production of goods or services and during the consumption/use of a product or service in the years 2006-2008 and 2012-2014 in Poland are presented in Fig. 1.

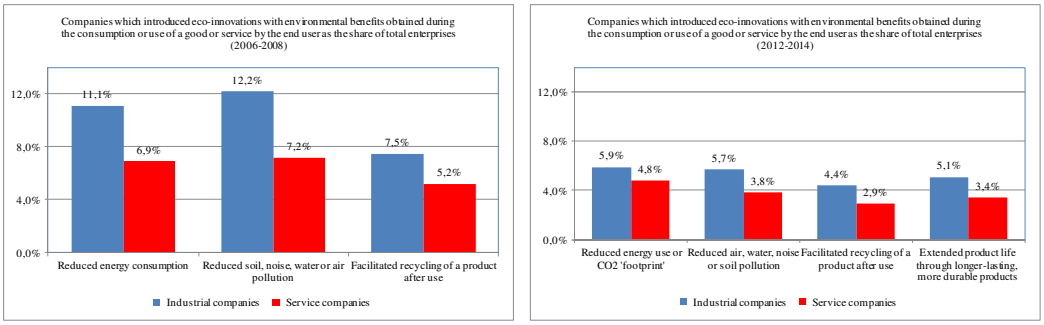


Fig. 1: Percentage of the total number of companies in Poland which introduced eco-innovations with environmental benefits obtained during the production of goods or services and during the consumption/use of a product or service by the end user in the years 2006-2008 and 2012-2014

Source: based on (GUS, 2010; GUS, 2015)

The survey results indicate that the factor with the strongest impact on a company's decision to introduce eco-innovations in the years 2012-2014 was the high cost of energy, water or materials, the importance of which was ranked "high" by 36.7% of industrial companies and 42.3% of enterprises from the service sector. Other factors of essential importance were also: improving the company reputation (rated "high" by 31.4% and 32% of industrial companies and the service sector enterprises, respectively) and existing environmental regulations (30.5% and 29.4%). The factor the importance of which the respondents rated as "high" the most seldom was government grants, subsidies or other financial incentives for introducing eco-innovations (9.9% and 9.1%, respectively). The relevant drivers prompting a company to introduce eco-innovations are presented in Fig. 2.

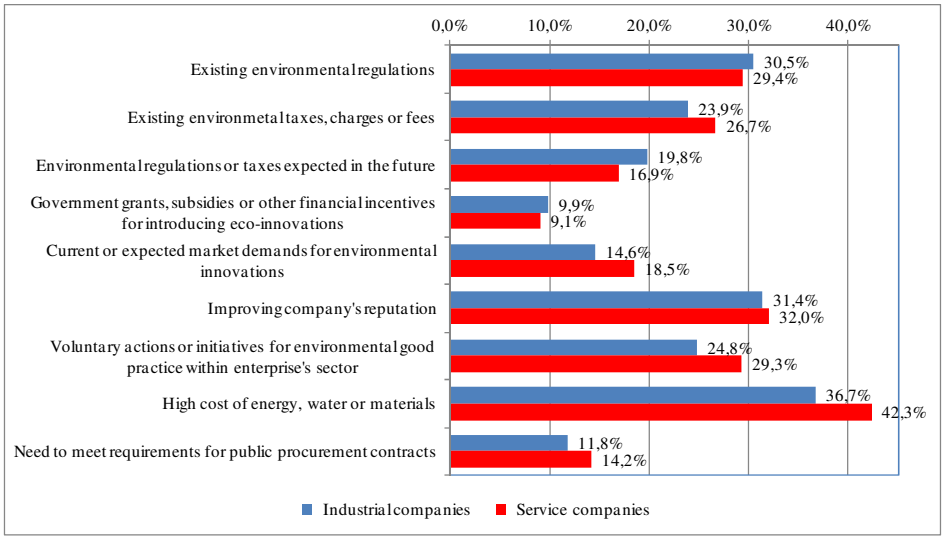

Fig. 2: Drivers of decisions prompting a company to introduce eco-innovations (importance rated as "high" as the share of companies which introduced eco-innovations) In the years 2012-2014

Technological Eco-Innovation Specificity and Drivers in Companies in Poland – Own Research Results

In relation to the issues discussed in this paper, empirical research was carried out on selected aspects of eco-innovation activity in companies in Poland in the years 2011-2013. The research method drew

on the computer-assisted telephone interview (CATI) conducted by the largest Polish research agency – PBS Sp. z o.o. The interviews were conducted among representatives of companies: owners, management board members or other decision-makers in the organization. In order to enable analysis in the established groups of companies in each determined category, ratios by industry and the number of employees were used. After the categories and the size required to carry out the research had been defined, companies were drawn randomly from the nationwide business database with a stratification procedure along the dimensions of the company size and selected industrial and service sectors. The questions concerning the substance of this paper were answered by 292 representatives of various companies, including 47 large, 95 medium and 150 small businesses.

In particular, the research focused on technological eco-innovation. Respondents were asked to assess statements reflecting on the number of product and process eco-innovations, the technological eco-innovation speed (i.e. the company agility in terms of launching eco-innovative products and developing new environmentally friendly processes) and on the technological eco-innovation quality (i.e. novelty and eco-efficiency of eco-innovative products and processes) as compared to key competitors. The assessed statements included as follows:

- TEI-1 – Product eco-innovation speed (i.e. "we usually were the first on the market to introduce new eco-innovative products"),
- TEI-2 – Product eco-innovation number (i.e. "we have introduced more products that are eco-innovative"),
- TEI-3 – Product eco-innovation quality (i.e. "we have introduced products that are more eco-innovative"),
- TEI-4 – Process eco-innovation speed (i.e. "we usually were the first to introduce new, environment friendly methods of manufacturing, maintenance and logistics"),
- TEI-5 – Process eco-innovation number (i.e. "we have introduced more new or significantly improved processes bringing environmental benefits")
- TEI-6 – Process eco-innovation quality (i.e. "we have been improving environmental parameters of our processes more effectively").

The representatives of the companies were also asked to evaluate the importance of drivers that could accelerate the development and uptake of eco-innovation activity in their company. The analysed drivers included as follows:

- D-1 – Existing environmental regulations,
- D-2 – Expected future environmental regulations,
- D-3 – Securing or increasing existing market share,
- D-4 – New market entry,
- D-5 – Increasing market demand for green products,
- D-6 – Opportunity of cost-savings,
- D-7 – Access to existing subsidies and fiscal incentives for introducing eco-innovations,
- D-8 – Voluntary environmental agreements and codes of practice,
- D-9 – Opportunity for improving company image.

The Likert-type seven-point scales (1 – strongly disagree/much worse; 7 – strongly agree/much better) were used for all relevant statements related to the specific results of technological eco-innovation activity and eco-innovation drivers.

The results of the survey on the specific effects of technological eco-innovation activity, taking account of the differences in eco-innovation in individual companies depending on the business size are presented in Fig. 3.

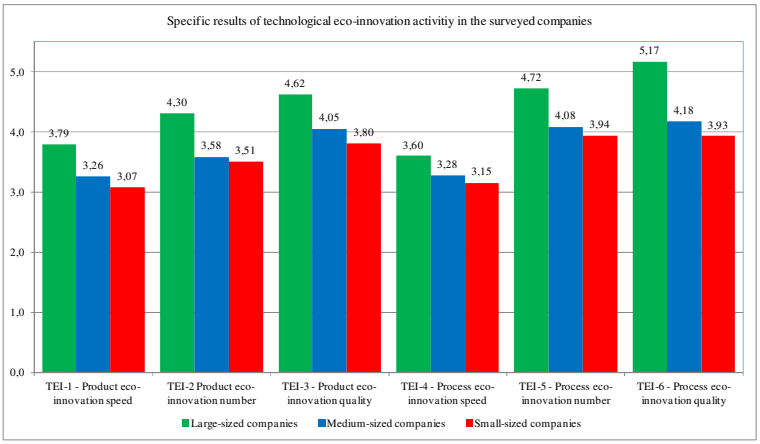

Fig. 3: Specific results of technological eco-innovation activity in the surveyed companies

The results of the analyses indicate that, irrespective of the entity size, the companies under consideration have the greatest problem with the speed of introducing either product- or process-related innovations. The number of introduced eco-innovations is rather unimpressive, too. When it comes to the effects of eco-innovation activity indicated during the surveys, the best performance can be observed in improving the process ecological parameters, i.e. the quality of the process eco-innovation. An analysis of the obtained results confirms that the advancement in eco-innovation activity depends significantly on the company size. The one-way ANOVA results prove that the company size has an essential impact on the differences in variables TEI-1 ($p<0.05$), TEI-2 ($p<0.05$), TEI-3 ($p<0.05$), TEI-5 ($p<0.05$), and TEI-6 ($p<0.001$). It should be added that large entities are characterized by definitely the highest level of eco-innovation. Considering the company size criterion, the greatest differences can be observed in relation to the process eco-innovation quality. In this area, small and medium businesses differ from large companies significantly.

Next, the analysis focused on eco-innovation drivers. The variables covered by the surveys, together with the results of the performed analyses taking account of the data obtained from companies depending on their size, are presented in Fig. 4.

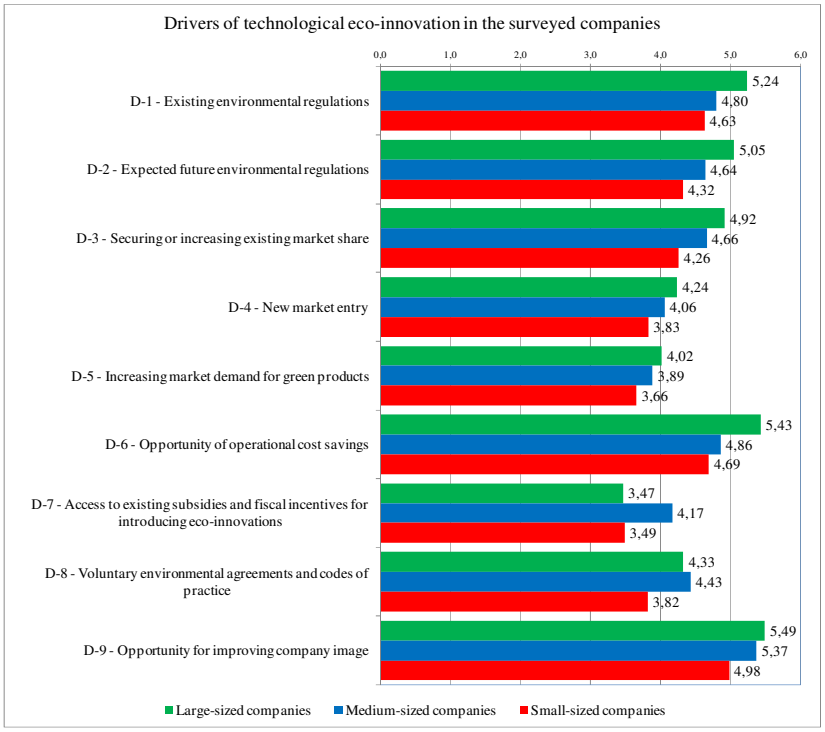

Fig. 4: Drivers of technological eco-innovation in the surveyed companies

The data presented in Fig. 4 indicate that the representatives of the surveyed companies generally agree as to the most important drivers prompting entities to take up eco-innovation activity. Regardless of the company size or the type of the business activity, the representatives believe that the most essential factors spurring eco-innovation implementation are the opportunity to improve the company reputation (D-9), the opportunity for operational cost savings (D-6) and the existing environmental regulations (D-1). This confirms the results of the research mentioned above concerning the importance attached to the company image, the potential reduction in costs or the need to comply with legal regulations. By far the least important factors are the following: access to existing subsidies and fiscal incentives for introducing eco-innovations (D-7), increasing market demand for green products (D-5) and new market entry (D-4), which may mean that most respondents fail to notice the market opportunities prompting companies to develop and implement eco-innovation.

In the next stage, the analyses focused on the relationship between the importance attached by company representatives to individual eco-innovation drivers and the specific results of technological eco-innovation activity in the surveyed companies. Multiple regression analyses were conducted where the eco-innovation drivers (D-1–D-9) were independent variables, whereas the specific results of technological eco-innovation activity (TEI-1–TEI-6) were the dependent ones. The results of the regression analyses are listed in Table 1.

Table 1: Results of multiple regression analyses

Independent variables	Dependent variables					
	TEI-1	TEI-2	TEI-3	TEI-4	TEI-5	TEI-6
Constant	0,618	1,268**	1,868***	1,008	2,074***	1,928***
D-1	0.112	0.018	0.036	-0.052	0.142*	0.066
D-2	0.021	0.075	0.030	0.057	-0.016	0.020
D-3	0.259***	0.138*	0.083	0.174*	0.029	0.054
D-4	-0.145	-0.104	-0.030	-0.008	-0.041	-0.027
D-5	0.114	0.205**	0.127	0.047	0.093	0.227***
D-6	0.048	0.076	0.126	0.163*	0.098	0.114*
D-7	-0.024	-0.006	0.036	-0.043	0.047	0.060
D-8	0.231**	0.097	0.143*	0.153	0.112	0.087
D-9	0.072	0.169*	0.082	0.104	0.120	0.058
R^2	0.254	0.266	0.191	0.199	0.190	0.256

* $p < 0.05$; ** $p < 0.01$; *** $p < 0.001$

The results obtained from the regression analyses prove that:

- existing environmental regulations (D-1) have significant effect on process eco-innovation number (TEI-5),
- securing or increasing existing market share (D-3) has significant effect on product eco-innovation speed (TEI-1), product eco-innovation number (TEI-2), and process eco-innovation speed (TEI-4),
- increased market demand for green products (D-5) has significant effect on product eco-innovation number (TEI-2), and process eco-innovation quality (TEI-6),
- possibility of reducing the operational cost (D-6) has significant effect on process eco-innovation speed (TEI-4) and process eco-innovation quality (TEI-6),
- voluntary agreements and environmental codes of practice (D-8) has significant effect on product eco-innovation speed (TEI-1) and product eco-innovation quality (TEI-3),
- improving company's reputation (D-9) has significant effect on product eco-innovation number (TEI-2).

Consequently, it follows that the introduction of product eco-innovations depends first and foremost on securing or increasing the existing market share and on voluntary environmental agreements and codes of practice. Implementation of this type of eco-innovation is also strongly affected by the increasing market demand for green products and the opportunity to improve the company image. Introduction of process eco-innovations depends primarily on the opportunity for cost savings, the increasing market demand for green products, securing or increasing the existing market share and the existing environmental regulations.

Discussion

The results of the presented analyses indicate clearly that regulatory, supply-side and market-pull factors have a diverse impact on the specific results of technological eco-innovation activity. Therefore, numerous and varied supporting measures are required to ensure effective eco-innovation stimulation due to the complexity of innovation drivers and understanding of the interaction between regulatory, demand and supply incentives. By doing so, demand for eco-innovative solutions is stimulated on the one hand and, on the other hand, eco-innovations will be more and more commonly embodied in business models of enterprises as a potential source of competitive advantage, thus generating the supply of such solutions. It should be emphasized that creating successful eco-innovation policy requires well-designed standards and regulations, including their appropriate stringency, flexibility and time frame. Supply measures should take into consideration equity support,

environmental research and development, pre-commercialisation, education and training for developing the human capital needed to deliver eco-innovative solutions, networking and partnerships target the development of eco-innovation and provision of essential infrastructure. Demand measures should include the shaping of environmental friendly attitudes and behaviours among customers, green public procurement, and technology transfer and know-how support (OECD, 2009).

The studies conducted in the EU member states indicate that the most widely used supply-side policy measures appear to be the support for research and development (R&D) and promotion of networking and collaborative R&D and innovation processes. Fiscal instruments, such as tax incentives for eco-innovative R&D, start-ups, and personnel, have not been reported as having a dedicated focus on eco-innovation support in any of the EU member states. The most widely used demand-pull instruments are: green public procurement, product and service certification and fiscal support for companies adopting environmental technologies. In addition, environmental regulations, national and EU targets, as well as the EU emission-trading schemes are very important in creating the framework conditions motivating companies to shift to greener practices, and in this way facilitate demand for eco-innovative technologies, products and services (EIO, 2012b).

The eco-innovation activity in Poland is supported by the following measures: (EIO, 2015; Baran et al., 2017):

- equity/business support – publicly co-funded ventures or guarantee funds,
- support for R&D in the public sector and industry – R&D funding and infrastructure, collaborative grants,
- education, training and mobility – tailored training courses, consulting for companies, entrepreneurs, a placement scheme for students, support for R&D workers recruitment,
- networks and partnerships – competence centres, clusters, science and technology parks, technology platforms and innovation networks, foresight and common vision building, market intelligence and other forms of information sharing,
- regulations and standards – regulations, targets, cap & trade schemes, performance standards, labelling, certification,
- public procurement – "green" public procurement of goods and services,
- technology transfer – advisory support for technology adopters, financial or fiscal support for technology adopters,
- support for private demand – tax reductions for products and services, demand subsidies, awareness raising and information provision.

However, as proved by the research results presented herein, the use of the instruments mentioned above is still insufficient, which is reflected by very poor performance of eco-innovation activity in Poland.

It should be noted that, irrespective of external incentives, engagement of companies in eco-innovation development and adoption depends to a great extent on the resources and capabilities available internally. These factors play a crucial role in facilitating the inclusion of eco-innovation into business models and creation of value which can enable companies to gain and maintain competitive advantage. Therefore, effective and efficient eco-innovation activity resulting in new or significantly improved products and processes may require comprehensive and reliable utilization of specific quantitative and qualitative tools applied both on the strategic and operational level (Baran, 2015; Brodny et al., 2016; Brodny et al., 2017; Janik, 2016; Loska and Paszkowski, 2018; Matusek, 2015; Szafraniec, 2015). In addition, eco-innovation activity involves the need to develop diverse innovative initiatives (Szmal, 2015) and suitable forms of internal and interorganizational cooperation (Brzóska et al., 2016).

Conclusions

The presented theoretical considerations and results of empirical research concerning the specificity and drivers of eco-innovation activity in companies in Poland point to a number of different motivations for and effects of taking up such measures.

The results of the CIS 2008 and the CIS 2014 indicate that the eco-innovation performance of companies in Poland in the years 2012-2014 was significantly worse compared to the period of 2006-2008. It should also be noted that the eco-innovation performance in the years 2006-2008 was already very low.

The own research findings prove that for the representatives of the surveyed companies in general the most important drivers that could accelerate the development and uptake of eco-innovation activity are the following: the opportunity to improve the corporate image, the opportunity for cost savings and the existing environmental regulations. However, considering the relationship between the importance that company representatives attach to individual eco-innovation drivers and the specific results of technological eco-innovation activity in the surveyed companies, the list of the most important spurs in this area is different. The results of the multiple regression analyses demonstrate that the product eco-innovation implementation depends first and foremost on securing or increasing the existing market share as well as on voluntary environmental agreements and codes of practice. The implementation of this type of eco-innovation is also strongly affected by the increasing market demand for green products and the opportunity to improve the company image. The process eco-innovation implementation depends primarily on the opportunity for cost savings, the increasing market demand for green products, securing or increasing the existing market share and the existing environmental regulations.

The results of the presented analyses demonstrate clearly that regulatory, supply-side and market-pull factors have a diverse impact on the specific results of technological eco-innovation activity. Therefore, numerous and varied supporting measures are required to ensure effective eco-innovation stimulation due to the complexity of eco-innovation drivers and understanding of the interaction between regulatory, demand and supply incentives. In Poland, eco-innovation activity is supported by diverse regulatory, market pull (demands side) and technology push (supply side) measures. However, as proved by the research results presented herein, the use of these instruments is still insufficient, which is reflected by very poor performance of eco-innovation activity in Poland.

Abstract

The aim of this study is to investigate the international students' satisfaction in different universities in Malaysia. A total of 3 different private universities were selected for data collection. All the universities were located within the Cyberjaya area. Total 400 questionnaires were distributed and 327 were returned. Later, total 318 were found valid for further analysis. For data analysis, this study has used multiple regression. The result shows that most of the foreign students think that the teaching method used by the universities is appropriate. Besides, most of them are highly satisfied with their education and think that the learning method is appropriate. In addition, the respondents are agreed that the online resources are available while most of them think that the web-based communication as a popular way of communication adopted by the university. It contributes to current theories on how consumers resolve sequentially inconsistent information about a university's service quality. The study of behavioral aspects of students is of great importance for university policy makers and this knowledge can be applied to find out the students' needs and wants.

Keywords: Satisfaction, teaching method, tuition fees, web-based communication, Malaysia.

Introduction

Customer satisfaction is a key determinant and a variable in the attitudinal concept of consumer behaviour as it is purely experiential (Kuo et al., 2009; Aurier & N'Goala, 2010). Jones and Sasser (1995) viewed satisfaction as purely cognitive whereas Kim and Ok (2010) links to their expectancy disconfirmation model and categorizes it as emotional. Satisfaction needs to be categorized as an attitude and not as a behavior as per se as it gains traction in an experiential state rather than at a static manner (Mizik & Jacobson, 2007). Satisfaction cannot be seen as cognitive aspect as it is the outcome of most relationships and therefore it leads to future repurchase intentions which is deemed to be conative and not cognitive unless the role of satisfaction is changes not as an outcome but as a perception ((Cronin and Taylor, 1992; Parasuraman et al., 1985). A more acceptable view would be that of Heskett et al. (1997) who sees it a post purchase behaviour leading to judgment towards future purchase decision making. Therefore we can ascertain that satisfaction is a key outcome which must be achieved by uiversities in order to encourage future student enrollment. Huang (2009) also found the service quality like academic aspects and non-academic aspects determine the student satisfaction. Hence, service quality and

satisfaction is observed positively in their relationships (Kuo et al., 2009; Aurier and N'Goala, 2010; Kim and Ok, 2010).

As universities are also a part of the overall service industry, therefore, determining the factors that leads to customer satisfaction (international students) needs to be identified. In this case, it should specifically identify the factors towards international students' satisfaction on Malaysian private universities. Moreover, precedent literatures show that the limited empirical evidence appears to exist concerning the student satisfaction especially in Malaysia. So, there is a lack of research in this area whereby this is very important to measure what factors influence international students' satisfaction in any international university in Malaysia. The findings will help policy makers and top management in terms of better policy making.

Literature Review

Teaching Quality

There are ample arguments within the higher education communities on schooling methods or effectiveness of teaching (Braskamp & Ory; 1994; Theall & Franklin, 2016). Hoyt and Pallett (2015) defined operative teaching as "that which produces beneficial and purposeful student learning through the use of appropriate procedures" (p. 42). Most universities in the world accept a procedure by which apprentices deliver unidentified response at the end of each subject they finish. These evaluations of teacher efficiency have been a burning issue since they were first working in mid of 1920's (Chang, 2016) and they generate a vast challenge for almost every institution that uses them (Hoyt and Pallett, 2015). Throughout the study period learner valuation of trainers has changed considerably particularly in purpose and methodology areas. They have altered from being predominantly used to support students in the course choice, serving academic stuffs for increasing their teaching abilities and additional development, help officers with respect to personnel judgments (Ory, 2000).

Learning Method

Nowadays, student ratings of lecturer are vastly applied for the purpose of creating personnel verdicts and faculty improvement references (Scriven, 1995; Ory, 2016). For managers, the evidence provided from ratings aids them in reaching both cumulative and influential decisions dealing with possession of academic stuffs, appointment, contract and their promotion, picking faculty for excellent rewards and honors, and handover courses to the lecturers (Franklin, 2016; Kulik, 2016). Braskamp (2000) advised teachers to use the information constructively to develop and increase their instruction efficiency. Many investigators have concentrated on whether or not learners are appropriate judges of teaching usefulness. However, considering the thrive of qualifications and overall senses the students are both coherent and consistent sources of confirmation (Braskamp and Ory, 1994; Arreola, 1995; Pratt, 1997; Franklin, 2016; Kulik, 2016; Kim and Ok, 2010), Whereas inside the classroom, students are showing all kinds of educational proficiencies (such as, lectures, instructional materials and aids, readings, exams). They are significant effect in investigational users capable to determine the excellence, consequence, effectiveness, and lecturer collaboration with learners However, Ory (2016, p. 12) summed it up best stating: "unless they have not been to class, as consumers they have a legitimate voice.

Infrastructure

To help the student's progress so many types of internet articles are used. Various types of e- learning adopt combinations of different as online blogs, social media software and virtual classes. Computers and tablet devices concede both learners and instructors to use the web portals and other online applications, such as MS Word, XL, portable document files and photography files. Also mobile application devices use m-learning. Students and teachers can share their ideas and thinking by web portals (Chang, 2016).

Blog writing concedes learners and teachers sharing their thinking as well as commenting on each other's thinking. That makes bilateral studding environment. Using the term learn, instruction and education with technology means the using of technology in wide speeded area than the computer based or computer aided teaching of two decades before the 2000. Learning technology is also different than some purely web-based learning as online learning or teaching. E-learning is now very popular in the sense of mobile applications (Chang, 2016). E-learning also has various types of applications. It conceives a Virtual Learning Environment (VLE) in the higher educational fields. There all types of study outlines are managed by an invariable user interface (UI) in all over the institution. In general, virtual academic course means one kind of course where either complete or partial part is delivered through the internet (Kulik, 2016; Kim and Ok, 2010). Actually, virtual course is a course by that students no need to go to school for learning. It is not the way of direct teaching but in concept it is as the teaching in the class. Virtual schooling means the extent learning. By this way, study tutorials are exchanged by different ways such as data files, audio and video clips. Now-a-days, the rapid use of YouTube video tutorials has made the distance learning easier. By these technologies teachers and learners exchange their opinion each other.

Resource Availability

As the wealth of any university, the necessity of library is initially mentioned. Library is the main part of an institution and fundamental goal of the library is to add materials aids with lecturers, learners and researchers. It also creates proper knowledge sharing as training and practicing environment. This is very necessary in library maintaining that to spotlight on handling the well-wishers wealth. Perfection and quality of any academy can be measured by the library contents, Agaba (2005). According to Popoola (2008) the data contents and facilities in academic data systems is necessary for providing research fields among the research students and teachers. Iyoro (2004) affirms the information usability is one of the primary concerns of the data using. According to Halsey (2005) the users will be more attracted to use the library resources if they can get their necessary contents will less number of attempts. A lot of universities and online colleges already have opened online admission opportunity and online study for various fields of studies. They also provide certificate after completion of the study. For some of the courses students participate in physical classes in classroom but most of the classes are being provided by online. Also some programs are totally internet based. Several universities provide online student portals. There all sort of students' information uploaded on regularly basis. Likely, online registration, book borrows or purchase, students leadership activities and student counseling etc. These online contents also take sometimes students reports regarding accessibility to attract user interest.

Methodology

The target population of this study was the international students studying in various private universities in Malaysia. The measurement tool was adapted from Firdaus (2005)'s HEdPREF model. For data collection, a total of 7 different private universities were selected randomly. All the universities were located within the Klang Valley area. Total 400 questionnaires were randomly distributed among the foreign students. Total 327 questionnaires were returned out of which total 318 were found valid for further analysis. For data analysis, this study has used multiple regression.

Results and Discussion

Prior to multiple regression analysis, reliability test is conducted. According to Pallant (2005), the Cronbach's alpha value should be more than 0.60 to be considered as reliable. The result indicates that the measurement tool used in this study is highly reliable as the alpha value is 0.891. The Bartlett test helps to measure correlation among the variables. In order to be significant, the value should be less than .05 (Hair et al., 2010). The study shows that the value falls within the required threshold that is .000. The range of MSA index is from 0 to 1. However, the minimum acceptable range is above 0.50 (Zikmund,

2003). Table 1 below shows the KMO (MSA) is .682 which is more than .50 and therefore it is satisfactory; in fact, it is very good.

Table 1: KMO and Bartlett's Test

Kaiser-Meyer-Olkin Measure of Sampling Adequacy (MSA)		.682
Bartlett's Test of Sphericity	Approx. Chi-Square	1283.891
	df	45
	Sig.	.000

Finally, this study performed the factor analysis to identify the measuring dimensions of the different factors used in this study. Total five factors were extracted based on the varimax rotation with eigenvalues greater than 1. It indicates that total 71.846% of the variance was explained by these extracted factors. As a result, it assumes that the information explained by these factors is independent to each other.

Multiple Regression Analysis

From Model Summary table (Table 2), we find R Square is 0.772, which indicates that 77.2% of the variance can be predicted from the independent variables. In addition, here the multiple correlation coefficient is 68 percent.

Table 2: Model Summary

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate
Constant	.777[a]	.772	.768	.681

From Table 3, we only have to refer the significance value which indicates that the combination of these variables does not significantly ($p < .005$) predicts the dependent variable in this particular situation.

Table 3: Analysis of Variance (ANOVA)

Model	Unstandardized Coefficients	Standardized Coefficients		T	Sig.		Colinearity Statistics
	B	Std. Error	Beta			Tolerance	VIF
1 (Constant)[a]	1.151	.500		2.30	.23		
Teaching Quality	.419	.061	.419	5.256	.000	.588	1.701
Learning Method	.349	.047	.349	7.820	.000	.728	1.373
Infrastructure	.375	.089	.375	8.711	.001	.347	2.880
Resource Availability	.212	.077	.212	8.682	.001	.273	1.782

[a] Dependent variable: Student's Satisfaction

The result shows that teaching quality is the most important factor that influences the international student's satisfaction in Malaysian private universities with beta value of 0.419 that is also significant at 0.05 level. Besides, infrastructure was ranked as second most important factors with beta value of 0.375 that is also significant at 0.05 level. Moreover, learning method has a beta value of 0.349 where as resource availability has a beta value of 0.212. All the hypotheses are statically supported in this study.

Conclusion

In this world of globalize economy, all of the business institutions are in a competition with a good number of other business institutions all over the world, in their corresponding sectors. It is similar for those universities which are facing the competition not only with the local universities but also with the foreign universities. They are encouraging both the local and international students. That is how good service and satisfaction of the students does a vital job for the universities to stay in the front line of the race. From this specific kind of research it can be deduced that higher the service quality can provide higher student satisfaction.

It contributes to current theories on how consumers resolve sequentially inconsistent information about a university's service quality. Moreover, the idea of student satisfaction and such marketing was not really a separate management function but rather the whole matter as seen from the student's point of view. In other words, the marketing concept employed in this study defines a distinct university culture, a fundamental shared set of beliefs and values that put the students in the centre of the university's thinking about strategy and operations. Finally, this study is important because the study of behavioral aspects of students is of great importance for university policy makers and this knowledge is applied to find out the students' wants and needs.

Possibilities of Stakeholders in a Harmony Game to Increase Ethical Behavior shown on basis of Expanded Game Theory

Thomas Kronberger, Faculty of Management, Comenius University, Odbojárov 10, 820 05 Bratislava, Slovakia, e-mail: thomas@kronberger.info

Abstract

First, short insights into the non-computable stakeholder theory and the game theory for the harmony game have been provided. The game theory is computable but does not explicitly consider ethical aspects of decisions. The expanded game theory presented here for the harmony game derives benefits from both theories: it is computable and takes ethical aspects into consideration. At a glance, all consequences for active decision makers and passive stakeholders are evident. The expanded game theory has been applied to the two examples of "objective agreement" and "tax evasion". In both examples, three ways in which stakeholders can motivate the decision makers to behave more ethically have been demonstrated: The stakeholders can educate the decision makers, for they understand the possible consequences of unethical cooperation. The stakeholders can use their power to directly control the decision makers. The third way for the stakeholder is to vary the payoff for the decision makers. By adopting this framework in the decision-making process the stakeholders can foster ethical behaviour in the decision makers.

These methods show how to influence the decision makers, and can help the management to set up a structure in which the decision makers behave ethically and a certain profit is ensured for all parties.Some ideas for further research have also been mentioned.

The expanded game theory for the harmony game is a new framework that serves as a basis for holistic tools, fosters ethical leadership and altruism, and inhibits short-term economic rationality in the decision makers.

Keywords: game theory, harmony game, ethical decision-making (EDM), stakeholder theory

Introduction

There is a vast amount of existing literature pertaining to the stakeholder theory. In general, the stakeholders are first identified and then classified according to several parameters such as "power" and "risk" (Hügens, 2004) or "power", "legitimacy", and "urgency (Mitchell et al., 1997). Many academic papers have been written on the ways in which the stakeholders can be influenced (Mayers, 2005). However, Mayers, in his paper, does not regard the influence of the stakeholders. Also, Freeman et al write that the "stakeholder contributes to the value that is created for the others." (Freeman et al., 2016), but they don't mention how. These are only a few examples from the broad literature that exists on the stakeholder theory.

However, none of the available literature explains how stakeholders can use their power. Therefore, the present paper aims to close this gap in literature. The following three different ways in which the stakeholders can influence decision makers will be examined on a theoretical basis:

1. Educating the decision makers
2. Controlling the decision makers
3. Adapting the framework, so that the payoff for the involved parties changes.

These ways are explained further with the help of the harmony game, which is a special case of the game theory, since it is an apt example for highlighting the conflict between the decision makers on one side and the stakeholders on the other.

The ways to influence decision makers will be regarded with the help of two examples where unethical cooperation can occur easily. In both cases, the decision makers have a strong motivation to cooperate which each other at the expense of the stakeholder. Each way demonstrates one exemplary method by which the stakeholder can foster ethical behaviour.

Some of the positive effects of the decision makers' ethical behaviour in the example of "objective agreement" include survival of the company, motivation of the employees, and perhaps, even higher satisfaction of the suppliers and/or customers, if the objective agreements are designed according to the interests of the stakeholders.

The benefits of the stakeholder's influence on the decision-making process in the example of "tax evasion" will include: satisfaction of the population, more money for the tax authorities, which can be spent on investments, or a possible reduction in the tax rates.

Of course, for each way there exists other methods to navigate the decision makers towards an ethically-correct direction. The choice of method and its application depends on the concrete situation. The intention is to demonstrate to the stakeholders that they have several paths to choose from, if they wish to have an influence on the decision makers.

Stakeholder Theory

Stakeholders are "any group or individual who can affect or are affected by the achievement of the firm's objectives" (Freeman, 1984, p. 25). The ethical basis of the stakeholder theory is that the decision makers will consider all stakeholders in their decision making. This is vastly different from the traditional shareholder view, which considers only the owners' opinions as important.

The stakeholder concept was first applied in 1963 at an internal memorandum of the Stanford Research Institute (Freeman, 1984, p. 31). The stakeholder theory itself is much recent and was explained in 1994 by R. Edward Freeman, who is called "the father of the Stakeholder Theory" (Laplume et al., 2008). Ethical strategists such as Noland and Phillips claim that the "stakeholders must be integral to a firm's strategy, if it is to achieve real success" (Noland & Phillips, 2010); but I was unable to find a model that highlights the consequences of the firm's decisions on the stakeholders.

The stakeholder theory comprises of the following three aspects:

1. Descriptive/empirical aspect: It "is used to describe and […] explain specific corporate characteristics and behaviours" (Donaldson & Preston, 1995, p. 70).
2. Instrumental aspect: It is used to identify the (lack of) connections between stakeholder management and traditional management (Donaldson & Preston, 1995, p. 71).
3. Normative aspect: It is used for providing "moral or philosophical guidelines for the operation and management of corporations" (Donaldson & Preston, 1995, p. 71).

As we can see, the stakeholder theory explains whom to consider and why, but none of the aspects throws light on the manner in which this should be done and the concrete ways in which stakeholders can influence decision makers. In addition, there is another limitation in the stakeholder theory: it is not a model for forecasting of decisions.

Classical Game Theory

The game theory, designed by von Neumann and Morgenstern, is computable. In the game theory, success does not depend only on one's individual decisions but also on the actions of others. John von Neumann first mentioned the game theory in 1928 (von Neumann, 1928) and later worked it out with

Oskar Morgenstern in 1944. They assume that, "the consumer desires to obtain a maximum of utility or satisfaction and the entrepreneur, a maximum of profits" (von Neumann & Morgenstern, 1944, p. 8). From this starting point, von Neumann and Morgenstern created a model that enables the forecasting of the decision makers' behaviour.

There are many examples to explain the game theory. For the purpose of this paper, only a special kind of game has been considered: the "harmony game" (Licht, 1999). The harmony game is a simple game with only one equilibrium. Therefore, the analysis (for the stakeholders) is easier than in most other games. This is the reason why examples based on the harmony game have been chosen. Considerations with many case distinctions would go beyond the scope of this paper.

Both decision makers (A and B) have the two options, to cooperate (C) or to defect (D):

A	C	8 8	3 2
	D	2 3	1 1
		C	D
		B	

Fig. 1: Harmony Game

This can be simplified to the following schema (that I did not find in any literature on game theory): If both cooperate, they receive a high payoff, otherwise they receive only a little payoff.

Payoff for A and B:	High	Low
Decision	both C	Else

Fig. 2: Simplified Harmony Game

As we can see from this little example, the prediction pertaining to the two decision makers is easy. They will probably cooperate. If this cooperation is at the expense of the stakeholders, there is an existent "unethical cooperation".

The possibility of prediction is a big advantage for scientific and practical utility, but it goes hand-in-hand with the loss of ethical contemplation. In their book, von Neumann and Morgenstern (1944) avoid words like "ethic" and "responsibility". The effects of the decisions on the stakeholders are not revealed.

As explained above, the stakeholder theory and the classical game theory have some structural weaknesses. A fusion of both theories may help reduce these weaknesses.

Reasons for Expanding the Game Theory

Simply placing ethical parameters in the flat game theory is not the desired fusion, because there are too many aspects that must be regarded. All decision makers have individual ethical settings, different knowledges, and different methods of handling this information:

For considering the ethical settings, Forsyth developed the Ethics Position Questionnaire (EPQ) to measure individual differences in moral thinking (Forsyth, 1980). By utilising his questionnaire, it is possible to classify people based on two scales – how idealist and how relativist people are. He highlights that there are no pure phenotypes but gradually draws differences between the decision makers' ethical settings. The conclusion is that it is best not to mix up the personal payoff of a decision maker and the ethical benefits of an action in one domain of the classical game theory diagram. As every decision maker has different ethical settings, every game theory diagram would have to be elucidated in a different manner. It is easier to look at only the personal profit of a decision maker in the game theory and present the ethical aspects in a different manner.

The individual ethical setting is only one reason for formulating a new game theory. The other reason is that taking unethical decisions can be driven by many reasons that may be personal or external for the decision maker. People ignore the real scope of problems either intentionally, negligently, or unknowingly.

Intent: Aristotle wrote in his "Nicomachean Ethics" that our ethics depend on whether we take the good or the bad as an intent (Aristoteles, 1911). Some people have bad intentions and force a low payoff for themselves as long as they can reduce the payoff for others too. In a lab-in-the-field experiment, Poncela-Casanovas et al. (2015) labelled such decision makers as "envious" and identified about 30% of the decision makers in this group.

Negligence: The decision maker has enough information but does not assess them in the correct way. The examples of cognitive bias are as follows:

- "Warm-glow-giving" is an effect that is frequently employed in cause-related marketing by companies to benefit their own businesses and the interests of a non-profit organisation. Mimouni Chaabane and Parguel (2016) demonstrated that with high payoffs for the non-profit organisation, the warm glow becomes smaller and the scepticism increases.
- "Scope insensitivity" makes people ignore the actual extent of a problem. To illustrate, in a study (Hanemann, 1994), people were willing to pay an average of US$78 in order to save 20,000 birds. Moreover, to save 2,000 birds (stakeholders), the amount they were willing to pay was almost the same.
- The "overconfidence effect" can lead to high costs (for the stakeholders). Friedman and Friedman (2010) cite two examples – the oil spill of Deepwater Horizon and the financial meltdown of 2008 that started with the collapse of Lehman Brothers. In both cases, too many risks were taken and there were conflicts of interest.
- The contrast effect intensifies the perception of information that contrasts with other present information. For example, referees who must evaluate two gymnasts will judge the second according to the first one. The judgement varies if the referee perceives the gymnasts to be from the same team or from different countries (Damisch et al., 2006).

These effects show that decision makers do not consider all stakeholders and their payoffs at the right magnitude while deciding upon the course action. Certain effects change the perception, how the decision makers consider the stakeholders (mostly reduces it) and some even make the stakeholder even invisible.

Lack of information is another reason for ignoring the real scope. The question lies in whether the decision maker does not want to have a holistic point of view or whether he does not have access to the required information. The decision maker behaves unethically, intentionally or negligently, if he does not realise the consequences of his actions. If he does not have access to the necessary information for deciding, the game theory cannot be applied and it turns into a lottery game.

Expanded Game Theory for Harmony Game

As discussed, there are various theories explaining the link between ethical adjustment of decision makers and their concrete actions. All these gradual and different phenotypes have their own reality and their individual versions of ethical behaviour. The idea is to present the individual benefit and the benefit of the stakeholders on different levels. A generalised schema of the harmony game from Fig. 2 for the decision makers appears in this manner:

Payoff for decision makers:	$P(A)_{\text{all C}}$	$P(A)_{\text{not all C}}$
Decision	all C	else

Fig. 3: Generalised Harmony Game

As observed before, the stakeholders cannot be included in this board, as some decision makers refuse [e.g. envious decision makers (Poncela-Casasnovas et al., 2015)] the stakeholders' interest, and some consider the stakeholders to be lesser in stature than they are [e.g. partly idealist decision makers (Forsyth, 1980)]. This necessitates putting one or more levels with the stakeholders' payoff on top of the game theory:

Payoff for stakeholder n:	$P(S_n)_{\text{all C}}$	$P(S_n)_{\text{not all C}}$
	…	…
Payoff for stakeholder 1:	$P(S_1)_{\text{all C}}$	$P(S_1)_{\text{not all C}}$
Payoff for decision makers:	$P(A)_{\text{all C}}$	$P(A)_{\text{not all C}}$
Decision	all C	else

Fig. 4: Expanded Game theory for harmony game with n Stakeholders.

The stakeholders' payoff depends only on the behaviour of the decision makers. The stakeholders do not have any direct influence on their own payoffs.

In many cases (however, not always), the payoff of the stakeholders S_1 … S_n can be subsumed to one level:

$P(S_n)_{all\ C}$	$P(S_n)_{not\ all\ C}$
…	…
$P(S_1)_{all\ C}$	$P(S_1)_{not\ all\ C}$
$P(A)_{all\ C}$	$P(A)_{not\ all\ C}$
all C	Else

Fig. 5(a): Harmony Game with payoff of several stakeholders.

$P(S)_{all\ C}$	$P(S)_{not\ all\ C}$
$P(A)_{all\ C}$	$P(A)_{not\ all\ C}$
all C	else

Fig. 5(b): Subsuming the stakeholders To one level.

If there is only one (relevant) stakeholder S, or if the stakeholders can be subsumed to one level, it is possible to present the global payoff $P(\sum)$ on the top as follows:

$P(S)_{all\ C}$	$P(S)_{not\ all\ C}$
$P(A)_{all\ C}$	$P(A)_{not\ all\ C}$
all C	else

Fig. 6(a): Game theory with subsumation of the stakeholders' payoff.

$P(\sum)_{all\ C}$	$P(\sum)_{not\ all\ C}$
$P(S)_{all\ C}$	$P(S)_{not\ all\ C}$
$P(A)_{all\ C}$	$P(A)_{not\ all\ C}$
all C	else

Fig. 6(b): Adding a top level for showing global payoff.

Normally, the summation at the top ($P(\sum)_{all\ C}$ and $P(\sum)_{not\ all\ C}$) cannot be viewed as a game theory model of the harmony game, because the decision maker tends to consider only their individual payoffs ($P(A)_{all\ C}$ and $P(A)_{not\ all\ C}$).

Relevance of the Expanded Game Theory for Harmony Game

The harmony game is an interesting example to highlight how expanding the game theory helps in getting a holistic view and considering the stakeholders.

As the harmony game itself appears very simple, it is very easy for the decision makers to ignore the stakeholders. If you have to decide whether both you and your partner will get a small or big payoff, you will probably opt for the big payoff. This cooperation is easy but it is unethical, when it is at expense of the stakeholder(s).

The stakeholders are not active decision makers, but they can influence the decision makers to behave ethically. In general, to achieve this they can do the following:

1. Educating the decision makers
2. Controlling the decision makers
3. Adapting the framework, so that the payoff for the involved parties change

In the following sections of this paper, two examples of unethical behaviour will be provided and the aforementioned methods will be applied. The first example is about a company as the stakeholder and an employee and his head of department as decision makers. The second example regards the society as stakeholder and two businessmen as decision makers.

Objective Agreement

Even if an objective agreement is not completely fulfilled, both the head of the department in a company and his employee have strong interest in declaring the agreement as fulfilled. Through doing this, the employee will get his bonus. Subsequently, the head of department has a proof to submit to his boss that his team member was successful, and he will utilise this as argument for getting his bonus too. By such unethical cooperation of the head of department and the employee, the company (=stakeholder) will pay for work that has not been carried out. In order to prevent this, the company can employ the three mentioned ways:

1. Educating the decision makers: Unfortunately, we do not live in an ideal world where all employees and all team leaders have received an ethics education at home and in school such that they behave ethically and refrain from taking advantage of the company they work for. Therefore, the company can educate the members of the management and perhaps also the employees how to act and decide in an ethical manner. For this, the provided model can be applied.

   Supposing that the company has a total excess (before bonus) of 4. If it has to pay a bonus of 6, it will have a negative profit of –2. The expanded game theory appears in this form:

Excess	4	4
Profit for company	–2	4
Bonus for employee	6	0
Decision	Give bonus	Don't give Bonus

Fig. 7: Expanded game theory for decision makers and company as stakeholder

   A company that produces enough loss will fail. If the company can make at least the head of department or the employee understand this, and if one of them refuses the bonus to be received, the company will have a positive profit and can survive. As a result, the head of department and the employee can retain their jobs.

2. Controlling the decision makers: If the company controls the set-up and the fulfilment of the agreements, the decision makers cannot declare unfulfilled agreements as fulfilled. One possible method for controlling this process is applying the S.M.A.R.T.E.R. criteria (Piskurich, 2006) instead of the often used S.M.A.R.T. criteria (Doran, 1981). This means designing the objective agreements that they are not only **S**pecific, **M**easurable, **A**ssignable, **R**ealistic, **T**ime-related but **E**valuated consistently and **R**ecognized mastery, too.

   Consistent evaluation implies high expenses in terms of time for the head of department, because he has to regularly assess the employees' work based on his goals and check that he does not neglect his normal work. A masterful reorganisation of the goals and their achievement by higher management or a special supervisor is also expensive, because it is not enough in order to verify whether the agreements are corrupting or misleading. There must also be a step that controls whether the head of department and the employee interpret the agreements too soft or malleable.

   By these two extra steps, the influence of the stakeholder on the decision makers is ensured. They are strong but expensive aids to avoid issues like the company being cheated.

3. Adapting the framework: If the company fixes a limit for the bonus depending on the own excess, the company can guarantee a minimum of profit for itself. Supposing that at maximum, 50% of the excess will be utilised for bonus payments, the bonus for the employee will be the minimum of 6 and 2 (=50% of the excess).

Excess	4	4
Profit for company	2	4
Bonus for employee	Min (6, ½ of excess)	0
Decision	Give bonus	Don't give Bonus

Fig. 8: Expanded game theory with limited payoff for decision makers and guaranteed profit for company

The bonus for the employee is reduced. This generates the effect that he will be motivated to work on increasing the companies excess in the following year in order to increase his own profit.

Even when this simplification ignores taxes, social security contributions, and other effects with leverage, it highlights how these ways can guarantee a profit for the company, leading to its survival.

The company as a stakeholder can work on all three ways independently and by this, it has strong means for forcing the decision makers to behave ethically. In the following example, the stakeholder is an external party to the company, but the methods are the same.

Tax evasion

Tax evasion is a typical harmony game. In general, both decision makers can make a profit if they cooperate, but in this case, none have any disadvantages. If only one defects, the taxes need to be paid. The society is the stakeholder. Unpaid taxes create problems for necessary expenditures of the government (social aid, pensions, road maintenance, safety, and so on).

The society has the three mentioned ways to influence the decision makers:

1. Educating the decision makers: This training can be provided at business schools for example (Remisova et al., 2014). The expanded game theory can be utilised for the training process. It can be taught that a small profit for the decision makers can have expensive side effects for the stakeholders through examples. It is interesting to observe that the lowest corruption perception indices are present in the countries with the highest education (Dose, 2017) and that the high education correlates with a high happiness index of the population (AFP, 2017).

2. Controlling the decision makers: One of the many tools for controlling are forgery-safe cash registers ("sales recording modules") for example in restaurants and companies that deal with over the counter sales. If they are installed, they impede such unethical comportments (Ainsworth & Hengartner, 2009).

3. Adapting the Framework: As we have observed before, in the harmony game, both parties tend to cooperate. (Fig. 2). In the first example, the payoff for one decision maker was reduced if the

decision makers cooperate. In this example, the payoff for one decision maker is increased if one defects. As a result, the game does not remain a harmony game anymore.

The decision maker who receives an increased payoff in the form of a tax refund obtains the benefit if he defects. Such games do not remain classical harmony games. However, certain special cases can be presented in the game theory for harmony games.
The "fiscal note Sao Paulo" ("nota fiscal paulista") is such an example in Brazil (UOL, 2011). If a consumer asks a retailer to register his tax identification number on the bill, the retailer cannot further evade taxes. As retailers don't usually let their consumers participate in evading taxes, the consumer has the following options to choose from:

Excess for stakeholder	70% – lottery	0
Tax refund for consumer	30% + lottery	0
Decision	Pay tax	Evade tax

Fig. 9: Tax identification number on bill

The idea of a lottery is discussed even in the EU (Höhler, 2017).

If the retailer lets the consumer participate in evading taxes, the model of the expanded game theory for harmony games cannot represent the situation adequately.

Discussion

As we can observe in the two provided examples, the expanded game theory for harmony games can be applied for the purpose of representing the benefits of the decision makers and the stakeholders. It can indicate three ways to influence the decision makers.

Table 1: Tools and Applications

Tools	**Methods in example "Objective agreement"**	**Methods in example "Tax evasion"**	**Approach**
Education	Training in company	School, Business School education	Consider the stakeholder
Adapting Framework	Limit the Payoff	Lottery as a Bonus	Modify payoff of the decision maker
Control	Control the work and results	Control using technical resources	Direct influence on decision maker(s)

The link between the **tools** and **approaches** can serve a good starting point for further research. The possible questions pertaining to this are as follows:

- Are the indicated connections between the tool and approach always the same or are they tied to the specifics of individual cases?
- Does ethical education lead to altruistic comportment?
- Are there more ways of influencing the decision makers?
- How to regard/include CSR activities?
- What if two stakeholders have contrary interests?

Conclusion

The expanded game theory for harmony games is useful for presenting the ways stakeholders can influence the decision makers. Depending on the way and the situation, individual methods for achieving the desired ethical behaviour are required to be found.

In the second example, the situation where one businessman offers another the chance to engage in the making profit through tax evasion was presented. In this context, the expanded game theory for harmony games is too simple. A more complex model of the expanded game theory must be applied (Kronberger, 2017).

The expanded game theory for harmony game furnishes a model that presents the benefits for all involved parties, decision makers, and stakeholders in an intuitive way. The expanded game theory helps in motivating the decision makers to focus not only on their own payoffs, but also consider the stakeholders' outcome.

The expanded game theory is in line with Responsible Capitalism (Freeman et al., 2016) because it matches the concepts of "pro-social, language-using collaborators" and is in accordance with the cooperative stakeholder concept that is applied there. Thus, the expanded game theory for the harmony game is a new framework that serves as a basis for holistic tools, fosters ethical leadership and altruism, and inhibits the short-term thinking pertaining to economic rationality in the decision makers.

The expanded game theory offers a holistic view of the decision-making process because it does not consider only the decision makers. In fact, it visualizes the consequences of a decision for all involved parties, regardless of if they are active decision makers or inactive stakeholders.

Characteristics of Audit Market in the Function of Audit Quality

Abstract

Audit market in most countries is characterized by a high concentration of audit firms. As a result, audit firms are now generally divided into two major groups: Big Four and non-Big Four audit firms. The main aim of this paper is to investigate if such strict division can be applied to the audit market in Croatia. In order to gain insight into the structure of the audit market in Croatia, an empirical research based on secondary data was conducted. Measures of descriptive statistics were calculated to identify audit firms that can be considered as statistical outliers according to their size. In order to determine the optimal number of audit firm groups, a hierarchical cluster analysis was applied. Measures of descriptive statistics show that the six largest audit firms can be considered as statistical outliers according to almost all observed size variables, while the remaining audit firms significantly lag behind. Although the individual market shares of Big Four audit firms are significant, there are also two additional audit firms that can compete with them based on the size criterion. This is confirmed with the cluster analysis. Therefore, although the audit market in Croatia is significantly concentrated, it is not dominated exclusively by the Big Four audit firms. Research results can serve as an input to regulators when considering possible measures for reducing market concentration. However, before taking any actions, an additional analysis regarding the effect of audit firm's size on audit quality should be conducted.

Keywords: audit quality, audit market, audit firm size, Big Four audit firms.

1Introduction

Audit market in most countries is characterized by a high concentration of the subjects on the supply side, despite the relatively high number of audit firms. At the international level, the audit market can be considered as an oligopoly since the 1980s, when the market was dominated by the eight largest audit firms, called the Big Eight (Ascher, 2008). The factors that most contributed to the creation of such a market structure include business combinations, economies of scale and high barriers to entry for small audit firms. Due to the additional business combinations that followed, as well as corporate scandals, the number of large audit firms has been halved. As a result of such developments, audit firms are now generally divided into two major groups: Big Four and non-Big Four audit firms. The main aim of this paper is to investigate if such strict division can be applied to the audit market in Croatia.

2. Oligopoly on audit market

Audit market, like any other market, can be viewed in the context of supply and demand of audit services. Market features, such as the number of participants on the supply and demand side, the homogeneity of products and services, freedom of entry and exit from the market, indicate the type of market structure. Audit markets are an example of imperfect competition, which due to certain factors has taken on the features of oligopoly in most countries (Ascher, 2008).

Measured by the amount of revenues or received total fees, the Big Four audit firms dominate the audit market for listed companies in most European Union countries with a market share exceeding 90% (European Commission, 2010). Oligopoly is a market structure where there are several market-dominated bidding parties and falls into the structures of imperfect competition (Samuelson and Nordhouse, 2005). If the size is measured by the total revenues earned, then the largest audit firm in the Big Four group is Deloitte which earned 36.8 billion USD in 2015 (Statista, 2017).

Observed at an international level, the audit market is considered an oligopoly since the 1980s, when the market was dominated by the eight largest audit firms called the Big Eight. The main characteristics of the oligopolies are the following: 1) large capital investments required, 2) control of necessary resources, 3) legal constraints and patents, 4) economies of scale, 5) top entrepreneurs, 6) mergers and acquisitions, and 7) barriers to entry (Kumar, 2017). The factors that have contributed the most to the increase in market concentration on the supply side of the audit market are business combinations, the economies of scale and strong boundaries to the entry of non-Big Four audit firms into the market of large and listed subjects of statutory audit.

Although the audit market has already been consolidated in the 1980s, the number of major international audit firms has additionally been halved - from the Big Eight to the Big Five, as a consequence of business mergers. After the Enron corporate scandal in 2001, the Arthur Andersen audit firm collapsed, further reducing the number of large audit firms and increasing market concentration on already highly concentrated market.

Numerous business combinations in the audit market were in the function of achieving the economy of scale. Namely, Big Four audit firms are able to allocate fixed business costs to a wider customer base. In the context of auditing, the auditor's effort measured by the number of working hours spent on one client can be considered as a variable cost. On the other hand, investing in audit technology is a fixed cost and involves acquiring knowledge and skills, investing in equipment and developing standardized audit programs (Sirois, Marmousez and Simunic, 2012). In this way, big audit firms are able to develop sufficient technical expertise and ability to conduct audits globally to meet the needs of complex international clients at lower costs in comparison to smaller audit firms (Government Accountability Office - GAO, 2008).

In addition to economies of scale and business internationalization, complexity of accounting standards and reputation are the main factors that pose potential barriers to the entry of smaller audit firms into the audit market. Oxera (2006) showed that less than 10% of FTSE 350 companies listed on the stock exchange considered the engagement of a non-Big Four audit firm. In addition, 82% of large and listed corporations in the United States (Fortune 1000) consider that their audit firm selection is limited to three or less audit firms (Government Accountability Office - GAO, 2008), which also demonstrated the importance of the auditor's reputation.

International Financial Reporting Standards are constantly changed according to the market needs. Since the Big Four audit firms have more staff to monitor regulatory requirements, big and listed companies are inclined more often to engage a Big Four audit firm. This is also confirmed by the ESCP Europe (*Ecole Supérieure de Commerce de Paris Europe*) research, which identified main barriers for smaller audit firms' entry into the listed companies' audit market. In particular, the main barriers are the lack of size or insufficient capacity in terms of number of auditors in mid-tier audit firms, limited geographical reach of mid-tier audit firms, a strong preference among large companies to choose Big Four audit firms because of their reputation, resistance among companies and the absence of incentives to change the audit firm (Le Vourc'h and Morand, 2011).

3. Domination of Big Four Audit Firms on Concentrated Audit Markets

Previous audit market concentration research has shown that the total market share of audit firms in the Big Four group differs considerably depending on the type of audit market being observed. The ESCP Europe (*Ecole Supérieure de Commerce de Paris Europe*) study, published in 2011, included all European Union Member States (27 at the time). Market shares at the level of the overall audit

market (calculated on the basis of total revenue of audit firms) led to the conclusion that the Member States could be grouped into four major groups. The first group includes countries such as Czech Republic, Poland and Slovenia, where the Big Four market share is less than 10%, with the smallest share (2%) registered in Slovenia. Countries in the second and third group are characterized by the Big Four market share between 10% and 20% (for example, Austria, Germany, Italy and Portugal) or 20% and 30% (for example, France, Finland and Belgium). The fourth group of countries marks the highest degree of concentration, given that the market share of Big Four audit firms is above 30%. The United Kingdom is located in that group with a concentration coefficient 4 equal to 40% (Le Vourc'h and Morand, 2011). The Big Four audit firms in the United Kingdom have a very large market share even in the entire audit market, due to the fact that they have the largest number of registered audit firms (together with Ireland: 7843). However, the same indicators are much higher at the level of listed companies. Namely, the average coefficient of concentration 4 for the European Union is 94% (Le Vourc'h and Morand, 2011). Since the average number of registered audit firms in the European Union is 985 per Member State, this means that the Big Four audit firms occupy 94% of the audit market for clients listed on national stock exchanges, while the rest (981 audit firms) account for only 6% of the market. At the national level, France has the lowest coefficient concentration 4 (81%), as a result of introducing mandatory join audits as an attempt to reduce audit market concentration.

The dominance of large audit firms is also characteristic of most developed western countries. In 2006, the four largest audit firms in the United States audited 98% of all public companies with revenues above 1 billion USD and 96% of public enterprises with revenues above 500 million USD (Government Accountability Office - GAO, 2008). Audit firms on American and European markets achieve 82% of the total revenue, which confirms the importance of these markets for audit firms (Big4.com, 2015). However, young audit markets in emerging economies, such as China and India, are less concentrated and more open. The share of Big Four in the market of listed companies in India is 41%, while the same indicator in China is 14%, where most of the clients are audited by the national audit firms (Huber, 2011). Consequently, it can be concluded that the market concentration depends on the category of audit clients as well as the development of audit market. The market shares of audit firms from the Big Four group are the highest for listed companies in developed western countries.

4. The Effect of Audit Firm Size on Audit Quality

Although large audit firms generally have a higher reputation and enjoy greater customer confidence, the question is whether they provide a better-quality service. In this context, the audit quality represents the auditor's ability to detect significant misrepresentations and to respond appropriately when expressing opinion (DeAngelo, 1981).

The audit quality primarily depends on the auditor's ability and independence. These are the two main factors that need to be taken into account when analyzing the impact of the audit firm size on the audit quality. Observed at the theoretical level, arguments can be found to support both views. In other words, there are reasons to support and deny the existence of a positive correlation between the size of the audit firm and the audit quality (figure 1.).

Compared to non-Big Four audit firms, Big Four audit firms have better financial and human resources, as well as more advanced information technology. They are therefore able to invest more in employee training and acquisition of other tools to ensure that their employees are skilled and capable of conducting audits in accordance with the highest quality standards (Sawan and Alsaqqa, 2013). In addition, a wider customer base increases negotiating power and reduces financial dependence on a particular client, meaning they should be more independent in expressing their opinions and less willing to tolerate management's attempts for earnings management.

According to DeAngelo's theory (1981), Big Four audit firms are operating with high reputation risk. High reputation risk results from the assumption that big audit firms have more to lose in case of

unprofessional behavior discovery. As auditors of public interest entities, they are also subject to greater oversight by the competent authorities, as well as under the surveillance of control mechanisms within the client itself (for example, activities of the audit committee). Hence, the greater ability to attract skilled employees and continuous investments in their education should contribute to the engaged audit team's ability to detect significant misrepresentations. On the other hand, greater independence as a result of reputation risk and stronger negotiating power should also result in expressing an appropriate audit opinion.

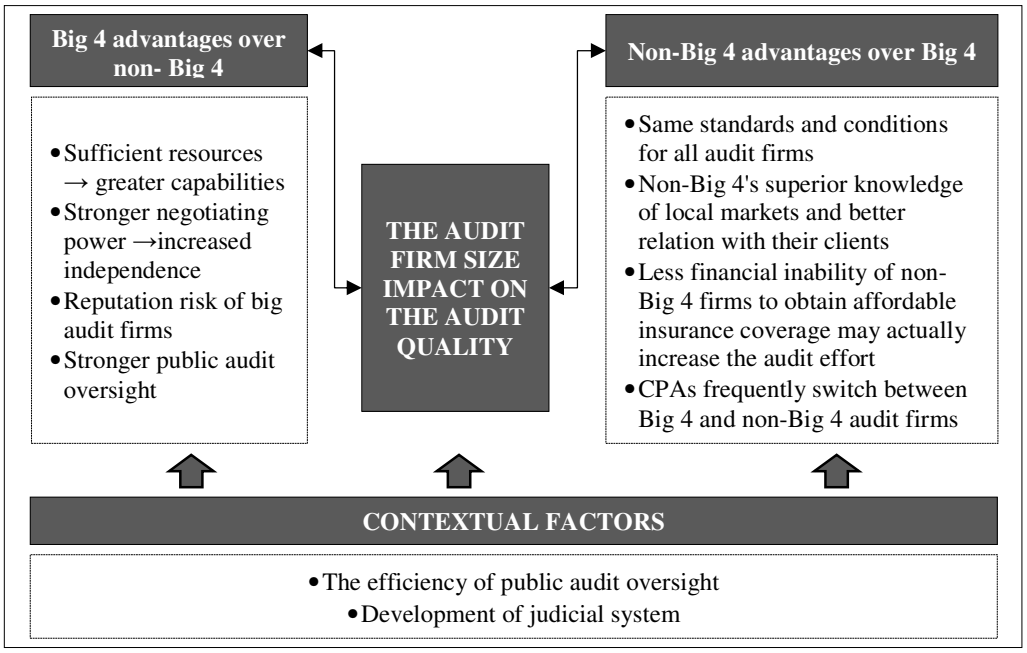

Figure 1: The impact of audit firm size on audit quality

Source: Systematization of authors based on previous research

However, there are also arguments as to why Big Four and non-Big Four audit firms could provide comparable audit quality. First, Big Four and non-Big Four audit firms are held to the same regulatory and professional standards, and thus both types of audit firms must adhere to a reasonable level of quality. Second, as non-Big Four auditors have superior knowledge of local markets and potentially better relations with their clients, these factors may enable non-Big Four audit firms to detect irregularities more efficiently. Of course, the converse argument could be made that closer relationships between non-Big Four audit firms and their clients could potentially lead to compromised independence; however, the net effect of these counteracting forces is unclear. Third, the inability of non-Big Four audit firms to obtain affordable insurance coverage may actually increase the audit effort of non-Big Four audit firms relative to Big Four firms because smaller audit firms cannot obtain a similar level of backing from insurance companies. Finally, CPAs frequently switch between Big Four and non-Big Four audit firms, and knowledge transfers can dilute the potential for one type of audit firm to become superior (Faroghi and Shahshahni, 2012).

In addition, contextual factors affecting the individual national audit market should also be taken into account. If the institutional framework at the national level does not encourage audit quality, the auditors will be less motivated to limit management's attempts to manage earnings, meaning that there will be no differences between Big Four and non-Big Four audit firms (Yasar, 2013). Key elements of an effective institutional framework in the context of promoting audit quality are an effective judicial system that guarantees the auditor's legal responsibility for expressed opinion and a developed system of public audit oversight. The public audit oversights system still significantly differs among the European Union Member States despite the attempts of international harmonization (for example by Audit Directives). Development of institutional framework should provide additional

incentives for better audit quality. However, an inadequate institutional framework, even assuming that big audit firms are generally able to perform better quality audits, clears the boundary between big and other audit firms, as none of them have appropriate incentives to improve audit quality above the required minimum level.

Many researchers investigated the relationship between the size of audit firm and the quality of auditing. In addition, this research has been carried out in different ways. Some researchers examined the attitude of different groups of respondents about the significance of the audit firm's size by conducting surveys. However, quantitative research was more numerous. The basic methodologies of these quantitative research lie on the application of multiple regression analysis where the audit quality is usually the dependent variable, while the size of the audit firm is an independent variable.

However, the definition of these variables differed considerably among the researchers. The size of the audit firm can be expresses as a discrete variable, which equals one if the audit firm belongs to the group of Big Four and zero in the opposite case. Prior to the world-wide corporate scandals and mergers of audit firms, there were the Big Eight or Big Six (Francis, Maydew and Sparks, 1999; Teoh and Wong, 1993; Krishnan and Schauer, 2000), followed by Big Four or the Big Three audit firms, depending on the country in which the research was conducted (Dehkordi and Makarem, 2011; Yasar, 2013). In addition, the size of an audit firm can be viewed as a continuous variable based on total assets, income or number of employees (Bae and Lee, 2013; Foroghi and Shahshani, 2012).

Since there is no agreement on how to measure the audit quality, there are variations in selecting the appropriate audit quality measure. The most commonly used measures are the level of discretionary accruals as a signal of earnings management (Yasar, 2013; Dehkordi and Makarem, 2011; Choi et al., 2010; Francis, Maydew and Sparks, 1999), as well as auditor's reporting on the going concern basis (Foroghi and Shahshahani, 2012). Considering that many other factors, apart from the size of the audit firm, may have an impact on audit quality, the empirically tested models include numerous control variables such as client's size, amount of cash flows from operations, selected financial ratios and others.

The results of the conducted research sometimes differ, which is certainly contributed by the different methodology of conducting the research, as well as the different institutional environment. Some research has shown that the size of the audit firm has a direct effect on the auditor's effectiveness and indirectly on the quality of auditing (Cheng, Chen and Chen, 2013). In addition, the degree of compliance with the required disclosures in accounting standards has shown to be higher when the financial statements are audited by a large audit firm (Krishnan and Schauer, 2001), and that such financial statements also enjoy greater investors' confidence (Teoh and Wong, 1993). According to the assumption of greater independence, Francis, Maydew and Sparks (1993) concluded that the audit firms that belong to the group of the largest audit firms are more capable of curbing the opportunistic and aggressive behavior of management when presenting financial results. A research conducted in Libya has shown that the respondents believe that: 1) the Big Four audit firms are more independent and more likely to issue qualified reports, 2) the Big Four audit firms can report the real financial situation of the clients more readily than other firms, and 3) that the Big Four audit firms perform more powerful, effective tests and are more credible than others (Sawan and Alsaqqa, 2012).

On the other hand, there are studies that did not reveal significant differences in the quality of audit performed by the audit firms from the Big Four group in comparison to other audit firms. One of these studies has been conducted in Turkey, where it was concluded that the affiliation of the Big Four audit firm is not related to the level of discretional accruals in the client's financial statements, which is justified by the fact that the audit environment in Turkey does not motivate enough audit firms to perform better quality audit (Yasar, 2013). Similar conclusions were reached from the research carried out in Iran, where it has been shown that the big audit firms are not more successful in reporting modified audit opinion due to the going concern issues (Foroghi and Shahshahani, 2012).

4. Cluster Analysis of Audit Firms in Croatia

Previous research has shown that the audit firms are usually divided into two major groups: Big Four and non-Big Four audit firms. The aim of this research is to test whether this hypothesis can be confirmed on the audit market in Croatia based on the cluster analysis. The size of the audit firm is described by the five variables based on the publicly available data. Three variables are related to the direct features of the audit firms (the number of employees, number of certified auditors and total revenues), while the remaining two variables reflect the market share of the audit firms and characteristics of their clients (number or clients and total income of clients). The best measure for the market share of the audit firms would be the total audit fee received but this information is not publicly available for all the companies, which is why the substitution measures were used. According to the Financial Agency data in 2014, there were 2.865 subjects of statutory audit in Croatia. However, the research population was reduced due to unavailability of data. In that sense, the subjects of the analysis are 182 audit firms which carried out statutory audit for 2553 clients.

The main features of the audit firms analyzed are shown in table 1. Mean values indicate that audit firms had seven employees on average, out of which approximately three certified auditors, with total revenues of 2.5 billion HRK. As for the clients' characteristics, the average number of clients was 14 and their total revenues in the year preceding the audit was 2.3 billion HRK. However, there is a noticeable dispersion on the level of all variables, especially the income of clients and the income of audit firms. Namely, the audit firm with the lowest income of its clients audited clients that generated only 2 million HRK in total income, while the maximum values of audit clients' revenues was 59 billion HRK. This fact results in a coefficient of variation of 356.2%. Due to the fact that the mean is not a representative, median is a better central tendency measure.

Table 1: Descriptive statistical measures for analyzed audit firms

	Number of clients in 2014	Clients' revenues in 2013	Number of employees	Number of certified auditors	Total revenues in 2014
Mean	14.03	2,343,909,188	7.14	2.81	2,591,573.75

Count	182	182	182	182	182

Source: Calculated by the authors based on the data retrieved from: Financial agency (2017), Croatian Chamber of Commerce (2017) and Croatian Audit Chamber (2017)

In the next step, the outliers were identified. Outliers are observations that deviate from the mean for at least three standard deviations (Bahovec et al., 2016). The standardized values (z) that meet these requirements are shown in table 2. Out of the total 182 audit firms, six audit firms meet the criteria of outliers for at least three of the five variables.

Table 2: Audit firms that represent statistical outliers according to at least one variable

Tax number of audit firm	Number of clients in 2014	Clients' revenues in 2013	Number of employees	Number of certified auditors	Total revenues in 2014
58960122779	**3.56**	**6.74**	**5.22**	**3.30**	**3.57**
81744835353	**6.86**	**6.33**	**5.03**	**6.54**	1.65

None of the remaining 176 audit firms are distinguished by any observable characteristics, i.e. the deviation from the mean does not exceed two standard deviations. The six observed audit firms belong to the Big Four group (EY, PricewaterhouseCoopers, Deloitte and KPMG), together with the two other audit firms (BDO Croatia and Baker Tilly Discordia). In conclusion, the descriptive statistics show that the audit market in Croatia is not dominated exclusively by the Big Four audit firms, but it is a group of six audit firms. Other audit firms are significantly lagging behind in terms of size. If the descriptive statistics (table 3) are recalculated after eliminating outliers, the mean will be much more representative. By observing the remaining 176 audit companies, every audit firm an average has 10 clients, two certified auditors and total revenue of over one million HRK.

In order to determine the optimal number of audit firms' groups, a hierarchical cluster analysis was performed. Cluster analysis or clustering is the task of grouping a set of objects in such a way that objects in the same group (called a cluster) are more similar (in some sense or another) to each other than to those in other groups (clusters). Hierarchical clustering is based on the core idea of objects being more related to nearby objects than to objects farther away. These algorithms connect *objects* to form *clusters* based on their distance. A cluster can be described largely by the maximum distance needed to connect parts in the cluster. At different distances different clusters will form, which can be represented using a dendrogram – a graph that explains where the common name *hierarchical clustering* comes from. In other words, these algorithms do not provide a single partitioning of the data set, but instead provides an extensive hierarchy of clusters that merge with each other at certain distances (Sarstedt and Mooi, 2014). Audit firms were classified according to the selected size

measures: the number of clients, clients' revenues, number of employees, number of certified auditors and total revenues. The process of merging audit firms into clusters is shown in figure 3.

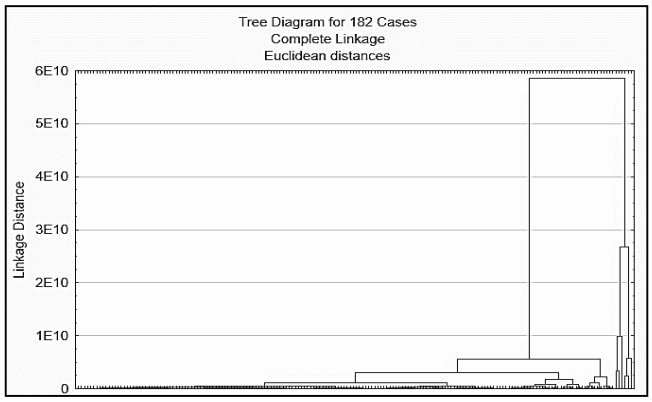

Figure 3: Dendogram of audit firms grouped by the size of the audit firm (*Statistica*)
Source: Calculated by the authors

A total of 181 steps was required for all audit firms to join into one cluster. The first 173 steps included only smaller audit firms, which was then followed with grouping the six largest audit firms together. It was necessary to determine the optimal number of clusters. Figure 4. shows how wide the distance between objects that were merged into clusters at each step was. It is evident that the first 179 steps were relatively small, followed by a noticeable jump. This means that the distance between the next two clusters was much larger. The conclusion is that the optimal number of clusters is three. The first cluster consist of two Big Four audit firms (EY and PricewaterhouseCoopers) and one audit firm that does not belong to that group but is considered as an outlier at the level of three size measures used (BDO Croatia). The same applies to the second cluster which includes Deloitte, KPMG and Baker Tilly Discordia. The last cluster is the largest and includes the remaining 176 observed audit firms.

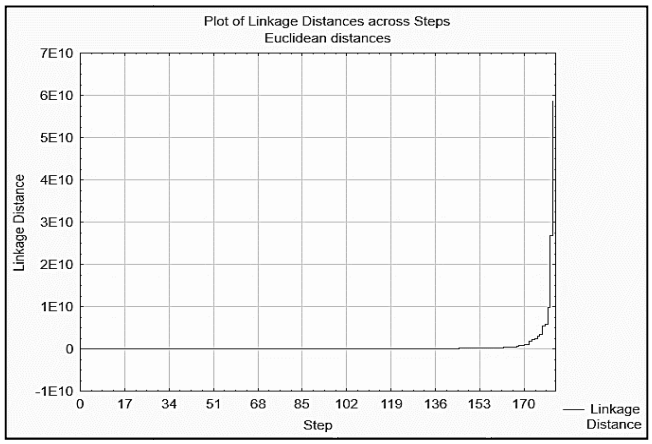

Figure 4: Euclidean distances – Plot of Linkage Distances across Steps (*Statistica*)
Source: Calculated by the authors

According to the measures of central tendency, it was expected that smaller auditing firms would be grouped into one cluster. However, there are significant differences between the six largest audit firms, which is why they are divided into two clusters. Cluster analysis of audit firms by the size gave the same results as the results of the descriptive statistics. Although the audit market in Croatia is highly concentrated, we cannot support the hypothesis that it is dominated only by the Big Four audit firms.

5. Conclusion

Audit markets are characterized by a high concentration and domination of Big Four audit firms, especially at the level of large and listed statutory audit subjects. Factors that contributed the most to this kind of market structure were mergers and acquisitions driven by the efforts to achieve the economies of scale and the consequent major barriers to entry for small and medium sized audit firms into the market. Although the audit market at the international level can be considered as an oligopoly since 1980s, the number of big audit firms has halved. As a consequence, it is commonly to group audit firms into two categories: Big Four and non-Big Four audit firms. High market concentration and size of the audit firms are especially important in the context of audit quality. The main question is whether big audit firms provide a better-quality audit service. There are theoretical arguments that support the positive relationship between audit firm size and audit quality, but it is also possible to find arguments that deny any difference. The empirical research was conducted in order to gain insight into the structure of the audit market in Croatia and to examine the importance of the audit firm size for audit quality. The hierarchical cluster analysis showed that the audit market in Croatia is dominated by six audit firms, which is why the hypothesis that only the Big Four audit firms are dominant was rejected. The domination of six audit firms, when compared to the domination of only four audit firms, should have a positive influence on the stability of the entire audit market.

Abstract

This paper proposes an analysis of the RDI sector in Romania from the perspective of the human resources employed in the system. Romania has an important recruitment base for human resource development in the national RDI, represented by more than 760 faculty graduates. Mean wages of the Romanian RDI system is close to the minimum, our country occupies the penultimate position at an European level.The lack of decent wages causes most young researchers to seek better working conditions or in another sector of the national economy or abroad.The RDI system became increasingly unattractive for young researchers since 2010, when the share of persons under 35 engaged in the system begins to plummet. Therefore, the present personnel structure is dominated by employees over 55 years, working in technical, administrative and other various fields of research. The business environment is the only sector characterized by the researchers of the RDI units below 50%. Romanian higher education, although filled with loads of research over the staff, excels at a national level in the field of scientific production. Reviving the national RDI system requires action from government officials and it involves salary increases and facilities for researchers, otherwise, a further decrease in qualified human resources and loss of sistem performance.

Keywords: RDI, HR, Romania

Introduction

Science is vital to the well-being of a nation, and the investment in basic science constitutes the condition for future economic prosperity. The favorable evolution of the national system of research-development-innovation, RDI can lead to an increase in the nation's welfare. Basically, the Commission states that the main challenge is that the European future of Romania must represent an increase in competitiveness (European Commission, 2013). National Strategy for Research, Development and Innovation (SNCDI) system, developed for the period 2014-2020, proposes national sector development through principal tool, the national plan for RDI (PNCDI3) 2014-2020, which is correlated with Regional Operational Plan for RDI (POS-CDI), 2014-2020. According to SNCDI 2014-2020, the chapter human resources system RDI, Romania recorded the ambiguous performance by comparison with Europe (the Romanian Government, 2014). Thus, the ratio of the number of new graduates in science and engineering and the total population of the relevant age exceeded the average for the past decade I 27. This was largely due to demographic trends and the dynamics of higher education, right up to the end of the last decade. The demographic trends are no longer as favorable as in the past, the forecasts for following years being reserved. The ratio of doctoral graduates in recent years and the population aged 25-34 years has recovered towards the European average. The ratio of the number of researchers employed in the private sector is far below the European average, the transfer of young doctors from the educational system innovative economic sectors being produced with difficulty (Stanciu, Sârbu, and Bucur, 2017). Romania is affected by the migration of researchers, with 15,000 specialists in the diaspora in the last period (World Bank, 2012). Human resource is the most important capital of the national RDI, being a decisive factor in the success or failure of its activity. The development of a company is determined and caused system performance education,

research and innovation, while ensuring the quality of the research activity results, i.e. equitable of potential users at services/products of this system. SNCDI specifies that a career in research should be appealing to both Romanian citizens and foreign ones, making it necessary to adopt the Charter and European Code of the researcher and to facilitate the employment conditions for foreign researchers in the Romanian research (Romanian Parliament, 2014).

Material and Methods

The informations regarding the human resources employed in establishments were selected for RDI from official statistics of the National Institute of Statistics NIS, the Ministry of Research and Innovation MCI, or the Reports of Worlds Banks WBO.The data was statistically processed and systematized. The results obtained were represented graphically and interpreted. For analysis, results were compared, where possible, with scinetific informations from literature to obtain credible conclusions.

The Research System Legislation

National SDI legislation system is represented by the legislative regulations covering the free access to information for public interest (Law 544/2001), the principles resulting from the case-law of the European Court of Human Rights (ECHR) in cases of default judgments handed down against a debtor's general public Law Research (National Strategy RDI 2014-2020, as amended), the Law on Education 1/2011, and other specific rules, the laws relating to The Ministry of Research and Innovation MCI (HG 13/2017 Organisation and operation of MCI, Regulation OM 2/2017 On the organisation and operation of MCI changed and completed, and other specific regulations), and the Executive Unit for Financing Higher Education, Research, Development and Innovation (UEFISCDI) related resource legislation (Government Ordinance no.62/1999 Approved with amendments by Law no.150/2000, as amended and supplemented. Regulation on organization and operation approved by the Minister of National Education and Research no. 5804/11.23.2016, Government Ordinance no.74/2010, Regulation on the organisation and operation of human resource 5804/2016, and other specific rules).

Romanian RDI Units

Romania has the potential of generating the staff for research, innovation and development, providing by 97 universities (56 of the public domain), with a total of 560 faculties. By 2016, 405,638 students were currently enrolled in undergraduate studies Level 6 ISCED (Bichescu, Chivu, and Stanciu, 2017). In the Level 7 ISCED were enrolled last year 106,794 graduates from the first level of higher education, national statistics indicating 19,154 students at the doctoral studies or postdoctoral (Level 8 ISCED), according to NIS (2017). It could be seen therefore that a recruitment database for educational units and national RDI system, which may be complemented by graduates of undergraduate degree programmes from other countries, Romanian or foreign citizens. The European strategy in the RDI proposed to create a national strategy of innovation, to provide necessary assistance to entrepreneurs to transform innovative ideas into products and services.

The national system of research and development is made up of all establishments and institutions governed by public law and private law with legal personality that have the object of research-development activity. MCI organises and leads national system of scientific research, technological development and innovation. According to the MCI (2017), Romanian RDI system comprises 263 public organizations, and about 600 enterprises with public or private property. 56 of the public organizations are public universities, 46 national institutes are research and development (43 being coordinated by MCI) and 65 are research institutions and centers of the Romanian Academy.

The National Network for Innovation and Technology Transfer (ReNITT) contains 50 specific organizations: technology transfer centers, centers for information technology, business and technology incubators and 4 science and technology parks.

The Business Research Performance Sector includes Business unities of the national economy that have their principal or secondary activity in research and development. The higher education performance sector includes all units from higher education and privacy, as well as medical clinics under direct supervision or administered in association with institutions in the higher education sector and conducting research and development activities.

Government sector includes all performance units (including ministries of budgetary appropriations intended for research and development), which provides public services the activities of research and development of the Central and local administration, as well as national institutes of research and development.

Private sector, non-profit performance comprises in unions, foundations, centers, associations, organizations, trade unions, political parties and political formations which carries out research and development activities, including family groups.

The evolution of the Romanian RDI units in 2011-2015 is shown in Figure 1. According to the information from NIS (2017), correlated with the data published by MCI (2017), the total units from the RDI Romania experienced a relatively steady trend in the period 2011-2017, reducing from 269 units in 2011 to 263 units in 2017. The private sector had an important decreased of RDI units, reduced by over 30 % in 2011-2015 (figure 1).

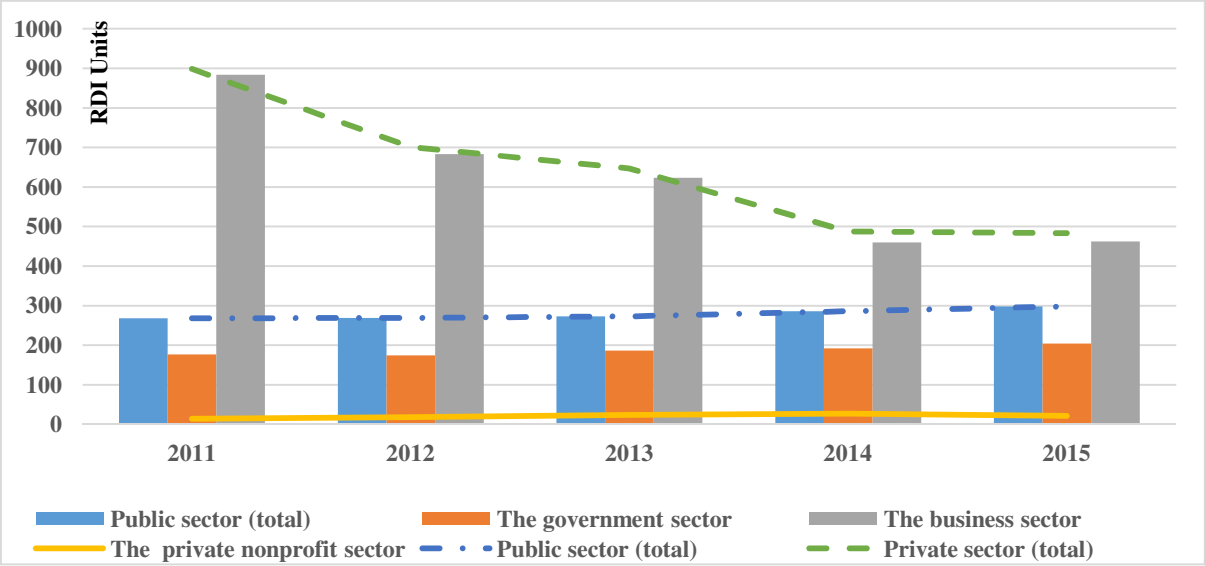

Figure 1: RDI from Romania's property types

Source Author, by using NIS Data (2017)

The most dramatic reduction has been observed for the business sector. During the period recorded in official statistics, the total number of RDI units from Romania down to 33% global reduction being caused by the decline in the number of specialized units in the private sector.

Although country-level, RDI system from Romania has a significant drop in 385 units, from 2011-2015 total number of employees experienced an overall increase of 5% (figure 2).

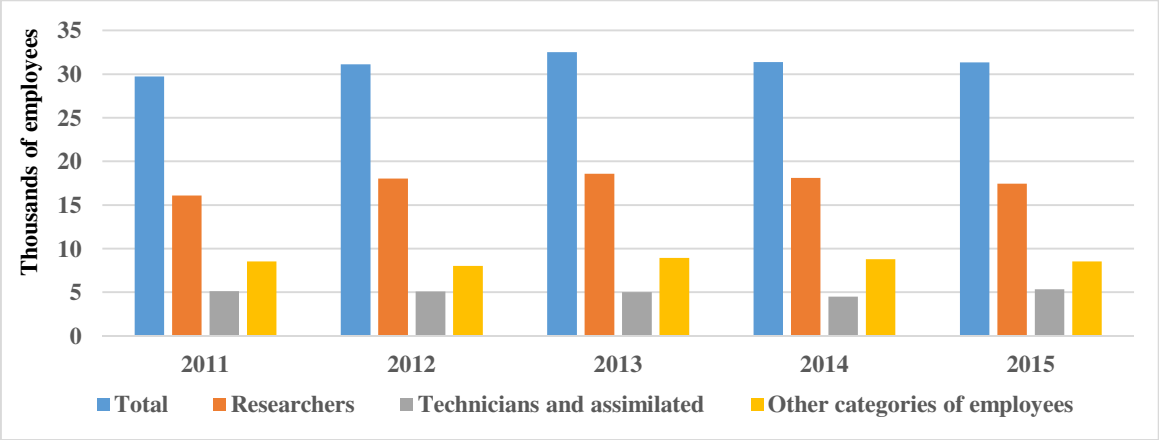

Figure 2: Employees in RD System by the occupation

Source Author, by using NIS Data (2017)

Researchers and technicians increased between 8.57% to 3.82%, and other categories of employees 0,82%. The evolution of Romanian RDI employees was backed by the State sector, in which universities and governmental institutions have engaged in personal research RDI system, while in the private sector there has been a reduction of personnel in the period assessed (figure 3).

The most consistent increase in staffing have been recorded in the governmental sector, where in 2015 were 13.16 % more researchers compared to 2011. In the Higher Education sector (1.45 %) and in Business (1.26%), the number of employees remained constant, increases being insignificant.

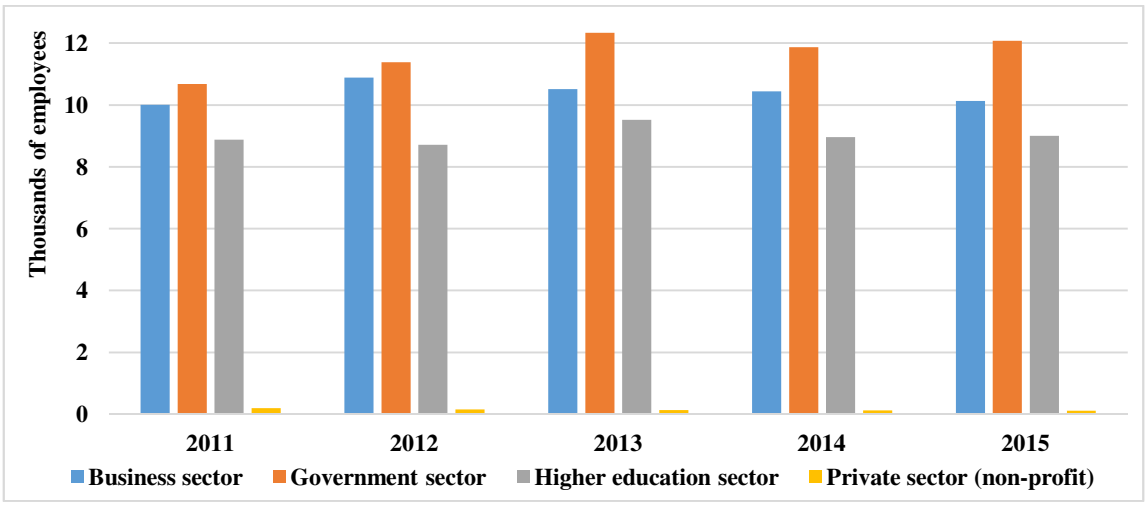

Figure 3: Evolution in the number of employees activity sector RDI

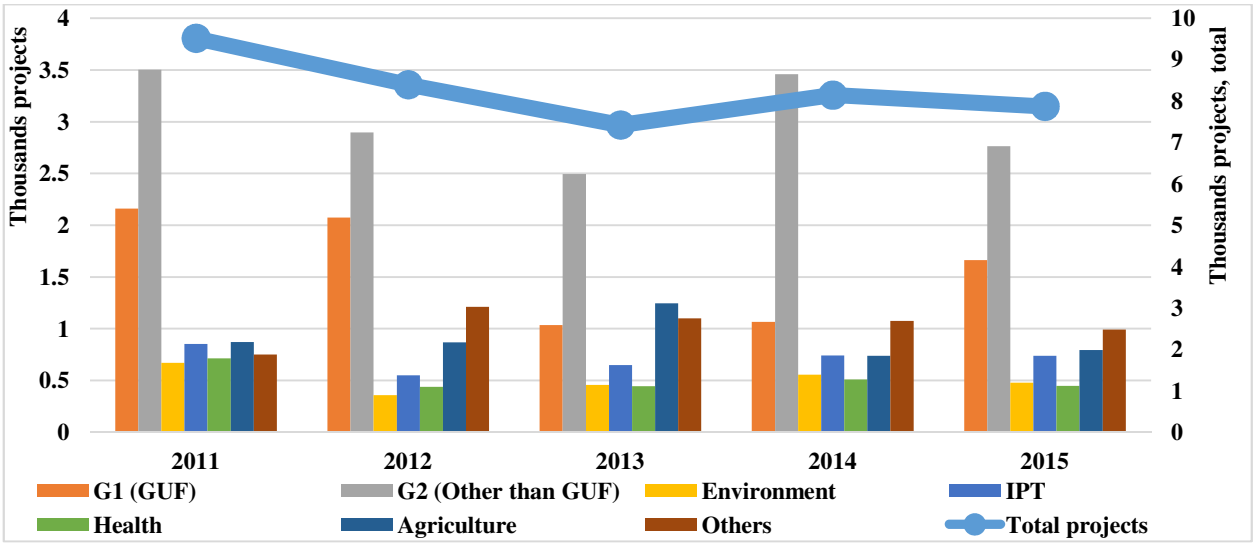
Source Author, by using NIS Data (2017)

The area in which there have been spectacular declines was the private non-profit sector, in which there were over 40% in loss on livestock. The explanation of this trend is mainly political and governmental in the economic sector business.

The massive reduction in the number of employees in the non-profit private sector can be explained by the fact that in the period 2014-2015 the access to European and Governmental funds was reduced, the financial year 2014-2020 being at the beginning and the financing of the R & D projects from the Community diminished (Figure 4).



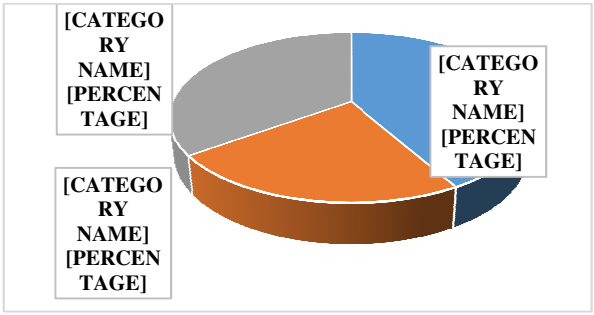


Figure 4: Projects for RD activity, according to NABS 2007

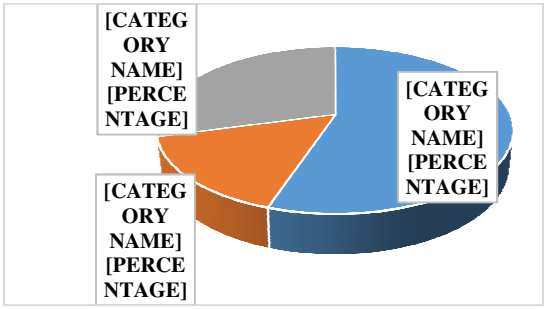
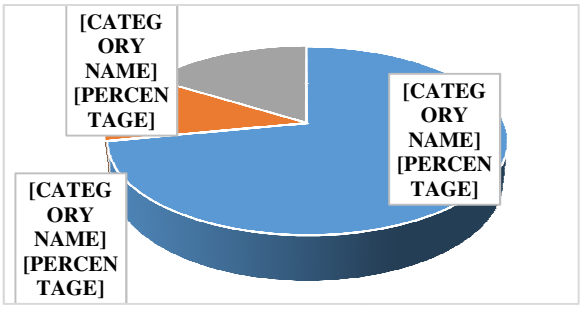
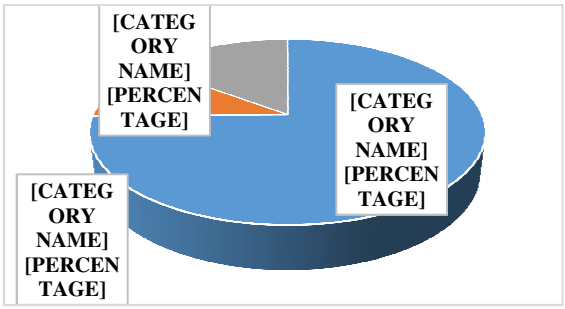


Source Author, using NIS Data (2017)

According to the data represented in Figure 4, it cuold be seen that during the period under review projects prevailed type G2 (General Advancement of Knowledge, financed from other sources than GUF), which accounted for over 30% of total funding. The second position in the top is occupied by fund G1 Type (General Advancement of Knowledge, financed from general university funds GUF). Projects for Agricultural and Industrial Production and Technology IPT are each about 10% of the total.



An interesting analysis is the evolution of the qualifications of the employees on the four areas of activity, as shown in Figure 5 (a, b, c, d). According to NIS (2017), excepts business, the share of researchers represents more than 50% of total employees.



5a) Business sector

5b) Government sector

5c) Higher education sector

5d) Private sector (non-profit)

Figure 5: Distribution of RDI employees (2015) by categories and sectors: 5a) Business, 5b) Government, 5c) Higher education, 5d) Private - non-profit Source Author, by using NIS Data (2017)

A possible explanation for the weighting for the category "other categories of employees" could be the need for businesses sector to sell research results, although official data indicates a reduced capacity for marketing results the Romanian research and innovation and a very few multinational companies have brought with them to the country a substantial research component (Romanian Government, 2014). Private non-profit sectors and higher education are characterized by the highest share of researchers employed in total.

University education has proved its capability of developing scientific research through the high number of publications and notable performances, surpassing substantially the scientific productivity of both the institutes and the institutes of the National Academy research and development.

The share of employees in the Romanian RDI by the age categories is presented in Figure 6. A problem of the National RDI system is the lack of young researchers. According to NIS data (2017), the share of young people, under 35 years, does not exceed 30 % of the total employed in the system, being between 15.14 % in 2014 and 29.11% in 2009.

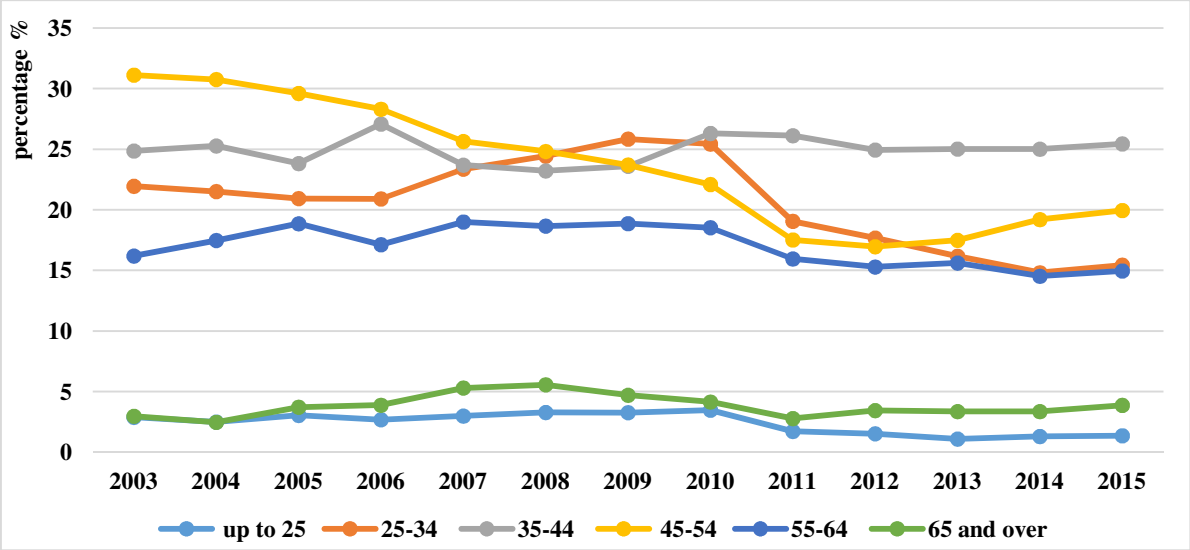


Figure 6: The share of employees on the Romanian's RDI, by age

Source Author, by using NIS data (2017)

Lack of attractiveness of the RD system for young researchers is becoming more evident starting in 2010, when begin to fall substantially of the number of people under 35 years of age. As a counterweight, young researchers under 25 years represent the least represented age group, being exceeded, including the pensioners/older than the limit for retirement and working in the system. The percentage of mature specialists, aged 35-45 years old, which must represent the majority of the employees does not exceed 25 % of the total human resource, except for 2006, when it was 27%. Unfortunately, the share of staff aged over 55 years is close to or even exceeds the Romanian young researchers the last years.

The cost of salaries for employees in the Romanian RDI fluctuated between € 92.62 million (2011) and € 159 million (2015), with a minimum of around € 77 million in 2013 (Figure 7).

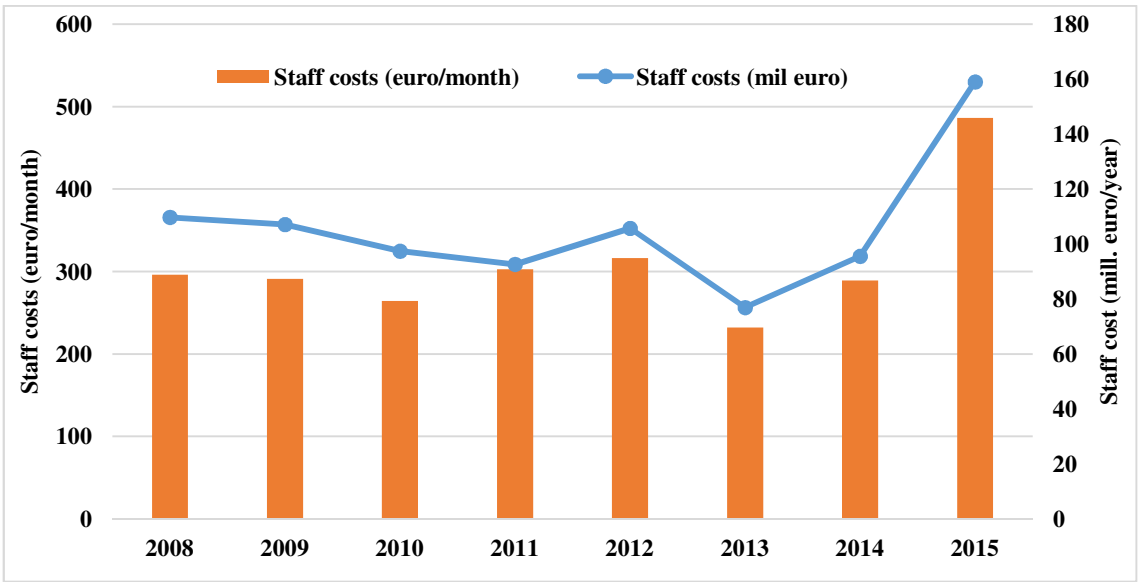

Figure 7: HR costs (annual – millions euro, respectively euro/employee monthly)

Source Author, by using NIS Data (2017)

Per employee, reporting total personnel costs by the total number of employees, it could be observe that an employee cost the Romanian RDI between 230 and 460 euro per month, which in terms of net revenue accounted for employees between 150 and 300 Euros/month.

At European level, Romania is situated just over Bulgaria at the salary of human resource (European Observatory of Working Life, 2017).

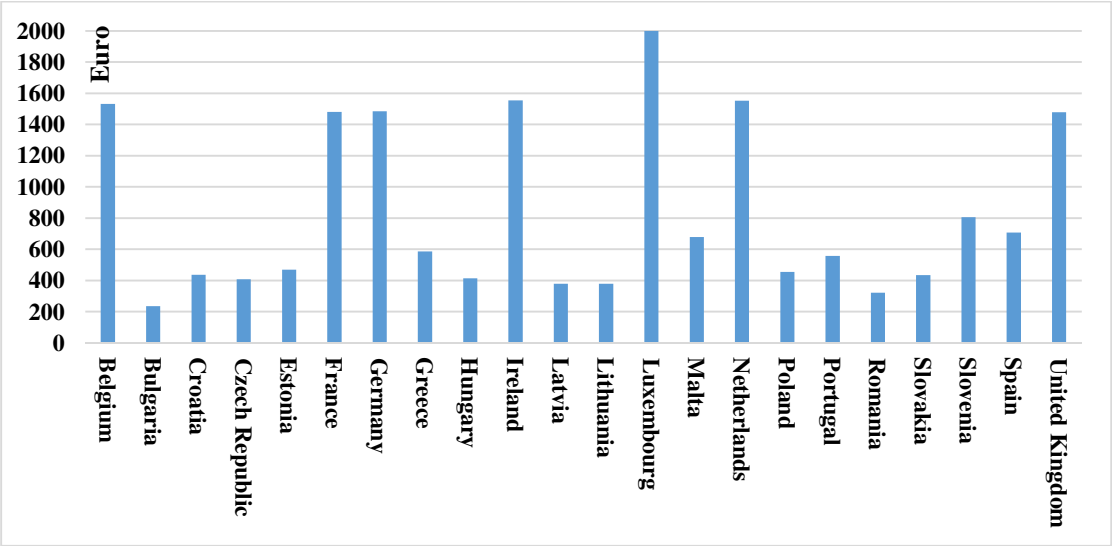

Figure 8: Minimum monthly wage level at European level (valid from 1 April 2017)

Source Author, using European Observatory of Working Life Data (2017)

Luxembourg ranks first position in top, with a minimum wage 2,000 euros/month, while in Ireland, Netherlands and Belgium is around 1,500 euros. Bulgaria (232 euro/month), Romania (321 euro/month) and Latvia-Lithuania (380 euro/month) occupy the last positions of the top. Under the conditions of wage discrimination, the researches from Babeș Bolyai notified the European Commission that the Romanian researchers partners in the Horizon 2020 programme have the level of the average wage of four times lower than that of Western European researchers, withdrawing from submitting/applying for funds (Ionel, 2016).

Following the Eastern Europe researchers' dissatisfaction, the European Commission announced on February 17th a change in the wage rules for Romanian researchers involved in the Horizon 2020 programme (HotNews.ro, 2017). The rule, by which researchers will be paid up to 4,300 euro/month, will help to reduce wage differentials between researchers involved in EU funded projects and eventually help East European countries to keep their most talented researchers home.

Conclusions

Most universities have limited connections with the economic companies and focused on burdening the research activities with didactic tasks. Consequently, full-time research posts are still unique in the academic environment, despite that its ability to disseminate scientific results had been demonstrated. The higher education system has a weak link with the private economic environment and a reversible opening of the university research environment to the private environment is needed. The share of employees over 55 is close to the share of young researchers in Rumanian RDI in 2011-2015. The wage of the domestic RDI staff is close to the minimum level, which does not encourage the performance and the engagement of prestigious researchers. For the Romanian RDI employees, passion for research could be an important factor, but when the level of incomes is too low, the temptation of other jobs in Romania or in other countries causes staff migration. We believe that in absence of concrete measures, like governmental support applied at a national level to sustain RDI, the sector will continue its descending course, with reducing the technical staff and experts.

Abstract

The aim of this work is to find out, which frameworks are used in companies in the field of IT Governance. The first part of this work deals with definition of the term IT Governance and its difference to IT management and compiles the list of used IT Governance frameworks. The most used frameworks are COBIT, ISO and ITIL, but it is recommended that companies should use more than one framework, because every framework is strong in a different field. The second part is devoted to research on how companies in Slovakia use these frameworks with regard to their size defined by a number of employees and due to the origin of the company's owners.

Keywords: IT governance, IT management, framework

Introduction

Different definitions of IT Governance put emphasis on different areas of ISIT. In our research we will analyse usage of various methods and IT services. In a certain sense, the core of IT Governance is setting of rules for input data provided into individual areas of IT governance and rules of decisive rights in ISIT. Aim of this article is to uncover which frameworks are used in companies with focus on Slovakia in the area of IT Governance.

Literature Review

Status of the issue in the area of IT Governance in Slovakia and abroad

It may be not simple to fully understand the term of IT Governance, especially if its meaning is crossing through several areas of the organization. IT Governance can be called a way of approach towards the IT processes governance in an organization. These put information systems and information technologies (ISIT) into accordance with company's strategy. In a long-term horizon, IT Governance provides a correct direction of investments into ISIT of the organization, based on clearly defined processes of assessment of all IT development strategic requirements. IT Governance contains a body of rules, relationships and processes, which provide the organization's management with tools to make ISIT support the strategic goals of the company in a highest possible level (ManagementMania, 2016). A very simple definition comes from Craig Simons (2005), a researcher of the Forrester agency: IT Governance is a process, which is used for making decisions in the area of IT investments. It determines the way of making decisions, by whom they are made, who is responsible and how the results of decisions are measured and monitored. All of this creates parts of the IT Governance. Based on the definition, every organization has a certain form of IT Governance. The definitions provided earlier may be easily summarized: IT Governance is a framework, which makes the ISIT infrastructure able to support and enables the company's strategies and goals (Calder, 2007). Other definitions replace the word 'framework' with 'processes'. This is how IT Governance is defined also by the advisory company Gartner (2017).

However, it is necessary to see the difference between IT Management and IT Governance. IT Management covers specific daily decisions, which are made based on a systematic decisive process

by people, who were given the right to make decisions (Weill, Ross, 2004). To attain the correct goals of company's performance, IT Governance uses values of company governance for the correct usage and management of IT (Alkhaldi, et al., 2017).

IT Governance is not only a question of IT. In the broadest sense of the word, it is a part of the overall company governance but with specific focus on improving governance and control of information technologies for benefit of the parties involved. IT Governance covers culture, organization, policy and procedures, which provide governance and control of IT in five key areas: (NCC, 2005)

- **Alignment** – Provision of strategic direction of IT and alignment of IT and company goals in the area of services and projects.
- **Value Delivery** – Organization should be able to get the maximal benefit of IT and to assess returnability of the investments in IT.
- **Risk Management** – There are processes in the company to ensure that the risks are correctly managed. It contains evaluation of risk aspects in IT investments.
- **Resource Management** – Provision of directions on a high level during obtaining and using IT resources. Supervision of overall IT financing on an enterprise level. Examination of adequate ability and infrastructure of IT to support the current and expected business requirements.
- **Performance Measurement** – Verification of strategic compliance, which means reaching strategic goals in IT.

Primarily, it is the IT Director in the company who is responsible for IT Governance; however, the nature of ISIT has influence on work of all leading workers in the organization. Properly implemented principles of IT Governance increase the level of protection of investments into IT.
Implementation of good IT Governance in a company requires a framework, which is based on three main pillars: (Simons, 2005)

- **Organization Structure –** Who is making decisions? Which organization units, commissions, positions will be created, who will participate in the units and what will be the setting of responsibilities?
- **Process** – How are the investments decision in IT being made? What are decision-making processes for investments proposal, control, approval and preference of an investment?
- **Communication** – How will the results of these processes and decisions monitored, measured and communicated? What mechanisms will be used for announcements about IT investments decision for board of directors, executive management, company managers, IT managers, employees and shareholders?

In case of IT Governance implementation into a company, it is recommended to implement one of the frameworks, like:

ITIL – Information Technology Infrastructure Library. ITIL focuses on administration of IT services. Its goal is to ensure, that IT services are able to support the main processes of business. ITIL consists of five bodies of confirmed management procedures of strategy services, design, transition (e.g. Change Management), operation and continual service improvement (Lindros, 2017).

It is the most widely used methodology in ITSM. ITIL is a body of best practices concepts and methods, which are used for management of IT services delivery. Its primary motivation is improvement of planning, usage and quality of information technologies, either from the perspective of the customer or supplier. ITIL is an extensive manual for IT services administration. Its core is made of the following 5 publications: (Persse, 2010)

- Service Strategy (SS) – Basic direction and goals of the services,
- Service Design (SD) – Proposal of services,
- Service Transition (ST) – Transition of services into operation,
- Service Operation (SO) – Operation of services,
- Continual Service Improvement (CIS) – continual improvement of the service.

Methodology of ITIL is not the only framework used for IT services administration. Among the other widely used frameworks applied in the area of IT services administration is primarily COBIT (currently in version 5), MOF (currently in version 4.0) and the set of standards ISO/IEC 27002:2005. (Jurkscheit, 2014)

COBIT – Published by the organization ISACA, COBIT is a comprehensive framework of globally accepted methods, analytic tools and models. It is designed for governance of company's IT. Using the basis in the area of IT audit, the company ISACA increased the competence of COBIT to fully support IT governance. The newest version of COBIT 5 is widely used by organizations focusing on Risk Management and reducing their impact. (Lindros, 2017)

COBIT is a body of best practice for governance and administration of company's information technologies (IT Governance). It is designed for all kinds of companies (commercial companies, public companies or non-profit organization) of any size. It was by ISACA (International System Audit and Control Association) based on experience from 15 years of practice. Currently, its fifth version is in use, issued in 2012. (ISACA, 2012)

Methodology COBIT provides extensive framework of methods, which are supposed to help companies in attaining their strategic goals by means of effective usage of available resources and minimisation of IT risks. It helps to create optimal value consisting of IT service by establishment of balance among usage of resources, optimisation of risk level and creation of benefit. Its view is closer to top managers than IT managers. It uses holistic approach to IT management, connecting views of enterprise governance and IT services management.

Principles and terms used in COBIT 5

COBIT is based on five key principles:

- Proper understanding of the company's owner needs – companies exist to create value for their owners.
- Coverage of the business as a whole – IT assets need to be handled as any other assets of the company.
- Usage of a united, integrated framework – concord among the individual standards being used must exist.
- Support of holistic approach – effective and precise IT services governance requires holistic approach, using multiple mutually cooperating components.
- Governance Department and Management Department – company's governance should guide, monitor and evaluate the company's requirements and management should plan, prepare and monitor the activities subordinate to them.

In COBIT methodology, a process approach is used with seven categories of elements defined:

- Principles, rules and frameworks – tools for maintaining a required behaviour.
- Processes – organized sets of activities and practices producing an output, which supports the IT goal.
- Organization structures – key deciding entities.
- Culture, ethics and behaviour – characteristics of an individual or a society, often underestimated factor of success.
- Information – entity, necessary for function of the company, often a final product of the business.
- Services, infrastructure and applications – tools enabling the processing of information.
- People, abilities and competencies – entities capable of action and decision-making.

Processes COBIT 5

COBIT 5 divides 37 processes of IT services in a company into 2 basic domains – Governance and Management. Each of the groups contains a set of processes. The domain of Governance contains 5 processes and each of them applies principles of evaluation, direction and monitoring. The domain of

Management contains 4 subdomains in accordance with responsibilities of the management – plan, build, run and monitor (PBRM) – and provides end-to-end coverage of IT services. The individual subdomains are as following: (Knapp, 2010)

- Align, Plan and Organise (APO) – setting, planning and organization of activities; it contains 13 processes.
- Build, Acquire and Implement (BAI) – creation, acquisition and implementation of activities; it contains 10 processes.
- Deliver, Service and Support (DSS) – delivery, service and support of activities; it contains 6 processes.
- Monitor, Evaluate and Assess (MEA) – monitoring, evaluation and assessment of activities; it contains 3 processes.

Comparison with ITIL

The methodologies are mutually fully compatible, since the fundamental principles of IT delivery governance are either identical in a certain level or at least they are not in a contradiction. However, from the organization-process view they are interpreted in a different way. It is more suitable to use COBIT framework, if it is needed to define a strategic direction of IT in the company and interconnect it with the overall company's strategy. Methodology of COBIT is more focused on governance of company informatics, describing all the areas of the management, which should be covered to create value in an effective and precise way. However, the practices of the COBIT framework do not describe the design of the individual processes, functions and activities.

In comparison with COBIT, the methodology of ITIL is more adjusted for implementation of system of IT services delivery management, as it does not deal with the strategic interconnection between IT service and direction of the company in such a detail. It is focused on a detailed description for the purpose of the individual processes implementation.

CMMI – Integration method of the model Capability Maturity, which has been developed by the organization Software Engineering Institute, represents an approach of company's performance improvement. CMMI uses a scale from 1 to 5 to measure performance, quality and profitability of the organization. Levels of maturity in CMMI provide a strict reference and assessment method, which enables the organization to compare its capabilities with its competitors, industrial branch and in time. CMMI provides five levels of maturity, which demonstrate evident course towards improvement. (CMMI, 2017)

At reaching level 4 or 5 of the CMMI model, the organization shows deeper commitment to continue in capability improvement by means of statistic and other quantitative methods. Organizations of high maturity are constantly developing, adjusting and growing to satisfy the needs of parties and customers involved.

ISO/IEC 38500 and other supplementary ISO norms – ISO / IEC 38500: 2015 provides governing principles for the members of directing bodies in organizations (which may include owners, directors, partners, executive managers, etc.) about effective and acceptable usage of information technologies (IT). Also, it provides consultancy for those who deal with consulting, informing or helping the directing bodies. The following can be contained here: executive managers, members of groups monitoring resources inside the organization, external business persons or technical experts, e.g. law or accountancy experts, retail or industry associations or profession bodies, internal and external providers of services (including consultants) and auditors. ISO / IEC 38500: 2015 is related to governance of the current and future usage of IT by the organization, including processes of management and decisions dealing with the current and future usage of IT. These processes can be directed by IT experts in the organization, external suppliers of services or business units inside the organization. It defines IT governance as a subset or domain of the organization governance, or corporate governance in case of corporation. (ISO, 2015)

Frameworks comparison

The best example of how we can explain the comparison or interactions between frameworks is the analogy with building a house. By building a house we are beginning with foundation. With frameworks, it is ITIL with its IT service management, which creates the foundation of our house, COBIT is the walls and the roof is ISO 38500. If directing bodies in organization want to implement ISO 38500 without COBIT or ITIL, it won't work and also, on other hand, if the organization has implemented COBIT and ITIL and doesn't have ISO, coverage of all aspects of IT Governance is not complete. The Table 1 covers the IT Governance framework overview.

Table 1: IT Governance Frameworks Overview

	COBIT	**ITIL**	**ISO 38500**
FUNCTION	IT Process	Service Level Management	Guiding principles for TOP management
AREA	4 Process and 34 Domain	9 Process	6 principles
ISSUER	ISACA	OGC	International Organization for Standardization
CERTIFICATION POSSIBILITY	NO	Certification of personnel	At this time - NO

Research Design

In our research we focus on the area of IT Governance frameworks used by companies in formalised ISIT management and in harmonisation of the organization's aims with aims of IT department. Based on the analysis of the available theoretical literary sources from paid scientific databases, expert books and journals and from the internet, we have created a list of existing frameworks used by organizations in the area of IT Governance. Using the method of synthesis, we selected out these frameworks and created the final list.

Within the theoretical bases of the researched area of IT Governance, the conclusions and the list of the frameworks were consequently verified in practice by means of survey. The survey was focused on finding how do the organizations of various size working in Slovakia in various branches currently handle the area of the specific IT process.

In the statistical analysis, the first part of the analysis was dealing with research on the connections between two nominal variables and their frequency, using the methods of measurement of the association between two variables (Phi, Cramer's V. and Contingency Coefficient). In the second part consisting of the analysis of dependence, a statistic method of Chi-Square (Pearson) was used with statistical significance of 0.05.

The survey was performed by means of an electronic questionnaire aiming to gain sample of 200 answers. We obtained a random sample of business entities. The survey was performed among the business entities working in Slovakia. The studied sample was divided into categories based on size (number of employees), legal structure, geographic influence, structure of owners and branch. The basic statistic information about the respondents is stated in the Table 2.

Table 2: The basic statistical information about the respondents

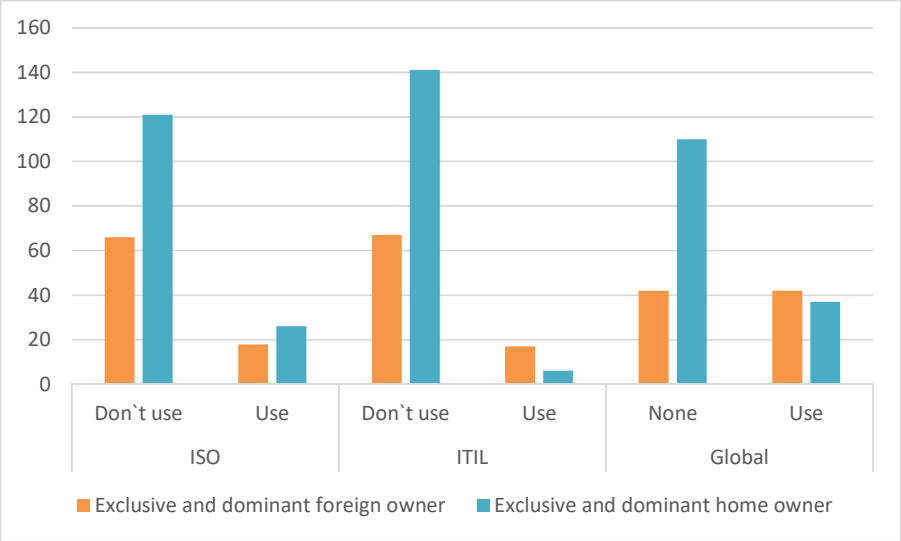
Statistical Data		Legal Structure	Branch	Geographic Influence	Structure of Owners	Number of Employees	Turnover
N	Contained	236	236	236	236	236	236
Median		Inc.	Financial and Insurance Services	Europe	Entirely Slovak Owner	10 – 49 Employees	667,000. – 1.6 mil. €
Modus		Inc.	Financial and Insurance Services	Only Slovakia	Entirely Slovak Owner	10 – 49 Employees	over 1.6 mil. €

In Table 3, the number of employees in the analysed companies is covered. We used distribution as reported by the Statistical Office of the Slovak Republic.

Table 3: Number of employees

Number of employees	Count	Percent	Cumulative percent
1 – 9	59	25,0	25,0
10 – 49	62	26,3	51,3
50 – 99	25	10,6	61,9
100 – 249	33	14,0	75,8
250 and more	57	24,2	100,0
Total	236	100,0	

Research Results and Discussion



The survey was aimed to find out, which frameworks are used by companies in practice in governance of the specific IT process. The overview of frameworks can be found in the Table 4.

Table 4: Overview of the frameworks used

Methods	Answers
	Percent
ISO	17.7 %
CMM	3.2 %
ITIL	9.4 %
COBIT	1.2 %
Other	7.5 %
None	61 %
Total	100 %

The highest number of cases does not use any of the listed frameworks in creation and governance of the specific IT process. In companies which used one of the methods, the ISO method is used most frequently, followed by ITIL, then CMM models and COBIT.

For the purpose of more detailed analysis of the results an overview is provided, containing the first

three most frequent options from the Table 2, based on the origin of the organization's owners, that is either Slovak or foreign origin. We presume that the origin of the owners shall have impact on usage or non-usage of some of the approaches listed. We suppose that the companies with entirely or dominantly foreign owner shall be more inclined to usage of some of the approaches listed than companies with Slovak owner. The numbers are listed in the Graph 1.

For better understanding of the results, we calculated a ratio between the number of companies not using any of the listed frameworks and the number of companies, which do use some of them. In case

where the companies stated that they do not use any of the listed approaches, we calculated a ratio between the number of companies not using any of the approaches and number of companies using at least one of the listed approaches.

Fig 1: Numerousness based on the origin of the organization's owners

Answers, in which the respondents reported no usage of any of the approaches listed, divided our sample of research into group of companies using at least one of the approaches listed and group of companies using no approach. For the further analysis, it is necessary to find out if there is a mutual connection between using/not-using some of the approaches listed and origin of the organization's owners. Since we deal with research of relation between two nominal variables and their frequency is lower than 5 in some of the table fields, the methods of measure of association between two nominal variables were used. The results can be found in the Table 5.

Table 5: Mutual relationships

	Value	Approx. Sig. (p)
Phi	.319	.000
Cramer's V	.319	.000
Contingency Coefficient	.304	.000

The third column of the Table 3 contains Approx.Sig. (p), reaching values 0.000 < 0.05, thus it can be stated, that at the significance level of 0.05, there is a relationship between the variables. Based on the calculated values in the second column of the Table 5, it can be stated that the relationship intensity is medium. The method used in assessing the specific relationship is marked with a grey background in the Table 5.

One in four companies with entirely or dominantly Slovak owner uses a certain approach in procurement of application software. In the case of foreign owners, it is one in two companies using a certain approach. Lower usage of some of the listed approaches by companies with Slovak owners in comparison to companies with foreign owners can result in a higher risk of incorrectly created and governed specific IT process.

In the case of ISO norms, the difference in ratio between using/not-using is lower to disadvantage of Slovak companies. The lower difference can be assigned to the fact, that ISO norms are relatively widely spread and used in Slovakia. There is an opposite situation with ITIL standards, containing a considerable difference in ratios to disadvantage of companies with Slovak owners. The reason can be assigned to lower knowledge of these standards in Slovakia, mainly in the area of small and medium-size companies.

The relationship between the size of a company and the fact of using/not using some of the frameworks listed was also analysed in an expert way. We presume that the larger the company is, speaking about the number of employees, the higher will be the number using some of the frameworks listed, because the larger number of employees creates better conditions and capacity for usage of some of the frameworks listed. Size criterion was summarised into two categories: 1–99 employees and over 100 employees. The results are shown in the Graph 2.

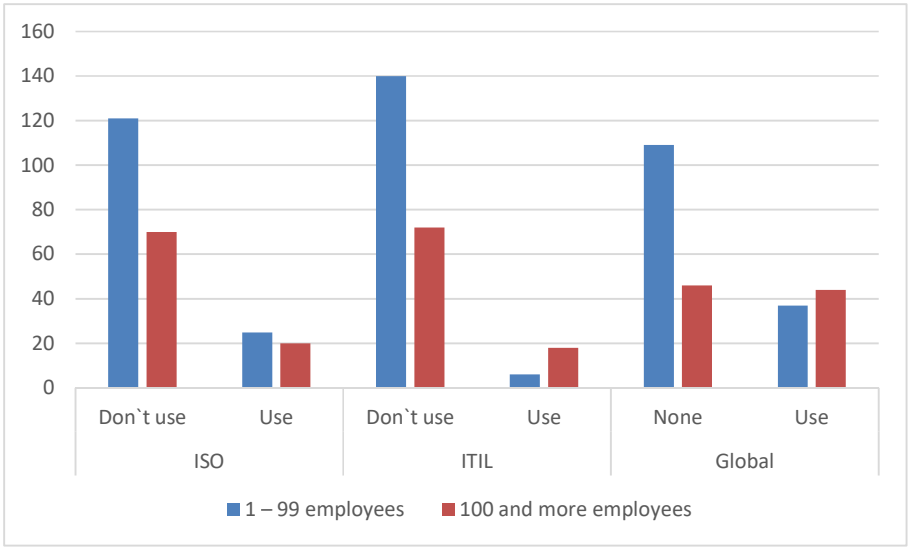


Fig 2: Frequency based on the size of the organization in regard to the number of employees

For analysis of relationship between number of employees and usage of some of the frameworks listed the statistic method Chi-Square was used, with statistical significance of 0.05. Based on the calculation of Chi-Square tests and by means of statistic software, results were uncovered and can be found in the Table 6.

Table 6: Chi-Square test

Chi-Square test	Value	df	Asymp. Sig. (p)
Pearson Chi-Square	28.271[a]	4	.000
a. No cell contains a value lower than 5. Minimal value is 8.58.			

The fourth column of the Table 6 contains Asmp.Sig. (2-sided) representing a minimal level of significance, based on which the mutual relationship can be either confirmed or denied. Since 0.000 < 0.05, it can be stated that in case of significance level of 0.05 there is a relationship between the variables. This relationship can be considered as strong.

Based on the results obtained it can be stated that in companies with more than 100 employees every second company is using some of the approaches listed. The situation is different in case of 99 or less employees. In this case, only one out of four companies uses some of the approaches listed. With the results uncovered, it can be stated that our presumption was confirmed.

Study limitations

In regards to the usage of ISO norms, it can be stated that their usage by companies in Slovakia is relatively high and the differences in ratios correspond with the previous findings. With ITIL standards, their usage by small and medium-size companies can be considered problematic, with only one in twenty-four organizations using this approach in procurement of application software. The lack of usage of these standards in small and medium-size companies may not be considered in a negative way, as these standards are more suitable for larger companies due to the increased complexity and demanding character of the standards.

The area of IT governance is related with the big companies and marginally also with medium size companies. The limitation of our research is that high amount of our data comes from small and medium size companies. We conducted the survey among the businesses only at a certain time. It would be desirable to verify findings with another survey or with a survey conducted in a different country.

Conclusion

IT Governance provides the company with many important functions as establishment and supervision over the organization's approach towards usage of information, digital services and related technologies. This contains, among the other things, the responsibility for digital services providing, the level of quality in services that meet the current and future business requirements, policies and methods for establishment of balance with compulsory law regulations and directives, strategic plans for ISIT, which enable the support of business strategy of the organization, transparent decision-making leading to rationale of investments with adequate balance among benefits, opportunities, costs and risks for the parties involved.

In the first part of the article, we attempted to summarise the basic grounds and definitions for the area of IT Governance and subsequently we created an overview of existing frameworks, which help companies in implementation of IT Governance and effective governance of their IT. Among the main frameworks there is COBIT, ITIL, ISO norms (mainly 38500) and others. Of course, organizations may use none of the frameworks listed, but in that case, they should follow the basic principles of IT Governance.

In the second part of the work, we focused to uncover the usage status of the selected frameworks used in IT Governance in Slovakia. Based on the research conducted among Slovak companies, the usage of these frameworks by the companies and impact of the company owner's origin and size of the company on the frameworks usage was analysed. Among the selected frameworks, ISO norms are the most widely used. Frameworks like ITIL, maturity models and COBIT are used in a lesser extent. It was uncovered that in companies with a Slovak owner there is a lower usage of some of the frameworks listed than in the companies with foreign owners. Speaking about the size of the company, usage of the frameworks is in direct proportion to the company's size and number of employees.

What is the most important for a company in the area of IT Governance is its effort to transfer the main business aim into the lower levels and harmonisation of their efforts to help in attaining the main aim.

Note

The article was prepared as a part of the project VEGA 1/0436/17 Conceptual frameworks of IT Governance and their influence on the competitiveness of companies in Slovakia (Original: VEGA 1/0436/17 Koncepčné rámce IT Governance a ich vplyv na konkurencieschopnosť podnikov v SR).

List of Abbreviations and Acronyms

IT – Information Technology
ISIT – Information Systems and Information Technology
ITSM – Information Technology Service Management
ICT – Information and Communication Technology
ITIL - Information Technology Infrastructure Library
COBIT - Control Objectives for Information and Related Technologies
CMMI - Capability Maturity Model Integration

Determinants of Pro-Environmental Behavior at Work: State-Of-The-Art Review and Integrative Research Framework

Adam Ryszko, Silesian University of Technology, Gliwice, Poland, adam.ryszko@polsl.pl

Abstract

The paper presents a comprehensive review of theoretical frameworks and models used to explain pro-environmental behavior. In particular, conceptual approaches and determinants of specific patterns of pro-environmental behavior at work are identified and characterized. The presented approaches applied to explain pro-environmental behavior at work include, inter alia, the theory of planned behavior, the value-belief-norm theory, the social exchange theory, the cognitive theory of stress, and multilevel motivational model. It is indicated that pro-environmental behavior in organizational settings is the effect of different internal and external factors compared to green behavior observed in the private sphere. Therefore, based on the analysis results, an integrative research framework is proposed for holistic studies on determinants of pro-environmental behavior at work.

Keywords: pro-environmental behavior, pro-environmental behavior at work, employee green behavior

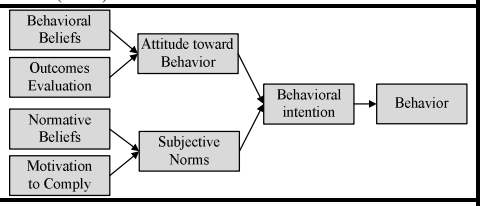
Introduction

Environmental sustainability depends strongly on human behavior patterns. Researchers distinguish different terms describing the same or similar types of pro-environmental behavior (PEB). However, all these studies focus on minimizing the negative environmental impact of human behavior. Kollmus and Agyeman (2002) claim that PEB is a kind of behavior that consciously seeks to minimize the negative impact of one's actions on the environment (Kollmuss and Agyeman, 2002). Ones and Dilchert (2012) define green behavior as scalable action and behavior that employees engage in that are linked with and contribute to or detract from environmental sustainability.

Stern (2000) points out that PEB in organizational settings is explained by different determinants compared to those which affect environmental behavior in the private sphere. In fact, many environmental researchers have attempted to identify the factors that influence PEB in household settings and different models have been developed for the purposes of the identification. The problem with the existing models is that they are applied to explain PEB in households, while research still fails to offer an exclusive explanation of PEB in the workplace. It is worth noting that employees spend about a third of their time at work. Consequently, it is expected that PEB in the workplace will contribute significantly to minimization of the negative impact of employees' actions on the environment.

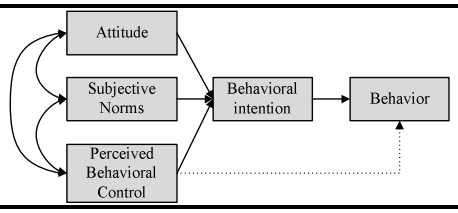
This paper presents a comprehensive review performed in particular to:

- present theoretical frameworks and models used to explain pro-environmental behavior,
- identify and characterize conceptual approaches used to explain pro-environmental behavior at work,
- identify and discuss determinants of pro-environmental behavior at work,
- propose an integrative research framework for holistic studies on determinants of pro-environmental behavior at work.



Selected Theoretical Frameworks Explaining Human Behavior In General

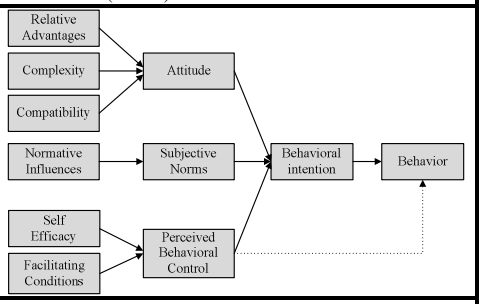
There are different basic conceptual frameworks and models explaining individual behavior that form the basis for further considerations related to PEB. In particular, they comprise as follows:



- Theory of Reasoned Action (TRA), drawn from social psychology, one of the most fundamental and influential theories of human behavior (Fishbein and Ajzen, 1975). TRA depicts a relationship that links beliefs, attitude, intentions, and behavior. Beliefs influence on one's overall attitude about an object. This in turn, guides the individual's intentions, which influence on behavior regarding the subject. Thus, according to TRA behavioral intention is determined by attitudes to behavior and subjective norms;
- Theory of Planned Behavior (TPB), extended TRA by adding the construct of perceived behavioral control. Therefore, perceived behavioral control is theorized to be an additional determinant of intention and behavior (Ajzen, 1991);
- Decomposed Theory of Planned Behavior (DTPB), to more reasonably explain and to predict human behavior on different conditions, Taylor and Todd (1995) decomposed the unidimensional belief constructs into multidimensional belief constructs. For example, the attitude is decomposed into the three constructs which include perceived usefulness, perceived ease of use, and compatibility (i.e. with values, experiences etc.);
- Multilevel Motivational Model (MM), general motivation theory as an explanation for specific behavior adapted for specific context in several studies. Vallerand (1997) presents an excellent review of the fundamental tenets of this theoretical base;
- Innovation Diffusion Theory (IDT), grounded in sociology has been used to study a variety of innovations (Rogers, 1983). Moore and Benbasat (1991) refined a set of constructs that could be used to study individual innovation acceptance;
- Norm Activation Model (NAM), developed in the context of altruistic behavior. The core of the NAM are personal norms which are actively experienced as feelings of moral obligation not as intentions. These personal norms are used in the NAM to predict individual behavior and they are determined by two factors: the awareness that performing (or not performing) the particular behavior has certain consequences, and the feeling of responsibility for performing the specific behavior (Schwartz, 1977);
- Value-Belief-Norm theory (VBN theory), provides a framework for investigating normative factors that promote environmental attitudes and behavior. The theory integrates value theory, the new environmental paradigm perspective and norm-activation theory. It suggests a chain of variables, from values and general environmental concern to specific beliefs about the negative consequences of certain actions and the individuals' ability and responsibility to avert these negative consequences, which in turn activates environmental personal norms for behavior (Stern et al., 1999).

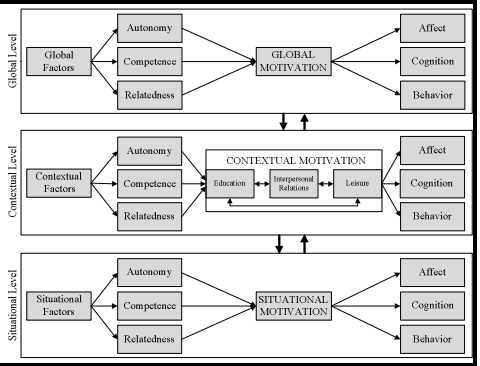
Table 1 presents the core constructs and structure of selected models of the above mentioned conceptual frameworks.

Table 1: Core constructs and structure of selected models of individual behavior



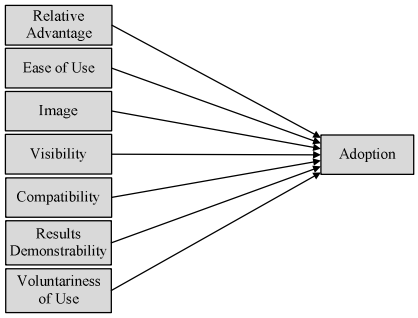
Core constructs	Structure of theoretical model
Theory of Reasoned Action (TRA)	
• Attitude towards behavior – an individual's positive or negative feelings about performing the target behavior • Subjective norm – the person's perception that most people who are important to him think he should or should not perform the behavior in question	
Theory of Planned Behavior (TPB)	

- Attitude Toward Behavior – adapted from TRA
- Subjective Norm – adapted from TRA
- Perceived Behavioral Control – the perceived ease or difficulty of performing the behavior, perceptions of internal and external constraints on behavior



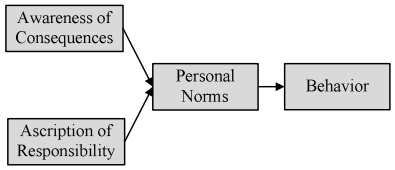
Decomposed Theory of Planned Behavior (DTPB)

- Attitude Toward Behavior – adapted from TRA
- Subjective Norm – adapted from TRA
- Perceived Behavioral Control – adapted from TPB
- Relative Advantage, Complexity, and Compatibility – adapted from IDT
- Normative Influences – influence of other people that leads one's to conform in order to be liked and accepted by them
- Facilitating Conditions – adapted from TRA
- Self-Efficacy – adapted from TRA



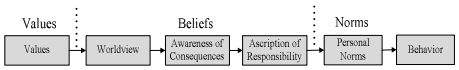
Multilevel Motivational Model (MM)

- Extrinsic Motivation – the perception that users will want to perform an activity because it is perceived to be instrumental in achieving valued outcomes that are distinct from the activity itself, such as improved job performance, pay or promotions
- Intrinsic Motivation – the perception that users will want to perform an activity for no apparent reinforcement other than the process of performing the activity per se



Innovation Diffusion Theory (IDT)

- Relative Advantage – the degree to which an innovation is perceived as being better than its precursor
- Ease of Use – the degree to which an innovation is perceived as being difficult to use
- Image – the degree to which use of an innovation is perceived to enhance one's image or status in one's social system
- Visibility – the degree to which one can see others using the system in the organization
- Compatibility – the degree to which an innovation is perceived as being consistent with the existing values, needs, and past experiences of potential adopters
- Results Demonstrability – the tangibility of the results of using the innovation, including their observability and communicability
- Voluntariness of Use – the degree to which use of the innovation is perceived as being voluntary, or of free will



Norm Activation Model (NAM)

- Personal norms – a person's self-expectations for a specific behavior which originated from norms and values pertaining to the behavior
- Awareness of consequences represents the person's tendency to relate his own behavior to the welfare of others
- Ascription of responsibility refers to the person's personal feeling of whether he is responsible for the consequences of the behavior

Value-Belief-Norm theory (VBN theory)

- Personal norms – adapted from NAM
- Awareness of consequences – adapted from NA
- Ascription of responsibility – adapted from NAM
- Worldview – a view that human actions have substantial adverse effects on a fragile biosphere
- Values – general value orientations such as biospheric values, altruistic values, egoistic values or self-transcendence and self-enhancement values.

Based on: Ajzen (1991), Davis et al. (1992), Fishbein and Ajzen (1975), Moore and Benbasat (1991), Schwartz (1977), Stern (2000), Taylor and Todd (1995)

Determinants of Pro-Environmental Behavior in General

Steg and Vlek (2009) distinguish three lines of research that focus on individual motivations to engage in environmental behavior, respectively: perceived cost and benefits, moral and normative concerns, and affect.

A wide range of studies on environmental behavior started from the assumption that individuals make reasoned choices and choose alternatives with highest benefits against lowest costs (i.e. in terms of money, effort and/or social approval). With regard to this issue, TPB (Ajzen, 1991) has proven to be successful in explaining specific types of environmental behavior, e.g. the use of public transportation or travel mode choice (Bamberg and Schmidt, 2003; Heath and Gifford, 2002), household recycling (Kaiser and Gutscher, 2003; Mannetti et al., 2004), the pro-environmental purchasing (Harland et al., 1999), and general pro-environmental behavior (Kaiser et al., 1999; Oreg and Katz-Gerro, 2006).

Studies focused on the role of moral and normative concerns underlying environmental behavior from different theoretical perspectives. This includes the value-basis of environmental beliefs and behavior (De Groot and Steg, 2008). This research shows that the more strongly individuals follow values beyond their immediate own interests (i.e. self-transcendent, altruistic or biospheric values), the more likely they are to engage in PEB. Research focused on the role of environmental concern has mostly used the New Environmental Paradigm (Dunlap and Van Liere, 1978), but it should be noted that indicated relationship between environmental concern and acting more pro-environmentally was moderate (Poortinga et al., 2004).

Research on moral obligations to act pro-environmentally are generally based on the NAM (Schwartz, 1977) or the VBN theory (Stern et al., 1999). The NAM and VBN theory appeared to be successful in explaining low-cost environmental behavior and willingness to environmental behavior (Nordlund and Garvill, 2003; Stern et al., 1999). However, they have far less explanatory power in situations characterized by high behavioral costs or strong constraints on behavior and the TPB was more powerful in explaining environmental behavior in such cases (Bamberg & Schmidt, 2003). With regard to research on the influence of social norms on behavior, the theory of normative conduct has been validated in experimental studies concerning littering in public places (Cialdini et al., 1990).

Some studies have examined the role of affect in explaining environmental behavior. For example, Steg (2005) indicated that car use is most strongly related to symbolic and affective motives, while instrumental motives are less important.

It should be emphasized that the three above mentioned theoretical perspectives (i.e. perceived cost and benefits, moral and normative concerns, and affect) involve rather different antecedents of environmental behavior but are not mutually exclusive. This is because motivations are not homogeneous and are active differently at any given time.

Environmental behavior are not influenced exclusively on intra-personal factors such as attitudes, affect and personal norms alone. Indeed, many contextual factors may influence on individual

motivations and may facilitate or constrain environmental behavior. For example, the availability of recycling facilities, the quality of public transport, the quality and pricing of environmental friendly goods can strongly affect engagement in PEB. This means that contextual factors may operate in different ways They may directly affect behavior. The relationship between contextual factors and behavior may be also mediated by motivational factors. In addition, contextual factors may moderate the relationship between different motives and behavior, and the effects of contextual factors on behavior may depend on personal factors (Steg and Vlek, 2009).

It should be also noted that individuals do not always make reasoned choices. In many cases, behavior might be habitual and guided by automated cognitive processes. Habitual behavior may involve misperceptions and selective attention (i.e. people tend to focus on information that confirms their choices and neglect information that is not in line with their habitual behavior) (Steg and Vlek, 2009). Aarts and Dijksterhuis (2000) develop and apply in their research on environmental behavior a response-frequency measure of general habit strength, relying on the assumption that goals automatically activate mental representations of habitual choices.

Theoretical Frameworks Used To Explain Pro-Environmental Behavior at Work

According to Steg and Vlek (2009), the effectiveness of behavioral interventions generally increases when they are aimed at important antecedents of the relevant behavior and at removing barriers for change. This makes it possible to understand which factors promote or inhibit environmental behavior.

Factors affecting PEB in organizational settings have been studied from different theoretical perspectives. Application of these frameworks include the theory of planned behavior (TPB) (Blok et al., 2015; Cordano et al., 2010; Greaves et al., 2013; Nye and Hargreaves, 2010), the value-belief-norm theory (VBN theory) (Andersson et al., 2005; Scherbaum et al., 2008), the social exchange theory (Paillé and Boiral, 2013; Paillé and Mejía-Morelos, 2014), the cognitive theory of stress (Homburg and Stolberg, 2006), and multilevel motivational model (Kim et al., 2017).

Blok et al. (2015) confirm that the theory of planned behavior can explain PEB in the workplace. They show that there are clear differences between factors influencing PEB in households and in the workplace. Furthermore, factors like leadership support and exemplary PEB by leaders are at stake in case of PEB in the workplace, and have a significant positive impact on employee's intention to act pro-environmentally.

Greaves et al. (2013) use TPB to explore environmental behavioral intentions in a workplace setting (i.e. across three scenarios: switching off PCs every time employees left their desks for an hour or more; using video-conferencing for meetings that would otherwise require travel; and recycling as much waste as possible). TPB constructs were found to explain between 46% and 61% of the variance in employee intentions to engage in three environmental behaviors, and to mediate the effects of specific antecedent beliefs (i.e. related to attitude, subjective norms and perceived behavioral control) upon employee intentions to engage in these behaviors.

Nye and Hargreaves (2010) compare two interventions to improve PEB – at work (Environment Champions) and at home (EcoTeams). They show that the interventions open up different levels of opportunity for reviewing and renegotiating new environmentally friendly behavior against the reactions and expectations of the immediate peer group, existing workplace or domestic roles. The most important difference they found is that at work it appears difficult to break out of old roles and, alternatively, that new ones can be difficult to play in the office. Moreover, at work there is a need for hard facts and data to justify new actions.

Anderson et al. (2005) prove that when supervisors perceive commitment of their company to environmental sustainability, they are more likely to respond with PEB that is, in turn, directed toward the employees they supervise. Apparently, the supervisors in surveyed multinational corporations are attuned to the values of ecological sustainability promoted by top management, and they enact these values in their everyday interactions with subordinates. Nevertheless, they concluded that VBN theory cannot be generalized in work settings because perceived corporate commitment to sustainability was the only one of the variables from adapted VBN framework to predict supervisor sustainability support behavior. It turned out that supervisors' personal environmentalism, their trust in top management, and their affective commitment did not predict sustainability support behavior.

Scherbaum et al. (2008) examine the individual-level factors related to energy-conservation behavior at work among employees of a large state university. They found that environmental personal norms predicted energy-conservation behavior, as well as behavioral intentions. Environmental personal norms also mediated the relationship of environmental worldviews with energy-conservation behaviors and behavioral intentions.

Paillé and Boiral (2013) focus on organizational citizenship behavior for the environment (OCBE) which constitutes a construct to capture PEB in the work setting. They validate three-factor model of OCBE, including namely, eco-helping, eco-civic engagement, and eco-initiatives. It is indicated that when employees feel supported by their organization, they become more committed and satisfied and are willing to engage in OCBEs. In addition, perceived organizational support and job satisfaction had an indirect effect on OCBE.

Paillé and Mejía-Morelos (2014) prove that perceived organizational support has an indirect effect on PEB through employee commitment to the organization. In addition, organizational support moderates the effect of a perceived breach on employee job satisfaction. Their findings reveal that the employee perception of a discrepancy between what was previously promised and what was provided by the organization may be conceptualized as an obstacle to performing PEB.

Homburg and Stolberg (2006) develop a model that aims at explaining individual PEB: environmental stressors (e.g. pollution in domestic and work contexts), mediated via appraisal processes (demand appraisal, self-efficacy), activate problem-focused coping. This in turn leads to PEB in various behavioral domains (including workplace). They indicate that appraisal processes activate problem-focused coping, which in turn leads to PEB. It is worth noticing that Homburg and Stolberg distinguished direct or indirect PEB. Direct PEB refer to actions resulting in improving the environment (e.g., recycling), and indirect PEB refer to worker motivation about providing advice or encouragement to others individuals in the workplace to adopt direct PEB.

Kim et al. (2017), drawing on a multilevel motivational model in work groups and socially responsible behavior, develop and test a multilevel model of voluntary workplace green behavior that explicates why employees voluntarily engage in green behavior at work. They find out that conscientiousness and moral reflectiveness were associated with the voluntary workplace green behavior of group leaders and individual group members. Furthermore, a direct relationship existed between leader green behavior and the green behavior of individual subordinates as well as an indirect relationship mediated by green advocacy within work groups.

Ones and Dilchert (2012) present comprehensive taxonomies for understanding green behavior in organizational settings. They indicate that employees' actions may impact the environment through five main behaviors which include: conserving (i.e. reducing, use, reusing, repurposing and recycling), working sustainably (e.g. changing how work is done), avoiding harm (e.g. preventing pollution), influencing others (e.g. encouraging and supporting others), and taking initiative (e.g. initiating programs and policies). With regard to categorization proposed by Homburg and Stolberg, conserving, working sustainably and avoiding harm are direct PEB while influencing others and taking initiatives are indirect PEB. It must be stressed that research on indirect PEB in the workplace remains less developed we addressed indirect PEB.

Determinants of Pro-Environmental Behavior at Work

Kollmuss and Agyeman (2002) point out three groups of factors that may have some influence, positive or negative, on PEB in the workplace such as demographic factors, external factors (e.g. institutional, economic, social and cultural) and internal factors (e.g. motivation, pro-environmental knowledge, awareness, values, attitudes, emotion, locus of control, responsibilities and priorities).

Internal and external factors are seen from the viewpoint of the specific individuals and these factors might be managed in order to enhance PEB in the workplace. However, demographic factors will not involve differentiated management policies and therefore they are of lesser importance in terms of possible organizational interventions. Therefore, based on a comprehensive literature review, Blok et al. (2015) distinguish two groups of factors which could predict PEB in the workplace: internal factors and external factors.

Internal factors consist of social factors (i.e. social norms, personal norms), cognitive factors (i.e. environmental awareness, intention to act, perceived behavioral control), and affective factors (i.e. values, attitudes toward the environment).

Various research has shown a positive correlation between PEB and personal and social norms (e.g. Bamberg and Schmidt, 2003; Borgstede and Anders, 2002). In addition, personal norms can be viewed as an important general predisposition to act pro-environmentally. Nordlund and Garvill (2002) show that the personal norms could be seen as derived from self-transcendent and ecocentric values and activated by problem awareness. The personal norm mediates the effects from general values, environmental values, and problem awareness on PEB.

Cognitive factors comprise environmental awareness and perceived behavioral control. Environmental awareness relates to environmental knowledge and the recognition of environmental problems (Grob, 1995). Consequently, it is expected that the higher environmental awareness, the more PEB people will show, for example in terms of eco-friendly purchase and disposal decisions (Van Birgelen et al., 2009). With regard to perceived behavioral control, Kaiser and Gutscher (2003) confirm this construct to be significant direct predictor of ecological behavior.

Affective factors consist of general values, environmental values and attitudes toward the environment. Studies show that self-transcendent people show more PEB than people without such values (Dietz et al., 1998). Altruistic or self-transcendent values have a positive effect on personal norms to behave pro-environmentally and also have a positive direct effect on PEB (De Groot and Steg, 2008). In addition, self-transcendence and openness to change are strong predictors of PEB (Karp, 1996). On the contrary, values related to self-enhancement and conservatism are strong negative predictors of PEB. Pro-environmental values can serve as a predictor of PEB (Rioux, 2011), and according to Clark et al. (2003), such values might be necessary conditions to promote PEB. Attitudes toward the environment also appear to have a positive influence on PEB (Meinhold and Malkus, 2005).

However, Blok et al. (2015) indicate that personal norms, environmental awareness and self-transcendent values (altruism and environmental values) do not have a significant positive relation with PEB in the workplace. With regard to environmental values the results are inconsistent depending on specific pro-environmental activities. The difference between the impact of these factors on PEB in households and in the workplace may be explained by the fact that employees cannot act completely according to their own personal norms and values in the workplace. This means that they are primarily dependent on the norms, values, roles and routines of the company (Nye and Hargreaves, 2010). Nevertheless, Blok et al. (2015) prove clearly that environmental awareness and personal norms have a significant impact on the intention to act pro-environmentally and therefore, have an indirect positive impact on PEB in the workplace.

With regard to external factors, PEB can be performed only if the required conditions and infrastructure are available. This means that the less possibilities available to PEB, the less people are

likely to show it. The external factors at work comprise situational factors and leadership support. Fujii (2006) pointed out that perceived ease of implementation PEB has a significant positive effect on intention to PEB. The access to necessary infrastructure is an important situational factor with a positive impact on PEB (Klőckner and Oppedal, 2011).

The effectiveness of environmental activities depends on leadership (Ramus and Steger, 2000). Robertson and Barling (2012) indicate that leadership and PEB play crucial role in the greening of organizations. Leaders influence their employees in the workplace by sharing values, inspirational motivation, intellectual stimulation, and establishing a relationship with their employees. However, the influence of exemplary PEB by leaders and heads of departments must be distinguished from leadership support of employees to act pro-environmentally (Banerjee et al., 2003). Environmental leadership should be provided by a company's top management while the middle management is likely to have a critical impact on employees' attitudes and behavior. Blok et al. (2015) show clearly that exemplary behavior by leaders has a significant impact on the intention of employees to act pro-environmentally. Individuals may engage in numerous PEB to help their organization achieve environmental sustainability. Research has shown that employees are willing to engage in PEB when they perceive organizational support from their supervisors (Cantor et al., 2012; Ramus and Steger, 2000). Employees who are more satisfied with their job and committed to their organization are more likely to display PEB at work. While a lack of support is one of the major impediments to green behavior at work, supportive decisions by the employer are important facilitators for employees to engage in such behavior.

Norton et al. (2015) propose an interesting theory-based conceptual model based on person–environment interaction, job performance, and motivational theories to structure a multilevel review of the employee green behavior (EGB) literature. They differentiate between required EGB prescribed by the organization and voluntary EGB performed by employees that exceeds organizational expectations. In addition, they explored institutional-, organizational-, leader-, team-, and employee-level antecedents and outcomes of EGB and factors that mediate and moderate these relationships. Norton et al. (2015) also posit that EGB consists of behavior required by employer (e.g., participating in environmental management practices) and voluntary behavior beyond employee's core job tasks (e.g., citizenship behavior for the environment) depending on the motivational states that precede performance. The required behavior is supposed to be driven by controlled motivation (i.e. employee expects company's reward for EGB), whereas voluntary behavior is expected to be activated by autonomous motivation (i.e. personal satisfaction from doing EGB) (Deci and Ryan, 1987).

According to Norton et al. (2015), the factors influencing EGB include:

- at the institutional level – external pressures from regulatory (e.g. laws and regulations), normative (e.g. industrial standards, market demand) and cognitive-cultural (e.g. community expectations) sources;
- at the organizational level – attitudes (with subcategories for attitudes towards business, such as a business strategy, and attitudes towards the environment, such as the importance of environmental sustainability), activities (with subcategories for incentives, such as rewards, resources, such as facilities, and organizational-level behavior, such as complying with regulations) and norms;
- at the leader level – leader activities (supporting behavior, such as encouraging employees, giving feedback, such as environmental performance, and own EGB) and a leadership style (e.g. environmental transformational leadership);
- at the team level – group attitudes (e.g. perceived support from colleagues), behavior (e.g. goal setting) and norms (e.g. green group climate);
- at the employee level – attitudes towards the environment (e.g. environmental concern), behavior (e.g. perceived behavioural control, habits, private green behavior), norms (e.g. personal norms), motivation (e.g. intrinsic motivation), job factors (e.g. task control) and personality (e.g.

conscientiousness). In addition, the within-person categories refer to positive affect and behavioral intentions.

Integrative Research Framework for Studies on Determinants of Pro-Environmental Behavior at Work

Based on the analysis results presented in this paper, this section identifies areas that deserve further scientific attention and make up the future integrative research framework for holistic studies on determinants of PEB at work.

The presented theories and the analysis results provide an appropriate perspective to explain the importance of PEB and, in particular, of the identified determinants of PEB at work. However, the literature review indicates that this area still needs comprehensive research. Studies of this type require formulation of a unified model that integrates specific elements and factors across the approaches and models applied so far.

Therefore, the proposed framework developed to study determinants of PEB patterns at work should comprise:

- Internal factors, including:
  - affective factors (i.e. general values, environmental values, attitude toward the environment),
  - cognitive factors (i.e. environmental awareness, perceived behavioral control),
  - social factors (i.e. social norms, personal norms),
- Contextual factors, including:
  - institutional pressures (i.e. regulatory, normative, cultural),
  - perceived organizational support (i.e. attitudes, activities, norms),
  - leadership (i.e. leadership style, exemplary behaviors, support behaviors),
  - team (group) support (i.e. attitudes, behavior, norms),
  - situational factors (i.e. perceived ease of implementation PEB, necessary infrastructure),
- Motivations:
  - autonomous (i.e. personal satisfaction)
  - controlled (i.e. expectation of corporate reward) ,
- Behavioral intention,
- Pro-environmental behavior:
  - required by employer (e.g., participating in environmental management practices),
  - voluntary behavior beyond an employee's core job tasks (e.g., citizenship behavior for the environment).

The proposed constructs and relationships to be tested and validated are presented in Fig. 1.

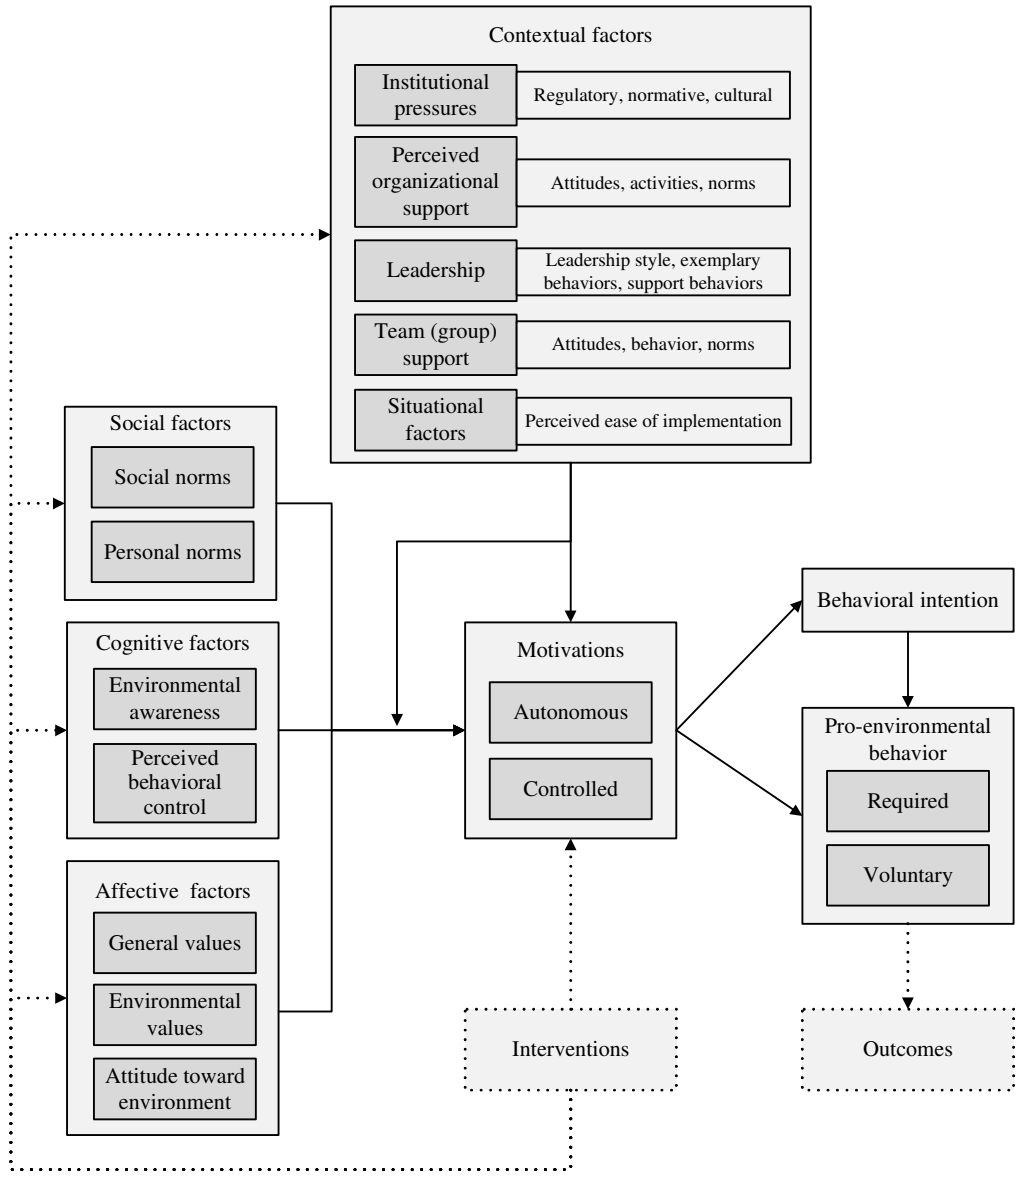


Fig. 1: Integrative research framework for holistic studies on determinants of PEB

It should be noted that the presented framework includes two additional elements: interventions (i.e. interventions that could best be applied to encourage PEB together with their effects) and outcomes (to examine the impact of PEB on the organization's or the employee's performance). These elements are not the subject of this paper, but it would be very interesting to analyze the possible relationships among all the issues presented in Fig. 1 in a holistic way. All the elements included in the proposed framework and all the postulated relationships (i.e. direct effects, indirect effects, mediation and moderation effects) should be analyzed simultaneously within integrated comprehensive research. The analysis could be based on cross-sectional data, but longitudinal studies carried out over multiple points of time, comprising different industries and various countries, would strongly support the obtained results.

Conclusion

Individuals can contribute significantly to achieving environmental sustainability by adopting various PEB patterns. Therefore, the challenge for researchers is to understand the determinants of green behavior so that PEB could be adequately facilitated.

The presented considerations aimed to identify and analyze the theoretical frameworks and models used to explain PEB. Due to the fact that PEB patterns in organizational settings are accounted for by different internal and external factors compared to those influencing green behavior in the private sphere in particular, conceptual approaches and determinants of PEB at work were identified and characterized.

Based on the analysis results, an integrative research framework for holistic studies on determinants of PEB at work is proposed. It comprises inclusion of internal factors (affective, cognitive and social), contextual factors (institutional pressures, perceived organizational support, leadership, team support, situational factors) and motivations (autonomous and controlled) which influence behavioral intention and pro-environmental behavior (required by the employer and voluntary behavior beyond the employee's core job tasks). The proposed framework also includes interventions and outcomes of PEB. It is suggested that all the elements and all the postulated relationships (i.e. direct effects, indirect effects, mediation and moderation effects) should be analyzed simultaneously within integrated comprehensive research. Such an analysis would make it possible to understand the interdependence of factors promoting or inhibiting PEB and, consequently, to implement adequate actions to achieve desired PEB patterns in organizational settings.

Patent Applications in Romania
Romanian Innovation in the European Context

Abstract

Innovation can represent for the modern society the main way to achieve economic growth and to solve certain local and global issues related to the threat to population's health, food security or environmental concerns. European strategies in the field of Research, Development and Innovation aim at increasing the role and significance of patenting and at enhancing the protection and implementation of scientific breakthroughs. Although Europe has made progress in this area, the European office is still behind those from China, USA. Japan or the Republic of Korea. European countries, through Germany and France, are among the world's top holders of patents. Romania, although it has nationally recorded a number of progresses in the field of patent registration, registers low international shares. in particular, due to the prohibitive costs of patents registration. Romanian universities occupy modest positions in the field of patenting, registering an average of 1.4 patents / year. Supporting and encouraging national innovation and filing patent applications should be supported at governmental level, by reducing formalities, the duration of acquiring the patent and the patenting costs.

Keywords: innovation, patents, Europe, Romania

Introduction

Applied research and innovation represent a current priority for the European policy. According to Community guidelines, innovation must be a strong point for States Member in economic growth and for the creation of decent, quality and stable jobs, especially for young people, economic growth and socio-economic convergence, migration, security and the fight against populism. Research and innovation can improve the living conditions of EU citizens, representing key elements of the European Commission's policies, which seek to stimulate employment, economic growth and investments. Research and innovation can provide scientific knowledge and practical solutions for diminishing / avoiding certain short-term threats to the European area that may affect the health of the population (poliomyelitis epidemics, Zika, Ebola, etc.), food security and safety (lack of food , genetically modified production, etc.), social balance and humanitarian issues (refugee crisis, unequal distribution of incomes, etc.), or can respond on long-term to certain society challenges related to transport, climate changes or energy (European Parliament, 2017). The European Commission's recommendations to States Member aim to increase the funds allocated to research and development, being recommended to exceed the threshold of 3% of GDP until 2020 (1% of public funds, 2% of private investments), which is estimated to generate 3.7 mill. of jobs and would determine an annual EU GDP increase of around 800 billion euros. At the same time, the European Commission proposes a reduction of up to 80% in patenting costs at European level, with simultaneous recognition of patents in the 25 signatory states of the agreement, to boost the European patenting activity.

Materials

Information on patent applications filed at European level has been selected from the European Patent Office's statistical database. For the Romanian patenting, data were collected from the official statistics of the Romanian State Office for Inventions and Trademarks. The analysis period was 2006-2016, depending on data availability. For the European legislation in the field, there have been used the official releases of the European Parliament and the European Commission. National patenting legislation has been selected from the website of the State Office for Inventions and Trademarks and official publications of the Government of Romania. Where necessary, one related also to other sources, represented by scientific publications or official journals. Data have been systematized, statistically interpreted and graphically represented.

Patenting at European level

At European level, the body responsible for registering and validating patent applications is the European Patent Office (EPO), body of the European Patent Organization, an intergovernmental organization consisting in 38 countries (the Member States and 11 other European countries including Turkey).
Globally, over 80% of patents granted worldwide are granted by the European Patent Office (OEB), the Japanese Patent Office (JPO) and the United States Patents and Trademark Office (USPTO) (Rasvan, 2017).

In the statistics World Intellectual Property Organization WIPO, EPO has been the fifth in the year 2015, as number of patents registered (figure 1).

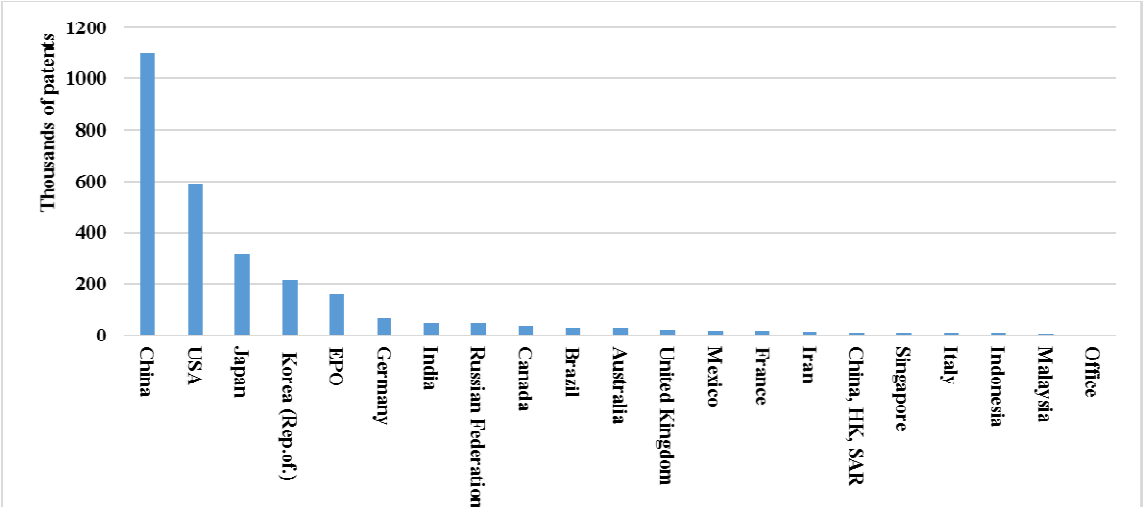

Figure 1: Patent - Applications for the top 20 offices (2015)

Source Authors, by using WIPO Data (2017)

It should be noted that in WIPO statistics, China, with an increase of 18.72% towards the previous year and with 1,101,864 patents registered in 2015, is the first state in the world to exceed the limit of 1 million patents registered. By comparison, USA and Japan, which are the second and third in Top 20 Patents WIPO registered, record cumulatively only 908,131 patents. Europe is represented by Germany, UK, France and Italy in the world top.

In Europe, the OEB examines the patent applications, being responsible for granting patents registered to the European Office if the necessary conditions are met. For the patent granted to be valid in a State Member, the inventor must apply for its national validation in each country where patent protection is sought. The process involves administrative and translation costs of up to € 32,000 when seeking for patents protection in EU-27, amount of which € 23,000 represent the translation fees. By comparison, obtaining a patent in USA costs an average of 1,850 euros. In order to preserve the validity of the patents, it is necessary to pay each year the extension fees in each country, and the patent transfer or a license agreement to use the patented invention must be registered in the same way (Romanian Permanent Representation attached to the European Union, 2017).

A statistic of patent applications registered depending on the residence state of the first author of the patent shows that 1,484,472 applications were registered to EPO during the period 2007-2016, from residents of 169 countries out of 177 registered in the European database. The dynamics of the applications registration during the analysed period is shown in Figure 2.

The largest share of registrations was recorded to EPO during 2015, when 160,004 applications were filed.

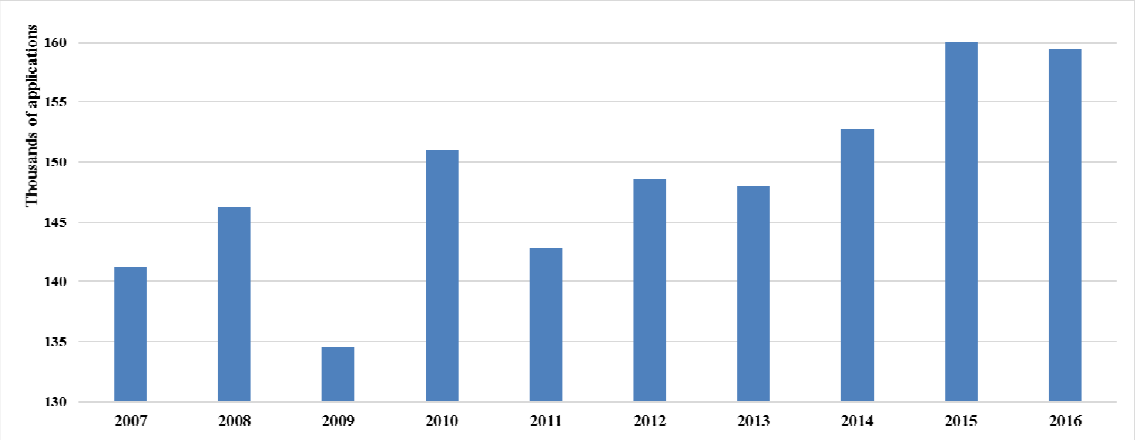

Figure 2: European patent applications 2007-2016

Source Author, by using EPO Data (2017)

Depending on the residence of the patent owner, in the top of the countries with the most applications to EPO during the analysed period, the USA ranks first, followed by Germany and Japan, covering over 50% of the total (Figure 3).

Benin, Bolivia, Botswana, Congo, Democratic Republic of Guadeloupe, Saint Helena, Vatican, and Zambia have no application registered during the analysed period.

With a total of 240 applications registered to EPO, Romania ranks 56 among the top of 177 countries from EPO base.

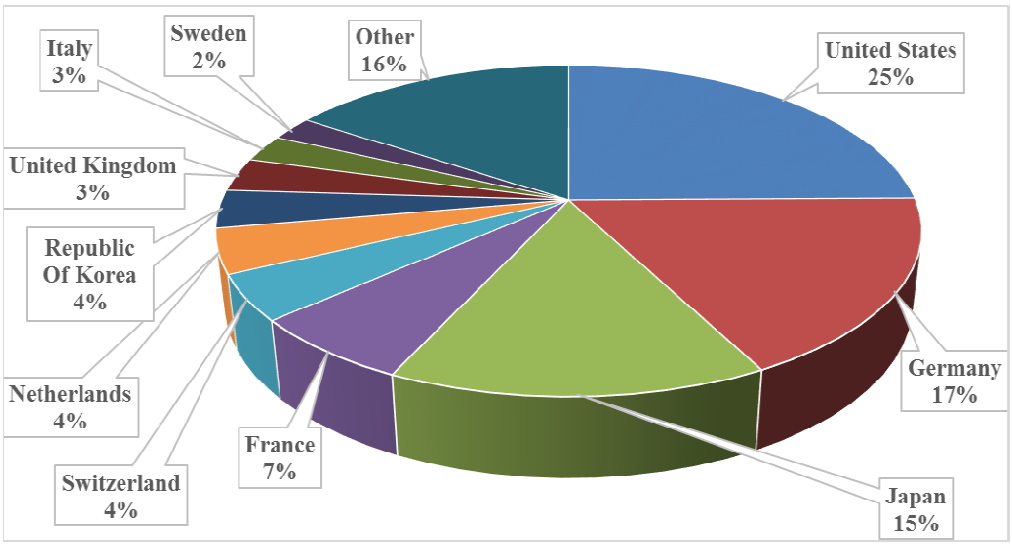

Figure 3: Top 10 European patent applications per country of residence of the first named applicant (2007-2016)

Source Author, by using EPO Data (2017)

Among the applicants residing in EPO member states, during 2016, 97,167 applications were submitted for patenting, increase with 370 units towards the previous year (Figure 4).

Germany is ranked first in the statistics of EPO members, a total of 31,815 applications being submitted last year, and representing more than a third of patent applications registered to EPO.

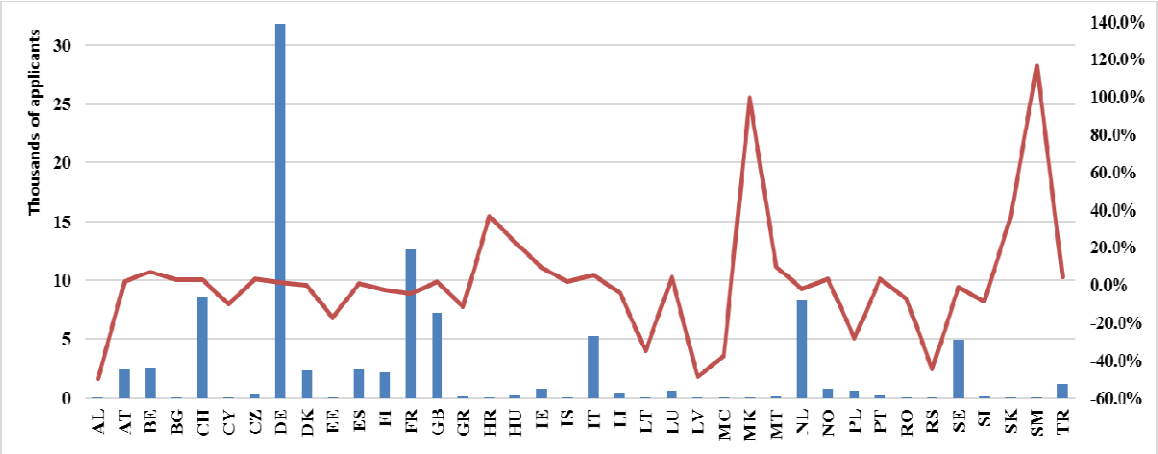

Figure 4: Patent applications registered by EPO state member during 2016 and Evolution towards 2015

Source Author, by using EPO Data (2017)

France ranked second in the hierarchy last year, with 12,726 registered applications (still having a decrease of 4.3% compared to the previous year). Although it recorded at its turn a decrease with 2.1% in patent applications compared to the previous year, the Netherlands ranked third in the top from 2016, with 8,339 applications. Leading positions are completed by the Netherlands, the Czech Republic and

UK. Leading positions are also occupied by Germany, France, the Netherlands, Switzerland and Sweden, which are included in Top 10 Worldwide Patents.

Patenting in Romania

The sole authority on the Romanian territory with tasks in ensuring the protection of industrial property, in accordance with the national legislation in the field and with the provisions of the international conventions and treaties to which Romania is part, is the State Office for Inventions and Trademarks, OSIM.

OSIM operation is mainly based on the Government Resolution no. 573/1998 (Government of Romania, 1998), amended and completed by Government Resolution no. 63 from 23 February 2017 (Government of Romania, 2017). According to the legal provisions currently in force, OSIM is a specialized body of the central public administration with legal status, subordinated to the Ministry of Economy. The legislative provision issued by the Government of Romania this year passes OSIM from the Government subordination to that of the Ministry of Economy. OSIM prepares and submits to the Government of Romania the strategy for the development of industrial property protection in Romania and applies its policy in the field. OSIM is entitled to register and examine the applications from the industrial property field by releasing titles of protection conferring to the holders exclusive rights on the Romanian territory, as well as the depositary of the national registers of applications filed and national registers of protection titles granted for inventions, trademarks, geographical indications, drawings and industrial designs, topographies of integrated circuits, new plant varieties, being liable for the national collection and its correlation with international databases. If necessary, OSIM performs, upon request, specialized services in the field of industrial property, holds training programs in the field and performs any other tasks in the field of industrial property resulting from the legal provisions in force and from the international agreements. The unique protection title of inventions in Romania is the patent of invention, valid for 20 years, from the date of establishing the regular national depositary. Patenting is a formalized and laborious process that can reach Romania up to 30 months. The costs of patenting and validation of patents in Romania are quite high, although there is a tendency to reduce them, process also registered at European level. In this direction, the Government of Romania aims to reduce the formalities and costs of patenting, the new tax grid is presented in Annex 1 of the Law on Intellectual Property Taxes (Government of Romania, 2015).

The Official Industrial Property Bulletin of Romania (BOPI) is the publication of OSIM where inventions are made public and other industrial property categories patented. OSIM edits and publishes the series of invention patents, the Romanian Industrial Property Magazine and other publications intended to promote its object of activity. Romania is part of numerous multilateral agreements and treaties in the field of invention patents, the most important being presented in table 1.

Patents Registered In Romania

Evolution of validated patents in Romania during 2006-2016 is presented in Figure 5. According to OSIM data, a total of 30,717 patents were registered and approved in our country, during the analysed period, out of which 27,062 after joining the EU. As share, more than 80% of patent registrations to the national office come from recognitions of European patents based on the international agreements to which Romania is part.

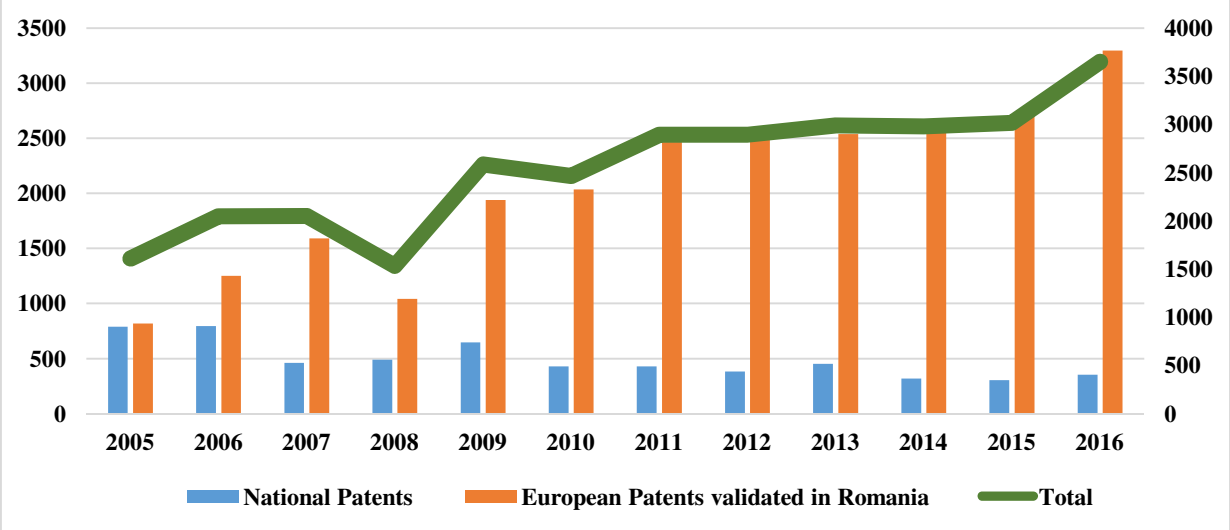

Figure 5: Patents registered in Romania (2005-2016)

Source Authors, by using OSIM data (2017b)

During the period 2005-2016, 13,331 patent applications were filed, out of which 12,672 belonged to the Romanian citizens, representing over 95% of the total. Residents abroad submitted only 659 patent applications to OSIM.

The main category of applicants for patenting research results consists in natural persons, which represent almost 50% of the total (Figure 6).

Although it has improved as share, the share of patents requested by universities accounted for just over 15% of the total number of applications registered during the analysed period, being close to the percentage recorded by private companies.

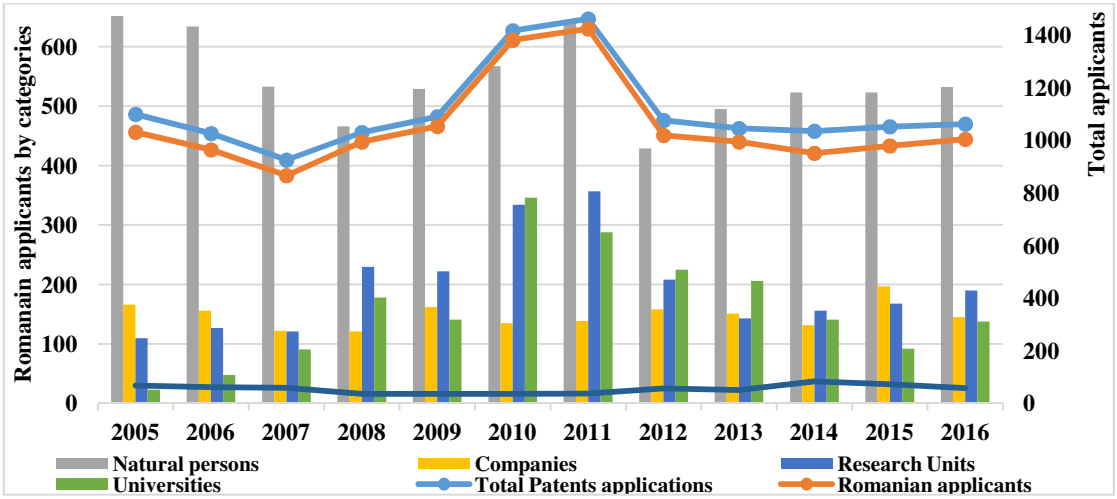

Figure 6: Patents applications submitted by Romanians

Source Authors, by using OSIM data (2017a)

The number of patent applications registered by universities has recorded a maximum in 2010, with 346 units, after which it recorded a significant decrease, reaching 92 units in 2015. Last year there was a slight increase of the applications, filed to OSIM with 138 units. Companies have registered between 150 and 200 validated patents, with a minimum of 122 units in 2007 and a maximum in 2015 with 197 patented applications. Specialized research units filed 2366 patent applications.

Patents applications registered and validated by universities

During the period 2005 - 2016 the evolution of patent applications registered by universities is presented in Figure 3. The data presented by OSIM are relatively differentiated according to the statistical department that presents them, there being small differences between the statistics from Figures 5 and 6.

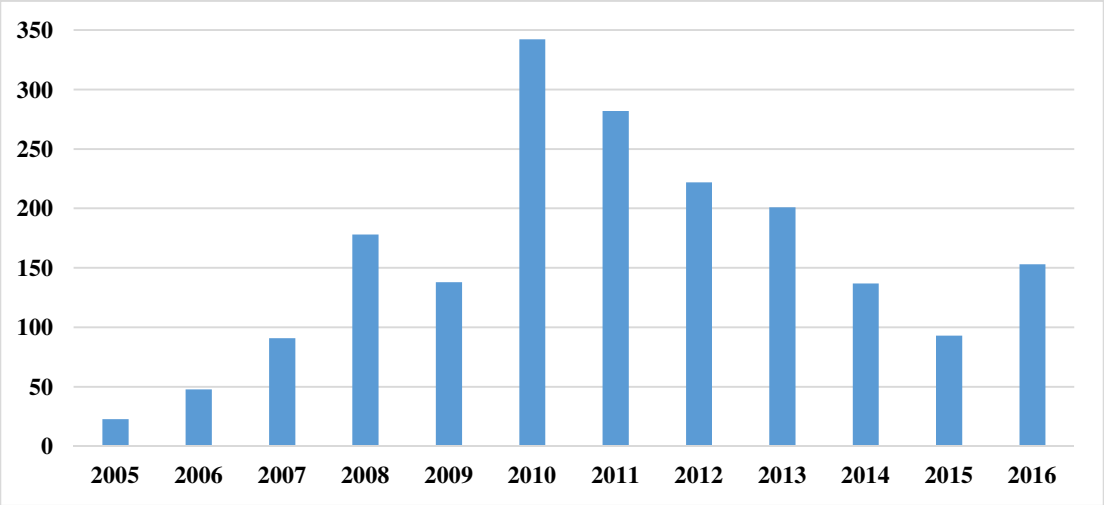

Figure 7: Invention patenting applications registered by Romanian universities

Source Authors, by using OSIM data (2017b)

The situation presented by OSIM regarding patent applications registered in 2007-2016 by the 37 universities from Romania with contributions in this field is presented in table 2.

Source Data processed by authors from OSIM statistics (2017a)

A single patent was required by the Land Forces Academy "Nicolae Balcescu" and the University of Medicine and Pharmacy of Târgu Mureș, while the first positions are occupied by Ștefan cel Mare University of Suceava, Transilvania University of Brașov and Gh. Asachi University of Iasi, with 515, 191, respectively 178 registered applications (Figure 8)

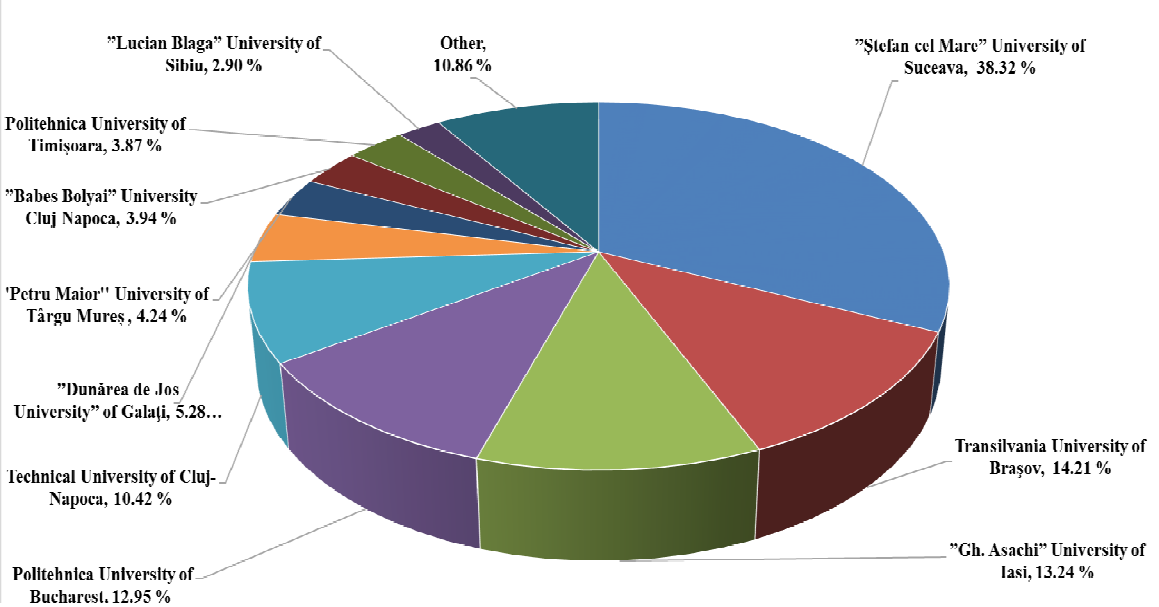

Figure 8: Patents application registered to OSIM, shares by university

Source Author, by using OSIM Data (2017a)

In fact, the first 10 universities, hierarchically ranked according to the number of registered patent applications, accounted for almost 90% of the total number of university patent registrations at national level. Engineering sciences, represented by technical universities, are the best represented in the statistics presented, the last positions being the military and medical fields.

Conclusion

Innovation and patenting of scientific research results is a priority at the European level, which has sought to maintain a leading position at international level and to reduce the gap towards the main competitors on the global patent market. Europe ranks the 5th among the patents registered to EPO, Germany being among the top 10 in the world. Romania holds modest positions at European and international level as number of patents registered, partly due to the high costs imposed by the registration and validation procedures. At national level, most patents are acquired by individuals, followed by research institutes, companies, and universities. The number of patents owned by individuals registered in the national database exceeds the cumulative value of patents validated for legal entities. The national legislation is correlated with the European rules, Romania being part of the main agreements and international treaties in the field of intellectual property.National economic growth can be sustained only by accelerating the national innovation process at national level and increasing the number of patents registered to OSIM and internationally recognized. The support for Romanian inventors should be carried out at national level through governmental measures to support RDI, both on public and on private level.

Improving Students' Self-directed Learning Outcomes on Mechanics Subject by Using E-Learning

Vina Serevina, State University of Jakarta, Jakarta, Indonesia, vina.serevina77@gmail.com, vserevina@unj.ac.id,

Abstract

This study aims to improve learners' self-learning outcomes on mechanics subject using E-Learning. The research method used was Miles and Huberman action research. Objects in this study were amounted to 31 students in the physics education program of State University of Jakarta. The research instruments used multiple choice questions and self-study learner questionnaire. The result of this research showed the effectiveness of E-learning on mechanics subject were obtained N-gain equal to score 0,818, so it was in very high category and there were increasing score of students' self-directed learning outcomes. In addition, the results of self-directed learning questionnaires were showed by aspect of the initiative with score 85%, own effort aspect with score 88% and aspect of responsibility with score 97%. The result of this study showed the improvement of students' self-directed learning outcomes on mechanics subject using E-learning.

Keywords: Improving Students' Self-directed learning outcomes, E-Learning.

Introduction

Technology development in globalization era is growing so fast. All sectors, including education, were demanded to be integrated with technology in order to produce competitive human resources (Kompas, 2012). Meanwhile, the development of information and communication technology in education has triggered a shift from face to face conventional learning to e-learning which can be accessed from any computers with no limitations. Along with the effects of globalization, education will be more open and two way, diverse, multi discipliner and related to competitive productivity (Kompas, 2014). Learning outcomes are the abilities of the students after they received a learning experience (Serevina, 2017).

In Antara News.com with topic Indonesia X and UNPAD release free online course explained that Indonesia X with State University of Padjadjaran (UNPAD) provide *Massive Open Online Courses* (MOOC) which gives free online course access for everyone in all over Indonesia. Free online course in indonesiax.co.id aims to democtratize education in Indonesia so that everyone, everywhere in Indonesia can be attended (Antara News, 2016).

Previous research by Maha Bali (Maha Bali, 2015) stated that cMOOCs gives opportunity to its participant to create a good collaboration which can help them to practice and develop skill in digital era.

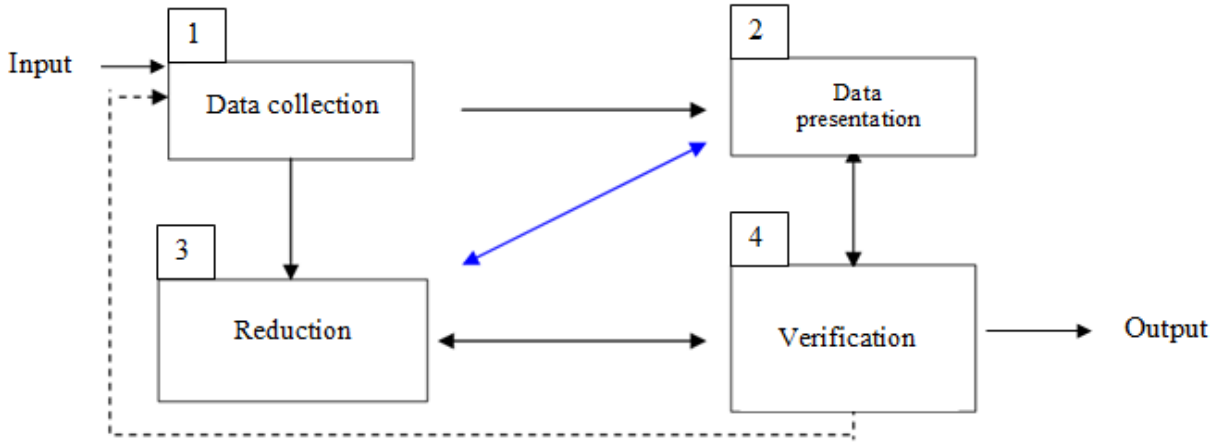
cMOOCs can survive because of participant transformation to build connection between participants. Whereas, this research will focus on cMOOCs web based multimedia development and limited to basic mechanics subject.

Meanwhile, in research about *cMOOCS And Global Learning: An Authentic Alternative* (Carol Yeager, 2014) explained that cMOOCs can be used as media to explore and develop knowledge, skill, and individual behavior through provided contents and also can be used as place to build connection through discussion forum.

In a research study by Kristina (Kristina, 2014) concluded that students participation in cMOOCs based e-learning encouraged students to develop self-ability and improved their motivation. cMOOCs also demands students to be more active in activity and collaborating with other participants in order to achieve their goals.

Observation result also showed that Open University in Indonesia has provided several certified online course materials in moocs.ut.ac.id. Those materials are introduction to moodle 2.9, parenting, and marketing management. Basic mechanics has not been available in the following web. So the topic in this research choose mechanics subject.

The result of questionnaire through google form which was given to 64 respondents from universities in Indonesia was 57.1% stated that their lecturers have already used online instructional media while 52.45% have not yet. Those online instructional media were website which provide pdf file while video or animation were not provided in those website. Discussion forum and certificate of graduation have not provided in those website either. However there were exercise questions to evaluate students learning outcomes.

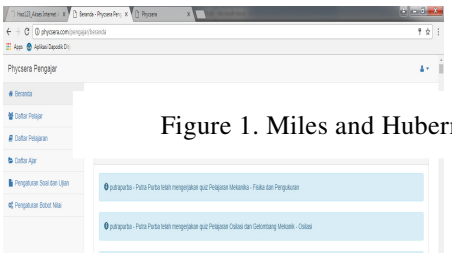


About 82,8% of respondents also stated that cMOOCs web has not already used as instructional media in their respective universities and 93.8% stated that the development of cMOOCs web based instructional media was necessary. Respondents were used to use gadget such as laptop or personal computer to access information with internet and 92.2% agreed that instructional media can encourage them to do a self-directed learning.

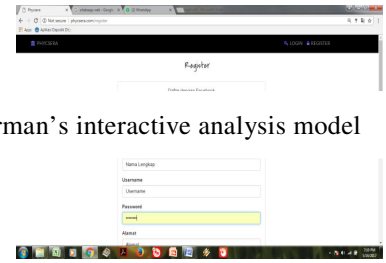
Based on argumentations above, this research about Improving Students' Self-directed Learning Outcomes on Mechanics Subject by Using E-Learning was done.

Research Method

Method used in this research was Miles and Huberman action research with steps as following (Miles & Huberman, 1994):



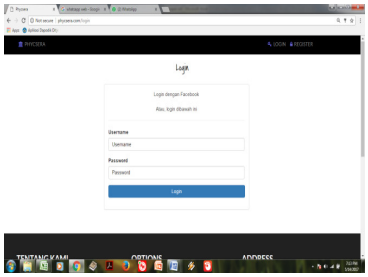
1) Data collection (secondary data, interview data, and event data)
2) Data presentation (pretest, mechanics subject learningusing e-learning E-learning and posttest)
3) Reduction / Exploration (collecting data based on research focus)
4) Verification / Member check: (analyzing focus to become more specific component)



Instruments used in this research were mechanics multiple choice questions which is consists of oscillation, mechanical wave and thermodynamics and students' self-directed learning questionnaire. Questions were validated using point biserial formula and KR 20/21 to calculate its reliability (Widiyanto, 2014). Questions were used to find if there was an improvement of students' self-directed learning outcomes. Questionnaire was used to rate students' initiative, self-efforts, and responsibility.

Result and Discussion

1. Data collection was done by taking secondary data, interview data and event data as follows:



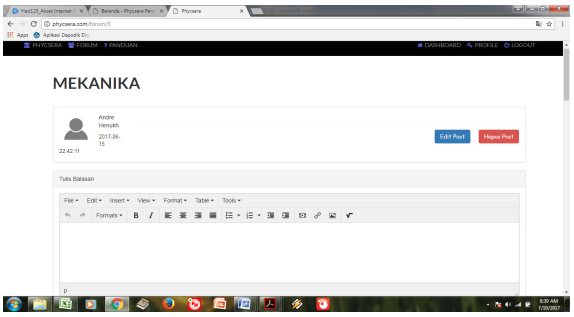


Figure 1. Miles and Huberman's interactive analysis model

Figure 2. Home of Web cMOOCs **Figure 3. a. Register** **b. Login**

2. Data presentation: Mechanics Subject

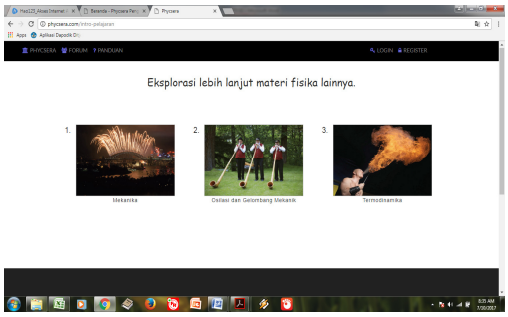

Figure 4a. Mechanics Subject Figure 4b. Mechanics Materials

3. Reduction of data was done by validating pretest and posttest questions.
   Validity and reliability test were done with results as follows:

a. Description of instruments' validity test.
   Validation of self-learning outcomes instrument was done by using point biserial formula at significance level of 5% for 31 respondents, obtained r table = 0.355. According to calculation, from 30 questions of mechanics subject only 20 questions considered valid; for oscillation and mechanical wave, from 20 questions, 14 questions were considered valid. Those valid questions were used as data collection instrument.
b. Description of instruments' reliability test.
   Reliability test used KR-20/21 formula. The result of reliability test were: 0.91 for mechanics questions, 0.91 for oscillation and mechanical wave questions, and 0.95for thermodynamics

questions. Those results were interpreted as a very high category. According to Widiyanto, instruments were considered to have a high reliability if its reliability coefficient is between 0.8-1.0 (Widiyanto, 2014). At significance level of 5% for 31 respondents, r table was obtained by 0.355 (Sugiyono, 2015).
According to calculation instruments used for data collection were valid and reliable.

4. Verification was done by analyzing pretest and posttest results.
Data verification was done in two ways, by data triangulation and N-gain test. N-gain is difference between posttest result and pretest result. N-gain indicated students' improvements after learning is done (Hake, 1999).

$$g = \frac{S_{post} - S_{pre}}{S_{max} - S_{pre}}$$

S_{post} is posttest score, S_{pre} is pretest score and S_{max} is maximum score of test. N-gain classifications are: (1) if $g \geq 0,7$, N-gain is in high category; (2) if $0,7 > g \geq 0,3$, N-gain is in good category; and (3) if $g < 0,3$ N-gain is in low category. According to calculation from 31 students who followed mechanics subject lecture, obtained N-gain = 0.818 and considered to be in high category.

Table 1: Test results

No	Test results		
	Pretest	Posttest	Max Score
1	45	88	100
2	40	90	100
3	30	93	100
4	45	85	100
5	30	88	100
6	30	86	100
7	40	83	100
8	25	88	100
9	45	88	100
10	35	93	100
11	40	92	100
12	25	93	100
13	30	86	100
14	25	92	100
15	45	85	100
16	45	87	100
17	20	96	100
18	30	86	100
19	40	84	100
20	35	90	100
21	55	88	100

No	Test results		
	Pretest	Posttest	Max Score
22	40	91	100
23	45	91	100
24	35	85	100
25	40	93	100
26	35	72	100
27	40	83	100
28	15	90	100
29	40	90	100
30	30	86	100
31	35	94	100
Total	1110	2739	3100
N-gain= 0.818			

Figure 5.a. Pre-Test (without E-Learning).

Figure b. & c. Post-Test (After with E-Learning)

Pretest and posttest result of students indicated that there was an improvement of students self-directed learning from E-learning usage.

Then, questionnaire was also used to find students initiative, self-efforts and responsibility. Questionnaire referred to Likert scale interval. Likert scale is used to measure behavior, opinion, and perception about social issue or phenomena (Riduwan, 2007). Obtained data then interpreted as follows:

Table 2: Likert scale (Sugiono, 2013)

Average Score	Interpretation
0%-20%	Very Bad
21%-40%	Bad
41%-60%	Enough
61%-80%	Good
81%-100%	Very Good

Questionnaire result is shown in figure 6.

Figure 6: Questionnaire result

According to graph above, initiative aspects reached score 85%, self-effort aspect 88% and responsibility 97%. The result of this three aspects were in very good category.

Djoko (Djoko Rahardjo, 2016) concluded that with maximum effort in searching of information will help student to reach their learning goal. Then, the result of aspects of initiative, self-effort and responsibility in this research equal to previous research.

Figure 7 : Students answer questionnaire

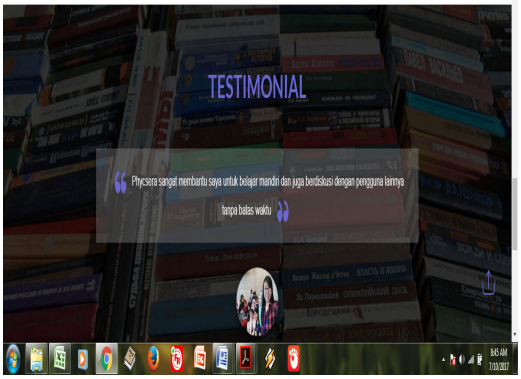

Figure 8 : Testimonial

Conclusion

According to assesment result of e-learning's effectivity, obtained N-gain= 0,818 (high category). This result indicated the improvement of students' self-directed learning outcomes. Questionnaire showed students' initiative score by 85%, self-effort by 85% and responsibility by 97%. So that, can be concluded that there was improvement of students' self-directed learning outcomes in mechanics subject using E-learning.

Combatting Tax Evasions

Darina Saxunova, Faculty of Management, Comenius University in Bratislava, Slovakia,
Darina.Saxunova@fm.uniba.sk

Rita Szarkova, Faculty of Management, Comenius University in Bratislava, Slovakia,
Rita.Szarkova@fm.uniba.sk

Abstract

Tax evasion is a threat to the society, the states and international organizations have been making an effort to combat negative phenomena associated with taxation, the tax evasion or tax fraud. Tax evasion represents a serious problem of each economy. It has a negative effect on the state budget and on the situation of public finances. The research object of a submitted paper is a tax evasion as a phenomenon that must be tackled and combatted. The primary goal of the paper is to focus on the connotation of the basic terms related to the tax evasions, to study in details their characteristics and definitions, highlighting the factors influencing remarkably occurrence of these phenomena. This scientific paper focuses on the tax evasion evolution, defining categories of the phenomena in this area sometimes resulting in tax fraud occurence. In addition, the strategies to detect potential tax evasion are highlighted to demonstrate governments' efforts worldwide, their being keen on stopping or minimasing negative consequences of tax frauds. No doubts about negative impacts of tax fraud and tax evasion to the national budgets. The countries and international organizations strive to combat the tax evasion or tax fraud, these issues are the main challenges of international tax agenda worlwide. Speculative businessmen could be found everywhere. Moreover, the partial, illustrative empirical research using the information from databases of big auditing commpanies is proving the relevance of tax issues that should be solved without no deferral.

Keywords: tax evasion, tax haven, tax fraud, controlled foreign companies legislation

Introduction

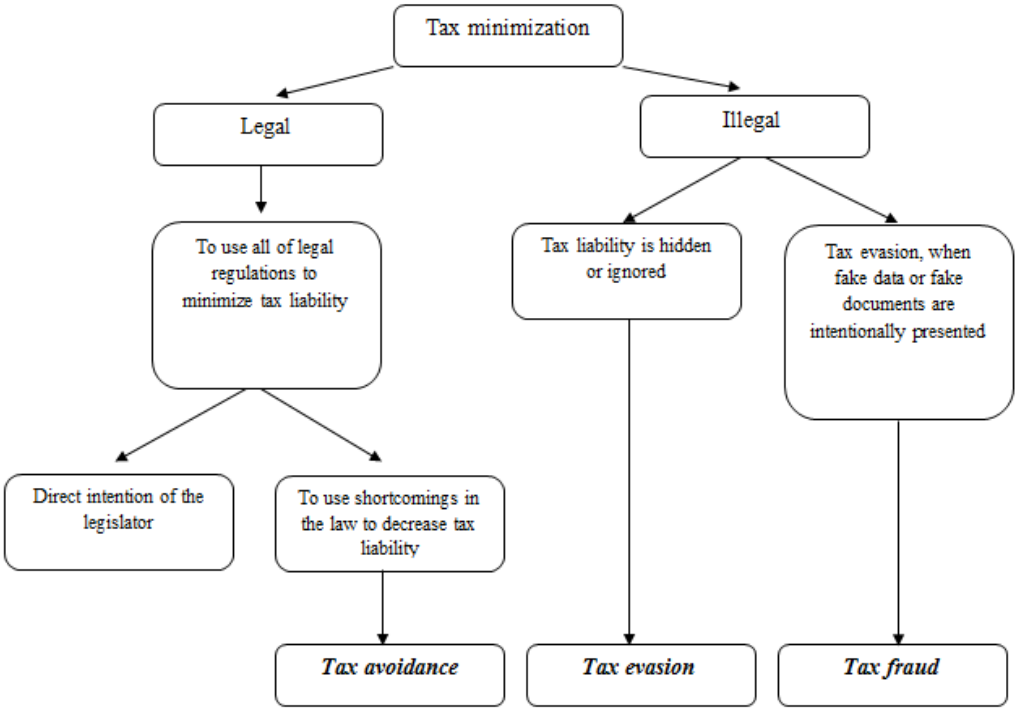
Individuals or entreprising entities have been levied taxes over centuries by a sovereign power. The resources were always necessary to fill in the state treasury, even deeply back to the era where they were not called taxes yet. There has always been a big dilemma on one side people would rather not pay taxes but on the other side they require high quality of public services ensured. People with common sense know everything costs something. Governments provide public services which companies in the market do not provide, because they are not economical for them, such as building roads, provide health care, legal system, security for the people, education for the people. To fund public expenditures requires a lot of capital and people would not be ready to contribute and pay for these services when they are needed so the states impose various fees and taxes. On the other hand, there always has been unwillingness to pay taxes or various fees. What is the reason why taxpayers are constantly looking for new ways to avoid taxation or at least to reduce the amount of tax liability? Tax evasion represents a serious problem of each economy. It has a negative effect on the state budget and on the situation of public finances. There is a big dilemma on one side people would rather not pay taxes but on the other side they require high quality of public services ensured. People with common sense know everything costs something. Why don't we want to avoid paying the taxes? The world is full of news that big corporation do not pay taxes but people who work hard every day, their tax is immediately reduced from their salary. Why this cannot be done also to big corporations, many ask. Nowadays, transparency where the money from the taxpayers go is the highest priority.

Objectives and Methodology

The objective of this scientific paper is a) to identify existing trends in the area of tax evasions and tax fraud in the theoretical focus and strategies and forms of tax evasion combatting. Comparison, analysis and synthesis, deduction as scientific methods were applied. No doubt when is business environment analysed or evaluated, tax system of the state should not be ignored, what strategies are implemented to protect state budget before the tax losses, in the practical level the analysis of selected countries – Slovakia, the Czech Republic, Hungary and Bulgaria were studied and analysed and empirical results are presented covering 2 recent years 2014 and 2016. The data of this economic crime started to be collected only recently therefore some data were obtained from the OECD database and from the research data of the auditing company PriceWatersCoopers, etc.

Literature Review

Tax evasion is a very old idea. The oldest evidences that confirm the existence of tax evasion are tax mutinies, first reported by ancient historians. The economic theory of a tax evasion is not as old as the phenomenon itself. According to Sandmo (2005), the beginning of the theoretical concept of tax evasion from the perspective of practitioners´ experience and theoreticians´ ideas can be dated to 1972. In this year, the first scientific paper about tax evasion was published, "Income Tax Evasion: A Theoretical Analysis" by Allingham and Sandmo.Tax evasion is defined by The European Commission as a phenomenon which "generally comprises illegal arrangements where tax liability is hidden or ignored, i.e. the taxpayer pays less tax than he/she is supposed to pay under the law by hiding income or information from the tax authorities". (EC – Taxation and Customs Union, 2017). Nowadays, a large number of domestic and foreign literature exists which deals with the topic of tax evasion and tax fraud. (Hayoz and Hug, 2007), (Gravelle, 2015), (Brown, 2011), (Tooma, 2008), (Murray, 2012). According to Webley et al. (2010) it is an old, but constantly developing issue. Beck, Lin and Ma (2014) are looking for the answer to the question: Why are companies constantly trying to avoid taxing? Other researchers are looking for new ways to reduce (Alm, 2012), (Piolatto, 2014) and measure tax evasion (Mo, 2013). There is an effort to compile different models for measuring, analysing tax evasion by applying various factors (Spicer, 1986), (Xiao, Liu and Lai, 2014), (Seidel a Thum, 2016). Thakur (2013) describes how to detect tax evasion by shares and how to catch fraudsters. Mawejje and Okunu (2016) examine the interaction between different indicators of the current business environment and tax evasion. Li and Ma (2015) focus on the relationship between the government and tax evasion.



The term of ***tax evasion*** is often used by the general public or in academic environment, but to find its general definition is difficult. Faltová (2015) found out that the common element of all definition of tax evasion was the illegality. Aleš (2000) writes that tax evasion is a failure of tax liability. The concept of tax evasion (Boháč, 2015) can be understood as a situation in which the tax is not determined in accordance with the law. The result of mentioned situation is a difference between the amount of tax payable and the amount of tax paid. The amount of tax paid by the taxpayer is lower than the amount stated by the law. On the other hand, Lenártová (2000) defines tax evasion as a result of targeted, legal or illegal, economic behaviour of a taxpayer, which leads to the reduction or elimination of tax liability or to other economic benefit resulting from taxes.

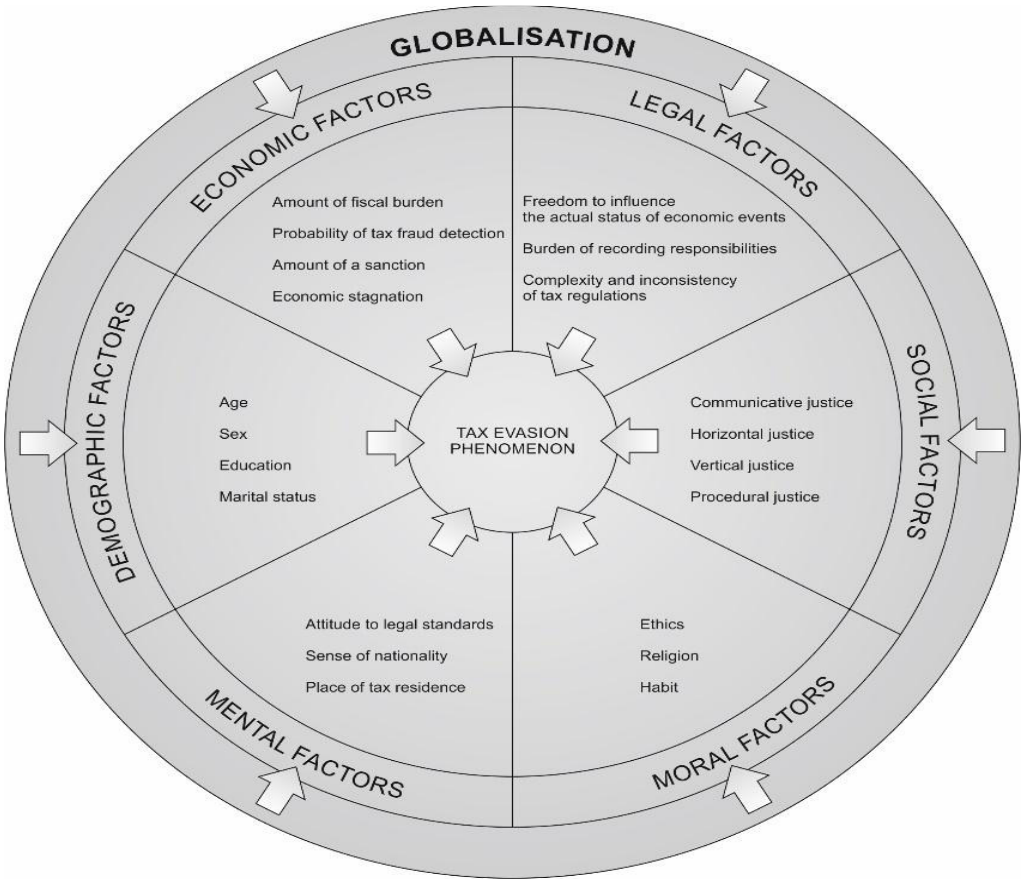
In this context, foreign literature uses terms of "Tax evasion" and "Tax avoidance". Experts characterize "Tax evasion" as a type of tax fraud activities for which taxable entity can be sanctioned. The form of sanction depends on the extent of tax reduction, the amount of tax not paid and also whether or not the intention of tax elimination was demonstrated. Tax evasion can also occur on the basis of ordinary ignorance, lack of information or negligence. The constantly changing tax laws and regulations contribute to the disruption of legal certainty and to unintentional misconduct of the taxpayer.

Tax evasion and tax avoidance

The topic of tax evasion is a very actual problem of our society. People and organizations all over the world strive to find methods for detecting and reducing tax evasions. The crucial question frequently raised is what tax evasion means and what a variety of tax evasion cases may exist. Tax evasion is characterized as the result of the economic behaviour of taxpayers, considered as a leakage of tax liability. Tax avoidance is considered as a legal tax optimization, when a taxable entity applies all legal provisions to minimize the amount of his tax liability. It is actually a tax evasion while the taxable person uses all the legal options. The taxable entity can apply all statutory exceptions, exemptions, tax reliefs, discounts, depreciation, joint taxation of husband and wife, standard or percentage expenses of income and reserves directly and intentionally settled in the legislation. Legal tax optimization can include the usage of gaps in law and regulations. For example in the case of the division of a trading company into smaller business units it is possible to avoid of higher tax rate, if progressive taxation is applied. "Schwarz system" is another way to achieve legal tax benefits. Schwarz system means hiring workers based on their business license instead of employment contract. (Faltová, 2015)

Illustration 1: The types of tax minimization

Source: Own elaboration based on (Krestesová and Rezek, 2013)



On behalf of the Ministry of Finance of the Czech Republic, Krestesová and Rezek (2013) drew up a scheme which helps to explain inconsistencies in the definitions of the terms in connection with tax evasion. The scheme showed and explained the terms used only in Slovak and Czech terminology and did not take into account the definitions presented by experts around the world. The new schema prepared by the authors of this paper shows different perspectives on the definition of tax minimization. The European Commission (EC – Taxation and Customs Union, 2017) clarified the concepts of the three most important phenomena that form the basis of our topic:

- ***Tax Fraud*** – "is a form of deliberate evasion of tax which is generally punishable under criminal law. The term includes situations in which deliberately false statements are submitted or fake documents are produced"
- ***Tax Evasion*** – "generally comprises illegal arrangements where tax liability is hidden or ignored, i.e. the taxpayer pays less tax than he/she is supposed to pay under the law by hiding income or information from the tax authorities"
- ***Tax Avoidance*** – "is defined as acting within the law, sometimes at the edge of legality, to minimise or eliminate tax that would otherwise be legally owed. It often involves exploiting the strict letter of the law, loopholes and mismatches to obtain a tax advantage that was not originally intended by the legislation".

Determinants of Tax Evasion

Tax evasion is affected by a number of different factors that have a strong impact on them due to globalization. Ciupek (2015) in her publication describes the causes of tax evasion from income tax, in six areas (see illustration 2):

Illustration 2: Determinants of Tax Evasion

Adapted from Ciupek (2015, 84)

- Economic factors – financial and economic situation of a taxable entity, general business conditions, the amount of tax burden, the probability of the detection of tax evasion, the amount of sanctions, business stagnation

- Legal factors – distrust in the state and in public institutions, freedom to influence the actual status of economic events, burdensome nature of recording responsibilities, complexity and inconsistency of tax regulations
- Social factors – exchange-related justice connected with tax payments and tax benefits, horizontal, vertical and procedural justice
- Demographic factors – age, gender, education, marital status
- Mental and moral factors – attitude to civil obligations, attitude to taxation

Lenártová (2000) in her scientific paper also examines the determinants of tax evasion, where she lists the following group of factors: economic, legal, socio-political, tax-technical, psychological, ethical and social factors.

Both researchers Ciupek (2015) and Lenartova (2000) identified as the reason of tax evasions financial and economic situation of the state, the amount of tax burden levied on the soleproprietors and corporations. After the financial crisis in 2008 a lot of countries in the European Union struggled to achieve any economic growth, governments in the CEE block wanted (belonging to the developing countries or in transition towards developed contries) to attract investors and FDI to support development and economic growth also by attractive tax rates. Simple generalisation offers the idea the idea of researching the countries that have a common, historical development bacground (Austrian –Hungarian monarchy) (Czech Republik, Slovakia and Hungary were the parts of the monarchy and we assumed a common mental and moral factors – attitude to civil obligations, attitude to taxation for these states would be similar and we have also selected the state with the lowest tax rates, and another criterium of the choice that rates should be aroung the average of the EU (around 20%, what is sufficiently low and the enterprising community should be assumed to pay taxes and tax fraud is assumed shold not be a threat for them. Which was not complitely n accordance with our assumption. Because Hungarians show the highest percentage of tax fraud and the tax rates are low.

Table 1: Tax rates after the financial crisis in a selected countries of the CEE

Tax rates (TR)	FO % PO %	FO % PO %	FO % PO%
	2010	2014	2015
BG Bulgaria	10,0 10,0	10,0 10,0	10,0 10,0
CZ Czech Rep.	15,0 19,0	22,0 19,0	22,0 19,0

Tax Fraud in Slovakia, the Czech Republic, Hungary, Bulgaria and in the CEE

PricewaterhouseCoopers examined economic crime in the countries around the world. Table 1 shows that tax fraud in the analysed countries reaches higher results than in the global environment. The number of respondents in Slovakia who had registered tax fraud in their environments in 2016 (11%) was higher by 75% than in 2014 (4%). This number in the Czech Republic is much higher than in Slovakia. According to respondents, the appearance of tax fraud in the Czech Republic from 2014 to 2016 increased by 100%. While Slovakia and the Czech Republic record an increase in the number of tax fraud cases, Hungary and Bulgaria registered a decline. In 2014, the number of respondents in Hungary who registered tax fraud in their environment during the analysed period was 25%. In 2016 it was only 21%. A decrease has been also noticed in Bulgaria, where the amount declined from 10%

to 7%. In 2016, Slovakia (7%) and Bulgaria (7%) showed lower values of tax fraud appearance than the CEE average (11%), while the survey´s results in Hungary (21%) and the Czech Republic (14%) exceed the CEE average. This information started to be collected recently, the simple comparision of selected countries and the CEE is conducted with the future prospects for a deeper research.

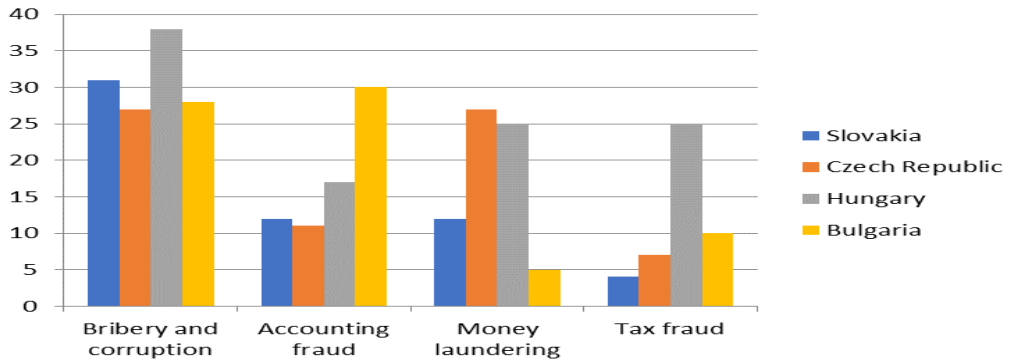

Table 2: Tax Fraud as Economic Crime: Slovakia, Czech Republic, Hungary, Bulgaria and the CEE.

In percentage [%]	Slovakia		Czech Rep.		Hungary		Bulgaria		CEE
	2014	2016	2014	2016	2014	2016	2014	2016	2016

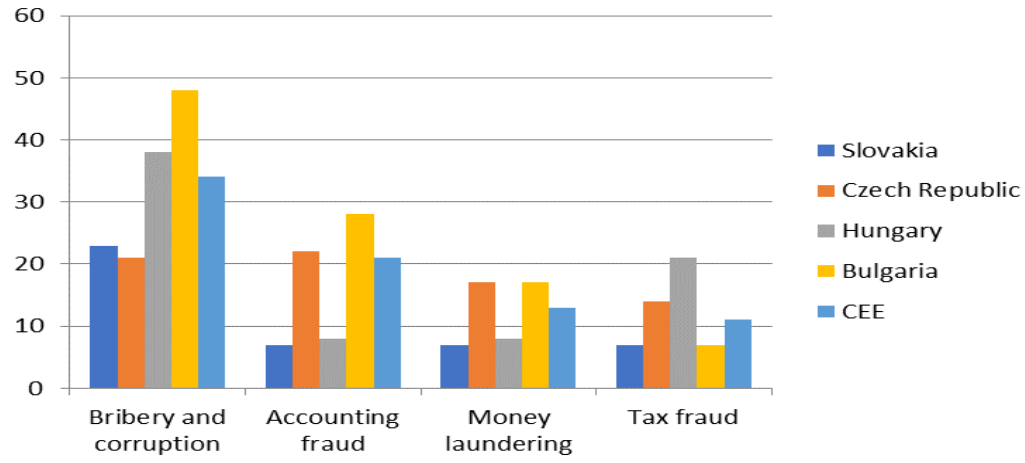
Illustration 3 compares the appearance of tax fraud and related economic crimes in Slovakia, the Czech Republic, Hungary and Bulgaria in 2014. Bribery and corruption were in the first place. In all the analysed countries, more than 25% of respondents met this type of economic crime in their business environment during the analysed period.

Illustration 3: Economic Crime in 2014



Source: Own elaboration based on (PwC, 2014b), (PwC, 2014c), (PwC, 2014d) and (PwC, 2014e)

Hungary reported much higher results as other countries - 38%. Slovakia and the Czech Republic showed the same level of accounting fraud occurence. This type of economic crime was the highest (30%) in Bulgaria. Money laundering was the most common in the Czech Republic and Hungary, while in tax fraud Hungary outran all the other analysed countries.

Illustration 4 compares the appearance of tax fraud and related economic crimes in Slovakia, the Czech Republic, Hungary and Bulgaria in 2016. Bribery and corruption were still in the first place. Slovakia and the Czech Republic had the lowest level of corruption, Hungary reported similar results as the CEE average. Bulgaria´s survey results transcend values in analysed countries. Slovakia and Hungary were on the same level in the occurrence of accounting fraud. This type of economic crime was the highest (30%) in Bulgaria, higher than the CEE average (21%). Money laundering was the most common in the Czech Republic and Bulgaria, while in tax fraud Hungary still outran all the other analysed countries.

Illustration 4: Economic Crime in 2016

Source: Own elaboration based on (PwC, 2016 a-e)

Bribery and corruption is very frequently defined as abuses of power by people in positions of authority. They're still going strong: it's estimated that more than US$1 trillion is paid each year in bribes globally, and that US$2.6 trillion is lost to corruption. That's 5% of global GDP – and the true figure is probably even higher. (PwC, 2016). Politicians in many countries with their political scandals related to the economic crime does not motivate businesses to behave ethically, but by this push away honest investors who look for stability and sustainability. If politicians cover the accounting or tax fraud because they may be involved as well, the public and ethical businesses have the only chance to start fight against these negative phenomena, and support and elect people who are moral and ethical and they really protect taxpayor's capital resources by accepting a suitable laws and legislation. The health business environment plays an important role for entrepreneurialship and combatting negative phenomena as economic crime, fraud, no possibility of law enforcement , etc. (Peracek, Noskova and Mucha, 2017). What steps have already been executed or strategically planned to combat e.g. tax evasions the following paragraph is dealing with.

Objectives and Strategies of Combatting Tax Evasion

Tax evasion limits countries in the implementation of their economic policy. It also represents a problem from the justice´s perspective. Countries, states, as well as the European Union, try to combat this phenomenon, analyse its range and to accept necessary actions to detect tax evasion and reduce the leakage. The biggest problem is that the evolution of tax evasion is faster than the actual regulation of legislation. The fight against tax evasion is undoubtedly a very actual, complex and sensitive issue at the same time. The goals of this fight are the efficient tax collection with unchanged tax rates, to discourage taxpayers from illegal actions and from using tax optimalization. The fight against tax evasion involves individual states, the European Union, as well as other international organizations. It can be successful only if all states and organizations join their forces and fight together against fraudsters. Actions to combat tax evasion are implemented at three levels: national level, EU level and international level. (Huba, Sábo and Štrkolec, 2016)

Table 2: Goals of the figth against tax evasion at national, EU and international level

Level	Goals
National level	Tax fraud elimination in indirect taxes Improve tax information exchange Eliminate the abuse of double taxation acts Fight against various forms of tax planning
EU level	Streamline information exchange between the EU and the member states Streamline income taxing from cross-border savings Cooperate in the field of taxation and in the fight against fraud Streighten the fight against not using double taxation in the area of hybrid structures Create a platform for taxation Improve administrative cooperation in the field of direct taxation Standardize information exchange
International level	Identify tax issues of the digital economy Neutralize the action of hybrid structures Strengthen the rules of controlled foreign companies Limit the tax base reduction through interest deduction and financial payments Streamline the fight against harmful tax practices with regard to transparency Eliminate the abuse of double taxation acts Create methodology for collecting and analyzing data on taxbase and profit shifting erosion Require taxpayers to publish their aggressive tax planning structures Explore the transfer pricing documentation Streamline mechanisms for conflict solution

Source: Own elaboration based on (Huba, Sábo and Štrkolec, 2016)

States, countries worldwide have recognized the need of the action adoption to combat tax evasion. These actions can be divided into two groups. The first group is created by the actions that have developed within the decision-making process of the general courts and they have the nature of criteria. These criteria are marked as tax doctrines. The second group is characterized as actions that have been adopted under an individual legislation. **General anti avoidance rule** (GAAR) has been introduced as a statutory action designed for the fight against tax evasion. It is defined as **a set of rules based on individual general principles existing in the national tax rules** and which are modeled to combat tax evasion. GAAR is a concept in the tax code which allows the tax authorities to deny taxpayers the right to recognize tax advantage. The goal of GAAR is also to penalize actions and transactions that may create a situation of illegal tax evasion. GAAR has been introduced as a statutory action designed for the fight against tax evasion. (Sábo, 2015). Generally, strategies to detect aggressive tax planning schemes can be divided into 5 main categories:

a) Disclosure and Reporting – taxpayers or third parties provide relevant information to the tax authorities. Initiatives proved to be useful for this strategy are special reporting obligation on losses, manadatory disclosure rules, ruling and co-operative compliance programs.
b) Investigations and audits – the tax administration itself seeks to detect relevant information by using its investigative powers.
c) Domestic and international cooperation – strategies that seek to build on information held either by government departments or that involve co-operation with the tax administration of another country.
d) Data analysis – strategies that seek to make the best use of internal tax administration information or external public data. The success of data analysis is dependant on the volume and quality of data available to the tax administration and how good they are at analysing, comparing, processing data and interpreting the information obtained to produce meaningful results.
e) Other detection strategies

Participating countries that have developed business models aimed at improving tax risk management and compliance by large business taxpayers through greater cooperation in Australia, Ireland, Italy, The Netherlands, New Zealand, Spain, Sweden, The United Kingdom and the USA. (OECD, 2016).

Novackova (2017) and her team studied tax havens and they state that tax havens are a big attraction for multinational companies to be utilised as international tax planning scheme, therefore they are in the focus of government tax policy initiatives. (Milosevicova, Novackova a Wefersova, 2017). Anti-haven legislation is introduced in many countries to protect their domestic tax base. There are some means how to control abusing tax haven for this purpose: such as a) pressure from supranational bodies for example the OECD, the EU threatens tax havens by imposing economic and trade sanctions on them; b) transfer pricing rules – they do not apply to arm's-length transactions, therefore no all forms of haven abuse are tackled, c) company residence rules- governments have been failing over years to define adequately entity's residence for tax purposes which caused that the tax haven abuse may be exercised, d) controlled foreign companies (CFC) legislation – the most effective method of eliminating deferral. The phrase controlled foreign company is used only in the meaning of a subsidiary resident in a country where it pays little or no tax. "Domestic shareholders of foreign companies must pay tax currently on their pro rata share of the income of the foreign company. Timing of the liability for domestic tax from the time of distribution of the foreign company's profits to its shareholders to the time at which it is derived by the foreign company is affected by CFC legislation. This legislation aims at bringing the timing forward." (Miller, Oats, 2016, p.567). How controlled foreign companies' CFC legislation is applied by the national government to a resident taxpayer the following scheme explains.

Table 3: CFC legislation

Resident shareholders' income	**Income generated by the subsidiary**	**Taxation is made ignoring**	**Usual tax rule is broken by the CFC country**
Will be taxed	Subsidiary is loca-ted in the tax haven	whether such income has been remitted to the shareholders' country of residence	Collection of independent entities instead of being treated as a multinational group of companies

Source: processed by authors

Miller and Oats (2016) state if the CFC legislation is applied to a resident taxpayer by a government, the tax is levied on the tax resident taxpayer as if the income had been earned by that tax payer.

25 years ago this American company, which owns 100% owned subsidiary in Anquilla, invented a patent for the mining industry. At that time the owners did not assume a real value of this intangible. The US company transferred the ownership title to Anquilla subsidiary for a minimal amout of USD. After years it has become a successful invention and it is licensed in the countries worldwide, earning company huge amount of royalties. The US is not able to tax the subsidiary on the royalty revenues not being resident in the USA and without any source of income in the USA. But government can impose the tax on the US company as if the US company received the royalties (which were received by the subsidiary). The company is taxed on all income generated by this subsidiary, albeit the US company has received any dividend, or interest from the Subsidiary in Anquilla. The application of CFC legislation prevents the US company to defer tax on the Anquila income until a dividend, interest is paid by Anquilla subsidiary. Because this deferral could be even indefinite. (meaning no payment ever to the USA from this Anquilla's income collected).

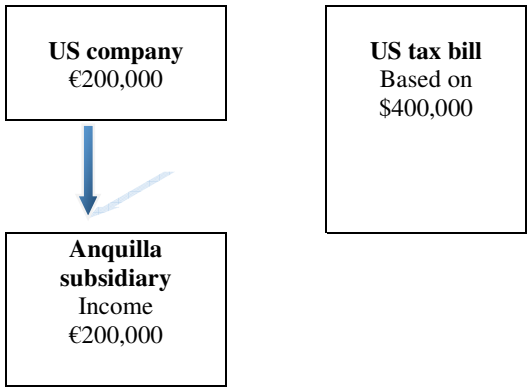


Figure 1: US company with 100% owned subsidiary in Cayman Islands

Source: Adapted by the authors based on the (Miller, Oats, 2016)

CFC legislation is usually focused on the resident shareholders' passive income of the foreign subsidiary (i.e. not on the trading earnings) with the purpose of taxing it. Passive income is derived from the financial investments and these are more likely to be transferred to the foreign subsidiary where they are taxed by the lower tax rate. It is a preferential treatment to transferring operations or business. The important arguments of advocates for relocating financial investments are two crucial points: price and complicated process of relocation, which is cheaper and less complicated compared to relocating factories and labour force.

Conclusion

While state authorities are trying to find a way to capture fraud and to adapt it to the legislation, tax entities already use new legal and illegal methods to avoid paying. Countries invest a lot of effort into interception tax evasion and tax fraud. Nevertheless, it is almost impossible to determine their size. PwC in its surveys has determined the size of the part what tax fraud presents in economic crimes. Analysis contains information about tax fraud as a part of economic crime from the global perspective, in Slovakia, Hungary, the Czech Republic and Bulgaria. According to the PwC survey, the highest tax fraud in the selected countries has been measured in Hungary. This area represents a large area of future research, an opportunity to look into the reasons of the phenomenon and how to fight against it.

Governmental and public concern over the tax practises of multinational gigants led to strenghtening the fight against the tax evasions and fraud. Especially NGOs are very active to push introduction of country by country financial reporting made by multinationals businesses (MNEs), especially disclosing earnings made and tax paid in each country where the MNEs do business. There are many aspects still not examined in this area of taxation, great opportunities for doing the research which, we all hope, will bring real successful results in the area of combatting the tax fcrimes.

Disclosure Practice and Perspectives of Notes to Financial Statements in Croatian Tourism Companies

Ivana Mamić Sačer, University of Zagreb, Faculty of Economics and Business, Zagreb, Croatia, imamic@efzg.hr

Ivana Pavić, University of Zagreb, Faculty of Economics and Business, Zagreb, Croatia, ipavic@efzg.hr

Ana Rep, University of Zagreb, Faculty of Economics and Business, Zagreb, Croatia, arep@efzg.hr

Abstract

Companies all over the world present their financial information in the financial statements. Notes to the financial statements are one of the principal financial statements and represent a valuable source of information for investors and other interested groups. Disclosure requirements for financial statements prepared under the International Financial Reporting Standards are set by the International Accounting Standards Board. According to the International Accounting Standard 1 Presentation of financial statements, the entities should disclose financial information either in the primary financial statements or in the notes to financial statements. Often, the preparers are not aware that they should make decision which information is significant and should be presented in detail and in doing this they need to exercise judgments. The practice has shown that over the time the notes has become very extensive. As a result, the process of finding relevant information has become very challenging for many financial statements users. In order to solve that problem, the International Accounting Standard Board published in March 2017 a Discussion Paper Disclosure Initiative—Principles of Disclosure to call for a discussion on the problems of the disclosure. The paper deals with theoretical discussion on actual problems arising from the disclosure of the notes to financial statements and the analysis of the notes in Croatian tourism companies has been done in order to examine actual disclosure practice in the companies. Finally, the perspectives of the notes disclosures are presented in the paper.

Keywords: notes to the financial statements; financial reporting; disclosure requirements; principles of disclosure

1. Introduction

There are a number of users interested in different kinds of information about a certain company. Financial reporting can provide a broad set of accounting information which is inevitable in business decision making process. Accounting information is a significant source of financial data needed for statistical purposes and many macroeconomic analyses. Financial data are presented in the form of principal financial statements - balance sheet, the statement of comprehensive income, the statement of changes in equity and cash flow statement. Additionally, financial and non-financial data can be found in the form of the notes to financial statements. The aim of the notes is to clarify financial information presented in the primary financial statements and provide necessary information for understanding financial position and business performance of a company. In order to satisfy the disclosure requirements, set by International Financial Reporting Standards (IFRS), the notes to financial statements have become very extensive. Very common critics on the notes topic indicate that the notes are so repetitive and it is difficult for investors to find the most important information (EY, 2014). Further, a

broad spectra of information presented in the notes is often the reason why investors are not able to "see the woods through the multitude of information trees" (IASB, 2016).

However, a quantity is not always the warranty of a quality. The information overload risk has been a subject of many discussions of standard setters (Paredes, 2013). In that context, the IFRS's standard setter the International Accounting Standards Board (IASB) "has observed there are three main concerns about information disclosed in financial statements: not enough relevant information; irrelevant information or disclosure overload; and poor communication of disclosures" (IASB, 2017). As a result of the Board's effort and the financial statements users' concern on the quality of disclosure, in March 2017 the Discussion Paper Disclosure Initiative—Principles of Disclosure (DP) has been published. The Initiative calls for a discussion on the problems of the disclosure.

The Board believes that the main problem of not appropriate disclosure is often behavioral and argues that entities sometimes apply disclosure requirements mechanically, using the IFRS requirements as a checklist for disclosures (IASB 2017). The preparers are not often aware that they should judge what information is relevant to the users of financial statements.

Considering that the financial statements disclosure is hot topic worldwide, the goals of the paper are to determine the principal theoretical requirements for the notes to financial statements set by the IFRS and to investigate the current state of notes disclosure for the companies in Croatian tourism sector. Finally, the paper covers the activities for the improvement of the notes to financial statements' quality with regard to possible changes.

The research methodology includes secondary research with the analysis of present IFRS requirements and active projects regarding disclosure in the notes. Other than that, the primary research of the current state on the notes to financial statements of the companies in tourism sector in the Republic of Croatia was made.

2. Theoretical Requirements for Notes to Financial Statements Set By International Financial Reporting Standards

International Accounting Standard 1 Presentation of Financial Statements prescribes the goal and basic content of the notes to financial statements. The most important issues about the notes required by IAS 1 are as follows:

- Notes should contain information which is addition to the information disclosed in the balance sheet, income statement, the statement of changes in equity and cash-flow statement but also the information that do not fulfill the requirements to be recognized in those statements;
- Management should explicitly state that financial statements are prepared under the IFRS;
- The content of the notes depends on the disclosures requirements from other standards and interpretations;
- There is information that can be presented either on the face of the main financial statements (balance sheet and others) or in the notes (for instance subclassifications of the line items presented);
- Information about the basis of preparation of the financial statements and the accounting policies used forms a part of the notes;
- Any additional information important for understanding other basic financial statements and not disclosed in other financial statements should be also disclosed in the notes;
- To be understandable and user friendly, the notes should be presented in a systematic manner, i.e cross-referenced to other financial statements;
- The following order of the notes are common:
  - a statement of compliance with IFRSs

  - a summary of significant accounting policies applied
  - supporting information for items presented on the face of other financial statements
  - other disclosures;
- "Information about the key assumptions concerning the future and other key sources of estimation uncertainty at the balance sheet date, that have a significant risk of causing a material adjustment to the carrying amounts of assets and liabilities within the next financial year" shall be a part of the notes;
- "The domicile and legal form of the entity, its country of incorporation and the address of its registered office (or principal place of business, if different from the registered office); a description of the nature of the entity's operations and its principal activities; and the name of the parent and the ultimate parent of the group" shall be disclosed in the notes provided not disclosed elsewhere;
- Along with its significant accounting policies or other notes, the judgments, apart from those involving estimations, that management has made in the process of applying the entity's accounting policies and that have the most significant effect on the amounts recognized in the financial statements shall be published in the notes;
- The notes also contain narrative descriptions;
- As in other financial statements, a line item that is not individually material is aggregated with other items in the notes and an item that is not sufficiently material to warrant separate presentation in those statements may warrant separate presentation in the notes (IAS 1).

Materiality concept is crucial for the notes. It is well known that material information is information which omitting or misstating could influence decisions that primary users make on the basis of financial information. Also, materiality is "an entity-specific aspect of relevance based on the nature and magnitude, or both, of the items to which the information relates in the context of an individual entity's financial report" (IASB, 2015). So, the content of the notes depends on management judgment "whether information could reasonably be expected to influence decisions that the users make on the basis of those financial statements" (IASB, 2015).

Additionally, the content of the notes depends on the application of separate IFRS, IAS and interpretations due to the fact that all of them prescribe the list of important information which should be disclosed in the notes.

3. Empirical Research of International Accounting Standard 1 Requirements' Application in Croatian Tourism Sector

Principal financial statements are primarily intended for external financial statements' users, so the requirements for their presentation are prescribed. In order to facilitate the understanding of financial statements to the users and to make comparisons between the financial statements of different entities, International Accounting Standard 1 Presentation of Financial Statements prescribes the basis for presentation of financial statements.

In order to obtain a more detailed insight into the compliance of financial statements with International Accounting Standard 1, a research of financial statements for financial year 2016 has been conducted for the selected companies from Croatian tourism sector. According to the data of Croatian Chamber of Economy, revenues from tourism in 2016 were count for 18.01 % of Croatian GDP. Since tourism has a major impact on the entire Croatian economy, all companies in hotel sector which issue shares on public market have been taken in the research sample. They account for 21.5 % of all entities whose shares are quoted on the Zagreb Stock Exchange. The research sample consists of 31 annual financial statements. Table 1 shows the selected entities taken in the research sample. The source of data was the Financial Agency, the Croatian agency to whom entities should deliver their annual financial statements. The main research objective was to determine whether the entities present their financial statements in accordance with IAS 1. Further, the research questions are set as follows: are the requirements from the International

Accounting Standards too demanding for the investigated companies and is there a reason for changing the standards in a way to simplify the requirements so the entities could be more productive and the financial statements more useful for decision making process.

There are a lot of presentation requirements for the notes to financial statements. However, for the purpose of this study certain requirements from IAS 1 have been tested. First, the order of the notes as it is prescribed under IAS 1 has been examined (IAS 1, 105):
(a) A statement of compliance with IFRSs;
(b) A summary of significant accounting policies applied;
(c) Supporting information for items presented on the face of the balance sheet, income statement, statement of changes in equity and cash-flow statement, in the order in which each statement and each line item is presented;
(d) Other disclosures, including:

(i) Contingent liabilities and unrecognized contractual commitments; and
(ii) Non-financial disclosures, e.g. the entity's financial risk management objectives and policies.

Table 2 shows how the observed companies in Croatian tourism sector meet the requests from the paragraph 105 of IAS 1.

Table 2: Presentation of the notes to financial statements

IAS 1, paragraph 105: An entity normally presents notes in the following order, to assist users to understand the financial statements and to compare them with financial statements of other entities:					
Entity	(a)	(b)	(c)	(d)	
				(i)	(ii)

According to paragraph 16 of IAS 1, all the entities taken into research have an explicit and unreserved statement in the notes that their financial statements comply with IFRSs. Most of the entities present the notes following the suggested order. The notes of four entities are not cross-referenced properly with primary financial statements (the order of the notes differs from the numbers in primary financial

statements). Since all of the entities belong to the same sector, it was expected that all of them are faced with the same types of risks. There is only one out of 31 entities that do not disclose the risks in the notes. While explaining some item the observed companies often apply the same wording which is a result of quoting the requirements from the Standards. For instance, in this part of the notes, the definition of litigation was quoted from IAS 37.

Paragraph 77 requires that an entity disclose, either in the balance sheet or in the notes, further subclassifications of the line items presented, classified in a manner appropriate to the entity's operations. The detail provided in subclassifications depends on the requirements of IFRSs and on the size, nature and function of the amounts involved (IAS 1, 78). According to the principle of materiality, one of the basic accounting principles, the entity should disaggregate the financial statements positions into separate categories according to their materiality with regard to other positions and the overall business. So, if the contribution of some financial statement position is not significant with regard to overall business, the entity is not obliged to disaggregate it in detail. The entity can present aggregated information in the balance sheet and income statement and do the subclassification in the notes to the financial statements. The disclosures vary for each item, for example (IAS 1, 75):

(a) Items of property, plant and equipment are disaggregated into classes in accordance with IAS 16;
(b) Receivables are disaggregated into amounts receivable from trade customers, receivables from related parties, prepayments and other amounts;
(c) Inventories are disaggregated, in accordance with IAS 2 Inventories, into classifications such as merchandise, production supplies, materials, and work in progress and finished goods;
(d) Provisions are disaggregated into provisions for employee benefits and other items; and
(e) Contributed equity and reserves are disaggregated into various classes, such as paid-in capital, share premium and reserves.

Table 3 shows the results related to the disclosure of property, plant, equipment, receivables, inventories, provisions, equity capital and reserves which are presented in the balance sheet or in the notes, or both.

Table 3: Disclosure of property, plant, equipment, receivables, inventories, provisions, equity capital and reserves

IAS 1, 75 An entity shall disclose, either in the statement of financial position or in the notes, further subclassifications of the line items presented, classified in a manner appropriate to the entity's operations. The disclosures vary for each item, for example:					
Entity	(a)	(b)	(c)	(d)	(e)

Source: created by the authors

Most entities do the disaggregation of the items of property, plant and equipment into classes in accordance with IAS 16 in the notes, while in the balance sheet they present only the synthesized information. All of the entities present synthesized information on receivables in the balance sheet, but in the notes to the financial statements they disaggregate it into amounts receivable from trade customers, receivables from related parties, prepayments, receivables for taxes, receivables from employees and other receivables. As the restaurants are a part of the hotels, the entities must have inventories, which are disaggregated, in accordance with IAS 2 Inventories, into classifications such as merchandise (food and beverages), production supplies, materials, small inventory and other inventories. Applying the principle of materiality, most entities do the disaggregation in the notes, rather than in the balance sheet, since the amounts of inventories are not significant. According to the IASs, an entity should record the provisions for employee benefits and other items, but not all of the entities record provisions. The ones which do so, mostly disclose it in the notes.

According to the paragraph 86, when items of income or expense are material, an entity shall disclose their nature and amount separately either in the income statement or statement of other comprehensive income or in the notes to the financial statements. The circumstances that would give rise to the separate disclosure of items of income and expense include (IAS 1, 87):

(a) Write-downs of inventories to net realizable value or of property, plant and equipment to recoverable amount, as well as reversals of such write-downs;
(b) Restructurings of the activities of an entity and reversals of any provisions for the costs of restructuring;
(c) Disposals of items of property, plant and equipment;
(d) Disposals of investments;
(e) Discontinued operations;
(f) Litigation settlements; and
(g) Other reversals of provisions.

The research results show that the entities rarely record the write-downs of inventories to net realizable value or of property to recoverable amount. The same is with the restructuring of the activities of an entity, disposals of investments and discounted operations, although several entities are in the process of the pre-settlement. More than 50 % of the entities are involved in a litigation over the ownership and division of lends, but not all of them record the provisions for litigations. The entities disclose that information in the notes, along with other provisions and sometimes also in the paragraph where they present contingent liabilities. Although an entity shall present an analysis of expenses recognized in profit or loss using a classification based on either their nature or their function within the entity, whichever provides information that is reliable and more relevant (IAS 1, 88), all the entities present the analysis of expenses using a classification based on their nature. Most of the entities have accumulated losses from previous periods in the balance sheet, so only two entities have distributed dividends to owners during the period of the FY 2016 based on the retained earnings from previous years and one entity which has the preference shares pays fixed dividend to their owners.

Based on the conducted research it can be concluded that IAS 1 consists of many disclosure requirements which the entity can disclose either in the primary financial statements or in the notes. The preparers are not often aware which information is relevant to the users of financial statements so they disclose the same information in the notes even they already disclosed it in other financial statement. Since the main purpose of the notes is to provide a more detailed insight into significant elements of other financial statements, the entities should put only the relevant information in it. There is no need to give the definition of the accounting elements and to list the items already presented in other statements, but to emphasize significant items, explain their importance for the entity as well as present the policies which are applied by an entity. Thus, a purpose of the notes is not to cite the definitions of accounting positions given in the IASs, but to present the significant and relevant elements of their business. According to the conducted research it seems like the entities often upgrade the notes prom previous years, only changing the values of the financial statements positions. In this way, the entities satisfy the requirements of the IASs, but the notes are too extensive. It is noted that the notes gain in the volume by the years, usually citing the definitions and the requirements from the standards.

4. Activities for the Improvement of the Notes to Financial Statements' Quality

Since the notes to financial statements have become voluminous and the source of many not so relevant information, while not enough relevant information from the users' perspective is omitted, the project of Disclosure Initiative—Principles of Disclosure has been initiated. The root standard which covers the principles for the notes' preparation and disclosure – IAS 1 has been recognized as the hot issue and the IASB suggests either "making amendments to the parts of IAS 1; or creating a new disclosure standard to replace the parts of IAS" (IASB, 2017).

Through the Initiative, the IASB suggests several levels for discussion and possible changes:
- Principles of effective communication
- Principles on the location of information (primary financial statements, notes, annual report)

- Principles to address specific disclosure concerns expressed by the users of financial statements (the use of performance measure, the disclosure of accounting policies)
- Principles to improve disclosure objectives and requirements.

Seven principles of effective communication between a subject and the users of financial statements include an entity-specific information reporting and the reporting without the duplication of information in different parts of the financial statements. One of the biggest problems of financial reporting communication is that the companies usually do copy paste of the requirements prescribed by IFRS Standards. According to the principles of effective communication, the information disclosed in the notes should be clear and simple, organized to highlight important matters, linked to related information, free from unnecessary duplication and comparable in an appropriate format (IASB, 2017).

Second group consists of the principles about the place where information should be disclosed. Disclosure Initiative considers balance sheet, the statement of comprehensive income, the statement of changes in equity and cash flow statement as primary financial statements. The notes are extracted as a separate statement because their role differs from the role of primary financial statements. While the goal of primary financial statements is to present the financial position, business performance and the cash flows of a company, the role of the notes is to further clarify the information that can improve the knowledge on abovementioned categories. There is a general opinion that the users of financial statements, especially investors, put more attention on primary financial statements rather than on the notes.

As financial statements are usually published within an annual report, the IASB discusses about the location of the IFRS and non-IFRS information. While it is common that the IFRS information is a part of financial statements, the IASB proposes that some "IFRS information" could be placed outside the financial statements part, i.e. it should be placed within an annual report. Further, "non-IFRS information" can be placed inside the financial statements too, provided certain conditions are met. Such information positioning would, according to the IASB opinion, achieve more understandable annual report whereas the financial statements remain understandable and the information faithfully represented, clearly identified and cross-referenced (IASB, 2017).

Further, general requirements for fair presentation of performance measures in the financial statements are aimed to be set through this project as well.

The discussion is also about the structure of income statement and the cash flow statement which should be prepared in a way which makes it possible to gain subtotals, additional line items about the performance, and that investors wouldn't have to put a special effort to find such information in the notes (IFRS, 2017).

The following the IASB's suggestion is about the principles of disclosures on accounting policies. The proposal distinguishes three categories of accounting policies depending on the policies' significance and necessity. For instance, first category includes the policies which are always necessary for the users because of the material significance of items, transactions or events (for instance the policy required by IFRS standards) and the level of significance decreases with the second and the third group.

Finally, the Discussion Paper calls for users' opinion on the possible methods for developing centralized disclosure objectives which will help the Board to set the general rules for judgments used in disclosure.

5. Conclusion

Investors and other users of financial statements use the notes to financial statements when make business decisions. However, practice has shown that the consideration should be given to the quality of the notes' disclosures. This is why, a large project of investigation of public opinion on the disclosure has been initiated. Although the project has been in a process and the final version of disclosure requirements depends on the respondents' opinion, it is sure that the notes' structure and information content will be changed. As one could expect less comprehensive notes' content as a result of the project, the reducing the volume of disclosures is not the main objective (Paredes, 2013). In order to examine the notes' disclosure state in the entities from Croatian tourism sector a research was done. Based on our research results it can be concluded that the annual financial statements of the observed entities comply with the disclosure requirements set in the IAS 1. Regardless of the presentation which is in accordance with the IAS 1, the entities disclose some items in two or more statements at the same time. This makes the notes voluminous, with unnecessary data already disclosed in primary financial statements. Certain part of the notes is occupied by definitions from the IFRS. Such disclosure has become a burden for effective communication between an entity and the financial statements users. The preparers are not often aware that they should judge which information should be disclosed in the notes and which should not. After finishing Disclosure Initiative, provided the EU accepts a new standard or the changes of present standard, Croatian companies from tourism sector, as well as other preparers are gone experience the new requirements in the notes preparation. Consequently, investors in such companies will enjoy the new content of the notes and business decisions would be possible to make based on the improved accounting information disclosure.

Abstract

Notes to financial statements, along with other annual financial statements, are an important source of information for financial statements users, especially for shareholders and creditors. Notes provide more detailed information about elements of financial statements. In this paper, special attention was given to the notes regarding operating leases. In 2016, the International Accounting Standards Board issued a new accounting standard on leases - IFRS 16. The Standard is effective for annual periods beginning on or after 1 January 2019 and changes the presentation of operating leases in the lessee's financial statements in relation to former accounting standard - IAS 17. The most significant change introduced by the new standard is the presentation of right-of-use assets and related long-term liabilities derived from operating leases in the balance sheet of the lessee. Additional disclosure requirements were also introduced in notes to financial statements. The IASB emphasizes in its publications that the changes in accounting treatment of operating leases will have the greatest impact on financial statements of companies in the airline, retail, tourism and transportation industry sector. The theoretical background of the changes in the Standard has been investigated in the paper. Other than that, the paper analyses the financial statements of several companies from the airline industry sector. Further, in order to assess the impact of new Standard's requirements on the financial position and business performance a model has been developed. Research results indicate that the presentation changes regarding operating lease will contribute to a better assessment of lessee's financial liabilities and its financial position. The changes will also affect ROA and EBITDA of the lessee.

Keywords: leases, notes, debt ratios, ROA, EBITDA

1. Introduction

In January 2016, the new International Financial Reporting Standard (IFRS 16 - Leases) was issued. IFRS 16 changes the accounting treatment of operating leases. This standard is effective for annual periods beginning on or after 1 January 2019, and it replaces IAS 17 – Leases, previous accounting standard that prescribes the accounting policies and disclosures applicable to leases, both for lessees and lessors. The new standard was issues as a result of formalized co-operation between the US Financial Accounting Standards Board (FASB) recognized by the Securities and Exchange Commission as the designated accounting standard setter for public companies and the International Accounting Standards Board (IASB) - not-for-profit, public interest organization established to develop a single set of globally accepted accounting standards- IFRSs. As the IASB emphasizes, US Securities and Exchange Commission (SEC) estimated that US public companies may have approximately US$1.25 trillion of off balance sheet leases (IFRS 16 – Leases, Effects Analysis International Financial Reporting Standard, 2016). Taking into consideration the critics of present disclosure requirements regarding lease liabilities, a project on accounting for leases was initiated by the IASB and the FASB. The current lease model has often been blamed for providing insufficient information on operating leases to the users of financial statements. Therefore, the most significant modification introduced by IFRS 16 refers to the application of unique accounting model for the lessees. New requirements seek from lessees to recognize assets and liabilities in the balance sheet for all long term leases (operating and finance) except for leases of low-value assets. The new standard

will have a significant impact on the financial statements of lessees, especially those who have a high share of operating leases in their portfolio. Four sectors with the highest value of off-balance sheet leases are; airline, retail, tourism and transport industry sectors. According to the IASB's assessment, this type of lease will account for 22.7% of total assets in the airline industry, 21.4% of total assets in retail industry, 20.7% of total assets in tourism industry and 11.7% of total assets in the transport industry (Mazars – auditor's firm, 2016).

Methodologically, this paper consists of three parts. The theoretical part of the paper involves the analysis of the most significant changes in financial reporting about leases i.e. we explored possible impact areas in the new Standard on leases - IFRS 16. The empirical research comprises two parts. First, the analysis of the notes to financial statements of the selected airline companies was conducted. Second, we made an influence analysis of the changes in accounting treatment of operating leases through a research model. The research model includes the assessment of airline companies' indebtedness, calculation of return on assets (ROA) ratio and the calculation of EBITDA before and after the new IFRS requirements' application.

2. Accounting treatment of operating leases according to IAS 17 and IFRS 16

2.1.The most significant changes in lessee's financial statements

Previous accounting model for leases designed under IAS 17 - Leases required from the lessee and the lessor to classify the lease as operating or financial lease. According to IFRS 16 "a lease is classified as *finance if it transfers substantially all the risk and rewards incidental to ownership of an underlying asset. A lease is classified as an operating lease if does not transfer substantially all the risks and rewards incidental to ownership of an underlying assets."* The accounting treatment of operating and finance leases under IAS 17 was significantly different. Such a model was often criticized for providing insufficient information on leases to the users of financial statements, particularly for operating leases. Specifically, the previous model did not require the recognition of assets and liabilities arising from operating leases in balance sheet of the lessee, which according to new model presented in IFRS 16, will be mandatory. According to IAS 17 Leases, operating lease in balance sheet of the lessee should be presented as a short-term liability and as a lease expense for the accounting period, no matter the lease is long-term or short-term. Therefore, long-term lease liabilities arising from leases were not visible in the balance sheet. From the financial statements users' point of view it was hard to estimate the real indebtedness of a company with significant share of assets under operating lease. With the adoption of the new Standard, the IASB decided to apply equal accounting treatment for all leases - operating and financial. Applying IFRS 16, in essence for all leases, a company is required to: (a) recognize lease assets and lease liabilities in the balance sheet, initially measured at the present value of unavoidable future lease payments; (b) recognize depreciation of lease assets and interest on lease liabilities in the income statement over the lease term; and (c) separate the total amount of cash paid into a principal portion (presented within financing activities) and interest (typically presented within either operating or financing activities) in the cash flow statement (IFRS 16 – Leases, Effects Analysis International Financial Reporting Standard, 2016). Under this approach, the lessee in operating lease shall recognize a right-of-use asset and a lease liability.

According to IFRS 16, assets in operating lease should be presented (1) separately from the other assets in the balance sheet of lessee or (2) together with a similar type of asset, with an explanation in the notes about the position of the right-of-use assets. Lease liabilities under IFRS 16 should be presented: (1) separately from other liabilities or (2) together with other liabilities, with an explanation which liability item includes lease liabilities. Liabilities should be presented as short-term or long-term. IFRS 16 does not require a lessee to recognize assets and liabilities for (a) short-term leases (ie. leases of 12 months or less) and (b) leases of low-value assets (for example, a lease of a personal computer). A lessee shall initially measure the right-of-use asset at cost. According to IFRS 16 a lessee shall subsequent measure the right-of-use asset applying a cost model unless it applies either fair value model or revaluation model (if the right-of-use assets meet the definition of investment property or property, plant and equipment). To apply a cost model, a lessee shall measure

the right of use assets at cost: (a) less any accumulated depreciation and any accumulated impairment loss. As can be seen in Table 1, lease accounting has changed substantially, but here is a small change for lessors. These changes in lease accounting will have a significant impact on the value of total assets and long-term liabilities of companies that have a significant portion of assets under operating lease.

Tab1e 1: Operating leases according to IAS 17 and IFRS 16 in lessee's balance sheet

Balance sheet items	IAS 17	IFRS 16
	Operating leases	Operating leases
Assets		+
Liabilities	-	+
Off balance sheet rights/obligations	Assets and Liabilities	-

Source: IFRS 16 – Leases, Effects Analysis International Financial Reporting Standard, available at: http://www.ifrs.org/-/media/project/leases/ifrs/published-documents/ifrs16-effects-analysis.pdf (20.09.2017.)

The most important change in the context of lease accounting under the IFRSs is the transition from off-balance sheet operating leases model to balance sheet operating lease model in lessee's accounting (Gulin, 2015). This change in operating lease will result in an increase in assets and liabilities in the balance sheet for companies that have high off-balance sheet operating leases. According to Gulin et al (2012) this change will result in a more transparent reporting about the companies' indebtedness which will be visible through the calculation of *solvency (leverage) ratios* such as *debt to asset ratio* (total liabilities/total assets) or *equity to assets ratio* (total liabilities/principal). The presentation of operating lease in the balance sheet will also result in some modifications in income statement since the operating lease assets will be depreciated on a straight-line basis, which will have an impact on the profitability ratios such as *ROA (return on assets)*.

For companies with material off balance sheet leases, IFRS 16 changes the nature of expenses related to those leases (Table 2). In IASB publication (IFRS 16 – Leases, Effects Analysis International Financial Reporting Standard, 2016) was noted that IFRS 16 replaces the straight-line operating lease expense for those leases applying IAS 17 with a depreciation charge for the lease asset (included within operating costs) and an interest expense on the lease liability (included within finance costs). The depreciation expense and the cost of interest for the right-of-use assets should be presented separately in profit and loss account as an operating and financial expense.

Table 2: Expenses of operating leases according to IAS 17 and IFRS 16 in lessee's profit and loss account

P%L items	Operating leases – IAS 17	Operating leases – IFRS 16
Revenue	x	x
Operating costs (excluding depreciation and amortization)	Single expense	-
EBITDA	Lower	Higher
Depreciation and amortization	-	Depreciation
Operating profit	-	Higher
Interest costs	-	Interest
Profit before tax	No change	No change

In order to ensure consistency between balance sheet, profit and loss account and cash flow statement, IFRS 16 requires from a company to classify cash payments for: (1) the principal portion of lease liabilities within financing activities; and (2) the interest portion of lease liabilities in accordance with the requirements relating to other interest paid. The expenditures related to short-

term leases and low value leases should be shown within operating activities. As can be seen in Table 3, IFRS 16 should reduce companies' operating outflows with a corresponding increase in finance outflows in cash flow statement. Applying IAS 17, companies should classify the outflows related to operating lease in operating activities while applying new Standard – IFRS 16 such outflows should be classified as finance activities in cash flow statement.

Table 3: Cash inflows and cash outflows related to operating leases according to IAS 17 and IFRS 16 in lessee's cash flow statement

Cash flow items	Operating leases – IAS 17	Operating leases – IFRS 16
Interest portion of lease liabilities	Operating/financing activities	Operating/financing activities
Principal portion of lease liabilities	Operating activities	Financing activities

2.2.The most significant changes in lessee's notes to financial statements

The notes to financial statements provide a more detailed explanation of the information presented in the other financial statements. Despite the notes represent very important source of information for evaluation financial position and business performance of a company, some authors point out that financial statement users are still paying more attention to the information presented in balance sheet and profit and loss account than in the notes (Pavić, Žager and Rep, 2017). The reason for that can be found in the insufficient quality of the notes to financial statements. Shortcomings in notes to financial statements were recognized in the past few years by relevant global accounting (FASB, IASB, ANC, ICAS, and ICAEW etc.) and non-accounting (EFRAG, ESMA etc.) organizations which conducted several projects in order to improve the quality of the notes to financial statements (Pavić, Žager and Rep, 2017). Although IAS 17 required the disclosure of information about short and long-term leases in the notes to financial statements, it was noticed that this kind of presenting a company's indebtedness was not sufficiently transparent. According to IFRS 16, numerical information on long-term operating lease liabilities and corresponding right-to-use assets will now be presented to the users through balance sheet. As IAS 17 seeks (International Accounting Standards Board, 2016), lessees in operating leases were required to disclose the following lease information in the notes to financial statements: (a) the total of future minimum lease payments under non-cancellable operating leases for each of the following periods: (i) not later than one year, (ii) later than one year and not later than five years, (iii) later than five years, (b) the total of future minimum sublease payments expected to be received under non-cancellable subleases at the balance sheet date; (c) lease and sublease payments recognized as an expense in the period, with separate amounts for minimum lease payments, contingent rents, and sublease payments; (d) a general description of the lessee's significant leasing arrangements including but not limited to the following; (i) the basis on which contingent rent payable is determined, (ii) the existence and terms of renewal or purchase options and escalation clauses; and (iii) restriction imposed by lease arrangements, such as those concerning dividends, additional debt and further leasing (Ernst&Young, 2012).

According to IFRS 16, the objective of disclosures in the notes of lessees is to, along with the information provided in balance sheet, profit and loss account and statement of cash flows; give a basis for the users of financial statements to assess the effect that leases have on the financial position, financial performance and cash flows of the lessee. IFRS 16 requires from lessee to disclose the following amounts for the reporting period in a tabular format, unless another format is more appropriate: (a) depreciation charge for right-of-use assets by class of underlying asset; (b) interest expense on lease liabilities; (c) the expense relating to short-term leases. This expense need not include the expense relating to leases with a lease term of one month or less; (d) the expense relating to leases of low value assets, (e) the expense relating to variable lease payments not included in the

measurement of lease liabilities; (f) income from subleasing right-of-use assets; (g) total cash outflow for leases, (h) additions to right-of-use, (i) gains or losses arising from sale and leaseback transactions; and (j) the carrying amount of right-of-use assets at the end of the reporting period by class of underlying assets (International Accounting Standards Board, 2016). Moreover, a lessee shall disclose additional qualitative and quantitative information about its leasing activities to meet disclosure objectives.

Unlike IAS 17, IFRS 16 does not include a list of prescriptive qualitative disclosures but rather sets out the objectives and requires from companies to determine information that would satisfy those objectives (IFRS 16 – Leases, Effects Analysis International Financial Reporting Standard, 2016). The reason is that IASB wants to improve lease reporting by focusing on information important for business decisions making. It can be concluded that, in relation to IAS 17, some information "migrate" from the notes to financial statements to balance sheet. Also, new disclosure requirements have been added to the Standard. It should be presented in a table to ensure better transparency of the notes. Such a request certainly contributes to a better overview of the notes that makes it easier for financial statements' users to find particular information. In addition, the presentation of long-term (non-current) lease liabilities in balance sheet contributes to a better understanding of the companies' financial position.

3. The Importance of Changes In The Notes About Leases On The Evaluation Of Indebtedness And Other Performance Measures – Case Of Airline Industry

3.1. Analysis of notes to financial statements on leases in airline industry

The airline industry is a leading industry in the world. It creates very high added value and thus contributes significantly to the economic development. „According to the IATA's (the International Air Transport Association) director general and CEO, currently, aviation provides 58 million jobs and contributes ~$2.4 trillion in GDP. This is expected to increase to 105 million jobs and $6 trillion in GDP in 2034" (Market Realist, 2014). On the other hand, it requires intensive, significant and continuous investments in new technologies and maintaining existing capacities. There are two ways of financing aircraft: the purchase or leasing. Direct purchase or bank financing is considered a traditional way of financing airline companies, but in recent years, there is a very intense trend of renting airplanes through operating leasing. Each of these modes of financing has its advantages and disadvantages (StartupBoeing , 2007). By buying an aircraft it is possible to realize maximum airline control of airplane configuration, airline acquires equity in fleet, some countries give tax benefits and similar. However, it seems that for some airlines (especially those small ones) such a way of financing is unavailable since they would not be able to obtain expensive assets and aircraft due to the lack of funds. On the other hand, this type of financing requires large investment and financing requirements. Also, there is a residual value risk - less fleet flexibility than operating lease. The operating lease of an aircraft may reduce the capital investment requirements and increase fleet plan flexibility.

Notes to financial statements are an important source of information for all users, and especially external. In order to find out how they look, how extensive and which information related to the leases they contain, the paper analyzed annual reports and the notes on lease of several airline companies (Air France, Turkish Airlines, British Airways, Lufthansa, Adria Ways and Croatia Airlines) – Table 4. The analyzed notes are prepared in accordance with the requirements of IAS 17. At the beginning, it should be noted that the scope of the notes to financial statements varies from company to company, but on average, they are written on more than 50 pages. Each analyzed airline defines what leases are and how the company records them in accounting evidence. This is done through the explanation of significant accounting policies in the notes. In almost all analyzed airlines, operating lease payments are recognized as an expense on a straight-line basis over the lease term, except where another systematic basis is more representative of the time pattern in which economic benefits from the leased asset are consumed. Contingent rentals arising under operating leases are recognized as an operating expense in the period in which they are incurred.

From Table 4 it can be seen that it was not possible to determine the exact number of aircraft that are under operating lease for all analyzed airline companies. Therefore, it is not possible to determine the exact effects of the application of the new IFRS 16 on the financial position of the observed airlines. In addition, it can be noted that aircraft lease cost significantly differ depending on the size of the airlines. Usually, smaller airlines largely rely on operating leases while larger companies have a much higher percentage of its own aircraft in the fleet. However, nowadays, all airlines, regardless of the size, turn increasingly to operating leases. "Over a third of the world's airline fleet is now rented and the proportion is likely to keep growing" (The Economist, 2012).

Table 4: Information on leased aircraft of the selected airlines in their annual reports

Airline	Country	Aircraft fleet	Number of aircraft in lease	Aircraft lease costs (on an annual base)	Other information
Air France – KLM Group (Consolidated financial statements 2016)	France	534 (total number of aircraft in operation)	-	1,073,000,000 €	The minimum future payments on operating leases for the period less than 1 year, between 1 – 5 years and over 5 year
British Airways (Annual Report 2016)	Great Britain	290 (total number of aircraft in operation)	-	159,000,000 £ (180,722,893 €) exchange rate 1 GBP = 1.13911 EUR	The minimum future payments on operating leases for the period less than 1 year, between 1 – 5 years and over 5 year
Turkish Airlines (Annual Report 2016)	Turkey	334 (total number of aircraft in operation)	-	244,000,000 $ (207,412,454 €) exchange rate 1 EUR = 1.1800 USD	The minimum future payments on operating leases for the period less than 1 year, between 1 – 5 years and over 5 year
Lufthansa Group (Annual Report 2016)	Germany	-	206	Costs under long-term operating leases with terms up to 2022 came to EUR 833,000,000 in the financial year 2016. Expenses for operating leases were mainly payable to affiliated companies; only EUR 13,000,000 related to an external lessor.	-
Croatia Airlines (Annual Report 2016)	Croatia	5 (owned aircraft excluding aircraft in lease)	7 (rental period between 2 and 10 years)	135,867,000 kn (18,145,475 €) exchange rate 1EUR = 7.487652 KN	The minimum future payments on operating leases for the period less than 1 year, between 1 – 5 years and over 5 year
Adria Airways (Annual Report 2013)	Slovenia	6 (owned aircraft excluding aircraft in lease)	5 (rental period between 3 and 11 years)	10,633,095 €	-

Source: Annual Reports of selected airlines (for more detail see Reference list)

One of the requirements of the IAS 17 is to present the total of future minimum future payments on operating leases for each of the following periods: (i) not later than one year, (ii) later than one year and not later than five years, (iii) later than five years. In accordance with the conducted analysis, almost all the observed airline companies met this request (except Adria Airways and Lufthansa Group) and published the information in the notes to financial statements. Finally, airlines are aware of the new Standard (IFRS 16) on leases. For example, British Airways Group is currently assessing the impact of the new Standard on their financial statements. "It is expected that both net debt and non-current assets will increase on implementation of this standard as obligations to make future payments under leases currently classified as operating leases are recognized on the balance sheet, along with the related 'right-of-use' asset" (British Airlines, 2016).

3.2. Implications of the new leasing standard on a company's financial position and performance – model design

It has already been stated that the changes of the new standard on leases (IFRS 16) influence the airlines that are relying on operating leases in financing their core business. The effects should be visible in two basic financial statements: balance sheet and profit and loss account. Since airlines nowadays often rent aircraft through operating leases it is not surprising that this industry is selected for a case study. Since the IFRS 16 is effective for periods beginning on or after 1 January 2019 it was not possible to analyze the impact of the new Standard on actual data. Therefore, the simulation of data was carried out for two airline companies that will serve as an illustrative example.

Table 5: Financial statements of two airline companies using IAS 17 and IFRS 16

Airline Company A (leases 1 aircraft)	**IAS 17**	**IFRS 16**	**Airline Company B (leases 10 aircraft)**	**IAS 17**	**IFRS 16**
BALANCE SHEET (in millions of EUR)					
Non-current assets	**80**	**96,2**	**Non-current assets**	**80**	**242**
- Property, plant and equipment	60	76,2	- Property, plant and equipment	60	222
- Other non-current assets	20	20	- Other non-current assets	20	20
Current assets	**20**	**20**	**Current assets**	**20**	**20**
TOTAL ASSET	**100**	**116,2**	**TOTAL ASSET**	**100**	**262**
Equity	**40**	**40**	**Equity**	**40**	**40**
Non-current liabilities	**12**	**28,2**	**Non-current liabilities**	**12**	**174**
- Lease liabilities	0	16,2	- Lease liabilities	0	162
- Other liabilities	12	12	- other liabilities	12	12
Current liabilities	**48**	**48**	**Current liabilities**	**48**	**48**
- Lease liabilities	1,8	1,8	- Lease liabilities	18	18
- Other liabilities	46,2	46,2	- Other liabilities	30	30
TOTAL EQUITY AND LIABILITIES	**100**	**116,2**	**TOTAL EQUITY AND LIABILITIES**	**100**	**262**
PROFIT AND LOSS ACCOUNT (in millions of EUR)					
Revenues	**90**	**90**	**Revenues**	**90**	**90**
Operating costs (excluding depreciation and amortization)	**84**	**82,2**	**Operating costs (excluding depreciation and amortization)**	**84**	**66**
- Lease cost	1,8	0	- Lease cost	18	0
- Other operating costs	82,2	82,2	- Other operating costs	66	66
EBITDA	**6**	**7,8**	**EBITDA**	**6**	**24**

Interest - expenditure	1	1,4	Interest - expenditure	1	5
Profit before tax	**2**	**2**	**Profit before tax**	**2**	**2**

Source: Created by authors

Model has ten assumptions: (1) both airlines lease aircraft for the purpose of carrying out the services of carriage of passengers, mail and goods. (2) Airline companies have the same number of aircraft in their ownership. However, the first airline (Company A) leases only one aircraft by using operating lease and the second one (Company B) with the same balance sheet is leasing 10 aircrafts under operating leasing. (3) The useful life of each aircraft is 25 years. (4) The linear depreciation method is applied. (5) Under the lease agreement, the annual rent of one aircraft is EUR 1,800,000, which is a total of EUR 18,000,000 for 10 aircraft. (6) Both of the companies leased each aircraft for a period of 10 years. (7) Present value of unavoidable future lease payments for the Airline Company A is EUR 18,000,000 and for the Airline Company B it is EUR 180,000,000. (8) Depreciation and amortization (when applying IFRS 16) for the Airline Company A is EUR 1,400,000 and for the Airline Company B it is EUR 14,000,000. (9) Interest - expenditure (when applying IFRS 16) for company A is EUR 400,000 and for Airline Company B it is EUR 4,000,000. (10) Revenues of both airline companies are EUR 90,000,000.

Table 5 shows the effects of the application of IFRS 17 for two airlines with different share of operating leases in their portfolio. As it can be seen in table 5, the model shows that lease agreement of one aircraft will increase the property, plant and equipment value (EUR 16,200,000 is net value of property, plant and equipment (18,000,000 – 1,800,000)) as well as the value of non-current lease liabilities (EUR 1,800,000 is presented as current lease liabilities (matured part of long-term liabilities for one year)) for EUR 16,200,000. For Airline Company B the increase in property, plant and equipment will be much higher because company leases 10 aircrafts (EUR 162,000,000).

On the other hand, different proportion of leased asset will affect only the structure of profit and loss account. Precisely, only the structure of the costs/expenses will be changed will change. Operating cost excluding amortization and depreciation will be lower for a yearly lease expense on annual basis (that is EUR 1,800,000 for Airline Company A and EUR 18,000,000 for Airline Company B). This means that EBITDA (earnings before interest, taxes, depreciation and amortization) will be much higher when applying IFRS 16 especially for Airline Company B. On the other hand, amortization and depreciation cost and interest - expenditure cost will be higher for the same amount. Therefore, the profit before taxes remained the same. Finally, it is possible to conclude that effects on balance sheet are significant for both airlines and especially for Airline Company B because of material off balance leases. However, the overall effect on profit or loss is not as significant as for balance sheet.

Table 6: The effects of different accounting standards (IAS 17 vs. IFRS 16) about leases on the selected financial ratios

Financial ratio	Formula	What it measures	Airline company A (leases 1 aircraft)		Airline company B (leases 10 aircraft)	
			IAS 17	IFRS 16	IAS 17	IFRS 16
Debt to total assets	liabilities/assets	Solvency (leverage)	0.6	0.66	0.6	0.85
Equity to total assets	equity/assets	Solvency (leverage)	0.4	0.34	0.4	0.15
Debt to equity	liabilities/equity	Solvency (leverage)	1.5	1.91	1.5	5,55
Asset turnover	revenue/assets	Activity	0.9	0.77	0.9	0.34
EBITDA – earnings before interest, taxes, depreciation and amortization	profit before tax + interest + tax + depreciation and amortization	Profitability	6.0	7.8	6.0	24
ROA	Profit before tax + Interest - expenditure/ assets	Profitability	3%	2,93%	3%	2,67%

Source: Created by authors

In order to evaluate impact effects of IFRS 16 application on the financial position, indebtedness and profitability of a company some of the most commonly used financial ratios were calculated (table 6). It can be seen that leverage ratios i.e. long term solvency is significantly affected. It is evident that debt indicators deteriorated. Both analyzed airline companies show increase in debt to equity ratio because of the increase of non-current liabilities for lease liabilities. For Airline Company B, the most significant change is seen in indebtedness indicator (debt to total assets ratio), where up to 85% of total assets are funded by debt. Total asset turnover decreased because lease assets were recognized as the part of total assets. Finally, we tested company's profitability. As previously stated, EBITDA is significantly higher and ROA is lower for Airline Company B because of the higher share of operating leases in its portfolio.

4. Conclusions

Leases play a very important role in modern business conditions and, as such, have a significant impact on the financial position and business performance of a company. Therefore, it is extremely important to supply users with transparent information on the company's business operations. This is particularly the case with operating leases. The previous model, formed in IAS 17, did not provide the users with complete picture of the lessee's indebtedness. The absence of information about leases on the balance sheet meant that investors and analysts could not asses the company's financial position and performance properly without making some adjustments. That is why the IASB made the revision of existing standards requirements and issued a completely new IFRS 16, which requires the recognition of assets and long-term liabilities for all leases except for leases of low-value assets.

Airlines industry will be significantly influenced by new Standard, especially those airlines that have a high share of operating leases in their portfolio. For the purpose of presenting IFRS 16 effects on balance sheet and profit and loss account a model design of two airlines with different portion of operating lease was developed. According to our research results it can be concluded that the changes in accounting treatment of operating leases result with; (1) higher indebtedness indicators, (2) lower asset profitability ratios (ROA), (3) higher EBITDA for airline companies with significant share of right-of-use assets. In order to see how companies reported on operating lease so far, we analyzed notes about operating lease of the selected airlines. According to the conducted analysis, it is evident that the information on leases can be found in the notes but in a non-transparent way. Therefore, the change of Standard will be of great benefit to all users when assessing the company's real debt. Some information "migrates" from notes to balance sheet; new disclosure requirements have been added to the standard and notes should be presented in a table.

Acknowledgments

This paper is the result of a project called „The improvement of the notes to financial statements„ which was financed by the University of Zagreb as short-term research support for 2017.

Attributes of Employee Engagement Best Practices: A Guideline of Widely Used Engagement Models

Kanwal Gul , Institute of Business Management, Karachi, Pakistan, std_17826@iobm.edu.pk

Dr. Ghazanfar Bozai , HoD HR & Management, Institute of Business Management, Karachi, Pakistan, ghazan.bozai@iobm.edu.opk

Abstract

Engagement leads to enhanced productivity and competitive edge but due to lack of proper employee engagement policies and practices, disengagement cost economies billions of rupees. The purpose of this study is to conduct a comprehensive literature survey of the major best practices used for employee engagement globally. It could be used as employee engagement best practices guide for business in developing countries where the concept of employee engagement is in its infancy stage. The paper provides background of employee engagement, identify attributes of engagement and analyze widely used engagement models. Analysis of engagement models with their respective concepts and constructs are summarized which would serve as a baseline for organizations to select the appropriate elements of models in the context of business domain and cultural norms.

Keywords: Attributes, Engagement, Employee Engagement, Performance

Introduction

The ability of an organization to create a sustainable competitive edge relies mainly on its prowess to have an engaged workforce (Porter, 1998). It is anticipated that employee engagement (EE) helps in developing positive attitude and motivated work relationship with in the organization. Because EE plays an important part in ensuring that employees will give their 100% even in tough times and in time when organization need them more than ever (Bates, 2004). According to Gallup's research the engagement levels are dismally low and only 33% of US workforce is engaged (Gallup, 2017). While engagement is considered as a predictor of organizational success because world's successful organizations are armed with 70% of the engaged workforce according to Gallup. Conversely, research is focused majorly on negative psychological aspects. Journal of Health and Occupational Psychology is dealing with negative psychology where only 5% of the research articles are based on positive psychology (Schaufeli & Bakker , 2004). There is little focus towards positive psychology and consequently EE has not enjoyed its due share of importance. Only in the last twenty years, the topic of EE has begun to catch attention of academicians, researchers and industry leadership.

Under positive psychology, employee engagement is a distinctive construct which gathers all positive job attributes under one umbrella like Job Satisfaction, Commitment, Organizational Citizenship and Willingness to help (Ramarajan & Sujatha, 2015). Studies had concluded that EE is significantly correlated with higher organizational performance, but it is also revealed that the picture is not so straightforward (Kahn, 1990). EE as a construct itself is a very unitary and typical thus, this study will summarize and elaborate different factors, drivers and features of EE, which will help organizations to identify needs of employees, to choose suitable engagement tools and identify the organization's gaps in achieving success. This research highlights (i) the organizational awareness about EE and (ii) various attributes of EE models.

Background

Employee engagement seems a new term but it has gathered importance couple of decades ago. Though the very first article on EE was published in 1990s but in the 70's and 80's employee satisfaction (Job Satisfaction) was used as an alternate expression for EE (Hallberg & Schaufeli, 2006). Kahn suggested that term employee satisfaction is more about employee-organization relationship (Kahn, 1990) where EE is about "employee itself". This concept was further substantiated by research that an employee if "engaged" will be satisfied but satisfied employee will not be necessarily engaged (Hallberg & Schaufeli, 2006). Paradigm of EE shifted, when "personnel" became "Human resource" (Perrin, Working Today: Understanding What Drives Employee Engagment , 2003). "Employee Commitment" which was used a substitute term for EE, again research concluded that employee commitment could be a predictor of EE but could not be used as a replacement (Durkin, 2007). Researchers suggests that EE could be understood as "Passion for work" (Truss, Soane, Edwards, & Wisdom, 2006) where commitment refers to "living and standing up to the vision of the organization"(S. Abraham, 2012; Davis, 2015; Durkin, 2007). EE concept matured when a paper "From People to Profits" published in 1990 and concluded that the freedom of "being oneself" at work place engages an employee more into work (Kahn, 1990).

"The harnessing of organizational members' selves to their work roles" is the first definition given by Kahn for the term EE. He determined that when an employee express himself cognitively, emotionally and physically during job performance, EE is said to have realized (Kahn, 1990). Recent era definitions of EE varies organization to organization. A survey report on EE in US analyzed that organizations fall into a trap of mistaking their employee engagement survey strategy (Aon Hewitt, 2012). Organizations ask common EE questions to measure their employees' engagement which obviously does not lead an organization towards improving performance (Adkins, 2016).

EE is a complex concept with different factors influencing engagement at different level. Consequently, EE also defined differently in different organizations. So it is important that the approach towards engaging employees, in organizational processes should be different (Thakur, 2014). EE's importance goes beyond a "happy worker" and organization's benefits. Hence, less than of 25% of the organizations believe that their employees are engaged (HBR, 2013). Another report by Harvard Business Review determined that after recessionary years, organizations were highly engaged in investing in growth and cost cutting strategies. This report further concluded that critical success factors considered by leaders for a successful business are customer services, effective communication and high level of employee engagement. Despite of having awareness about importance of EE in western countries, results of Gallup poll shows consistent low levels of EE. It shows that for the last fifteen years engaged employees' percentage in United Sates remained less than 33% while in 2014 to 2015 percentage of engaged employees increased from 31.5% to 32%(Adkins, 2015).

In modern time with cost cutting and organizational culture, engagement is the most important issue companies are facing. The story of oil market downturn is not very old when organizations were facing challenge of retaining workforce as well as keep them engaged with work when business crashes kept employees' moral down (Ross, 2011). Evidence suggests that US lost 350 billion dollars per year to the disengagement of employees at work (Ross, 2011). The study also revealed that engagement is highly co related to the high performance thus, highly engaged employee outperform 400% more than a moderately engaged coworker (Ross, 2011).

Employee Engagement Conceptualization

History of EE definitions suggest that EE as construct consistently misinterpreted (Shuck & Wollard, 2009). Khan (1990) suggested that "people act out momentary attachments and detachments in role performances" with the reference to internationalist theory given by Goffman (Goffman, 1961; Kahn,

1990). Kahn (1990) drew suggestions from different psychologists' research work and hypothesized that for engagement employee safety, meaningfulness and availability are important attributes (H. M. Abraham, 1970; Alderfe, 1972; Goffman, 1961; Kahn, 1990). Safety referred to the ability to express one-self without fear of negative influence on image, status and career, "return on performance" as meaningfulness and availability referred as emotional, psychological and physical resources are available or not (Kahn, 1990).

Until 2001 personal engagement and disengagement was focus of empirical research linked with employee burnout. It was posited that EE is antithesis to the employee burnout (Maslach, Schaufel, & Leiter, 2001). Schaufeli and Baker in 2002 suggested that being engaged is a psychological state. When an employee feel enthusiastic, energized, joyful at work he/she will definitely get involved and remain engaged with the work (Schaufeli & Bakker, 2004). In 2009, Slaski gave psychosocial model of EE which suggests that when people find psychologically positive and socially acceptable work environment, they tend to get engaged in work. The positive environment is important for EE (Slaski & Cowan, 2009).

Current Status of Employee Engagement

A question, an organization should ask and should be asked that what kind of tools and techniques it is using to measure its employee performance. In this global era where workforce is different and digital, companies are still relying on surveys, tools, correlation techniques and models which can only predict the retention rate of employees but cannot provide any insights on employee engagement (HBR, 2013). And suppose if they provide insights, then those insights do not help organizations to outperform. In US, there is $1 billion worth market of survey agencies, who provide surveys with statistical models which measures level of engagement considering variety of job engagement predictors e.g. leadership style in organization, job satisfaction, commitment, enjoyment, rotation of work and work life balance (HBR, 2013). Models are reliable and valid but actionable results are far from consideration level (Ray, Hayland , Dye , Kaplan, & Pressman, 2014). Issues of engagement have risen in the minds of business leaders on the basis of the findings of current research which is as follows:

A report by HBR Analytic Services identifies the most impactful EE drivers as follows:

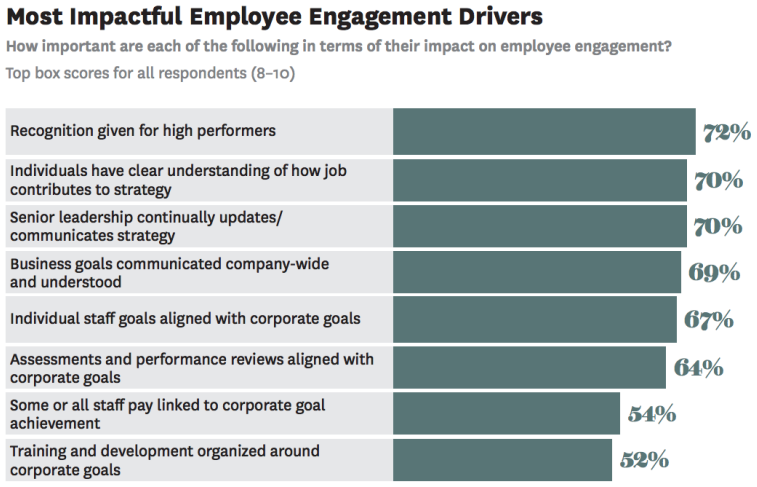

Figure 1.1: EE drivers

Source: (HBR, 2013)

- 54% employees recommend that Glassdoor (a company which ask their employees to rate and evaluate their employers) is a place to work (Brown, Melian, Solow, Chheng, & Parker, 2015)
- 50% of the employees would never recommend their peers to join their employer (Volini & Dussert, 2015)
- According to Victorian equal opportunity rights 80% of the work force want to be a part of an organization which is highly committed and compassionate about diversity (Deloitte, 2013)
- 72% of the employees seek recognitions as an important factor to get themselves engaged (HBR, 2013).

Literature Survey

Employee Engagement and Relationship Attributes

Before identifying construct based attributes of EE, individual factors are necessary to be defined and identified because engagement is more of a personal and decisional attitude rather than learned, altered or acquired (Lawrence, 2016). Relationship attributes or subjective attributes of EE are relationship of employee with

a. Co-workers and peers
b. Line managers
c. Organization itself
d. And outside the organization (stakeholder of the organization like suppliers and customers)

Researchers argue that employee and employer relationship should be a mutual-gain relationship to improve business productivity (Lawrence, 2016). Consequently, psychometric assessment is also used widely to analyze relationship and changing association between employer and employee (Khan, Yar, Khan, Nawaz, & Khan, 2013). 72% of the employees agreed that recognition given by employer having a positive impact of EE (HBR, 2013) (See Fig 1.1).

Employee Engagement and Demographics

To understand employee engagement concretely, an organization needs to understand changing demographics of human resource. According to research, changes in age composition of employee will have significant impact on business (Pitt-Catsouphes et al., 2011). Workforce demographics significantly affect satisfaction, commitment, engagement and productivity (Shah & Jalees, 2004).

Gallup (2015) reported that “different people should be managed differently”(Robison, 2015). This report revealed that college graduates are more disengaged than high school diploma workers. College graduates spend more time to earn their degree than keep themselves engaged in the work field. Generation X seems to be concerned about what their organization stands for, and so as baby boomers, who kept engaged at work where they feel their managers are doing extra efforts to show them that they are important part of the organization (Robison, 2015). The manager/leader should understand the thought process of an employee and do some extra efforts to recognize employees’ talent, experiences, skills, mind evolution and working style which needs to be managed and polished individually according to their age, race, gender, generation and psychometrics (Robison, 2015).

Methodology

For data analysis authors have selected qualitative method called Content Analysis. In mass media research this method is also called data collection method because of extraction of data through sources e.g. newspaper, contents, articles and etcetera (Mayring, 2014). In Content analysis, approach any kind of material like interviews, observations documents could be analyzed. For this study, Secondary Content Analysis approach is used in which data is collected from secondary texts, database, study material, scientific researches, white papers, annual and research reports. In qualitative content analysis, video materials can also be used to analyze and interpret (Mayring, 2014; Glaeser-Zikuda, Seidel, Rohlfs, & Groesc, 2005). Summarizing is the approach under content analysis by which secondary data on EE was collected, analyzed and explained.

Employee Engagement Models

Managers should stop only looking at what their organization is trying to achieve, which is success. Because success can be easily achieved by completing financial and operational goals but how organization achieve those goals is the part of organizational strategy (Gates, 2010). Strategy carried out by individuals working in that organizations thus their interest in the organization, willingness of work, sense of responsibility and pleasure will help managers to take organization on the path of sustainable success (PWC, 2017). Therefore, engagement of employee is an important aspect in which managers and leaders shall invest their time and resources. For this study three models have been chosen (1) Zinger Model, (2) Aon Hewitt's Model, and (3) X-Model of employee engagement. Rational for choosing these models is that these models are used globally and model's validity and reliability is checked constantly by the respective organizations (Aon Hewitt, 2015; Zinger, 2013).

1. Zinger Model

David Zinger, a Canadian ManagementC designed EE model to increase engagement in organizations. With 25 years of experience in management field, and the experience of extensive research he developed a workable model with 10 key aspects that managers must consider and follow to achieve organizational success (MSG Experts, 2017). Under this model, managers being accurate by not give too much work or burden to their employees which could result in disengagement fatigue and disinterest (David Zinger, 2012). Being accurate means managers are aware of organization's mission, goals and values. They are responsible to share knowledge about organization's strategies and let them (employees) know that an employee too have a role to play in the success of the organization (Vrouvas, 2016). When managers and subordinates work together to achieve an organizational goal, engagement level automatically rise (David Zinger, 2012) .

David provided a bold pyramid for EE which suggests that engagement could be achieved if an organization is equipped with practices according to the blocks of the model (David Zinger, 2012). Blocks of engagement are achieving goals, increasing performance, path progress, building relationships, recognition, master moments, strengthening, making meaning, enhancing wellbeing and enduring energy.

Model Summary

Zinger model lined EE with actionable and result oriented performance (Zinger, 2009). The pyramid starts from the top block of **achieving results** which is directed towards EE. Therefore the model starts with a key question that who wants to achieve what, in the organization (Zinger, 2013). In order to achieve results, an organization must **improve performance** by letting employees' know that how they are going to achieve and what organization is intended to accomplish in order to achieve organization's

ultimate goals (Schachter, 2012). **Crafting strategy** grabbed an essential place in the pyramid because according to Aon Hewitt's report biggest drop in EE is due to mangers not providing or failing to provide a clear perception of what organization wants to achieve (Aon Hewitt, 2012). Hence performance cannot be increased if jobs are not crafted properly (David Zinger, 2013). Job crafting is a practice of making cognitive and physical changes in the job in order to keep employees engaged (Berg, Dutton, & Wrzesniewski, 2008). Although job crafting makes tasks little bit difficult to achieve but in challenging jobs employees remain motivated to invest their efforts and time (Gorgievski & Hobfoll, 2008). Next block is **path progress**, progress principle 2012 determined that progress facilitation is most effective way to engage and motivate employees.

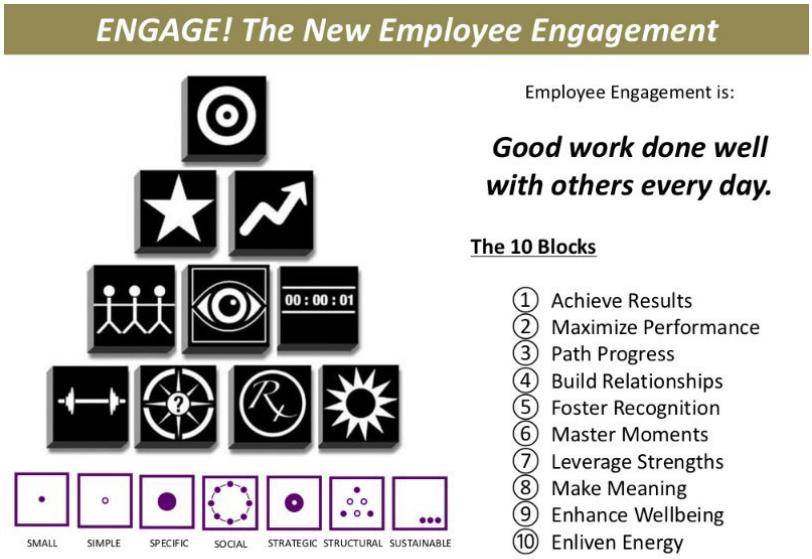

Fig: 1.2: Engagement Pyramid

Source: (Zinger, 2016)

The survey was conducted on 12000 daily diary entries of employees which summarized that even progress happen in small step or small chunks but it is important to make an employee realize that he/she at least succeed or achieved something or took another step towards its goal. This realization will create sense of motivation amongst employees and will keep them engage at work (Amabile & Kramer, 2012). When managers feel their responsibility to help, train and motivate an employee, a relationship of trust will automatically be build, which is the next block of the pyramid. **Building relationship** (Zinger, 2012) is foundation of EE. John M suggest that successful mangers are those who are able to develop and maintain networks and build relationships (John M, Gottman, & Joan, 2005). **Fostering recognition** is the block after relationship (Zinger, 2013) suggested by Zinger. In which he elaborated that (Re-cognition) which means managers needs to re-evaluate the meaning of the word recognition which is beyond roasters, donuts, minimum encouragements like saying "good job" kind of thing (Zinger, 2013). Today's work environment and workers are diverse. For this modern generation recognition could be using social media network at work, it can be an eat al fresco and also can be totally personal. According to Gallup survey it is suggested that EE and employee recognition are highly correlated variables, results were also endorsed by The Corporate Leadership Council and Towers Perrin (Perrin, 2003; Perrin, 2005; Council, 2004; Gallup, 2017). After recognition, model points towards **master moments** and **leverage strength.** Campbell (the parent organization of Campbell soup) introduces touch points to transform

disengagement onto engagement. They demonstrated that each point has ability to touch opportunity and establish high performance in someone's life. Touch points could be a get together between two people to get some task done so a manger needs to identify such touch points so that employees realize and memorize their master moments at work and try to **make meaning** out of it. Employees who are engaged can enhance their **wellbeing** as an engaged employee not only work for the organizational success but also for his/her own satisfaction. This will further induce **energy** and motivation in an employee.

2. *Aon Hewitt's EE Model*

Aon Hewitt a management consulting and human capital provider in at least more than 120 countries developed a model of measurement of employee engagement (Aon Hewitt, 2015). Engagement 2.0 a report by Hewitt suggest that organization's ability to take step to improve EE is going backward hence organizations are in dire need of engaging employees and retaining them (Aon Hewitt, 2015). Aon model of engagement gives insights of psychological state of an employee which leads an employee towards better performance (Aon Hewitt, 2017).

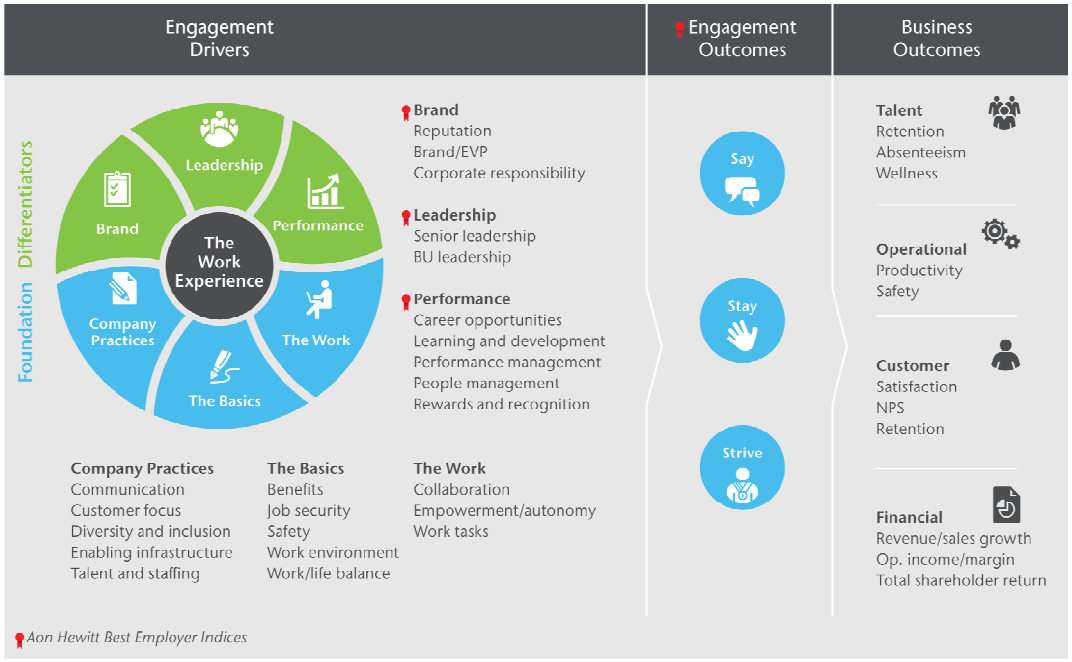

Fig: 1.3: Aon Hewitt's Model

Source: (Aon Hewitt, 2012)

Model Summary

If an organization focus on employee outcomes, it will help organization to keep its employees engaged. This model initially describes drivers of engagement which are **brand, leadership**, **performance, company practice, the basics and work** (Aon Hewitt, 2017)**.** Though drivers of engagement differ organization to organization, culture and country wise (Aon Hewitt, 2015), it is also suggested that drivers differ in terms of job segment. Hewitt model determined that engagement culture starts with the leader, his beliefs, experiences and displayed behavior effect psychological attitude of an employee (Aon

Hewitt, 2015). Aon Hewitt's model further describe the outcome of engagement which are **say, stay and strive** (Aon Hewitt, 2012)**.**

These outcome constructs are also known as observable facets. These outcomes suggest that when an employee is psychologically satisfied and get engaged in the work he/she **say** good words about the organization, **stay** affiliated with the organization for the longer period and **strive** for success of the organization and it self. After engagement outcomes, model determine business outcomes as well. **Retention** of talent, **productivity**, **satisfied customers** and **improved financials** are the business outcomes which are predictors of engagement in Aon Hewitt's model. Achieving these business outcomes is not as easy in today's global environment. Economic conditions continue to be a leading indicator for investments in talent and employee engagement.

3. X-Model of Employee Engagement

Managers as well organizations are eager to maximize the contribution of individual employee, individual employees are in need of purpose and satisfaction which is a return on their contribution (Cheryl, 2014). Increased contribution needs more engaged people is the one half of the engagement equation where other half of the equation is individual employees (BlessingsWhite, 2010). Individual employees have separate path or work definition and they work for their personal values, goals, career, promotion, compensation, satisfaction and success. Here individuals are managers, executives, employees and laborers who peruse their own individual definition of success (BlessingsWhite, 2013).

Model Summary

Organizations are pursuing their goals and achievements and so are employees. These two strategies intersect each other which is called "Job" (BlessingsWhite, 2013). The job intersection is all about what employees want to get from the job and what organization will give from the job. This model states that intersection of engagement is the **maximum contribution** to the organization and **maximum satisfaction** of an employee is point A "Apex" means the engaged one. People on the Apex are the maximum contributors and highly satisfied employees of the organization. But there are some other people on the intersection point as well. Some people might be highly satisfied with work (Like newly hired, highly paid or promoted) called **honeymooners** who are satisfied with the job but are not sure what their contribution is towards the organization. Right to opposite side, organizations have employees called **crash and burners.** whose contribution is really high but they are not aware of the benefits of the current job means rarely satisfied from the job but high in contribution. In simple words, they are not satisfied with what they do. Then the opposite of apex there are employees who are not satisfied nor contributing in the organization called the **disengaged**.

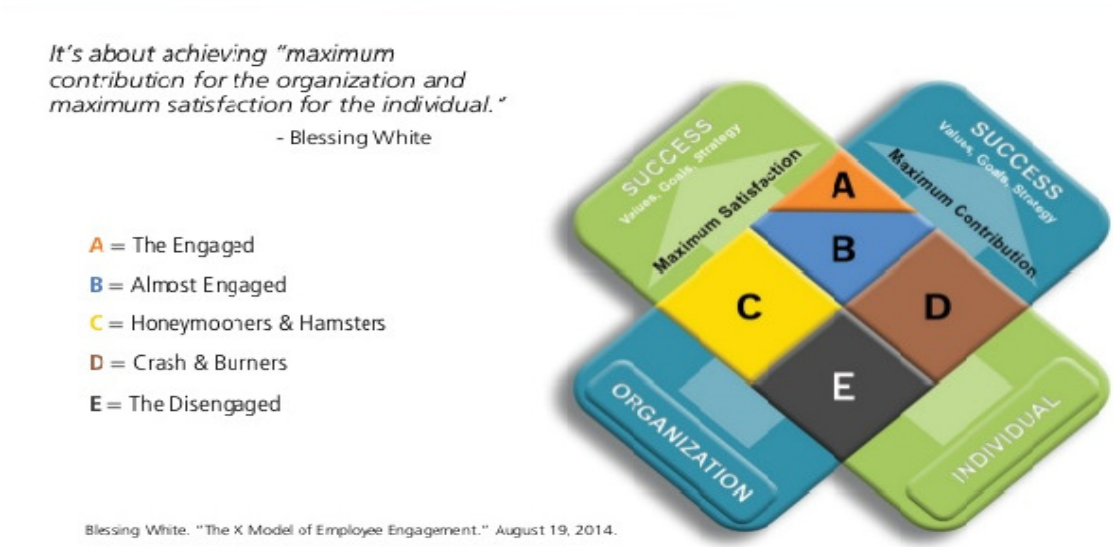

Fig: 1.4: X – Model of EE

Source: (BlessingsWhite, 2010)

Learning for Organizations

What could be done to improve employee engagement is a significant question in today's global environment. Where switching job is becoming a norm if an employee feel things are not going according to his/her interest (Purcell , Kinnie, Swart, & Rayton, 2008). To engage employees, organizations need to identify its drivers according to the culture of the organization, culture of the country, diverse workforce, nature of job and individual and organizational goals (Robinson, Hooker, & Hayday, 2007; Bates, 2004). In U.S. billions of dollars being spent on the employee engagement because they know it cost more than an organization to spend on a new hiring rather than retaining an old performing employee. There are many drivers, which do not need any expenditure of capital for identification but literature and models identified above in the paper. Now organizations need to identify that which of these drivers are important to target. Current literature survey identified drivers of engagement, which could be universal in nature. Like every organization need a leader who do not manage, employees but engage employees. So organizations need to identify leaders or create leaders in the organization. **Satisfaction** is the driver which is closely positively related to engagement (Abraham S. , 2012). IES study suggests that line managers have a very important role in fostering trust, recognition and relationship with employees (Robinson, Hayday, & Perryman, 2004).

Hence there is clear link between employees' personal experiences, personal life and sense of being involved at work and therefore engagement levels engagement are linked with their feelings of being valued and involved. One step beyond satisfaction, is engagement and it is linked with employee's commitment of long stay in the organization. So it makes sense that organizations should monitors employee's level of engagement and try to nurture this feeling. Integrating all EE drivers, a graphical depiction is presented in Fig. 1.5.

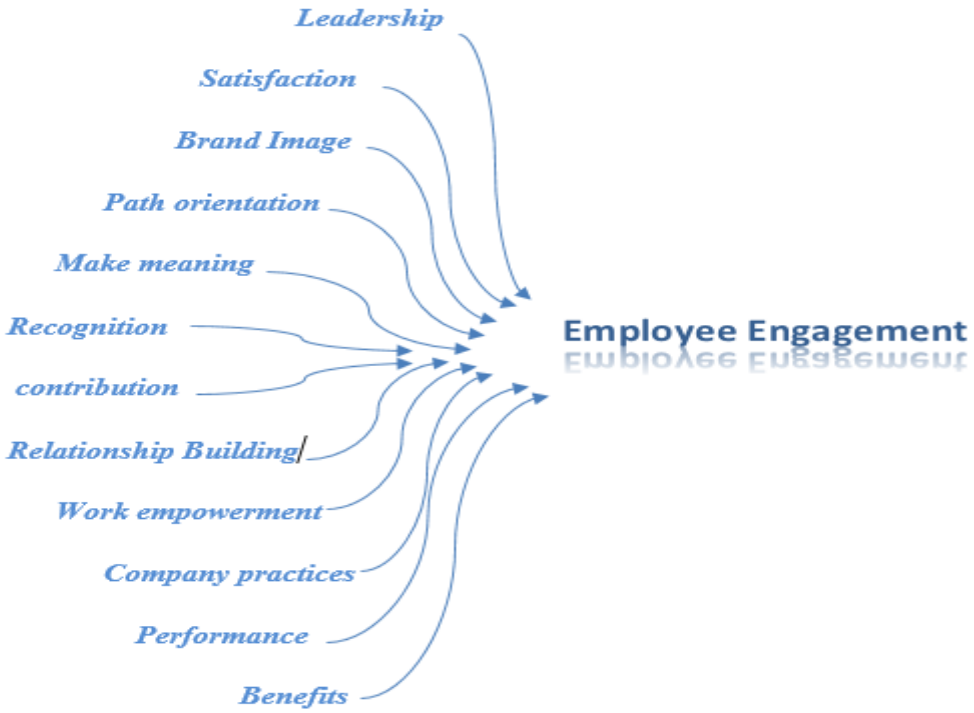

Fig:1.5: Drivers of EE

Source: Current Literature Survey

Discussion

Success is like a classical snakes and ladder game where achievements and accomplishments are ladders while setbacks are snakes. It is human psyche that snakes (setbacks) affect more strongly than achievements. So it is essential to build an attitude in which small loses could not eradicate small achievements. This attitude will be built when employee will realize importance of his/her work and existence in the organization. Employees often feel disconnected when they do not understand or informed about their progress at organization (Harter & Adkins, 2015). Research suggest that organizations, which have well established Performance Management System are more likely to engage their employees as compared to other organizations (Gallup, 2017). Performance management is not only telling employees what they need to do but managers often discuss about employees' responsibilities and personal development. These types of activities play major part in engaging employees at work because employees want their managers to help them in work as well as hold employees' accountable for their performance (Harter, Schmidt, Killham, & Asplund, 2011). Hence Zinger model is an ideal model for the organizations which are successful at performance management because the model suggests that from employee performance, recognition, employee strength and making meaning for employee everything should have proper check and balance and management system. This model offers ability to ability to structure and tackle each block at a time (Zinger, 2013). Model suggests that every block should be focused and analyzed at time. This model was originally designed for the managers to increase engagement of those employees who report them and then model was also used by managers to measure their performance level in the organization. Because an engaged employee can only engage others. Table 1 presents the summary and comparison of the three models discussed above.

Table: 1 Outcomes of EE

Model	***Key Drivers***	***Outcomes (Individual)***	***Outcomes (Organization)***	
Zinger Model	*Recognition* *Path orientation* *Relationship Building* *Leverage Strength* *Make meaning*	*Maximum performance* *Enhanced Wellbeing*	*Achieve results*	
Aon Hewitt's	*Brand* *Leadership* *Performance* *Company practices* *Benefits* *Work empowerment*	*Say* *Stay* *Strive*	*Talent* *Productivity* *Retention* *Revenues*	
X-Model	*Maximum Satisfaction* *Maximum contribution*	*Individual success*	*Organizational success*	

Hewitt's model suggests to engage employees is not about to making tools or technologies, or about HR survey and or managing engagement's score. Rather, It is about changing the culture (engagement culture) and leadership. Engagement culture align people, jobs and infrastructure where leadership demonstrate value of human capital and suggest strategies to make engagement happen.

Conclusion

What an organization could do to significantly engage their employees? This is the question organizations quest for (Purcell , Kinnie, Swart, & Rayton, 2008). It is not necessary for an organization that to engage an employee has to be expensive but positive energy and right timing is needed to engage an employee and off course benefits will outweigh these costs (Bates, 2004; Robinson, Hooker, & Hayday, 2007)

Engagement is all about feelings. Carl W. Buehner quoted that people will forget what you do, what you said but will never forget what you make them feel (Buehner, 1971). Engagement is an emotional connection of employees with their leader as described in Hewitt's model. Engagement is critically important for the bottom line. As in the U.S disengagement cost $350 billion a year and 445 billon in Australia (Ross, 2011). Despite thousands of studies on engagement, Gallup results shows that only 33% of the employees are engaged. That shows a threat with an opportunity that remaining 67% are waiting for a leader to engage them, they are waiting for the psychological benefits, they are waiting for say, stay and strive or waiting for to be treated as individuals (Aon Hewitt, 2017; Zinger, 2009; Vrouvas, 2016). If organizations want to stay competitive, it is imperative that following steps must be taken:

1) Who is sinking the ship

Mangers and leaders need to find the "sweet spots". Sweet spots are those employees who are highly engaged. Engaged employee is 30% more effective and productive so he/she needs to be identified and shall be given much attention to retain that employee. Then managers must identify 'Bad apples' too and target them as well. Mangers need to help them identify their area of interest and their motivation of

working with the organization. They must be given consultation regarding their reasons of disengagement and to be asked to adjust their attitude or should be given help out find a new place for work.

2) Leaders with Engagement Intelligence

Great leaders have emotional intelligence but quite a few are exceptional in driving real results. Leaders must possess EI2 called **engagement intelligence** (Wright, 2013). The leader High on EI, will be the key contributor in maintaining psychologically healthy work place (Nowack, 2008) Leaders with self-awareness, social awareness, self-management and social management are able to push employees to do better for him/her and for the organization as well as improve moral, attitude and results. They are the key motivators and mentors.

3) Recipe to engage People

Above models are repeatedly discussing the strategies of engagement of an employee which can be used as pills to get rid of the disease of disengagement. David Zinger's models points out building trust, give rewards and recognition to improve EE. Hewitt's model focuses on psychological wellbeing of an employee and X-model suggests that crash and burners needs to be attended first because they produce great results but not satisfied with what they want from work.

Future Research

With few exceptions (Kahn, 1990) there is a dire need of EE literature as well as quantitative results. In developing countries there are many agencies who conduct engagement surveys but in developing countries concept of engagement is not widely used. There is also need of studies on engagement in developing countries and also longitudinal studies on engagement globally. There is need of reliable and valid tools for measuring engagement in developing countries as engagement drivers could be different due to diverse culture and economy. This study can be further nourished if other engagement models could be analyzed and also a comparative analysis of the models could be done.

Luís A. Amaral, Universidade do Minho, Portugal, amaral@dsi.uminho.pt

Abstract

Public procurement represents the largest component of public expenditures and, for that reason, is one of the most sensitive areas of the risk of corruption. There are several governmental investments in this area to accomplish the principle of integrity and to achieve more transparency.

In Portugal, in the e-government context, the strategy was the adoption of electronic platforms for procurement, as the main reinforcement measure of transparency in public procurement. Through an exploratory literature review, based on OCDE recommendations and European Union official reports, this paper aims at contributing to the discussion on the use of information and communication technology, specifically electronic platforms, in Portuguese public procurement. While the gains are potentially significant, it should be noted that the implementation of the principle of integrity implies articulated measures of technological and political dimension as well as organizational culture.

Keywords: public purchase, electronic platforms, transparency, prevention of corruption.

1. Introduction

The literature commonly highlights the potential of information and communication technologies (ICT) in the design of new public governance models that promote transparency and accountability, which are considered critical requirements to an efficient resource management and to fight corruption. In this context, the specific sector of public procurement sector is critical, since it represents a large portion of public expenditures and is one of the most sensitive areas with respect to risk of corruption.

With a focus on enhancing transparency, several investments have been made by governments to implement e-procurement, representing one of the most relevant initiatives of digital government. Among other advantages, e-procurement can be an important tool to promote competition, to foster more transparent decision-making processes, to reduce corruption and bureaucracy, and to save time and money.

Among European countries, Portugal is considered a good example of e-procurement policies and practices and has focused on the complete dematerialization of pre-contractual procedures. The application of the Public Contracts Code (CPC) in 2009 entailed, among other measures, mandatory adoption of public procurement electronic platforms by contracting entities in support for pre-contractual procedures.

These instruments reinforce the promotion of transparency in public procurement, but can they be strengthened in another way to increase transparency? Based on an exploratory literature review on this subject, and focusing on a set of recommendations by the Organization for Economic Co-operation and Development (OECD) the European Union (EU) and the analysis of the instruments mentioned above, this article aims to discuss the contribution of electronic platforms in the increasing public procurement

transparency in Portugal. It adds the identification of limitations they present and, in this sense, the presentation of guidelines to promote their use.

In what follows, Section 2 addresses the importance of public procurement and the emphasis on transparency. Section 3 discusses how e-procurement is an instrument for promoting transparency and preventing corruption. The analysis of technological instruments adopted in Portugal, namely public procurement platforms, is presented in Section 4. Section 5 deals with threats to transparency. Finally, Section 6 presents discussion topics and further work to be made.

2. Public Procurement and the Focus on Transparency

Public procurement is an important part of the European Member States' national economies. It accounts for around one fifth of EU annul GDP (EU, 2014). In the OECD area, it represents about 12% of GDP and around 4.2 billion euros in 2013 (OECD, 2016).

For a number of reasons, particularly for the financial flows they create and for the close links between public and private sector, public procurement is a breeding ground for corrupt practices (Boehm, 2007; Lamsdorff & Nell, 2006; Rose-Ackerman, 2002; UE, 2014; OECD, 2016), as evidenced by several studies. According to a study on public procurement indicators, corruption practices lead to a 20 to 25% increase in spending on public procurements, and in some cases may reach 50% (EC, 2011). Taking into account the principles of integrity in OECD procurement, mismanagement ("governance deficit") of public procurement undermines competition and increases the prices of goods and services purchased by public entities, thus impacting public expenditure and income from taxpayers (UE, 2014). A study on detecting and reducing corruption in EU public markets concluded that, in 2010, the overall direct cost of corruption in public markets on only 5 sectors (road and rail, water and waste, public works, training, research and development) of 8 Member States (France, Italy, Hungary, Lithuania, the Netherlands, Poland, Romania and Spain) amounted to between 1.4 billion and 2.2 billion euros (EC, 2003). In addition, more than half of the cases of foreign briberies occur to obtain public procurement contracts (OECD, 2016) and several cases of illegal financing of political parties had favorable decisions in public procurement procedures as currency of exchange (OECD, 2009).

Public procurement presents a high risk of corruption and, in recent years, Member States have adopted reforms in the public procurement field, which have made it possible to strengthen transparency, competition, and prices (EU, 2004; OECD, 2009; Boehm, 2007; Lamsdorff & Nell, 2006).

Reforms to enhance transparency are essential, since public procurement accounts for a substantial proportion of taxpayers money and therefore requires efficient management and high levels of integrity in order to safeguard public interest (OECD, 2016; Armstrong, 2005). According to Armstrong (2005), accountability, understood as reporting information on the use of public resources to stakeholders of achieving the defined objectives, brings transparency improvement. Transparency, according to the same author, can be defined as the "(...) public access, with no restrictions, to on-time and reliable information about decisions and efficiency of public sector" (Armstrong, 2005: 1). However, transparency and accountability imply integrity and reliability, that is, honesty and trust. In brief, accountability, transparency and integrity are the essential pillars in safeguarding public interest.

In this context, OECD (2009) refers to ICT use as a fundamental instrument of reforms, especially in the area of public procurement. ICTs allow creation and strengthening of a culture of transparency, facilitating the monitoring of information as well as control of public procurement (OECD 2009; Bertot, Jaeger, Grimes, 2010). For example, "unique portals/platforms" can supplement traditional means of supporting transparency. The challenge is to ensure a degree of transparency that reinforces the anti-corruption fight, without undermining the efficiency and effectiveness of public procurement (OECD, 2009), while allowing citizens to monitor how public money is managed (Lourenço, 2013).

3. Electronic Public Procurement: A Tool for Transparency

According to the European Commission (2010), e-procurement generally means replacing pre-contractual, paper-based procedures with communication and processes based on information technologies and systems (TSI) (EC, 2004) and considers that it promotes the effectiveness of procedures and provides additional guarantees in terms of detecting and preventing corruption, since they enhance transparency, enable better application of standardized procedures and facilitate monitoring (EU, 2014).

A literature review by Ferreira and Amaral (2016) points out several benefits of ICT adoption associated with purchasing practices, highlighting: (i) the simple and efficient way of buying, allowing a reduction of transaction costs; (ii) identifying and negotiating with suppliers more efficiently; (iii) automation of workflows that can subsequently be extended to the entire supply chain and to the entire organization, enabling information sharing and integration; (iv) processing of orders, monitoring and control of acquisition activities; and (v) transformation of the way an organization conducts pre-contractual processes (Schoenherr & Tummala, 2007; European Commission, 2010).

Ronchi *et al.* (2010) focus on: (i) strategic benefits (related to comparative efficiency); (ii) transactional benefits (concerned with efficiency and effectiveness of transactional activities); and (iii) informational benefits (as well as decision support and timely communication). According to the authors, these benefits translate into financial and organizational gains, with impact on improving governance. To these advantages, Talero (2001) adds: (i) the increase of transparency in the relations between public organisms and the market (emphasis on the G2B components). Kassim and Hassin (2010) refer to (i) value creation, (ii) increased transparency, (iii) improved information flow, (iv) support for decision-making, (v) creation of open markets in order to all suppliers be able to compete, taking advantages from the aggregated power of governments to achieve dynamic prices of goods and services and improving the purchasing cycle efficiency, like (vi) the benefits in adopting e-procurement systems.

In sum, ICT has clearly the potential to play an important role by facilitating the access of suppliers/providers of goods/services to information more easily and in real time. ICT also facilitates monitoring of the public procurement process information, as well as its subsequent execution. This aspect is crucial for public procurement control by stakeholders, characterized by a multiple network of different actors, both internal and external: (i) in the context of governance and definition of public policies; (ii) in the context of public procurement activity - relationship between contracting entity and external entities in procurement processes; (iii) in the context of public procurement activity - internal actors of contract formation processes (Ferreira, 2016).

Understanding the context of the public procurement activity is also crucial in order to reach the concept of transparency, as presented by Heald (2006; 2012): process transparency and transparency of events; macro-level transparency and micro-level transparency; real-time transparency and transparency in retrospect (Lourenço, 2013). This discussion is imperative for the purpose of determining the overall government transparency strategy for public procurement in order to enhance accountability through the use of ICT (Lourenço, 2013), always in the defense of public interest.

4. The Portuguese Case in the Use of Electronic Platforms for Public Procurement

The gains of transparency attributed to the adoption of technologies in public procurement processes are recognized in the literature. However, it is also important to take into account the costs of adopting electronic public procurement platforms, as well as their maintenance costs, which probably vary according to the size and sophistication of the electronic platform (Ferreira & Amaral, 2016; European Commission, 2010). To these, it must be added the costs of licenses, internal and external resources, security systems, implementation and maintenance, integration solutions, process design, configurations and customization, training and communication (Ramanujam, 2012). In this context, the financial risk and risk in the development of technological solutions and legal issues, are determinant factors in electronic

public procurement projects (Oliveira & Amorim, 2001) and, consequently, the increase of transparency in procurement processes.

In addition, Ferreira and Amaral (2016) advert that the simple adoption of technological components does not mean necessarily that the organization automatically reap the benefits indicated. In this respect, the European Commission (2010) identifies a number of problems that may create obstacles in the adoption of e-procurement and hence transnational participation in e-procurement procedures (European Commission, 2010): (i) inertia and fear of contracting authorities and suppliers (reorganizing costs of internal systems; lack of knowledge regarding associated advantages; risks linked to the integration of procurement technologies with existing IT systems); (ii) lack of guidelines in electronic public procurement processes (suppliers are confronted with an electronic public procurement architecture composed of different platforms and devices); (iii) costly technical requirements, especially in authentication of tenderers.

However, Heald (2013) draws our attention to the existence of certain obstacles in open government initiatives that have implications for transparency gains. Legislative initiatives, public processes and the way information is made available, does not necessarily translate into improved transparency and, consequently, have implications in terms of accountability (Lourenço, 2013, Heald, 2016). To these it is also added models for technological development of artefacts, particularly in public procurement (Ferreira, 2016). In turn, Bertot *et al.* (2010) refer to usability, issues related to acceptance and implementation of technologies, education and culture, as potential barriers for transparency, enhanced by the adoption of technology.

In order to correct these problems and to promote transparency, smart, healthy and inclusive growth, the European Commission defines in its 2020 strategy the following vision for public bodies and services: creating public value through ICT, attributing to public procurement a crucial role in the definition of policies and concrete measures in this area. However, with regard to the effective use of public electronic procurement in most of the EU countries, the global adherence remains weak (Ferreira, 2016; European Commission, 2010). Portugal, according to this same report from the European Commission (2010), constitutes an exception in the legal sphere, for the complete dematerialization of contract formation processes, through CCP application, approved by Decree-Law no. 18/2008, of January 29th, with corrections introduced by subsequent legislation, thus transposing the guidelines of Directives 2004/17/CE and 2004/18/CE into the national plan, a key tool for implementation of the defined objectives associated with the National Public Procurement System (SNCP), mainly those related to electronic public procurement (Ferreira, 2016).

As a result, the translation of the European policy to national laws has been marked by the definition of a technological model that includes a set of measures and projects, among which e-platforms for public procurement in support for pre-contractual procedures, of mandatory use by the contracting entities and established in terms of development in the private model: the electronic public procurement platforms. These platforms, of mandatory use by contracting authorities in public procurement processes, according to BASE Gov, the Online Public Procurement Portal, consist of a technological infrastructure made by a set of applications, means and services necessary for the operation of the procedures national public procurement contracts to support the operation of the phases of the pre-contractual procedures legally envisaged for the realization of public expenditure. In this sense, these platforms must support the following functions: (i) receiving of proposals, applications and solutions; (ii) opening of proposals and applications, and providing information to competitors; (iii) evaluation of proposals, according to qualitative and quantitative criteria; (iv) characterization of the procedure and aggregation of its parts; (v) publication of the procedure, or delivery of invitations, making known its contents to all interested parties; (vi) making available the parts of the procedure for consultation; (vii) receiving of requests for clarification; (viii) delivery of answers, clarifications and rectification of parts of the procedure (CCP, 2008).

In September 2017, according to data available in BASE Gov, five electronic procurement platforms and their respective management entities were licensed in Portugal. A year ago, in July 2016, 10 platforms were licensed.

The introduction of public procurement platforms resulted in substantial gains, recognized in terms of pre-contractual procedures: (i) in transparency; (ii) in trust by competitors; (iii) in construction of organizational memory; (iv) in competition; (v) in the working methods of actors; (vi) in information management; and (v) in cost reduction (Ferreira, 2016). Concerning transparency, changes potentiated by the platform in phases where the jury intervenes, often accused of being the center of corrupt practices (EC, 2014). In this context, there is a strengthening of transparency in the process (Heald, 2006; Heald, 2012; Lourenço, 2013).

In short, e-platforms have contributed to improve transparency levels in the submission, analysis and evaluation phases of proposals, that is, in the phases where the jury intervenes. Thus, while in these phases the risk of corruption has decreased, in the remaining phases, especially those not supported by platforms, corruption risks have increased (EC, 2014; OECD, 2009). This may indicate that the focus on corruption has shifted from one phase to another, due to ICT introduction, which means in general terms that public procurement remains a very sensitive area in terms of preventing corruption. The question arises as to whether ICTs can contribute to enhancing transparency, and therefore to reduce the risk of corruption at all stages.

OECD (2009) stresses the importance and necessity of enhancing transparency at all stages of public procurement, in particular, at the phase of assessing needs, the phase of implementation of contracts and payments, phases not normally covered by regulation and not covered by platforms. This also occurs in the Portuguese case. Platforms support legal requirements, but fall short on OECD transversality (2009).

Considering the Integrated Management Model for Public Procurement oriented to Public Value presented by Ferreira (2016), in Portugal, e-platforms only support the contracting phase (from authorization of expenditures to adjudication and contract signature) and yet they do not present themselves as end-to-end solutions. This limitation of technological solutions, according to the same author, makes it difficult to manage public procurement processes at the organizational level.

In this context, despite good practices and considerable gains, other technological tools are needed to support a culture of integrity at all stages of public procurement, from the assessment of needs to the preparation of parts of the procedure and to the phase of implementation and payment (OECD, 2009; Ferreira, 2016), all based on a system for monitoring, managing and evaluating performances and impacts of public policies and public value based on the following modular components (Ferreira, 2016): (i) Management and evaluation of public policies oriented to public value: a) authorization of public policies; b) policy-making; c) integrated management of policies, programs and projects; (ii) Management and evaluation of public procurement: a) management and evaluation of the purchasing cycle (strategically manage planned purchases with public policies, manage prior authorization process for expenditure execution, manage processes of public procurement and evaluation); b) manage the execution of the contract, oriented to the execution of policies, programs and projects; c) manage suppliers and evaluate the execution of contracts; d) contract evaluation: evaluate social and financial outcomes (impact on public value).

Furthermore, it is stated that the model of development and implementation of technological solutions on the field of public procurement is presented as a limitation to the development of electronic solutions based on the above referenced view.

In Portugal, the model of development of electronic platforms of public procurement, as previously mentioned, is the private model. I.e., technological development tasks and risks are assumed by private entities, managing bodies of the platforms (Ferreira, 2016; Oliveira & Amorim, 2001).

In this sense, will this private model be an obstacle for the implementation of the integrity principle and enhancing transparency in the procurement process? Will the private entities be willing to take risks in

developing solutions that are not included in the legal plan, but considered key to foster an appropriate degree of transparency and integrity in all phases of the procurement cycle to ensure a fair and equitable treatment of potential competitors and contractors?

These issues need to be discussed and reflected, since these depend on new measures to strengthen transparency, fundamental to reduce risk of corruption (OCDE 2009, US, 2014).

5. Threats to Transparency

According to Ferreira, Cunha, Amaral and Camões (2014), with respect to Portugal, the high degree of implementation of e-procurement and the consequent gains in terms of transparency are not yet reflected in the perception of corruption indicators. Their data supports shows that the levels of perceived corruption remain high.

At the European level, Eurobarometer data on corruption (EU, 2014) revealed that more than 50% of companies report corruption in public procurement as a common practice. Results from this survey show that: (i) 32% of companies that submitted tenders in the context of public procurement claim that corruption prevented them from obtaining their tenders; (ii) bureaucracy (21%) and criteria that seem to have been designed to match certain competitors (16%) are identified as the main causes why companies do not compete for public procurement; (iii) more than 40% of companies report there are several illegal practices in public procurement.

In this alignment, the First Anti-Corruption Report of the European Union (2014), which devotes a chapter to the issue of corruption in public procurement, identifies as main problems: (i) specifications drafted with intention of favoring certain competitors; (ii) conflicts of interest at various levels and in various stages; (iii) disproportionate and unjustified award criteria; (iv) unjustified exclusion of competitors; (v) undue recourse to urgent procedures; (vi) insufficient analysis in case of abnormally low prices; (vii) excessive weight of the lowest price criterion (to the detriment of criteria regarding quality of goods/services and execution capacity); (viii) unjustified exemptions from publicizing procedures. This report also concludes that the main risks in terms of corruption are focused on the needs assessment, procurement planning and strategies, definition of evaluation criteria and selection of proposals and management of contract performance.

All these threats to the promotion of transparency and good governance add to the restricted vision of the procurement process underlying the design of e-platforms, fragile organizational culture and learning, disaggregation between legislation and platform functionality; the costs of access to platforms by suppliers (Ferreira, 2016; Ferreira & Amaral, 2016).

As can be seen from the problems and risks pointed out, the need to strengthen transparency is transversal to the whole process, including work practices and organizational behavior and requiring intervention beyond ICT. Therefore, it is concluded that reinforcement of transparency requires intervention at the ICT and decision-making level.

6. Discussion

Based on the Portuguese reality and the recommendations and reports of the OECD and EU, this article discusses the use of ICT as a means of strengthening and promoting transparency in public procurement. It seems consensual that the Portuguese case revealed gains in terms of transparency, at least in certain stages of the public procurement process, namely in submission, opening, analysis and evaluation phases of the proposals.

Since, as highlighted in several reports, platforms do not yet cover all the stages of the procurement process, several problems and risks remain though. Moreover, the risk areas still need to be addressed.

Public procurement has a technical dimension, where ICTs are very useful, but one must not forget the political dimension, the decision-making plan. Technology can help solve problems, but that does not

mean that problems are solved solely the use of technology. The fulfillment of the integrity principle and, thus, improvements of transparency on public procurement policies requires the coordination of technological, political and cultural measures.

Abstract

Nowadays, society demands new and more sustainable production models, seeking the long-term sustainability of the Earth and taking into account both, the scarcity of resources, and the reduction of waste generation. The construction sector is one of the largest waste generators (Esa, Halog and Rigamonti, 2017). The Circular economy (CE) could help this sector to diminish their environmental impact. One of the issues in order to develop the CE is the need for measuring the degree to which circular economy is implemented in construction projects. However, for the moment, there is no scale of measurement that can resolve this issue.

For this reason, this article has developed a scale of measurement of the degree of circularity for the construction sector. First, it was designed a scale-based literature review on the topic, and after that, the Monte Carlo simulation method was proposed to predict values. The scale is based on an analysis in five phases of construction projects: design, production of building materials, construction processes, maintenance and liquidation. Then, three levels of consideration are proposed in the model: organization, process, and workgroup. Results show that the scale can be useful for measuring the circularity thinking in the construction sector what, in turn enables to create more effective strategies by construction companies.

Keywords: Circular economy, building sector, scale measurement, organizational behavior.

Introduction

Building has been a sustainable sector since ancient times. Both materials and building techniques represented efficient construction, featuring ecologically designed buildings and eco-friendly materials with high reusability and recyclability. This model of construction was circular. However, the adoption of more resilient and durable building materials during the 20th century converted the sector into one of the most environmentally harmful, unsustainable and waste-generating industries in the world.

Fortunately, businesses worldwide have started to express increasing concern about environmental issues. In this context, the building sector, being one of the larger emitters of harmful gases, generators of waste, and consumers of resources (Esa, Halog and Rigamonti, 2017), plays a relevant role. The main causes of the building sector's environmental impact are found in the consumption of non-renewable resources and the generation of contaminant residues, both of which are increasing at an accelerating pace. The sector's primary effect is the accelerated destruction of the stock of natural capital (Wadel, Avellaneda and Cuchí, 2010; Lo Presti, 2013).

Modern materials, which are useful for construction and enable excellent building features, have the side effect of dramatically increasing the building sector's environmental impact. Furthermore, the

maintenance phase that follows a construction also has a significant environmental footprint. It is also necessary to focus on deconstruction, which is a key aspect for minimizing waste, so as to create more effective strategies (Esa, Halog and Rigamonti, 2017). Furthermore, the reuse of elements (e.g., parts of buildings) requires deep consideration of their quality, their usefulness in terms of dimensions (do they fit the new place?) and marketing issues (do people want to buy used materials?).

For these reasons, the circular economy (CE) can be presented as a business model of sustainability that is especially useful in the building sector, so it is necessary to create a specific framework for this business model, providing answers to questions about how to implement the CE in the building industry? However, there is a lack of circularity indicators that would allow us to measure the circularity thinking in the enterprises. Lewandowski's (2016) literature review on the CE reveals only eight references which were focused on evaluation models, some of which analyzed a scale of measurement of the CE. Besides, the indicators introduced by other works such as that of Lihong and Hui (2011) are generic, considering, e.g., emission levels or energy consumption. This scarcity of scales is acting as an obstacle to the development of the circular economy in construction companies. This research was aimed to create a measurement model of circularity thinking in the building sector based on a set of indicators, which would allow businesses to manage the degree of implementation of the CE, collecting information from the project life cycle.

Therefore, the main contribution of this paper is a CE measurement scale specifically designed for construction projects. It will be a useful method to evaluate the degree of implementation of CE, generating valuable information not only for the company (contractor), but also for other project stakeholders. This can be a step towards developing CE which is really useful in practice.

Theoretical Framework

Industrial Ecology theory as base of circular economy in building sector

Ecology is concerned as 'creation, use, and management of resources for the adaption, human development, and sustainability of environments' (Bubolz and Sontag, 1993), focusing on the interactions between humans (individuals, groups, and society) and the environment. The entire system comprises the cultural norms and beliefs that influence the other systems, which represent the framework for legislative changes. An ecological transition occurs whenever a person's position in the ecological environment is altered as the result of a change in role, setting or both (Bronfenbrenner, 1979; Bauer and Dolan, 2011).

This view is enriched and focused on the industry through industrial ecology theory, a new framework that is useful to describe sustainable building, which pays attention to designs, flows derived from the building process, energies used, and outputs generated (Boons *et al.*, 2017). The main assumptions of this theory are (Ehrenfeld, 1997) as follows. First, the Earth is configured as a closed ecological system in which the scale and design of development are inconsistent with long-term ecological survival. Second, human society and natural ecosystems have co-evolved; thus, nature has now an intrinsic value, and the ethical and moral underpinnings of economic actions overlook concerns for the world. Third, sustainability means independently maintaining stocks of human and natural capital. Fourth, policy strategy focuses on several issues, such as an economy based on functionality, moral and ethical transformation, technological realism, precautionary management of uncertainty, and the life cycle framework, all of which are useful for closing material loops in deconstruction (Kibert, 2007; Silvestre, De Brito and Pinheiro, 2014).

Tibbs (1993) articulated a framework for industrial ecology that was adapted to the building sector. Thus, industrial ecology is a strategic framework that can be used as a guide for the development of building practices. In the concept, the impacts of the design phase play a key role, guiding the flow of materials in and out of the environment (Hao *et al.*, 2017). It is crucial to consider buildings in their whole life cycle. According to Lenox and Ehrenfeld (1997), the first phase of design is a conscious, explicit activity to

establish new forms of technology, organizational or industrial structures, human competence, and rules. The design must be the starting point that allows the implementation of the CE in the building sector. Moreover, the current building misdirection is quite clear so the implementation of this new economic model based on circularity has to be done by generating a framework useful for practitioners. Thus, four paths are useful through which the CE can be applied to the building design process, based on the model of Tibbs (1993) and Ehrenfeld (1997). First path is to improve the current metabolic pathway of building processes and material used. The second one involves the need to implement the principles of CE in the industrial ecosystem. Third path dematerializes building output, keeping in mind the idea of the product as a service, Cradle to Cradle (McDonough *et al.*, 2003; Mulhall and Braungart, 2010; Van Dijk, Tenpierik and Van Den Dobbelsteen, 2014), and managing resources carefully. The last one systematizes the pattern of energy used (Braungart, McDonough and Bollinger, 2007).

The building sector in Europe and the Circular Economy

The building sector in Europe is strategic for the economies of the most European countries. In 2014, 1,545,460 million euros were invoiced, generating employment for 12,730,700 people[1].

Europe's building industry is highly fragmented and often local, possibly because of each country's legal restrictions. Because of the high inflow of physical goods and personal interaction, the employment ratio in the building industry has remained relatively stable in the various states of the European Union (EU). It usually ranges from 4.5% to 6.5% of total employment.

Currently, the amount of waste generated in the EU appears to have declined: approximately 2.5 billion tonnes of waste (or approximately 5 tonnes per capita) continue to be generated each year (according to: http://www.europarl.europa.eu/RegData/etudes/BRIE/2016/573899/EPRS_BRI(2016)573899_EN.pdf). Some EU members generate significant amounts of recyclable waste in the building sector (the Netherlands, Germany, France, Italy), whereas other countries' recycling share is lower. Figure 1 shows the total waste generation in European countries in 2014 according to Eurostat, Figure 2 shows waste generation decomposed by sector, and figure 3 the level of recycling.

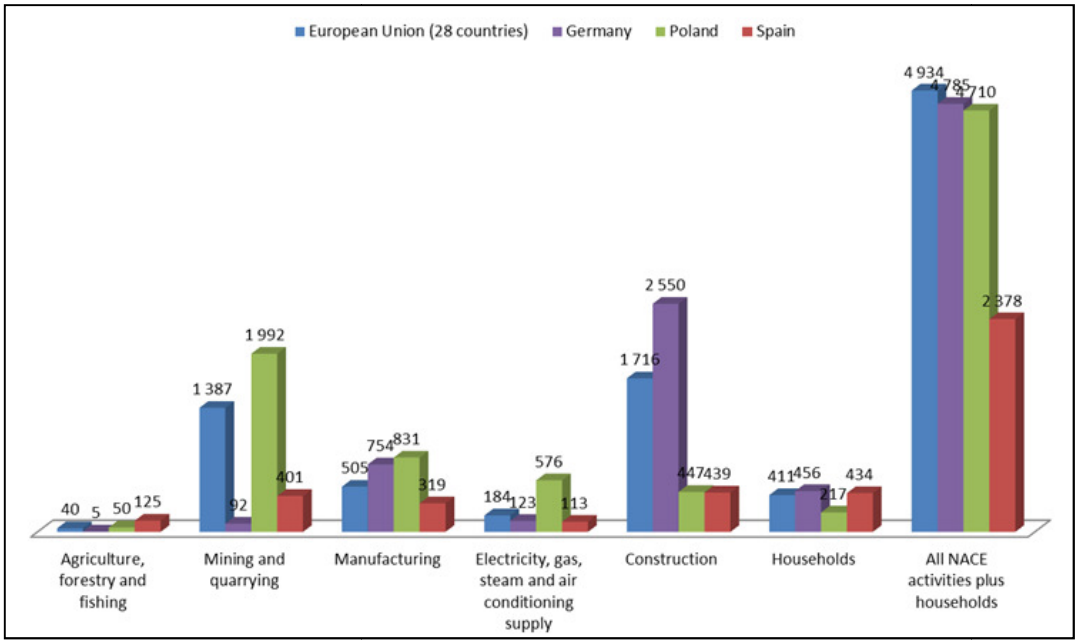

Fig. 1: Generation of total waste in Europe in kilograms per capita (2014)

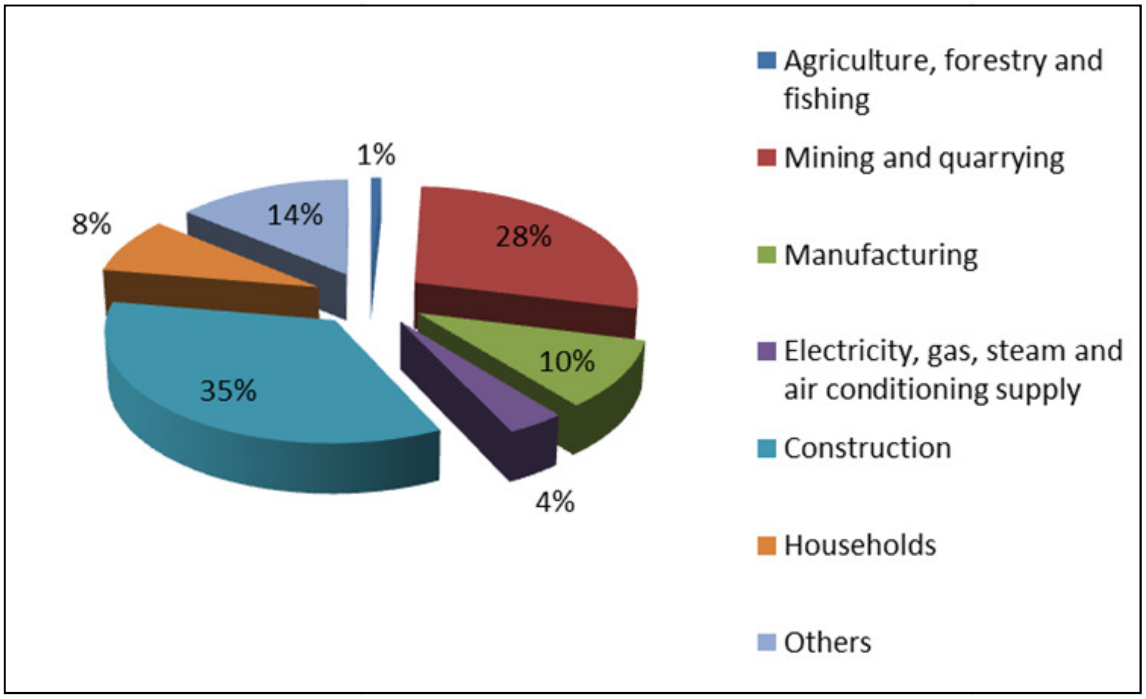

Fig. 2: Breakdown of total waste generated in European Union in 2014 by sector

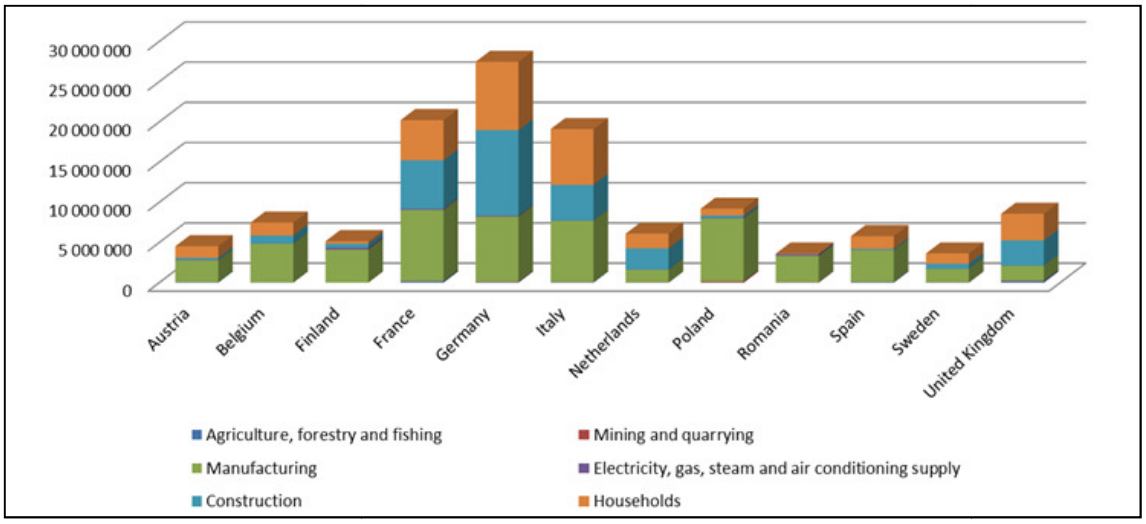

Fig. 3: Generation of recyclable waste by sector in Europe in 2014

Building sector is characterized by both its intensive energy and water consumption and its generation of negative externalities in the form of environmental pollution. The sector itself is aware that it must change its management model to become more sustainable and that it can comply with the new approach to the 'sustainable use of resources' set out in the European Building Products Regulations, which have been in force since 2013 and state that products' environmental declarations should be used when assessing the sustainable use of resources and the environmental impact of building works.

In addition, the EU is considering initiatives to the use of environmental variables as factors as a basis for establishing public procurement criteria. It is worth noting the EPD (Environmental Product Declaration) methodology, whose purpose is to provide quantitative information about a product or service's environmental impacts throughout its life cycle. In addition, the initiative regarding products' environmental footprint (PEF) attempts to raise awareness and value the environmental impact of the inputs that are incorporated into the production or building process. Thus, taking all of this into account, the sector must consider the transition and progressive incorporation of the new paradigm of the CE, approved by the European Commission, which determines, not only the efficient use of resources in environmental terms, but also the minimization of resources that are consumed, reincorporating them into a new productive or other type of process in which they are considered a productive factor. In this way, the building industry will contribute to a cyclical process in which product life will be as long as possible.

A Proposal for an Indicator of the Ce Based On an Analysis of the Building Life Cycle

Scale Inputs

In order to have the initial indicators of the scale, a systematic review of the literature has been carried out, whose purpose has been to obtain a complete view of the existing research on the subject. In this paper, it was presented the research that has been done so far, after having used explicit methods to narrow the search and to evaluate in a critical and justified way each of the related studies (Vázquez and López, 2011). The basic criterion is to show valid and applicable evidence for future research. The review should be methodological, transparent and reproducible with the aim of enhancing the knowledge base to make appropriate decisions (Tranfield, Denyer and Smart, 2003).

Review is a fundamental scientific activity and its logic is based on several premises. The first is that the large amount of existing information should be reduced to smaller, more manageable units to facilitate their understanding and management. In this way it will be possible to effectively use the previous scientific evidence, identifying key works and future lines of research. The second is that the review should show evidence of the process developed, it should be auditable and repeatable so that other researchers who follow the search and analysis guidelines can perform comparable work, avoiding search bias and analysis, and the third is that the review should summarize the evidence (Tranfield, Denyer and Smart, 2003; Rousseau, Manning and Denyer, 2008).

The research was based on the approaches of Vázquez and López (2011), and Nuñez-Cacho et al. (2012) defining the aspects to be investigated, developing subsequently the search in the bibliographic databases, i.a. ProQuest, limiting the results to a sample that includes the main journals in the study area. Specifically, based on the search terms: "Buiding", "Circular Economy", "Measurement Scale". A list of researched journals appears in the references section. Moreover, each authors analysed the content of each of the selected articles in order to identify the indicators that were to be introduced. It has to be underlined that in the research were involved professional experts responsible for construction projects. They were responsible i.a. with the authors for choosing the circularity indicators and for estimating parameters used in the simulation model. The selected indicator group was classified according to the Life Cycle Model. The selected indicators, and their desired value are shown in table 1, 2 and 3.

Table 1: Circular economy indicators in the construction sector: Organizational level

Level	Perspective	Indicators (Measures)	Desired value of the indicator (Target)	Justification
ORGANISATION	DE	'Designing for deconstruction' strategies - percentage	100%	Majority of experts pointed it out
	MM	"Better …" initiatives for sustainable production - percentage	80%	Majority of experts pointed it out
	CP	Complement of the Energy Use Intensity[2] index - percentage	90%	Majority of experts pointed it out
	MA	Building management strategies - percentage	80%	Majority of experts pointed it out
	EL	Decision accuracy of demolition time and transition to another loop - percentage	70%	Majority of experts pointed it out
DE – design phase, MM – manufacture of materials phase, CP – construction process phase, MA – maintenance phase, EL – end-of-life phase, CE – circular economy [2] - Complement of the Energy Use Intensity = 1-EC/GVA, where: EC – Energy Costs, GVA – Gross Value Added. Both EC and GVA are estimated for the whole organisation on the basis of particular projects				

Table 2: Circular economy indicators in the construction sector: Process level

Level	Perspective	Indicators (Measures)	Desired value of the indicator (Target)	Justification
PROCESSES	DE	Designs prepared in full BIM standard - percentage	100%	Majority of experts pointed it out
	MM	Continual improvement in CE (management control system) - percentage	90%	Majority of experts pointed it out
	CP	Construction site waste sorting - percentage	100%	Majority of experts pointed it out
	MA	Processes based on BMS - percentage	80%	Majority of experts pointed it out
	EL	Decision accuracy of demolition methods - percentage	90%	Majority of experts pointed it out
DE – design phase, MM – manufacture of materials phase, CP – construction process phase, MA – maintenance phase, EL – end-of-life phase, BIM – Building Information Modelling, CE – circular economy, BMS – Building management system				

Table 3: Circular economy indicators in the construction sector: Workgroup level

Level	Perspective	Indicators (Measures)	Desired value of the indicator (Target)	Justification
WORKGROUP	DE	'Close loop' instructions for designers - percentage	70%	Majority of experts pointed it out
	MM	More sustainable sources (reused components, recycled and controlled virgin feedstock) - percentage	100%	Majority of experts pointed it out
	CP	Waste collected for reuse and recycle - percentage	40%	Majority of experts pointed it out
	MA	CE / BMS instructions based on BIM - percentage	90%	Majority of experts pointed it out
	EL	Decision accuracy of demolition techniques - percentage	90%	Majority of experts pointed it out
DE – design phase, MM – manufacture of materials phase, CP – construction process phase, MA – maintenance phase, EL – end-of-life phase, BIM – Building Information Modelling, CE – circular economy, BMS – Building management system				

Method: Deterministic calculation

The environmental impacts of building are primarily evaluated on the basis of the life cycle assessment, which enables the examination of all stages in the product life cycle (Jiménez Rivero, Sathre and García Navarro, 2016; Shadram *et al.*, 2016; Nasir *et al.*, 2017). A theoretical framework for waste minimization using the concept of the CE in the life cycle of the projects has been proposed (Esa, Halog and Rigamonti, 2017), which observes the main principles of Industrial Ecology.

A sustainable life cycle consists of five phases: the sustainable design process; the sustainable production of sustainable materials and equipment; the sustainable building process; sustainable maintenance; and sustainable liquidation, meaning the conversion of outputs into the inputs of reuse, remanufacturing or recycling. These phases involve three different levels of study: organizational, meaning decisions related to planning and organizing in the company; processes, meaning decisions regarding the processes of the building; and workgroup, meaning decisions related to the worker level.

The model proposed in this paper can be useful for measuring the circularity thinking in a construction company. The following concept represents deterministic calculation of the Circular Economy Index (values: 0 - 100%) understood as a total performance of the company in terms of the CE.

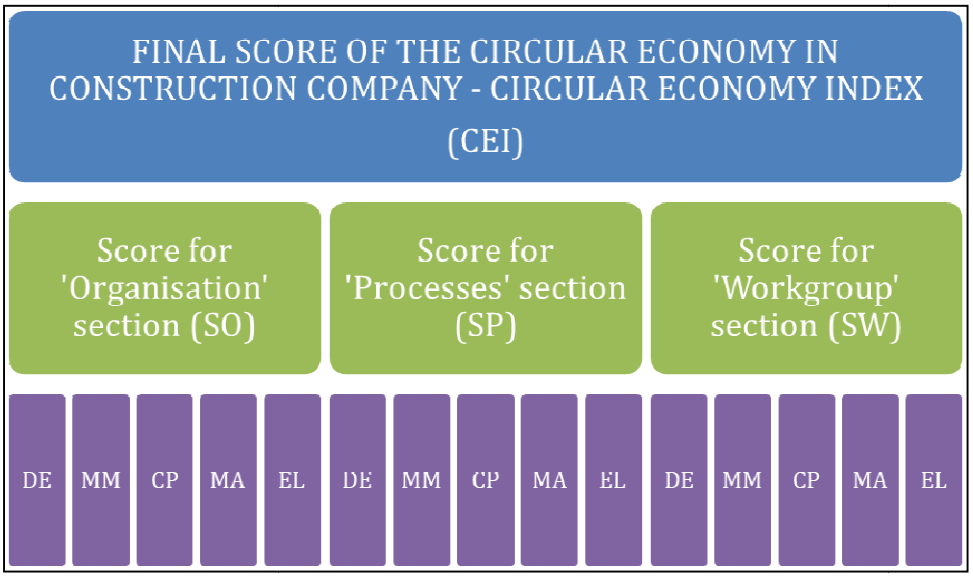

Fig. 4: Conceptual model of measuring circularity thinking in construction companies

The above figure shows a conceptual model of measuring company's circularity thinking, which is based on the formula described by the following equation:

$$CEI = \text{Arithmetic mean}(SO;SP;SW) = \text{Arithmetic mean}(\text{Weighted arithmetic mean}(SO_DE;SO_MM;SO_CP;SO_MA;SO_EL);\text{Weighted arithmetic mean}(SP_DE;SP_MM;SP_CP;SP_MA;SP_EL);\text{Weighted arithmetic mean}(SW_DE;SW_MM;SW_CP;SW_MA;SW_EL)) \quad (1)$$

where:
CEI – Circular Economy Index
SO – Score for 'Organization' section
SP – Score for 'Processes' section
SW – Score for 'Workgroup' section

SO_DE – Score for 'Design' level in 'Organization' section
SO_MM – Score for 'Manufacture of materials' level in 'Organization' section
SO_CP – Score for 'Construction' level in 'Organization' section
SO_MA – Score for 'Maintenance' level in 'Organization' section
SO_EL – Score for 'End-of-life' level in 'Organization' section

SP_DE – Score for 'Design' level in 'Processes' section
SP_MM – Score for 'Manufacture of materials' level in 'Processes' section
SP_CP – Score for 'Construction' level in 'Processes' section
SP_MA – Score for 'Maintenance' level in 'Processes' section
SP_EL – Score for 'End-of-life' level in 'Processes' section

SW_DE – Score for 'Design' level in 'Workgroup' section
SW_MM – Score for 'Manufacture of materials' level in 'Workgroup' section
SW_CP – Score for 'Construction' level in 'Workgroup' section
SW_MA – Score for 'Maintenance' level in 'Workgroup' section
SW_EL – Score for 'End-of-life' level in 'Workgroup' section

Method: Probabilistic estimation

This section explains the Monte Carlo simulation method used to analyse the CE in the building sector. The simulation is a powerful technique to analyse and solve complex problems. It is a technique that imitates the operation of with a system of the real world that evolves over time. The simulation takes the shape of a set of suppositions about the operation of the system, expressing through mathematics the relationships between system components (Winston, 2008).

The Monte Carlo simulation is a technique that generates a random variable based on probability distributions. Because of its flexibility, most assumptions can be relaxed so that operating rules, including policies and components ageing processes, can be accounted for in the model (Zio, 2013). After defining a parametric model, saving the values begins the simulation process. Next, the iterative process is repeated thousands of times until the moment that each rank becomes a frequency distribution, allowing us to evaluate descriptive statistics such as variance, confidence, limits, and so on (Tate, 2012).

The output of the Monte Carlo simulation proposed in this paper is a probability distribution for the final result, showing a degree of the enterprise's involvement in the CE. Monte Carlo simulations have been used to research many aspects of not only enterprises and projects (Dutra, Ribeiro and de Carvalho, 2014; Mangla, Kumar and Barua, 2014; González Dan *et al.*, 2016) but also sustainability issues (Olaru, Şandru and Pirnea, 2014; Arnold and Yildiz, 2015; Pask *et al.*, 2017). However, its previous applications, for example, in the field of economics, do not concentrate on the CE, particularly the construction sector. Such a possibility is discovered in this paper.

The simulations run according to the following equation:

$$CES = \frac{\frac{\sum_{i=1}^{5} w_i \cdot x_i}{\sum_{i=1}^{5} w_i} + \frac{\sum_{j=1}^{5} w_j \cdot x_j}{\sum_{j=1}^{5} w_j} + \frac{\sum_{k=1}^{5} w_k \cdot x_k}{\sum_{k=1}^{5} w_k}}{n} \quad (2)$$

where:
CES – Circular Economy Scale
w_i – weights of particular indicators in 'Organization' section
x_i – set of probabilistic indicator values in 'Organization' section
w_j – weights of particular indicators in 'Processes' section
x_j – set of probabilistic indicator values in 'Processes' section
w_k – weights of particular indicators in 'Workgroup' section
x_k – set of probabilistic indicator values in 'Workgroup' section
n – number of sections (n=3)

The parameters x_i, x_j and x_k are input random variables that affect the probabilistic results of the construction enterprise maturity in terms of the CE. The probability distributions of the variables and their statistical properties may be input from a database or may be specified by experts. The probability distributions, which are established for each random variable, enable simulation of the corresponding random numbers. The Circular Economy Scale (CES) is generated in subsequent iterations by values of the input variables. After each iteration, the output is different because each time a new draw is performed, the CES values gained in the simulation, after a defined number of iterations, create a random variable f.

Multiple iterations allow to calculate the probability of the construction enterprise maturity in terms of the CE and thus the reliability of the deterministic estimation of this indicator. The simulations were conducted with an add-in called "@RISK" Risk Analysis Add-in for Microsoft Excel Version 7.5.1: Industrial Edition.

Results of the simulation

The indicators were grouped into three different levels - organizational level, processes and workgroup, looking for the best indicator selected by experts and authors from the literature review, of each phase of the life cycle. The key indicators at the organizational level with their desired values are shown in Table 1, at process level in Table 2, and at work-group level in table 3.

Table 4 shows calculation results of the Circular Economy Index (CEI). In the sample case, its value is 58,78%.

Table 4: CEI calculation results

YEAR:	2016	STAKEHOLDER:	Designer			Manufacturer			Contractor			Investor					
		NO. / PHASE:	DESIGN	target	w_i	MANUFACTURE OF MATERIALS	target	w_i	CONSTRUCTION PROCESS	target	w_i	MAINTENANCE	target	w_i	END-OF-LIFE / DEMOLITION	target	w_i

	80,43%		0,09	0,21		0,76	0,95		0,665	0,38		0,075	0,45		0,3	0,36	
CLOSING LOOP 58,78%		<- FINAL SCORE OF THE CIRCULAR ECONOMY IN CONSTRUCTION COMPANY															

The deterministic calculation was followed by a probabilistic estimation of the Circular Economy Scale (Figure 5).

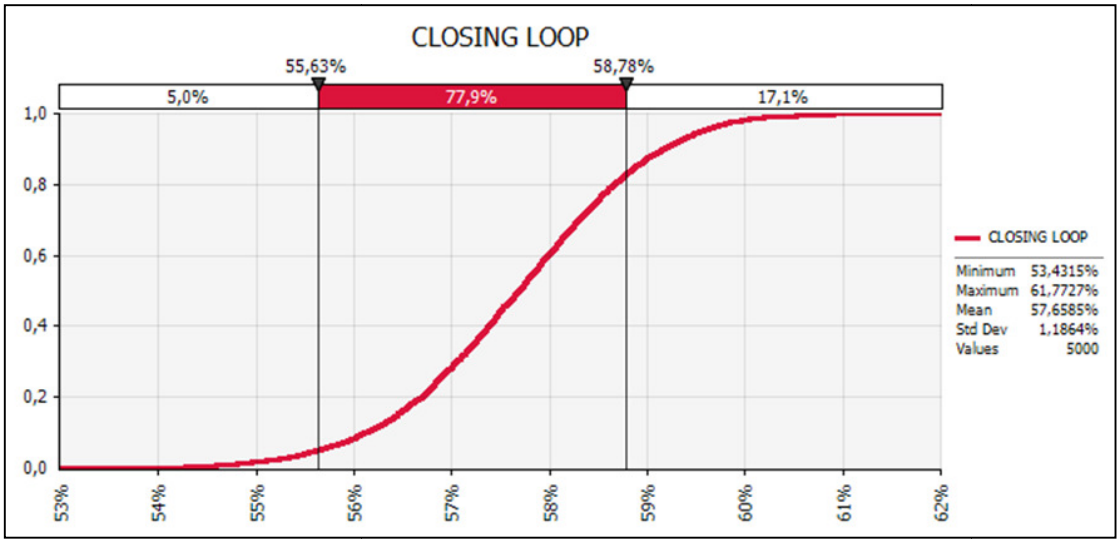

Fig. 5: Cumulative distribution of the CES after 5000 iterations

The simulations were conducted in "@RISK" during 5000 pre-set iterations. For the same case as for deterministic values, a level of 58,78% in Circular Economy Index can be reached only in 17,1% configurations what can be treated as a reliability of the deterministic estimation of the Circular Economy Index.

Discussion

The construction sector needs to undertake profound reforms to minimize its negative externalities, particularly in the areas of waste generation and resource management, which will ultimately result in a reduction in its environmental impact.

Therefore, the transition to another model of production such as the CE is not a question of social responsibility alone, but instead has become a strategic factor that guarantees the company's future continuity. In this scenario, the CE is shown as a model upon which the construction sector can rely to achieve its environmental impact reduction objectives.

A new paradigm guarantees the maximum use of resources and their biodegradability. The consideration of resources and technological nutrients leads us to consider the outputs of production processes as future inputs in other processes. The ideas of reducing, reusing and recycling are the basis of the new productive systems. Their application will translate into future sustainability. Moreover, public administrations, companies and institutions that seek sustainability have the right to ask companies to build their facilities in a manner that applies the CE in their processes. The problem is that there is no scale that allows us to measure the degree to which the CE is implemented.

To resolve this issue, a scale of desirable indicators of the company's circularity thinking was prepared. However, the application of life cycle theory to the building sector allows to establish 5 phases in which circularity thinking of the company is considered: the design phase, the manufacture of materials phase, the construction process phase, the maintenance phase, and the end-of-life phase. From practical point of view, it is easier to minimize the environmental impact in a systematic manner. In addition, it is useful to establish the level of the decisions, distinguishing between the organizational level, processes, and workgroup. Measuring the degree of the implementation of CE in each phase, the companies can be ranked, allowing businesses and administrations to evaluate the sustainability and create more effective strategies.

After the design of the scales, a Monte Carlo simulation method was used to evaluate the reliability of the CE measure. The results indicate that this scale will be useful to assess and evaluate each building project's environmental impact. The results show the relevance of each indicator and the desirable target, keeping in mind both each phase and each level.

First, the design phase indicators as design thinking on deconstruction strategies are a key indicator, with 100% being a desirable value (at the organizational level); in addition, the scale uses indicators related to design based on the full BIM (Building Information Modelling) standard (at the process level), 100% being the desirable value; indicators of 'Closed loop' instruction for designer (at the workgroup level) are also relevant; the desired value of this group would be 70% of fulfilment.

Second, in the phase of material manufacturing, the initiatives for sustainable production are a key indicator of the CE at the organizational level, and the desirable value is 80%. Moreover, continual improvement in the application of the CE at the process level is relevant, requiring a value of 90%. Focusing on the workgroup level, the indicator uses more sustainable sources, reuses components, recycles, and applies 3R (Reduce-Reuse-Recycle) ideas to the process; its target is 100%.

Third, in the phase of the construction process, focusing on the organizational level, it is desirable for the indicator energy use intensity to show a value of 90%, whereas at the process level, a percentage of

construction site waste generated must be established, with a value target for this item of 100% of fulfilment. However, at the workgroup level, we need to measure the level of waste and components recollected for reuse and recycling by applying 3R principles. The target for this indicator is 40%.

Fourth, in the phase of building maintenance, analysed at the organizational level, the management of building strategies is a key indicator with a value of 80%; processes based on BIM at the process level have an expected value of 80%, and instructions based on CE and BIM at the workgroup level have a desirable value of 90%.

Finally, the phase 'end of life' includes, at the organizational level, the indicator decision accuracy of demolition time and transition to another loop, with an expected value of 70%; the decision accuracy of demolition methods regarding the process level has an expected value of 90%, and the indicator of the decision accuracy of demolition techniques at the workgroup level has an expected value of 90%.

Conclusion

Based on the results, the paper contributes to developing the transition of the linear model to the circular model. Low scale values imply building companies working in the linear model, whereas high values of the final score for the CE show that companies make a commitment to implementing this model. Therefore, this paper's primary contribution lies in designing a scale of measurement of the degree of CE implementation, which will be useful for both government and businesses by facilitating the transition to the CE. Besides, a use of Monte Carlo simulations to rate construction enterprises in terms of their propensity to conduct activities based on the CE concept is an innovative solution. This may be treated as other of the paper's contributions.

Limitations and Future Research Line

This paper has the limitations derived from the use of a simulation method. It could be solved through a quantitative study using a Confirmatory Factor Analysis, which allows to establish the statistical properties of the scale. Another limitation originates in the horizontal nature of the research. The indicators are gathered at one point in time. It would be worthwhile analysing the circularity from an evolutionary perspective. Such an approach would use extended periods to isolate temporal phenomena that could distort the outcome. The limitations and the depth of the study have led to a series of future research proposals that are set out below. It is believed that it would be interesting to design a scale, not for a specific moment in time, but over a broader period of time and using longitudinal analysis to observe the evolution of the indicators.

Development of Web Extended Massive Open Online Course (xMOOCs) on Thermodynamics Subject to Increase High Order Thinking Skill of Students

Vina Serevina, State University of Jakarta, Jakarta, Indonesia, vina.serevina77@gmail.com

Ruly Lasrina Octavia, State University of Jakarta, Jakarta, Indonesia, vserevina@unj.ac.id,

Abstract

This study aims to develop web-xMOOCs phydu.com as E-learning on thermodynamics subject and to increase higher order thinking skill of students. This research method used research and development by the ADDIE (Analyze-Design-Development-Implementation-Evaluation) model. The object of this study was amounted of 41 students in the physics education program of State University of Jakarta. The validation in this research used expert material validation sheet, E-learning expert validation sheet, learning validation sheet, multiple choice questions, and higher order thinking skill questionnaire. Expert material validation results show 85,00 % (very good). E-Learning expert validation results show 81,25 % (very good). Learning validation results show 82,00 % (very good). Based on the results of the investigation on the effectiveness of phydu.com web on thermodynamics subject, obtained N-gain equal to score of 0.6878 in good category. This shows the increased score of higher order thinking skill participants. Based on the above data, this study showed that the development of web extended Massive Open Online Course (xMOOCs) on thermodynamics subject can increase high order thinking Skill of Students.

Keywords: Development of Web xMOOCs, Higher Order Thinking Skill.

Introduction

Education is an essential aspect of life which is needed to build a personality, attitude and behavior. Education is not only change of behavior process but also a process to educate. There are some efforts done by government to improve education quality. The improvement of education quality will be achieved if all components of education put their efforts to do a change to become better. School has to provide facility to enhance students, teachers as facilitator, and perfects curriculum. Learning outcomes are the abilities of the students after they received a learning experience (Serevina, 2017).

Development of technology also require students' learning skills to support learning activity. Nowadays, development of information and communication technology has changed the way of learning. Education is changing at a rate that has never been happened before. To prepare students to be success in global condition, they need a new skills.

According to Republika, 23rd January 2016, technology has a role to improve education quality in Indonesia as means of learning for teachers and students. Interactive technology will be a catalyst for occurrence of change in the role teachers, from information to transformation and students activity from passive to be more active in order to access new knowledge (Republika, 2016).

Online based learning is currently developing especially *Massive open online course.* Many students follow this kind of online learning. According to National Geographic Indonesia in 20th February 2015, in one month, recorded that college students study online for 400.000 hours. Also, online university platform in England recorded that there were one million students registered for their lectures (**Kompas, 2015**).

Massive Open Online Courses provider company claimed that interest for online lectures has increased by 20% in three months by 2014. Online lectures can be followed by every college students all over the world.

Nowadays, there are many instructional media which used ICT. Besides, learning process also use website, blog, e-book and internet as instructional media. However, web instructional media has not included whole multifunction yet. In Indonesia, indonesiax.co.id is online learning media that can be accessed freely by user. State University of Semarang also has already used online learning through their University web (Semarang, 2015). In real life, students are more quickly to understand things if they are directly involved or demonstrate it by searching in internet and tends to remember for a long term. If students only read and memorize, they will remember for a short term.

In order to achieve skills that correspond the learning purpose, learning materials that encourage students to achieve learning purpose are needed. Those learning materials also should facilitate students in learning process. Technology development is very useful and helpful in learning and also has a positive effect in education.

This research did a preliminary study of students' curriculum and then, researcher gave a questionnaire for lecturers and students of Physics Education Department. According to the questionnaire results, from 51 respondents, 96.1% respondents have already attended online learning, 25,5% of online learning used discussion forum, 11.8% gave certificate as a proof of graduation, 10.9% used xMOOCs web. Observation results in PUSTEKKOM (Technology and Computer Center) shows that for undergraduate students, this kind of media has not been built yet.

According to Chaterins Adams, xMOOCs is a trans medial pedagogic lecture that proved to be adaptive in education. xMOOCs can be interpreted as online learning way that used internet or interactive learning that can be accessed with another students (Adams, 2014).

xMOOCs as e-learning can be assessed by measuring six aspects, as follows: 1)text, 2)picture, 3)graph, 4)animation, 5)sound, and 6)video. There are also seven aspects of e-learning as online lecture which are Curriculum, video, quiz, module, discussion forum, exercises, and certificate.

Learning material on thermodynamics subject includes Interpreting thermodynamics phenomenon, Analyzing zeroth law of thermodynamics, Analyzing pure substance properties, Applying state equation of thermodynamics systems, Analyzing work done by or to the system, Analyzing heat and first law of thermodynamics, Ideal Gases Real Gases, Analyzing second law of thermodynamics, Analyzing entropy, Analyzing thermodynamics potential, enthalpy, Helmholtz and Gibbs (Hadi, 2009).

Definition of Higher Order Thinking Skill by Haladyna and Bloom are as follow: analysis, evaluation and creation (King, 2013).

According to argumentation above, this research is conducted to develop web based e-learning that gives positive benefits for anyone who want to study independently, discussing with another user, and access the information more freely

Research Method

This research used *research and development* (R&D) method with ADDIE model. Steps of ADDIE model that is used are (Pribadi, 2014):

1) *Analysis*
   Analysis is the first step in ADDIE model. In this step program designer have to do a need analysis to collect information related to problems faced by students in undergraduate degree.
2) *Design*
   Design is the second step in ADDIE model where researcher designs the e-learning with xMOOCs characteristic so that students are expected to achieve goals and competence of following subject.
3) *Development*
   Development is the third step in ADDIE model. In this step, learning materials for e-learning are produced and developed.
4) *Implementation*
   Implementation is the fourth step in ADDIE. In this step, instructor implemented the e-learning in class according to teaching plan.

5) *Evaluation*
   Evaluation is the last step in ADDIE model. In this step, e-learning is evaluated in order to improve its efficiency and effectiveness. Based on this evaluation results any improvements are done to perfects the e-learning.

Research instruments that were used in this research are: learning material experts validation sheet, e-learning expert validation sheet, learning validation sheet, and multiple choice questions. Question instrument was validated using point-biserial formula and its reliability was computed by using KR-20/21 (Widiyanto, 2014).

Results and Discussion

Results

Product of this research is website phydu.com as thermodinamics e-learning. This website is open to the public and can be accessed anytime and anywhere. Main components of this website are:

1) Administrator. Administrator organizes students data, teachers data, hire teachers, and updates website.
2) Teachers. Teachers apply learning data, updates learning materials, and organizes test questions and score.
3) Students. Students attend online learning in phydu.com such as taking quizzes, final exam, discussion forum and information sharing with another user through social media. Student must register to login phydu.com.

Features in phydu.com are: 1)Register, 2)Login, 3)Home, 4)Learning Materials, 5)Discussion Forum and certificate, 6)Our Team, 7)Activity Log, 8)About Us, 9)Testimonials.

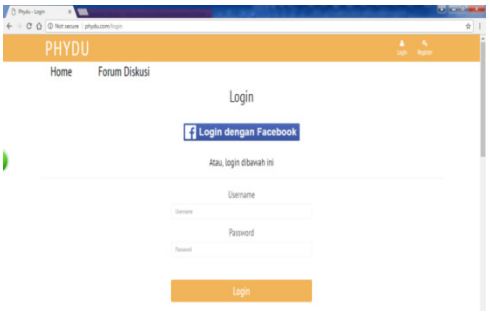

Figure 1. Login page

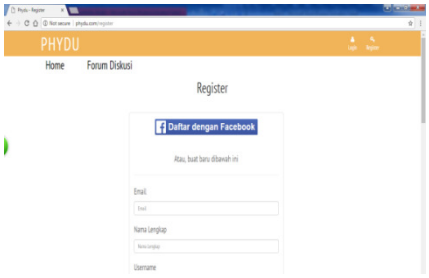

Figure 2. Register page

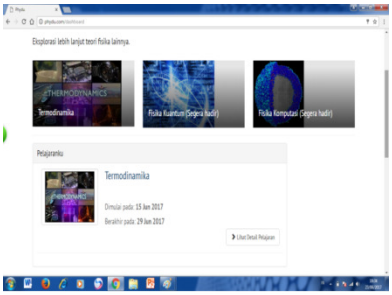

Figure 3. Learning Materials page

Table 1: Learning Material Expert's Validation Results

ASPECT	PERCENTAGE	INTERPRETATION
Interpreting thermodynamics phenomenon	85%	Very good
Analyzing zeroth law of thermodynamics	85%	Very good
Analyzing pure substance properties	90%	Very good
Applying state equation of thermodynamics systems	80%	Very good
Analyzing work done by or to the system	85%	Very good
Analyzing heat and first law of thermodynamics	90%	Very good
Ideal Gases Real Gases	90%	Very good
Analyzing second law of thermodynamics.	90%	Very good
Analyzing entrophy	100%	Very good
Analyzing thermodynamics potential, entalphy, Helmholtz and gibbs	100%	Very good
Average Percentage	**85%**	**Very good**

Validation by experts referred to Likert scale interval. Likert scale is used to measure behavior, opinion, and perception about social issue or phenomena (Riduwan, 2007). Obtained data then interpreted as follows:

Table 2: Likert scale (Sugiono, 2013)

Average Score	Interpretation
0%-20%	Very Bad
21%-40%	Bad
41%-60%	Enough
61%-80%	Good
81%-100%	Very Good

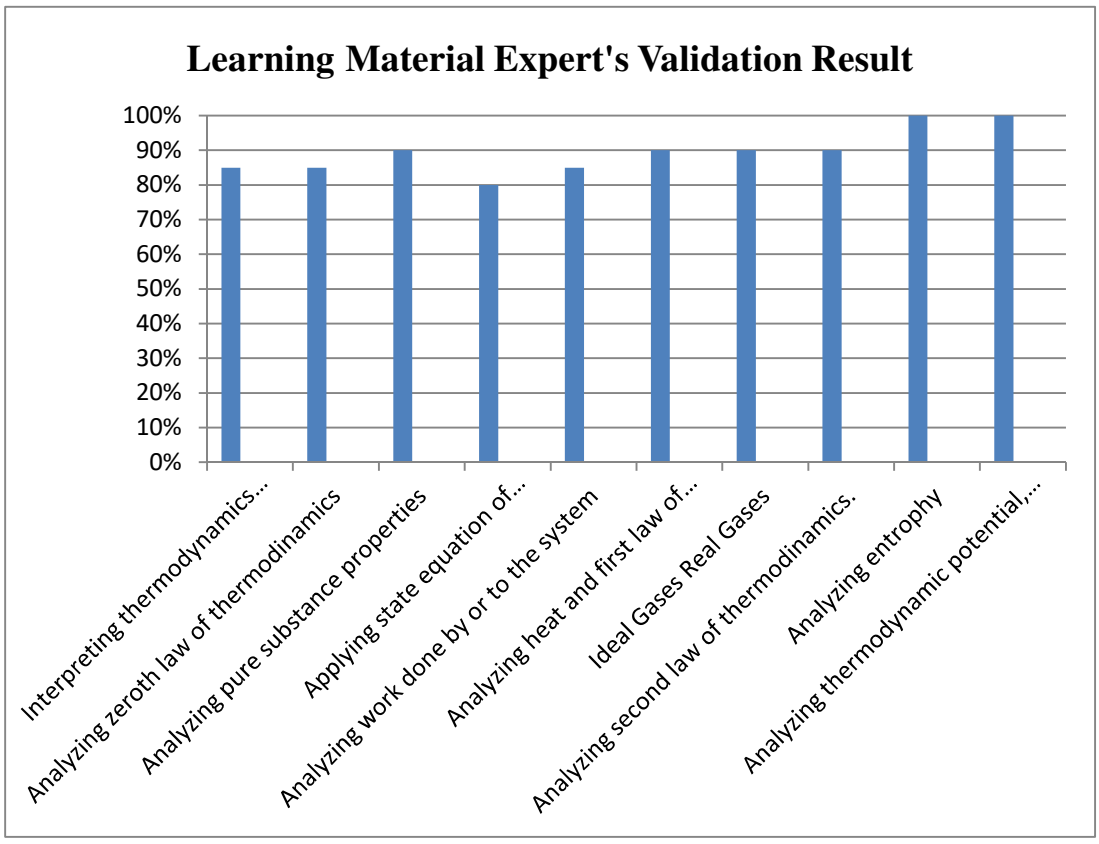

Figure 4: Learning Material Expert's Validation Results

Validation result by learning material expert by aspect Interpreting thermodynamics phenomenon 85%, Analyzing zeroth law of thermodynamics 85%, Analyzing pure substance properties 90%, Applying state equation of thermodynamics systems 80%, Analyzing work done by or to the system 85%, Analyzing heat and first law of thermodynamics 90%, Ideal Gases Real Gases 90%, Analyzing

second law of thermodynamics 90%, Analyzing entropy 100%, Analyzing thermodynamics potential, enthalpy, Helmholtz and Gibbs 100%.

This shows that web based instructional media achieve a very good result. Learning material expert's validation result obtained average score 85%. Based on this result, the developed e-learning is considered worthy of use for thermodynamics. E-learning expert's validation result was shown on table 2.

Table 2: E-learning Expert's Validation Result

ASPECT	Category	Expert		Total Score	Percentage	Average Score
		1	2			
Text	1	5	4	65	81.25%	81.25%
	2	5	3

	30	4	4			

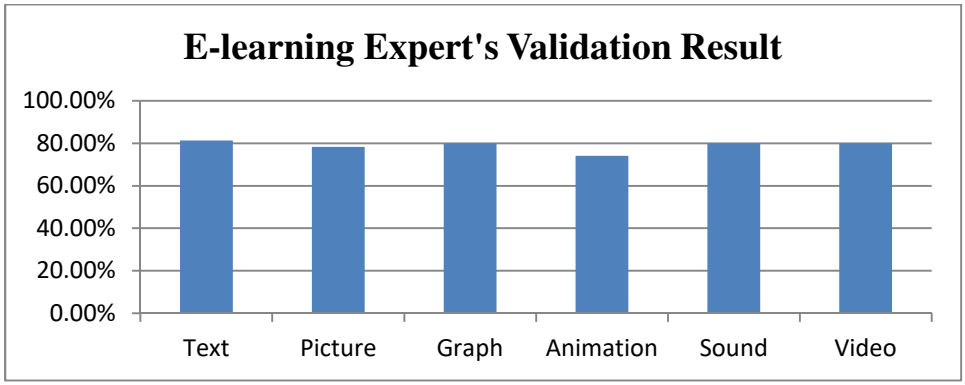

Figure 5: E-learning Expert's Validation Result

The result of e-learning expert's validation consists of six aspects: text (81,25%), picture (78,33%), graph (80%), animation (74%), sound (80%), and video (80%). Average validation result obtained is 81,25%. From this result can be concluded that the developed e-learning can be used in thermodynamics learning.

By referring to Likert scale, the result of learning expert's validation at table 3

Table 3: Learning Expert's Validation Result

ASPECT	PERCENTAGE	INTERPRETATION
Curriculum	82%	Very good
Video	77%	Good
Quiz	82%	Very good
Module	80%	Good
Discussion Forum	85%	Very good
Execises	90%	Very good
Certificate	85%	Very good
Average	**82%**	**Very good**

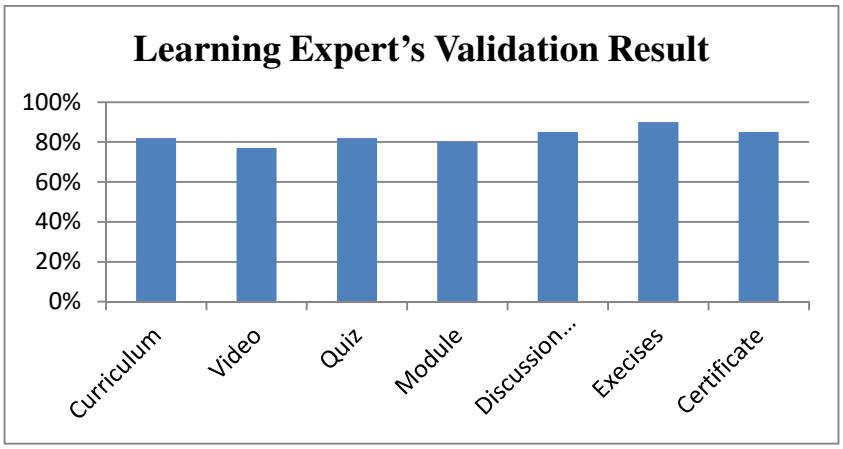

Figure 6: Learning Expert's Validation Result

Learning validation consists of seven aspects which are Curriculum (82%), video (77%), quiz (82%), module (80%), discussion forum (85%), exercises (90%), certificate (85%). Average validation result obtained is 82%.

From this result can be concluded that development of web extended massive open online course (xmoocs) on the thermodynamics subject has a very good result and can be implemented in thermodynamics learning.

The next step is validity and reliability test of question instruments. The result of validity and reliability test were:

1. Description of validity test data
   By using point-biserial at significance level of 5% for 41 respondents, obtained r table is 0,308 (Widiyanto, 2014). According to the calculation, from 50 questions of thermodynamics, 35 questions are valid and used as data collection instrument.
2. Description of reliability test data
   Reliability test was done using KR-20/21 formula. The result of reliability test is 0.83 which is a very reliable category. According to Widiyanto (Widiyanto, 2014) an instrument has very high reliability if reliability coefficient is between 0.8 to 1.0.

After validity and reliability test of question instruments, then do pre-test and post-test to 41 students. From the result of pretest and posttest, N-gain was obtained by 0.6878. According to Hake (Hake, 1999) N-gain was in good category ($0.3 \geq g \geq 0,7$). N-gain is normalization that obtained from pretest and posttest result (Hake, 1999). N-gain calculation is used to find the improvement using web based media before and after usage. Questionnaire was used to calculate students' higher order thinking skill improvement and its aspects using likert scale. Likert scale is used to measure behavior, opinion, and perception about social issue or phenomena (Riduwan, 2007).

Documentation

Figure 7. Pre-test

Figure 8. Post-test

The result of development of web extended massive open online course (xMOOCs) on the thermodynamics subject showed that student's high order thinking skill can be increased. This research was supported by several factors as follow:

1. Cooperation and tolerance of physics education department coordinator, faculty of math and science, State University of Jakarta.
2. Students' active participation during research.
3. Students' cooperation to attend online learning in phydu.com.
4. Students' maximum efforts during online learning.

According to previous research, maximum effort in order to search for information will help students to achieve their learning goals.

Conclusion

Expert material validation results showed 85,00 % (very good). E-Learning expert validation results showed 81,25 % (very good). Learning validation results showed 82,00 % (very good). This web extended massive open online course (xMOOCs) as E-Learning can increase students' Higher Order Thinking Skill (HOTS), proved by N-gain result = 0.6878 in good category. So, development of web extended massive open online course (xMOOCs) on the thermodynamics subject can increase high order thinking skill of students.

Comparison of the Concepts of "Flow" And "Flow Process" In Logistics

Georgiy Greyz, South Ural State University, Chelyabinsk, Russia, ggreyz09@mail.ru

Yuliya Kuzmenko, South Ural State University, Chelyabinsk, Russia, julia.kyzmenko@gmail.com

Irina Okolnishnikova, South Ural State University, Chelyabinsk, Russia, okolnishnikovaii@susu.ru

Irina Saveleva, South Ural State University, Chelyabinsk, Russian Federation, mim@susu.ru

Abstract

The article presents a spectrum of views on the definition of the main object of logistics. The features of the main variants of definitions of "flow", "logistic flow", and "flow process" are presented and analyzed. A comparative analysis of these concepts is performed as an object of logistics. The problem of identity or difference of the concepts of "flow" and "flow process" is considered and the authors' variant of its solution with definition of the parity of these concepts in logistic sphere and the choice of object of logistics is offered. The definition of the flow process applied to the industrial sphere is given.

Keywords: logistics; theory of logistics; flow; flow process; flow process of an industrial enterprise.

Introduction

When determining the main object of logistics in a professional environment, currently, there is no unity of opinions, as an object, both (logistic) flow and (logistic) process are considered. At the same time, some scientists share these concepts, and some view them as synonyms. The purpose of this publication is to analyze the relationship between the concepts of flow and flow process in the context of the object of logistics.

Logistic flow as an object of logistics

As the analysis of scientific literature shows, in most cases the main object of studying logistics are flows (material or economic), rather than processes (Sergeev, 2005; Novikov, and Uvarov, 2000; Rodnikov, 1995; Semenenko, 2001, etc.). Butrin (2005) rightly noted that, despite the rather rapid development of the theory of logistics, the flow as a logistic category remains insufficiently studied.

Consider the spectrum of known views about this concept. In determining the most general properties of the flow, without "linking" it to the logistic system of an industrial enterprise, there are no special discrepancies. So scientists at the St. Petersburg School of Logistics believe that "a flow is a collection of objects perceived as a single entity and existing as a process over a certain time interval, and measured in absolute units over a certain period" (Novikov, and Uvarov, 2000; Parfenov, 2001). It should be noted that the described version of the definition of flow is the most common and generally accepted. The authors agree with this, the most general definition of this concept insofar as a flow is a collection of moving objects, perceived as a single whole.

The discrepancy in the views of various researchers manifests itself in the process of the appearance of variants of concretization of this concept. Thus, in work by Forrester (1971) flow is identified with a network and, at the same time, several types of networks are considered, combined with information:

orders, materials, money, labor and equipment. In book by Plotkin (1996), the category of "economic flow" is introduced into the scientific revolution. We should agree with the opinion of Stepanov (2007) in that part of the treatment of the economic flow, where all (and not only local) types of resources are indicated in their interrelationship. However, if we consider flows in relation to the enterprise, this definition of the nature of the economic flow is rather vague.

A certain concretization is present in the definition of economic flows as interrelated and interdependent processes of movement of the company's own, borrowed and attracted resources to achieve the company-wide goals (Kostoglodov, D.D., Savvidi, I.I., and Stakhanov, V.N.,2000).

Note that there is a rather large number of definitions not of the flow in general, but of specific flows with their constituent objects of a certain nature, first of all, of material flows. In the opinion of the authors, the most general concept of the flow was introduced by V. Popov and I. Krainyuchenko in the form of the generalized term of "MEI-flow". These specialists consider the flow as a composition of matter (M), energy (E), and information (I) (Popov, and Krainyuchenko, 2002). Indeed, any production process is a transformation of MEI-flows. At the input to this process we have some MEI parameters, and at the output - others. The production process consists in bringing energy and information flows to the objects of labor. As a result, the subject of labor is transformed into a product of labor - the flow of finished products. The following definition of flow is given in work by Sidorov, 2001: "Flow is a purposeful and ordered movement of matter, its elements (matter, energy, information)".

Logistic process as an object of logistics

Thus, despite some differences in the definition of flow, most logisticians hold the view that it is the flow that is the main object of logistics. In contrast to this point of view, in works by Katochkov (2005), and Katochkov, V.M., Greyz, G.M., and Okolnishnikova, I.Yu. (2013), as an object of logistics, economic flow processes are indicated. In accordance with the approach described in work by Katochkov, V.M., Greyz, G.M., and Okolnishnikova, I.Yu. (2013), the main feature of the flow is the motion of homogeneous objects, and for the flow process the main is the change in the qualitative state of the flow. As a consequence, flow processes reflect not only quantitative, but mainly qualitative changes - the transformation of flows within one form of existence, as well as the flow from one form to another.

Before considering the existing variants of the concept of the flow process, consider some of the definitions of the term "process" in general.

The Great Explanatory Dictionary of the Russian language (Kuznetsov, 2000) gives the following definition of the term "process" (from the Latin "processus" - advancement): 1) Consecutive change of phenomena, states in the development of something. 2) A set of sequential actions to achieve a result (e.g., a production process). 3) The order of consideration of cases in court, legal proceedings; a court case. In some works, the definition of the Great Explanatory Dictionary is practically repeated (Kuznetsov, 2000): the process is understood as the successive change of states, the change in the phenomenon, the stages of development when any result is achieved.

Very useful for understanding this concept is, according to the authors, consideration of definitions of the concept of "business process". A business process is a collection of various activities within which one or more types of resources are "used at the entrance," and as a result of this activity, a product representing value for the consumer is created at the "output" (Repin, and Eliferov, 2004). A term close to the content is interpreted in modern sources as a set of sequentially executed operations that together form a single process of converting raw materials into the desired product. Useful in considering approaches to the interpretation of the term "process" is the definition used by the German company SAP (System Analysis and Program Development), which sells software for the ERP logistics system. According to this interpretation, the process is a sequence, complete in terms of content, temporal and logical sequence,

necessary for processing an economically significant object. The business process is a special process that serves the implementation of the main objectives of the enterprise and describes the central scope of its activities. In the standard ISO 9001: 2015 on the quality management system is given a more concise definition: process is a set of interrelated and interacting activities that converts inputs to outputs.

Thus, in the authors' opinion, the process common to the definitions of the concept considered above, primarily to the processes within the enterprise, is the presence of purposeful transformative activities (works), as a result of which the initial resources (at the input of the process) are transformed into the planned product (at the output process), which has value for the consumer.

Correlation of the Concepts of Logistic Flow and Logistic Process

The relationship between the concepts of "process" and "flow" in the work of A.I. Semenenko and V.I. Sergeev on the theory of logistics (2001) is given through the prism of concepts the object of logistics and the subject of logistics. In the opinion of these scientists, the object of studying the theory of logistics are the material and the corresponding financial, information or their combinations of the flow processes of economic and other activities in reproduction and circulation, organized into flows. In this case, the flow is defined as a directed movement of the aggregate of something conditionally homogeneous (e.g., any processes, products, information, finances, materials, resources, etc.).

The authors agree with the representation of the process in work by Semenenko (2001) as a regular sequential change in the phenomenon, its transition to another phenomenon (transformation, development) to achieve any result. Also, there is no objection to the representation of processes by the property of matter, space and time, a property characteristic of both inanimate and living nature (including society).

According to many experts, flow processes differ from non-flow processes in that they can take a flow form (independently or under an external organizing influence). In accordance with the concept developed in work by Semenenko (2001), processes are an objective reality, and flows, as the movement of one environment into another, in particular flows in the economy, are abstract models, since in reality there is no economic environment in which information, financial and similar environments move. As proof of this provision, six content conditions for the existence of flows are given, the main of which is the presence of a structured (ongoing, continuous, or conditionally accepted for such) medium. Assuming that the economic environment can at best be considered to be poorly structured, research scientists (Semenenko, 2001) come to a rather controversial conclusion, according to the authors, that flows do not exist explicitly, and economic reality is different processes.

Moreover, in work by Semenenko (2001), on the basis of the fact that flows in economy are recognized as abstract constructions (models) necessary for their study and optimization, a paradoxical conclusion is drawn that simulation and organization of flows are the tasks of the corresponding professionals: suppliers, transport workers , forwarders, warehouse workers, etc. According to A.I. Semenenko and V.I. Sergeev, flows in a market economy cannot be managed, as one cannot manage, for example, atmospheric flows. It is only possible to optimize the use of flows by optimizing the processes in them in the name of the final target results. As follows from this, the object of logistics are flow processes of a different nature, and the subject of studying, researching and researching the theory of logistics is the optimization of material and corresponding financial and information flows.

The authors of this article are in agreement with the conclusions of A.I. Semenenko and V.I. Sergeev (2001) in the part that the task of logistics is to optimize the flow processes, rather than the flows themselves. However, the representation of the flows themselves as abstract models with the simultaneous assertion that their modeling and organization can be performed not by logisticians but by suppliers, transport workers and warehouse workers looks, in our opinion, somewhat artificial.

In a number of works on logistics, the concepts of flow processes and flows are not opposed, but implicitly used as synonyms. Thus, in book by Golikov (2000) optimization of flow process control is defined as the achievement of the maximum level of interaction of flow processes during the motion of these flows. Synonymous with this concept, in our opinion, is the following definition of the flow: "... economic flow should be considered as a sequence of interrelated events occurring in a single economic process" (Ivakin, 1997). In accordance with the rules of formal logic, this statement is identical to the following variant of the concept: economic flow is equal to the sequence of interrelated events and is equal to the economic process, i.e. we can assume that economic flow is equal to economic process. Identification of these concepts, in the opinion of the authors, is also present in work by Butrin (2005), etc. Also, some similarity of these concepts is present in the above definition of the flow from (Novikov, and Uvarov, 2000; Parfenov, 2001).

In the study of A.V. Parfenov (2001), the relationship between the concepts of flow and the flow process is represented as follows: "... the flow process as an object of management in logistics should be understood as a set of purposeful, sequential, one-parameter transformations of a system of structurally interrelated elements carried out for a specified purpose within a specified period of time." It is clarified that the category of "flow process" reflects a consistent change of states (stages of development) of a certain flow, and one-parameter transformations of flow elements are achieved by performing basic and/or additional logistic operations. In work by Parfenov (2001) it is rightly asserted that the more complex the flow processes, the more effective methods of managing them are required. At the same time, the complexity of the flow processes is determined by the scale of enterprises.

In one of the previous collective works of the scientists of the St. Petersburg State Economic University, the opinion is expressed that "... the object of study in logistics is the controlled flow and the fluxing process that generates it ..." (Shcherbakov, 2015). Thus, both the flow and the flow process are considered as objects of logistics without opposition. In the same work, apart from the traditional definition, the most general definition of the flow is given as an entity that manifests itself over a period of time and is measured in motion. Logistic flow is defined as an integrated flow, which is a directed movement of the aggregate of material, financial, information and other types of resources. The logistic process is defined as the sequence of operations, organized on the principles and methods of logistics, aimed at achieving the goals of the economic system.

The authors, in comparing the concepts of flow and the flow process, occupy some middle position between the complete identification of these terms and their qualitative separation.

In a number of special sources (Katochkov, 2005, etc.), along with the general definition of the flow process in general, there are references to the flow process in logistics, and various approaches to determining its essence are considered. Taking into account the analysis carried out by the authors of the concept of the process and for the chosen field of research, with regard to logistics in the industrial sphere, it is expedient to formulate the following definition of the flow process. The flow process of an industrial enterprise is a set of various interrelated activities (operations) that transforms the initial resources in the form of material, financial and information flows into a planned product also in stream form, and performed within the micro- or mesological system of the enterprise.

Commenting on this definition, we note that if in general the activity is understood as "a specific human form of relation to the surrounding world, the content of which constitutes its expedient change in the interests of people; condition for the existence of society" (The Great Encyclopedic Dictionary, 1998), then the addition of the definition of "operations" in the definition of clarification allows to reflect the specifics of the activity of an industrial enterprise.

Note that the proposed definition does not contradict the definition given by Katochkov (2005). Thus, the part of the definition: "the aggregate of various interrelated types of activities (transactions) that transforms the initial resources in the form of material, financial and information flows ..." can also be understood, including the transformation of interacting flows with the interchange of flows from one form to another, as this is presented in the study by Katochkov (2005). In our opinion, the proposed definition is not universal, but it reflects the most significant features that distinguish the flow process of an industrial enterprise from a multitude of other processes and phenomena.

Considering the specifics of logistic flow processes, it is necessary, in our opinion, to refer to the opinion of A.V. Parfenov (2001), which points out that any flow processes associated with various economic flows, which, in turn, are objects of logistic management methods, can be referred to logistic ones. Such flow processes, expediently, by analogy with logistic flows (material, financial, information, etc.), are called logistic flow processes. Professor A.V. Parfenov proposes to call such processes simply logistic processes, rightly referring to the fact that logistics a priori involves a flow approach. Such naming of these flow processes makes it possible to distinguish the features of their organization and regulation as objects of the logistics management system. The authors support the point of view of A.V. Parfenov, who considers the term logistic process as a synonym for the term of logistic flow process. Given the synonymity of these terms, it is possible to use both the term "logistic process" and "logistic flow process".

Conclusions

Thus, consideration of the problem of identity or differences in the concepts of "flow" and "flow process" allows to draw the following conclusions: these concepts are not synonymous, although they are similar in their logistics content. The flow fulfills the role of the initial "material" for the process, being an object of labor, which transforms the process, as a certain activity. From the position of the authors, the term "management of logistic flows" is not entirely accurate. The term "management of logistic flow processes" more accurately reflects the real situation, because actually they control not the flows themselves, but the activity of changing the logistic flows.

I find it difficult to make familiar strange for the power of the familiar is overwhelming Wisniewski , 2000

Abstract

Nowadays, with the lack of qualified workforce in almost all sectors, understanding the attitudes of students and employees towards their duties and career paths becomes more and more important. The paper deals with the findings of the first-order survey of heroes taken for behavioural models by the groups of 4th grade and 8th grade pupils of three different primary schools in Slovakia. Even though the samples are small, the differences identified in hero categories can be significant for understanding the tendencies and the further research. Our findings show that the most admired categories of heroes are family members as well as friends (especially in Roma community). Generally, these categories are common, but they cause several problems in above mentioned community. The reason is that the heroes they admire are often unemployed and uneducated and do not provide enough stimuli for pupils to progress, especially in future professional life.

Keywords: hero, behavioural model, function of the model, disadvantaged social group, Roma community

Introduction

Over time human beings develop not only physically, but also psychically and socially. Developmental psychology as an umbrelling field (integrating findings of a number of disciplines) focuses on identifying the developmental processes and their outcomes. It looks at the development of humans in micro sense, as they develop from babies to mature adults, but also in macro sense as the culture constituted by the humans in question evolves during the years.

The theories of developmental psychology moved from the "stage theory" suggesting that all humans develop through similar paths (represented primarily by Jean Piaget) to the social contextualization theory, i.e. adults' interference in development during critical stages known as "zones of proximal development", of Lev Vygotski, and many views inbetween.

It is important to take into account the fact (identified in many research findings) that social and emotional competencies acquired within the early development of human beings are linked to later academic achievement, whereas social and emotional problems or challenges are linked to academic difficulties as well as success or failure in working life (Blair and Diamond, 2008; Konold and Pianta, 2005; National Research Council and Institute of Medicine, 2002; Raver, 2002; Romano, Babchiskin, Pagani and Kohen, 2010). Indeed, skills within the social and emotional domains are believed to lay a

critical foundation for later life success across a wide variety of outcomes (e.g. Jones, Greenberg and Crowley, 2015, Moffitt et al., 2011).

Collectively, the research suggests that there are specific social and emotional competencies that parents, caregivers, educators, and policy makers should be promoting in early childhood for the sake of long-term individual and social well-being.

In the early stages, the process of an individual's socialization is executed via exemplification (the forms of the cultural context in which the individual lives and grows), i.e. the impact of an example as a means or method of inter-human influencing which can significantly change or produce relations and performance of the human (Grac, 1990). Jim Taylor coins the term hero for the example serving as a model (Taylor, 2010).

The examples can be categorized by their functions primarily into four following categories (Vrabec, 2013):

1. **instructional function of the model:** the percipient tries to act as the hero acts because he/she perceives his/her own behaviour as not as good as the hero's
2. **warning function of the model:** the percipient assesses the behaviour of the hero as bad one and he/she refuses to behave in the hero's way
3. **repulsive function of the model:** the percipient perceives the hero's behaviour as well as that of his/her own as bad and wants to change it (motivational impulse for change)
4. **assurance function of the model:** the percipient perceives his/her behaviour equally positive as the hero's one

From the point of view of the individual's future social role the instructional function of the hero/s is vital. Numerous surveys looked at the heroes and their impact on the percipients (e.g. Albert Bandura in Bobo Doll Experiments, 1961, 1963; Australian Childhood Foundation, 2006).

Thus, to identify the heroes admired by children now and here can give the picture of their current and future orientation. Therefore in our survey we looked at the heroes admired by pupils of three different primary schools. Firstly we identified the heroes of 4th grade pupils (approx. 9-year-old pupils) and those of the 8th grade (approx. 13-year-old pupils). Secondly we compared the heroes of different groups of pupils attending state and faith primary schools and a state school attended by socially disadvantaged pupils primarily from Roma population. We focused on the change or stability in the hero repertoire in 4 years span, compared the hero ranking among three different groups of pupils and, finally, compared the results with the data on the trends in the pupils' future career, i.e. the further studies of the pupils in question at secondary schools and the types of secondary schools they selected.

Research and Methodology

The survey aims to identify the heroes as behavioural models for pupils and possible shift in their structure within 4-year period. The categories of heroes include: a family member/relative, friend, teacher, sportsman/woman, singer, movie character, animated character, fairy-tale character, fiction character, sci-fi character, actor/actress, religious character, publicly known person, animal, and others.

The sample included 127 pupils from 3 primary schools differing in the following characteristics:

1. primary school in Kezmarok, faith school (42 respondents)
2. primary school in Spisska Teplica, state country school (34 respondents)
3. primary school in Hranovnica, state school with 100% pupils coming from socially disadvantaged background – Roma community (51 respondents)

The sample includes the pupils from all classes of the particular grade who were present at lessons when the survey took place.

The respondents of the 4th and 8th grades at primary schools represent an age group with the more or less clear image what they want to achieve to become the peers of their heroes. Even though they follow the wishes of their parents because they are not autonomous in their decisions, their image of the success (materialized in their hero) allows them for either getting fully involved in the steps leading to the objective (e.g. attending a particular school, course, or other career building activities), complying with their parents' decisions (passive resistance), or fighting their parents' decisions (active resistance). All these attitudes have vital consequences for the pupils' future performance. The behavioural patterns have a strong motivational potential. Therefore, we assume, to know who and what attract the pupils' imagination in terms of their hero/s is important to identify even in this early developmental stage. The problem area stays with the pupils who claim that they have no hero to admire and follow.

A questionnaire was used for the first-order survey. In addition to demographic questions related to age, gender, type of primary school, it included two questions:

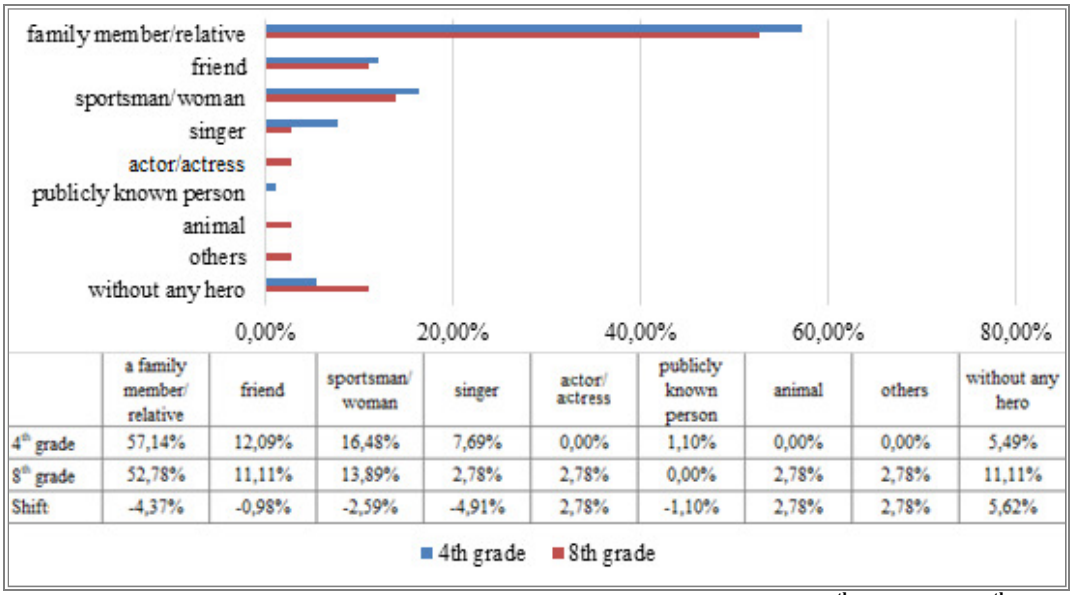
1. **Write down who you take for a hero in your life, i.e. for the person you admire and you want to be like him/her. If there is nobody in your life, please, put it down as well.**

   (This question was open and the respondents introduced their responses in the way they wanted, i.e., as a single word or a phrase or described their responses in full sentences.)

2. **Choose the category your hero/model introduced in the question above belongs to.**

   (This question was closed with the possibility to choose just one option out of the range provided.)

The questionnaire was available electronically (Google Forms) and the pupils filled it in in their computer laboratories. During the process either the author or a teacher was present. The teachers were instructed how to work with the questionnaire and were ready to answer potential respondents' questions. The respondents could ask questions while filling the questionnaire in. The closed question was included to make the answers more objective and helped process the results. The acquired data were processed by MS Excel.



We assumed that the environment of the individual schools would show high level of homogeneity. Based on quantitative analysis we identified the heroes the respondents from individual schools introduced and identified the shifts between the 4th grade pupils and the 8th grade pupils' views. Based on the qualitative analysis we interpreted the results by individual schools and compared them with the success of the pupils in admission to the secondary schools if they decided so. The data on the latter was gained from the documents provided by individual schools.

Analysis and Discussion

As comes from Figure 1, family members account for the highest representation in the 4th grade group (57.14%). Other categories of heroes are represented markedly less and they come in the following order – sportsmen/women (16.48%) and friends (12.09%). The respondents of this group include also singers (7.69%) and other publicly known persons (1.10%) as well. No hero was stated by 5.49% of respondents in this group.

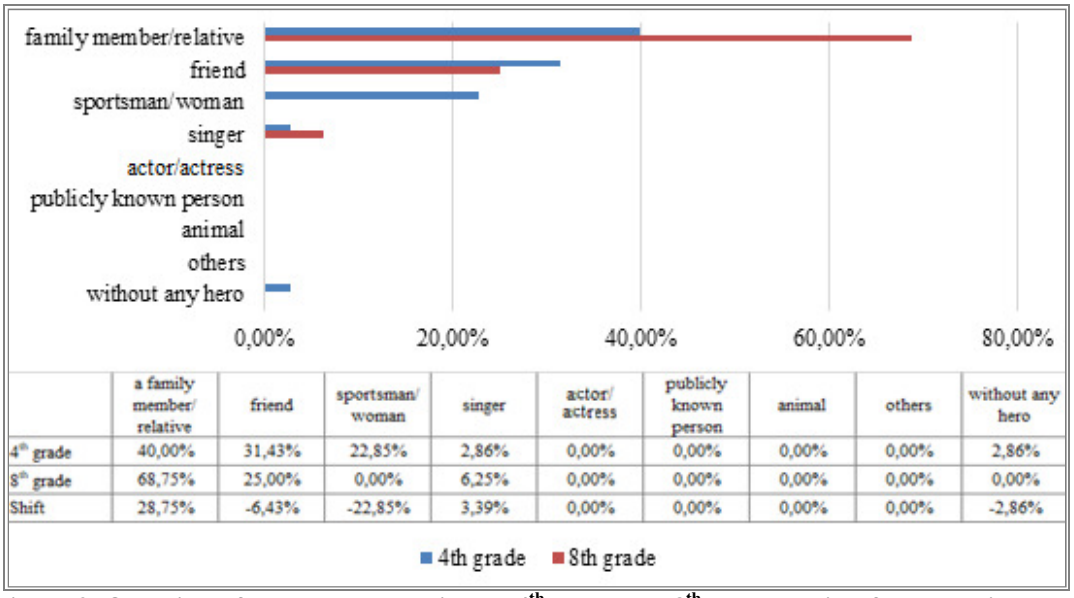
Similar results are achieved for 8th grade group. Family members account for 52.78%, however, the figure decreased by 4.37%. Sportsmen/women (13.89%), friends (11.11%), and singers (2.78%) follow. The

respondents of this group introduce also actors/actresses (2.78%), animals (2.78%) as well as others, i.e. not categorized (2.78%). No hero is introduced by 11.11% of respondents that accounts for 5.62% increase.

	a family member/ relative	friend	sportsman/ woman	singer	actor/ actress	publicly known person	animal	others	without any hero
4th grade	57,14%	12,09%	16,48%	7,69%	0,00%	1,10%	0,00%	0,00%	5,49%
8th grade	52,78%	11,11%	13,89%	2,78%	2,78%	0,00%	2,78%	2,78%	11,11%
Shift	-4,37%	-0,98%	-2,59%	-4,91%	2,78%	-1,10%	2,78%	2,78%	5,62%

Figure 1: Overview of the hero representation by the surveyed groups of 4th grade and 8th grade pupils

Figure 2 presents the total representation of heroes by individual schools. In comparison, the outstanding figures appear in three categories of heroes. Kezmarok (faith school) and Spisska Teplica (country school) primary schools do not account for the representation of friends at all, on the other hand, Hranovnica primary school (primary school with Roma pupils) achieves the representation of friends as heroes at 29.41%. Another category – family member – accounts for similar representation in Hranovnica primary school (Roma pupils) and Spisska Teplica (state country school) reaching 49.02% and 44.12% respectively, however, in Kezmarok primary school (faith school) it rises to 73.81%. Spisska Teplica (state country school) primary school manifests no hero in 20.59% which achieves an extreme figure when compared to other respondent schools (while Kezmarok faith school and Hranovnica state primary school with Roma pupils reach 2.38% and 1.96% respectively).



In other categories of heroes, the differences do not display such outstanding differences.

	a family member/ relative	friend	sportsman/ woman	singer	actor/ actress	publicly known person	animal	others	without any hero
ZS Spisska Teplica	73,81%	0,00%	14,29%	7,14%	0,00%	2,38%	0,00%	0,00%	2,38%
ZS Hranovnica	49,02%	29,41%	15,69%	1,96%	1,96%	0,00%	0,00%	0,00%	1,96%
ZS Kezmarok	44,12%	0,00%	17,65%	11,76%	0,00%	0,00%	2,94%	2,94%	20,59%

Figure 2 : Overview of hero representation by the surveyed primary schools

For the illustration we have chosen the responses of the Hranovnica state primary school respondents (Figure 3) because they are those who enter the labour market first (see Figure 4). When comparing 4th grade and 8th grade respondents' views, the most evident shift relates to sportsmen/women category where the percentage plummets by 22.85%, the friend category lowers by 6.43%, however, family member category rises by 28.75%.

	a family member/ relative	friend	sportsman/ woman	singer	actor/ actress	publicly known person	animal	others	without any hero
4th grade	40,00%	31,43%	22,85%	2,86%	0,00%	0,00%	0,00%	0,00%	2,86%
8th grade	68,75%	25,00%	0,00%	6,25%	0,00%	0,00%	0,00%	0,00%	0,00%
Shift	28,75%	-6,43%	-22,85%	3,39%	0,00%	0,00%	0,00%	0,00%	-2,86%

Figure 3: Overview of hero representation by 4th grade and 8th grade pupils of Hranovnica state primary school

The lowest level of admission to secondary schools (Figure 4) is reached by the pupils coming from Hranovnica state primary school (with Roma pupils). They mostly continue studying at a secondary school (apprentice and vocational schools) accomplished without school leaving examination[1] (75.86%)

and, even worse, 24.14% do not continue in studies at all and accomplish just the compulsory education. The characteristic feature of this group is the hero – behavioural model – a friend or a family member. This means that *status quo* is their career prospect, even staying at the level of the same or similar age group. The heroes they admire (friends, family members often unemployed and uneducated) representing the background they come from does not provide enough stimuli for further progress. The results show the importance of providing these pupils systematically with other behavioural models.

Other two primary schools (Kezmarok and Spisska Teplica) achieve similar success in the admission; the pupils usually continue studying at vocational secondary schools accomplished with school leaving examination or grammar schools. In these cases, the heroes include mostly family members (successful in professional careers and educated), sportsmen/women, and singers. It shows that their ambitions lead them towards progress, success, and recognition as substance of exercising effort and hard work.

	Grammar school	Secondary schools with state-leaving examination	Secondary schools without state-leaving examination	Accomplished compulsory education
ZS Spisska Teplica	25,00%	75,00%	0,00%	0,00%
ZS Hranovnica	0,00%	0,00%	75,86%	24,14%
ZS Kezmarok	19,05%	80,95%	0,00%	0,00%

Figure 4: Overview of the pupils' future career paths by the surveyed primary schools

As comes from the above analysis, the behavioural models indicate the tendency of the respondents to follow their heroes. Even though the sample is small, the shift in hero categories in Kezmarok and Spisska Teplicka documents crossing the familiar context of the family and taking into account the models represented primarily by mass media and social media (sportsmen/women, singers), i.e. looking for new models even though to follow them would be demanding.

On the other hand, Hranovnica state primary school with the disadvantaged group of Roma pupils shows the tendency towards encapsulation in the familiar community. Even though the percentage of friend category decreases, the family member category rises by 28.75%. Functioning in the familiar context does not require extra effort and offers safe and comfortable feeling of familiarity.

Conclusion

The first-order survey of heroes at the level of 4th grade and 8th grade pupils shows that analysing the behavioural models can contribute to understanding the attitudes of people towards academic and work-related achievements. The employers, primarily those who employ unskilled or low-qualified workforce, should be aware of the fact that the behavioural model of the employee can crucially influence his/her attitude towards work-related tasks. This overview is important for secondary schools as well. The

students' success or failure (drop out) can be based on admiring achievement-supportive or achievement-unsupportive model, and not exclusively on the qualities of the student in question.

Of course, the combination of conditions leading to the success or failure in one's work career is complex, but the methodology using heroes as indicators of one's preferences is helpful. The pupils coming from low-stimulating background tend to imitate their family members leading towards having large family, friends, and stay happy with what is available at hand.

The survey provides evidence that pupils do not read books (global trend) because the categories of literary characters are missing in their responses.

The high percentage of responses without any hero is appalling and needs deeper analysis. This group consists of the youth easily influenced by *ad hoc* behavioural models, even negative ones.
Further research is needed not only in survey of higher age groups' heroes to see how categories change, but also in deepening to identify values with motivational as well as disvalues with de-motivational potential in the groups' career paths. This should be linked to the respondents' images of the successful careers they want to follow in the future.

[1] The state-leaving examination allows for further studies at universities, similar to *Matura* in Germany or *baccalauréat* in France.

Abstract

This paper is formulated to demolish the confusion among researchers in terms of applying the theoretical model in research. As to demolish, this paper introduced issues that faced by researchers. These includes analysing the advantages and disadvantages of theoretical model application. Through the analysis, an extensive explanation of the model has been divided into two (2) categories. These include explaining on the advantages and disadvantages of theoretical model. By applying a scoping review technique as a methodology applied in this paper, the entire aspects of theoretical model are adequately analysed. This is then has led to the formulation of figure as to present the overall result of analysis. As presented, the advantages and disadvantages of theoretical model are firmly justified. Through these justifications, the several elements in each of categories which define in the literature are listed and explained. At last, this paper has concludes that, the entire explanation which resulted from the analysis is expected to resolve the confusion among the researchers.

Keyword: Theoretical Model, Application, Advantages, Disadvantages, Confusion.

Introduction

Nowadays, the development of model in research has become the main concern of the researchers. Part of the model concerned is on applying the theoretical model in research. As stated by Nilson et al. (2017), the theoretical model is an important tool to qualify and optimize the evaluative research process. However, Lenhardt and Schiffmann (2016) stated that theoretical model is not directly applicable to real world problems. This followed study conducted by Liu et al. (2017) which have not applied the multiphase theoretical model in their research because of the lagging in finalising the related theories. Therefore, this is where the details on advantages and disadvantages of applying theoretical model in research need to be clearly justified.

Literature Review

As to justify, there are two (2) subsection are designed for extensively described the advantages and disadvantages of theoretical model application. This designed is to ensure the exploration towards the entire literature that related to theoretical model application has been adequately conducted.

Advantages of Theoretical Model

Based on the literature, the theoretical model application has generates a number of valuable aspect while conducting a research. The research conduct by Chiariotti et al. (2015) have shown that a development of theoretical model in their research is not developed for a specific system but it can be applied to any real system that satisfies its assumptions. As it being satisfied, Ràfols and Molas-Gallart (2016) stated that, a theoretical model is needed for linking the research mission to be captured with the specific data to be measured. This followed by Burgio et al. (2017) which have specified that, a good theoretical model is required to interpret the observation and use it to place

constraints on fundamental theory. Through these literature reviews, it is proven that the application of theoretical model in research have facilitate researchers in fulfilling part of the research work.

Disadvantages of Theoretical Model

In this section, there are several arguments from the scholars are presented. These includes presenting the weaknesses of applying the theoretical model in research. Based on Tu and Yuan (2014), theoretical model is developed through literature review and has never been tested. This followed by Afsa and Givord (2014) which stated that, the theoretical model must be tested on a case-by-case basis. On top of that, Gonca et al. (2015) stressed that the verification of theoretical model need to be conducted using the experimental result. In fact, the research conduct by Ni et al. (2015) shows the theoretical model is not precise enough to present their entire data findings. Overall, the literatures have shown that, the application of theoretical model is only applicable for assuming the earlier stage of research findings.

Methodology

As for the methodology, this paper adopted a scoping review technique. According to Veronica Gutchell (2014), *a scoping review is an approach to summarizing the literature that assesses the relevancy and contribution of a published work, and not solely the methodological approach for inclusion criteria*. Then, Snyder et al. (2016) have stated that, *a scoping reviews are a form of a literature review that seeks to identify and map out the existing body of work, the research gaps that exist, and the opportunities for knowledge mobilization and communication efforts*. In fact, *the goal of the scoping review is to access and review published research that focuses on identifying competencies related to the innovation* (Metz, 2016). Through these justification, this is where this paper has adopted this review technique in searching the literatures.

Result

Through the entire analysis, this section is designed to present the entire result. These includes explaining each of the result into two (2) categories. As for the details, the overall result of analysis is visualised in the figure below.

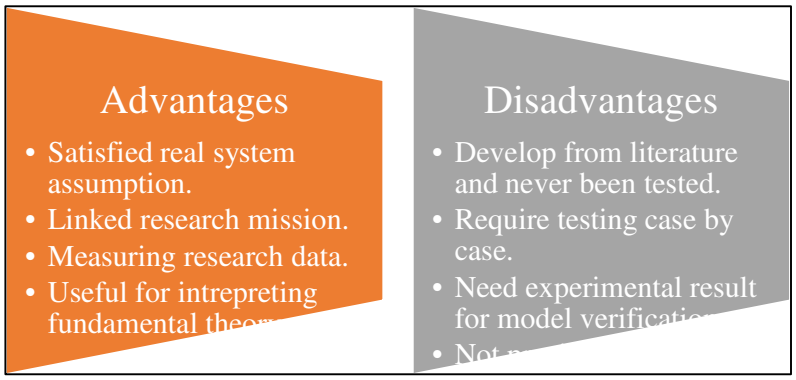

Figure 1.1: Advantages and disadvantages of Theoretical Model

Figure 1.1 above has visualised the advantages and disadvantages of theoretical model. As visualised, there four (4) advantages and disadvantages of theoretical model presented. The advantages includes satisfied real system assumption, linked research mission, measuring research data and useful for interpreting fundamental theory gathered from the literature. However, the disadvantages of theoretical model are includes develop from literature and never been tested, require testing case by case, need experimental result for model verification and lastly it is not precise enough to present entire data findings. Through these explanations, the comparative analysis regarding the application of theoretical model is adequately presented.

Conclusion

As a conclusion, demolish the confusion regarding the application of theoretical model in research among the researcher has become the main aim of this paper. Triggered by several argument from the scholars, it has led to the conflict of preferences either the theoretical model is requires or not while conducting research. By presenting advantages and disadvantages of applying the theoretical model, it is expected that the confusion and conflict of preference can be delineated precisely. Hence, this is also would act as a guidelines for the researchers in terms of developing a successive research model.

Abstract

This article discusses the principles and methods of constructing hybrid model multivariate index analysis treatment of tangible assets on the example of retail trade enterprises. Analysis of the time and speed of the current assets held in respect of the current inventory storage for uniform positions of the group range shoe department of the economic entity. Separately were built time model and the turnover rate. And the final stage, the crossing using the index procedure was constructed by *vlt*-model, which comprises five separate signs factors. For each of rounds signs factors hides its standard statistical measure, which is traditionally carried out by an economic analysis based on defined goals and objectives, both in enterprises and for special applied research. These indicators serve as indicators of the financial condition of any economic subject, are comparative characteristics in assessing the competitiveness of the subject in the commodity markets and can be used to assess the market value of the business. The resulting model is verified, it held on reliable calculations. The model opens up new horizons of financial and economic analysis of movement of material assets of the enterprise, and allows you to put together a comprehensive study the parameters of speed and time of commodity circulation. The latter is complicated, and it is sometimes even impossible, in multivariate econometric models in connection with the phenomenon of multicollinearity of signs factors. This circumstance makes it promising for the first time built a similar hybrid model for solving the problems of short-term forecasting, and for the purpose of operational planning of material circulating assets.

Rumors of slowness crocodiles are spread by the crocodiles themselves.
(From the observations of a nature lover)

Introduction

Research in the field of industrial production, as well as in wholesale and retail trade links issues of turnover of tangible assets is a separate and important area of analysis of the financial condition of any economic subject. The effectiveness of such asset management is reflected immediately in terms of solvency and stability of the enterprise. There is considerable domestic and foreign bibliography dedicated to the study of time and the speed of certain types of tangible assets. This article is related to the construction of a fundamentally new hybrid *vlt*-model multivariate analysis on the example of the dynamics of asset inventory of a particular trader.

Among the most important economic characteristics and generalizing Stick efficiency of movement in the market space and the commodity circulation mass in the form of raw materials and fuel finished product inventories and etc. within the production cycles are indicators – *The time of the work-*

ing capital and *the velocity of the working capital*. These indicators generally serve a special economic concept as turnover of goods.

The economic analysis of these characteristics is particularly important in setting conditions of the market mechanism of management of industrial enterprises of the real sector, sales, trading and purchasing of specialized applications and systems, improvement of commercial calculation and the increasing importance of financial leverage in the market of diverse relationship partners [1; 2].

Formulation of the problem

Analysis of the time and the velocity of inventory included in the scheme of analysis of working capital, but it should be carried out taking into account the results directly analyzing the volume and structure of sales production and trade. Let us consider the measure currents security indicator turnover of inventory, i.e. during the treatment of a fixed mass of commodities, in order to build a multifactor index model analysis of treatment of tangible assets of the economic entity [3-5].

Analysis of the inventory of the current storage for example, by the trade organization, can be illustrated by the example shown in the table 1 (columns 7-8). After analyzing the current inventory storage overall economic entity by techniques is analyzed by comparing individual headings range. Research Methodology, used here by the author, based on the technique of index analysis with the assistance of the First and Second Index systems, the development of which directly involved the works of authors [6-8].

The range of instruments used in the study includes the construction of simple and multivariate analytical indexes, with the release of a result on the construction of the five-factor model, a hybrid of retail turnover. Author's model contains the analysis of the time factors, material assets turnover rate, size, inventory and analysis of two structural components with respect to the value of one-day sales and stock SKUs current storage company.

Analysis of the Speed treatment of inventory (v-model). Analysis of the current inventory storage, one of whose tasks is to identify deviations of the actual stock on a specific date from the commodity standard of this period can't be complete without examining the rate of turnover of tangible assets, which has independent significance.

It is recalled that already considered above the indicator for the asset or the time-reversal of inventory – is the term or period of time during which marketed the average inventory. The faster committed commercialized products, the less working capital in the form of tangible assets required for uninterrupted treatment process in trading systems, and the lower, hence, distribution costs are developing in trade and value chains.

Acceleration asset turnover, in turn, leads to a reduction the duration of the process of handling the material benefits in the form of a complete production and supply cycle, and, accordingly, to increase profitability, strengthen the financial condition of the company and etc. On an indicator of security turnover inventory is closely related indicator of the *speed of circulation of commodities*, or the turnover of tangible assets having independent analytical value.

The rate of circulation of commodities, or *inventory turnover*, or even *the turnover speed* characterizes the number of revolutions of the mass of commodities, taken in the amount of the average commodity stock, which is calculated every time specifically for the analyzed period. The practical content of this characteristic can be interpreted as follows with the options a comment: how many times renewed commodity stock during the analyzed period, or a sales occurs during the reporting period in the amount of the average commodity stock.

Table 1 – Calculation of deviations from the norm of inventory storage current *j*-th type retailer Limited Liability Company "Trading House" for the III quarter of 2015*

Order №	At the beginning of the month reporting year	Credited (planned) turnover for the quarter, ths. rubles		The actual inventory of the current storage		Deviation from the norm		The actual turnover per month, ths. rubles
		total	day turnover ИП$_3$/n_{pl}**	cost of, ths. Rub.	turnover in days	cost of, ths. Rub.	turnover in days

* *Data source*: the official state reporting data operational and technical and managerial accounting;
** *Note*: n_{pl} = 90 days.

In analyzing the dynamics of the rate of circulation of commodities and commodity-supply treatment time is traditionally used index method is simple, it is a clear, reliable and generally efficient comparison tool in conducting analytical calculations factor in the following areas: analysis of growth in turnover through faster turnover of goods; calculation of volume released (mobilized) or overly involved (immobilized) current assets as a result of the rate of change and the time the time of turnover of goods [9].

In order to illustrate these aspects of the example analysis of said range of footwear companies, which is listed in Table 2, should be to build the index dynamics of the average rate of turnover for the three *k*-th commodity items $(k=\overline{1,s})$, that are reflected in the table for the reporting and the base period. This measure of the average speed will be the index of variable composition – characteristic of a productive attribute the so-called First index system (I *IS*):

Table 2

The analysis of turnaround time of (*t*-model) and of turnover speed (*v*-model) material current assets in trade for the shoe department of Limited Liability Company "Trading House" for the III quarter of 2014-2015

Order №	Name of product group footwear	Quarterly volume of turnover by period, ths. rubles		Individual quarterly turnover index	Average inventory on current storage periods, ths. rubles		Individual index of inventories	Structure of average inventory for the period, %		The speed of turnover by period, time	
		basic	reported		basic	reported		basic	reported	basic	reported

1	**2**	**3**	**4**	**5**	**6**	**7**	**8**	**9**	**10**	**11**	**12**
1	Leather	24 260.00	29 820.00	1.2214	6 990.00	6 130.00	0.8770	27.67	23.03	3.47	4.86
2	Combined	21 350.00	30 640.00	1.4346	10 100.00	12 340.00	1.2218	39.99	46.36	2.11	2.48
3	Sports	12 080.00	12 110.00	1.0150	8 170.00	8 150.00	0.9976	32.34	30.61	1.48	1.49
–	Totally:	57 690.00	72 570.00	1.2579	25 260.00	26 620.00	1.0538	100.00	100.00	2.284	2.726

$$\Im_{\overline{v(\overline{З},v)}\,1/0} = \overline{{}_{З_1}v_1^{(k)}} : \overline{{}_{З_0}v_0^{(k)}} = \frac{\sum_{k=1}^{s} v_1^{(k)}\overline{З_1^{(k)}}}{\sum_{k=1}^{s}\overline{З_1^{(k)}}} : \frac{\sum_{k=1}^{s} v_0^{(k)}\overline{З_0^{(k)}}}{\sum_{k=1}^{s}\overline{З_0^{(k)}}},$$

$$\begin{array}{|c|}\hline v^{(k)}{}_0 => v^{(k)}{}_1 \\ \hline З^{(k)}{}_0 => З^{(k)}{}_1 \\ \hline \end{array}$$

where $\overline{{}_{З_1}v_1^{(k)}}$ – the average speed of the mass of commodities turnover in the reporting period specified in the Table. 2 commodity groups shoe range.

Thus, the relative *growth rate of turnover* in the reporting period compared with baseline was 19.35%. This increase occurred both through the growth of the actual speed rate (circulation of commodities) on all commodity positions range (see: Individual indices rate of commodity circulation in column 13 of table 2), and due to changes in inventory structure for the same commodity items, that is, i.e. on the analyzed groups of shoes – leather, combined and sports (respectively, columns 9 and 10 of table 2).

In other words, the very average increment rate in the dynamics has taken place due to the simultaneous and combined effects of these two factors taken into account traits that should be resolved by the analyst on the individual components. Consequently, this increment should be laid out on the factors noted specifically that will take into account their impact on the isolated change in the average characteristics of the velocity under the First *IS*. The index schema of factor analysis in this case can be in constructed by the expansion of variable composition of the index. But for the purposes of further analysis, the simple index of variable composition present in its *modified form* entry through the structural component – the proportion of margin in the range of graphs 9 and 10 table 2.

Continuation of Table 2

Individual index of commodity circulation speed	The volume of trade turnover for the one-day period, ths. rubles		Individual commodity mass index of a one-day turnover	The structure of the one-day turnover by period, %		Treatment in time periods, days		Individual index time reversal commodity weight
	basic	reported		basic	reported	basic	reported	
$i^{(k)}_{v_{1/0}} = \frac{v_1^{(k)}}{v_0^{(k)}}$	$W(1)_0^{(k)}$	$W(1)_1^{(k)}$	$i^{(k)}_{W(1)_{1/0}} = \frac{W(1)_1^{(k)}}{W(1)_0^{(k)}}$	$d^{(k)}_{W(1)_0} = \frac{W(1)_0^{(k)}}{\sum_{k=1}^{s} W(1)_0^{(k)}}$	$d^{(k)}_{W(1)_1} = \frac{W(1)_1^{(k)}}{\sum_{k=1}^{s} W(1)_1^{(k)}}$	$t_0^{(k)}$	$t_1^{(k)}$	$i^{(k)}_{t_{1/0}} = \frac{t_1^{(k)}}{t_0^{(k)}}$
13	**14**	**15**	**16**	**17**	**18**	**19**	**20**	**21**
1.4006	271.00	331.00	1.2214	42.28	41.07	25.79	18.52	0.7181
1.1754	237.00	340.00	1.4346	36.97	42.18	42.62	36.29	0.8515
1.0068	133.00	135.00	1.0150	20.75	16.75	61.43	60.37	0.9827
1.1935	641.00	806.00	1.2574	100.00	100.00	39.407	33.027	0.8381

$$\Im_{\bar{v}(d\bar{\Im},v)1/0} = \frac{\sum_{k=1}^{s} d^{(k)}_{\bar{\Im}1} v_1^{(k)}}{\sum_{k=1}^{s} d^{(k)}_{\bar{\Im}0} v_0^{(k)}}.$$

$d_{\bar{\Im}_0} \Rightarrow d_{\bar{\Im}_1}$

$v_0 \Rightarrow v_1$

The aggregate index, all the values of the factors taken into account ($d_{\Im}$ и v) change their value during the transition from reporting period to the base period. For this reason, it should be recalled, the index is called the index of variable composition resultant variable. In order not to clutter the calculation formulas in the following text, the expression "hell" over the symbol of the sign as a characteristic of a statistical averaging of inventory on the corresponding headings of the analyzed sign-factor $\overline{\Im_0^{(k)}}, \overline{\Im_1^{(k)}}$ will have to be omitted.

To assess the impact of the turnover rate of individual headings to change the average velocity for the entire range of goods should be built within the I *IS* have analytical index of constant composition. Actually, the analytical index is constructed according to the rules of construction of factor analytic index with weights appropriate period taking into account the statistical nature of the indexed attribute [10]. In the case of constructing the index of constant composition – on the balance of the reporting quarter of 2015 in relation to the secondary feature – the velocity of the mass of commodities (*v*)

Calculations show that the decrease in the average turnover rate of 2.36%, reflecting the structure of index changes, there by reducing the proportion of the fastest on the winding assets against the share of growth relatively "slow" the winding assets (compare the reduction in the share of leather shoes and footwear increased percentage combined in rows 1 and 2 in column 9). This brings to mind a quote from Carroll, quoted in an epigraph to the article, where there categories *Comparability*, *Relativity* are treating terminologically extremely informative and very modern.

Built system indices can also be determined in accordance with the above trend analysis of the absolute amount of growth in turnover due to the acceleration of the turnover of individual products. This

value is defined as the difference form the index of constant composition formula, presented in a familiar, for analytical indexes, aggregate form. The presented scheme of construction of I and II *IS*, followed by analytical calculations and comments reveal certain possibilities of deepening and detailed economic analysis of the characteristics of the retail turnover of the company investigated. Opening possibilities allow further discussion during case study material to build more complex multivariate index structure in the form of analytical models involving, in addition to the characteristics of the turnover rate of current tangible assets (v), and the characteristic time of their treatment (t).

For the construction of the aforesaid models were used index methods of analyzing the dynamics of inventory homogeneous range with the assistance of the First (I *IS*) and the Second index system (II *IS*). And if I *IS* allows factor analysis with elements of degradation of resultant variable with respect to changes in the structure and composition of the assets, the II *IS* directs the analyst on the study of direct communication characteristics of statistical factors and their components.

Thus, in the course of transformation was obtained 3-factor model of the volume index of turnover, depending on changes in the average of inventory, changing its structure and changes in the average speed (rate) of its commodity circulation. This model can be called *three-factor model* analysis of trade, depending on the state and dynamics of commodity stocks. In terms of content model must be "streamlined" as indicated in the scheme of logical and quantitative link located directly below the expression.

$$\underset{1,2579}{\mathfrak{I}_{W(v,3)\frac{1}{0}}} = \underset{1,2224}{\mathfrak{I}_{\bar{v}(v)\frac{1}{0}}} \times \underset{0,9764}{\mathfrak{I}_{\bar{v}(d_3)\frac{1}{0}}} \times \underset{1,0538}{\mathfrak{I}_{3\frac{1}{0}}},$$

$\mathfrak{I}_{\bar{v}(v^{(k)},3^{(k)})\frac{1}{0}} = 1,1935$

$\mathfrak{I}_{W(v,3)\frac{1}{0}} = 1,2579$

Analysis of the treatment time (t-model) of tangible assets in the form of stock. Similarly, the above analysis the turnover rate can be analyzed during the treatment of inventory on the scheme I *IS* suitable for a homogeneous mix. However, here the pair Rounds and independent of each other factors ($t^{(k)}$, $W(1)^{(k)}$) of the multiplier determines the average size of the current storage stock ($3^{(k)}$). Needless to say, the influence factor calculations similar to the calculations for the analysis of asset turnover rate.

The index indicates a decline in the average time of treatment of inventory by improving the day-sales structure: in particular, significantly decreased the proportion of third heading (from 20.65% to 16.75% – see graphs 16 and 17 in Table 2), in which observed the most significant treatment time (see graph 19 in the same table 2). Upon completion of the analysis of current assets can be cut to obtain another interesting derivative of the dependence of the analyzed indicators. To do this, repeat all the necessary transformations with algebraic expressions, used as the component of I *IS*. Namely, with the index of variable composition, the average time reversal of inventory depending on changes in the actual turnaround time and one-day volume of turnover.

But the resulting ratio is definitely not the ultimate goal of the done reforms and is only an intermediate structure for the purpose of a more detailed study of the state and dynamics of current assets with the involvement of other optional examined similar analysis systems. It is also permissible already used technique *index cross connection*, which allows due to differences in the analyzed attributes index systems to implement a kind of factorial addition. So, on the one hand, according to the expression, of variable composition index $\mathfrak{I}_{\bar{t}(t,W(1))\frac{1}{0}}$ is equal to the product of two factor indices treatment time and one-day turnover

$$\mathfrak{I}_{\bar{t}(t,W(1))\frac{1}{0}} = \mathfrak{I}_{\bar{t}(t)\frac{1}{0}} \times \mathfrak{I}_{\bar{t}(W(1))\frac{1}{0}}.$$

On the other hand, the same index $\Im_{\bar{t}(t,W(1))1/0}$ in accordance with equation coincides with the expression

$$\Im_{\bar{t}(t,W(1))1/0} = \Im_{\bar{3}(t,W(1))1/0} \quad : \quad \Im_{W(1)1/0}.$$

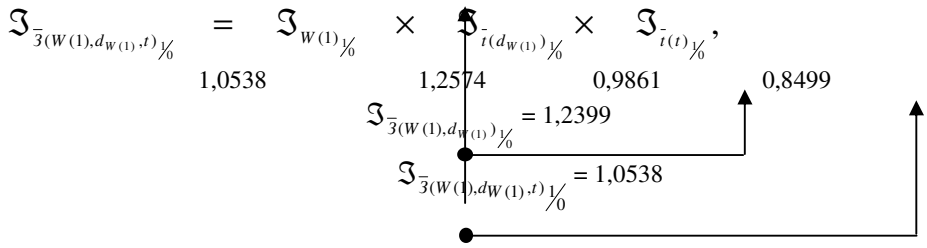
Considering the last two entries in the expressions as a system of two equations with the same left-hand sides, we solve the system of equations for the index $\Im_{\bar{t}(t,W(1))1/0}$, taken as an unknown variable.

Then place all the existing (pre-built) codes on the right side of the multiplier factor in a strictly meaningful sequence to link the goals of these indices in the system.

In this way the updated causal mechanism of statistical relationships and productive factor, in this case, the primary feature of this time stands for average commodity index storage inventories current reporting period compared to the base period.

$$\Im_{\bar{3}(t,d_{W(1)},W(1))1/0} = \Im_{\bar{t}(t)1/0} \times \Im_{\bar{t}(d_{W(1)})1/0} \times \Im_{W(1)1/0},$$

1,0538 0,8499 0,9861 1,2574



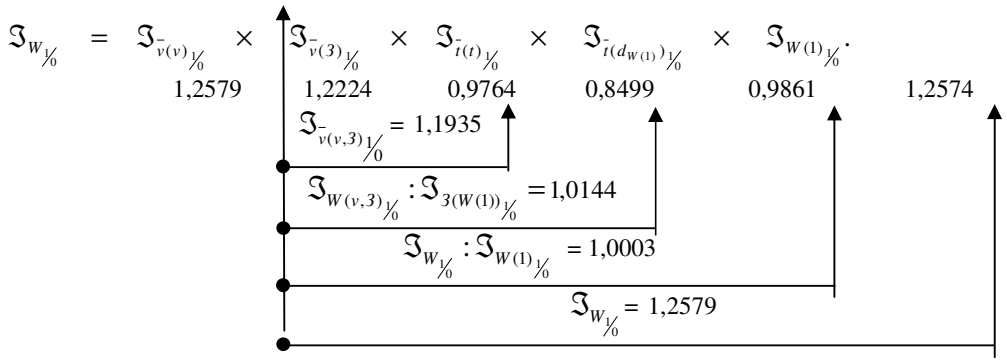
$\Im_{\bar{t}(t,W(1))1/0} = 0,8381$

$\Im_{\bar{3}(t,d_{W(1)},W(1))1/0} = 1,0538$

As a result of conversions received three-factor index model of average inventory-dependent changes in the mean time reversal of inventory ($\bar{t}$), a one-day change in the structure of trade turnover ($d_{W(1)}$) and the dynamics of one-day sales ($W(1)$).

This pattern of expression can be called *three-factor t-model* analysis of average inventory, depending on changes in the average time of treatment of assets, changes in one-day sales structure and dynamics of the one-day turnover. In terms of content and organizational terms aforesaid medium model of inventory of current storage must also be "ordered" or "linked" in a way that has already been used up, and as it is shown in the diagram, located directly under the multiplier from the expression. Such an ordering mechanism for causality of the phenomenon allows expert- analysts ably to perform, in addition to analysis of the influence of factors taken into account in the relative form, as an analysis of the impact of all the factors taken into account signs on the average size of inventory storage and the current in absolute terms, that is extremely important in the operational work of the specialists of the enterprise.

The data from this example table 2 permit to conduct such analysis of the impact of factors taken into account in absolute terms by the example of the same shoe product groups. For this it is necessary to arrange signs factors in the circuit of expression, starting with *a primary feature*, which is one-day trade $W(1)$, and further, in order of the content of their linkage in the index multiplier middle of inventory ($\bar{3}$). Then skip to the absolute account level of symptoms-factors, taking already as calculated indices and make a difference by calculating the index of the form, using the method of *chain substitutions*.



Because calculations on the scheme in the expression that due to a change in the structure of one-day sales (-1.39%), the mean of inventory increased by 23.99%. But due to the reduction of the time reversal of this reserve at 15.01% increase in the average stock of goods necessary for the reporting period was limited to only the size of a 5.38% compared to baseline.

Control countable check the balance of the partial effects (increments) factors on the change in the size of inventory in the reporting period compared to the base period gives a total of the amount of the total increment of the expression with the proviso of possible acceptable rounding error. All private, increment factors may be, if necessary, for the purpose of clarity, are summarized in a single standard analytical table of the table 3 type.

The Results of Research

In this article the author presents the conceptual hybrid *v*|*t*-model multivariate analysis (velocity-time), allowing much more detailed and much more fully explore the phenomenon of turnover of tangible assets of the economic entity.

Using the index schema of the expressions we can without difficulty obtain analytical relations that will link the complex into a single index variable composition scheme, both the index and three simple index of turnover dynamics, dynamics of average commodity stocks and the dynamics of one-day sales. The effectiveness of a sign, given the linear relationship (direct statistical relationship characteristics) of all indices in the form of a multiplier, will the index of retail trade turnover dynamics as dependent Rounds held in the analysis of the relative signs of factors, according to the regulations following *the five-factor model*

If *quantitative linkage* of all indices in direct communication performance does not cause technical difficulties, the meaningful economic docked each step with scoring indication (change of retail trade turnover) is not always obvious. Here, the expert-analyst should show patience in building a causal

chain of interrelated signs, to find the necessary parts of the circuit with fixed them actual performance. And finally, it is necessary to carry out a detailed interpretation of the results consistently. This is extremely important and is associated primarily with the fact that the plug-in hybrid model factors are manageable, they can predict and plan in orientation mode, the final economic results.

Bearing in mind the analysis of the absolute influence of the factors taken into account on a productive feature (in this case – the amount of retail goods turnover), the starting index of the chain in the formula of the expression should be the primary composite index only for its statistical nature trait-factor on the right side of the multiplier. He is a simple index of the dynamics of one-day sales – $\Im_{W(1)_{1/0}}$.

The next element of the chain linking "begs" to be an index that contains, at least in the numerator or the denominator of the aggregate characteristic of one-day sales volumes throughout the shoe assortment. That index is the index of one-day sales structure – $\Im_{\bar{t}(d_{W(1)})_{1/0}}$. Therefore, carefully calibrated and meaningful economic aspect of the method of chain substitutions, you can build the required analytical chain indices strictly specified sequence recorded chart below from the expression.

$$\underset{1,2579}{\Im_{W(W(1),\bar{t}(d_{w(1)}),t(t),\bar{v}(d_{\bar{3}}),\bar{v}(v))_{1/0}}} = \Im_{W(1)_{1/0}} \times \underset{1,2574}{\Im_{\bar{t}(d_{W(1)})_{1/0}}} \times \underset{0,9861}{\Im_{\bar{t}(t)_{1/0}}} \times \underset{0,8499}{\Im_{\bar{v}(d_{\bar{3}})_{1/0}}} \times \underset{0,9764}{\Im_{\bar{v}(v)_{1/0}}} \cdot \underset{1,2224}{}$$

$$\Im_{\bar{3}(d_{W(1)})_{1/0}} = 1,2399$$

$$\Im_{\bar{3}_{1/0}} = 1,0538$$

$$\Im_{W(d_{\bar{3}})_{1/0}} = 1,0289$$

$$\Im_{W(W(1),\bar{t}(d_{W(1)}),t(t),\bar{v}(d_{\bar{3}}),\bar{v}(v))_{1/0}} = 1,2579$$

As a control test is necessary to carry out an algebraic coherent meaningful linkage of each of the index built into the hybrid *v*|*t*-model (velocity-time) of turnover of tangible assets represented by the formula of the expression one by one, moving phases of this scheme in the direction *of the left – right*. We carry out a second factor linking the analytical index of the expression in the scheme of the index multiplier model. The second account is the index of the influence of the structure on the daily sales average time of treatment of the current inventory storage – $\Im_{\bar{t}(d_{W(1)})_{1/0}}$. The product of the first pair of indices gives the following interesting and understandable analytical dependence

$$\Im_{W(1)_{1/0}} \times \Im_{\bar{t}(d_{W(1)})_{1/0}} = \frac{\sum_{k=1}^{s} W(1)_1^{(k)}}{\sum_{k=1}^{s} W(1)_0^{(k)}} \times \left[\frac{\sum_{k=1}^{s} t_0^{(k)} W(1)_1^{(k)}}{\sum_{k=1}^{s} W(1)_1^{(k)}} : \frac{\sum_{k=1}^{s} t_0^{(k)} W(1)_0^{(k)}}{\sum_{k=1}^{s} W(1)_0^{(k)}} \right] =$$

$W(1)_0 \Rightarrow W(1)_1$

$d_{W(1)_0} \Rightarrow d_{W(1)_1}$, $t_0 = const$

$$= \frac{\sum_{k=1}^{s} t_0^{(k)} W(1)_1^{(k)}}{\sum_{k=1}^{s} t_0^{(k)} W(1)_0^{(k)}} = \Im_{\bar{3}(d_{W(1)})_{1/0}}.$$

$d_{W(1)_0} \Rightarrow d_{W(1)_1}$, $t_0 = const$

As a result, changes in the expression obtained an analytical index of commodity stock, depending on changes in the structure of one-day sales $\Im_{\bar{3}(d_{W(1)})_{1/0}}$. The next (third in a row) factorial analytical index in the formula of the expression, which is to be linked to the multiplier circuit is the index of

constant composition, the average time of inventory turnover – $\Im_{\bar{t}(t)1/0}$ of course, affects the size of the average stocks of this storage. We show below the necessary conversion

$$\Im_{\bar{3}(d_{W(1)})1/0} \times \Im_{\bar{t}(t)1/0} = \frac{\sum_{k=1}^{s} t_0^{(k)} W(1)_1^{(k)}}{\sum_{k=1}^{s} t_0^{(k)} W(1)_0^{(k)}} \times \frac{\sum_{k=1}^{s} t_1^{(k)} W(1)_1^{(k)}}{\sum_{k=1}^{s} t_0^{(k)} W(1)_1^{(k)}} = \frac{\sum_{k=1}^{s} t_1^{(k)} W(1)_1^{(k)}}{\sum_{k=1}^{s} t_0^{(k)} W(1)_0^{(k)}} =$$

$$= \Im_{\bar{3}(d_{W(1)},t)1/0} = \Im_{\bar{3}1/0}.$$

Next, for each factor to implement the scheme linking multiplier the fourth at the row components – index changes in the average turnover rate of tangible assets due to a structural shift in the composition of inventories. Here the result of the previous link of the index $\Im_{\bar{3}1/0}$, i.e. a simple index of the expression should be multiplied by an analytical index $\Im_{\bar{v}(d3)1/0}$. Should whenever approached carefully, guided by the rules of construction of the index scheme, the economic content of the technical and economic indicators and thoroughly carrying out the necessary changes in the aggregate parts conjugate of factor analytic index to the circular linking procedure codes into the system.

Noteworthy is the fact of "as if" automatic clarify the location of primary and secondary symptoms-factors $(W(1)^{(k)}, d_W^{(k)}, t^{(k)}, d_3^{(k)}, v^{(k)})$ in the corresponding intermediate chain links of the hybrid *v*|*t*-model up to the resultant variable factor - *W* from the expression. However, this seemingly natural ease laid analyst in advance in the preliminary selection of the factors taken into account and building up in the meaningful chain of interrelated indicators.

Conclusions

In the end, a case study based hybrid index model analysis of cost volume of the quarterly turnover, depending on the value of inventory and the current storage volume of daily sales. It is enough for the reader a clear economic sense of the final result of the conversion from the expressions, and allows managers to logistics and distribution business processes of production and trade, wholesale and retail trade and retailers to establish reasonable standards of current inventory storage. This approach can also be timely to make these regulations required course corrections as taking into account the intensity of daily sales, and taking into account an accurate assessment of the seasonality factor purchases-sales. Thus, even when taken separately and piecemeal, but a row, analytical indexes pair give in linking cost-clear and transparent results in the assumption that the factorial scheme in a straight multiplier characteristics of the statistical relationship is sufficiently pre-calibrated.

Semantic analysis of the scheme by individual expressions and, can be interesting to be interpreted as analytical indices built by a group of assessors "dual structural shift", which occurred in the first place, as a part of inventory, providing trade reporting period, due to changes in the structure of sales of daily trading enterprise of shoes. And this turned out to be an adverse structural shift was the cause of a different shift has happened as a result in the range of sales for the period under review. This is the second circumstance, as a result, led to a slight, barely noticeable, but the growth of retail trade turnover in the reporting period compared with the base only by 1.44% (compare with the previous indicator of growth +19.36% expression of formula) in the calculations of the analytical chain.

In fact, the first structural shift in the assessment of significant symptoms are caused by (as the cause) of the second structural shift of another, no less significant feature for quite appropriate analogy with the movement of geologic plates or reservoirs under tectonic phenomena of nature. The proposed model allows the author simultaneously and jointly explore and speed, and time of turnover of tangible assets with respect to typical primary reporting indicators and standard indicators of economic activity of the economic entity.

The hybrid model provides a reliable assessment of the effects of each factor on a productive sign and, accordingly, the carrying circular linking increments of each factor, not only in relative form, but also in absolute terms, i.e. at cost, using the method of the first differences as a special case of the method of chain substitutions with respect and dynamics, and targets, and the level of the plan. Table. 3 shows the influence of the absolute size of each of the five signs of factors on the amount of the quarterly retail turnover, as well as the values of these increments in comparison with both the overall increase (column 6), and in comparison with the base level of a productive attribute (column 7).

Table 3

Summary description of the analysis of the dynamics of material circulating assets of retailer Limited Liability Company "Trading House"

Order №	Factor name, which has been taken into account	Unit measurement	Contingent designations	Impact in absolute terms, Rub.	Relative deviation, % to	
					the total change	the level of the base period
$k=\overline{1,K}$	x_k	module	$\Delta W(x_k)_{1/0}$	$\Delta W(x_m)_{1/0} = x_{11}.x_{21}...\Delta x_{m1/0}...x_{k0}$	$\frac{\Delta\sum_{j=1}^{m} W(x_k^{(J)})_{1/0}}{\Delta\sum_{j=1}^{m} W(x_1,x_2,x_3,x_4,x_5)_{1/0}}$	$\frac{\Delta\sum_{j=1}^{m} W(x_k^{(J)})_{1/0}}{\sum_{j=1}^{m} W_0^{(J)}}$
1	2	3	4	5	6	7
1	The volume of one-day sales	rub. per day	$\Delta W(W(\mathrm{l}))_{1/0}$	15 043 700.13	101.10	26.08
2	The structure daily sales average time of treatment of the current inventory storage	days	$\Delta W(\bar{t}(d_{W(\mathrm{l})}))_{1/0}$	-3 008 815.39	-20.22	-5.22
3	The average stock turnover time	days	$\Delta W(\bar{t}(t))_{1/0}$	-6 073 615.21	-40.82	-10.53
4	Change in the average rate of inventory turnover due to a structural shift	speed for the period	$\Delta W(\bar{v}(d_{\bar{3}}))_{1/0}$	-4 374 671.48	-29.39	-7.58
5	The average velocity of circulation of inventory	speed for the period	$\Delta W(\bar{v}(v))_{1/0}$	13 293 401.95	89.33	23.04
–	In total:	rubles	$\Delta W(x_1,x_2,x_3,x_4,x_5)_{1/0}$	14 880 000.00	100.00	25.79

Of course, the above scheme is proposed based on a factor analysis of the hybrid model of the index is not the only possible one. There are other, no less interesting patterns of economic analysis of the state and dynamics of current tangible assets with a different set of factors that characterize the level of inventory at different angles and in different aspects, and with not necessarily the index method, and correlation and regression methods analysis, and other analytical methods, complexity; at the expense of more serious mathematical apparatus, for example, with the use of matrix methods of research [12], and so forth.

The Direction of Future Research

However, due to set out in a two-part article considerations, it seems very promising is the use of hybrid aggregated *v*|*t*-model systems integrated analysis of financial and economic state of the business entity as well as, say, a ratio analysis and multivariate models predicting the subject of bankruptcy. Of particular interest are the undoubted opportunities offered by the author of the model to be useful in order to adjust the state of the accounting (financial) statements of the enterprise in making its management informed management decisions in the organization, in assessing the market value of the business, as well as in the provision of engineering and operational long-term planning.

Abstract

In this paper we discuss the growing phenomenon of collaboration between governments and other sectors, Non- Profit Organizations (NPOs) in particular. We aim to define global types of collaboration, find which macro environmental factors influence them and what the role of local authorities is. The types of collaborations between NPOs and government in Israel will be examined and six types of formal collaboration will be defined. The subjects interviewed are non-profit organizations and consulting firms' Chief Executive Officers (CEOs). A case study of *informal collaboration* between an NPO and the government in Israel between the years 2016-2017 will be presented. In order to understand the reason of collaboration, its benefits and limits, we interviewed 5 NPO staff members and 3 senior representatives of the Ministry of Education who took part in the collaboration. We found that formal collaboration between NPOs and the government is based on: specific regulation or existing regulation, collaboration through a third party or as a joint venture, collaboration with exemption of tender or by tender. Each type has different advantages or disadvantages which NPOs managers should take in to consideration. The government in Israel is taking steps to rationalize the management of the formal connection. In the informal collaboration we found that both the NPO and the government are looking to gain knowledge. Though, the gap of different work rate of each party can be a problem in maintaining this collaboration.

Keywords: NPOs, collaboration with government, growth strategies

Introduction

As part of the global trend of privatization and decentralization of public services, we witness more governments around the world increasing collaboration with businesses and organizations from the nonprofit sectors. This phenomenon helps promote global and local economy in developing and developed countries (Gebba, et al., 2013).

Privatization can be defined as the form of transferring the ownership from the government to private organizations (NPOs or business) or transferring public tasks through some types of collaboration (Solecka, K. 2013). In addition, we can witness models of organizations which are state-owned enterprises (SOEs) or partly owned by the government (Powell, et al., 2014)

Due to this process, NPOs are playing a significant role in the life of people, from birth to old age in various aspects. These nonprofit organizations have become a significant provider of many services for the citizens. Some of the services used to be provided by the government and some were new creations, meant to bridge the gap between public needs and the lack of government response to

these. Although each country is influenced by local aspects of regulation, model of civil society, diversity of population, culture and leading values, there are some similarities in the case of NPOs collaboration with governments. Each side can profit by coping with its own weaknesses and taking advantage of opportunities for the benefit of the civil society.

On the one hand, economic models show that in some cases, NPOs can be more efficient and deliver services more effectively, be more flexible to public needs than the government. NPOs play an important role in advocacy, and represent marginalized groups. However, they can have difficulty with structure, definition of goals, fund raising, and dependence on the requirements of stakeholders. On the other hand, governments can be in some cases more reliable, have broad strategic visions, an appropriate broad infrastructure, be legally mandated and financially more resourced than NPOs, though political interests interfere sometimes. However, they can be cumbersome regulatory and be influenced by political interests (Brinkerhoff, et al., 2002) cited in Teegen, at al., (2004).

Theoretical Background

Types of relationships between NPOs and government

Scientific articles analyze the relationship between NPOs and the government from different points of view in terms such as duration of time, degree of formalism, the degree of change required from each partner, the degree of risk they take. As the collaboration grows deeper, a better understanding of the relationships, its risks and opportunities becomes more significant for managers of NPOs as part of their growth strategies and for governments in order to become more efficient. In this article, we analyze several possibilities of collaboration between the parties and pinpoint the advantages and disadvantages involved in the process. We will refer to some points of view, both formal and informal in order to explain types of collaboration. These include specific settings regarding the effective competition, cost consideration, the way of the form of winning, tenders among them (Gazley, B. 2008). We will elaborate on the types of tenders between the government and NPO's in Israel.

Cooperation and collaboration

The degree of cooperation between the government and businesses and NPOs can affect the size of the collaboration, the amount of time it will last, the degree of formality of the relations between the managers of the collaborators and the amount of budget investment required of each partner for the collaboration to succeed. Because each partner invests considerable resources in the development and accomplishment of the collaboration, it is important to try and define the type of partnership. Table no. 1 shows the general settings for possible collaboration types.

Table 1: Types of potential collaboration between NPOs and the government

Type of collaboration	Explanation	Goals
Cooperation means short term, informal, voluntary relations between people and organizations (Houge 1994; Ciger 2001).	The two participants in the cooperation share information and location but are independent and look for establishing relationships with others to achieve individual development. Partners have low trust, and infrequent communication.	Short term, informal, achieve individual development

Coordination refers to partners that comprise strategies and responsibilities that entail information sharing, mutual planning and decision-making, mutual policy, projects and funding initiatives (Lawson 2002).	As Ovretveit (1993: 40) and others (Litterer 1973; Dunshire 1978) suggest the exercise of coordination intends to bring together interdependent parts in order to give birth to a whole. Though independent, organizations join forces in order to get to an agreed outcome. Since coordination means more than information and resource sharing, joint planning and operation, it calls for a higher level of commitment. In this way organizations lose autonomy and increase shared risk.	Medium term, more formall, joint planing to get an agreed outcome
Collaboration means a stable and long-term denser relationship (Gray 1989; Ciger 2001).	The collaboration parties are independent entities. Still, they have to share resources, data, clients, geographic issues. The parties will make major changes in their operational mode, face risks, and achieve strategic synergies leading to original solutions. Mutual tasks will be accomplished but the focus will be on the processes and institutional arrangement used to achieve them (Keast et al. 2007a, b; Mandell 1994, 2001).	Stable and long-term, major changes to achieve strategic synergies

Influence of macro environmental factors on the collaboration

Government, business or social sectors can be affected by their macro environment. These effects can be specific to any industry in a particular country or global in a number of countries.
Environmental factors taken into account are: economy, demographics, technologies, wars, which are specific to a region/country. For example, in Israel, following a steep increase in the prices of real estate in the last decade, the government enacted new laws that allow businesses to receive significant benefits for the expansion of residential construction for young couples in the geographic periphery outside the central cities at discounted prices. This move demanded the response of new services which were provided by the collaboration of the government with business and NPOs such as educational frameworks, employment, leisure activities and so on. In many countries in the world, we can see research on the macro-environmental effects on the relationship between government and non-profit organizations. Those researchers attempt to explain why and when collaboration between NPOs and government grows with the purpose to solve complex region problems by sharing their expertise, knowledge, resources to produce public value together. This point of view can be found in developing and developed countries such as Russia, (Cook, L. J. 2015), Netherlands, (Brandsen, et al., 2015), Israel, (Schmid, et al., 2016), Egypt, (Gebba, et al., 2013), Australia, (Keast, et al., 2014).

Collaboration of government with NPOs through local authorities

As part of the decentralization process, central government delegates responsibility and resources to local authorities to reinforce local communities for reflecting their local needs. Bar-nir, et al., (2011) state that they are provided by strong, new relationships with NPOs. In Israel, for example, in view of the sharp increase in the number of road accidents at the national level, the government decided to invest resources in delivering training courses for young and old drivers throughout the country. Since the populations of young people and adults in Israel differ from city to city, the government put the responsibility for implementing the program on the local authority, which accepted the budget and guidelines for the program's goals. Each local authority could have carried out the program in a manner that best suited the target populations in the city, together with the businesses or NPO's partners it chose.

As Archambault et al., (2002) cited in Bar-Nir, et al., (2011) noted, the bonds between NPOs and local authorities were formed because the latter saw NPOs as equal partners in their contribution to the benefit of civil society, such as the government. The main advantage of this type of collaboration lies in the good understanding by both sides of the target audience, the local needs and the local culture in order to succeed in the assimilation of the projects. At the same time, the budget for joint projects can be more limited for a local program in relation to direct national collaboration between the government and the NPO.

Informal relations between NPO's and government

Another view of relationship that is less analyzed tries to understand the informal collaboration between NPOs and government outside the contract formal arena. Researches like Gazley, B., (2008) show that government representatives engage in collaboration with NPOs for professional learning. This collaboration is based mostly on trust. This collaboration emerges from mutual goals trying to solve a civil problem. In this way, the joint work process can be created quickly and be very effective for the benefit of the public. Nevertheless, it is risky from the NPOs' point of view as they cannot resave financial support from the government. In this article we will present a case study of an informal collaboration between an NPO and the government in Israel.

Study

Israeli view on NPOs collaboration with the Government

In the preceding two decades, the nonprofit sector has grown significantly in both economic terms and the number of organizations (GuideStar Israel 2014[1]). The total job employment only in the NPOs sector is 13.6% (448,000) from the total employment in Israel. NPOs provide services for education, culture, religion, health, welfare. Incomes of Israeli NPOs are divided as - 50% from the public, 35% self-generated income and 15% philanthropy. Since 1980, 1,600 new NPOs have been registered. Between 1980 and 2013, over 52,000 NPOs have been registered in total. 36,000 NPOs were active in 2015 (Almog-Bar, M., 2016). The major change took place in 2008 when the government approved a decision which acknowledged the contribution of the civil society - NPOs - to the Israeli society. As a result, the government took decisions intended to build partnerships with NPOs. This strengthens the collaboration, at the same time maintaining the partners' independence. (Prime Minister's Office 2008, 18). Since 2008, round-tables have been serving as a vehicle meant to create a dialogue between the government, the business sector, NPOs and the corporate-philanthropic sector. This mutual acquaintance and contact with each other has led to a better collaboration between sectors, supplying an efficient mechanism which promotes joint activities. In this article we will focus on NPOs-government collaboration in Israel. While the NPOs offer the flexibility, creativity and basis for innovation that the government lacks, the government sector provides the resources, technologies and license needed to diffuse innovative approaches and to make them sustainable (Salamon et al., 2015). According to the Bureau of Statistics, the government's social purchasing budget in 2014 in Israel was- 2.1 milliard EUR which constitutes 40% of the total government procurement of that year.

Methodology

We will investigate the collaboration between the Israeli government and NPOs both in its formal (according to the definitions of the law on Government Decision 1950[2]) and informal system. First, in the following tables we will present and define 6 ways of *formal collaboration* between the government and NPOs, the advantages and disadvantages of each method. The definition of the form of collaboration was taken from the website of the Ministry of Finance in Israel[3]. In order to define

the advantages and disadvantages of each method, we interviewed 3 CEO's of leading consulting firms on this specific issue in Israel, 5 CEO's of NPOs that have cooperated with the government for more than two years and the Director of Cooperation in the Israeli Ministry of Finance. Second, we will discuss a case study on *informal collaboration* between an NPO and the Government in Israel.

Formal ways of collaboration with the government in Israel

Table no.2 defines and presents the advantages and disadvantages of 4 ways of formal collaboration between NPOs and the Government in Israel. They will be followed by the presentation of two more methods.

Table 2: Advantages and disadvantages of different ways of collaboration between NPOs and the government in Israel

Form of Collaboration	Advantages	Disadvantages
1. Specific Regulation - a designated regulation given according to a government decision to allocate funds to specific issues for a limited time until the issue is solved, e.g. The development of agriculture in a particular geographical area. The government creates a specific regulation by accurately defining the objectives it wants to achieve, the best possible partner will receive a budget, for a specific period of time	✓ Suitable NPOs can receive significant budgets for several years from one or several government departments. ✓ NPO's manager can assess the chances to get funding according to the amount of collaborations in the previous year (from public information).	☒ NPO's relatively small chance for matching the specific regulation conditions. ☒ The budget approved for the specific regulation will be divided among all organizations that applied and found suitable. ☒ The process is relatively long and can take up to a year for approval. ☒ It can be a relatively expensive process for an organization to submit the request itself.
2. Existing regulation - An existing regulation was created to provide a long-term solution to a civil issue which the state considers similar to the Specific Regulation just not temporarily. The government is not required to update the regulation, but it can increase the budget it invests in. For example, the government wants to provide a permanent solution for those who need immediate emotional help by having a telephone conversation with a professional 24 hours a day in order to prevent suicide. In Israel, the NPO called ERAN- (Emotional First Aid by	✓ Suitable NPOs can receive significant budgets for several years from one or several government departments. ✓ NPO's manager can assess the chances to get funding according to the amount of collaborations in the previous year (from public information).	☒ NPO's relatively small chance for matching the specific regulation conditions. ☒ The budget approved for the specific regulation will be divided among all organizations that applied and found suitable. ☒ The process is relatively long and can take up to a year for approval. ☒ It can be a relatively expensive process for an organization to submit the request itself.

Telephone & Internet) provides this service along with significant government support.		
3. Collaboration through a third party – collaboration with the government through a third partner who is already in direct partnership with the state. This requires an adjustment on the part of the organization in order to provide synergy to a third-party partner and not to be a direct competitor to it.	✓ NPOs could quickly get into the partnership with a third partner that already knows the whole process, and is used to the conditions of collaboration with the government. ✓ NPOs learn how to work with the government through a third party. ✓ NPOs share risks with a third-party.	☒ It may be difficult for NPO to locate a suitable third-party partner. ☒ NPOs are limited by the other third-party partner needs. ☒ The budget from the government has to be split between the two partners**.**
4. Collaboration as a joint venture - enables a government ministry to create high-level collaboration with an organization partner without the need to respond to a tender. The government usually initiates joint ventures with NPOs/Business in fields in which it already operates, and it already has insights on how to lead the field. The partnership is created in order to acquire new tools / knowledge from the NPO and to integrate them for several years on a regular basis in the governmental system. In such a joint venture, the degree of involvement of the government ministry is relatively high and the financial terms of the partnership require the government to invest money in it up to 49% and the NPO 51% of it. A joint venture can last for 3-5 years.	✓ NPOs get the opportunity to realize their long-term professional and financial vision with the largest partner. ✓ NPOs can acquire significant and broad information about target audience. ✓ This method is relatively achievable for both sides. ✓ Allows NPOs for multi-year collaboration with the government.	☒ Requires a high financial capability on the part of the NPOs for several years (51% each year). ☒ Requires the government to produce quantitative targets for the success of the plan that will justify its long-term investment, and the NPO to meet them.

Source: Authors' own contribution

Two additional ways of formal collaboration between NPO's and Government in Israel are presented below.

5. Collaboration with exemption from tender

This is a duty imposed on government in the Mandatory Tenders Law of 1992, and the Minister of Finance is charged with its implementation. Tender exemptions are intended to provide contractual arrangements while maintaining equality, fairness and integrity between government and

organizations. They are suitable only for organizations that can prove some uniqueness in their field, without other competitors. They are presented in Table no.3.

Table3: Collaboration via exemption from tender between government and organizations by specific committees in Israel

Type of committee	The budget amount that the committee can approve as an exemption from tender
In 2017 every ministry in Israel has an office tender committee and its members are the director general of the ministry (who serves as chairman of the committee), the accountant and the legal advisor, or their representatives, and two other employees from the ministry;	36,000 EUR
Since 2009, an office exemption committee has been operating in every ministry, including the director general of the ministry, the accountant and the legal advisor of the ministry;	from 36,000 EUR to 952,000 EUR
Central Examinations Committee, which is authorized to approve contracts with an exemption from a tender of all government ministries, whose members are the Accountant General and the Legal Advisor of the Ministry of Finance or their representatives and an additional member.	above 952,000 EUR

Source: Authors' own contribution

The data on the activity from the government's tender with other sectors is difficult to collect accurately

Because of the different reporting format of each government department to the Ministry of Finance

Illustrative data is presented to the public. As an example, table 4 presents the database of 17 government offices exemption tenders, from 2015 found on the government procurement administration website[4].

Table 4: Data from 17 government offices exemption tenders from 2015

Number of government offices which passed the information	Number of exemption tenders	Government data for 2015
17 government offices	16,521	43% of total engagements of the government this year.
The total value of the order in all the contracts of the government in 2015 were approximately 4.5 milliard EUR, and about 25% of the amount paid for the collaboration as exemption from tender.		

Source: The Knesset Research and Information Center [3]

To sum up, we can say that the advantages of collaboration between government and NPOs with exemption from tender can be time saving for NPOs and quickly approved, can be multi-year and have the option of extension and expansion for financing NPOs. Collaboration enables large budget collaboration between the NPO and the government. The disadvantages of this method of this collaboration can be the difficulty of the NPOs to prove their exclusivity. Furthermore, competitors can try to copy the NPO's uniqueness and file a petition against the exemption tender and, by doing so, stop it.

6. Collaboration by tender

There are a number of definitions and types of tenders according to law between NPO's and government. Detailed in Table no.5 are three main and most common tenders in Israel:

Table 5: Leading tenders in Israel

Type of tender	Explanation	Advantages	Disadvantages
Ordinary public tender	A tender where a request for proposals is made in a notice published to the public. Any organization can apply. Winning the tender with the government is examined according to specific scored criteria.	✓ Multi-year and has the option of extension and expansion. ✓ Enables NPO's large budget activity.	☒ May take a long time until the answer for NPO's is published. ☒ May be totally ceased from reasons of the government. ☒ NPO's standing in front the risk of investing resources without winning the tender at all.
Limited Public Tender	Tender in which negotiations are conducted with tender bidders.	✓ The NPO has the ability to influence the outcome. ✓ Multi-year and has the option of extension and expansion. ✓ Enables NPOs large budget activity.	☒ May take a long time until the answer for NPO's is published. ☒ May be totally ceased from reasons of the government. ☒ NPOs risk investing resources without winning the tender at all.
Closed tender	A tender where requests for proposals are addressed only to certain suppliers;	✓ There is a higher chance of winning the tender. ✓ Multi-year and has the option of extension and expansion. ✓ Enables NPO's large budget activity.	☒ May take a long time until the answer for NPO's is published. ☒ May be totally ceased from reasons of the government. ☒ NPOs risk investing resources without winning the tender at all.

Source: Authors' own contribution

In this first section, we presented six methods of cooperation between the government and the state, emphasizing the advantages and disadvantages of each method from the NPO's point of view. The Minister's Office in Israel presented at the annual conference on effectiveness in Israel[5], (May 2017) what they considered to be *problems* in the formal collaboration with NPO's from the government's formal point of view, and how *they are planning to deal with those problems* in the next few years in Israel. Table no.6 presents the problems and solution proposed by the government.

Table 6: Problems with formal collaboration and solutions proposed by the government

Problems	Solutions
☒ Problems in managing tenders-pursuit of renewal of engagements. ☒ Insufficient competition; from other organizations approaching proposals for cooperation with the government.	✓ Government responsibility for service – more quality and available service over time. ✓ Government infrastructure – more planning ability, standards and supervision. ✓ Objectives and measures - more determining

☒ Control is deficient - little enforcement of sanctions, tenders with inputs, and no results, limited ability to compare service operators. ☒ Bureaucracy cumbersome –it can take a long time from the moment of writing the tender until the winner is announced.	and translating them to improve the quality of service. ✓ Reducing dependence on individual suppliers. ✓ Provide to the public a three-year plan to upgrade the tender process, strengthen control, and reduce the burden on the process of the collaboration.

Source: MIDOT organization- cite of the annual conference, may 2017[5]

After analyzing possibilities for formal cooperation between the government and non-profit organizations, we also examined an informal relationship between the parties, and the following is a case study in Israel.

Case study of an informal collaboration between NPO and the government in Israel

An informal collaboration between an NPO and the government between the years 2016-2017 in Israel will be discussed. The NPO is a medium-sized one in the education sector. In 2017 the NPO 45 trainers (some of them outsourced) provided services to 7,500 beneficiaries spreading over more than 80 local authorities in Israel. Following the vision of the Minister of Education in Israel to promote the field of science, and especially the achievements of teachers and students in mathematics, the NPO developed a new professional program. It was meant to strengthen the resilience and personal motivation of teachers and students in high level mathematics. In 2016-2017 the program was offered as a pilot to high level mathematics teachers from all over the country. Registration for the program was on a voluntary basis and not compulsory by the Ministry of Education. In an independent initiative, taken by the NPO representatives, they appealed to the professional directors at the Ministry of Education and asked to inform them about the program and to think together how they can collaborate. This request was met positively by the representatives of the government ministry. As a result, professional discussions developed between the parties in the timeframe of 2016-2017.

The collaboration was defined from the beginning as informal, and was meant to deliver professional knowledge only. No agreement was signed by the two sides.

In this case study we interviewed five NPO staff members who ran the program, and three senior representatives of the Ministry of Education who managed the collaboration with the organization. In the interviews we asked three open ended questions:

- What were your goals in this collaboration?
- What were the benefits / gains from this collaboration?
- What were the difficulties / drawbacks of this collaboration?

From their answers we can see that the informal collaboration is important to the NPO. They needed this information for a deeper understanding of how to further collaborate formally with the government and to expand their knowledge. From the government point of view the importance of this informal collaboration was to gain professional knowledge. Nevertheless, there were difficulties in bridging the differences of methodology and the different pace of work of each side.
Table no.7 presents a summary of the responses of the interviewed people.

Table 7: NPO and government representatives' answers to the interview

Questions	NPO answers (n=5)	Government answers (n=3)
What were your goals in this collaboration?	1. To study/understand the objectives of the Ministry of Education for such a program for a future wider collaboration. 2. To learn how to reach the target audience of the program nationwide. 3. To add relevant professional information to the facilitators of the program.	To support the program so that it can prove the feasibility of its pilot cycles in order to possibly become a permanent program in the Ministry of Education in the future.
What were the benefits / gains from this collaboration?	1. The organization acquired significant professional knowledge for the success of the program in connection with her target audience. 2. The organization acquired knowledge of how to work in the future with a government ministry (also by ways like joint venture or tender) and how to measure the success of the program.	The government has been exposed to an innovative new method of motivating teachers and preventing them from dropping out of the educational system, without taking financial risks.
What were the difficulties / drawbacks of this collaboration?	The gap in professional methodology and the difficulty in engaging government officers.	1. A relatively fast rate of work for a government ministry. 2. Difficulty in creating professional trust for a new organization relative to the ministry office knowledge.

Source: Authors' own contribution

Conclusions

In view of the process of global privatization, we are witnessing the phenomenon of expanding collaboration between governments and other sectors especially with NPOs. These collaborations can be either formal or informal and are influenced by diverse environmental and local processes. In Israel, too, this process has become significant in the last decade and it places greater importance on the services that the government provides to its citizens. In this article we presented six formal types of NPOs which can collaborate with the government in Israel. NPOs that choose collaboration with the government as part of their growth strategy, may encounter difficulties with regulation, investment of resources, and sometimes uncertainty about the success of the process. Nevertheless they can benefit from a vast resource of knowledge, funds, easier access to target audience and achievement of goals at the national level. In addition, we presented a case study of informal contact between an NGO and the Israeli government. In the informal collaboration we found that both the NPO and the government are looking forward to gaining knowledge. Though, the gap of different work rate of each party can be a problem in maintaining this collaboration. These types of collaboration should be further investigated.

Securing Smart Cities with Monitors

Orhio Mark Creado, Monash University, Caulfield East, Victoria, Australia,
mark.creado@monash.edu

Phu Dung Le, Monash University, Caulfield East, Victoria, Australia,
phu.dung.le@monash.edu

Abstract

Advances in technology, population increase, climate change, international business and sustainability, now mandate the need for smart cities to accommodate increasing demands. However, current implementations of smart cities lack the security architecture to interlace all the essential components such as effective development, monitoring, and administration. Currently, many computer-based systems pose a high security risk due to the lack of a secure architecture which integrates these various components, opening the possibility for lapses in communication which can be exploited by cyber-attacks, and can prove to be extremely costly from a disaster recovery perspective. With no concrete definitions available to define a smart city, it is paramount to define a highly secure operating architecture for computer-based system which can be integrated within smart city implementations capable of supporting essential components such as energy distribution, health support, transport management, etc. A system built with such an essential security architecture can be more effective in preventing attacks and thereby increasing the system's availability and reliability through secure operations. This paper proposes a conceptual architecture of monitors which can be applied to modern day smart cities to secure lower level operations. This novel application of the monitor concept would allow any implementation to be more practical and realizable for many computer-based systems currently being used in smart cities.

Keywords: Smart city security, Security architecture, Computing system security

Introduction

Advanced and mega cities cannot function well without automation. More importantly, smart cities cannot be built without automation engines which are used to deal with population increase, climate change control, international business, and sustainability. For example, in a smart city, transport systems should be able to cope with increase in population and business demand, energy reliability must be considered as part of the city's security, telecommunications are critical to businesses and everyday functions of the whole city. These aspects cannot be treated as independent operations, but instead as subsets of a larger, more complex system.

However, the exact definition of a smart city is open to debate and varies based on perspective. This raises more questions when looking at how big problems should be tackled in the information and energy-hunger age for smart cities. Advanced infrastructure is no doubt the first requirement (Hall et al. 2000). Then, is the need to assess how secure and reliable such infrastructure can be. Economically and socially, there are always budget constraints and risks. Let's take an example of building a smart city where more people can live, work, and feel safe, and its government and businesses should be able to deal with its duties and benefits well. To achieve the objectives of such a smart city, many computer-based systems should be constructed in a way which allows them to work reliably, and protection against attacks on those systems should be a high priority. Such a system would mandate that security and reliability are essential to the computer-based systems managing the smart city. However, guaranteeing these aspects is purely dependent on the efficiency of the automation engines in use. Automation engines are associated with a computer system and therefore the reliability and security of automation engines

need be considered. Most approaches which exist to address this aspect treat security and reliability as independent objectives of the system, and focus explicitly on improving one and then perhaps improving the other. However, both approaches have advantages and disadvantages and they are either limited by low level management or open more security risks at the high level of operations. An alternative perspective is to aim for a deep secure core within an automation engine, and through secure operations of smaller independent subcomponents, ensure reliability of the larger system.

The rest of our paper is structured as follows. Section 2, studies some of the available literature to understand the current situation of security and reliability within computer-based systems used in smart cities. Section 3, describes our work at a high level in a more formal way to improve the security for automation engines used in smart cities and implicitly improve their reliability. Section 4, provides a theoretical evaluation of the automation engine in terms of operations and security. Lastly, section 5 concludes our work and provides directions applicable for future research.

Background

The literature review for our paper adopts a two-pronged approach, wherein the first subsection will address smart cities in general, and will aim to illustrate the concept of security and its application within these smart cities. The second subsection will address our proposed concept of monitors and their direct applicability towards achieving security within Computing Systems (CS). The last subsection will address our motivation behind this research undertaking.

Reviewing Smart Cities

Security and privacy are key essentials when considering any smart city (Martinez-Balleste et al. 2013)? However, when considering a system of the size and scale of a smart city, these issues also grow larger in size as they are fully dependent on the underlying implementation and execution behind the plan for such a city (Elmaghraby and Losavio 2014).

However, one of the key challenges which remains is the loose association and the use of the terminology “smart-city”. The lack of academic and scientific publications shows very little insight into the development of these cities as their development and implementation are open to debate, even less is evident from the perspective of securing the massive infrastructure which is essentially the key to a successful implementation (Chourabi et al. 2012).

Monitors to enhance Security

The use of monitors to ensure computer system security is by no means a novel concept. In fact, the concept of a monitor has been around longer than the notion of a personal computer and has been documented in the literature as far back in the work by Hansen (1970). The goal of the monitors, initially, were designed as mechanisms to structure the operating system (Hoare 1974), wherein monitors could be defined with administrative data and could be hierarchically nested to allow for inter-monitor calls. One of the challenges with this approach was the result of a deadlock scenario due to monitors at the same level within the hierarchy (Howard 1976). Future research by Lister and Sayer (1977), and Lister (1977) proved the viability behind this concept through structured implementations wherein realizable security was achievable within the CS.

Modern implementations of the monitor concept have been distilled into various sub implementations, some of these include the reference monitor within modern operating systems which enforce access control lists and capability based systems (United States Department of Defence 1985, Murdoch et al. 2012), trusted computing through the Trusted Platform Module (TPM) and its variants (Nibaldi 1979, Pfitzmann et al. 2001, DiRossi 2007), microkernels (Tanenbaum et al. 2006, Liedtke 1995, Klein et al.

2010), and other hybrid approaches which combine one or more of the above concepts, such as a Virtual Machine Microkernel model by Karger et al. (1991), a TPM based implementation of the Bell-LaPadula formal model by Nie et al. (2006), a TPM Microkernel model by Setapa et al. (2010), a TPM model to enforce hardware security by Hendricks and van Doorn (2004), a capability based system model by Gong (1989), and a capability based system called CHERI (Neumann and Watson 2010) operating via means of two independent kernels - a separation kernel linking the hardware with the OS kernel Capsicum (Watson et al. 2012).

The above is by no means an exhaustive list of possible implementations and applications, but these do illustrate the relevant key concepts and some example variants which are directly applicable to our proposed work.

Motivation

The main motivation behind our work stems from the lack of a concrete definition of the term 'Smart City'. To the best of our knowledge, not much available literature aims to define a security based smart city which can emphasize reliability and security as core functionality. Furthermore, with the move towards smart devices and electronic communication, our perspective is that automation within our everyday lives is no longer just a myth, but a reality. With such information being transacted on a global scale by automated machines, security and privacy will soon become requirements which cannot be compromised within any automated system. With this concept in mind, our proposed work aims to define security as a fundamental inclusion within the architecture
of a more complex system which is made up of several components that work together to fulfill a higher objective. The main contributions our paper aims to make are as follows:

- Propose a novel architecture, which has not been addressed before in the literature, which is capable of incorporating security as a key fundamental component within the architecture of a CS which can facilitate achieving security by design.

- Propose a model wherein this architecture can be directly applied to the concept of a smart city, both within existing implementations and new variants to provide a higher level of security, a higher level of reliability, and a greater reduction in cost in terms of secure operations and disaster recovery.

Proposed Theory

Smart cities are essentially large, complex, and distributed CS which mandate a single communication channel to operate as a singular unitary system. It is possible to break down such a large complex system into its various underlying components as shown in Fig 1.

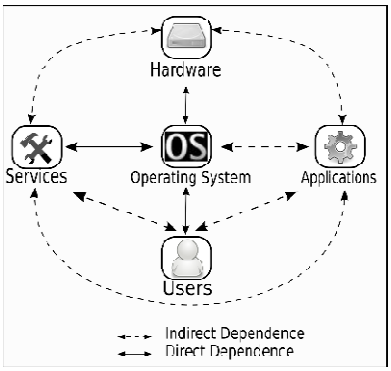

Fig 1: Smart City Components and their Interdependence

The five main components which comprise any functional complex system include the Hardware, Operating System (OS), Services, Applications, and Users. However, breaking down each individual component within this complex system can also be done into the same five components. This facilitates for a recursive breakdown of any complex system into a subset of these five key elements.

With this proposed view of our complex smart city, we can stipulate that the defined components are essential for macro level functionality, and due to their direct or indirect interdependence, vulnerabilities which affect any single subcomponent can propagate throughout the smart city. This renders a strong need to compartmentalize the subcomponents, which we address in the next subsection.

Compartmentalizing Smaller Independent Systems

Component operations can only be compartmentalized and isolated, if and only if:

- Operations can be unambiguously identified.
- Operations conform to specific rules which govern their execution within the system.

This logic allows us to further disintegrate independent components purely based on their underlying mode of operation. The commonality which we identify between the various functional components within a smart city system is that all components must execute digitally compiled code to provide the required functionality and to fulfill their stated operational objectives. With this notion, we define the following terminology:

Definition 1. *Block(s) of Code (BoC) - Is a self-contained set of low level instructions which can be interpreted and executed, one at a time, at the processor level within a CS. Within the proposed work, each instruction contained within a BoC is defined as per an instruction set architecture. Collectively as a unit, a BoC can accept inputs, produce outputs, and has an associated manifest which stores an integrity signature, indication of ownership, a set of trust levels, a set of resources which need to be accessed along with associated permissions for it to complete its execution, and a set of states which define the valid range of possible states for each instruction executed.*

The requirement and importance of this definition is paramount as no previous or current literature has proposed a segmentation of executed instructions in this manner. Some previous approaches towards partially addressing executed instructions includes the use of ordinary procedures, functions or methods which can form self-contained set of instructions provided all embedded function calls have their code unrolled. Some examples include programming languages such as Eiffel, which allows logical annotations of inputs and outputs past on pre and post conditions; and Rust, which attaches ownership labels to data belonging to procedures. While many of these aspects allow for signed operations at the

application level, these requirements for enforcing security are not applied to the BoC assigned to a component within the system.

The isolation of component operations aims to achieve security within the system as follows:

1. Reduce each component to its underlying BoC thereby alleviate any complexities based on definition, implementation, or execution.

2. Defining security within a CS in terms of independently enforceable characteristics.

3. Underpinning each of the defined characteristic with one or more underlying properties which can validate different aspects of security.

4. Defining a framework of monitors to enforce the above aspect.

Security as a set of Characteristics

The proposed work envisions security as an amalgamation of five independently satisfiable characteristics designed to be evaluated either prior or post execution of the BoC, or post the execution of an instruction within the BoC being executed. The requirement is for each underlying BoC to enforce these characteristics via means of logically sound properties. The degree of satisfaction of each property allows for a determination of the overall level of security of the CS. The included characteristics are as follows:

1. Is Invulnerable (Inv)
   The proposed work classifies errors to arise during execution because of invalid inputs or outputs which are not validated within a BoC prior to being processed. Hence, this characteristic can be achieved through strict validation of inputs and outputs to reduce the number of errors through the use of secure programming languages, secure coding practices, and rigorous testing.

2. Has Integrity (Int)
   Integrity, in this context, defines the requirement for authenticity, as well as an accountable owner, and can be achieved by having accountability standards via publicly verifiable metrics, such as a digital signature.

3. Is Verified (Ver)
   Verification can be achieved through rigorous state management to prevent unauthorized changes in the state of operation for each BoC executing within the system. While similar to the Is Invulnerable characteristic, the Is Verified characteristic mandates that any instruction can only exist in a finite set of possible states while being executed.

4. Is Trustworthy (Tw)
   The proposed work advocates that trustworthiness can be achieved by maintaining summarized operating history, and user-defined weighted variables which serve as inputs to a deterministic algorithm to obtain a calculable metric.

5. Is Secure (Sec)
   As the proposed work envisions security for any BoC as an amalgamation of the above characteristics, this can be represented as:

$$Sec(BoC) = Inv(BoC), Int(BoC), Ver(BoC), Tw(BoC)$$

Structuring Monitors to Compartmentalized Components

This section discusses the use of the structuring notion of Monitors and their underlying attributes to enforce security as a set of characteristics to achieve the compartmentalized isolation of components for secure execution of a BoC. Table 1 defines some of the notations which will be used through the rest of this section.

Table 1: List of Notations

Notations	Definition	Notations	Definition
A	Monitor Operational Access Level	A*	Monitor Functional Access Level
BoC	Block(s) of Operating Code	C	Monitor Class
E	Monitor Permissions	EM	Error Monitor
F	Monitor Functions	H	Monitor Hierarchy
IM	Integrity Monitor	Inv	Invulnerable
Int	Integrity	M	Monitor
O	Monitor Mode	Ψ	Computing System
R	Monitor Rules	S	Monitor Scope
S*	Monitor Functional Trust Level	Sec	Secure
SM	Security Monitor	T	Monitor Operational Trust Level
TM	Trustworthy Monitor	Tw	Trustworthy
Ver	Verified	VM	Verification Monitor

Defining Monitors

Definition 2. *Monitor: Is a self-contained, independently operating, programmed unit with a strictly defined operation boundary specified by a set of attributes which govern its underlying behaviour.*

Each monitor can be represented as a set of the following attributes.

Operational Attributes: Define monitor operations to enforce a specific security characteristic for each BoC, represented as follows:

$$M_{Operational} = C, O, A, T, S$$

where:

– Class (C)
Defines the level of operation and the degree of information sharing allowed. Includes:

- System-Only Class (C_O) - Allows operation over the entire system, but only monitors system level code and restricts information sharing to other C_O monitors only.
- System-Wide Class (C_W) - Allows operation over the entire system and sharing of information with other secure monitors.
- Local Class (C_L) - Allows local operations only with restricted access to system user space.

– Mode (O)
Defines the operational mode of the monitor to procure and store information to facilitate decision making. Includes:

- Analysis Mode (O_A) - An active observe-react-respond mode allowing for the use of historical data to perform run time statistical analysis and make decisions accordingly.

- Tracking Mode (O_T) - A passive observe-track-record mode only allowing the acquisition and storing of information to facilitate statistical analysis for later executions.
- Hybrid Mode (O_H) - Defined for high level system BoC only. Facilitates run time switching between O_A and O_T modes.

- User Mode (O_U) - Defined for use only in user space under any of the above modes, but only allows sharing of information to a system level monitor but not vice versa.

– Access Level (A)
Is closely related to the associated functional trust level of the BoC, and defines the level of resource access permitted. Includes:

- System Access (A_S) - Highest level of access, specifically for trusted system-only operations isolated from user intervention.

- Normal Access (A_N) - Default access level, for non-critical system or user operations.

- Restricted Access (A_R) - A restricted level of access for BoC without integrity signatures, or an untrustable trust level.

– Trust Level (T)
Associates the BoC's FT level to the monitor. Includes:

- Critical Trust (T_C)

- Verifiable Trust (T_V)

- Denied Trust (T_D)

– Scope (S)
Defines the operational visibility to other monitors or components. Includes:

- Global Scope (S_G) - Allows visibility across the entire system and facilitates information sharing with all other monitors in appropriate classes.

- Local Scope (S_L) - Allows visibility only within that component's operations. Information sharing is allowed with other monitors defined at the same level or via an S_G monitor.

Functional Attributes: Define monitor functions and behaviour while monitoring the execution of a BoC, represented as follows:

$$M_{Functional} = \{H, \{S*, A*, F, E, R\}\}$$

where:

– Hierarchy (H)
In conjunction with the monitor's class attribute, the hierarchy attribute defines the priority in the decision-making process. Includes:

- System-Only Global (H_{OG}) - Allows analysis and decision making across the entire system, and is reserved for system monitors.
- System-Wide Global (H_{WG}) - Allows analysis and decision making across the entire system, but does not allow intervening in any system level process.
- System-Wide Local (H_{WL}) - Allows analysis and decision making locally only. Monitors can only affect the operations of other H_{WL} monitors through the intervention of an H_{WG} monitor.

- Local Local (H_{LL}) - Allows analysis and decision making locally only, and cannot influence the operations of any other monitor.

– Functional Metrics
Define the available functions which outline monitor behaviour during the monitoring of a BoC. Includes:

- Trust Level (S*)
Associates the BoC's TT level to the monitor's functional attributes to facilitate the evaluation of future executions. Includes:

  * Transitional Trust (T_T)

  * Untrustable Trust (T_U)

- Access Level (A*)
Defines the access rights to assigned resources and is partially dependent on the resources required to facilitate BoC operations.

- Functions (F)
Outlines the set of instructions to be performed to enforce the underlying security characteristic while monitoring a specific BoC, and is restricted by the mode operational attribute defined for the monitor.

- Permissions (E)
Defines the rights to perform a specific action(s) within its set of functions.

- Rules (R)
Defines the specific set of conditions to be met to determine the degree of satisfaction by a BoC in enforcing the underlying security characteristic being monitored.

Monitor Operations: This section defines the basic monitor operations to be performed to enforce each security characteristic. Figure 2 illustrates the interdependence between each monitor assigned to a BoC.

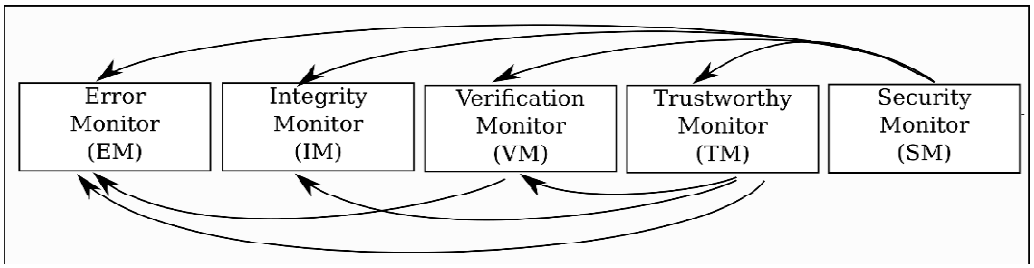

Fig 2: Monitor Interdependency

Each monitor assigned to a BoC is defined to operate independently of each other to determine the degree of satisfaction of its assigned security characteristic, via the fulfillment of each of the underlying properties. However, each monitor can accept as input the output of another monitor to facilitate part of that process. The SM acts as the fulcrum of execution, instantiates all other monitors, and ascertains the security level of the BoC as a combined result of all the other monitors. The SM serves two primary functions within the proposed framework:

1. Ensures each of its associated monitors are enforcing the required underlying security characteristic for the monitored BoC.

2. Negotiates with the SM belonging to other BoC to ascertain its security level prior to allowing communication between them during execution.

The following lists the basic operations for each defined monitor.

Error Monitor (EM): The EM is responsible for monitoring an executing BoC to ensure that no errors are encountered, specifically for handling all inputs and outputs. This can be achieved based on the definition of a BoC, wherein the previous, current, and the next probable instruction can be known. As a given BoC is a complete set of instructions to enable a specific functionality, an error state can be identified when the execution of the BoC does not execute the identified next instruction but defaults to another instruction within the same BoC. Thereby indicating a handled error during execution. The output status of the EM can be accessed by the TM to determine the level of trust to be associated with the executing BoC for future executions.

Integrity Monitor (IM): The IM is responsible for two functions – validating and verifying the authenticity and ownership signature for a BoC, and associating an authenticity and ownership signature for any BoC generated by the system as an output of an execution. The choice of enforcement mechanism to ensure integrity, at this stage, is independent of the monitor operations. But the basic requirement entails the provision of a valid metric, such as a signature, to identify ownership and authenticity, which can then be validated to ensure correct ownership.

Verification Monitor (VM): The VM is responsible for monitoring the instructions being executed within a BoC to ensure no unauthorized changes in the state of operation are encountered. While similar in operation to the EM, the V M only triggers when the next instruction being executed resulting from an error is outside of the set of instructions included within the BoC being executed, indicating that the error state resulted from an unhandled exception.

Trustworthy Monitor (TM): The TM is responsible for two functions – validating existing trust levels, and calculating new trust levels for generated outputs or for the BoC post execution. The TM can directly obtain the output states of the EM, the IM, and the VM to facilitate its operations within the system. The choice of the trust algorithm and the underlying metric weighting is out of scope of this paper at this time.

Security Monitor (SM): The SM is responsible for facilitating inter-monitor communication between monitors assigned to various component BoC within the system, and has three independent phases of operation, which involve:

1. Instance creation for each monitor and associating them with the underlying BoC prior to execution. Instantiates the monitors for each security characteristic and determines the enforcement attributes for each.

2. Monitors the enforcement of each security characteristic during execution. Requests inputs from the other monitors for each of the other security characteristics to ascertain the degree of

satisfaction, by the BoC being executed, for each of the underlying security properties for each characteristic.

3. Updating errors, trust levels, and other metrics post execution to facilitate secure future operations. Post execution, the trust levels associated with the executed BoC need to be updated to assist in determining the probability of successful future executions.

Monitor Component Integration: To facilitate for complex system designs comprising of diversified components, the architecture proposes a monitor engine which serves as the first point of contact for all components that are required to execute code within the system. The monitor engine facilitates for the creation and assignment of monitors to each component. This allows for distributed control and process execution, reinforcing compartmentalized isolation, ensuring that any compromise within one specific component does not indirectly affect the operation of another. Fig. 3 illustrates a high-level representation of the monitor engine in respect to the other components within the CS.

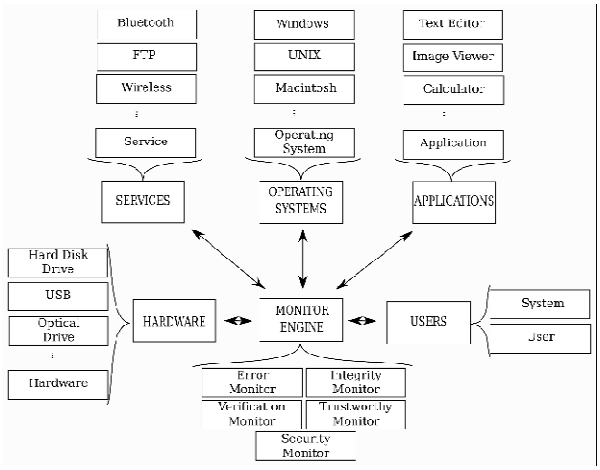

Fig 3: Monitor Engine and Component Integration

Monitor Engine Operations: The monitor engine views every component independently, and performs a list of operational procedures for each request made by a component needing to execute a BoC on the system. The operations of a CS are segmented into three distinct phases - start-up, running, and shutdown. While the basic operation procedures for the monitor engine are similar for all component levels, the sequence is reversed for the shutdown phase. These operational procedures include:

1. Validate the calling component for the existence of a programmable interface which would allow for the possibility to execute instructions.

2. Validate the integrity of the calling component.

3. Create a set of independent monitors with defined attributes to enforce each security characteristic.

4. Assign the defined monitors to be responsible for all communication to and from that calling component only.

5. Establish any monitor-component communication guidelines to facilitate both inter component and system-wide interactions.

The proposed monitor engine concept aims to alleviate the single point of failure within a CS. As traditionally the OS is responsible for functionality, security, communication, etc., secure verified code within the OS is not practically realizable. The monitor engine is defined as the primary facilitator within the CS, and as its operations only involve facilitating the interaction between components, the possibility for defining the monitor engine as a secure verified code operating within a larger system to facilitate security by design can be more practically realizable.

Achieve System Security: This section illustrates the inner workings of compartmentally isolated instruction execution by specifically addressing each component layer and the associated monitor attributes to facilitate the basic operational procedures outlined above, as follows:

- Secure Hardware - Fig. 4 illustrates the monitor attributes to enforce the basic operational procedures between the hardware component layer and the monitor engine.

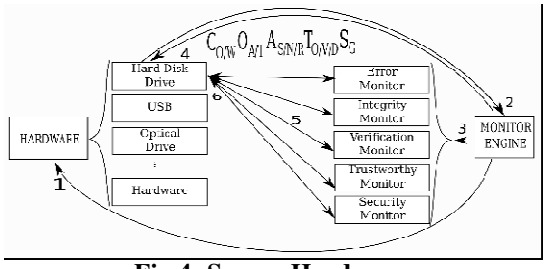

Fig 4: Secure Hardware

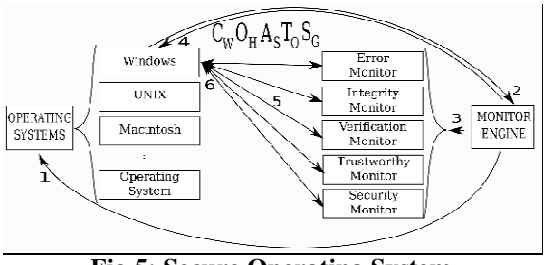

Fig 5: Secure Operating System

- Secure Operating System - Fig. 5 illustrates the monitor attributes to enforce the basic operational procedures between the OS component layer and the monitor engine.

- Secure Services - Fig. 6 illustrates the monitor attributes to enforce the basic operational procedures between the services component layer and the monitor engine.

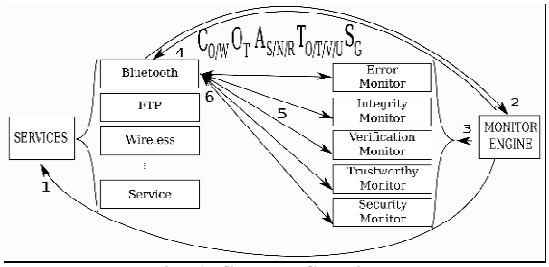

Fig 6: Secure Services

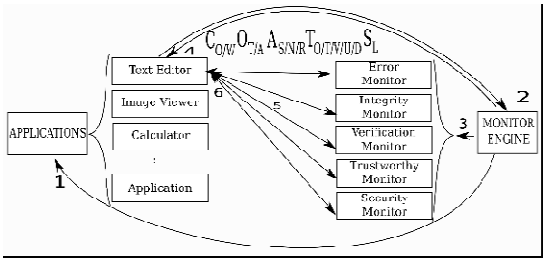

Fig 7: Secure Applications

- Secure Applications - Fig. 7 illustrates the monitor attributes to enforce the basic operational procedures between the applications component layer and the monitor engine.

- Secure Users - Fig. 8 illustrates the monitor attributes to enforce the basic operational procedures between the users' component layer and the monitor engine. To alleviate ambiguity in securing users, two broad classes of users have been defined: the system user and the regular user, each operating with its own set of independent monitors. Furthermore, as users initiate, run, and terminate functionality, only the specific subset of Integrity Monitor, Trustworthy Monitor, and Security Monitor are applicable to the users' component layer.

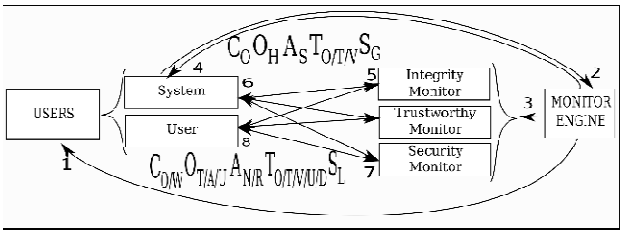

Fig 8: Secure Users

Structuring Using Monitors: Fig. 9 illustrates the allocation and assignment of monitors once instantiated to each BoC. The theory behind prior implementations suffered from nested hierarchical communication between monitors. The proposed architecture addresses this problem via the defined attributes assigned to each monitor. As the enforcement of the defined security characteristics by each monitor is independent of any hierarchy, the monitor operations, to ensure compliance and satisfaction for each characteristic, are thereby independent of any other operation. A scalable hierarchy between monitors based on operational attributes further streamlines monitor operations within the system to avoid deadlocks, which were another issue encountered in past implementations. Fig. 10 illustrates the proposed hierarchy within the architecture.

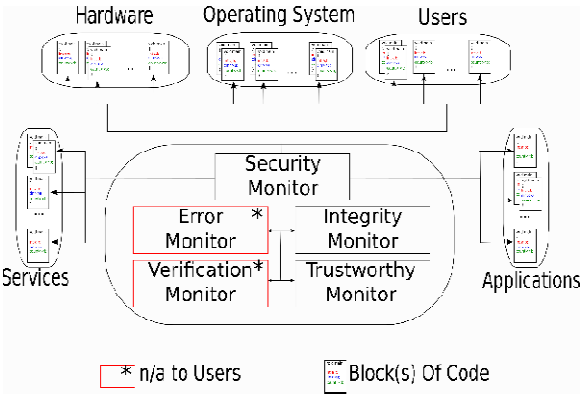

Fig 9: Monitor Component Allocation

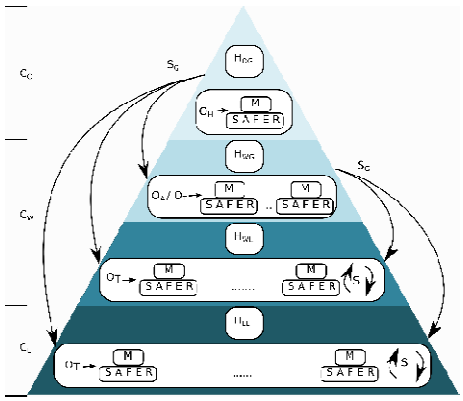

Fig 10: Monitor Hierarchy

Achieving Overall System Security

Definition 3. *Security: Is the amalgamation of a set of independent characteristics - Is Invulnerable, Has Integrity, Is Verified, and Is Trustworthy, such that it can be associated with the BoC's of each individual component within the CS.*

We can formally represent the overall level of security for any CS Ψ, as the associated level of security for each of its m BoC being executed independently, as follows:

$$Sec\ (\Psi)\ =\ \{Sec\ (BoC_1)\ ,Sec\ (BoC_2)\ ,\ldots,Sec\ (BoC_m)\}$$

Applying the proposed framework of monitors to enforce security, the formal definition of security for any specific BoC_x can be defined as follows:

$$Sec\ (BoC_x)\ =\ SM\ (BoC_x)\ =\ \{EM\ (BoC_x)\ \cup\ IM\ (BoC_x)\ \cup\ V\ M\ (BoC_x)\ \cup\ T\ M\ (BoC_x)\}$$

Applying the proposed definition of security, the overall level of security for the entire CS Ψ executing m BoC can be defined as the summation of the degree of satisfaction for each of the defined security characteristics by each BoC being executed within the CS, as follows:

$$Sec\ (\Psi) = \bigcup_{i=0}^{m} \{SM(BoC_i)\}$$

$$Sec\ (\Psi) = \bigcup_{i=0}^{m} \{EM(BoC_i) \cup IM(BoC_i) \cup VM(BoC_i) \cup TM(BoC_i)\}$$

Evaluation and Discussion

The adopted evaluation model adopts a theoretical bias in terms of proposing a formal example implementation of the proposed framework followed by an analysis of the architecture in terms of the level of security attained vs. the trade-off in performance.

An Illustrative Example

The proposed architecture achieves a higher degree of overall system security through the following:

- Compartmentalized isolation of instruction execution for all components.
- Structured monitoring of each BoC independent of any other.
- Enforcing independent criteria capable of deterministically ascertaining the degree of security for any executing BoC.

The defined illustrative example makes the following assumptions:

- A CS which executes the following simplistic BoC:
  - BoC 1 - An application executed in user space without system privileges.
  - BoC 2 - A service dependent application accessible across the system requiring some system level access.
  - BoC 3 - A service accessible from system start-up to system shutdown requiring system privileges.
- The underlying functional attributes are assumed to be dependent on the intended purpose of each BoC, and have not been defined at this stage as they are implementation specific aspects which need to be defined as high-level code which then can be represented as a BoC.

For each calling BoC, the monitor engine assigns a set of monitors with defined attributes as follows:

- BoC 1 = $\{C_L, O_T, A_N, T_V, S_L\}$ $\{H_{LL}, (S^*, A^*, F, E, R)\}$
  Operates with a local class, a tracking mode of operation, normal access, verifiable trust, and a local scope.
- BoC 2 = $\{C_W, O_T, A_N, T_V, S_L\}$ $\{H_{WL}, (S^*, A^*, F, E, R)\}$
  Operates with a system-wide class, a tracking mode of operation, normal access, verifiable trust, and a local scope.

– BoC 3 = {C_W, O_A, A_S, T_C, S_G} {H_{WG}, (S*, A*, F, E, R)}
Operates with a system-wide class, an analysis mode of operation, system access, critical trust, and a global scope.

– System = {C_O, O_H, A_S, T_C, S_G} {H_{OG}, (S*, A*, F, E, R)}
Operates with a system-only class, a hybrid mode of operation, system access, critical trust, and a global scope.

Fig. 11 illustrates a relevant subset of the main operations during the execution of each of the assumed BoC and depicts the communication flow, and enforcement of security via the framework of monitors.

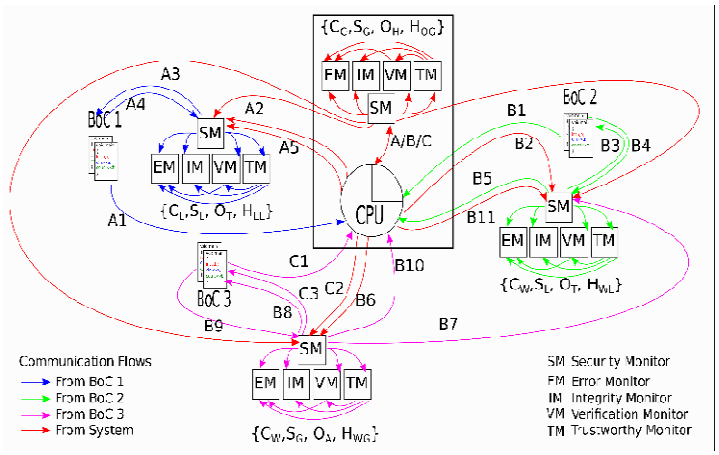

Fig. 11: Illustrative BoC Execution and Monitor Communication

The interactions of BoC 1 with the rest of the CS are isolated and are only possible via the system monitors.

BoC 2 is dependent on the service provided by BoC 3, and its local scope requires the system monitors to relay information between its SM and the SM of BoC 3 to obtain the provision of the service.

BoC 3, operating with a global scope, can communicate via its SM to the SM of any other monitor which operates on the same or lower hierarchical level within the system.

Lastly, the system's monitors have the highest defined attributes, allowing the system to relay between various SM of different BoC, collect execution information from other monitors, perform run time tracking and analysis of executions, and intervene into hierarchical operations to resolve conflicts or ensure enforcement of security characteristics by independent monitors.

The defined approach facilitates for the independent execution, monitoring, reporting, and enforcement of security characteristics for each BoC. The SM is responsible for ensuring communication and data flow only to and from other secure monitors, with the system's monitors responsible for the overall security of the system. Thereby preventing any insecure component from communicating with a secure component or inadvertently propagating errors or vulnerabilities to the rest of the system.

Defining a Probability Space

System security is always a direct result of the presence of a vulnerability which can then be exploited resulting in system compromise. Let us assume a probability space $\Omega \rightarrow \{0, 1\}$ for all $f \in F$ where f is an event with a probability outcome of some al$0 \leq a \leq 1$.

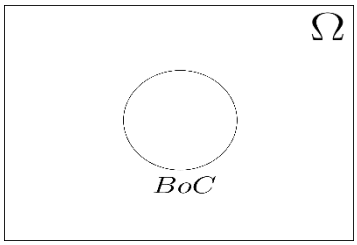

Fig 12: Default BoC

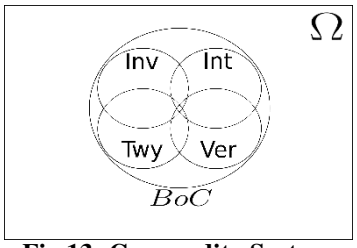

Fig 13: Commodity System

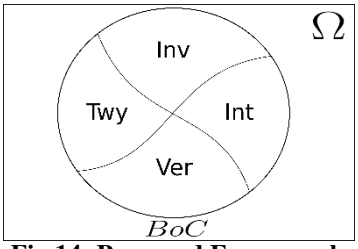

Fig 14: Proposed Framework BoC

As a BoC is defined as the smallest foundational unit of operation, any enforcement of each of the defined security characteristics must be enforced through the inclusion of operating code. A basic functional BoC, not enforcing any security enforcing code. would require a default number of instructions to provide this basic functionality. We can represent this default BoC as a set of n instructions as shown in Fig. 12.

If we consider a regular commodity system which enforces security through instructions specified in code, this is often done without any explicit segmentation or segregation of code. Some of the defined security characteristics might also be applicable to a commodity system although their enforcement might be left as optional add-ons at the user's discretion. Considering this type of code definition, we can represent this commodity BoC as a set of n + X instructions where X represents the total number of additional instructions to enforce security which is directly dependent on the number of security characteristics accounted for, as shown in Fig. 13

The proposed framework however, explicitly mandates the requirement for additional code within a BoC to ensure enforcement of the security characteristics, additionally the definition and operation of monitors allows the system to enforce overall system security as a culmination of the enforced characteristics. This allows us to represent any BoC to include the default instructions but also account for additional instructions which can enforce security. This renders the defined characteristics as a partition set within any BoC, thereby allowing each partition to be disjoint of the others. Considering this type of code definition, we can represent this a BoC within the proposed framework as a set of n + Y instructions where Y represents the total number of additional instructions to enforce each of the security characteristics within a BoC, as shown in Fig. 14.

Security Evaluation

Using the defined probability space, we apply a probabilistic model to compare the proposed framework vs. a regular commodity system in terms of the security offered by each system. We summarize our analysis in Table 2.

Based on this probabilistic calculation, considering all factors equal for simplicity, we can define the most ideal representation of the aforementioned probabilities for both systems considered as shown in Fig. 15. We note a strong indicative difference between the p(system security) for the considered systems, with the exception of all criteria being equal to zero implying no security or all criteria being equal to one

implying perfect security, neither of which are practically realizable. Furthermore, the indicative results obtained have considered commodity systems to equally enforce each of the defined security characteristics which isn't always the case thereby resulting with the associated probability being far lower than the ideal in most cases of commodity system operations.

Table 2: Security Evaluation

p(f)	Commodity System	Proposed Framework
For any CS executing m BoC, applying the five security characteristics in conjunction with the defined probability space and the rules for probability distribution for each BoC we can establish the overall p (system security) as the culmination of the enforcement of each of the defined security characteristics as follows:		
$p\ (Sec\ (\Psi\ )) =$	$\sum_{i=0}^{m} \begin{Bmatrix} Inv(V_i) \cap Int(V_i) \cap \\ Ver(V_i) \cap Twy(V_i) \cap \\ Sec(V_i) \end{Bmatrix} \mid i \in N$	$\sum_{i=0}^{m} \begin{Bmatrix} Inv(V_i) \cup Int(V_i) \cup \\ Ver(V_i) \cup Twy(V_i) \cup \\ Sec(V_i) \end{Bmatrix} \mid i \in N$
$p\ (Sec\ (\Psi\ )) =$	$\sum_{i=0}^{m} \begin{Bmatrix} p(Inv(V_i)) \cap p(Int(V_i)) \cap \\ p(Ver(V_i)) \cap p(Twy(V_i)) \cap \\ p(Sec(V_i)) \end{Bmatrix} \mid i \in N$	$\sum_{i=0}^{m} \begin{Bmatrix} p(Inv(V_i)) \cup p(Int(V_i)) \cup \\ p(Ver(V_i)) \cup p(Twy(V_i)) \cup \\ p(Sec(V_i)) \end{Bmatrix} \mid i \in N$
$p\ (Sec\ (\Psi\ )) =$	$\sum_{i=0}^{m} \{\alpha_i * \beta_i * \gamma_i * \delta_i * \mu_i\} \mid i \in N$	$\sum_{i=0}^{m} \{(\alpha_i + \beta_i + \gamma_i + \delta_i + \mu_i) / 5\} \mid i \in N$

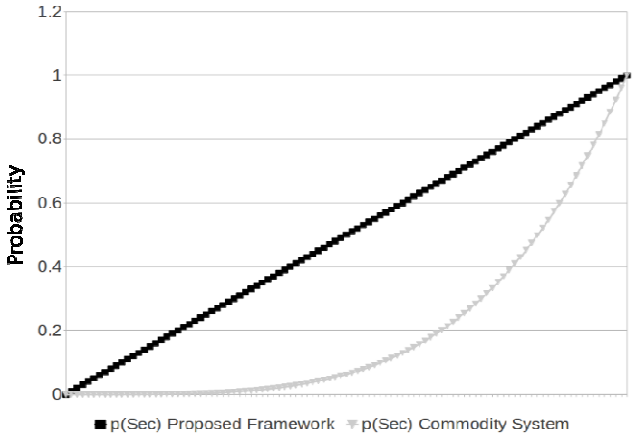

Fig 15: Comparative Analysis of p(Security)

Performance Evaluation

Performance evaluation within modern day commodity systems can often be measured in total number of instructions executed. Considering the proposed monitors to structure CS operations, we compare the proposed framework vs. a regular commodity system in terms of the total instructions executed. The assumption we make for our analysis is that all commodity systems incorporate each of the security characteristics to some degree. We summarize our analysis in Table 3.

Table 3: Performance Evaluation

Security Characteristic	Commodity System	Proposed Framework
The default Number of Instructions (O) for any functional BoC can be defined as:		
$O\ (default)$	$n \mid n \in N$	$n \mid n \in N$
The total number of instructions to enforce the Inv characteristic can be defined as:		
$O\ (Inv)$	$v \mid v \in N$	$a \mid a \in N, a > v$
The total number of instructions to enforce the Int characteristic can be defined as:		
$O\ (Int)$	$w \mid w \in N$	$b \mid b \in N, b > w$
The total number of instructions to enforce the Ver characteristic can be defined as:		
$O\ (Ver)$	$x \mid x \in N$	$c \mid c \in N, c > x$
The total number of instructions to enforce the Twy characteristic can be defined as:		
$O\ (Twy)$	$y \mid y \in N$	$d \mid d \in N, d > y$
The total number of instructions to enforce the Sec characteristic can be defined as:		
$O\ (Sec)$	$z \mid z \in N$	$e \mid e \in N, e > z$
The total number of instructions to enforce all Monitors (Mon) can be defined as:		
$O\ (Mon)$	0	$f \mid f \in N$
The total number of operations for securing the CS executing m BoC can be represented as follows:		
$O\ (\Psi) =$	$\sum_{i=0}^{m} \left\{ \begin{matrix} O(default) + O(Inv_i) + \\ O(Int_i) + O(Ver_i) + \\ O(Twy_i) + O(Sec_i) \end{matrix} \right\} \mid i \in N$	$\sum_{i=0}^{m} \left\{ \begin{matrix} O(default) + O(Inv_i) + \\ O(Int_i) + O(Ver_i) + \\ O(Twy_i) + O(Sec_i) + \\ O(Mon_i) \end{matrix} \right\} \mid i \in N$
$O\ (\Psi) =$	$\sum_{i=0}^{m} \{n_i + v_i + w_i + x_i + y_i + z_i\} \mid i \in N$	$\sum_{i=0}^{m} \{n_i + a_i + b_i + c_i + d_i + e_i + f_i\} \mid i \in N$

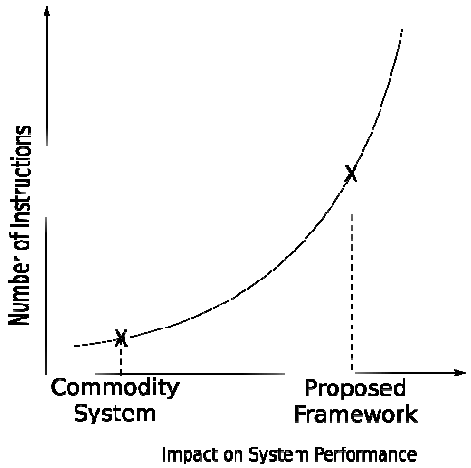

Fig. 16: Comparative Analysis of Operational Overhead

Based on this probabilistic calculation, considering all factors equal for simplicity, we can define a hypothetical representation of the aforementioned performance in terms of operational overhead for both systems considered as shown in Fig. 16. We note that there exists a strong potential for operational overhead with the proposed framework. However, at this stage in the conceptual development, these results are only indicative as implementation level empirical data doesn't exist. Furthermore, the

assumption made in the depiction of the graph is that the instruction execution process outlined in Fig. 16 is carried out irrespective of the BoC being executed. In real world situations, this is far from ideal. Keeping this in mind, we proceed to discuss some of the advantages
and shortcomings of the proposed framework in the next section.

Summary

We address some potential concerns which may be construed as gaps by an avid reader include:

Theory: Envisioning a practically relatable model is always a challenge in theoretical computer science. Presenting a conceptual framework, we have stepped away from any suggested implementations with the aim of outlining an area wherein CS security can be enhanced through architectural enhancements.

Evaluation: The presented evaluation, although not to scale graphically, has aimed at presenting a benchmark based on low level operations within a system. The probabilistic approach models extremes in a plausible operating scenario. External factors are exempted from consideration at this time but will always remain a factor for operational overhead.

Challenges: The proposed framework relies on standardization of characteristic definitions to enforce security, this will always be an on-going challenge as universal applicability is not always possible. With this in mind, the proposed framework considers characteristics which allows for generic applicability of CS operations at lower levels thereby facilitating seamless integration of operating code irrespective of complexity, and/or desired functionality.

Limitations: The defined security characteristics may be subject to biased scrutiny, but the selection of which ensure minor relatability to modern day systems to attain a realizable model. By adhering to existing accepted standards, the proposed work defines a framework which structures these ad-hoc metrics so as to be able to deterministically evaluate subjective criteria within CS.

Conclusion

Current computer-based systems are either designed to achieve functionality and performance goals or have low level of security. Their security is an add-on or dependent on the OS, database, services and libraries in use. This leads to higher potential of much lower reliability and higher possible disaster when under attack. Since smart cities have many automation engines which determine the liveability and efficiency of many people and organisations, a new approach to support security and reliability of such automation engines is highly desired. In this paper we have proposed a new approach to allow the construction of computer-based systems with higher security and reliability. This is now a crucial inclusion when constructing computer-based systems for smart cities for our modern-day world.

The security is associated with the concept of monitors which allow the flexibility and system-specific structure. This makes the proposed work more adaptable to many important systems. From the design concepts with flexibility, our approach not only can benefit general purposed computer-based systems, but also specific systems, at least at the level of design, and at some higher levels of specific implementations.

Our future directions and goals for our research includes possible attempts to simulate our work to demonstrate some real applications of our theory to demonstrate its usefulness when applied in a computer-based system to support either automation engines or smart city control systems.

Voluntary Simplicity in Consumer Behaviour – Necessity, Challenge or Utopia

Abstract

Our society is burdened by an unbearable weight of consumerism, which promises to overcome all personal and social problems by boosting consumption. Reasonable needs, which are associated with so called voluntarily simple lifestyle, have been more and more frequently discussed in relation to the increasing material needs. The article deals with the issue of (un)sustainable consumption and so called voluntary simplicity as a way of life. Voluntary simplicity is a phenomenon that triggers contradictory reactions. Its main objectives include the least possible waste of energy, efforts to live more environmentally friendly, and to avoid consumerism. As long as a person decides to live in more simplicity, they have to make some important steps in their daily consumer behaviour, which are dealt with by our article.

Keywords: Consumer behavior. Consumption. Unsustainable consumption. Sustainable consumption. Reasonable needs. Voluntary simplicity.

Introduction

Modern society is more and more confronted with systematic, deliberate and increasingly sophisticated ways of environmental degradation, on which human existence is almost entirely dependent. This degradation is partly due to environmentally unfriendly production technologies, supported by the developing profit-oriented lifestyle, purchasing and accumulation of things, which degrade environment to goods that can be carelessly used to satisfy supposedly ever-growing human needs.

This article deals with the issue of life in voluntary simplicity, as our attention is focused on an alternative to the lifestyle prevailing in society, i.e. the style of majority. Such a way of life is lived with an intention and on the basis of a voluntary choice, particularly a value-based choice, and enables a sufficiently dignified, joyful and satisfying life in the ecological distress.

Significance of Reasonable Needs from the Perspective of Modern Marketing Revaluation and Voluntary Simplicity

Everybody has their own needs, whether material and/or psychological, and products (goods and services) and their consumption are intended to satisfy such individual needs.

The problem of modern society, especially the developed or rapidly developing economies, is a constant and unstoppable growth in their needs. They do not only include the needs in the strict sense, i.e. those introduced by A. M. Maslow (2000, p. 158) but also the needs generated by a whole series of pressures. From social through historical to economic ones, most frequently created and supported by the marketing communication tools (e.g. advertising). Modern economic systems are built on the concept of people having to buy and spend as much as possible, otherwise the whole system ends up in a crisis. People buy things that they actually do not need but that bring them at least a short-term happiness, that can make them relaxed or think about pleasant things. We believe those are false needs, sometimes called pseudo needs that are unnatural, artificial, the needs of markets or producers, not leading to natural human growth and development.

However, we have to point to the fact that more and more people believe that unlimited satisfaction of needs does not lead to lasting happiness not only because most of thus satisfied needs only result in momentary delight, but also because the advancement, whose benefits people used to rely on so much, rather leads to ecological threats, and economic growth is further dividing the world into the rich and the extremely poor. (Fromm, 1992).

So called *reasonable needs* have been more and more frequently discussed in relation to the increased material needs. Strict definition of reasonable needs and reasonable consumption is difficult, even impossible. The perception of what people actually need and what their reasonable needs are is not only highly subjective but is significantly affected by a great number of different aspects. E. Fromm (1992) is aware of the fact that people cannot be directed to buy or not to buy something, but he is persuaded that the state could define standards of what is healthy and what is so called pathological consumption. In spite of the fact that it is very problematic to identify where the reasonable needs end and the artificial needs start, we assume that a few general attributes, which can help define reasonable needs, can be recognised. Such needs are most frequently associated with so called voluntarily simple / voluntarily moderate, or ecologically friendly, environmentally friendly, sustainable, or simple lifestyle. Even though some authors, such as Librová, H. (2003), Shrader-Frechett K. (1992), insist on the exact differentiation and definition of individual terms, common major characteristics can be identified in the views of all of them. They especially include a value-based orientation on the rejection of consumerism and intended or mediated environmental friendliness. The emphasis on spiritual values or ethical principles are also included. All these lifestyles, with all their greater or smaller differences, can be referred to by a very popular adjective nowadays - alternative.

Foreign literature has adopted term *voluntary simplicity* (Alexander – Ussher, 2012). Simplicity is based on the awareness of the fact that only a little is necessary to live a happy life.

A question arises in this relation: Why do some people living in the richest countries in the world live in moderation and simplicity compared to others despite the fact that with their income, they could afford to live luxurious lives full of shopping and spending? Several reasons can be identified. On the one hand, they can include purely religious, spiritual or ecological reasons, or their combinations.

On the other hand, paradoxically, E. Fromm (1992) understands the efforts to give up pleasures and to live austere lives as resulting from a great desire to own property and lead a consumer lifestyle. Such people suppress their desires however the issues of property are embedded in their mind.

Consumerism In Comparison To Voluntary Simplicity Activities

Consumerism is a lifestyle that some sociologists view as problematic from the perspective of their own environment as well as from the perspective of human culture. It is a way of life in which permanent

increase of material consumption is especially important. If people have more material possessions they will be better, their lives will be more beautiful, and identical to the life presented by the "mass" marketing communication tools (e.g. advertising of consumer goods). The world is becoming a reservoir of resources, and people are becoming so called *one-dimensional consumers*.

An implicit triple assumption appears in the background: the goal of life is to have more and more, and the only role of the state is to enable it, as consumption increase overcomes all the problems people cannot solve themselves. Everything else has to wait. The essential need is to produce - more and faster. (Kohák, 2010). Dynamism is significant to consumerism nowadays.

Consumerism is not a phenomenon observable for only last decades. The first indications of such tendencies are sometimes associated with a renowned trend predictor, founder of the techniques and tools of communication between institutions and companies and the public E. L. Bernays (the 1920s and 1930s), who shifted the paradigm in the approaches to shopping from the customer´s position "*I need to buy*" to "*I want to buy*".

However, the major wave of consumerism appeared not sooner than in the 1950s, after the Second World War, especially in the United States of America (war-torn Europe was less affected), and was accompanied by the post-war development of commercial transport and the idea to import resources and goods from distant areas as an alternative to local production. A decade later, in response, especially young generation rejected consumerism, and the schools of thought emerging in the turbulent 1960s significantly influenced also others.

The beginning of the 1980s, affected by neo-liberal capitalism (represented by M. Thatcher and R. Reagan) is considered to be the second wave, followed by globalisation since the second half of the 1990s. To a certain extent, this phenomenon has facilitated consumption habits of the people supporting this way of life in the global perspective, and has "standardised" the level of commercial services, especially in the first-world countries.

The approach best describing consumerism is that it would love to absorb the entire world. E. Fromm compares the consumer to an "infant forever eager to get a bottle with milk". Earlier, poets and philosophers were dealing with the question of whether a man works in order to live, or lives in order to work. The question of whether a man has to consume in order to live, or whether they live in order to be able to consume is dealt with nowadays. However, that means that we are still able and feel the need to differentiate between life and consumption.

A "counterweight" to consumerism is a lifestyle that can be named voluntary simplicity. Some authors prefer the term thoughtful choice for such lifestyle. To simplify it, we could say that a voluntarily simple person does not spontaneously buy every "trifle" that others have, or that a television commercial "tells" them to buy. Voluntarily simple people endeavour to buy only necessities and are interested in the origin of goods (environmental impacts in their manufacturing processes, during use, after end-of-life, during their transport and logistics) and/or how such goods destroy human dignity of the employees making them. From the point of view of the consumer typology, it can be said that the representative of voluntary simplicity is an eco-friendly consumer or alternatively a responsible consumer.

Voluntary simplicity is not only manifested in buying but also in travelling, housing, holiday, or choice of career. People living this lifestyle hold spiritual or intellectual values rather than consumption values. Majority of them does not believe that they lack something due to their choice of life; the exact opposite is claimed. (Librová, 2003).

Steps in transition to consumption exhibiting characteristics of voluntary simplicity

As long as a person decides to live in more simplicity, they have to make some important steps in their daily consumer behaviour.

The right approach and attitude to life are especially important. When people understand that real wealth is not in owning the latest products, they realise that they are much richer at that moment. As Alexander and Ussher opine, humility and efforts to only impress ourselves are also of importance. Liberating the mind from the modern consumer culture requires much effort. (Alexander – Ussher, 2012).

The approach to finance is of equal importance. People show their preferences through money. What they spend (their) money on reflects their choice of what will exist in the world. The purchase of a product sends a message to the market, acknowledges its existence, ecological impacts, manufacturing processes, etc. Money has power, which is accompanied by responsibility. If people invest their money elsewhere this world can be changed. It is essential to be thoughtful and consider where to invest our "vote", to support businesses deserving our support, e.g. fair-trade businesses. Fair-trade is a business ensuring workers from developing countries a fair remuneration for their work. In the fair-trade system, farmers (growers) and craftsmen receive the feed-in-tariffs corresponding to production costs and ensuring them dignified lives. As Ambler states, fair-trade also offers consumers an opportunity to simply and efficiently support a sustainable economic model, to vote for a different method of trade and production, and last but not least, to acquire high quality products for corresponding prices. Organisations that actively commit to support producers, increase the awareness of this concept, and to arrange campaigns aimed at changing the rules and practices of conventional international trade are an inseparable part of fair-trade. (Ambler, 2003).

Another important step is to consider how much time one will spend working. The more one consumes, the more time they have to spend working in order to be able to afford the consuming lifestyle. Once they find a way how to considerably reduce the overall expenses of their households, they realise that they do not have to work overtime. It results in significantly more free time for other interests and their families. It is thus a method of reducing material wealth and increasing the quality of life. Home offices or teleworking can also save the commuting expenses and costs of clothing. According to Treľová, it is an effective method of working, which is more and more favoured by both employees and employers. (Treľová, 2016).

Food is among the key human needs which one can consume with more modesty. Nowadays, majority of food products originates in corporations, which prefer their profit to nutritional values. Food products can be produced on one´s own however it is not possible for everybody. If it is impossible to produce own food products, or if such production is too small, the necessary food products should be bought from local farmers, thus supporting local production and avoiding supermarkets and hypermarkets as much as possible. Certain food categories can be reduced, and seasonal foods and pick-your-own farms should be preferred.

Clothing is almost exclusively a matter of fashion nowadays, as well as it determines a social status of the person wearing it. Wearing simple, modest and functional clothing can be an external manifestation of simplicity and an expression of disapproval of the consumer culture. (Pajtinková Bartáková – Gubíniová, 2012). It is not necessary to spend much financial resources on clothing, and many people living in voluntary simplicity are able to mend their clothes, or very often sew them themselves. Great amounts of clothes are delivered to second-hands every day.

Life in voluntary simplicity first of all includes a revaluation of the mode of transport. It is essential to find an escape from the contemporary car culture. The greatest challenge of car transport is short distances, while most of such places do not require a car transfer. It is suitable in such cases to walk or use a bicycle as much as possible. Bicycles can be equipped with further improving accessories such as seats for children, offering their transport to school, and the "adventure" as a bonus. Other benefits include the fact that we do something for our health at the same time. An alternative in the case of unfavourable weather is public transport. Car sharing is also among very effective methods.

Reducing the costs of housing and energy is an important step in the transition to voluntary simplicity. Housing typically represents the highest cost in our lives, which is why where and how we will live needs to be thoroughly considered. Low-cost housing helps save even years of hard work. Housing in passive houses is very effective, as they are designed based on the principle of utilising passive heat gains in the building. Living close to the place of work contributes to establishing the life in voluntary simplicity. The latest researches ((Pajtinková Bartáková – Gubíniová, 2012) show that commuting to work is among the most unpleasant aspects of modern life and everything should be done to prevent it.

Energy consumption needs to be radically reduced, as carbon dioxide concentrations are continuously increasing. Fossil fuel combustion is the fundamental process causing this increase. (Nátr, 2015). Alternative energy resources, such as solar panels for water heating, are becoming greatly supported. Even small steps are therefore important in this aspect, such as the use of energy-efficient appliances.

One of the most worrying aspects of consumerism is excessive waste production. Voluntary simplicity includes essential steps (Beniak - Križan - Matúš - Svátek, 2015) that help prevent waste production. For instance, drinking tap water is preferred to buying water in plastic bottles (of course, if the situation allows it). Do not buy new shoes before the "old ones" stop fulfilling their function. Prevent unnecessary flights, use textile shopping bags, etc.

Living in simplicity does not mean that we necessarily have to give up all these things, but it means that we should reduce them as much as possible, and buy thoughtfully. Such life requires a certain level of creativity, so it is rather an aspiration that should be further developed.

Since there is an interest in the sustainability and the ethical dimensions of products and services already with customers themselves, retailers should take several activities. As an integral part of their promotion and sales, they should increasingly focus on offering healthier food, emphasizing the environmental and social aspects of cooperating with suppliers, producing less waste, more recycling, promoting employee volunteering.

Conclusion

Consumerism defined as buying of products and services or material consumption exceeding the fundamental needs is as old as the first civilisations. After consumerism entered the awareness of people, a different way of life in the form of voluntary simplicity was established.

Voluntary simplicity is an issue that triggers contradictory reactions among both the public and academics. Its main objectives include the least possible waste of energy, efforts to live more environmentally friendly, and to avoid consumerism. It is a way leading not back into the past and behavioural patterns typical of the past; on the contrary, it is a way leading ahead. Such life requires a certain level of creativity, so it is rather an aspiration that should be further developed.

In conclusion, it is necessary to state that people who decide to take this demanding way to fulfil their dreams frequently experience misunderstanding or even contempt, even though the situation requires exactly opposite reactions.

Current Problems of Unemployment in Slovakia

Peter Bajzík, Comenius University in Bratislava, Bratislava, Slovakia,
peter.bajzik@fm.uniba.sk

Abstract

The article focuses on the current problems related to the unemployment in the Slovak Republic. Based on a blended descriptive-analytical approach to data on unemployment, the article critically reflects the employment policy of both the European Union and Slovakia and points at certain problems that arose together with fundamental changes in several sectors of the economy, namely the mismatch between peoples' skills and vacancies offered and pertaining regional disparities in Slovakia. In its first part, the article deals with brief delineation of the phenomenon of unemployment and its types. Consecutively, the next section focuses on the economic and social consequences of unemployment in Slovakia. Furthermore, the article offers an overview and analysis of unemployment in Slovakia based on selected demographic factors.

Keywords: employment, unemployment, labour market, regional disparities, Slovakia

Introduction

The process of economic transformation in Slovakia was accompanied by an increase in unemployment. At present, the policy of eliminating unemployment is one of the priorities of the Slovak government and the European Union under the Europe 2020 strategy (European Commission, 2010). Unemployment in Slovakia averaged 13.02% from 1994 until 2017, reaching an all-time high of 19.79% in January 2001 and the lowest 6.5% in august 2017. The priorities of the Slovak Republic's strategic investments are to fund the system for creation of new jobs, mainly for the long-term unemployed and disadvantaged groups. In this context, it must be taken into consideration, that the importance of work in human life is undeniable. Work, by its nature, stimulates the development of people and the advancement of the society as a whole, and above all, work assists people to fulfil their needs. Unemployment often leads to poverty, which also negatively influences the regional development. Slovakia is one of the countries with the largest regional disparities of the GDP per capita. This is directly related to the varying levels of unemployment in the regions, higher level of poverty and increased crime in the regions concerned, which has a negative impact on the progress of regions in question. One of the causes of regional differences is the lack of job opportunities in the region and low sectoral diversification of the economy. Other factors of unemployment include low level of education, lack of flexibility, incapability to work, lack of job opportunities, and insufficient information about job vacancies. This paper focuses on the current problems related to employment policy in Slovakia. The labour market policy is a part of economic policy and it represents an instrument for solving a wide range of socio-economic problems. Eurostat defines unemployed persons as people aged 15 to 75, who are without work, are available to start working within the next two weeks and have actively sought employment during the last four weeks period. The unemployment rate is the number of people unemployed as a percentage of the labour force. There are different types of unemployment, the most common include frictional unemployment, structural unemployment, real wage unemployment, mismatched unemployment, cyclical unemployment (Investopedia, 2017). In this context it should be noted that a certain amount of unemployment is natural. Full employment does not mean that no one is without a job. To effectively combat with unemployment, governments throughout the EU now aim to increase the number of jobs rather that cut the unemployment numbers (De Castella & McClatchey, 2011).

The Aims and Methodology

The objective of the paper is to present the current state of unemployment in Slovakia. The paper analyses selected aspects of unemployment in the economy based on the data derived from Eurostat,

Statistical Office of Slovakia, and several other sources. Using a blended descriptive-analytical approach, the unemployment policy from the point of view of both theory and practice is analysed. One way to address this social problem is to ensure synergy between education and the requirements of economic practice, as there are currently many vacancies in Slovakia. It is undisputable that awareness of new jobs should be increased and services provided by authorized bodies should be closer to the citizen.

Delineation of Unemployment and its Types

Unemployment is one of important macroeconomic problems of the market economy. As a global phenomenon it leads to serious economic as well as social consequences. For almost every person, the job loss has traumatic consequences and is associated with uncertainty, loss of regular income, drop in living standards, etc. From a person's point of view, loss of employment can cause a sense of failure, uncertainty, and embarrassment.

The unemployment rate is the basic criterion for assessing the success or failure of employment policy. The unemployment rate is one of the measures of labour market performance in developed market economies.

The Europe 2020 strategy for sustainable and inclusive growth includes the commitment to raise the average EU employment rates to 75% (within the age cohort of 20-65 years old) by 2020 (European Commission, 2010).

According to the definition of the International Labour Organization (ILO), unemployed people are without work, but seeking work and available for work. The unemployment rate is still high in the European Union (EU), namely 8.2% by 31st December 2016 (European Commission. 2017) compared with other developed countries. Many of the unemployed would like to work, and are actively looking for a new job or are available to work. (ILO, 1982). The European Commission has adopted similar definition as ILO. The main aspects are that they someone aged 15 to 74 (in Italy, Spain, the United Kingdom, Iceland, Norway: 16 to 74 years), without work during the reference week, available to start work within the next two weeks (or has already found a job to start within the next three months), actively having sought employment at some time during the last four weeks (European Commission, 1999).

The employment rate covers all people, including the inactive population (students, children, the retired, etc.). It represents the total number of people in employment as a percentage of the overall population of a given age. It is worth noting that the Europe 2020 strategy has been framed in terms of the employment rate, not the unemployed rate.

The unemployment and joblessness represent both a social and economic stress, including risk of poverty, homelessness, physical and mental illnesses, or suicides (Bell and Blanchflower, 2009). It is also one of the main sources of reduced social, material and psychological well-being.

Economic and Social Consequences of Unemployment in Slovakia

The long-term unemployment rate in Slovakia is one of the highest amongst the EU member states. Almost two thirds of unemployed people are unemployed for more than 12 months. It is known that many people who found jobs have been unemployed for longer than a year. This can be caused by the long time that takes for people to find a job and get employed.

The main economic consequence of unemployment is the issue of the labour force potential, as well as the skills, knowledge and capabilities of individuals that do not produce an economic effect. This results in decrease of the gross domestic product as well as the economic loss through measures of unemployment elimination and its consequences. In addition to the unemployment support itself, it is the contribution to funds (health, social), employees of labour offices, and so on.

In Slovakia, foreign investment is one of the main sources of employment. Foreign organizations belong to the largest employers in Slovakia. Unemployment also has negative consequences from a social point of view. It is true that the longer people are unemployed, the more negative emotions are present, such as the loss of motivation and the ability to work, the feeling of failure, etc. The impact

on mental and physical health is another significant aspect. Loss of income resulting from unemployment leads to growing inequality in redistributing income. (Weffers, 2017) With several programs through the Structural Funds, the EU helps to eliminate unemployment. For the programming period 2014-2020, Slovakia has allocated approximately 14 billion EUR for cohesion policy. Labour mobility within the EU is one of the ways with the help of which workers are guaranteed the opportunity to improve their living and working condition. (Novackova, 2014) Labour mobility itself helps economic migration and enables citizens from Member States to find a job.

Unemployment can be characterized also as a social phenomenon of involuntary and long-lasting interruption of work because of the impossibility of finding a job. The causes for unemployment may vary, but unemployment is closely linked to the qualifications of the unemployed. According to the information published by the Ministry of Finance of the Slovak Republic in 2016, 54 thousand of new job positions were formed, and the unemployment rate has dropped to the lowest level since the end of 2008. In the fourth quarter of 2016, it reached the level of 9% and 54 thousand job positions were formed in 2016, the second most successful year in the history of the Slovak Republic. (Ministry of Finance of the Slovak Republic, **2017).**

An Overview of Unemployment by Selected Demographic Factors and Regions

Table 1 shows the differences in unemployment and vacancies by regions in Slovakia.

Table 1: Unemployment and vacancies by Slovak regions in August 2017 (ISTP, 2017); Ústredie práce, rodiny a sociálnych vecí. (2017)

Region	Number of job seekers	Unemployment rate calculated from the total number of job seekers	Unemployment rate	Economically active population	Number of vacant work places
Bratislava	12,783	3.94%	3.64%	350,998	21,709
Trnava	9,024	3.74%	3.05%	296,274	18,270
Nitra	16,463	4.66%	3.88%	348,020	11,559
Trenčín	11,768	5.76%	4.73%	303,588	9,570
Žilina	17,414	5,90%	5.07%	343,513	8,103
Banská Bystrica	30,306	11.21%	9.43%	321,332	8,585
Prešov	42,325	12.29%	10.53%	401,819	7,438
Košice	38,170	12.53%	10.59%	360,294	5,605
Slovakia	178,253	7.70%	6.54%	2,725,838	94,364

Two regions with the lowest unemployment (Bratislava, Trnava region) have more vacant job positions available than there are job seekers (12,783 vs. 21,709; 9,024 vs. 18,270). In three regions (Banska Bystrica, Presov, and Kosice) there are for several times more job seekers than there are vacant positions (42,325 vs. 7,438; 38,170 vs. 5,605). Presov, the region with the highest number of economically active population, has most job seekers, the second highest unemployment and second lowest number of vacant positions (401,819 job seekers; 11.21% and 9.43% respectively; 7,438 vacant positions). Furthermore, there are about twice as much job seekers than vacant positions in Slovakia (178,253 job seekers and 94,364 vacant positions).

Slovakia's real GDP growth rate of more than 3% as of June 2017 (Trading Economics, 2017), increasing employment rates and decreasing unemployment have not translated into resolving one of the most frustrating problems – long term unemployment.

The employment rate in Slovakia had been steadily increasing from 2001 until the depression in 2008. In 2009 and 2010 it somewhat declined, and it has been recovering since, for example, the employment rate in 2015 reached 62.7% according to Eurostat (European Commission, 2015).

The unemployment rate decreased from almost 20% in 2001 to pre-crisis 9.6% in 2008, afterwards it soared to almost 14% in 2013. However, a declining trend started in 2013 which resulted in today's 6.7% of statistic unemployment or 7.91% according to job seekers as of July 2017. There are also significant regional differences between western and eastern part of the country. In five counties, the unemployment rate is below or just slightly above 5%. Bratislava and Trnava regions have the lowest unemployment rates in the country (3.7% and 3.12%, respectively). On the other hand, unemployment in other three counties is oscillating around 10% This is the case of Bansks Bystrica, Presov and Kosice regions (9.43%, 10.53% and 10.59% respectively).

Age

The unemployment of youth is a persistent problem in the Slovak labour market. In 2008, it reached its historic low at 19.3%, yet during the crisis it rose up to 33.9% in 2013. Since then, it is continuously declining. Yet, amongst the Visegrad countries, Slovakia has the highest rate of young people between 15 to 34 years, that are neither employed nor in education or training (NEET).

Ethnicity and Nationality

The Roma population is one of the most disadvantaged groups in the Slovak labour market. There are no net data on the population, though unofficial estimates talk about 450,000 people (approx. 8% of population). Though the unemployment and employment rates in Slovakia shift, the rates for Roma population are quite stable.

Foreign workers represent about 1% of the entire workforce in Slovakia. Majority of foreign workers are from the EU/EEA states, namely Romania, Czech Republic, and Hungary. According to the Slovak government's official employment strategy, the gaps in labour market should be filled primarily by domestic workforce, and only if there are no suitable candidates, they should be occupied by foreign workers. This policy ignores the need to cope with skill and labour shortage and its practical monitoring and control remain questionable.

To conclude, it is estimated, that in Slovakia about 12% of active workforce work without any type of work contract, which means they are engaging in undeclared labour (European Commission, 2016). The most common form of undeclared work in Slovakia and in the EU member states are home repairs and products purchases. In the case of product purchases, car parts are the leading product (European Commission, 2014).

While the risk of poverty in Slovakia declined in the last two decades, it has not diminished completely. It is estimated, that in 2016 the amount of population at risk of poverty was around 12.7%, representing approx. 670,000 persons. It is not surprising, that the unemployed are in the highest risk of poverty (around 48% in 2016). But the economically active population is not save from poverty as well. The number of working people at the risk of poverty is still very high. Some estimates state that it accounts for about 10%. Another group of people are those who earn minimal or slightly above minimal wage.

Conclusion

Perhaps the most unfortunate consequence of unemployment is that an individual or group of people, who have certain mental and physical abilities to perform certain types of work, do not perform and do not use their skills to work. Slovakia's unemployment reduction policy has produced positive results, but current information from Ministry of Labour, Social Affairs and Family of the Slovak republic points at the fact that there are many vacancies in Slovakia. This leads to the issue of why the unemployed are not interested in finding a job out of the current vacancies. Effective co-ordination and partnerships in different areas (e.g., employment, job creation, employment services, education, youth, social affairs, and support through the European Social Fund) can contribute to the systemic solution of the respective problems. To eliminate unemployment, the Labour Code, which

has introduced the institute of flexi-work (Business Dictionary, 2017), also contributes to the reduction of the negative effects of sectoral changes in the economy. This type of measure helps create new jobs and at the same time is a tool for harmonizing family and work life.

Abstract

Economic growth is one of the ultimate goals of any economic system. The relationship between the development of the financial system and economic growth is a subject of longtime debates. Although it seems that it has reached indicative consensus, economists still have different thoughts on the importance of financial system for the economic growth of one country. The primary purpose of banks is to mobilize otherwise idle resources for use in productive investment. A wide array of theoretical models has appeared in the growth and development literature in the past decade to formalize the link between financial-system functioning and the growth of the real economy. In comparison to the traditional growth models in which output was seen as a function of capital, labor, and disembodied technological progress, the current models provide a richer framework for interpreting the potential impact of financial systems. The main issue of this paper is to analyze the relation between development of the financial system and economic growth by using the secondary analysis of literature and historical descriptive analysis for empirical research. The purpose of research is to put the Macedonian banking system and its economic growth in comparative and historical perspective with the banking systems of Central and Southeastern Europe countries.

Keywords: Banking sector, Development, Economic growth, Financial system.

Introduction

The relationship between the development of the financial system and economic growth is a subject of longtime debates. Although it seems that it has reached indicative consensus, economists still have different thoughts on the importance of financial system for the economic growth of one country.

Economic growth is one of the ultimate goals of any economic system. The need to stimulate and manage economic growth is from a big importance in advanced, emerging, and developing countries. Despite the burgeoning research on finance and growth, the importance of financial-system structure has yet to be determined. Much of the debate over banking reform in the United States hinges on the assumption that certain types of financial systems allocate an economy's resources more efficiently than others.

Research objective

The primary purpose of banks is to mobilize otherwise idle resources for use in productive investment. A wide array of theoretical models has appeared in the growth and development literature in the past decade to formalize the link between financial-system functioning and the growth of the real economy. In comparison to the traditional growth models in which output was seen as a function of capital, labor, and disembodied technological progress, the current models provide a richer framework for interpreting the potential impact of financial systems. For their motivation, nearly all appeal to the observed correlations between financial-system development and industrial growth uncovered by economic historians and development economists during the 1960s and '70s.

In global framework the relationship between the banking, and wider - the financial system and economic growth is a subject of many research studies. The literature suggests that when the financial system is bad, so is the rest of the economy. For example, when bank balance sheets are heavily burdened with nonperforming loans banks may not be able to provide new loans to companies, even to those that have good investment opportunities. Lack of finance, of course, reduces investment and economic activity and, ultimately, economic growth. In the extreme, a credit crunch impacts adversely even on trade finance and can grind all economic activity to a halt.

More broadly, it is now widely accepted that a fragile financial system can impair long run growth. Recent research, for example, shows that the combination of lax prudential regulation and supervision with inadequate corporate governance practices in banks can have disastrous consequences for the rest of the economy.

Methods and methodology

The research is processed by using a wide scale of the scientific methods and procedures. The specific range of methods was based on the research needs of the individual parts. The intention is to follow the logical continuity of the articles' parts, the correctness and the adequacy of information and data. First part is focused on the different definitions. This section is prepared by using the analytical methods – the analysis, the casual analysis, the synthesis. We analyzed scientific publications and scientific articles, papers by various authors (e.g. Burton, M., Brown, B. (2009, Delong J. Bradford (2001), Levine, R. (2005), Thierry, B. (2012), Thompson, D. (2011)). Pawera, R. (2007), Janać, J. – Mariak, V. (2013), Šlahor, Ľ. – Majerčáková, D. – Barteková, M. (2016), Komorník, J. – Majerčáková, D. – Husovská, M. (2011), Komorník, J. – Janać, J. (2011), Gejdoš, P. (2013) and (2015)). The first part is based on preparation and explanation of key terms. (Mitková, L. 2010) Methodology contains of identification of research assumptions, as well as methods and sources used in the paper. Results part consists of the main findings and is prepared by using a comparative and historical descriptive analysis.

Theoretical Background

Empirical evidence generally suggest a positive relationship between financial development and economic growth. Some studies even, found that good financial development could predicts future economic growth rates. Panel studies, studies of individual countries, as well as analysis of the level of industries and firms, have documented periods in which financial development had a crucial impact on the speed and the course of economic development. (Thompson, D., 2011) However, a study of this type, according to our best knowledge, is not made specifically for country that is coming from Southeastern Europe. That will be our main motivator which will drive us to compute this research in best possible way and found a satisfying outcome with computing various test and based on underlying real data.

Role of the banking system in the economy

A banking system is a sum or a structural network of institutions that provide a diversity of financial services within one economy. These institutions are responsible for operating a payment system, providing loans, taking deposits and helping with investments. The main role of the banking system is to provide entities with surplus funds to invest and transfer them into entities that lack the financial resources (entities with plans for new projects), and ultimately making profit. (Burton, M., Brown, B., 2009) In other words financial systems, i.e. financial intermediaries and financial markets, channel funds from those who have savings to those who have more productive uses for them. They perform two main types of financial service that reduce the costs of moving funds between borrowers and lenders, leading to a more efficient allocation of resources and faster economic growth. These are the provision of liquidity and the transformation of the risk characteristics of assets. By performing these roles, the banking system

supports the economic activity and creates the basis for large investment ventures and technological innovations.

As stated in the introductory part, the banking system exists to allow overcoming of the difficulties that arise in the operation of enterprises and to provide financing of the long-term investment projects or maintenance of the current (short-term) liquidity.

In order for a one company to finance in investment projects that are basis for its growth, it should have the available funds. This reserve of financial resources can be funds from past profits of the company, investments from the owners and funds provided through an issue of new equity securities. But if the funds cannot be created in such ways (so-called equity capital), then they need to be borrowed from external sources (i.e. debt capital). The population of one economy can invest their surplus funds to theses deficient enterprises. Here the financial system is appearing as a balancing agent between deficit and surplus entities with aim to enable the channeling of these funds to be at minimal cost and with minimal risk.

If the channeling of funds from surplus to deficit agents are going straight, without the existence of financial institutions, there will be two types of costs: informational and transaction costs. Savers (surplus agents) will generate informational cost in order to learn about the operations of the company (deficient agent) or to assess the productivity of the project (its ability to repay borrowed funds). J. Bradford DeLong (2001) in informational costs includes the costs generated for depositors to feel safe, measures to increase operational safety of the deposit. Transaction costs, however, are measured by the required time and resources for the implementation of a transaction. If such costs did not exist, also the necessity for financial system would not exist. Since they are present in the complex reality, the role of financial institutions consists in minimization and overcoming of these costs for effective allocation of the resources and indirect support of the economic growth.

Place and role of the banking system for economic growth of the economy

According to the above discussion, the role the banking system is to identify the needs for financial services, with reducing of transaction and information costs, creation of needed products and their sale at affordable prices. In this way the banking system is developing, and while responding to the needs of the economy, it could contribute to overall economic development. The development of the banking system is closely linked to the competition between banks in the economy, because motivated by increased competition, banks can offer more products and services. At the same time, the growing international movement of capital contributes for increasing the participation of banks in international financial markets, consolidation of banks from different geographical areas and emergence of regional banking groups. These development trends of the banking system contributes to reduction of prices of bank products, that, in turn, stimulates investments in new projects and technological advances, which in final stage stimulates economic growth. By providing its basic functions the banking system influence its own growth. At the same time, performing these basic functions defines channels that support the overall growth of the economy. These functions are:

1. Generating information for potential investment opportunities and allocation of capital;
2. Mobilization of savings;
3. Monitoring and control of enterprises-borrowers;
4. Risk Management;
5. Specialization and concentration of banking activities.

Below we will explicate in details how the performance of each of these functions can affect the economic growth of one country.

Generating information for potential investment opportunities and allocation of capital

Before deciding on approving of a loan, the bank always make a detailed analysis of the enterprise performance or the borrower. This analysis creates information and transaction costs accumulated for determining the solvency of the company, all the future plans for investment and risk assets that might not be recovered if the investment projects fail. If the banking system does not exist, then these big costs for finding the right information and assessment of enterprises will keep individual savers from proper allocation of their capital, which would ultimately prevent the companies to continue their investment plans. By reducing these costs, the banking system improve the allocation of capital and channels it to the places of his most productive use. In this way, investment projects can be realized and they represent the basis for economic growth. In addition, with the advantages from the increased scope of information available and due to the diversity of its loan portfolio, the bank reduces the credit risk, i.e. the risk that a given asset might not be recovered.

Lower credit risk reduces the cost of investment - the interest rate, which makes capital cheaper and more accessible. Consequently, on an aggregate level, by managing the information on borrowers, financial intermediaries contribute for realizing greater investments, reduction of interest rates and thus stimulate greater economic activity. All this support and boost economic growth of one economy.

Mobilization of savings

Closely related to the previous function is mobilizing of resources or collection of funds from a number of individual savers. The savings deposits are financial instruments with a small denomination, which provides also depositors with lower income opportunity for savings. According to Levine (2005), as well as in the process of allocation of capital, the process of mobilization of savings also includes overcoming of the transaction costs related to collecting the savings of many different subjects and overcoming the information costs related to the confidence of depositors in the financial institution, and sense of control over their savings. In other words, to reduce these costs, the bank uses economies of scale, where one information that it possesses can be exploited for multiple clients.

A typical example of this is the so-called delegated supervision, when the bank control the investments of companies funded by her and share this information with the individual savers (potential investors). If each depositor is left to analyze the company again on its own, huge costs will be accumulated making the overall process more expensive and less efficient. Thus, by exploiting economies of scale, banking systems increase efficiency in the mobilization of savings from individuals, and allow faster allocation of funds, supporting investment projects and technological innovation, and positively influencing the economic growth of one economy.

Monitoring and control of enterprises-borrowers

Third channel through which the banking system can influence the economic growth is with control by the bank over the way of utilizing debt capital within the companies-borrowers. According to previous discussion, the banks mobilize savings of many individuals and lend to businesses. Banks on behalf of depositors, oversee the use of funds by businesses. If savers individually performed this, monitoring costs will be high, which will make the price of capital (interest rate) increase. Therefore, monitoring and control on users of funds by the bank lender, will influence on rational and productive utilizing of capital, which will increase the value of the company and consequently will contribute to overall economic growth.

Some studies state that the role of banks as controllers of the use of funds by companies have positively effect on creating long-established relationship between enterprises and the bank, which offers the possibility of gaining mutual trust and opportunity for financing new long-term capital projects and innovative technologies. And by directing capital into long-term projects to support economic growth.

In the short term, however, when the bank has already established effective monitoring of the enterprise and it knows the operation and performance of the same, the procedure for financing the activities of the company are shortened. The short term financing allows the company to reduced cash holding to a minimum. The excess of free money can be invested in financing of its own activities and increase the productivity of operations. Consequently, monitoring the activities of the company reflects positively on productivity, the accumulation of capital and the growth of the company. Thus lead us to conclusion that monitoring of the companies by the bank supports the overall growth of the economy.

Risk Management

Banks can also reduce information and transaction costs by proper management of financial risks. Bank holds various debt instruments in the form of deposits with different maturities and regular interest. On one side there are savers that most often want to deposit the funds on shorter periods, but are reluctant to risk. On the other side appear borrowers who have riskier and longer-term projects. Bank as an intermediary is collecting mass of savings with shorter deadlines, perform maturity transformation and place funds on longer deadlines, but in different economic agents thus credit risk is diversified. Individual savers cannot diversify their funds and reduce credit risk, so if banks were not existing, investments in risky highly profitable projects will lag behind. At the same time, by offering savings accounts with short maturity, the bank satisfy the liquidity needs of its savers.

Banks also play a huge role in the management of liquidity risk enterprises. During the production process, companies are in need of additional funds, mostly to support production activities and the maintenance of current liquidity. Here the banks offer a variety of short and medium-term credits (revolving loans, loans for the purchase of raw materials, financing of inventory, financing on construction in progress, short-term loans to finance foreclosure and etc.). (Thierry, B., 2012) By maintaining the current liquidity, companies have continuous workflow and production, which have positive impact on overall economic performance and maintaining the liquidity of the entire system and in final stage supports economic growth. Moreover, according to the aspects discussed in previous sections, the long-term liquidity will enable financing long-term projects, which influence the development of the enterprise and hence the overall economic growth.

Specialization and concentration of banking activities

The Banking system may be the basis for the growth by specialization and concentration of its activities. Banking systems which contribute for reduction of transaction and information costs are influenced by the specialization of banks in their operation. Therefore with utilizing economies of scale, increased operational efficiency and increased set of financial services at lower prices, technological innovation, etc., they are influencing the economic growth of one economy.
As a conclusion, banks can influence economic growth through achieving its five functions, which are down to two conceptual directions:

- Increased saving is the basis for enhanced and efficient allocation (lending) in yielding projects, which is the basis for economic growth;
- Monitoring and control of enterprises, risk diversification of the loan portfolio and increased efficiency in banks' operations reduce the cost of financing (interest rate), allowing more projects to become profitable, which is the basis for economic growth.

Modern concepts for the link between economic growth and banking sector

Stable and well developed financial system is a key factor for an efficient functioning of any market economy. The banking institutions have the central place within the financial system in one country. The reason for this may be the fact, that banks are continuously expanding the scope of activities they perform, and this activities were operated only by non-banking institutions, in the past. But despite this, the primacy within each financial system belongs to the banks. (Scott, S. 2014) Stability and liquidity of banks are essential for maintaining the stability of the financial sector in each national economy.

Many authors are sceptic for the positive link between the development of the banking system and economic growth. They indicate that higher development of the banking system result with stronger competition between banks, which according to them, in many cases could have negative influence on the economic growth of one country.

Measures for the development of the banking system

Similar to the determinants of economic growth, the literature is not unanimous in terms of indicators by which we should measure the development of the banking system. However, when banking system is placed in the context of economic growth, then there is greater consensus on the measurement of its development. Thus World Bank divide the indicators in two groups: traditional and modern; While the traditional measures for development of the banking system can be brought in direct relation to economic growth. Therefore, the main measures for the development of the banking system are drawn from traditional indicators. It is considered that some of the shortcomings of traditional indicators can be exceeded by using new, modern indicators. However, as we shall see below, they are more related to the availability of banking services to households and not directly related to economic growth. They are: density of the network of subsidiaries, branches and ATMs; average size of credits and deposits per capita in relation to GDP; number of loans and deposits per capita; percentage of the population that has a credit or deposit account in the bank; and percentage of firms that finance their investment activities through loans. Having in mind that cannot be brought in direct relationship with economic growth, and also the fact that a significant proportion of information for them are inaccessible for Macedonia, we decided that we are not going to use them in our analysis.

Consequently, we use the following indicators of development of the banking system:

Indicators of banking development: loans to private sector / GDP; liquid liabilities (short-term deposits from private agents) / GDP; total assets / GDP; net interest margin; and operating expenses / total asset

Base on this indicators we are going to test and prove the link between economic growth and development of the banking system.

Central, Southeastern Europe and Macedonia: Comparative and historical descriptive analysis

The purpose of this chapter is to put the Macedonian banking system and its economic growth in comparative and historical perspective with the banking systems of Central and Southeastern Europe countries. First, we present a comparative analysis between the countries from CEE and SEE, and then we observe the Macedonian banking system in historical perspective and examine the current situation today.

Comparative analysis

For the purposes of this comparative analysis, firstly we needed to define the exact number of countries that will be included in this comparison. In order not to analyze this phenomena only in a partial sample, we defined a wider set of countries belonging to the two geographic areas: Central Eastern Europe (CEE: Slovakia, Poland, Czech Republic, Hungary, Estonia, Lithuania, Latvia and Slovenia) and South Eastern Europe (SEE: Macedonia, Croatia, Serbia, Bosnia and Herzegovina, Albania, Kosovo, Romania and Bulgaria). For comparison purposes we took the aggregate or average data for the Eurozone 15. This classification corresponds to the fact that CEE countries are characterized by considerably higher GDP per capita and greater development of the banking system in terms of SEE countries; while the average GDP per capita of Eurozone 15 is the highest and have the most developed banking system in terms of all countries in the comparison group.

Macedonia belongs to the group of SEE countries, and the road to integration into the Eurozone should pass the stage of development that currently have the CEE countries. Sources of data for this analysis are: the IMF, the ECB, Eurostat and the Internet pages of individual central banks of the selected countries.

Development of the banking systems in CEE and SEE countries

In recent years, the banking systems of CEE and SEE have been marked by two structural changes: 1. Strengthening of the dominant share of foreign shareholders and international banking groups in domestic banks, leaving only a fraction of state-owned banks that can be privatized; and 2. Introduction of international financial reporting standards, the principles of Basel 2 agreement and more effective regulation and supervision of the banking industry. The group of CEE countries is farther ahead than SEE countries on both trends. These reforms were aimed for supporting the development of the banking system and securing its efficiency and stability on the path of integration of these countries in the financial system of the Eurozone. In this comparative analysis, we will observe the development of the banking systems through the following coefficients: total loans / total deposits; annual growth of private loans; and annual growth of short-term deposits. The movements of these indicators for CEE and SEE are shown in Figure 1 – Figure 3.

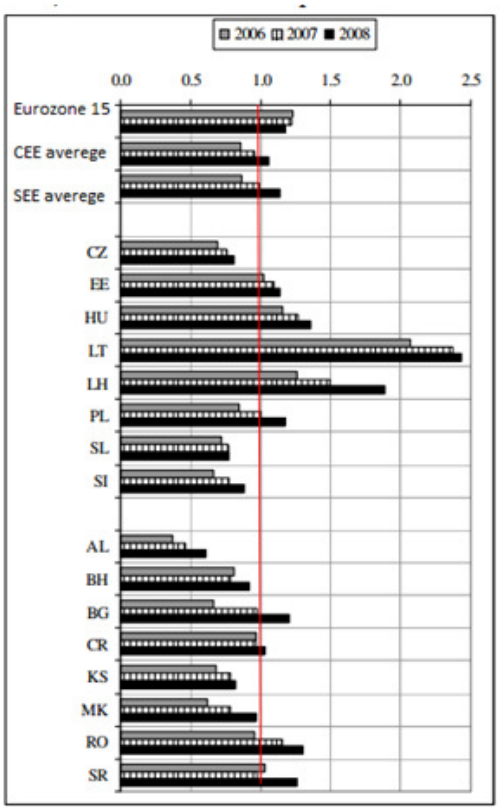

Fig. 1: Indicators for the development of the banking systems of CEE and SEE countries – Total loans / Total deposits

The coefficient total loans / total deposits (Figure 1) measures the channeling of deposits in private loans, or what proportion of domestic savings is channeled into loans and furthermore in investment and consumption. The average value for the CEE and SEE countries rises in the period of 2006-2008, so in 2008 exceeds the value of 1.00 and amount to 1.06 and 1.14, respectively. These developments are rough indicator of convergence of the financial systems of these two groups of countries towards the financial system of the Eurozone which, on average remained at a similar level of development in the last three years (around 1.2). However, it seems that it the group of Central and Eastern Europe there is a greater diversity of the value of the indicator, unlike the SEE countries within which only Albania significantly lags behind with (0.6). In the observed three years, Macedonia has achieved a greater growth of this indicator in comparison with the other countries from the SEE group (annual growth of 20% in 2007 and 2008), and reaches a ratio of close to 1.00, but still lags behind Romania (1.3), Serbia (1.3) and Bulgaria (1.2). According to the movement of this factor, Macedonia is approaching to the average of the CEE countries, although still lags behind most of these countries.

In 2008, private loans experience a significant decline (Figure 2), as a result of the tight credit policy and lower investment (due to reduced economic activity) as well as measures set by the central banks of these countries. In the last three years, the SEE countries have the higher growth rate of private loans compared to CEE countries and the Eurozone 15, which mainly reflects the lower initial development of the banking systems of these countries, as well as the larger development needs of their economies, in general.

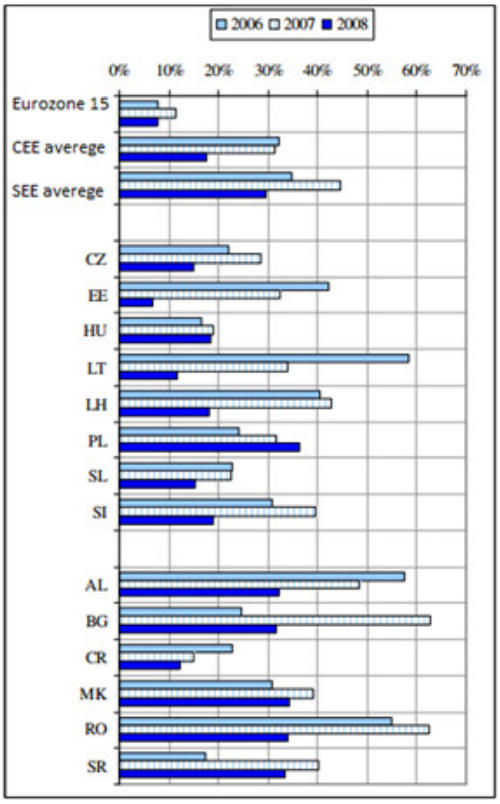

Fig. 2: Indicators for the development of the banking systems of CEE and SEE countries – Annual growth of private loans

Furthermore in 2008, the growth rate of the short-term deposits (Figure 3) was marked with drastic slowdown; in SEE countries amounted to only 0.8% and in CEE entered the negative zone with score of -5.8%.

The efficiency of the banking system is measured by the size of the operating costs in terms of total revenues. We associate this factor with profitability of the banking system, which is measured by the ratio for return on assets (ROA). Through diagram of circles (in Figure 4) we observe the potential connection between these two indicators. The size of the circles represent the relative size of operating costs of the banking system.

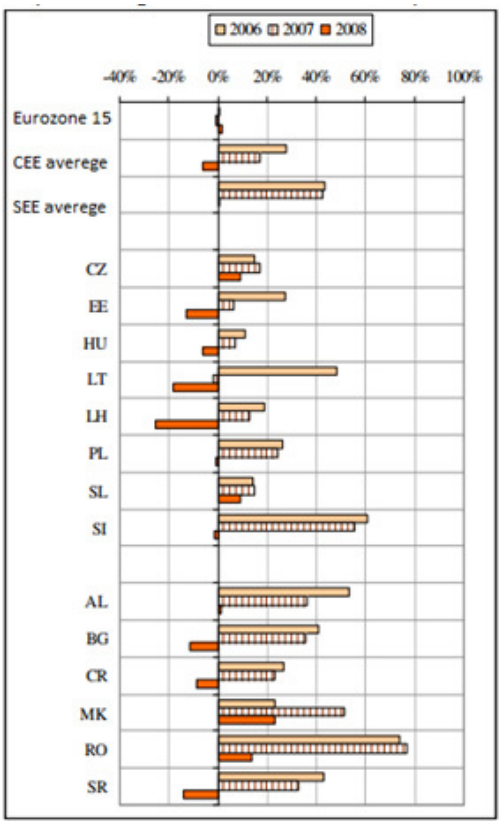

Fig. 3: Indicators for the development of the banking systems of CEE and SEE countries – Annual growth of short-term deposits

Looking at Figure 4 we can notice that the larger circles are placed at the bottom of the diagram, which indicates the possible negative relationship between operating costs and profitability of the banking system. This tendency is particularly expressed for the Eurozone, where in 2007 and 2008 the operating costs have increased by 105.1% and 99.8%, respectively, compared to 2005 and 2006, and reduce ROA to 0.2% in 2008. In the CEE countries, by 2007, the decline in costs was accompanied by increased profitability. Yet this connection is not so obvious in 2008, when despite of unchanged operation costs it comes to decline by (27.4%) of the ROA. The latter, probably due to the more obvious effects on the profitability of the global financial crisis. This is probably due to negative effects that the global financial crisis have on the banking system and economies of Europe countries. In the SEE countries, the link between the performance of the banking system and its profitability appear negative, although there is no significant reduction in profitability and an increase in operating costs, as was the case with the Eurozone. From 2007 to 2008, operating costs in SEE countries increase from 41.5% to 48.0% and ROA was reduced from 1.7% to 1.6%.

In Macedonia, from 2005 to 2007 there was a trend of decline in operating costs (From 75.2% to 58.4% of total revenue) while increasing profitability (from 1.2% to 1.8%). These trends reflect the increasing efficiency of the Macedonian banks in this period. But in 2008, operating costs in Macedonia (62.2% of total revenues) follow the same trend as in the SEE countries, and are accompanied by a decline in ROA of 1.8% to 1.4%.

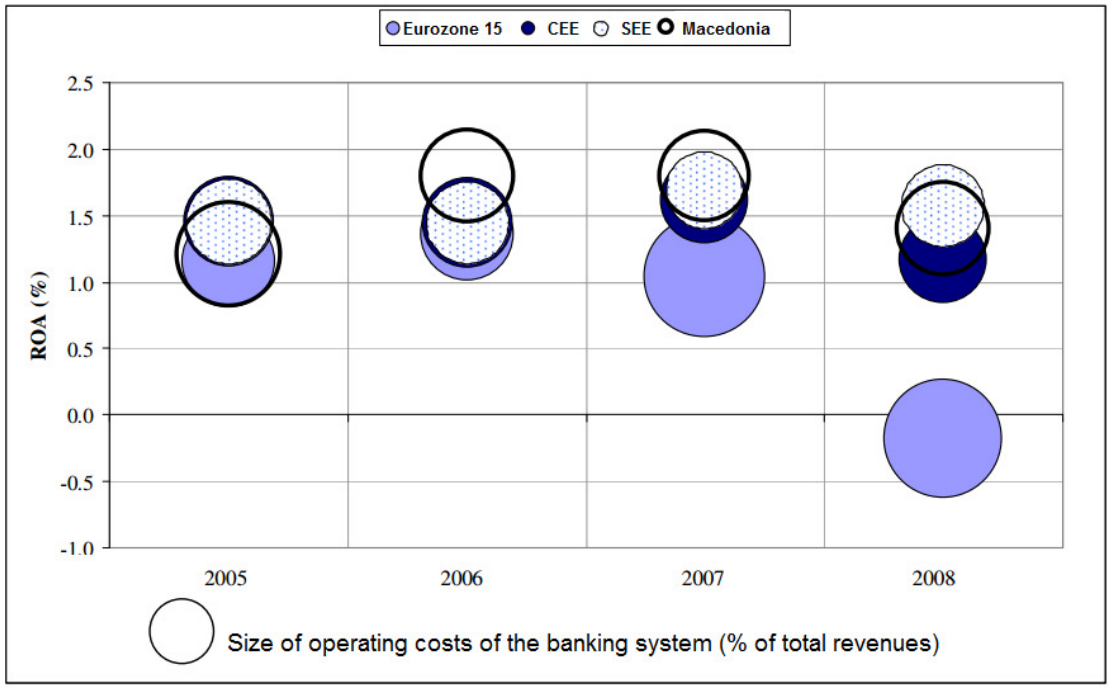

Fig. 4: Indicators for efficiency of banking systems in the Eurozone, CEE, SEE and Macedonia

Link between the banking system and economic growth in CEE and SEE countries

On the road to European integration, the countries of CEE and SEE need to go through the process of reforms, which implies convergence of their national income and living standards to the same in EU. Figure 5 represent the GDP per capita, expressed in international dollars for CEE and SEE countries and the average for the Eurozone. It can be observed that the average of CEE countries ($ 21,271) is higher than the average of SEE countries ($ 11,126), which implies that the first group is far ahead in the actual process of EU integration, compared with the second group. In the CEE group, countries that particularly stand out are Slovenia, Czech Republic and Slovakia. Higher economic growth of this group of countries is linked to their higher starting point, and their early membership in the EU (the process of real convergence). On the other hand, the SEE countries are significantly lagging behind, with an average GDP per capita, which amount almost half of the average of CEE. Also, the countries of this region are more heterogeneous than the countries from CEE region, only Romania, Bulgaria and Croatia are EU members, and Macedonia, Serbia and Bosnia and Herzegovina signed the Stabilization and Association Process with EU and Albania and Kosovo are still facing certain political problems.

However, for the process of real convergence in context of the banking system, these countries have made significant restructuring and privatization of the sector, and implied numerous reforms which turn out to be quite beneficial for them and for their economies. The observations from this statistical data just confirm our expectations that for positive potential relationship between development of the banking system and economic growth of one country.

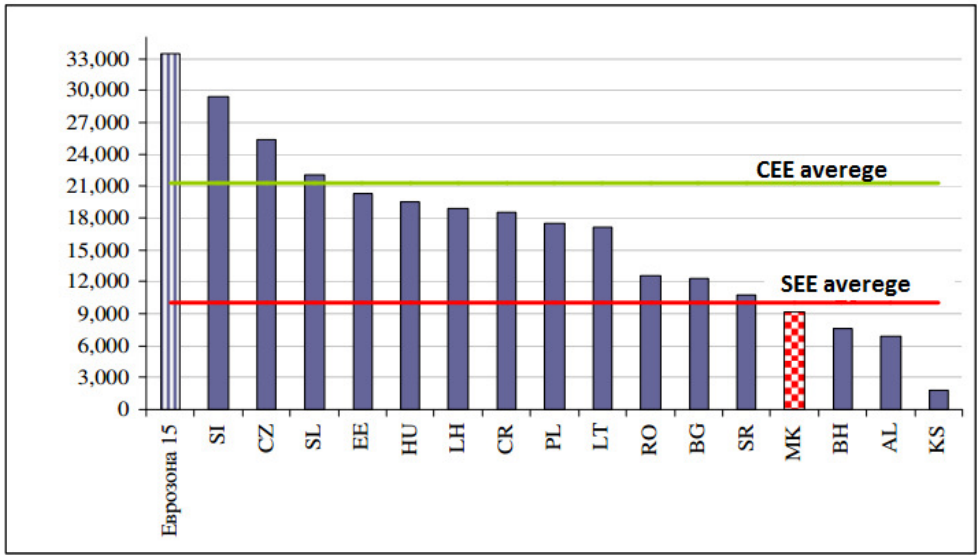

Fig. 5: GDP per capita CEE and SEE countries

Conclusion

The objective of this paper was to investigate the potential link between development of the banking system and the economic growth of one country. Special attention was drawn to Macedonia, in a comparative analysis between the countries from CEE and SEE region. From the research of the theoretical literature we can conclude that the banking system can influence the economic growth by performing its basic functions: First of all by generating information for potential investments and allocation of capital, the banking system contributes for improving the information available about current status of companies in the economy, as well as their future plans and decisions. This information decreases the risk factor and reduces the cost of borrowing and the interest rates of loans offered by banks, and thus stimulates economic growth. Secondly through mobilization of savings, which includes overcoming of transaction costs related to collection of savings from different entities and information costs for increasing the confidence of depositors in the financial institution, the banking system can support high-volume projects and technological innovation in the economy and thus stimulate growth. Finally via specialization and concentration, the banking system can exploit economies of scale and introduce a wider range of products that can reduce the cost and the risk of borrowing which in the end will support the economic growth of one country.

In conclusion, the comparative analysis showed us that: 1) The development of Macedonian banking system is mostly average compared with the level of development of banking systems of SEE countries, but significantly lags behind averages of CEE countries; 2) We concluded that there is a potential positive relationship between the level of banking depth and economic growth and potential positive relationship between profitability and efficiency of the banking system and economic growth in one country. These observations are in direction of our initial expectations that the higher development of the banking system could imply higher economic growth.

Although the survey of this paper did not face significant constraints still we have to highlight those related to the lack of appropriate variables or lack of variability in the series of certain variables at the moment. One example is the analysis of the capital market, which although desirable, could not have been exercised mainly because his participation in the financial system of Macedonia is still small in

relation to the share of the banking system; Another constrain was that movements of Macedonian Stock Exchange seems to be still driven by speculations, and as a result of that these series were not included in this survey.

One direction for expansion of the topic treated in this paper is examining the relationship between development of the banking system and economic growth in times of economic crisis. Another direction for extension of this topic is examining the impact of financial stability and the concept of risk management on economic growth. From this perspective, the financial stability will cover the behaviour of the two key agents: households and corporate sector, on one hand, and the behaviour of financial institutions through the acquisition and management of risks, on the other hand, and their impact on the economic activity in one country.

These two alternative streams for expansion of the topic suggest that although in terms of the relationship between banking development and economic growth there is a tentative consensus, directions in which it can be explored are numerous and dynamic.

Analysis of the Evolution and Influence of Final Energy Consumption on Gdp in Eu Countries

Georgeta Soava, University of Craiova, Romania, georgetasoava@yahoo.ro

Anca Mehedintu, University of Craiova, Romania, ancamehedintu@yahoo.com

Abstract

Starting from the decisions of the European Union (EU) to reduce energy consumption by 20% by 2020 the overall objective of this paper is to analyze the impact energy consumption on the development of the EU countries, thus implicitly the gross domestic product (GDP) of these countries. To this aim, the study realized in the paper was carried out in two directions: firstly, we analyze the evolution of GDP in the EU countries, and secondly, we analyze the influence of final energy consumption (FEC) on GDP of each EU country. For this we collect the information provided by Eurostat for the period 2006-2016 for the 28 EU states members on the evolution of macroeconomic indicators: GDP and FEC (nominal and on capita). We analyze these series of data using the EViews 9 econometric software package. The Dickey-Fuller and Philips-Perron unit roots tests and the Granger causality standard test were applied to examine the relationship between GDP and FEC at both nominal and per capita. The results of the analysis did not indicate a cointegration relationship between the studied variables, but this can be considered as a positive element, because the reduction of the final energy consumption can lead to the reduction of the gas emissions, which can have a beneficial effect on the economic development and implicitly of living standards. However, in developing countries there is still the possibility of increasing FEC leading to GDP growth, and positive shocks in GDP per capita cause positive shocks in the FEC.

Keywords: final energy consumption, economic growth, panel countries, Granger causality

Introduction

Europe's developed countries have a developed economy and a higher standard of living than most of the world's states. Emerging economies are dependent on the economies of developed countries, economic growth in Western European countries can lead to an increase in emerging economies, but their recession has a strong negative impact on developing nations. A major difference between rich and emerging states is per capita income, which determines their consumption, so developed economies tend to consume more energy than the poor.

Gross domestic product (GDP) is the most commonly used macroeconomic indicator for the global assessment of an economy. Nominal GDP is commonly used to determine the economic performance of a country or region and to make international comparisons. For statistical comparisons, each country's data should be converted into a common currency, respectively nominal parity and purchasing power (PPP).

Another widely used indicator derived from this is GDP per capita that is used to eliminate the influence of the absolute size of the population, allowing for easier comparison of living standards between different countries. GDP per capita in PPP is a general economic indicator of living standards that allows comparison of the dynamics of economic development both over time and between economies of different sizes, regardless of price levels.

At present, energy is one of the main factors influencing economic systems, and can have a leverage effect on economic growth. Final energy consumption (FEC) includes the energy consumption of all users, except for the energy sector itself. The European Union (EU) has committed itself to reducing its final energy consumption by 20% by 2020.

Starting from the European Commission's decisions on the need to reduce FEC, the overall objective of this paper is to analyze the evolution and the impact the GDP on FEC of each EU country. EU countries governments are more and more interested in studying relationship from GDP and FEC because of the international goal of curbing the increase in global temperature to a maximum of 2^{o}C in the context of global warming. To this aim, the study was carried out in two directions: firstly, we analyze the evolution of FEC and GDP in EU countries, and secondly, we analyze the impact the GDP in FEC.

The paper is organized as follows: Section 1 discusses a brief review of literature on empirical studies concerning FEC and GDP, Section 2 describes the empirical models, estimation methodology and the data source, Section 3 presents empirical investigation and results and the last section concludes the study.

Literature Review

Energy arguably plays a vital role in the economic growth and livelihood, both in terms of demand side (energy is needed by the consumer to maximize its utility), and supply side (energy is a key factor in production, together with capital, labor and materials). This means that there should be causality between final energy consumption to national income or gross domestic product as well as vice versa. Naturally, the following questions arise: “Is energy consumption a stimulus to economic growth?” or “Is economic growth a stimulus for energy consumption?”

Many economists and researchers have studied the relationship between energy consumption and GDP from different perspectives and using diverse methodologies. Their methods have ranged from descriptive time series analysis to cointegration applications with panel data.

A multitude of authors have studied the relationship between GDP and energy consumption by providing a wide range of results in terms of causality, statistically highlighting either a one-way causality, a bidirectional causality or none. Such analysis were performed in (Anwar et al. 2017) on a panel of 29 OIC countries, data period 1990–2014; in (Alper, Oguz 2016) on a panel of 8 east-central European countries, data period 1990–2009; in (Sadorsky 2009) on a panel of 18 emerging countries, data period 1990–2003; in (Bhattacharya et al. 2016) on a panel of top 38 countries, data period 1990–2003; in (Inglesi-Lotz 2016) on a panel of OEDC countries, data period 1990–2010; in (Bozkurt, Destek 2015) on a panel of OEDC countries, data period 1980–2012; in (Tugcu et al. 2012) on a panel G-7 countries, in (Okyay et al. 2014) on a panel of developed countries in Europe, data period 1990–2011; in (Chontanawat et al. 2008) on a panel of 100 countries, data period 1960–2000 or 1971–2000.

In the final consumption, the evolution of final energy consumption is of particular importance, as energy contributes to the stimulating of growth and economic development, and there is a dynamic causality between energy in general and economic growth (Wada 2017).

Lee (2005) investigated the causal relationship between FEC and GDP for 18 developing countries in 1975-2001, and the results showed a unidirectional GDP causality in FEC (increased FEC led to growth GDP).

Narayan et al. (2010) examine the impacts of energy consumption on GDP in for 93 countries during the time period from 1980-2006.

Aslan (2013) studied the relationship between energy consumption and economic growth for 22 OECD countries, highlighting the strong correlation in most cases.

Similar studies for the case of individual countries and for different periods of time can be found for Algeria (Amri 2017), for Saudi Arabia (Wada 2017), for China (Lin, Moubarak 2014), for Turkey

(Ocal, Aslan 2013), for Brazil (Pao, Fu 2013), for U.S. (Stern 2000; Yildirim et al. 2012), for Lithuania (Bobinaite et. al 2011).

Research Methodology

Starting from the above-mentioned elements, in this paper we analyze the evolution of GDP and FEC (nominal values and per capita), in EU countries and relationship between FEC and GDP. The survey is based on indicators taken from the Eurostat and World Bank database for the period 2006 - 2016 for the 28 EU member states.

We will use panel series (cross-section and time series that contain information on the value of the indicators analyzed: GDP, GDP/capita, FEC and FEC/capita between 2006-2016) for the 28 EU Member States.

Models analysis on these data, based on classic regression, show that important properties of time series data can be more restrictive than similar properties for cross-section data.
In the first part of the study we will make a statistical analysis of the indicators evolution and the second part of the study aims to analyse the impact of final energy consumption on economic growth, where we will use a linear regression model:

$$LGDP_{it} = \alpha_i + \beta_i LFEC_{it} + u_{it}, \quad (1)$$

$$LGDP_CP_{it} = \alpha_i + \beta_i LFEC_CP_{it} + u_{it} \quad (2)$$

where $i = 1, \dots, N$, is the index of a country in the panel, $t = 1, \dots, T$, refers to the time period, while $LGDP_{it}$, $LGDP_CP_{it}$, $LFEC_{it}$ and $LFEC_CP_{it}$represent natural logarithms of real GDP and GDP/capita, and FEC and FEC/capita for the country i at the time t, respectively. The terms α_i, β_i are unknown parameters to be estimated, whileu_{it}, are the error terms (assumed to be independent and identically distributed with a zero mean and a constant variance, for each i).

Variables in natural logarithms can be interpreted in growth rate after taking the first difference into account.

The above theoretical models will be estimated using panel data techniques, with the aid of EViews 9 software product.

The analysis of the regression model is performed in four steps. Firstly, two different unit root tests are used to investigate whether the variables are stationary or not and the order of integration of the variables. We used Augmented Dickey-Fuller (ADF) (Dickey, Fuller 1981) and the Phillips-Perron (PP) (Phillips, Perron 1988) test to this purpose. Secondly, when all of the series are found to be integrated of the same order, we test the co-integration relationship between the variables in Eq. (1) and Eq. (2) using the Johansen maximum likelihood method (Johansen, Juselius 1990) and Pedroni cointegration test (Pedroni 2004). The existence of cointegration indicates that there are long-run equilibrium relationships among the variables, and thereby, Granger causality exists among them in at least one direction (Engle, Granger 1987).

Next, the parameter estimates for the regression equations (1) and (2) are evaluated using the fully modified least square (FMOLS) regression method (Phillips, Hansen 1990). This cointegration equation can work with variables that are stationary at different levels. An analysis of the estimations error using the Jarque and Bera test (Jarque, Bera 1980) for normality is also performed. Finally, the Granger causality test (Granger 1969) is used to find unidirectional or bidirectional causalities between the GDP and FEC.

Empirical Findings and Results

Statistical analysis of data

To empirical analysis is based on series of FEC and GDP (nominal and per capita) data on a panel of 28 countries of UE during the 2006-2016 period.

From Eurostat's data on nominal GDP in trillion euro for the analyzed period, it is observed that at the level of the EU states, the GDP has grown with a relatively constant year-on-year rate for the EU founding states, and the new entrants in EU marked a sustained and robust growth of over 70% in 2016 over 2006 (Malta 83.67%, Slovakia 77.82%, Bulgaria 74.05% and Romania 72.30%). The only country whose GDP declined steadily by 2015 was Greece, but there is a slight increase in 2016 (0.11%) compared 2015. The increase was due to the governments' commitments of these countries to realize a stable monetary policies, of trade policies (export-oriented), low rates of fixed tax and the use relatively cheap labor.

To assess living standards, we analyzed GDP per capita of EU countries and found a major difference between countries. Thus, Luxembourg has the highest GDP per capita (largely due to cross-border workers in Belgium, France and Germany), followed by Ireland, Denmark, Sweden, the Netherlands and Austria (with a GDP of more than 40000 euro per capita). In the other side of the list are Romania (~ 8000 euro/capita) and Bulgaria (~ 6000 euro/capita) who occupy the last places, followed by Croatia, Hungary and Poland with a GDP/capita of less than 12000 euro/ capita, then Latvia, Lithuania and Slovakia with up to 15000 euro/capita.

After analyzing the FEC at nominal values, expressed in thousands of tonnes of oil equivalent TOE, using Eurostat data, we found as energy consumption it remained relatively unchanged between 2006 and 2008, then FEC decreased by 5.8% in 2009 due to predominantly economic and financial global crisis. FEC level in the EU-28 in 2015 is lower than in 2006 in all countries except Malta and Poland. FEC per capita for countries studied also shows a year-on-year decline. Finland has the highest average per capita consumption (around 16,000 kwh), followed by Sweden (around 14,000 kWh) and Luxembourg (around 12,000 kwh). The largest increase in FEC/capita was registered by Malta 46.46%, followed by Poland 23.68%, Czech Republic 16.12% and Estonia 13.44%. FEC/capita had the largest decline in Greece (25.33%), Ireland (24.19%) and Hungary (22.23%).

In table 1 we presents descriptive statistics of the GDP and FEC (nominal and per capita) series for each country. The GDP and FEC series data follow a normal distribution for all countries. Germany has a GDP that is higher than the regional average at 2716.87 billion euro with a standard deviation of 330,925.9. In contrast, Malta has an average GDP in market prices 7.2 billion euro. This is the lowest figure amongst all the countries, with a standard deviation of 1.464513. The largest average of GDP per capita is held by Luxembourg with 79792 euro/capita, with over 200% compared to the European average, and the lowest value is recorded by Bulgaria with 5389 euro/capita. Distribution shows positive asymmetry at all states, which means that during the analysed period, GDP had a trend of growth, and kurtosis has a value less than 3 in all countries, i.e. the distribution is flatter than the normal curve (platykurtic), except for Croatia, Czech Republic, Ireland Slovenia and Slovakia which has a sharper distribution than the normal curve (leptokurtic).

In terms of FEC, all EU countries have a normal distribution, the average of consumption in nominal values is highest in Germany (213622.8 TOE) and the smallest in Malta (485.52 TOE). At FEC/capita, the highest average holds Finland (15922.76 kwh) well above the EU average (6344.48 kwh) and Lithuania has the lowest value (2896.66 kwh). The distribution shows a slight positive asymmetry in all states, being a platykurtic distribution.

Testing causality between GDP and FEC (nominal and per capita)

a. Results of unit roots tests

The time series properties of the variables in Eq. (1) are evaluated through two different unit root tests, namely ADF and PP. We find that for most of the countries the four time series are stationary in their first difference, at least at 10% level (table 2).

Table 2: Results of the unit roots tests, 2006-2016 Variables LGDP and LFEC

Figure 1: The critical values for ADF and PP tests

We proceed analogously, to make the tests for Eq. (2). According to the results, for some countries, namely, Cyprus and Portugal, the null hypothesis of the existence of a unit root cannot be rejected at level and first difference both to FEC, FEC/capita and GDP, GDP/capita. The null hypothesis of the existence of a unit root cannot be rejected at level and first difference for GDP series at Ireland, Estonia and United Kingdom.

In the next step we test whether the variables in Eq. (1) and Eq.(2) are cointegrated. The results for the Johansen test for each cross-section we performed are indicating the existence of a cointegrated relation between GDP and FEC at the 5% significance level.

b. Estimation of regression parameters in Eq. (1) and Eq. (2)

The parameter estimates for Eq. (1) are reported in Table 3.

Note: Figures in parenthesis indicate the p-values of the t-statistic.

The results of the test in Table 3 show that the coefficients determined for linear regression in eq1 are not significant in most countries, therefore this regression model is not relevant to the impact of final energy consumption on GDP. Analogously we found the same thing for eq. (2).

Estimation of regression parameters in Eq. (1) show that the coefficients determined for this linear regression are significant on the 5% level for Bulgaria, Czech Republic, Denmark, Luxemburg, Malta, Romania and Slovakia. So, for these countries this regression model is relevant for the impact of final energy consumption on real GDP. In eq. (2) the coefficients determined for this linear regression are significant on the 5% level for Austria, Denmark and

Luxembourg, and for these countries this regression model is relevant for the impact of final energy consumption per capita on GDP per capita.
The model properties were evaluated using the Jarque and Bera test for normality of the errors. Analyzing the values of the estimated regression coefficients $\hat{\beta}_i$ corresponding to the variable $LFEC_i$ and $LFEC_CP_i$ we note that:

- all coefficients $\hat{\beta}_i$ are negative, indicating a unfavorable impact of final energy consumation on economic growth;
- these coefficients are smaller than 1, indicating that the impact of final energy consumption on economic growth is not very significant.

c. Granger causality test

In table 4 below the results of the Granger causality test between variables LGDP and LFEC are presented.

Table4: Granger causality test between variables LGDP and LFEC

Country	Null hypothesis 1			Null hypothesis 2		
	L_FEC does not Granger-cause L_GDP			L_GDP does not Granger-cause L_FEC

Note: * Denotes that the null hypothesis is accepted at 0.10 level.

The conclusions emphasized within this table have the following significance:

- "Accept" - means that the null hypothesis is accepted, that is the left variable does not Granger-cause the right corresponding variable;
- "Reject" - means that the null hypothesis is rejected, that is the left variable does Granger-cause the right variable.

Both the results of the standard Granger LGDP and LFEC, and LGDP/capita and LFEC/capita causality tests show that there is no causal relationship between FEC and GDP (nominal and per capita) for the period 2006-2016. An analysis over a longer period 1995-2016 shows that there is bidirectional Granger causality FEC↔ GDP for 12 countries in the panel, namely Czech Republic, Ireland, Greece, Croatia, Cyprus, Lithuania, Luxembourg, Netherlands, Austria, Poland, Slovakia, Finland;

- unidirectional Granger causality FEC → GDP for 11 countries, namely Belgium, Denmark, Estonia, Spain, France, Italy, Hungary, Portugal, Romania, Slovenia, Sweden;
- unidirectional Granger causality GDP → FEC for 4 countries, namely Bulgaria, Denmark, Latvia, United Kingdom;
- no Granger causality for Malta.

Conclusion

This paper aimed to extend the research on the causal relationship between economic growth and final energy consumption using a panel of data for 28 countries of European Union over a period from 2006 to 2016.

Motivated by EU Directive of decrease of final energy consumption by 2020, we did statistical analysis of final energy consumption within the data panel.

The empirical results showed a positive impact, although statistical small, of energy consumption on economic growth. Also, causalities were not found between GDP and FEC macroeconomics indicators. For emerging countries there is a large gap between nominal GDP and PPP, but at the level of advanced countries the difference is much lower.

By means of linear regression, a decreasing trend was found for the between final energy consumption to all EU countries but less for emerging countries. However, in developing countries we still have the potential to increase final energy consumption that may (be) leads to GDP growth, and positive shocks in GDP/capita that cause positive shocks in final energy consumption. The causal link is greater for developing countries then any restraint on energy consumption will have a bigger effect on these countries compared to the more affluent industrialized countries. In this case it could be argued that any reduction in energy consumption should predominantly be undertaken by the developed world so as not to inhibit the development of the less developed nations.

The lack of causal relationship between GDP and FEC for the past 11 years can be considered as a positive element, because in the context of global warming debates, lower energy consumption involves reducing greenhouse gas emissions, but does not mean a drop of living standards, but on the contrary by using low energy-consuming modern technologies, economic growth and, implicitly, raising the standard of living can be recorded.

Abstract

Credit risk is considered as one of the important issues for financial institutions. It provokes great losses for banks. To this objective, numerous methods for credit risk evaluation have been proposed. Many evaluation methods are black box models that cannot adequately reveal information hidden in the data. However, several works have focused on building transparent rules-based models. For credit risk assessment, generated rules must be not only highly accurate, but also highly interpretable. In this paper, we aim to build both, an accurate and transparent credit risk evaluation model which proposes a set of classification rules. In fact, we consider the credit risk evaluation as an optimization problem which uses a genetic programming (GP) algorithm, where the goal is to maximize the accuracy of generated rules. We evaluate our proposed approach on the base of German and Australian credit datasets. We compared our finding with some existing works; the result shows that the proposed GP outperforms the other models.

Keywords: Credit risk assessment, rule generation, genetic programming, feature selection.

1. Introduction

Nowadays, risk management is the most important issue in the financial institution. High-quality risk management allows banks to build a robust decision-making system and to reduce losses. In fact, banks are exposed to various types of risk such as credit risk, liquidity risk, market risk, interest rate risk, etc. (Rose, 2002). According to Basel Committee on Banking Supervision Basel II (Basilea, 2006), banking risk is measured considering three types of risks: credit risk, market risk and operational risk.

Therefore, the credit risk has become an important and widely studied topic in banking field (Angelini et al., 2008; Nazari and Alidadi, 2013; Wang, 2013). It presents the largest risk facing banks. According to (Buehler et al., 2008), credit risk represents 60% of the overall risk that banks face. Hence, many researchers have focused on defining and developing a credit risk measurement and management systems. In this way, the credit risk evaluation has gained increasing attention and has been very considerable (Akkoç, 2012; Danenas et al., 2011; Finlay, 2011). However, most of the existing works about credit evaluation relies on applicants' classification (Hens and Tiwari, 2012; Lee et al., 2006;

Oreski and Oreski, 2014a). In fact, it is the task to classify applicants into two classes: "good applicant" or "bad applicant". In this context, credit scoring is considered as the most popular model used for credit risk management (Marzal and Jiménez, 2012).

Recent research has focused on increasing the accuracy of credit risk evaluation model. To fulfill this aim, many classification techniques are used for building accurate models that can be grouped into three categories, i.e. statistical techniques, artificial intelligence techniques and hybrid techniques. While the most statistical techniques used for the credit risk assessment are the discriminant analysis and logistic regression (Malhotra and Malhotra, 2003), many others artificial intelligence techniques such as support vector machine (SVM), neural network (NN), genetic algorithm (GA), and decision tree (DT) have been widely used in credit risk evaluation (Bellotti and Crook, 2009; Hens and Tiwari, 2012; Yang, 2007). In recent years, an important number of effective hybrid techniques have been also proposed (Oreski and Oreski, 2014a; Šušteršič et al., 2009). However, there is no consensus about the most optimal technique which can be used in building credit evaluation models. In spite, numerous methods of evaluating credit risk have been successfully applied to the classification of applicants; most current assessment methods are black box models. Although the black box patterns expression can provide an accurate knowledge of data but they are effectively incomprehensible. In contrast to transparent box expression whose provides understandable and easy interpretable patterns.

For this aim, credit risk assessment has been conducted using several proposed rules-based techniques (Hayashi, 2016; Martens et al., 2010) called also induction-based techniques (Huang et al., 2006). The reason why rules-based techniques remain popular is that they are able to extract practical knowledge from a given datasets and transform it into usable and understandable information. A useful credit risk assessment model is a model that can achieve a good balance between accuracy and comprehensibility (Bock, 2017; Hayashi, 2016). Therefore, using rules allows financial institutions and experts to generate transparent decision model which is capable of classifying and evaluating easily new applicants.

Credit risk evaluation is mainly based on various historical data such as the amount and duration of credit, customer credit history, the purpose of the loan, etc. which is associated with real-world datasets. But, there is no consensus about data or indicators that should be used to classify customers. For credit risk evaluation, it is important to use all existing data in the real-world datasets to enhance accuracy. Therefore, refining these data is considered as a crucial phase which allows eliminating irrelevant data in training dataset, and, it is required to select the most significant data to increase the accuracy of proposed evaluation model. In this context, many research studied consider feature selection processes as optimization problem. For instance, (Oreski and Oreski, 2014b) highlighted the importance of feature selection to build an accurate and scalable credit risk evaluation model. In fact, feature selection aims to select the most relevant attributes for determining the default risk. It allows reducing the search space and increasing the accuracy of generated rules. Thus, (Oreski and Oreski, 2014b) reported that feature selection is the important key to create sophisticated credit risk detection method. To this end, they proposed the hybrid feature selection heuristic (HGA-NN) to address this issue.

In this context, the goal of our proposal is to generate classification rules based on genetic programming algorithm to evaluate automatically the customers' banks. The GP has been widely used for classification problems (Z-Flores et al., 2015). In addition, it's considered one of the most recent techniques that have been applied in the field of credit risk assessment. Unlike the traditional statistical methods such as the logistic regression and the discriminant analysis which need the assumptions of the dataset and the attributes, the GP is a non-parametric tool and can adaptable for different datasets. In fact, we consider the rule generation process as an optimization problem where the goal is to maximize the accuracy of the proposed model. Thus, we will focus on this work to increase the accuracy of classification rules generated from the GP. In fact, we suggested that well accuracy is obtained by generating a set of rules that combining the most relevant and important user's characteristics for making decision.

The remainder of this paper is organized as follows: Section II will review some related work on GP technique applied to the credit risk assessment problem. Section III will represent the research methodology. Section IV will highlight the experimental setup. Section V will report the results of the empirical analysis. Finally, section VI will draw the conclusion and future directions of research.

2. Related work

Recently, several researchers have applied genetic programming (GP) or genetic algorithm (GA) models for credit risk assessment, because of its high capabilities in solving different complex problem. Furthermore, the GP and the GA algorithms have been the most widely used in the field of credit scoring (Marqués et al., 2013).

Therefore, one of the widely used methods to evaluate customer credit is the function-based approach. In this way, (Ong et al., 2005) presented the GP in the analysis of credit scoring models. The experimental results showed that GP algorithm achieved the highest accuracy compared with neural networks, decisions trees, rough sets and logistic regression. (Cai et al., 2009) applied also the genetic algorithm to solve credit scoring problems. The experiments over the German dataset prove the effectiveness of the new model. Moreover, (Abdou, 2009) investigated the ability of GP in the analysis of credit scoring models in Egyptian public sector banks. The experimental results showed that GP algorithm achieved the highest accuracy rate and the lowest misclassification cost compared with probit analysis and weight of evidence models. All these studies used the GA and the GP to find a discriminate equation which takes into account the values of both good and bad customers in the training set. However, the main problem of these methods is commonly described as opaque structure because they generate complex mathematical internal works which are hard for human interpretation. To this end, the induction-based approach has become a popular technique for evaluating credit risk because the result is easily interpretable, visualized and facilitate the construction of risk detection models.

In this way, (Huang et al., 2006) proposed two-stage genetic programming (2SGP) for building credit scoring model based on IF-THEN rules. They reported that this type of model able to provide intelligent decision-making systems easily understandable by users. In This study they suggested the use of GP due to its ability for extracting automatically and heuristically IF-THEN rules based on specific fitness function that validate simultaneously the referred objective. In addition GP can perform well with small or big data and it is able to manipulate any type of data. The accuracy of the model was compared with GP, MLP, Classification and regression tree (CART), C4.5 algorithm, rough sets and LR using the two datasets: German and Australian datasets. They reported that 2SGP can obtain better classification accuracy compared with the other models. Furthermore, (Zhang et al., 2008) developed a hybrid credit scoring model based on GP and SVM. In the first stage, GP is employed to derive the IF-THEN rules. Then, the remaining dataset which does not satisfy any rules or satisfy more than one rule is used to train SVM and build the discriminant function. The result showed that this method provides superior accuracy compared to other models (support vector machine, genetic programming, Decision tree classifiers, Logistic regression and Back-propagation Neural network). In addition, (Tran et al., 2016) build a robust credit model in which they combine the deep learning and the genetic programming algorithm. In this paper, the GP is employed to generate the IF-THEN rules. All research works mentioned above proposed a hybrid model based on genetic programming which used to drive the IF-THEN rules. Still, the hybrid techniques are difficult to formulate and implement than simple methods because more than one classifier are used. Also, the extraction of rules from black box model can minimize the accuracy. To this end, our contribution aims to generate automatically a comprehensible classification rules for credit risk evaluation based only on GP that allows the coverage of the most of the creditor's characteristics. We suggested generating simultaneously the accurate and comprehensible rules that combine only the most relevant data for credit risk assessment.

3. Credit Risk Evaluation Approach

In this research, credit risk will be evaluated as an evolutionary problem with two real-world datasets. In fact, we propose a search-based approach using genetic programming algorithm to generate automatically classification rules. Our approach consists of using knowledge from previously manually collected examples. We use the GP to generate classification rules. In fact, GP allows us to generate randomly, from a given dataset, a combination of customer's characteristics for each class type. The final goal of our approach thus is to generate the best classification rules among all possible rules that maximize the accuracy. Maximizing the accuracy achieved by generating rules that combines the most relevant attributes for determining the default risk. The rule generation process so aims to find a good combination of the characteristics which have the high weight.

As showed in Fig 1, rule generation process takes as inputs datasets of credits and generates as output a set of classification rules. During the rule generation process, our approach combines randomly the characteristics of customer within logical expressions (intersection AND) to create rules. A fitness function calculates the weight of each rule using the instances from datasets.

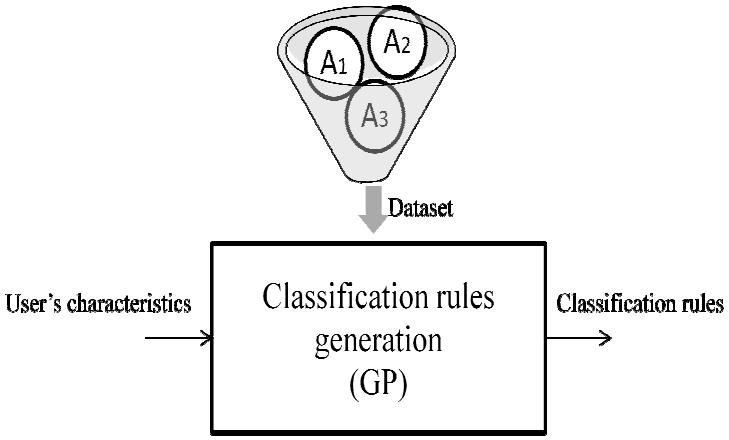

Fig. 1: The proposed approach overview.

The pseudo code for the algorithm is given in Fig 2. The algorithm takes as input set of customer's characteristics and datasets of credits. Lines 1–3 construct an initial GP population which is a set of the individual that define possible classification rules. Lines 4–13 encode the main GP loop, which searches for the best classification rule. During each iteration, the quality of each individual is evaluated, and the solution having the best fitness (line 9) is saved. Then, a new population of solutions is generated using the crossover operator (line 10) to the selected solutions; each pair of parent solutions produces two new solutions. We include the parent and child variants in the population and then apply the mutation operator to each variant; this will provide the population for the next generation. Steps 4 to 12 are performed repeatedly until maximum iteration is fulfilled. The output of the algorithm is the set of best extracted classification rules.

Classification rules generation

- *Creation of Initial population:*

We aim to assess credit risk based on historical data. To this end, we propose to generate classification rules which will be used to predict risks. In our work, an individual is a set of IF – THEN rules. The IF clause (premise) corresponds to the condition that combining user's characteristic. THEN clause corresponds to the type of detected class. This kind of rules representation has the advantage of being intuitively comprehensible for the user. A classification rule has the following structure:

IF "Combination of customer's characteristic" THEN "Class of customer"

This step takes as input customer's characteristics (checking account, purpose, guarantor, saving account, etc.), and class type (good or bad) and generates, as output, a random initial population from a possible combination of customer's characteristics. Our solution is modeled as a tree representation, when, the terminals (leafs nodes of a tree) correspond to different customer's characteristics with their threshold values. Fig. 3 represents an example of individual (solution) represented as a tree. This representation corresponds to an OR composition of three sub-trees, each sub-tree represents a rule:

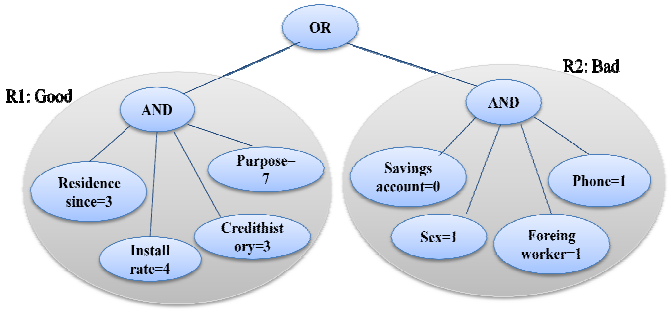

Fig.3: A tree representation of an individual

- *Genetic operator*

To better explore the search space, we use this three genetic operator: crossover, mutation, and selection:

Crossover: this operator aims of generating offspring. To this end, the proposed algorithm starts by selecting randomly two parents. These parents will be split into two sub-tree. After that, they are combined to generate two new individuals (offspring). Each child combines information coming from both parents. An example of crossover process is shown in Fig 4.

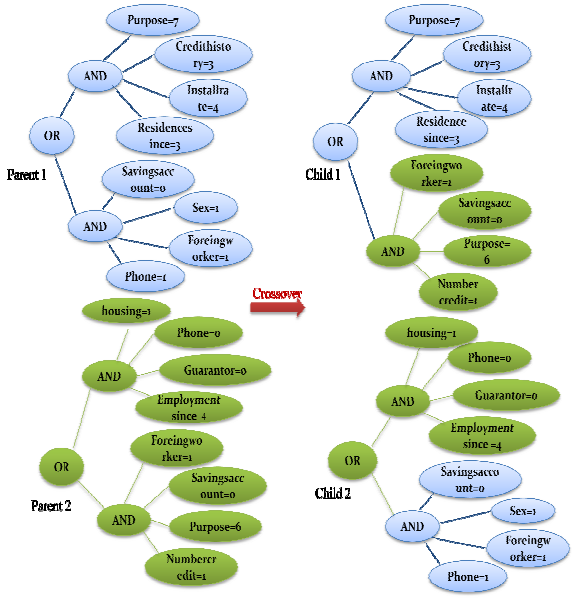

Fig. 4: Crossover operator

Mutation: Normally, after crossover has occurred, each child produced by the crossover undergoes mutation with a low probability. This phase consists of changing randomly one or more rules in the solution. The modification of rule aims to change randomly the value of customer characteristic. Fig. 5 shows a new solution derived from the one of Fig. 4.

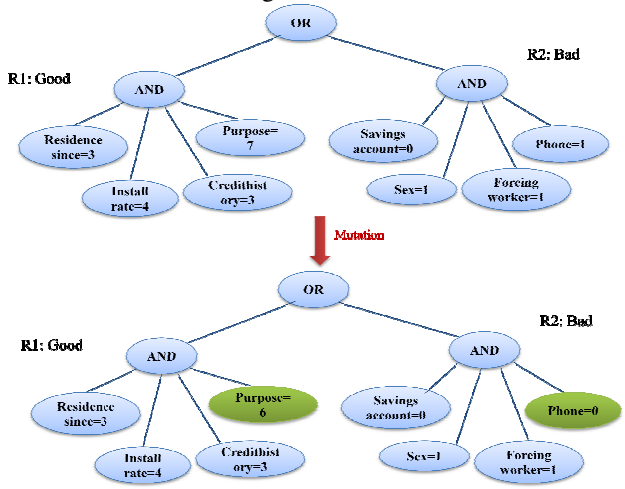

Fig. 5: **Mutation operator**

Selection: In this phase, the set of solution that will participate in the crossover and mutation operators are selected. Two parents (individuals) are selected from the initial population. Thus, proposed algorithm use binary tournament selection to guide the selection process. In fact, this step aims to select the best individuals to be reproduced in the child population.

- *Evaluation of individuals of the initial population:*

In this step, we evaluate the generated solutions of the initial population (Pt) in order to estimate and discover the interesting classification rules. In fact, generated individual should be validating with a fitness function that quantifies the quality of generated rules. So, it is crucial to use an efficient and performant fitness function in order to reduce computational complexity and maximize the accuracy. This evaluation is based on the calculation of the fitness function Weight given in equation (1) which will evaluate the weight of classification rules. It aims to generate a set of best rules that can be used in the decision process to classify new customer. The idea is to improve the accuracy of classification rules by maximizing the weight. Weight function aims to select validate rules that combining characteristics with high weight of evidence (WOE) (using the information values).

$$Weight = \frac{\sum WOE\ of characteritics}{number of characteristics\ of\ rules} \qquad (1)$$

We suggested integrating the feature selection in the rules generation process. In fact, the problem of credit risk evaluation has high dimensionality due to the high number of input features and the high number of examples. However, the irrelevant and redundant features in the training set can produce less accurate results. Therefore, using the appropriate set of features is an important issue. According to (Fayyad et al., 1996), the selection of relevant features is defined as a preprocessing step of knowledge discovery. It is applied to enhance the performance of generated evaluation model. It is an important step to find out the best subset of attributes and to improve the prediction accuracy of the genetic programming classifier. Moreover, it aims to remove redundant and irrelevant features and reduce the amount of data needed for learning. This reduction facilitates the understanding of the data and increases the interpretability of the models (Oreski and Oreski, 2014b).

In this study, the selected feature was performed by the weight of evidence method (WOE). According to (Weed, 2005), the WOE is a quantitative method used in the context of risk assessment. It provides weight to each attribute and also determines variable importance ranking and gains data (Abdou, 2009). It is a standard pre-processing technique applied to credit risk assessment problem (Finlay, 2011). The weight of evidence is then defined as the logarithm of the fraction of the proportion of 'goods' in the attribute among the proportion of 'bads' in the attribute. Each attributes can has positive or negative weight. High negative weight, therefore, correspond to high risk while high positives weight correspond to low risk. The WOE of an attribute is expressed in the following equation (2):

$$\mathrm{WOE} = \ln\left(\frac{g_i/G}{b_i/B}\right) \qquad (2)$$

Where: G and B represent the total number of good and bad observation, respectively, gi and bi are the number of goods and bads within the attribute i. The use of WOE as a technique for ranking the importance of variables allows us to find those variables that are more significant in determining the risk of default, which is helpful to eliminate the ineffective applicant's variables. In our work, the generation of classification rules is based on the weight of features. In addition, the variable with greater value means that is able to predict the most accurate results.

4. Experimental Setup

Description of the experimental datasets

The performance of the proposed GP classifier is evaluated using two published credit datasets: German and Australian credit datasets. These two credit datasets used in this work were obtained from the university of California, Irvine (UCI) Machine Learning Repository (see www.ics.uci.edu/mlearn/ MLRepository.html). A summary of the main characteristics of these two datasets has been presented in the following table.

Table 1: characteristics of two real datasets

Name	Instance	Predictive Attributes	Good credit	Bad Credit	No of classes
German credit	1000	20	700	300	2
Australian credit	690	14	303	387	2

German and Australian datasets are randomly partitioned into two parts, training set and testing set. In this study, 70% of the data are used for training and the remaining 30% are exclusively used to evaluate the performance of the model.

Evaluation criteria

Different evaluation criteria are used to verify the effectiveness and the feasibility of the proposed technique for credit risk assessment include, accuracy, error rate, Gini coefficient, kolmogorov-Smirnov statistic, mean squared error, area under the ROC curve (AUC) and type I and type II errors. Among all these standard evaluation criteria, AUC, accuracy, type I and type II errors are the most commonly used measures to evaluate classification performance [13]. The definition of these metrics can be explained with respect to a 2×2 confusion matrix as that given in the following table:

Table 2: A confusion matrix

	Predicted class (%)	
Actual class (%)	Good credit	Bad credit
Good credit	TP	FN (Type II error)
Bad credit	FP (Type I error)	TN

Most credit risk assessment studies employ the accuracy as the criterion for performance evaluation. It indicates the proportion of correctly classified instances (both good and bad applicants) on a particular dataset. The accuracy can be defined by equation (3):

$$\text{accuracy} = \frac{\text{TP} + \text{TN}}{\text{TP} + \text{FP} + \text{FN} + \text{TN}} \qquad (3)$$

5. Empirical Analysis

Our study addresses two main experiments, which are defined below. In this section, we explain how we designed these two experiments. The goal of the study is to evaluate the performance of our proposed method in terms of its AUC, accuracy, and error rate for generating classification rules.

Experiment 1: GP performance

To emphasize on the necessity of using an evolutionary technique, we empirically experiment the performance of GP when randomly generating a classification rules. During the rules generation process, we combined customer's characteristics randomly within logical expressions (intersection AND) to create rules. Where, the number n of possible combinations is very large. This process consists of finding a good combination between "c" customer's characteristics. In addition, each customer's characteristics can take different attributes; thus a huge number of rules can be generated. Moreover, each class can be defined using several symptoms. There is no definition or consensus about how to classify the customer as bad or good. Consequently, to ensure the scalability of our solution, we considered the rule generation process as a combinatorial optimization problem.

First, we need to set out GP parameter because it influences significantly the performance of a search algorithms on a given search problem. It is usually difficult to preemptively set the best tuning setting. To this end, we use the trial and error method in order to obtain a good parameter configuration. Table 3 shows the important setting parameters.

Table 3: the parameter setting of GP

Parameter	Value
Population size	100
Number of generation	100
Fitness function	Equation (2)
Selection	Tournament selection
Crossover rate	0.9
Mutation rate	1

To study the impact of using weight of each characteristic attribute, we run the process of generating rules using only a simple function (Quality) which aims to validate the generated individual by comparison to the expected ones in the dataset, and then we measure average coverage score of the execution of the generated rules on our system. Then, we run the process of generating rules using Weight function and we report the evolution of their relative coverage scores over the two datasets in the Fig 5.

The results of Fig.6 demonstrates that using Weight function increase the median fitness function of the last generation of the algorithm. Thus, the use of Weight function helps the algorithm in better exploring the search space and generates near-optimal solutions. Weight function aims to capture the relevant attributes that enhance accuracy and so achieve better coverage.

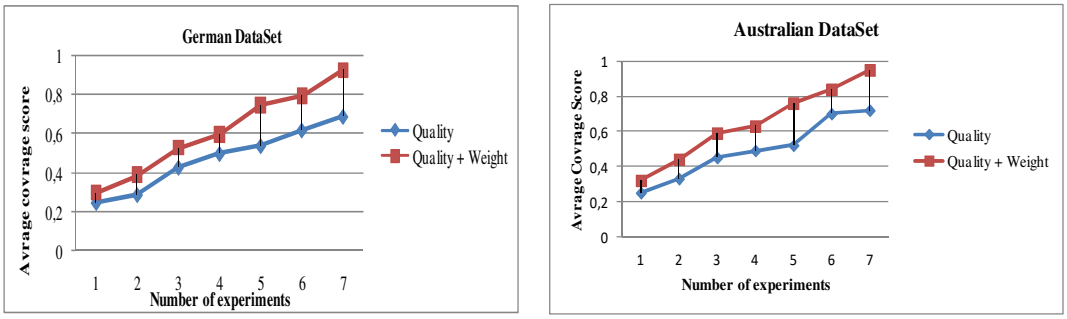

Fig. 6: Average Coverage Score of Quality and Weight.

Hypothesis: given a specific rules set generation, the accuracy of these rules set is strongly correlated with their weight.

We performed the Pearson correlation test and the t-test for accuracy and weight, at a significance level of 0.01, based on the last generation of 31 independent run and the testing set of German and Australian credit dataset in order to test the aforementioned hypothesis. Table 4 shows the results of the Pearson correlation test (R) and t-test for the values of accuracy and weight. The result shows that there is a strong correlation between accuracy and weight (0.942). Thus, we can confirm that our fitness function is effectives to validate the generated rules. So, our suggested model is able to generate accurate and interesting rules which help financial institutions for making decision. To this end, we can accept our hypothesis. According to the finding results, we can conclude that using weight as fitness function allows generating comprehensible rules and enhancing the accuracy of this proposed model. Therefore, our findings confirm the effectiveness of our credit risk assessment models.

Table 4: The Pearson correlation test and t-test between accuracy and weight

	Weight		
	R	**p-val.**	**t-test**
Accuracy	0.942	0. 328	-0.8997

Experiment 2: Comparative study

At the present, several data mining techniques such as support vector machine, genetic programming, genetic algorithm and neural network have been successfully applied to credit risk assessment, and they usually have good prediction accuracy. Therefore, to estimate the efficiency and the performance of the proposed GP algorithm, we compare its accuracy and its error rate with the accuracy and the error rate of the existing techniques in the literature.

Table 5: The comparison of the accuracy of different models for the two credit datasets

Algorithm	German credit (%)	Australian credit (%)
GP	93	95.6
SVM+GA (Hens and Tiwari, 2012)	77.92	84.05
GP+SVM (Zhang et al., n.d.)	79.88	89.45
HGA+NN (Oreski and Oreski, 2014b)	78.10	73.4
GP (Huang et al., n.d.)	75.5	85.5
2SGP (Huang et al., 2006)	83.1	78

Table 5 compares the accuracy results of our proposed GP with other existing techniques on the German and Australian datasets.

As can be seen, the GP has the highest accuracy value 93% for the German credit, followed by 2SGP with 83.1% and GP+SVM with 79.88%. Also, GP outperforms all the other techniques with accuracy 95.6% for the Australian credit dataset. Therefore, we conclude that the GP extraction rule outperform all other techniques for the two datasets in terms of accuracy rate. As a result, we can conclude that the proposed GP technique is a feasible solution to improve the accuracy and comprihensibilty of credit risk evaluation

6. Conclusion and Future Works

In this paper, we propose to generate classification rules based on GP to tackle customer credit risk assessment. We aim to propose a comprehensible evaluation model based on IF-THEN rules and to maximize the performance of the generated classification rules. The performance of our proposal is evaluated using the Germany and Australian credit datasets and compared with various techniques that exist in the literature. According to experimental results, our proposed model outperforms existing methods and the rule sets generated from the GP provides the best accuracy rate. Several directions for further research have emerged from this study:(i) to apply a multi-objective where many others objectives should be satisfied (ii) to use different credit datasets with different sizes and attributes for extra validation.

Abstract

The trade theory seeks to identify the variables determining international exchange between countries. In recent years, variables not traditionally considered in traditional models, such as geographic location, the cost of transport, and cultural and institutional factors have emerged as important explanatory variables, and therefore need to be incorporated in the analysis. In order to make new contributions, this paper contains an extended business gravity model with panel data and random effects that combine institutional, economic and cultural changes as one of the determinants of bilateral flows between the country of origin (Germany) and its trade partners (Latin-American region) during the period 1995-2011, through the use of different aggregate indicators, incorporated as explanatory variables in different design specifications. The main objective of this research is to analyze the determinants of trade between Germany and Latin America with an extended/modified model of trade where the economic characteristics of countries are combined with the institutional and policy factors of trade, such as trade agreements. The strong determinants of international trade between Germany and Latin America are free trade agreements, property rights index and corruption index.

Keywords: Gravity model, International Trade, Institutions, Free Trade Agreements, Economic and Political factors.

Introduction

This study analyses how economic and institutional factors influenced Latin American trade with Germany and vice versa. The estimated behavioral parameters and break-even points of robustness will be used for the analysis of policies and institutional factors of trade (exports and imports). Five econometric approaches are used to estimate the gravity equation. Total of 17 Latin American countries[1] were selected as a sample for a more detailed analysis of trade flows between this region and Germany. The quality of institutions is an important element in the smooth functioning of a market. On this basis, we can explore this research topic: If the institutions are more developed and business oriented the firms' transaction costs will be lower which makes the efficiency of international trade as a whole greater.

De Groot et al. (2003) highlights the positive correlation between trade and institutional quality, and with the help of a gravity model, the author shows how the similarities between countries tend to increase bilateral trade between them. Other authors associate the institutional factors with the country risk rating, which could affects the investments in the countries Popa, S., (2012). About the institutions and how state's sovereign rights (as traditionally understood) could represents a

significant barriers wrote Padmanabhan (2012) and the impact of International Agreements can have on foreign direct investment (FDI) flows.

This paper will analyze the development of trade during the period 1995-2011 of Germany. It designs five gravity models with variables dealing with economic environment, institutional infrastructure, Free Trade Agreements, and political factors. The main objective of this research is to analyze the determinants of trade between Germany and Latin America. Also, the objective of this research will be the contribution of new insights into the trade flow mechanisms of these countries based on an econometric model and its comparison. The first section of this work reviews the literature, which illustrates the links between institutional factors and trade concerns. The second section describes the characteristics of the gravity model, the methodology and data sources used. The third section summarizes the methodological specifications of the research, and the last section contains the results of this research.

Theoretical Background

Jan Tinbergen, the first Nobel laureate in economics, was one of the pioneers in the application of mathematical tools in economics. He was the first economist to use the concepts based on the law of universal gravitation, developed by Newton in the field of physics. He applies it to economy, specifically for the determinants of trade flows between the countries, in his 1962 work *Shaping the World Economy*. In this work (1962), he states that the trade volume increases between two countries (or regions) with the size of their economies and decreases with the distance that separates them. The gravity model is used to estimate the structure of international trade. The basic model consists of factors related to geography and spatiality. It was subsequently expanded and used to test hypotheses about economic theories of international trade. We will use the gravity model as an empirical way to analyze the determinants of trade flows between different geographical entities.

The empirical strength of this model is well known for its ability to identify extreme cases of artificial trade barriers, as well as the role of distance and the effects of the customs unions and commercial agreement between different geographical regions. Norman Aitken (1973) used the gravity model to analyze the impact of different trade policies between different geographical entities. This econometric model has been applied to different areas such as the analysis of foreign direct investment, tourism and migration, among others. Aitken (1973), along with several others; Bergstrand (1985) and Thursby & Thursby (1987), was part of a series of economists who were all commissioned to show that European trade blocs had increased their trade during the 1960s and 70s.

Helpman and Krugman, P. (1985) also completed the gravity model using explanations based on the Heckscher - Ohlin Model and their new international trade theory. With the theory of Geography and International Trade, Paul Krugman (1991) affirmed that the dominant factor used to explain a concentration of trade is geographic proximity between trading partners. The distance can represent the geographic proximity when inserted as a significant parameter in the gravity equation (Anderson 1979, Anderson 2003, Anderson and Wincoop 2011).

Subsequent work by Frankl & Weiss (1993), Frankel et al. (2005) and Frankel (1997) found evidence of trade creation between trading blocs in Asia and North America from 1970-1992, while the Soloaga & Winters study (2001) found significant evidence of trade creation in Latin America during the nineties. The work of Rose (2000), Feenstra et al. (2001), and Frankel and Rose (2002) found, too, that the agreements are, in general, trade makers. Rose (2002) explains the effects of multilateral trade agreements, added variables such as culture, common language, geography and history; in conclusion, it is possible to say that the World Trade Organization (WTO) and the Agreement General Agreement on Tariffs and Trade (GATT).

Current research in Latin America is oriented at dynamic gravity models and different approaches to measuring the distance variable. Lewer and Saenz, M. (2004) analyze the equity release EFET on trade flow through a gravity model extended to 20 countries in Latin America. Acosta et al. (2006) show the relevance of the preferential trade agreement in the Andean Community of Nations, as well as the importance of geography and infrastructure as key elements in the development of trade

between these countries. Martínez-Zarzoso and Nowak-Lehmann (2003) analyzed MERCOSUR sectoral exports to the EU: the role of economic and geographical distance by gravity model, while Martínez-Zarzoso (2003) applied the gravity trade model to assess Mercosur - European Union trade and the trade potential following agreements recently reached between the trade blocks. The model tested a sample of 19 countries. Carrillo and Li (2002) discussed the importance of preferential trade agreements in Latin American trade, referencing the Andean Community and the Southern Common Market (Mercosur). The study of international trade in Latin America through the use of the gravity model has proven to be an efficient tool for analyzing regional trade. However, a lack of continuity can be observed.

Traditional gravity models analyze the trade rigidity by incorporating the distance into the equation. Clearly transport costs are related to distance, but this dependence might not be linear. Babeckii, Kukhartchuk and Raiser (2003) added also the factor of being land-locked, and other border related variables. The next step draws from our own recent experience in modeling the attraction of FDI flows by 32 European countries (Benacek et al., 2012) where we found that, except for fundamental economics and macroeconomic policy variables, there are also important political risks that influence the capacity to invest and trade.

Globalization tendencies (free trade agreements, global value chains, communication and networking, etc.) are important factors of international trade but there are many more variables of interest. For example, Druláková and Zemanová (2016) introduced Un Global Compact corporate sustainability initiative variable to account for differences between countries. Other interesting factor is the level of the integration into German distribution channels (Taušer, Arltová and Žamberský, 2015) or the level of fiscal activism in times of economic crisis (Macháček, 2013). Globalization factors are hard to measure. Thus, on the right side of the gravity model equation variables of interest are incorporated: tariff/non-tariff preferences, indicators of institutional quality (government effectiveness, the rule of law and corruption level). Indicators were taken from the database created by Daniel Kaufmann et al. (2006). Government Effectiveness (GE) refers primarily to the quality of bureaucracy, professionalism of staff and the credibility of the commitment to policies, including trade. It is; therefore, a measure of the quality of government functions. The rule of law (RL) indicator approximates the level of public confidence in the law. It reflects the quality of the legal system and the enforcement of contracts. It encompasses indicators of the incidence of crime, the effectiveness of the judiciary and the ability to enforce contracts. The Corruption Control (CC) indicator reflects the level at which public authorities are used for private gain.

Methodology and Data

According to the standard gravity model of trade, exports X_{ijt} from country i to county j in year t are a function of domestic GDP Y_{it}, partner's GDP Y_{jt} and the impediments to trade represented by distance between countries D_{ijt}:

$$\mathbf{X_{ijt} = a * Y_{it}^{b} * Y_{jt}^{c} * D_{ijt}^{d} * \varepsilon_{ijt}} \qquad \mathbf{(1)}$$

where exponents of these variables are the behavioral parameters to be estimated, ε is the error term and i, j = {1, 2, 3, ... , m} are countries and t = {1995, 1996, ... , n} represents the years.
Two vectors with institutional variables are denoted N and R. The former represents various dummies with integration/treaty arrangements and the latter dummies for variables of risk, cultural or psychic factors of trade:

$$\mathbf{X_{ijt} = a * Y_{it}^{b} * Y_{jt}^{c} * D_{ijt}^{d} * N_{ijt}^{n} * R_{ijt}^{r} * \varepsilon_{ijt}} \quad \mathbf{(2)}$$

Our analysis will be derived from the econometric estimation of trade flows (e.g. exports) between countries i and j (i≠j). The estimation procedures will draw from our past experiences with this kind of modeling by means of panel data (see Benacek et al. 2005 and Benacek et al. 2006). The usage of estimation techniques depends on the characteristics of data. We will utilize the one-way panel estimation. The default method will be Ordinary Least Square (OLS) and Poisson estimation (PO). The other methods we will use are derived from them: Poisson Pseudo-Maximum Likelihood, LSDV – Least Square Dummy Variable and panel estimation method "Mundlak" (Mundlak, 1978). We will control for time characteristics by time dummies or by the inclusion of linear trend. The individual fixed effects will not be controlled for, at least not directly. This is because of the nature of the gravity

model and its exact sciences heritage. We are aware of the drawbacks and insufficiency of the model and its cross-sectional setting (see Milner and Greenaway, 2002).

The LSDV framework along with Poisson estimation (PO) is commonly used in standard gravity models of trade. Panel estimation is possible and we are utilizing only the "Mundlak" estimation which allows relaxing the assumption in the random-effects estimator that the observed variables are uncorrelated with the unobserved variables. Standard fixed effects estimation (not reported) removed a lot of variation and it changed the nature of analysis to within estimation without the distance variable. Standard random effects model (not reported) failed to provide consistent estimation and didn't pass the Hausman test. The linear dynamic panel-data method, the generalized method of moments (GMM) estimation is another way to get the results for our gravity model; however, this estimation requires well selected instrumental variables, which might be problematic to vindicate, with the risk of underestimating of standard errors. Our (not reported) consistent estimates only suggested significance of lagged variables (dependent and GDP) in the robust two way estimation.
These findings have brought us back to the selected methods (LSDV, PO, Mundlak) which describe rather a general tendency in trade relations. We are aware that for one region or a country the time series analysis (for example: vector error correction model, vector autoregressive model) will be the proper estimation technique to obtain clear-cut results. The standard errors will be reported as a cluster robust, i.e. adjusted according to the group variable which is the country identifier. The policy analysis will rely on the estimation of exports to various territories using the parameters describing behavioral characteristics of real trade, meanwhile the policy/institutional variables will simulate their presence or absence of given instruments. The data are collected from Eurostat, European Commission, the World Bank, IMF, CEPII, Geobytes, Heritage Foundation, WTO, UNCTAD & our own estimation.

Instead of basing the gravity model econometrics on data for a single year of observation, we will concentrate on the panel data of bilateral trade by countries for 16 years, from 1995-2011, with more than 20 explanatory variables, which will require processing thousands observations for each country. We are using five models which we selected after sensitivity analysis.

M (1): Basic regressions (OLS) with "cluster robust" standard errors, i.e. we have controlled for the time trend and adjusted our measurement error according to country specifics.

M (2): Time specific dummy regression (LSDV)[2] with "cluster robust" standard errors, i.e. we have controlled for time effects (one way panel) and we have adjusted our measurement error according to country specifics.
M (3): Poisson (PO) time specific regression with "cluster robust" standard errors, i.e. we have controlled for time fixed effects (one-way panel, GDP Germany dropped out) and we have adjusted our measurement error according to country specifics.

M (4): Poisson Pseudo-Maximum Likelihood (PPML) time specific regression with "semi robust" standard errors (Santos Silva and Tenreyro 2006, Santos Silva and Tenreyro, 2010).

M (5): "Mundlak" random effects (MRE) estimation with group-means of independent variables added to the model (group variables are not reported).

Results

We can observe that German exports to Latin America and Caribbean (sample of 29 countries) depends on the distance, the size of the economy (GDP) of the trading partner, some institutional factors, like Government Spending, Financial Freedom (from the Heritage Foundation) and three indicators from the World Bank: Control of Corruption, Political Stability, and Voice and Accountability, which we can observe in the results shown in Table 3. The distance in the exports to Latin America and the Caribbean has a negative effect which ranges from -1.19 % to -1.34 %. On

[2] LSDV estimator (Least Square Dummy Variable)

average, if a Latin American country has 1 % higher real GDP then the German exports to this region will be from 0.98 % to 1.099 % higher (ceteris paribus). Exports could be higher between 17.8 % and 42.4 % in the countries where an FTA exists, which is the case of Mexico, Chile and Caribbean countries. Between institutional factors, it seems that with an increase of 10 % in the Political Stability, exports could increase up to 3.18 % while the same increase in Government Effectiveness could increase German exports to Latin America between 1.2 to 2.75 %.

Standard errors in parentheses, * $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$, Observations = 289, [1)] inverse hyperbolic sine transformation of explanatory variables in PPML model, LN – logarithmic transformation, IHS – inverse hyperbolic sine transformation. Selected variables.

In the case of German imports from Latin American countries, we can observe a dependence on Germany's Real GDP, the Real GDP of the trading partner, Property Rights, Government Effectiveness, Political Stability and Rule of Law variables (Table 1). On average, the trade agreements are not significant in comparison to the case the exports. Even in the PPML model, the FTA variable is only significant with a 10 % alpha and suggests a 0.28 % increase in imports. We note that the distance is not significant to the imports from Latin America to Germany as it was in the case of exports. On average we observe that if a Latin America country increases its GDP in 1 %, the imports from Latin America will increase from 0.83 % to 0.91 % if the economic conditions do not

change. If we look at institutional factors we can see an import increase from 1.1 % to 2 % if the Property Right variable increases in 10 %. Another significant variable is the Rule of Law, in which a 10 % increase could lead to 2.4 % to 4.32 %.increase in imports. The other analyzed variables were not statistically significant. In the PPML model where no country specifics are controlled for, a 10 % lower Fiscal and Monetary Freedom can lead to 5.55 % and 6.1 % higher exports, respectively. It seems that more goods will flow into countries with bad fiscal policies (wasteful public spending) and bad monetary setting (currency depreciation and inflation).

Conclusions

This paper applied a gravity model to analyze bilateral exports and imports between Germany and the countries of Latin America. The total sample was 29 countries, 17 years and about 30 variables of interest. The main objective of this research was to analyze the determinants of trade between Germany and Latin America. We looked at the behavior and determinants of trade in this European country in order to compare it with that of Latin America (29 countries including the Caribbean countries). We observed that for a bigger economy such as Germany, the distance does not affect imports from Latin America, while for a small economy; the distance can negatively affect these imports. We investigated the role of free trade agreements and they were not as significant as expected. However, the role that institutions play was much bigger than expected. The relation of institutions and trade is very important, with some of the stronger determinants being Political Stability, Government Effectiveness, and Rule of Law. Our results support the hypothesis of the importance of these variables, as most of them are statistically significant expected. This paper also contributed by incorporating 5 different gravity models. The beta coefficients differ substantially between models. This suggests limited comparability of results and also inefficiency of some models to provide unbiased results.

Creating Organizational Culture under the Influence of Leadership and Training – A CA Approach

Agnieszka Kowalska-Styczeń, Tomasz Owczarek,

Faculty of Organization and Management, Silesian University of Technology, 41-800 Zabrze, Poland, e-mail: Agnieszka.Kowalska-Styczen@polsl.pl

Abstract

In order to study processes in organizations such as creating or changing organizational culture, more and more often computer simulations are used. In this study we examined how the density of ties between organization members and the size of non-formal groups affect the creation of organizational culture in context of two mechanisms: the influence of leaders and the organization activities (training). To analyse the dynamics of the transfer of attitudes that are consistent with the culture expected by an organization the cellular automata (CA) model was used. The model is based on local interactions between members of the organization, that take place in the nearest neighbourhood. These groups of close neighbours are represented by von Neumann's neighbourhood and Moore's neighbourhood of radius r = 1 and r = 2.

Keywords: cellular automata, agent-based modelling, network of contacts, organizational culture, organization

Introduction

The word 'culture' for organizations and managers refers to the climate and organizational practices that develop around people and values that are part of the organization's views and principles (Schein, 2004). Culture is a dynamic phenomenon created by our interactions with others and with leadership behaviours. As Amah (2012) points out, culture helps in the day-to-day operations of employees to meet specific goals, and allows organizations to react quickly to the organization's environment. Corporate culture is, therefore, an 'automatic pilot' that manages employees in a way that is consistent with organizational expectations (McShane and Von Glinow, 2006). It is a form of deep-seated social control that drives employee decisions and behaviours so that the organization achieves the success. Organizational culture is also referred to as shared values, shared assumptions, shared understandings and ways of thinking that are shared by members of the organization and passed on to the new members as right (Duncan, 1989).This means that we learn culture, and it is not inherited from generation to generation and thus can be changed.

Organizational culture is intrinsically linked to leadership, it begins with leaders who impose their own values and assumptions on a group (Schein, 2004). Foremost, it is a mediator of the relationship between transformational leadership and organizational innovation and performance (Prather and Turrell, 2002; Xenikou and Simosi, 2006). Transformational leadership does not exhibit external motivation (based on exchange relations) but internal motivation. In this concept, the transformational leader is a charismatic visionary, who sets ambitious goals; he is a model for his followers; he inspires them to act (Burns, 1978). In view of the above, in this work, leader is a charismatic leader with a strong influence (not having a formal leadership role) interacting with other members of the organization through a network of informal contacts.

We are interested in the process of creating culture under the influence of leaders and organization activities (employee training, etc.). Our goal is to gain insights into the global behaviour of the analysed system based on local interactions within groups of employees. Organizational culture is created through exchanges of information between members of the organization. The organization is therefore perceived as a social system.

The methodological approach that is increasingly used by the organizational researchers is agent-based simulation (Dolley, 2002). In the context of social systems, this is an agent-based social simulation, which implements a paradigm of studying system dynamics based on local interactions of their elemental components (Gotts et al., 2003). This approach applies when the system is described by units that respond to each other and to the environment (agents follow the rules, interact and learn). A special type of agent models are cellular automata (CA). CA is a mathematical object consisting of a network of cells in D-dimensional space, a finite set of states of a single cell and a rule, which determines the state of the cell at time $t + 1$ depending on the state at time t of the cell and cells that surround it. Surrounding cells are called the neighbourhood of the i-th cell. To simulate the process of creating culture, we use the CA model.

The agent-based modelling and cellular automata approach for the study of knowledge transfer was used for example by Morone and Taylor (2004), Xuan et al. (2011), Hirshman et al. (2011), Giacchi et al. (2016).The organization members are modelled as CA space (network of cells), and each employee is a cell (agent). Each agent is under the influence of other agents (its neighbours) and influences others at the same time. In the proposed model, each person has a "culture" as understood by Axelrod (1997), that is a set of individual characteristics that are subject to social influence. It is a vector consisting of n elements - cultural features (cultural dimensions such as religion, language, way of dressing, political views). Our simulation experiments were conducted to answer this question: how the density of ties between organization members and the size of non-formal groups affect employees' adoption of the organizational culture under two mechanisms: the influence of leaders and training. The members of the organization adjust to the organizational culture by exchanging their knowledge on the subject with other employees. In addition to the influence of leaders, we propose a mechanism of training, as modifying members' knowledge through training is very important for the knowledge transfer (Argote and Fahrenkopf, 2016).

Model

In these studies, a two-dimensional cellular automata (CA) with periodic boundary conditions is used. The organization is presented as a square network of L x L agents. Initially agents are distributed randomly on the lattice, i.e. with probability $p \in [0, 1]$ a cell is occupied and with probability $1 - p$ it is empty. The total number of agents will be donated by M, $M = pL^2$. The behaviour of the agents (members of the organization) depends on their nearest neighbourhood and it is described by appropriate rules. Employee groups are represented by von Neumann's neighbourhood (4 and 12 elements neighbourhood) and Moore's neighbourhood (8 and 24 elements neighbourhood)- see fig. 1and 2.

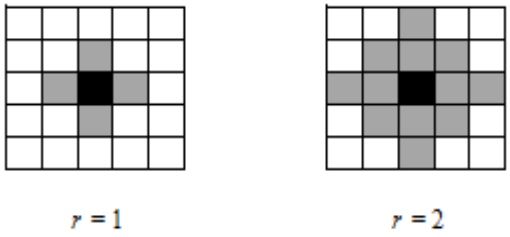

Fig. 1: Von Neumann's neighbourhood for r = 1and r = 2 (neighbours are grey cells)

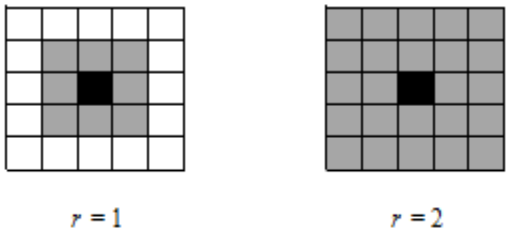

Fig. 2: Moore's neighbourhood for r = 1and r = 2 (neighbours are grey cells)

In the proposed model, the culture of each agent is described by a vector consisting of *n* elements - cultural dimensions (such as religion, language, way of dressing, political views), each of which is expressed by 0 or 1 (which can mean 'yes' or 'no ' for a particular cultural dimension). The culture of each person is expressed in *n*-element sequence 0 and 1.

The basic rules for agents are as follows:

- At the beginning of the simulation, every agent in the network has a 'culture' assigned randomly i.e. a vector of *n* - features consisting of 0 and 1.
- In each simulation step, the agent checks each attribute of its neighbours' vector and changes its value to the dominant in the neighbourhood. If it has the same value as the dominant one - nothing changes (we call this rule of assimilation).

The rule of assimilation is illustrated in figure 3. In this example we assume $n = 3$ (agents' culture consists of 3 features) and von Neumann's neighbourhood with $r = 1$. At the beginning of the iteration the vector of culture of the agent in the middle is 101. But it is changed at the of the iteration to 110, because the dominant value in its neighbourhood for the second feature is 1, and the most common value of the third feature is 0.

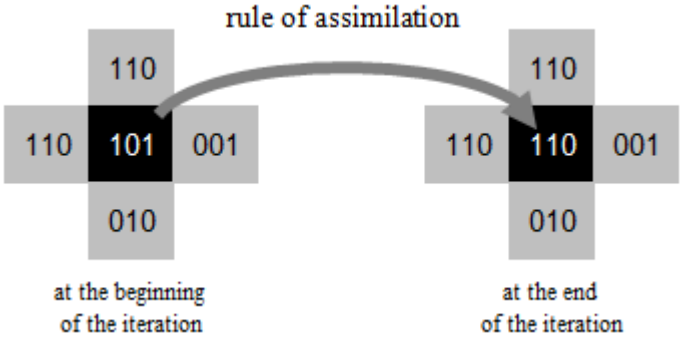

Fig. 3: Example of the rule of assimilation at work

Agents (members of the organization) can be influenced by leaders, who are assumed to promote the culture preferred by the organization. In this context, a leader has strong influence, affecting the other members of the organization mainly through a network of informal contacts.

Leaders rules are as follows:

- Leaders have a culture preferred by the organization (in the presented model, it is a vector consisting of only 1).
- At the beginning of the simulation, *l*% of all agents are randomly selected as leaders.
- Leaders do not change their culture, all other agents act according to assimilation rule.

Organization members may also acquire the elements of organizational culture during training and courses organized by the organization. Training may involve different aspects of an organizational culture, that is, the adoption of culture may involve different elements, depending on the subject matter of the training. We model this aspect of organization by introducing external field *t,* which represents the rate of employees that are send for training.

The influence field *t* works as follows:

- At each simulation step, one attribute in the culture vector is randomly selected, and then *t%* randomly chosen agents change their value of this attribute to 1.

Experiments

The conducted experiments were designed to investigate the impact of the leaders and the organization activities (training) on adopting a culture consistent with the organization's policy. Our goal was to examine how the density of ties between organization members and the size of non-formal groups affect the creation of organizational culture. For this reason the following parameters were chosen as independent variables:

- *p* – population density,
- *r* – neighbourhood size ,
- *n* – number of cultural attributes
- *l* – fraction of the leaders,
- *t* – the intensity level of training.

To model different density of ties between employees and diversify the size of non-formal groups we assumed three levels of the population density: $p = \{0.5, 0.75, 1.0\}$ and four levels of neighbourhood size: von Neumann's neighbourhood of radius r = 1 (4-elements neighbourhood), von Neumann's neighbourhood of radius r = 2 (12-elements neighbourhood), Moore's neighbourhood of radius r = 1 (8-elements neighbourhood), and Moore's neighbourhood of radius r = 2 (24-elements neighbourhood).

The population density *p* represents the density of ties between employees – greater value of *p* causes more interactions (because more cells are occupied by other agents), so the network of contacts is denser. On the other hand, by testing different neighbourhoods we wanted to check how the size of the non-formal groups (represented by the neighbourhood) influences the dynamics of organizational culture diffusion.

The size of the vector describing a culture was held constant with five elements (n = 5). The leaders fraction level *l* was changed from 1% to 50% with a step of 1% and the intensity level of training *t* ranged between 0% and 25% with a step of 1%.

As the dependent variable describing organization members behaviour we used the fraction of agents with the desired organizational culture (the "desired culture" could be any fixed combination of zeros and ones, we chose a sequence consisting only of ones). In this work we treat it as a measure of effectiveness of two mechanisms: leaders (*l*) and training (*t*). This measure was adopted after Daft (1998) who defines effectiveness as 'the degree to which goals are attained'.

The simulation stopped after the first iteration when no change in any agent's culture occurred. Each of the simulation experiment variant was performed 1000 times and the results were averaged.

Simulation Results

Initially, the impact of the leaders on the organization members culture was analysed. Population densities p = 0.5, p = 0,75 and p = 1.0 were tested to see what is the influence of the leaders' presence on the diffusion of appropriate culture between employees in the network with sparser and denser ties of contacts. Simulations were carried out for the network size L = 50 and four types of neighbourhoods (see Fig. 1 and 2). These neighbourhoods represent informal groups in an organization that consist of a different number of members. Leaders represent the views consistent with company policy, that is they try to convince others to the culture preferred in the organization. Figure 4 shows the percentage of the organization members, who have accepted the culture of the organization at the end of simulation runs, depending on the percentage of leaders, different population density and different neighbourhoods.

As can be seen in Figure 4, the leaders impact is more effective in larger network densities (p = 0.75, p = 1.0). In this case smaller value of *l* has a bigger impact on accepting culture proposed by a leader (which is consistent with the organization's culture) than for p = 0.5. This dependency is visible for all types of neighbourhoods. The leaders effectiveness depends also on the size of neighbourhood. The larger number of the employees group (r = 2), the greater effectiveness of leaders - this means larger number of employees who have adopted required organizational culture. Thus, with a high number of interactions, smaller number of leaders is required so that the acceptance level of the desired culture increases significantly.

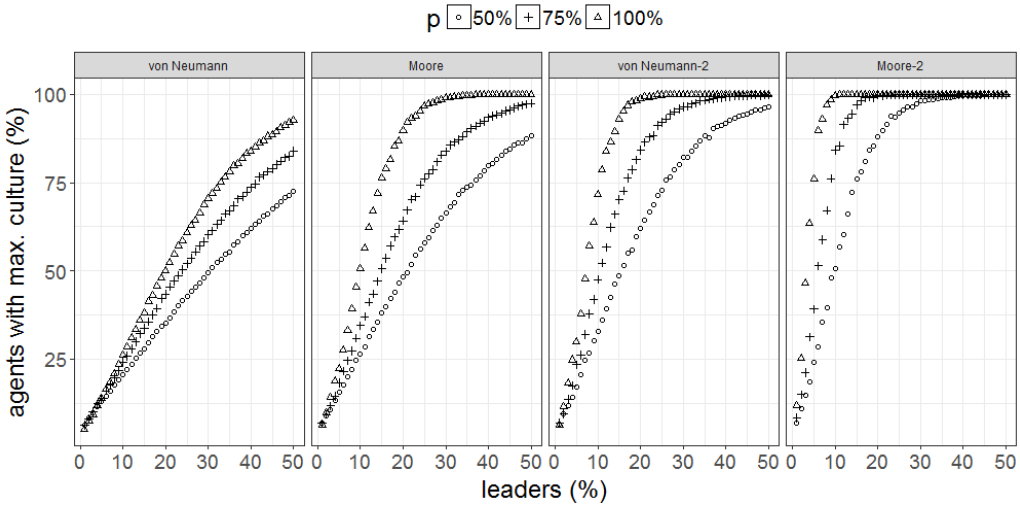

Fig. 4: Fraction of employees depending on the percentage of leaders, population density (p) and neighbourhood

The second experiment was performed to examine how the training (courses) organized by the organization impacted the adoption of organizational culture. Similarly, population densities p = 0.5, p = 0,75 and p = 1.0 were tested and simulations were carried out for the network size L = 50 for four types of neighbourhood. Figure 5 shows the percentage of the organization members, who have accepted the culture of the organization, depending on the intensity of organization's training.

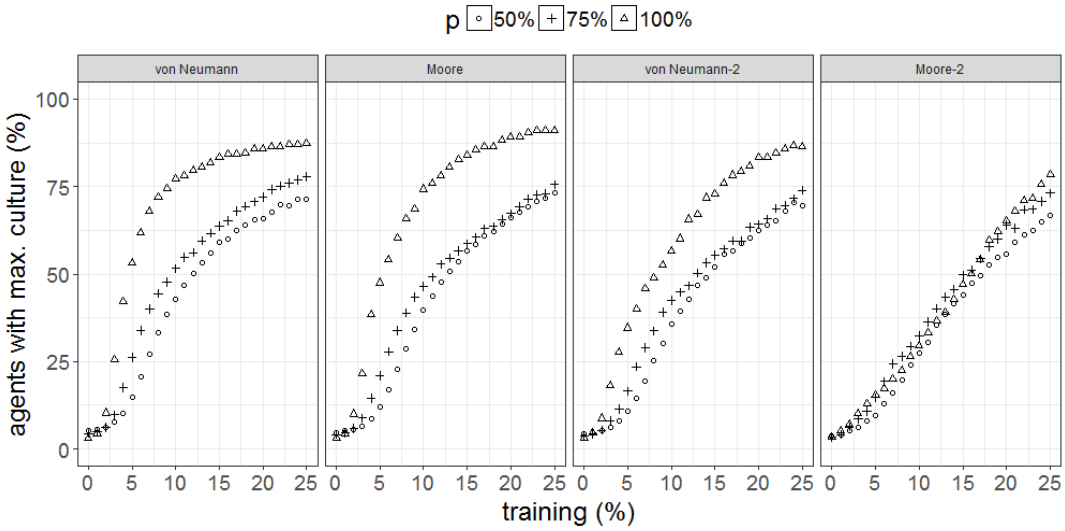

Fig. 5: Fraction of employees depending on the intensity level of training, population density (p) and neighbourhood

Generally, greater *t* (training) causes bigger percentage of people who have accepted the culture of the organization. The larger network density (p = 0,75 and p = 1.0) causes, that the training is more effective. This is not so clear in the case of the largest neighbourhood. In contrast to the previous tested case (with leaders), here it is the smaller neighbourhood size (r = 1) that is conducive to the acceptance of the organization culture. Furthermore, as can be seen on the two most left panels of fig. 5, when t exceeds 5% the effectiveness of training grows slower. Of course, in addition to the 'training' mechanism, all agents are also influenced by the assimilation rule described earlier. This rule causes that denser contact networks (larger p) contribute to the spread of the desired culture, but with the increase in the size of groups (larger r), the effect is getting weaker.

Summary and conclusions

The proposed model has been designed to investigate the impact of the leaders and training on the employees culture. Apart from the leaders and the training, all of the agents in the network were also influenced by those members of the organizations which were close (in the "social" sense) to them. In our model it is represented by the assimilation rule, which reflects informal interactions. It is consistent with numerous studies which show the relationship between social interaction (i.e. informal contacts) and the rate of knowledge transfer and organization efficiency (e.g. Ingram and Roberts, 2000; Reagans and Zuckerman, 2001; Reagans and McEvily, 2003; Chen and Huang, 2007). The transfer of knowledge (which relates to diffusion of organizational culture) takes place mainly through informal contacts between the organization members. These contacts were modelled by different neighbourhood sizes and population density. Our goal was to answer the question: how the density of ties between organization members and the size of non-formal groups affect employees' adoption of the organizational culture under two mechanisms: the influence of leaders and training. To answer this question, we performed two simulation experiments.

Our results show that the density of the network as well as the size of the neighbourhood affect the effectiveness of the leadership and training mechanism. Bigger groups and denser network strengthen the influence of the leaders. With a high number of interactions even a small number of leaders is enough to make the level of acceptance of the desired culture very high. In case of training effect, the results are a

little different. Denser network of contacts contributes to the spread of the desired culture, but with the growth of groups this effect is getting weaker.

As Alipour et al. (2011) emphasize “the organization can facilitate knowledge sharing and offer incentives for dialogues and team work”. To facilitate the transfer of knowledge in the organization, the manager should design a structure in which members of the organization can easily exchange information and experience. Based on the results we can formulate two practical hints in this regard in the context of adopting organizational culture. Leaders should often meet with their employees and encourage them to interact with each other to ensure that organization's views and practices are stated clearly and understood correctly. On the other hand, training should be carried out in a targeted manner, as its positive effect can be limited by local "islands" of a different organizational culture inside the groups of closely collaborating workers. This is in line with Albrecht et al. (2015) who argue that “systematic focus on training needs, training delivery, training transfer and training effectiveness should be an integral focus of effective performance management and development processes”.

Agent-based simulations are used in situations where precise analytical descriptions of the observed phenomenon are inaccessible or direct experiments are impossible. This is the case in complex social systems where many relationships, interactions between individuals, can be identified, but it is not possible to perform an experiment that will examine the effect of their interaction over time. Although the results shown in this study are rather general and largely qualitative, they can be interesting for decision-makers in organizations, as shown above. The applied simulation approach should be considered as complementary to traditional empirical research.

The model presented in this work can be easily extended and other factors describing the process of adoption of organizational culture could be taken into account. One of them could be e.g. homophily because research show that it affects the frequency of the interaction between agents (Hirshman at al., 2011). Additionally, it would be interesting to include some diversity between leaders, e.g. to consider the differences between transformational and transactional leadership (Odumeru and Ogbonna, 2013).

Abstract

The contribution is dedicated to didactics, teaching technique, learning tools and their functions and teaching methods in vocational training of a metal worker. In the theoretical part we want to point out on the vocational training as an important aspect of the students´ training for his future profession. Teaching aids are a very important part of teaching. The advantage of a teacher of practical lessons compared with a teacher of vocational subjects in theoretical teaching is that he works more hours with real didactic machines. In the experimental part we evaluated teachers' access and the availability of teaching resources. We evaluated it by a questionnaire.The results show that teachers have sufficient access to teaching means, and that they use them in practical teaching for clearer explanation of curriculum.

Keywords: didactics, teaching techniques, teaching aids, teaching methods, vocational subject

1. Introduction

The contribution is focused on the creation of teaching aids for the teaching of machinists. Teaching aids and teaching techniques are in vocational training very important part of teaching and they mean the increase of clarity of teaching substances. Use of aids in teaching is a necessity today, teaching is becoming more diverse, more understandable for students and it is easier for teachers to interpret the substance. Currently there are major changes in the Czech vocational education, the structure of secondary vocational schools has changed. It is mainly about merging several schools in new units, as well as they did it at the Secondary School of Crafts and services in Strakonice, which merged on 1.1.2012 with the College and the Secondary Technical School in Strakonice. These changes bring positives in the form of adaptation to the current demand for schools, apprenticeship programmes, modernization of classrooms and teaching aids and teaching improvement. To make these changes it is necessary that the teachers would be involved in this process, because they have a pivotal role in the learning process and many demands are placed on them because they have to use all the latest findings of modern technology in their lessons of theoretical and practical training (Ližbetinová and Farkašová, 2016). The best is a combination of traditional elements of education with innovative forms of teaching so that the educational process has brought satisfaction for both educators and pupils (Kampf et al., 2017; Lorincová et al., 2016).

2. Material and Methods

The word didactics comes from the Greek word didaskein - or learn to teach and learn. Exact name of didactics is "general didactics" - but normally even in the professional expression is used the abbreviated name "didactics" (Průcha, 2009). Didactics is according to Průcha, Veteška (2014) the basic discipline of pedagogy. It is its important component because the teacher has educational influence especially in teaching where youth is the immediate subject of a planned and purposeful action (Drahovrzal et al., 1997). Čadílek (2005) indicates didactics as a theory of education. Drahovrzal et al.

(1997) also says that education is focused on exploring all forms of deliberate (international) effect on personality development, didactics of vocational subjects is focused on the peculiarities of this work in the education - learning process (Hitka et al., 2016; Hitka et al., 2015). Didactics is the theory about intentional (deliberate purpose-planned) educational processes: it designs the models of learning and teaching, models of contents and goals of educational processes, methods and forms of teaching, a method of detecting and evaluating the results of educational processes. As the educational processes are carried out in a very large and variable number of educational environment, didactic theory is very differentiated: there is a school didactics within which there are the didactics of individual types of schools, individual educational fields and subjects (for example didactics of history in elementary schools, didactics of anatomy in the education of medical students, etc.).

Means of vocational training

Securing of adequate conditions and means for achieving the objectives and fulfilling the objectives of vocational training in accordance with the teaching principles and rules is didactically, technically and economically long and difficult process. However, it is absolutely necessary to meet the desired objective. Generally as the means we consider those realities (objects and phenomena), which serve and help to achieve the objectives. Similarly in the pedagogy term educational resources in a broad sense include everything that is conducive to meet the educational goals (Čadílek, 2005).

The didactic under the term means we understand everything what teachers and students can use to achieve learning objectives. Such means can be a method of teaching, teaching form, teaching principles, reaching a stopover is a means of achieving final goals, but the means also include the school board, textbooks, teaching facilities, computer equipment, etc. (Kalhous, Obst et al., 2002).
Teaching resources in practical training can be divided into material and immaterial:

immaterial resources - organization and methods used in teaching of practical training

- training organization - the allocation of classroom in learning periods, teaching practices, coordination of practical training and theoretical training, organizational forms (place of teaching, teaching methods, teaching day)
- teaching methods in practical training - working with technical and accountancy documentation, training, simulation methods, problem methods, staging methods, excursions (Čadílek, 2005).
- material resources - equipment and items that are necessary for practical training, and those that assist by their didactic function to acquire the curriculum effectively.
- the means of production (machinery, tools, gauges), educational resources (teaching materials, teaching techniques).
- the fiction of didactic material resources stems from the fact that man gains 80% of information visually, 12% by hearing information, 5% of the information by touching and 3% by other senses (Kalhous, Obst et al., 2002).

Teaching methods in teaching vocational subjects

Authors of professional literature agree that the main objective of teaching method is the effective management of pupils by their teachers in order to meet the educational goals. Accivities of pupils and teachers should always be coordinated and should be closely linked.

According to Maňák and Švec (2003) a teaching method is understood on the base of the interaction of a teacher and pupils, it acts as a structured system of teaching activities of teachers and learning activities of pupils aimed to achieve the educational objectives. As a teaching method can be considered such system of teaching activities of a teacher and learning activities of a pupil which leads to the fulfillment of the educational objectives set by a teacher and received by a pupil (Kalhous, 2002).

Drahovzal et al. (1997), states that vocational subjects are characterized by a rich variety of traits, which connect them through technical and technological base with related groups of learning subjects and disciplines. According to this fact the centre of teaching leads to laboratory and practical methods

where the professional skills and habits of future technician are formed the most intensively. The essence of teaching methods is such management of active cooperation of students with a teacher, which leads to efficient mastering the curriculum ensuring fulfillment of educational goals. Material teaching means are used for successful implementation of teaching methods. Methodological mastering of their proper use in teaching is get by the creation of the necessary professional skills of teachers. Teaching methods are characterized by their close connection to the internal conditions of teaching (especially in the professional view), while organizationbal forms are part of the external conditions (Mura and Orlikova, 2016).

- Průcha (2009) as a teaching methods also considers the lecture, discussion, dramatization, written work with text.
- visual methods (demonstration) – they allow on the baiss of the direct watching the demonstrated object or phenomena to recognize immediately its the most important features. We include here observation and demonstration in the classroom. Průcha (2009) states also the watching the paintings, models, experiments, film or computer projections.
- methods of work - work can be a source of valuable knowledge, but it also can create its own educational content. According to its character we distinguish the laboratory methods, craft works. According to Průcha (2009), among these methods we also include creative activities, manual work in the workshops.
- activation methods – require the increased share of activity of each pupil on the process of teaching and learning. Activation of pupils is reflected in the teaching methods as a problem teaching, discussion and staging methods, program teaching and learning methods of individual work with the textbook, literature and trainer training.
- methods of screening and assessment of pupils - have considerable educational importance by their controlling function (as a feedback to pupils and teachers) and their motivational functions (encouraging to the next learning eventually early correction and initiative to remedy).

Methods of control of the study results are divided into oral tests, written tests and achievement tests (Drahovrzal et al., 1997).

Didactic Technology

According to Průcha, Veteška (2014) the educational technique is the general term indicating information and communication technology equipment, which are used in learning and teaching. As a result, the overall development of technology the type and method of use of these means has changed. While in the 60-ies of the last century were typical for example didactic projector, overhead projector, educational film etc, currently these means are much more developed represented mainly by audiovisual equipment, such as computers and educational software, videotechnical equipment, CD player, interactive whiteboard , a language lab and others. Prucha et al. (2001) distinguishes traditional didactic technique (slide projector, overhead projector, film projector, etc.) and modern (computer for educational programs, language lab, multimedia tutorial system, etc.), new technologies in education, technology education. The placement of educational technology in teaching significantly changes the style of work of the teacher.

Function of educational technology

Function of educational technology consists of the mediation of education - learning content. Its upbringing - educational outreach must be always assessed in the unity with the appropriate contents and forms of media programs that animate their work and develop it in the classroom. By incorporating the educational technology into teaching of vocational subjects varies significantly overall style of the teacher's work as a leading factor. In the process of teaching management there occurs a tendency to implement so called automated system of education, which includes:

a) learning management program, ie. the estimated algorithm of pupils´education, structure of presumed methods of teaching and learning, teacher´s optimal variant of the process for achieving educational objectives,

b) material didactic aids (teaching aids, teaching techniques, architectural design of micro - and macrospace)

c) diagnostic technique for evaluating the results and control of educational processes,

d) own learning activities of students and their teacher in the intent of program management (Drahovrzal et al., 1997).

Nowadays, the term didactic technology is replaced by terms such as instructional media, instructional technology (Průcha, 2009). These are visual, audio and audio-visual means, such as eg. overhead projector, educational film, educational television, a language lab, teaching simulator, computer tutorials, internet.

Overview of didactic techniques used in secondary schools:

1) Means of visual techniques

a) for not screened aids (means DT aid carrier of information), blackboard teaching drawing, magnetic board, paper materials, articles on ferrite, flannel boards, utilities taped flannel or velcro, plexit blackboard, teaching drawing, flipchart teaching drawing, rack or hook on the whiteboard, wall or blackboard painting, map)

b) for static projection (DT aid means (medium), epiprojector aid opaque backing, stereopticon slides)

c) for dynamic projection (DT aid means (medium), film projector, a silent film, film loop

2) Means of auditory technique (DT aid means (medium), gramophone records, reel tape, tape, cassette recorder, cassette tape, player CV CD (compact disc), radio, radio broadcast)

3) Production of audiovisual equipment (DT aid means (medium), film projector sound film, television broadcasts, videotape, DVD player, DVD, multimedia computers, CD - Rom with multimedia programs, data projectors, data in computers or other sources

4) Other electronic educational resources (visualiser (document camera), Interactive whiteboards, voting system, interactive touch panel, DVD player, copying whiteboards, mobile interactive system, overhead projector, device onto a transparent pad or a large-format slide

Teaching aid and its functions

It is also necessary to distinguish what a didactic technique is and what a teaching aid is. There is often the confusion between these two concepts. Čadílek, Loveček (2005) state that for example the blackboard, tape recorder, overhead projector, projection device , etc. are also a didactic technology. Teaching aids are for example the image on the screen, drawing on the blackboard, film, etc. Teaching aid is actually the carrier of didactic information which are used directly in the educational process and to illustrate teaching event or activity. Teaching aids are part of the teaching process, because they directly relate to the subject matter. Drahovzal et al. (1997) state that aids by their function are used as:

a) means of motivation and stimulation, ie. the means inducing the inner relationship of pupil towads learning, problem solving and problem situations promoting creative search, discovery and action,

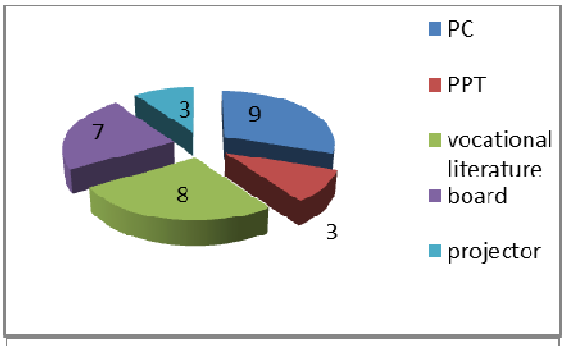
b) sources of information that help the student to approach the curriculum (content and interpretive information) so that the process the acquisition of knowledge would be as much as possible facilitated. Teaching aids should lead the student as means of verbal and non-verbal communication to understand the nature of phenomena in various ways,

c) the means of systematization of knowledge inducing the connection with new concepts and knowledge acquired in advance. Teaching aids should help the student to organize the curriculum not only into logical structures, but to facilitace him from the way of knowledge from specific to the general,

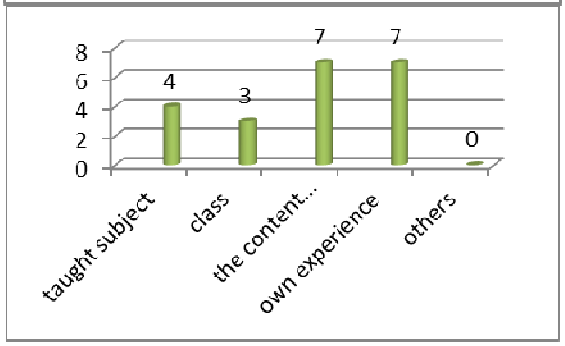
d) means for controlling the working methods simultaneously with the discovery of new phenomena,

e) means of connection the school with practice,

f) the means to implement a differentiated approach to the pupil to develop better his psychological and physical abilities.



Didactic technology and teaching aids can act as an educational, communication and media means, which the teacher uses for his influence on students in the educational process.



3. Results and Discussion

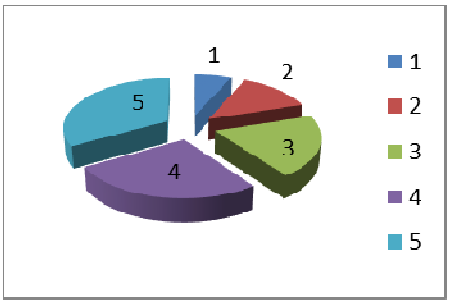
The research was conducted in January 2016. We chose the method of quantitative research using a non-standardized questionnaire. The questionnaire was divided among individual respondents – teachers of practical training of the Secondary School of Crafts and Services Strakonice. The questionnaire was created as a form that respondents filled in.

The research was conducted within the framework of practical training by teachers of practical training. In the workshops where practical training of SOŠŘaS Strakonice takes place are educated 36 pupils of the apprentice field of machinists. The questionnaire survey was realized by 11 teachers of the practical training, including the Deputy Director for practical training.

Evaluation of questionnaire
For setting the hypotheses there was created the questionnaire with eight questions. Type of questions was always chosen as closed. In some cases it was possible to select multiple answers. Questionnaires were distributed to the teachers of practical training of the apprentice field of machinists. A total of 11 questionnaires were filled in by teachers.
Question No. 1 - What equipment do you use for the practical teaching of your vocational subject?
a) PC
b) presentation
c) technical literature - textbooks
d) the board
e) projector
Question No. 2 - How do you decide which teaching aid will you select?
a) taught subject
b) class
c) the content and topic of the curriculum
d) own experience
e) others (mention): .....

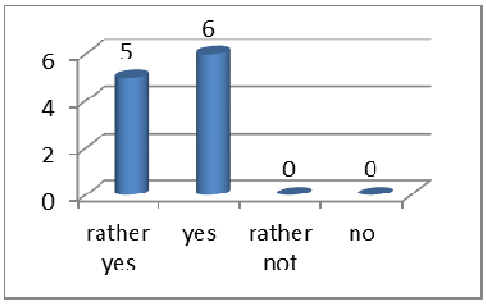
Graph 1 Used aids **Graph 2 Decision for aid choice**

The question 1 was answered by all respondents. There could be marked more than one answer that´s why we have a total of 30 responses. The aim was to find out what aids are mostly used by teachers during practical training. A total of 9 respondents (30%) responded that they use PC and other the most used aid is the literature (27%), which corresponds to eight answers. Furthermore, seven of the respondents (23%) said the board and the three responses (10%) involved a presentation and data projector.



Question No. 2 again allowed multiple responses and a total of 21 responses were identified. The question was tasked to determine whether the teachers emphasize the pupils' actual needs and pay good attention to the selection of teaching aids. The same number of teachers (33%) responded that they decide according to the content and curriculum topic and according to their own experience, which is also related to the length of their experience and knowledge and experience as the practical training is taught by many teachers with their experience of more than 15 years. Four respondents (19%) responded that they decide according to the subject taught and a further 3 respondents (14%) according to a class.

Question No. 3 - Are you happy with your school facilities for teaching technical subjects?

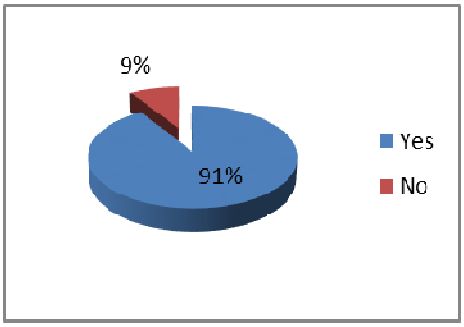


a) rather yes
b) yes
c) rather not
d) no

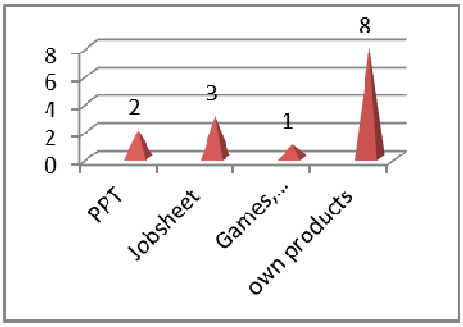
Question No. 4 - Evaluate how your school is equipped with the teaching equipment on a scale 1 to 5 as at school.

a) 1
b) 2
c) 3
d) 4
e) 5

Graph 3 Satisfaction with the aid equipment of your school



Graph 4 Evaluation of school by aids

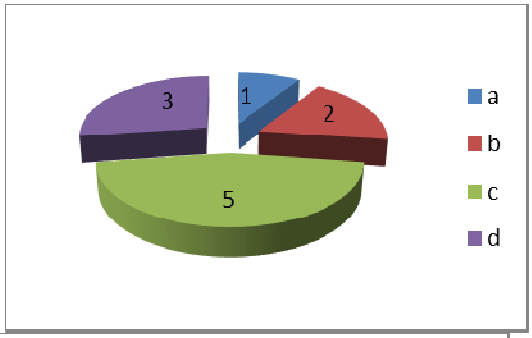


The question 3 shows that teachers generally perceive the didactic technique available to the practical training as adequate and well equipped (graph 3). As many as 55% said they are satisfied with school equipment for teaching technical subjects and rather yes responded 5 respondents representing 45% of overall respondents. Nobody responded negatively.

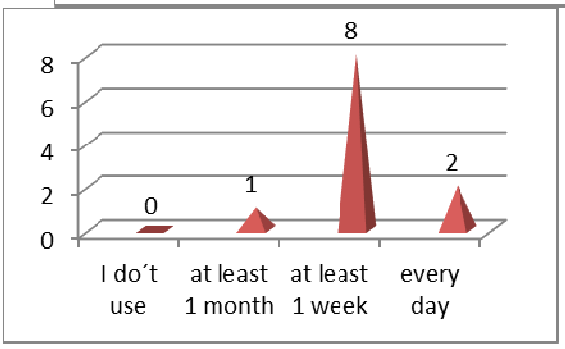
Question No. 4 the respondents assessed mostly positively too (graph 4). Most (73%) judged the equipment by education technique with mark 2. One respondent even assessed by the mark of 1 and the last two respondents would rate by the mark of 3. This and the previous question No. 3 refer to the hypothesis No. 2. Both questions confirm the hypothesis , because teachers are satisfied with school equipment for teaching technical subjects.

Question No. 5 – Do you create for your subject your own teaching materials and aids?
a) yes
b) no
Question no. 6 - If yes, what? (Answer only if you answered yes for question No. 5)
a) Power Point presentation
b) worksheets
c) games, competitions
d) own products

Graph 5 Creation of own aids



Graph 6 Types of aids



91% of respondents said that for their subject they create their own materials and teaching aids. Only one respondent replied that he does not create aids for teaching vocational subjects.

The aim of question No. 6 was to determine what teaching aids are used in teaching vocational classes. There could be marked again more answers. Respondents in 58% of the responses marked own products, further 21% use worksheets. Only two respondents (14%) described the use of PowerPoint presentations and one respondent (7%) uses games and competitions. From these responses it is clear that teachers are accustomed to the traditional demonstrations using their own products, which are produced by the pupils themselves.

Question No. 7 - What is your relationship to the use of educational technology?

a) I do not like using a teaching technique
b) only certain types of educational technology, because I cannot deal with all the technology perfectly
c) I use the available didactic technique, but I would welcome greater amount compliant with modern standards of practical training
d) I often use didactic technique and I'm happy with it
Question No. 8 - How often do you use didactic technique?
a) I do not use it at all
b) at least 1x per month
c) at least 1 x per week
d) every day

Graph 7 Relation todidaktictic technice **Graph 8 Interval of use of aids**

By the question No. 7 we investigated how respondents are related to the use of educational technology. Only one respondent replied that he does not like using it, the other two only use certain kinds of techniques because they cannot handle them perfectly. Satisfaction with didactic technology is 27%, and most respondents (45%) use available didactic technique, but consider it as too outdated and obsolete.

The aim of question No. 8 was to determine the interval of using didactic technique by respondents. Most up (73%) respondents use it at least 1 time a week and even two of the respondents (18%) use it every day. One respondent (9%) responded that he uses it at least 1 x per month and no one was found who would not use the didactic technique.

4. Conclusion

The aim of this paper was to investigate by using a questionnaire the teaching aids for practical training. Practical training is specific in that these are the entire 6-8 hour sessions. Pupils are opposed to theoretical subjects able to test their practical work on machine tools and acquire the basic habits and

skills. Questionnaires were completed by teachers of practical training. The survey was focused on teachers' satisfaction with available teaching aids and didactic technology, which is used in practical training.

The survey showed that teachers are satisfied that the didactic technique is often used. At the same time it became clear that they would welcome more modern classrooms equipped with teaching equipment and teaching aids. The most used are boards, textbooks, training simulators for CNC programming or computers in teaching programming of CNC machines. As a solution to the current situation and conditions that are currently in training workshops on SOŠŘaS in Strakonice and based on the outcomes of the survey results we suggest to increase the use of data projectors and interactive whiteboards, because those I consider to be modern teaching techniques. By using a data projector or interactive whiteboard in conjunction with a PC, it is possible to prepare the appropriate audio-visual aids and better explain the problem to pupils. To use the projector more effectively, it is necessary to start to use power point presentations and videos more. Teachers have more time for other activities, such as demonstrations on CNC machines, and other machine tools, and while doing these activities they will meet the educational goals.

As the survey shows that there is a need to modernize the existing equipment, we suggest to buy the interactive whiteboard with the touch display for the practical training. It also results that the teachers are active to engage in projects which promote the curriculum innovation and the creation of teaching materials. They use the created teaching materials in their teaching, because in most cases they have the activation component which leads pupils to participate in the teaching process.

Abstract

This paper investigates the drivers of bank performance overtime, between Islamic and Conventional banks by using a dynamic panel approach. The study period covers ten consecutive years (2006-2015), we use ROAA (Return on average Asset), ROAE (return on average Equity), and NIM (Net Interest Margin), Sharpe ratio, Jensen and Treynor indices as measures of performance. We applied panel regression by using the technique of fixed effect estimation instead of random effect, and then to address the issue of endogeneity and omitted values we applied two step system of GMM (Generalized Method of moment). Results suggest that bank performance is mainly driven by non-performing loan provision (NPLP), cost to income ratio as measure of bank efficiency, and size, net loan to total asset with NPLP and cost to income ratio being significant when using different performance measures. Within a dynamic panel framework NPLP has a negative impact on CBs performance whereas it affects positively IBs performance. This is consistent with Beck et al. (2013) who suggest that IBs have higher asset quality than conventional banks. This study also contradicts the idea that IBs are less cost-efficient than CBs because the cost to income ratio as a measure of efficiency is more significant for IBs than CBs.

Keywords: corporate governance, Islamic banks, performance, stock market risk adjusted measures.

JEL classification: G30, G01.

Introduction

During the last recent years, the speed at which Islamic banking has been growing and its resilience to the 2007 financial crisis(see for instance Beck, Demirgüç-kunt, & Merrouche, 2013; Olson & Zoubi, 2016) provide evidence of its ability to compete with or outperform well-established conventional banks (CBs).Martin & Hesse (2010) and Olson & Zoubi (2016), document that more than 300 IBs are operating throughout 51 countries in the financial industry and hold almost $ 1.5 million dollars of assets. Similarly, Ernst & Young (2016) argue that over the period of 2009-2013, Islamic banking assets value growth reached 17%.The creation of Islamic stock market indices in the world's largest stock exchanges such as the MSCI Global Islamic Indices (2007), FTSE Global Islamic Indices and S&P Sharia Indices (2006), Dow Jones Islamic Market Indices (1999), or the Russell-Ideal Ratings Islamic Indices (2013) is important to sustain the idea of IBs growth.

As Compared to conventional banks, Islamic banks rely on a sharia-compliant finance that prevents them the right of charging interest, does not allow for illicit investments and speculation as well as strengthening the risk sharing principle both on assets and liabilities. For Gueranger (2009) Islamic finance is an ethical finance whose priority objective is not only the frantic search of profit.

Following the aforementioned literature, our study's objective is to assess what determines the performance of IBs compared to conventional banks. We seek to contribute to the literature in two ways. (I) First, we follow the existing literature on the performance in the banking industry in general. Most generally, bank performance is measured by accounting ratios such return on equity, return on asset and net interest margin (see for instance Athanasoglou, Brissimis, & Delis,(2008); Dietrich&Wanzenried,(2011);García-herrero,Gavilá,& Santabárbara,(2009); Pathan&Faff,(2013). In most recent studies, some use measures of stock performance such as Tobin's Q (Mollah & Zaman, 2015), Sharpe ratio (Gropper, Jahera, & Chul, 2015) and stock return. Our innovation relies on the fact that we use both Jensen ratio and Treynor ratio (both as stock performance measures) that have not been used as proxy of bank performance to the best of our knowledge. We will provide an answer to how well systematic risk is able to predict bank performance by distinguishing between IBs and CBs. (II) we use mainly African conventional banks because African banking industry is still the least developed in the world. By doing so, we complement the existing literature by documenting the gap between conventional banks evolving in least developed country (which are supposed to have low margin) to IBs.

The remainder of this paper is organized as follow as. (1) We document the existing literature on conventional bank and Islamic performance. (2) In the following section we present the data and the methodology that are used to study performance. (3) Section 3 presents our results from different empirical applications and section 4 concludes.

Literature Review

Performance is among the most discussed issues within the banking industry in an empirical perspective. Some researchers used to investigate bank performance in terms of ownership structure (knyaeva et al 2013) by comparing private to public bank, foreign to host banks. Other studies focus on the factors driving performance without relying on bank-type analysis (see Poin Hoin et al 2016; Rashid & Jabeen 2016; Jawadi 2016).For instance Figueira, Nellis and Parker (2006) have studied the ownership structure and performance of African banks. They found that, when private shareholders introduce foreign shareholders into the ownership structure of African banks, this tends to have a positive effect on the performance of the latter. These studies have documented for some cases significant link between governance mechanisms and banks performance (mollah & Zaman 2015) or relevant information about comparative performance between IBs and CBs (Johnes et al 2013).

Prior to the tremendous growth of Islamic banks, an important body of literature have emerged to most importantly address to which extend Islamic banks are different from conventional banks. To address this issue, Bourkhis & Sami (2013) investigate the difference between IBs and BCs resilience to the 2007-2008 financial crisis and find no difference with regard to their soundness because IBs tend to diverge from their business model. Beck et al. (2013) addresses business model and efficiency issues by comparing Islamic to conventional bank. They found that IBs are better capitalized, have higher ratio of intermediation, high asset quality although they are less cost-efficient. They also suggest that IBs were less affected by the 2007-2008 financial crisis because of the high asset quality their carry.

In the same spirit, Olson&Zoubi(2016) investigates the convergence of IBs and CBs performance. They argue that CBs converge faster than IBs especially after the financial crisis.

Methodology

This study focuses on publicly traded African conventional and worldwide Islamic banks. We choose publicly traded banks since our study employs equity performance measures as proxies of performance in the banking industry. Our sample is split into 48 IBs and 61 CBs on the period of 2006-2015. To conduct this study, our data are retrieved from different sources: (I) Bank level data are retrieved from Bankscope database which was provided by Bureau Van Dijk Belgium until December 2015 (II), stock market data (here stock prices and market capitalization) stem from

DataStream and (III), Macroeconomic data to account for country heterogeneity in terms of economic performance and financial depth are obtained from the World development indicator part of the world Bank website. (iv) Risk-free rates were mostly downloaded from Central Bank websites and it is represented by a 91 days' maturity treasury bills and some countries we proxy the risk-rate by a one-month US treasury bill retrieved from Kenneth Fama-French data library[1]. We compute stock return using arithmetic approach[2], Treynor and Jensen performance measures are driven from a CAPM[3] model using different stock indices as market proxy as retrieved from DataStream. Overall, our correlation matrix as reported in Table 4.1 suggest that our variables as mostly significantly correlated although their value are not high to suspect a potential multicolinearity. Descriptive statistics are reported in the annex and show that Islamic banks have higher asset quality than conventional.

In order to investigate factors driving bank performance, we follow Athanasoglou, Brissimis, & Delis(2008); Dietrich & Wanzenried (2011); García-herrero, Gavilá, & Santabárbara, (2009) and Pathan & Faff (2013) from whom we choose to set up the following specification:

$$PFO_{it} = \beta_0 + \gamma_{it} PFO_{it-1} + \sum_{i=1}^{k} \beta_i X_{it} + \sum_{i=1}^{k} \delta_i F_{it} + \mu_i + \varepsilon_{it} \quad (1)$$

Where PFO_{it} stands for the performance of the bank i at time t (here the year), βi and δi are the parameters we intend to estimate, Xit represent bank specific and Fit denote macroeconomic variables and other control variables, e_t the error term, μ_i represent fixed-effects among different banks. $PFOi_{t-1}$represents the lagged value of the performance measured due to the persistence of bank performance with respect to regional and macroeconomic factors as suggested by Berger, Bonime, Covitz& Hancock (2000).To estimate our parameters, we use a dynamic panel approach suggested by Arellano, M.; Bond, (1991).

Table 0-1Variables presentation and expected signs

Variables	Description	source
Depend variables: bank performance		
ROA	Net income over the average assets in %	Bankscope
ROE	Net income over the average equity in %	Bankscope
Net interest margin	Net interest margin as overs total revenue or total assets	Bankscope
Sharpe ratio	Average excess return over standard deviation the portfolio risk	Author calculation using DataStream data
Treynor ratio	Excess return over the beta market (systematic risk)	Author calculation using DataStream data
Jensen ratio	Difference between the return and the expected return	Author calculation using DataStream data
Independent variable		

[1] http://mba.tuck.dartmouth.edu/pages/faculty/ken.french/data_library.html

[2] $R_t \frac{P_t - P_{t-1}}{P_{t-1}}$

[3] Capital Asset Pricing Model: $E(R_i) = R_f + \beta_i\big(E(R_i) - R_f\big)$

Bank specific variables		
Capital ratio	Equity to total assets value	Bankscope
Loan to deposit ratio	Loan value divided as percentage of deposit	Bankscope
Overheads to total assets	Operating expenses over total assets	Bankscope
Nonperforming loan provision	Loss provision over total assets	Bankscope
Bank size	Log of total assets	Bankscope
Cost to income ratio	Ratio of total expenses to total revenue	Bankscope
Bank Age	Number of years the bank was established until 2015	Bankscope
Bank Category	Either Islamic Bank or commercial African bank	
Macroeconomic variables		
GDP growth	Yearly GDP growth rate in %	World development indicators
Inflation rate	Yearly consumer price index variable in percentage %	World development indicators
Boone indicator	Competition measure derived from Boone-type model	Global financial development

This table reports pair-wise correlation levels among our main variables. Significantly different to zero correlations at 0. 1%, 1% and 5% are marked ***, **,* respectively. The sample include both conventional banks and Islamic banks from 2006 to 2015 for a total sample of 109 banks split in 61 conventional banks and 48 Islamic banks. For notation, see Table 3.1 above.

Empirical Results

Fixed effects estimation are presented in Tab 4.2 and Tab 4.3 which respectively account for only bank-specific variables and macroeconomic variables. The R-squared of our models are different when we split our sample into IBs and CBs compared to when we use the full sample. Indeed, the first estimation report much higher R-squared than the second which can be explained by the heterogeneity between the two types of bank. In general our models fit with fixed effect according to the Hausman test. Globally we found that, when we only control for bank-specifics variables, size, Cost-to-income ratio, NPLP and Overheads to total assets are the main determinants of bank performance.

Our findings are consistent with the existing literature on the size impact on bank performance. When we measure performance by ROAA, ROAE and Sharpe ratio, we find a negative effect of size. These results are consistent with the findings of (Beck et al., 2013; Dietrich & Wanzenried, 2011; Mollah & Zaman, 2015; Olson & Zoubi, 2016).As our study encompasses also the crisis period, it is possible that bigger banks had large amounts of non-performing loan provision, which might affect negatively their performance. For Islamic banks especially where loans issued through the so-called Mudarabah have to be provisioned with a special account (IADS), which would affect IBs performance with a long term mechanism and most importantly have larger size.
However, some studies such as Gropper et al., 2015; Pathan & Faff, (2013) among others have found positive link between size and bank performance. Because bigger banks have higher diversification possibilities, they might enjoy economies of scale and hence high performance.

As a measure of credit quality, non-performing loan provision is highly significant in this study for all our performance measures. Using all these performance measures, this variable shows a negative significant impact on bank performance either for conventional banks or Islamic banks as well as for the full sample. This results entails the fact that the higher the loss provision, the lower the credit quality of the bank and hence the lower the performance. Empirical studies (see for instance Beck et al., 2013; Gropper et al., 2015) provide supporting evidence that high loss provision is detrimental to bank performance because the amount of provision allocated decreases the bank net income. Although significant, loan provision are not as important as for conventional bank(Beck et al., 2013), Islamic banks' performance is also negatively affected by high loan loss provision because some products have to be covered by amount of provision.
In table 4.3 we control for macroeconomic variables. Boone indicator as a measure of bank competition has a negative and significant impact on bank performance. Indeed, the structure-Conduct-Performance hypothesis suggests that a highly concentrated market indicates a low degree of competition and hence high profitability for banks. Our results support the competitive nature of the banking industry since the financial liberalization. Some studies however, use HHI concentration measure to assess the impact of bank market structure on the performance. Mirzaei, Moore, & Liu, (2013) demonstrate that market structure has a positive impact on banking both in developed and emerging economies. Moreover, we have mentioned so far that Islamic banking is growing at high pace. This result suggests that Islamic banking profits could be highly affected by the market structure despite the existence of unique regulation.

This table reports result from a fixed effects estimation which is adopted from a Housman test. The study is applied to both conventional and Islamic banks to determine what drive bank performance in the two banking industries we control only for bank specific characteristics. Our full sample includes the period of 2006-2015 with 61 conventional banks and 48 Islamic bank. Dependent variables a respectively return on average Assets (ROAA), return on average equity (ROAE), Net interest margin, Sharpe ratio, Treynor ratio and Jensen ratio. Statistically significant coefficients at the 1%, 5ù and 10% level have ***, **, * symbols respectively.

With respect to the GDP growth, our study suggests both positive and negative link with bank performance. Mirzaei et al.(2013)document that GDP growth influences bank performance through raising demand for loans. Bashir (2003) who evaluated the determinants of profitability in Middle East Islamic Banks, found a strong positive impact of GDP growth on profitability because of competition environment and innovative products channels. Goddard, John, Phi, & Wilson (2004)also estimated the profitability of 583 European Union domestic banks where cross sectional regression showed a significant positive effect of GDP on profits. Ghazali (2008) considered a six years data of 60 Islamic banks operating in 18 countries. Results ascertain that GDP and inflation positively influence the revenue of banks. On the other hand, negative links have also been reported by Naceur (2003) who found an insignificant link between Tunisian bank profitability and the annual growth rate and inflation.

This table reports result from a fixed effects estimation which is adopted from a Housman test. The study is applied to both conventional and Islamic banks to determine what drive bank performance in the two banking industries we control both for bank-specific and macroeconomics variables. Our full sample include the period of 2006-2015 with 61 conventional banks and 48 Islamic bank. Dependent variables a respectively return on average Assets (ROAA), return on average equity (ROAE), Net interest margin, Sharpe ratio, Treynor ratio and Jensen ratio.. Statistically significant coefficients at the 1%, 5ù and 10% level have ***, **,* symbols respectively.

In a short term perspective, inflation is an important factor to growth rebound. However, this link appears to be positive when the performance is measured by Sharpe ratio. The explanation behind this may be drawn from speculative and anticipative investors' behaviour on the financial market. The positive link between inflation and performance is documented by Albertazzi & Gambacorta (2009 ; 2010).

To address the issue of endogeneity and omitted variables bias, we follow(Dietrich & Wanzenried, 2011; Liang et al., 2013; Pelster, 2017) and use the Arellano & Bover (1995) and Blundell & Bond (1998)two-step system GMM that uses lagged values of dependent variable in level and difference as well as lagged values of explanatory variables in level.

Table 0-3: System GMM estimation of bank performance

This table reports result obtained from a system GMM approach of the determinants of bank performance both conventional and Islamic banks. Depend variables a respectively return on average Assets (ROAA), return on average equity (ROAE), Net interest margin, Sharpe ratio, Treynor ratio and Jensen ratio. We follow Arellano & Bover (1995) to estimate our coefficients given the endogenous nature of bank performance determinants. Statistically significant coefficients at the 1%, 5ù and 10% level have ***, **,* symbols respectively. Standard errors are reported between brackets. Over-identification test is constructed from Hansen and Arellano Bond test of autocorrelation is represented by autoregressive process respectively AR(1) and AR(2)

Results reported in Table 4.4 suggest that, our model fit the system GMM estimator. In fact, Hansen-J statistics of over-identifying restrictions and Arellano-Bond second order autocorrelation tests are not statistically significant. The first-order auto-correlation on the other hand appears to be statistically significant which is true by construction. All in all, after we have controlled for heterogeneity, dynamic endogeneity and simultaneity, non-performing loan loss provision, equity to total asset, cost-to-income ratio appear to have a significant impact on both conventional banks and Islamic banks performance.

This study also confirms the persistence nature of bank performance during our study period. Except, Sharpe ratio, all the first-order lagged values of our performance measures are statistically significant. These results are consistent with those of Dietrich & Wanzenried, (2011); Guidara, Lai, Soumaré, & Tchana, (2013); Liang et al., (2013); Pelster, (2017).

We have to stress that the use of stock performance measures as proxies of bank performance, especially the Treynor ratio and Jensen did provide evidence that risk-adjusted performance can provide management style for bankers.

4 Conclusion

The main objective of this study was to determine what drives the performance of Islamic vs conventional banks using both classical measures (ROAA, ROAE, and NIM) as well as stock market risk-adjusted measures. A sample comprising respectively 48 Islamic and 61 conventional publicly traded banks during the period stretching 2006 to 2015 is employed in our analysis. To test how Islamic banks' performance differs from conventional banks', we employ a two-step system GMM estimator which allows controlling for endogeneity and unobserved variables bias.

Our findings reveal that bank performance is mainly driven by non-performing loan provision, cost to income ratio, and size, net loan to total asset. Within a dynamic panel framework NPLP has a negative impact on BCs performance whereas it affects positively IBs performance. This is consistent with Beck et al. (2013) who suggest that IBs have higher asset quality than conventional banks. This study also contradicts the idea that IBs are less cost-efficient than CBs because the cost to income ratio as a measure of efficiency is more significant for IBs than CBs.

Controlling for macroeconomic variables within a fixed effect approach, this study is consistent with the Structure-Conduct performance hypothesis that suggests a positive link between market concentration and bank performance. Measured by Boone indicator, competition as the opposite of market concentration affects negatively both IBs and CBs.

This study also confirms the persistence nature of bank performance during our study period. Except, Sharpe ratio, all the first-order lagged values of our performance measures are statistically significant.

Our study has provided evidence that bank performance could be measured both by JENSEN and Treynor ratios.
The conclusion from this study is related to our sample and would have been different in some other specific cases. For instance, a longer study period or/and a larger sample could have led to different conclusion as the sample size and heterogeneity would impact the consistency of our results. Moreover, accounting for regulatory differences, constructing a single index for each category of banks would affect our results.

Comparing the Brand Personality of Nike in Slovakia and Czech Republic

Lucia Vilčeková, Faculty of Management, Comenius University in Bratislava, Odbojárov 10, 82005 Bratislava, Slovakia, lucia.vilcekova@fm.uniba.sk

Abstract

The concept of brand personality originated in human psychology. Because of the differences in personalities within cultures, there has been a need to examine the brand personality construct from an international perspective. The purpose of this study is to evaluate the personality of the brand Nike and to examine the differences between Slovak and Czech consumer perception. An online survey with a sample of 500 Slovak and Czech consumers was carried out with the main goal to describe Nike as a person, characterize the friends of the brand and suggest hobbies of the brand. In general, Slovaks see the brand as an active man, a winner and a sportsman. His hobbies are all kinds of sports, and fashion and he is very health-conscious. His friends are also very active, attractive and young. Slight differences were found when comparing the Slovak and Czech perception. The cultural differences result in differences of perception and attitude regarding brands. Therefore, it is beneficial to examine the global brands in national contexts.

Keywords: Nike, brand personality, Slovak consumers, Czech consumers.

Introduction

Brand personality is defined as "the set of human characteristics associated with a brand"(Aaker, 1997). To describe a brand any human feature can be used. The associations might be linked to certain demographic features (such as age, or gender), beliefs, hobbies, and personality traits (Rojas-Méndez, Erenchun-Podlech and Silva-Olave, 2004). This concept works because consumers often describe the brands with help of human personality traits.

By assuming the brand as a person, it can create a self-expressive benefit that becomes a vehicle for the customer to express his or her own personality (Aaker, 1997). Kotler and Keller (2016) confirmed customer usually choose the brands which match their self-image or sometimes consumers choose a brand based on their ideal self-image or social self-image.

Literature Review

Since brands, like persons, are usually described with adjectives, the psychological approach seems to be a good method for identifying the main characteristics of brands' personalities in the perception of consumers, and to select the best adjectives for conveying certain characteristics (Caprara, Barbaranelli and Guido, 2001). Consumers can easily view a brand as having a friendly or exciting personality or as a person with whom they may choose to have a relationship (Blackston, 2000).

In the field of marketing and consumer behavior understanding and measuring brand personality is very important because brand personality can be used as one of the means of communication to increase consumer preferences. It can differentiate the brand within a product category, (Aaker, 1997; Biel, 1992).

Consumers can make attributions about the brand's personality, "inner character", goals and values. In some marketing strategies, the brand is actually made to be "alive" and action-oriented (Aaker, Fournier,

1995). Fournier adds brand personality has an impact on various key variables, such as attitude, preference, usage imagery, and emotion (Fournier, 1998).

According to Khani et al, (2013) brand personality comes from three main sources:

- the relationship that customers have with the brand;
- the image which is a company trying to present;
- the unique features of product.

Aaker (1997) used methods similar to human psychology to identify five brand personality dimensions: sincerity, excitement, competence, sophistication and ruggedness. Further researches suggested different traits, e.g. Levy and Rook (1999) divided brand personality into five dimensions, which are excitement, competence, peacefulness, sincerity, and sophistication. In the Japanese context there was no Ruggedness dimension as in the American study, and another dimension – Peacefulness, was identified as a very strong trait. In Spain, in addition to the Sincerity, Excitement and Sophistication dimensions (that also existed in the USA and Japan), Peacefulness (found in Japan but not in the USA) and Passion (not found in the other two countries) were identified. In Brazil, the dimensions of brand personality were Credibility, Joy, Audacity, Sophistication and Sensitivity (Muniz, Marchetti, 2012).

Because of the differences in personalities within cultures, there has been a need to examine the brand personality construct from an international perspective.

Material and Methods

The goal of the research was to examine the personality of the Brand Nivea in Slovak and Czech consumers. The participants were evenly distributed 500 Slovak and Czech subjects. Average age was 26 years with standard deviation of 5.17. They were chosen on principles of convenience sampling and the participants have been selected from available population.

Respondents were presented a questionnaire. First, they were asked if they know the brand and only those reported knowing it were considered for the study. Then they were asked to imagine Nike was a person. “What kind of person it would be?”, “Who would be Nike friends with?”, “What kind of hobby it would have?”, “Would it be male or a female?” – These were the questions to describe the brand personality.

To visualize the results from the open-ended questions, word cloud Tagxedo was used.

Research results

The personality of Nike is very much related to the product that the company sells (active and athletic) as well as the characteristic of athletes (competitive) and of a heroic person (determined and focused). According to Mark & Pearson, Nike is perceived as a hero, the one who triumphs, gets through challenges and, in doing so, is an inspiration to all of us, it is a warrior and a leader. Nike’s personality is athletic. The company is positioned as providing the best athletic gear to all athletes no matter what sport. They have successful products in every major sport around the world. The brand created a personality of being a cool, successful and athletic.

According to Slovak consumers, concerning the demographics of Nike’s personality, 70 percent of Slovaks see it as a man and for 30 percent it is a woman. The average age is 33 years, ranging from 16 to 80 with a standard deviation of 11.

As a person, Nike is seen as (see Fig. 1) an athlete who is strong, fit, energetic and determined. Other qualities of the brand are kindness, openness, and confidence. It is also described as winner, friendly, adventurous, competitive, dynamic and clever. Furthermore, this brand is perceived as well as fast, stylish, tireless, flexible, modern, sporty and brave. The strongest associations are connected with sports, activity and energy, but also with fashion and style. All of the traits were positive, Slovak consumers do not associate Nike with any negative feature.

Fig. 1: Personality of Nike according to Slovak consumers

To a question "What kind of people would Nike hang out if it was a person", most of Slovaks answered it would be sportsmen and athletes. Young, active and attractive people would be friends of the brand. Funny, energetic, outgoing, extroverted, successful, easy-going, fit and smart. These are the qualities of potential friends of Nike. They copy the personality of the brand as an active, outgoing athlete who is enjoying life.

To get a complex view of the brand, Slovak respondents were asked to describe what kind of hobbies the brand Nike would have if it were a person. The most frequent answer was doing sports and healthy lifestyle. Nike is connected to a lot of sporting activities like hockey, climbing, running, yoga, fitness, tennis, basketball, and indoor sports, cross fit, hiking and athletics. Other hobbies would be traveling, fashion, hanging out with friends, going to parties, long walks in the nature and relaxing. We can conclude, Nike is a very active brand and also a brand that is modern, trendy and fashionable.

Czech consumers see Nike as a man in his 30ties. They describe the brand (see Fig. 2) as determined, athletic, active, energetic and strong. Other features of the brand are kindness, ambition, independence and friendliness. The man Nike is also very social, competitive, driven and smart. For some Czechs it depicts a hardworking, fashionable and proud man. He can also be described as a restless, brave leader. Almost all of the features connected to the brand were positive. The only two negative attributes were selfishness and arrogance, but they were only mentioned by less than 3 percent of the respondents.

Slovak consumers see Nike as a young, active man who is interested in sports, fashion and is living a healthy lifestyle. He is smart, outgoing and a natural winner. He would spend his time with young, attractive people who love sports. Czech consumers see Nike as determined, active and kind. It is a man in his thirties and likes to who practice various kinds of sports.

Nike is unique in the fact that the company has a broad target market. They target athletes, both professionals and non-professional. However, they don't focus on a specific age range. Nike has appeal to athletes from adolescence, to adulthood, to parenthood. Anyone who strives to be an athlete can be seen wearing Nike. This identity is reflected in the personality of the brand.

The overall personality of the brand is very similar in both Czech and Slovak consumers. According to both, Nike is positive, young, active and dynamic. It is in accordance with the overall image of the brand communicated worldwide no major differences in brand image and brand perception were found.

It is important to realize if the concept of human personality is applied to marketing, the principles of different cultures and different perception apply to humans as well as to brands. The cultural differences result in differences of perception and attitude regarding brands. Therefore it is beneficial to examine the global brands in national contexts.

Both researchers and practitioners have given considerable attention to brand personality because it is clear that perceptions associated with a brand go beyond functional attributes and benefits of a product. Brand personality can diverse the brand from other brands since brand has its own individual character. Having a favorable and unique brand personality, which creates positive brand equity, is important because it is a basis for competitive advantage and can even generate revenue for a company.

Stylized Facts About The Mortgage Market In The Czech Republic: A Cross-Correlation Approach

Ing. Mgr. Vlastimil Reichel, Masaryk University, Brno, Czech Republic, reichel.v@mail.muni.cz

Bc. Jana Gajdošová, Masaryk University, Brno, Czech Republic, 418267@mail.muni.cz

Abstract

This paper investigates a relationship between central bank interest rate (PRIBOR3M) and housing (mortgage) cycles in the Czech economy. The aim is to determine whether central bank's interest rate is leading indicator for monitoring housing cycles. To assess the crucial role of interest rate in the set of mortgage interest rates is used methodology of leading indicator applied by OECD. Moreover, the cross-correlation approach identifies the relationship between quarterly interest rate and the following individual variables: house price index, average mortgage interest rate, average fixed 1, 3 and 5 year mortgage interest rates, number of new mortgages, volume of new mortgages, average mortgage amount and mortgage installment. The data set covers a period between 2006:Q1 and 2016:Q3. The results of the paper will be used for later research and modelling of the housing sector in the Czech economy.

Keywords: house prices, business cycles, cross-correlation approach

Introduction

As housing sector still plays a significant role in the functioning of the Czech economy. For this reason, it is in the interest of the monetary authority to control and supervise the sector as an important part of the economy (Brůha and Polansky, 2014). One of the tools to influence the mortgage market is the interbank interest rate. This process begins with the operations on the open market by setting the interbank interest rates. From there, the transfer can take place through many channels, which is described by Mischkin (2007) or Michelva and Sebastian (2010).

We will focus on the relationship between the interbank interest rate and the variables describing the real estate market. The relationship is depicted on Figure 1. The solid lines show connections to be verified, the dashed lines display these, which are not subject of our examination. The plus sign means that pro-cyclic behavior of the time series is expected, the sign minus means that counter-cyclical behaviour of the time series is expected. If we assume that mortgage banks set their mortgage rate according to the central bank's rates then the behavior of mortgage interest rates should be pro-cyclical and delayed. Following the delay in response to mortgage interest rates, the average mortgage amount and mortgage installment should also be delayed. Because they both depend negatively on the mortgage rate, we assume the counter-cyclical relationship of the variables. Therefore, we expect the relationship between the interbank interest rate and the average mortgage amount and the mortgage installment to be delayed and counter-cyclical. The relationship between mortgage interest rates and the number of new mortgages or volume of new mortgages can be considered negative. The rise in mortgage interest rates affects the economic agents who borrow less and decrease the number and volume of new mortgages. This has an impact on the demand for real estate, which decreases and reduces the price of real estate (Iacoviello, 2000 or Hloušek, 2016).

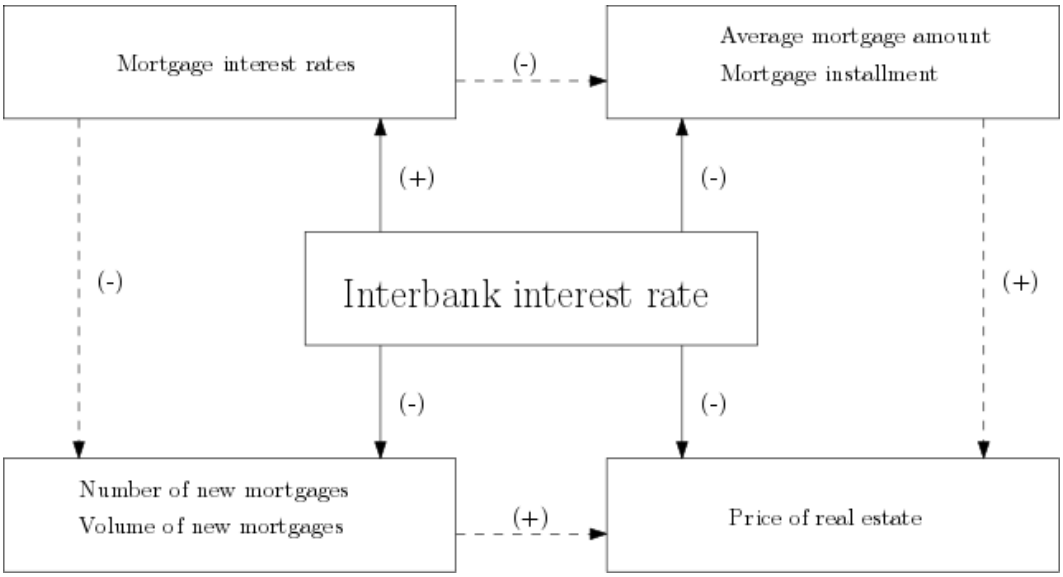

Figure 1: Relationships description

Methodology

The research briefly follows the OECD (2004) methodology of composite leading indicator (CLI) for monitoring and predicting business cycles. The methodology is composed of three steps (i) collection and preparation of data set, (ii) the peak analyses and (iii) a cross-correlation calculating. The same algorithm was used in the work Reichel (2016).

Data

The following variables were used in the research of monetary influence on the housing sector: house price HP, interbank interest rate PR_{3m}, average mortgage interest rate R_m, average fixed 1 year mortgage interest rate R_{1m}, average fixed 3 year mortgage interest rate R_{3m}, average fixed 5 year mortgage interest rate R_{5m}, number of new mortgages NN, volume of new mortgages VN, average mortgage amount (mil) AM, mortgage installment (1 million CZK for 20 years) Mi.

The data set was obtained from the Czech Statistical Office, the Czech National Bank and financial hypoindex databases (FH) and cover period 2006:Q1 – 2016:Q3. Time series with a monthly period were transformed into series with a quarterly period. The seasonally adjusted quarterly time series were all in logarithms, except for mortgage interest rates and interbank interest rate. Hodrick Prescott filter was used (with lambda=1600, see Hodrick and Prescott, 1981) to obtain the cyclical component of the variables. More detailed description is quoted in Table 1.

Table 1: Time series description

Time series		Data source	Frequency
Interbank interest rate PRIBOR3M	PR_{3m}	CNB	quarterly
average mortgage interest rate	R_m	FH, CNB	quarterly
average fixed 1 year mortgage interest rate	R_{1m}	FH, CNB	quarterly
average fixed 3 year mortgage interest rate	R_{3m}	FH, CNB	quarterly
average fixed 5 year mortgage interest rate	R_{5m}	FH, CNB	quarterly
number of new mortgages	NN	FH	monthly
volume of new mortgages (mil)	VN	FH	monthly
average mortgage amount (mil)	AM	FH	monthly
mortgage installment (1 million CZK for 20 years)	Mi	FH	monthly
Offering price of flats	HP	CZSO	quarterly

The peak analysis

Peak analysis is based on identifying the location of the global maximum and global minimum values in each time series and their comparison with a selected variable. Following section presents (i) global maximum of the time series and delay between global maximum of central bank interest rate and others variables, (ii) first global minimum of time series after this maximum and delay between global minimum of central bank interest rate and other variables and (iii) length of time period between maximum and minimum.

The Cross-Correlation Approach

The cross-correlation approach is a method of estimating the degree to which two series are correlated. The theory and algorithm were adopted from Paul Bourke (1996). We consider two series x_i and y_i where $i = 0,1,2 \ldots N-1$. In our case x_i is the vector of all variables mentioned above and y_i is interbank interest rate (PRIBOR 3M). The cross correlation $r(d)$ at delay d is defined as

$$r(d) = \frac{\sum_i [(x_i - \bar{x}) * (y_{i-d} - \bar{y})]}{\sqrt{\sum_i (x_i - \bar{x})^2} * \sqrt{\sum_i (y_{i-d} - \bar{y})^2}},$$

where $\bar{x}$ and $\bar{y}$ are the means of the corresponding series. If the above is computed for all delays $d = 0,1,2, \ldots N-1$ then it results in a cross correlation series of twice the length of the original series. The range of delays d and thus the length of the cross correlation series can be less than N, for example the aim may be to test correlation at short delays only. The denominator in the expression above serves to normalise the correlation coefficients such that $-1 \leq r(d) \leq 1$, where the bounds indicate maximum correlation and 0 indicates no correlation. A high negative correlation indicates a high correlation but of the inverse of one of the series.

Results

Table 1 presents leading and lagging variables. For maximal peak of PR_{3m} are lagging variables $R_m(6)$, $R_{1m}(5)$, $R_{3m}(5)$, $R_{5m}(6)$, $Mi(3)$ and $HP(1)$. Delays in individual fixed mortgage rates were expected. Individual mortgage banks respond to a change of the central bank with a delay. They are often unwilling

or unable to respond immediately because of additional costs, for example. The delay of the average monthly repayment is related to the mortgage rate fixation - the fastest growing average mortgage payments are for the one-year fixations, then for the three-year fixations and the slowest for the five-year fixations. This claim is also linked to the varied volatility of individual interest rates. The last column in the table shows the highest volatility in short-term interest rate fixations, while the lowest volatility has interest rates with a longer interest rate fixation. The volatility of the average mortgage rate is slightly higher than the three-year fixation rate volatility.

For maximal peak of PR_{3m} are leading variables NN (-4), VN (-4) and AM (-1). According to economic theory, the result is unexpected, but the findings due to the culminating boom are justifiable. The number of new mortgage loans is generally strongly correlated (Reichel and Gajdošová, 2017) with the volume of these loans (in currency). For this reason, we assume that both of these variables respond to the rise in interest rate equally. With the initial rise in the interest rate, mortgage interest rates increase and the total volume of these new mortgages drops. As a result, if the mortgage interest rates rise household's volume of new mortgage loans should decrease before the interest rates reach the maximum. Because of this, NN and VN may be the leading variables around the maximum. We see that the standard deviations for these two variables are the highest. Therefore, we can assert that the variables are the most volatile and the economic agents are very sensitive when drawing on these loans. Exceeding the average amount of the mortgage loan can also be considered as a consequence of the decline in interest in new mortgages due to increased interest rates and the economic downturn.

Table 2: Time series - peak analysis

Var.	Max	L_{max}	Min	$L_{\min}$	$\Delta_{Max-Min}$	STD
PR_{3m}	08:Q2	-	10:Q2	-	8	0,55
R_m	09:Q4	6	13:Q1	11	13	0,39
R_{1m}	09:Q3	5	13:Q1	11	14	0,45
R_{3m}	09:Q3	5	13:Q1	11	14	0,38
R_{5m}	09:Q4	6	12:Q4	10	12	0,37
NN	07:Q2	-4	10:Q1	-1	10	21,92
VN	07:Q2	-4	10:Q1	-1	10	20,50
AM	07:Q4	-2	15:Q4	18	32	6,78
Mi	09:Q1	3	13:Q1	11	16	3,09
HP	08:Q3	1	13:Q2	12	19	6,29

Source: Authors` calculations

For minimal peak of PR_{3m}, only one variable behaves differently than the maximum (AM is now the lagging variable). Other variables remain the leading or lagging variable. Furthermore, based on the results, it can be argued that the delay in reaching the minimum of individual variables compared to the minimum interbank interest rate $L_{\min}$ is much higher than in the case of the maximal interbank interest rate $L_{\max}$. Note that the highest delays $L_{\min}$ reach the variables R_m, R_{1m}, R_{3m}, R_{5m}, Mi and AM that are determined mainly by mortgage banks. This fact can be described as a kind of asymmetric behavior of mortgage banks. The results show that mortgage banks react more quickly to tightening monetary policy than to relaxing (as shown Guerrieri and Iacoviello, 2015 or Hloušek, 2012). On the other side, the lowest reactions between global minimums (due to interbank interest rate) have variables NN and VN, which are determined by the behavior of economic agents (households, firms), that are more sensitive to changes in interbank interest rate.

The cross-correlation values of central bank interest rate (PRIBOR3M) with the gaps of the examined time series are denoted in Table 2. Statistically significant values are shown in bold and the highest correlation values are underlined.

Even in this simple view of the data, there is evidence that the link between monetary interest rate and the mortgage interest rates has procyclical behavior over time. Moreover, all of the highest cross-correlations display shows mortgage interest rates as lagged variables and the lag of each series is different. This can be explained by the fact that mortgage banks consider (with longer fixation of interest rates) the future development of the interbank rate. For comparison, the average interest rate is delayed (the maximum value of the correlation is 0,62) as well as the mortgage interest rate which is fixed for five years. This may indicate that the clients of mortgage banks prefer longer and less risky fixation of mortgage interest rate. However, it should be noted that differences in the amount of correlation for each delay $0 \leq t \leq 5$ were negligible and statistically insignificant.

Table 3: Cross-correlation between interbank interest rate and the other variable

Variable	t-5	t-4	t-3	t-2	t-1	t	t+1	t+2	t+3	t+4	t+5

Source: Authors` calculations

The variables NN and VN are expected to be countercyclical and delayed with the interbank interest rate. Furthermore, we expect that the delay will be higher than delay between monetary interest rate and mortgage interest rates. This fact has been fully confirmed only in case variable NN where the highest value of the correlation was -0.51 with the delay of 5 years. Since we were not fully satisfied with the result, we decided to investigate the longest possible delay until time t+10. Unfortunately, it failed to prove that the longer the lag time, the higher are some of the negative correlations. From the variable AM we expected counter-cyclical and delayed behavior. For horizon $-5 \leq t \leq 5$, the highest correlation coefficient (0,41) was positive and no delay was established. For horizon$-10 \leq t \leq 10$, the lowest negative value of the correlation coefficient was -0.28 at time t+6. Therefore, at a longer horizon, it cannot be clearly stated that there would be a statistically significant delay, although some indications are captured in the data.

Looking at the value of cross correlation coefficients between interbank interest rate and real estate price, we can see a pro-cyclical relationship (correlation coefficients is positive 0,80). The similar results are denoted in Tsatsaronis and Zhu (2004). One would expect that higher interbank interest rate will also increase mortgage interest rates and simultaneously reduce demand for loans, which in turn will decrease demand for real estate and property prices should fall. This mechanism is not captured by the cross-correlation coefficient in the data. The result may indicate the inefficiency of the policy due to the longer time adjustment of economic agents.

Conclusion

The aim of this work was to briefly introduce how housing sector in Czech is related to the interbank interest rates of Central Bank. In the first part of the paper, we described general expectations of the relationship between the real estate market and interbank interest rates. Subsequently, the peak analysis was described. We found that the real estate market reacts faster with the growth of the interbank interest rate than with the decline. The last part of the paper focused on identifying the cyclicity of time series and finding the delays between them using correlation coefficients. The results coincided with expectations in: all pro-cyclical and delayed mortgage interest rates and variable number of new mortgages, which was counter-cyclical and delayed. For other variables, relationship expectations were not supported by the results.

Acknowledgment

This paper was created as a part of the specific research project no. MUNI/A/0943/2016 at Masaryk University.

Abstract

The article describes factors affecting effectiveness of complex technical systems, their relations and dependencies. Currently used complex technical systems performing operations that in past were done in separate, standalone machines are very sensitive for any disturbances as they are representing serial structure work centers. Fault of one chain of it causes downtime of all system. Each unit that system consist of has a different specifics and it's sensitiveness is in different area. Analysis of system environment requires detail researches in area of relations between factors that have direct influence on each unit and finding the way they influence indirectly on the rest of system elements. The article shows structural analysis carried out using MICMAC tools, that allow creating map of dependencies, build the model and find the key areas influencing system the most. The analysis of subject shows that OEE relevant to find root causes of standalone machine problems is not enough for finding reasons for complex technical systems downtime reasons.

Keywords: effectiveness, complex technical systems, OEE

Introduction

The changes that took place in the 21st century in the sphere of industrial production as a result of the continuous technological race led to significant reduction of production cycles by increasing the efficiency of the machinery parks (Juszczyński and Kowalski, 2013; Saniuk et al., 2015). As a result of the interaction of various external and internal factors in the operating complex technical systems, various cases are occurring causing processes to lose their usefulness. The problem of systems with a serial structure availability that was described in this article (due to the structure of the work center) should be interpreted in the category of faultless operation. The combination of machines and devices in this way expresses an object where its state of functioning occurs only when all its components are in a state of functioning. The object is down if one of its elements is broken (Niziński, 2002; Macha and Niesłony, 2010). This means that the elements of the system that interact with each other when performing certain functions at a given decomposition level are indivisible (Chybowski, 2014).

The aim of the paper is to present the possibilities offered by problem modeling by means of structural analysis to solve problems related to the effectiveness of complex technical systems. As a result of the analysis, a key factor was chosen for the downtime of the work center.

Structural Analysis Background

The advantage of structural analysis is the ability to identify compounds that combine features whose mutual influences are not obvious and may remain unrecognized by experts in the field (Loska, 2016). The use of structural analysis in the research problem enables the organization and analysis of collections involving a large number of variables (factors) that have mutual influence. The visualization of the relationship between the observed factors makes it possible to understand the problematic situation and to estimate whether the influence of factor A on factor B is significant or not (Nazarko et.al, 2017). From the network of links thus established, a comprehensive picture of the situation emerges, which takes into account the chains of interactions between elements and loops – causal links. Linked factors create loops, reinforce or counterbalance the problem (Piekarczyk and Zimniewicz, 2010). Using the methodology of structural analysis, one should interpret the force of interactions between the features by (Loska, 2016; Zimniewicz 1999):

- constructing of matrix of influences and direct and indirect dependencies between particular characteristics,

- transforming the matrix of influences and dependencies into a graph whose vertices correspond to the particular features,

- determining the interactions of external environment characteristics based on the number of paths and loops entering each node and exiting from each graph node, respectively,
- developing a map of interactions between the characteristics of the external environment.

The result of such analysis is a graphical image of clusters, described in the form of sets of factors (Fig.1).

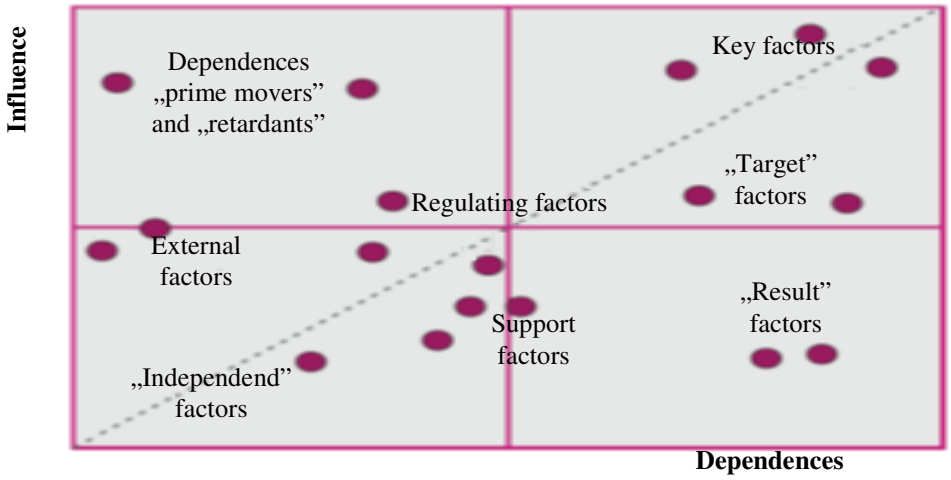

Fig. 1: Example analysis of technical system features (Nazarko, Wnorowski and Kononiuk, 2011)

The analysis includes the following group of factors (Nazarko, Wnorowski and Kononiuk, 2011; Loska, 2016):

- key factors: combining high impact force with high degree of dependence,

- factors "targets" that most often change by influence of other factors that affect the others, representing the objectives of the system,
- "results" factors, characterized by low impact and high complexity from other factors, are therefore susceptible to changes of determinants and key factors,
- decisive factors, which have a very strong influence on the tested system, i.e. driving and braking but also difficult to control,
- regulatory and ancillary factors that, although having a small impact on the analyzed system, can help to achieve the strategic objectives,
- autonomous factors, which have the least effect on changes occurring in the system,
- external factors that have an average impact on the system and at the same time have little impact on it.

The structural analysis matrix can be transposed using the MICMAC computer program. The basis of the software is the Boolle's algebraic logic principle, developed by Godet and experts from the French Computer Innovation Institute 3IE. The purpose of the application is to support scenario modeling based on La Prospective technology (Czaplicka-Kolarz, 2007). The application used at the initial stage of the analysis leads to the determination of the relationships between the variables indicated, in order to indicate the key factors. Taking into account the direct and indirect effects, the risk of not noticing the problem by the expert group is reduced. The expert group in the course of modeling decides on the interrelationships and relations between the elements of the system on the basis of brainstorming. Such a program is especially useful in the analysis of complex technical systems, which are made up of many driving forces, allowing the system to be represented in a simplified form, indicating the key factors of the examined problem situation.

Research object characteristics

The research object is a technical system built from an automatic feeder, a double end tenoner, a turning device, a second double end tenoner, an automatic conveyor, two drilling units, a turning device, a conveyor and an automatic stacker. The task of a complex technical system (Figure 2) is to obtain from the processed solid wood or wood based material element, the desired shape, size, accuracy and roughness of the edges, as well as drilled circular and blind holes, shape and diameter depending on the type of drill bit used. Depending on the production needs and the type of product produced, working centers are supplemented with additional processing units necessary for the process. Each complex technical system in this case in actual production is operated at a speed of 0.5 to 1.3 m/s, including a throughput of the drilling machine which is 1.4 to 1.6 m/s.

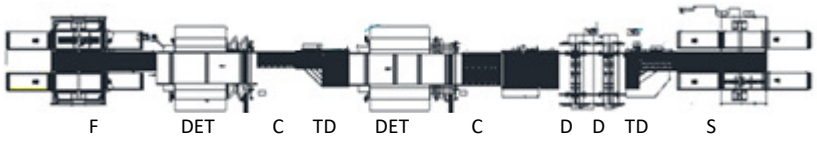

Fig. 2: An example of a numerical controlled working center used in large furniture manufacturing companies - as a system of serial structure, own elaboration (F-feeder, DET-double end tenoner, TD-turning device, C-conveyor, D-drilling machine, S -stacker)

Manufacturing companies to evaluate the machines and equipment use efficiency are based on the OEE Performance Indicators (Jasiulewicz-Kaczmarek and Bartkowiak, 2016). The OEE model is a key performance identifier used in the Total Productive Maintenance (TPM) strategy. Total Machine and Equipment Efficiency is used to estimate the efficiency of machine utilization during the planning phase and to verify that their implementation results. OEE compares the maximum theoretical capacity with actual production and indicates the development potential, defining the product of the three sub-indices

(Hamrol 2015; Jasiulewicz-Kaczmarek and Drożyner, 2011). Readiness, availability, and quality are expressed in the form of a product:

OEE = AVAILABILITY × PERFORMANCE × QUALITY (1)

where:

AVAILABILITY – technical readiness indicator,

PERFORMANCE – performance indicator,

QUALITY – Quality indicator defining the percentage of errors in the total number of items/products or work cycles.

Based on the performance index for four complex technical systems operated in a comparable manner (Table 1), it was noted that the overall machine evaluation model does not indicate the most critical system components. This problem is already recognized in the literature (Hedman, Subramaniyan and Almström, 2016; Zammori, Braglia and Frosolini, 2011). The table indicates that the quality index of the items produced is high, and the final performance indicator is low.

Tab.1: Example of evaluation of the OEE indicator for complex technical systems in selected companies (own elaboration based on enterprise data)

CTS **Indicator**	**„A" CTS**	**„B" CTS**	**„C" CTS**	**„D" CTS**
Availability	60%	58%	58%	61%
Performance	65%	60%	59%	66%
Quality	99,56%	99,61%	99,62%	99,86%
OEE	**38,98%**	**34,25%**	**34,17%**	**40,71%**

Low operating efficiency of complex technical systems obliged companies producing products for the same customer (benchmark analysis of Table 1), appointing their join experts group supervising the production processes in all their factories. Experts have analysed the downtime of complex technical systems and selected factors that affect the effectiveness of the operation. Factors selected by the expert group were focused on: technical, preventive, management and information areas.

Technical factors (T) were violent, unforeseen damage to system or destruction of its components, resulting in interruption of operation or loss of performance. Preventive factors (P) were related to preventive strategies and involved planning and implementing various types of activities to avoid failure and undesirable downtime. Management factors (Z) concerned the non-use of the normal production capacity of complex technical systems and the lack of a system of procedures, instructions and mechanisms to achieve the objectives set by the company. On the other hand, the information factors (I) concerned the stopping of the machining centre without affecting the other factors, which means that there was no technical failure. The results of the expert workshop on identification and organization of features are presented in Table 2.

Tab. 2: List of major factors affecting downtime of complex technical systems (from company documents)

Factor group	Symbol	Factors name
Technical	T1	unforeseen events (failure)
	T2	repair time
	T3	interruptions in delivery of production media
	T4	lifetime of moving parts of machines

	T5	setup conversion
Preventive	P1	Machine diagnostics (CTS monitoring)
	P2	schedule of diagnostic actions
	P3	undertaken improvement actions during work
	P4	unidentified cause of downtime
Managing	Z1	operational intensity (production plan)
	Z2	no raw materials or components
	Z3	deviation from quality requirements
	Z4	knowledge and competence of employees
	Z5	knowledge and competence of superiors
	Z6	stability of employment
	Z7	waiting for repair
	Z8	standardization of the production process
	Z9	standardization of spare parts supervision
Informative	I1	information exchange / communication

An expert group based on 19 factors identified the following research task: *What are the direct factors that affect the downtime of complex technical systems with a serial structure?*

Results of structural analysis carried out using MICMAC tools - Direct Impact Matrix

Internal group of experts initially carried out an assessment of the impact of characteristic a on characteristic b, based on the following scale: "0" - without influence, "1" - slight impact, "2" - moderate impact, "3" - significant influence (Zimniewicz, 2015). Such prepared forms allowed one to form a dominant matrix of direct influence and the degree to which individual factors influencing the downtime of complex systems were affected. The matrix of the values of direct influence and dependence of the interrelated features of the analyzed causes of downtime of complex technical systems is shown in Table 3.

Tab. 3: Direct Impact Matrix (own elaboration on the basis of company documents)

©LIPSOR-EPITA-MICMAC

The property characteristics of the direct influence matrix is shown in Table 4.

Tab. 4: MDI characteristics

INDICATOR	VALUE
Matrix size	19
Number of iterations	5
Number of zeros	231
Number of ones	58
Number of twos	44
Number of threes	28
Number of P	0
Total	130
Fill rate	36.01108%

When analysing filled matrix fields, there were 231 cases in which there was no relationship between variables and 58 cases had a poor relationship. Moderate impact occurred in 44 situations and strong correlation was observed in 28 cases. Identified by experts dependencies accounted for 36% of the matrix area.

Results of structural analysis carried out using MICMAC tools - Direct Impact Forces Analysis

The combined effect of the 19 factors affecting the downtime of complex technical systems indicates that the direct effect on other factors is due to the technical viability of the moving parts of the machine (T4); the technical factor described as repair time (T2), the machine diagnostics (P1) as well as two management factors, focusing on the intensity of complex technical systems (Z1) employed and the skills and preparation of employees for machining centers (Z4) as well as the information factor expressing the direct exchange of information between changes (I1). Direct effects, however, do not exert a factor in the supply of production media (T3), which can be interpreted as a factor independent of the production capabilities of complex technical systems. High dependence on other factors is due to technical factors indicating the system component's repair time (T2) and the lifespan of the moving parts (T4). System diagnostics (P1) are assigned to preventive factors. Management factors that determine the intensity of complex system operation (Z1), employee knowledge and competence (Z4), and standardization of process and spare parts (Z8 and Z9) also show strong dependencies. Factors that exchange information (I1) may indicate a lack of communication between departments and changes. The impact force is shown in Table 5.

Tab. 5: Total direct impact force between structural analysis factors (based on MICMAC software)

N°	VARIABLE	STRENGTH OF INFLUENCE	STRENGTH OF DEPENDENCE
1	T1	12	10
2	T2	19	17
3	T3	6	0
4	T4	25	21
5	T5	10	2
6	P1	17	21
7	P2	12	7
8	P3	11	11
9	P4	10	6
10	Z1	14	21
11	Z2	5	5
12	Z3	4	8
13	Z4	17	19
14	Z5	13	13
15	Z6	7	4
16	Z7	7	4
17	Z8	13	17
18	Z9	10	20
19	I1	18	24
	Totals	230	230
