The results of the first stage of the analysis which focused on evaluating the English version of the websites of 41 public universities in terms of Search Engine Optimization, Content, Design, Performance and Accessibility are presented in table 1.

Table 1 : University website result analysis obtained from www.site-analyzer.com

	University Website	Summary	Search Engine Optimization	Content	Design	Performance	Accessibility
1	University POLITEHNICA of Bucharest	48	65.6	17.7	57.6	63.8	35
2	Technical University of Civil Engineering Bucharest	37.3	20.6	37.5	51.4	75.5	28
3	"Ion Mincu" University of Architecture and Urbanism in Bucharest	49	49.6	37.9	71	53.2	35

Source: https://www.site-analyzer.com (browsed and calculated between 11-14 of July 2016)

The SEO component analyses header information, indexation, duplicate content, multimedia and networking.

The average SEO value for Romanian public universities is 46.54, compared to 51.75, the average SEO value of the top 10 universities. However, when it comes to this particular aspect of online marketing, Romanian universities seem to invest more, as the highest SEO value of 67.3 belongs the "Gheorghe Asachi" Technical University website. Also 8 Romanian universities websites registered SEO values higher than 60.5, which is the highest value for the top 10 universities. This is a positive aspect, considering that the research conducted by Gomes and Murphy (2003) revealed that half of the students stated that they use search engines to find a higher education institution website.

The Content component refers **to** content performance (Text/Code ratio), semantic and keywords. The average Content value for Romanian public universities is 31.4, compared to 43.51, the average value for the top 10 highest ranking universities, but the highest value for Content (80.3) is registered by "Dunărea de Jos" University of Galati while Cornell University has a value of 65.4.

The Design component examines standardization, layout quality, server configuration and security. The average Design value for Romanian public universities is 50.22 compared to 62.97 for the first ten universities. The highest value for Design is registered by the University of Pennsylvania website – 78.8, while the highest value for Design in Romanian websites is registered by "Ion Mincu" University of Architecture and Urbanism in Bucharest and "Iuliu Haţieganu" University of Medicine and Pharmacy Cluj Napoca – 71.

The Performance component **refers to** download and loading optimization. The average Performance value for Romanian public universities is 58.22 compared to 60.58 for the top 10 universities websites. The highest value is registered by the University of Medicine and Pharmacy of Târgu Mureș - 76.6, while Stanford University website has a value of 64,9. Eight Romanian universities registered Performance values higher than 64.9, mainly due to the fact that according to Ookla Net Index published in April 2015, the average download speed of fixed broadband connections in Romania is 72.15 Mbps, the third highest in the world, after those in Singapore and Hong Kong and nine cities in Romania are among the top 15 cities in the world with the highest download speed of fixed broadband internet connections.

The Accessibility component evaluates usability, internationalization (if content language is defined), sharing options and mobile compatibility**.** The average Accessibility value for Romanian public universities is 36.6 compared to 61.04 registered by the top 10 universities. The highest value for accessibility registered by a Romanian university is 64.8 ("Al. I. Cuza" University Iasi) compared to 93, the accessibility value of Stanford University website.

The highest difference was registered in the accessibility component, mainly due to the fact that many Romanian universities don't have mobile responsive websites.

4.1. Content analysis

Considering that manual website evaluation provides more details that automated testes, the content analysis was done manually, by accessing each one of the 43 universities websites which had an English version in order to determine if the content they publish on their website corresponds with the

information needs listed by students in the 2014 E-Expectations Report - The Online Preferences of College-Bound High School Seniors (2014).

The list resulted from the study was used as coding unit, and the research team took into consideration the different translations and adaptation for each of the terms, for example, the coding unit "academic program listings" was also presented on universities websites under "study programs", "educational offer", "academics", "academic programs", "education offer" or "study programmes". The content of these sections varied from specific academic programs addressed to English speaking students to presentations of all faculties and programs regardless of the language requirements.

The coding unit "cost" was translated as "tuition fees", "taxes", "study fees" or "tuition & fees" and included specific information regarding the fees and the ways to pay them.

The next two coding units, "scholarships" and "financial aid" were used as such with most of the websites providing no or limited information regarding those aspects, and when they did, the information was included in the menu referring to "tuition and fees".

The "academic program details" were used as such, most of the websites providing no information on homepage.

The coding unit "housing details" appeared most often as "accommodation" and included information about the university campus.

The coding unit "enrollment/admissions information" was also found under "admission information", "entrance examination" or "admittance" and it was the section included in most universities websites providing information, documents and links to governmental bodies involved in the admission process. One university presented the admission information under the menu "useful information" and another under "students". Three of the universities included in the study presented outdated information, referring to the admission for 2015 academic year.

The coding unit "student life information" was found as such or under "student info" and most often included information on students associations and on and off campus facilities.

All university's websites included a section in the main menu for research.

The extensive content research revealed that 88.4% out of the 43 English version websites included in the analysis were exact replicas of the Romanian language websites, providing the same structure and the same type of information.

Nine universities, representing 20.9 % only had the menu of the website in English or had the information presented both in Romanian and in English.

Table 2: Content analysis results

Coding unit	Academic program listings	Cost/fees	Scholarships	Financial aid	Academic program details	Housing details	Enrollment/ admissions information	Student life information
No of universities	28	10	5	1	10	4	31	14
Percent	65.1	23.3	11.6	2.3	23.3	9.3	72.1	32.6

Out of the 43 university websites analyzed, 3 covered 6 out of 8 coding units, 2 covered 5 out of 8 coding units and 8 covered 4 coding units, while the rest of 30 websites covered between 0 and 3 coding units. The websites which only had the menu in English and the subsequent information in Romanian were included in the 0 coding unit category.

Out of the 5 university websites which covered between 5 and 6 coding units, 2 are Medicine and Pharmacy Universities which is correlated with the statistical results showing that the highest percent of students from abroad are studying in the" health and welfare" fields.

In the same cluster of universities that covered between 5 and 6 coding units, 4 of them had SEO and Performance scores higher that the average value resulted through the analysis conducted with the automatic website evaluation tool, which was 46.54 for SEO and 58.22 for Performance. The result regarding the Content, in terms of the analysis conducted with the automated tool was somewhat surprising, as 3 of the university websites that cover 5 or 6 coding units, registered values under the average (31.4), proving once again the necessity to use manual evaluation alongside automated tools.

The manual content analysis conducted on the first 10 universities ranked in Webometrics Ranking of World Universities revealed that 9 of the 10 universities covered 5 or 6 coding units, and one covered 4 coding units. All universities covered "academic program listings", "financial aid" and "enrollment/admissions information" on their homepage. One relevant element in the content of the homepage was the fact that all 10 universities had a section entitled "alumni" an aspect often overlooked by Romanian universities.

Conclusions, Limitations, and Future Research

The world of higher education has dramatically changed in recent years and Internet technologies are playing a key role in this transformation. Considering the decision making process of foreign students in search of study abroad programs, the university website and the overall online marketing strategy become a key element of the enrollment process.

This particular research shows that although, the number of international students enrolled in Romanian higher education institutions has been on a steady increase for the past 7 years, there is still room for improvement in terms of online communication with prospective students.

On the positive side, the fact that 88% of all Romanian public universities have an English version of their website, shows an increased interest toward internationalization; and the fact that 19 university websites registered SEO values above the average and 8 university websites registered SEO values higher than 60.5, which is the highest value for a university website in the 10 ten ranking reveal that universities are beginning to understand the need to be visible and to perform online and invest accordingly. In terms of Content, Design and Performance 19 of the university websites analyzed registered values higher than the average for Romanian universities and in terms of Accessibility, 15 university websites were above the average.

The content analysis revealed that 88.4% of the websites were exact replicas of the Romanian version websites in terms of structure and content; plus, there are different translations of the same term, which can have a negative impact in terms of search engine optimization.

The first limitation of the research comes from the lack of specific statistical data regarding the number of international students enrolled in each university in order to be able to make explicit correlations.

The second limitation refers to the content analysis manual evaluation performed on universities websites as the websites are dynamic and can suffer consistent modifications both in structure and content since the research was conducted.

Our future research will focus on the integrated online marketing strategies implemented by public universities and will cover not only their website communication, but social media communication as well.

Abstract

Currently, the high efficiency of the university in Russia and beyond is the most important and desirable for achieving indicator. There are many ways to evaluate performance: different internal methods and international ratings. Most of the available methods are not exhaustive, and not many of them consider the effectiveness of the university from the position of the labor market. The analysis was carried out through comparison of methodologies and ratings in order to assess the effectiveness of universities. Conclusions are drawn with intention of converting the elaborations in future research more complex and reasonable models for assessment of university performance.

Keywords: efficiency, economic efficiency, efficiency of the university, ratings of universities, methods of evaluation of efficacy.

Introduction

The effectiveness of higher educational institutions is one of the most urgent topics for today, which are raised by both the scientific community and representatives of the state executive power. The quality of educational services, their correspondence to the real needs of the economy and society, the level of competitiveness of Russian education in comparison with foreign ones, the level of practical applicability of the knowledge of competencies that students receive, the social and educational functions of universities, the place of universities in the economy of cities, the country and the economy in in general, only some areas of discussion within the framework of this topic.

Since there is no consensus both in Russian and foreign literature on the method for conducting assessment of university effectiveness, we believe that it is reasonable to contribute to the scientific field comparison of different approaches in order to create in future research basis for elaboration of one methodology, which will cover all the angles.

Literature Review

This paragraph is dedicated to the description of different methods and methodologies, which are used for assessment of university socio – economic performance. This overview provides detailed information, concerning each discovered methodology.

In Russia, all universities are obliged conduct self assessment of their effectiveness. The methodology is determined annually by the Ministry of Education. There are eight main groups of indicators: educational activity, scientific activity, international activity, financial activity, salary of the teaching staff, graduate employment, student contingent and some additional parameters. These indicators are intended to describe the general activities of universities, but do not reflect the level of efficiency and effectiveness of the university.

The methodology for assessing the socioeconomic impact of the University of Birmingham applies the latter to assess the impact of the university on the city, region and country as a whole. A distinctive feature of this approach is that it is not so much an assessment of the effectiveness of the

organization's activities as an assessment of the impact of this organization on the life of the city and the region. In total, the assessment is conducted according to six main parameters: the university as a teacher; as an employer; economic effect of the university; as a research hub; as an international gate; as a neighbor.

THE World University Rankings - until 2010, a global study and the accompanying rating of the best higher education institutions of world importance. The level of achievements of universities is assessed based on the results of a combination of statistical analysis of their activities, audited data, as well as the results of an annual global expert survey of representatives of the international academic community and employers who express their views about universities. The criteria for selecting experts for the survey is scientometric analysis of productivity and citations, as well as teaching and research activities in higher education institutions for more than 16 years, the availability of at least 50 published scientific papers and other criteria. The analysis of the activities of higher education institutions consists of 13 indicators. The main evaluation criteria are international student and teaching mobility, the number of international scholarship programs, the level of scientific research.

Model of the quality management system in accordance with the international standard ISO Assessment of compliance with the expectations of the consumer in terms of the performance of the educational institution, in the context of the training of professionally trained specialists.

Model EFQM (European Foundation for Quality Management) is a model of the European Fund for Quality Management, designed to encourage organizations to improve the quality of products and quality of management. The fund was established in 1987 by 14 leading European companies.

The rating of the best universities of the world (QS World University Rankings) is the global rating of the best educational institutions of the world in terms of their achievements in the field of education and science. Calculated by the methodology of the British consulting company Quacquarelli Symonds (QS). The rating evaluates the universities in terms of the following indicators: the activity and quality of research activities, the opinion of employers and career potential, teaching and internationalization. As a result, the rating of the top 500 universities in the world is made, as well as the ratings of universities in separate disciplines. The level of achievements of universities is assessed based on the results of a combination of statistical analysis of the activities of educational institutions, audited data (including information on the citation index from the Scopus database, as well as data from the global expert survey of representatives of the international academic community and employers who express their opinions about universities

Some authors assess the effectiveness of the university as a contribution to the economy, for example, Breznitz & Feldman (2012) suggest that there are five different roles that can be implemented by the university: economic initiatives, policy development, knowledge transfer, teaching and basic research. In the course of their research, the authors tried to systematize the practice of universities in the United States, aimed at assessing their contribution to the economy.

The work of Kelly, McNicoll & White (2014), for example, was devoted to the question of assessing the impact of universities on the UK economy, including such indicators as direct incomes, expenditures, impact impacts on the economy, the additional influence of foreign students and visitors, the contribution of higher education to gross domestic product of the UK and the effectiveness of spending on higher education to ensure economic activity.

The Russian author Rivchun TE (2010) in his article suggests assessing the university by calculating the integral efficiency, identifying key areas of effectiveness.

Author Gurtov V.A. (2012) suggested to calculate the efficiency of activity of high school graduates from the standpoint of employment, taking into account supply and demand in the labor market. In Russia, this factor influencing employment has a stronger impact than in countries with developed market economies, since the infrastructure of a market economy is less developed.

Key Results

It is proposed to review the methodology and evaluation ratings from position of problem areas identification. The following parameters have been selected: assessment of the effectiveness of the university (self-examination), from the position of the person (Student, entrant, graduate), from the position of the state (how the state regulates and influences this technique), from the position of the labor market.

Analyzing the existence of aspects that affect the effectiveness of the university in connection with changes in the labor market, which is developing quite rapidly, the authors consider it advisable, since universities are modern centers of innovation, graduates have more specific skills and are able to compete in the labor market, which makes it change. The development of the market for the provision of educational services significantly increases the competition between higher education institutions. This raises the need for more effective management and use of their logistical, labor and financial resources.

The authors offer a comparative analysis of methodologies and ratings, both domestic (Russian) and international, for compliance with these parameters (Table 1).

Table 1: comparative analysis of methodologies and ratings

Method name	State	Human	University	Labor market
Methodology for assessing entrepreneurial activity of budget educational institutions (according to MV Niyazova)			+	
Methodology for assessing the organizational effectiveness of non-profit organizations (J. Gibbson, J. Ivantsevich)				+

"Technique and technology of measuring" quality of the university "as the basis for the system of			+	

regular rating of Moscow universities"				
Methodology for assessing the effectiveness of higher education institutions of the Ministry of Education and Science of the Russian Federation	+		+	+

Discussion

Most of the methodologies considered assess the effectiveness of the position of the university. This is almost all methods that involve rating, calculation of an integral indicator, licensing and accreditation. There is also a lack of methods that assess the effectiveness of an educational institution from the position of a person (an applicant, a student, a graduate).

It can be seen that the Russian methodologies are mainly aimed at assessing the university in terms of meeting the needs of the state, as well as the satisfaction of applicants and students. International methods encourage universities to conduct self-examination.

At the moment, there are few methods aimed at the labor market. The university is a stable operating system, however, in the conditions of developing new technological structures, when the regional economy requires more and more qualified specialists, the university needs to focus on the labor market, and labor market performance indicators should be evaluated and taken into account in the efficiency evaluation system.

Institutions of higher professional education are the main element of training personnel for building a new economy and transforming society. Their effective functioning is a necessary condition for obtaining qualified personnel whose competencies and knowledge meet modern demands of the economy.

Conclusion

On the basis of the analysis given by the authors, it becomes obvious that the existing methods of evaluation and rating are not perfect, they do not have institutionalized and tested criteria on which reliable indicators can be constructed that measure the social and economic effectiveness of the university. Therefore, it is necessary to develop a more complex methodology, which would include the evaluation of the university in terms of employing graduates. Investigating this aspect, the methodology should take into account the indicator of the employment of graduates (including in the specialty), the regional economy's need for cadres. Having such data, the university will be able to improve its efficiency by taking correct management decisions.

Managing the Architecture of Life-Cycle Processes Of Unique Technical Objects

Valery Maslennikov, Doctor of Economic Sciences, Professor, Academic department of Management theory and business Technology, Plekhanov Russian University of Economics, Moscow, Russia, vvmaslennikov@gmail.com

Irina Kalinina, Ph.D. in Psychology, Associate Professor, Academic department of Management theory and business Technology, Plekhanov Russian University of Economics, Moscow, Russia, Kalinina309@yandex.ru

Abstract

The aim of this article is to explore the approaches to to the construction of a system for managing life cycle processes of unique technical objects – space systems regarding to the constant development of complex projects operating technologies. The main attention is paid to the features of the transition from an enterprise administrating to management of a unique objects (a chain of creating space systems) creating cooperation based on life processes control of the space object. The article includes the analysis of application of normative costs calculating methods, calculated to a unit of useful result of a space system at its full life cycle stages using program facilities for processing data base and statistic material of implemented programs and projects.
Recommendations on using the methodology of life cycles system engineering to a solving of a target aim of locating methodology PLM to an object of a "system of systems" are based on studying Roscosmos and NASA experience on system engineering and life cycles of space systems strategy planning and are given in this article.
The research results are directed on solving a problem of complex space systems administration reorganization with building the architecture of financial and economic management of life cycles of space systems (including ground-based and orbital components).

Keywords: the architecture of life-cycle processes, unique technical objects, space systems, strategy planning, space systems cost.

Introduction

Space industry is having a restructuring of management now. The principal approaches to building the architecture of financial and economic management of life cycles of space systems (including ground-based and orbital components) are being reconsidered. The reason is that the problem of estimating the value of unique objects – space crafts as products/technical items of various applications has not been solved.

So when calculating the cost of the result for the state customer, specific consumptions on the volume of the transferred communication data, sq.km of shooting and other natural instruments of measuring the result parameters are not considered. For example, at increase in need for data transmission the volume of processing of of telemetric parameters of orbital SC (spacecraft) monitoring exponentially grows at the same time, and that demands new investments into the technologies of a ground-based complex of management and reception.

The problem becomes even more complicated in managing since estimation of cost of space systems (further SS) not solved.

The existing pricing methods on purchases of SC by the state:

1) do not provide effective control of cost of SC depending on the useful result of use of SC (result parameters);

2) do not provide preservation and development of assets of the enterprises and organizations creating SC;

3) do not lean on cause and effect relationships in processes of practical increase of expenses in process and following the results of implementation of the SC projects.

Relevance of the Research

The analysis of space branch from the point of view of management showed importance of two directions of researches - risk management and management of technologies, from the point of view of increase in efficiency of business operations and receiving the state support of new businesses creation [1].

Definition of basic elements of process design that has to consider the changed economic conditions in Russia and give abilities to integrate into national economy for space industry presented in publication [2, pp. 90-98]. The similar research of economic management for space industry presented in publication [3, pp. 80-89]. At the same time it is proved that the over expenditure of means negatively affects reputation of project management and it is required to minimize this effect by means of training of future managers of economic administration instruments.

Many researches are dedicated to intellectual systems and technologies. So, V.O. Karasev and V.A. Sukhanov [4, pp. 142-147] open use of intellectual systems and technologies in a modern control system of life cycle of a product on the basis of a multi-agent program system. The similar result presented in publication [5, pp. 70-79, 6, pp. 387-398]. Life cycle of a product is also investigated from the point of view of business models efficiency [7].

Research conclusions [8, pp. 271-282] concerning a problem of the choice of spacecrafts durability in the conditions of the reduced starting price and at various costs of durability models are of special interest. In a research study mention that the cost of long-term use of SC includes the increased risk of retardation of technology owing to a progressive tense of the updating of technology leading to loss of cost and competitive advantages. Practical aspects of management of life cycle of spacecrafts it is stated in material of NASA [9, 10, 11].

At the same time, the technique of more exact assessment of costs of obtaining the result, useful to the state, from use of KS (the volume of the transferred data, the areas of photographing, etc.), taking into account the decomposition of objects/works/cost on a systematic basis with coordination of an orbital and ground-based component of obtaining the set result volume from space system is necessary.

The task - to approach formation of reference books, specifications, the integrated database on SS of different function then it will be possible to use standard methods of forecast/calculation of costs of SS on unit of useful result, on all stages of its life cycle, based on use of software for processing of databases and statistical material according to already realized programs and projects is in the long term set.

Besides, it is about support of unification and standardization of space components and platforms based on which SS of different function are created. On the example of the spacecraft unification concerns, for example, the following decisions:

- the unified execution of the basic functional and structural elements;
- uptight execution of a design on the basis of cellular panels;
- providing the thermal modes with use of thermal pipes;
- high-precision provision of orientation and stabilization by means of astrodevices, a complex of the operating dynamic engines flywheels (COEF);
- use of the electroreactive engine system with a high specific impulse providing long functioning of the small space crafts (SSC) at limited stocks of mass of working fuel and high purity of own atmosphere of SS;

• use of highly effective arsenide-gallium heterostructural photoconverters for solar batteries;
• use of the command radio line compatible to the State ground-based automated complex of management of the Russian Federation.

Contents of the Study

We consider management of life cycle of unique technical objects as the actions connected with the organization of targeted transition of system from one state to another within life cycle. In relation to space industry, it means that in the management process the problem of conditions combination of stages of life cycles of orbital group with ground-based technical complexes in the conditions of uncertainty based on the feasibility study is being solved.

The scientific problem of creation of processes architecture of life cycle of unique technical objects - space systems is that the orbital complex includes the small spacecrafts (SS) and ground-based objects a part, having the essential features. So, SSC possess the life cycle consisting of the ground-based and flight stages differing in complexity of the project of creation of SSC – from the specification to creation of an object, complexity of service conditions and start of an object, impossibility of maintenance and regular repair, etc.

Life cycle of a land part passes through modernization stages that change characteristics of objects and their technical capabilities in use.

Now there is no uniform representation of understanding of system of economic management of life cycle of space systems, the technology of information support of life cycles of orbital and ground-based components is not defined.

As the customer of useful result from the state speaks on behalf of space industry is the state, and it is the owner of assets of space systems, there is a task of economic management of the useful result unit cost received from SSC on condition of preservation, modernization and development of objects of land infrastructure.

Therefore, the state customer cannot estimate objectively required expenses and terms of creation of SSC, and modernization of objects of land infrastructure now.

The solution of this problem is possible with use of intellectual PLM technology (Product Lifecycle Management). It is offered to develop actively by analogy with the technical directions having the general or chief designer of the chief architect of space systems given authority to organize a control system of life cycle of the making space systems by means of interaction of all participants of creation, operation and development of MC (managing committees) (fig. 1).

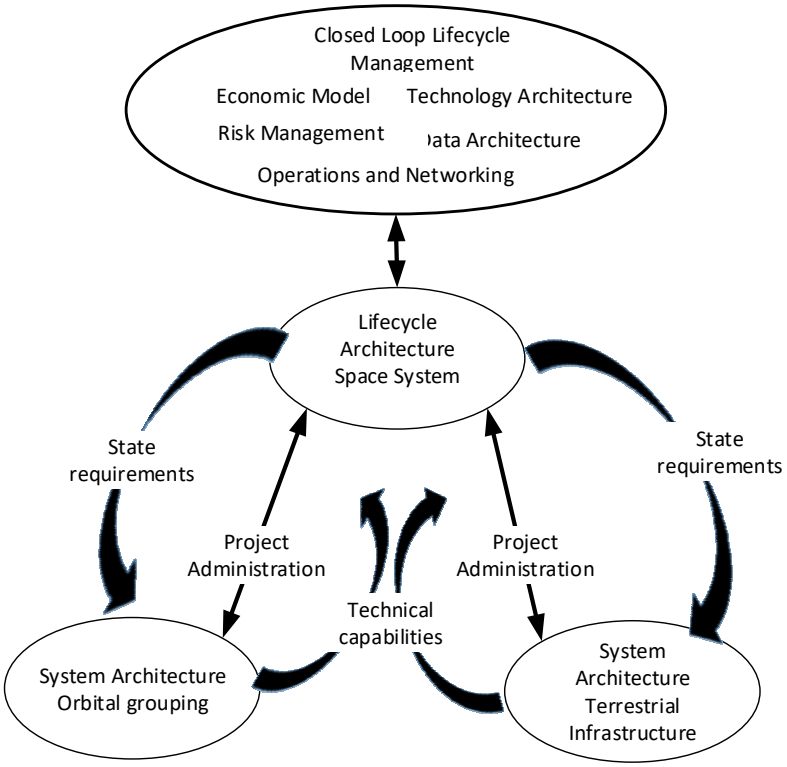

Fig. 1: Architecture of lifecycle management of space systems

Management of SS cost at all stages of its life cycle includes:

1) formation of the budget project (budget planning of the project),
2) an investment assessment in maintenance and development of the assets necessary for realization of the state purposes in space branch,
3) pricing on SS,
4) examination (check of definition reliability) of the cost of materials, knots and components necessary for SS creation,
5) cost formation of SS,
6) cost control of process of implementation of the KS project,
7) analysis of the actual expenses (SS cost).

At creation of architecture of processes of life cycle of unique technical objects - space systems it is also required to consider that technologies of management of complex projects continuously develop. In world practice the integrated teams the providing collaboration of the customer, parent organization, the contractor and producers of knots and units at a stage of development of a concept and design of unique objects begin to be applied. It allows giving more precise estimation of the cost of unique objects at early stages of their creation.

At the same time one should mean that in recent years actually there was a transition from business management to management of cooperation of creation of unique objects (a chain of creation of KS), and also transition from release of a product - to management of life cycle of an object.

1. Considering the fact that the methodology of traditional system engineering is focused on a product and a control system of life cycle of a product it is necessary to solve a target problem of localization of methodology of PLM to a "system of systems".

At the same time as a product in engineering of life cycle not the technical product – the spacecraft, and composite heteroton "System of systems - in the form of the space system (SS)" is considered. In world practice importance of study of methodologies of "System of systems" is realized, recognized on flowing the moment priority for researches and developments in hi-tech spheres of action.

2. To determine parameters of the state order for creation of SC (criterion function of the project for the state customer), for example, result for the state – the SS concrete parameters for all term of its active existence.

3. To create approach to pricing methods on SS taking into account the space and land making obtaining useful result KS (criterion function for the state customer). For this purpose to include methodology of calculation of justification of cost of services of orbital and land components in summary calculation of cost of SS.

4. In the course of government procurement to use complex contracts for the KS components determining the cost of unit of useful result for all length of life of SS taking into account the cost of services of the space and land components presented in operational architecture of space systems (by an example of NASA). For this purpose it is possible to use as examples of stages of life cycle of SC the decisions on system engineering stated in handbook of NASA and ESA (fig. 2).

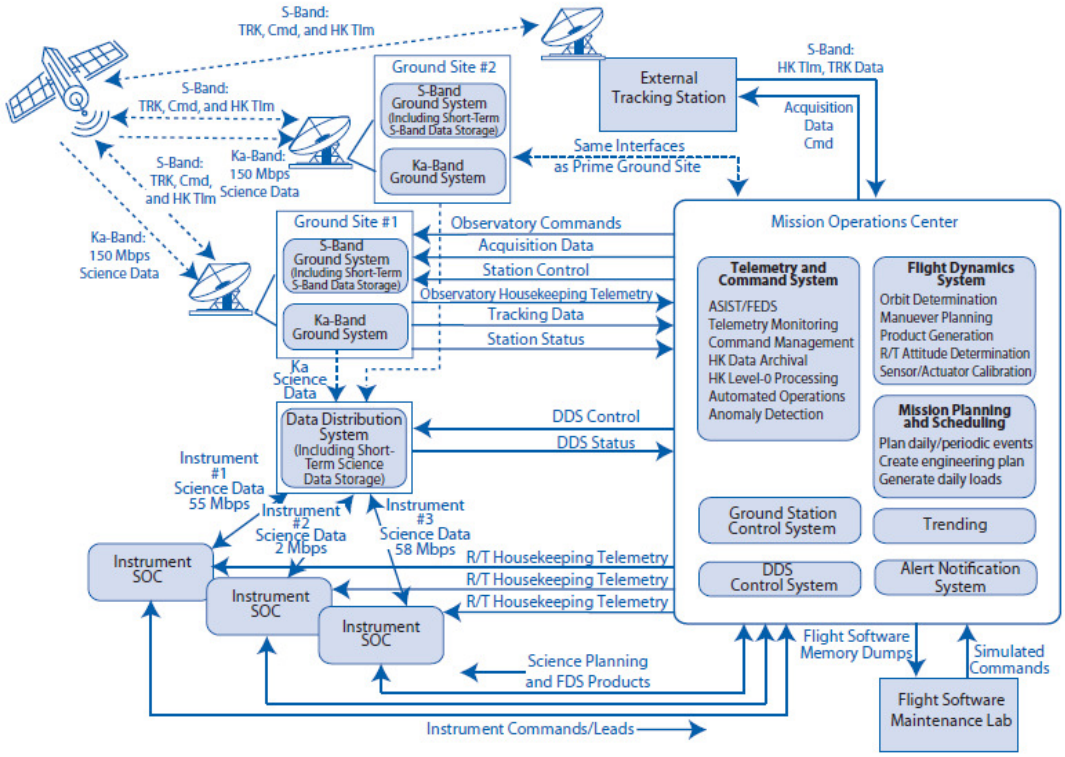

Fig. 2:Example of an associated end-to-end operational architecture [9, p. 36]

5. The end of technology of creation of processes of life cycle of unique technical objects - space systems is offered to be finished in the handbook "Architecture of System of Financial and

Economic Management of Processes of Life Cycle of Space Systems (including Land and Orbital Components)" format which turns on the following modules:

• localization of methodology of system engineering and management of life cycle in relation to the considered type of objects – space systems;

• an assessment of results of creation and use of SS on the basis of the concept "space systems cost" including grouping of spacecrafts, launch vehicles, a fairing, accelerating modules, a land part - a) the flights control center (FCC), b) reception stations + all objects necessary for correction of spacecrafts, c) other objects of a complex;

• the model/scheme of pricing on SS on unit of useful loading / useful result taking into account direct costs on creation of SS and distribution of the general expenses of orbital and ground-based complexes and their integration among themselves;

• system model of management of SS cost at all stages of life cycle of SS (process and cost design);

• procedures of coordination of decisions on pricing in space branch with a state orders for SS according to the current legislation;

6. As an expedient form the organization of the project of development of the decision to choose a form of cross-functional design group of profile specialists in a target task.

Conclusion

The carried-out analysis showed the need to develop system engineering of SS more actively that provides a solution of the problem of management of life cycle of the ground-based equipment and an orbital component of SS. For justification of a control system of life cycle of SS it is necessary to solve a problem of a combination of operating activities of SC and an assessment of a condition of a ground-based part.

The offered approach will allow proving the conclusion of contracts for purchase of the SS components for the state needs taking into account formation of technological platforms, based on the choice of the conteractors and subcontractors providing preservation and development of their assets potential. It is for this purpose possible to use a technique of the summing up sliding on time costs of the SS project at early stages of its life cycle and definition of the rest of investment before end of the project.

Besides, there is a need for further development of a scientific methodological support of creation of architecture of processes of life cycle of unique technical objects - space systems. In particular, the Agency of strategic researches [4] predicts the need for a profession "The designer of life cycle of space constructions" which can appear until 2020. This profession means activity of the specialist in design of space constructions (stations, satellites, etc.) taking into account problems of their modernization, reorganization and utilization. It is emphasized that demand for these experts arises in the next years in connection with more intensive development of near-earth space and renewal of plans for colonization of the Moon and Mars.

Abstract

This paper deals with knowledge based designing of classic mechanical engineering products. This approach to machine design allows acceleration of the design process. Using the knowledge also reduces the number of poor quality products and reduces the time of manufacturing. In addition it saves money in all phases of the product lifecycle.An example of knowledge based (project database) designing is introduced. The example used is a press tool for serial production in the automotive industry. The strategy which is used to create a 3D CAD model is also introduced in the paper.

Keywords: Machine Design, 3D model, CAD, Knowledge engineering, Knowledge based engineering

Introduction

Designers work in multidisciplinary environments with many constraints such as functionality, manufacturability, aesthetics, etc. The work of a designer is carried out in a competitive environment where industrial companies are constantly forced to speed up the development process while lowering the price of the final product. It puts considerable demands on company processes and process management. This article focuses on the design process that fundamentally affects all the following processes such as manufacturing processes, assembly processes and the successful launch of a product on the market. To enhance the efficiency of the designers' work, it is possible to involve and integrate Knowledge-Based Engineering (KBE) and Knowledge-Based System (KBS) into the design process. Knowledge-Based Engineering (KBE) can be defined as "The use of advanced software techniques to capture and re-use product and process knowledge in an integrated way" (Stokes, 2001). A certain analogy in this way of designing can be found even in Industry 4.0 which encourages the use of machines (software and control systems) to take on repetitive and simple activities that people have done so far. "Knowledge based engineering (KBE) stands at the cross point of diverse fundamental disciplines, such as artificial intelligence (AI), computer aided design (CAD) and computer programming" (Rocca, 2012).

A 3D CAD model allows full visualization of part geometry. "Engineers can draw more details and exact shapes in 3D, enabling them to consider the design from a multi-functional perspective" (Baba and Nobeoka, 1998). It also allows digital pre-assembly and it is a data source for many different simulations, computations and manufacturing processes (FEM - Finite element method, CAM – Computer aided manufacturing, rapid prototyping, etc.).

The key for repetitive design success is reusability of enterprise knowledge. Consequently it is necessary to have management of company knowledge which is integrating known practices with new technologies. "KBE is not suitable for all design tasks but this does not mean that it is not applicable to a wide variety of products. For example, if a product's design is heavily influenced by its style, then traditional methods may be more appropriate for completing the exterior styling" (Cooper et al., 1999). Which means that KBE, or KBS, cannot be used to their full extent for each type of product, but the basic principles can be

applied. The key pillars in the presented knowledge database and designing are a finished project database with strict CAD model strategy and project design guides.

"The identification of the appropriate approach to application development depends upon the particular application requirement. However, a structured method of development in which user requirements are carefully identified and used to drive the construction of the application architecture will help to ensure success" (Cooper et al., 1999).

3D CAD Model Strategy

What is a 3D CAD model? "The product model represents the engineering intent behind the product design, storing the how, why and what of a design. The product model is an internal computer representation of the product design process and can contain information on both the product and processes that go to create the part" (Chapman and Pinfold, 2001). "According to the typical methodological approach to practice KBE, before starting with the development of any KBE application, it is required to proceed, first, with the identification, then the acquisition and, finally, the codification of the relevant knowledge that will have to be embedded in the KBE application itself" (Rocca, 2012).

It is suitable to have a large number of similar characteristics to use KBE for CAD design. In an ideal case it is possible to build the CAD model to make it work as a "program" that will only be fed by the basic parameters. In this case, it is possible to program the CAD model to work almost like a knowledge based system (KBS). The only functional requirements are fed into the generative model. "The parts can have rules and methods applied to them, rules such as costing rules, stress rules and process rules" (Chapman and Pinfold, 1999). But this can only be used on models that differ merely on a small scale. However, in the press tool industry (which is used as an example of the simplified use of KBE), many parameters are varied on the basis of customer requirements and these may vary fundamentally in some cases. Therefore, a simplified model is applied. Subroutines, constrains and control tools parameters are created in the CAD model.

Example of Knowledge CAD Design and Project Database

The model of a press tool for serial production in the automotive industry is used as an example. These tools produce acoustic parts and carpets for cars. The press tool is usually made of solid blocks of material or from casting. This semi product of the tool is machined to its final shape. The press tool contains many unified parts that do not differ or differ only in basic dimensions. An example of a press tool model assembly is shown in figures 1 and 2.

The basic model is controlled by basic specifications, parameters and values, such as:

- external dimensions (height, width, length)
- wall thickness (in relation to used material)
- type of clamping system to the press
- heating/cooling type
- insulation type and thickness
- maximum weight of tool assembly
- type of guide system

- shape type of manufactured part (flat, complex geometry, etc.)

Firstly, it is necessary to carry out tasks such as "Capturing the information in the form of knowledge by putting the data in a specific context with attached rules, processes, and instructions" (Rezayat, 2000). In the case of press tools, the geometry forming the produced part (see the example in Figure 3) must be easily editable and interchangeable. For example, see the upper and lower tool surfaces in Figure 4. This is necessary due to frequent surface design changes by the customer. Another reason is that it is easy to use an existing 3D model to reproduce a new tool by simply changing the tool work surface. The interrelationships in the 3D model must be set so that when the 3D geometry is regenerated, the geometry will not crash. Crashes lead to challenging repair and problem-solving which must be addressed by the designer. In some cases some parts of the press tool are so specific that is not possible to automate the process. In these specific cases, expression with subroutines and parameters would be too hard, with doubtful results.

The "programmed CAD model" has to be accompanied by guides and guidelines so it is possible for the design to be easily reworked by any available designer. An example of another document allowing effective design work with such a model is the database of approved designs and technologies. The manual can be in the form of a structured PDF including a 3D model in PDF format. This makes it easier for new or beginning designers.

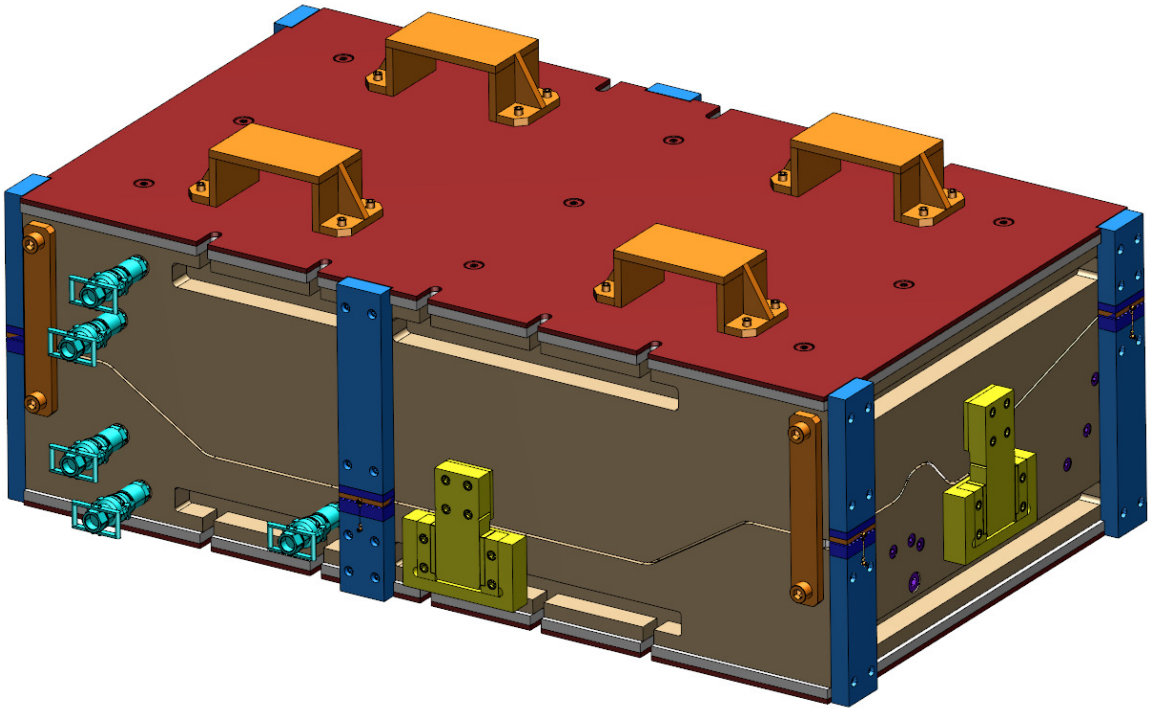

Fig. 1: Example of tool assembly

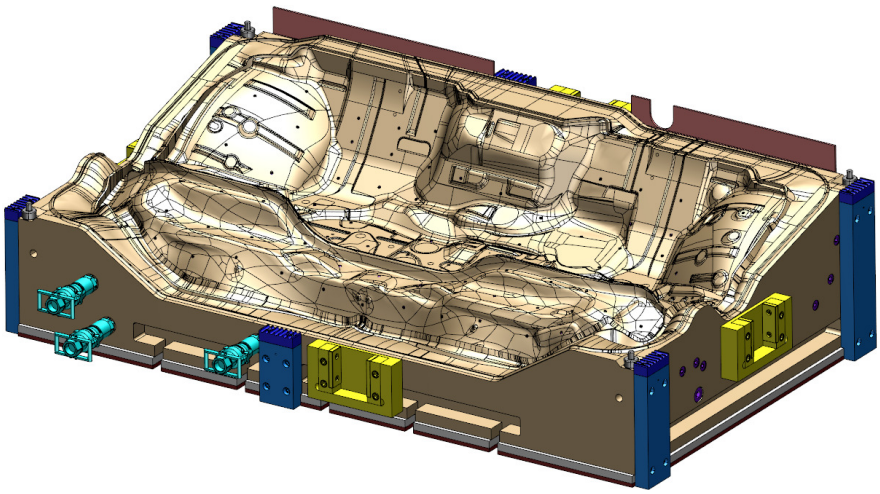

Fig. 2 :Lower part of tool assembly

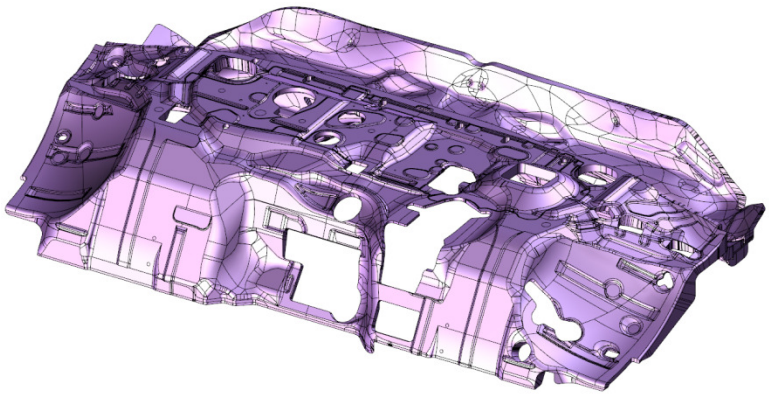

Fig.3 : Part produced by the tool

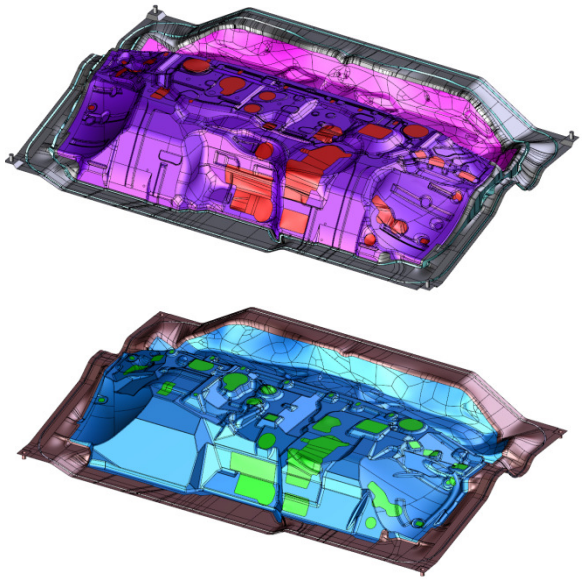

Fig. 4 :Lower and upper tool surfaces

Summary of contributions

- Accelerates the process from the beginning of the project to the production of the final product
  - It brings competitive advantages
  - Fast editing of CAD model - in all possible phases of the project
- Saves money and time
  - In integration of newcomers (designers) into the work process. Another contribution related to this topic is that "This makes the company more resistant to staff turnover" (Sandberg, 2003)
  - In learning and training of workers
  - In the design process ("Automation of repetitive and non-creative design tasks" (Rocca, 2012)
  - In the process of manufacturing and assembling
  - Reduces the number of faulty products
  - Reduces the price of product

University Project Database

These projects are mentioned in this paper as they contain some elements necessary for practicing KBE. In these projects, which are converted into study materials, students can get acquainted with know-how from practice which is very frequently "hidden". The PPD (Professionals' Projects Database) was created at the University of West Bohemia (UWB). "PPD consists of real design projects created by local engineering companies and were reworked by academics at UWB into a form suitable for learning purposes" (Hynek et al., 2014). Study materials are passed to students in the form of an interactive PDF. It is also possible to find models that were partly designed according to the principles and methods of

KBE. Study materials are described in detail by (Hynek et al., 2013). Each part of these electronic study materials is introduced there and a special focus is dedicated to the 3D models imported to the structured PDF file. The PDF is accompanied by additional related information.

Summary

Using KBE methods provides industrial companies with tangible financial savings and competitive advantages. It is not necessary to use KBE to its full extent in order to achieve benefits for the company. It is therefore up to the company to determine the extent to which these processes should be implemented. From the point of view of future development, it is obvious that these methods will play a more important role in designing components and the design process itself. The higher the level of implementation, the higher are the input costs for creating them. The economic benefits are indisputable at a suitably chosen level of implementation of these principles and methods. "Implementation of each new project or idea is based on experience and knowledge gained from previous projects" (Hynek et al., 2014). So when the knowledge is stored properly - also transferred into the CAD model rules, subroutines and constrains - each finished project could mean one developmental step which will not be lost in time or in the memory of the employees.

Abstract

Working conditions and their interaction on Quality of Working Life (QWL) perception in health sector employees from Barranquilla-Colombia were studied and modeled in a sample of 333 people aged between 16 and 73 years old. Reliability analysis, exploratory factor and principal components analysis with VARIMAX rotation, and binary logistical regressions was performed. Results show acceptable internal reliability of the scale ($\alpha = 0.996$) and satisfactory adequacy of factorial matrix data (KMO = 0.934). Sixty-three items grouped into ten elements presented the factorial structure: four belong to working conditions and six to QWL. The results showed that occupational safety and psychosocial aspects positively affects the Quality of Working Life, with an overall classification rate of 92.2%. QWL in the health sector is a function of environmental variables, which can have an impact on the quality of the service and, therefore, on social welfare.

Keywords*:* Quality of working life, working conditions, Occupational Safety, psychosocial aspects.

Introduction

From the twentieth century, with the contributions made by Elton Mayo and the humanist approach to labor organizations, the perception of the man as a machine was transformed by placing greater importance on the psychological and sociological concept of the employee (Chiavenato, 2000). Since then, the aim is generate and revolutionize working conditions in order to satisfy the basic needs of workers and also raise or increase productivity rates in carrying out their duties (Boz, 2013; Rodríguez Salvá et al., 2010).

In 1927, *the Hawthorne experiment* was carried out, in which the physical conditions of the work environment were studied. In the experiment, light intensity, noise, fatigue, among others variables were evaluated. It was demonstrated how comfortable a worker can feel throughout the working day and as a result the influence of this aspect on productivity (Cubillos Rivera, Velásquez Muriel, & Reyes Nova, 2014). These standards discovered almost a century ago are those used today for employee satisfaction and good professional practices (Hart, 2012). In the 1970s, Quality of Working Life was born, in which an approach of efficiency and effectiveness of the workers was sought through the development of the systems that affect an organization (da Silva, 2006; Yeo & Li, 2011). Louis Davis was responsible for introducing the term that would ensure the health, safety and satisfaction of the employee in their duties (Gómez, 2010).

"Quality of Work Life (QWL) is defined as a planned, cooperative and evolved process that involves actions tending to create working conditions conducive to the development of people's abilities and potentialities to improve levels of job satisfaction and to strengthen worker identification with the organization" (Camacaro, 2010). QWL encompasses different heterogeneous environments in which

is conceived: possibility of future in the organization, satisfaction of the work executed, recognition for results obtained, salaries received, benefits offered, human relations in the group and in the organization, psychological and physical environments of work, freedom to decide, among others (Cardona & Zambrano, 2014; Chiavenato, 2000).

However, institutions in health sector have focused their attention on improving the quality of the service provided and consequently the functions that their employees develop (Velásquez Vásquez, Quintero, Sánchez, & Burgos Campiño, 2010). The attention given to the public is a vital factor in this sector because of its constancy. In order to improve the quality and living conditions of human beings, managing accurate diagnoses, specialized care and the highest quality in the execution of their duties it is necessary. Medical, administrative and support staff must ensure that the service can be provided under optimum conditions during the working day.

At the moment of interacting with the patient, the service can only be provided by specialist doctors, nurses, bacteriologists, internists, among other health professionals in charge of the recovery, check-up and procedures performed during patient care (Rivero & Dabos, 2017). Therefore, it is necessary for medical staff to feel satisfied with the working conditions in which they provide the service, such as, luminosity, temperature, appropriate clothing and basic utensils indispensable to perform their duties, as well as medicines for each treatment (Bernal González, Pedraza Melo, & Sánchez Limón, 2015; Kanten & Sadullah, 2012).

Cases associated with occupational safety occur constantly in health sector, where employees are exposed to conditions that in most cases are not controlled under a safety and prevention plan that can prevent injuries that affect health of the employee. Occupational safety is relevant since many of the actions performed repetitively under inappropriate conditions generate wear, labor fatigue and long-term deterioration of life; promoting occupational diseases (ILO, 2005).

The purpose of the International Labour Organization (ILO) is to raise awareness of the consequences of work-related injuries or illnesses, as well as to stimulate and support practical action at all levels. Safety at work is responsible for controlling many irregularities generated by a lack of a solid strategy to prevent accidents, injuries or occupational diseases, which leads to early retirements, loss of qualified personnel, absenteeism, as well as injury insurance premiums (ILO, 2004).

On the other hand, remuneration received by the employee is a key to satisfaction and good conditions of QWL. There are also salary incentives for services rendered and extra bonuses for some of the employee's own qualities that are used to reward performance of well-executed jobs and functions. In addition, non-salary remunerations, which stands, mentions of honor, awards for an exemplary service, among others (Saldarriaga Ríos, 2013). These practices are scarcely implemented in Colombian companies in health sector according to the results of Cañón Buitrago & Galeano Martinez (2011).

The present research aims to study and model the interaction between working conditions and quality of working life in employees linked to health companies in Barranquilla - Colombia. Particular interest in this research arises because the results can be a valuable substrate for strategies that dignify work in the sector, improve the models of Human Talent Management and, as a consequence, contribute to collective well-being.

Methodology

Participants

For the present investigation, 333 surveys were carried out to different employees of the health sector in Barranquilla - Colombia, aged between 16 and 73 years. Participants could belong to the medical, administrative or support staff, indistinctly. Regarding the distribution of participants with respect to sex, 70.3% were women, while 29.7% were men. The participation was by consent agreement. A

random sampling was carried out in companies of different sizes (SMEs, medium and large companies).

Instrument

The instrument used in this research was an adaptation of the instruments of working conditions and QWL performed by Martínez-Buelvas et al (2015). The first section is aimed to obtain a comprehensive overview of work safety, physical environment conditions and risks associated with the routine (Hayes, Perander, Smecko, & Trask, 1998). In the second section, it was asked about the principles of the QWL, that is, evaluation of the impact generated by subjective variables such as organizational or social level and wages or promotion (Casas, Repullo, Lorenzo, & Cañas, 2002).

The instrument consists of a total of 136 items: 44 from the literature of working conditions and 92 items for dimensions of QWL. Participants were required to respond on a Likert scale from 1 to 10 according to their agreement with each of the statements presented, being 1 Totally Disagree and 10 Totally Agree.

Variables

The contrast caused by the goals of production and human development was the product of what is now known as QWL, in which it is possible to improve living conditions through labor practices (Hernández, Naranjo Valencia, & Álvarez Giraldo, 2007). The study of the working conditions represents a prominent need of the work environment in which economic, political, humanistic, ergonomic and other parts are involved (Blanch, Sahagún, & Cervantes, 2010). Other variables such as safety, professional growth or burnout have been included as fundamental in the integral conception that companies must offer for the employee's quality of life.

In this research, the impact of working conditions on QWL in health sector in Barranquilla, Colombia will be studied by the following dimensions:

- Working conditions: it contains 44 items through which the worker's perception of variables such as physical load, lighting, noise, thermal environment, mental load, work safety and occupational hazards are obtained.
- Salary conditions: it contains 20 items through which the worker's perception is known for the variables salary, labor stability and schedules.
- Career development: contains 12 items through which the worker's perception is known for the variables mental ability, promotion and career, training and research.
- Subjective conditions: it contains 54 items by means of which the worker's perception is obtained with respect to the variables private sphere and labor world, individual and labor activity, individual and labor group: organizational plan; individual and work group: hierarchical plan; individual and work group: technical plan; individual and work group: social plan; support and collaboration between units; and institution and management function.

These dimensions and variables mentioned above are considered appropriated because they can help to understand physical and social environment in which employees are exposed.

Analysis

Internal consistency analysis was performed by calculating the Cronbach alpha coefficient and the construct validity evaluation was performed using exploratory factor analysis: principal components analysis with VARIMAX rotation. In order to obtain a satisfactory factorial structure, it was validated that the included items had commonalities higher than a value of 0.5. This value is considered appropriate to maintain the internal consistency of the construct or theoretical dimension. This was done by checking that the results of the Bartlett sphericity test and the KMO test were satisfactory.

Then, a reliability analysis of each component was carried out, and the correlations of each factor were calculated by r-Pearson Correlation Statistician. Finally, a binary logistic regression model was calculated using the Labor Quality of Life as the dependent variable, and the Working Conditions variables as independent variables. The analyzes were carried out with the Statistical Package for Social Sciences (SPSS), version 24.0 for Windows

Results

Reliability Analysis

Using Cronbach's alpha, it was possible to verify the consistency of the items since the values obtained were close to 1, that is, they reflect a good reliability index. As results of the univariate analysis, an average of 8.07 and a standard deviation of 2.43 were obtained.

The homogeneity of the data measured by Cronbach's alpha was greater than 0.789 in all cases. Consequently, there is statistical evidence of the high degree of reliability of the data collected; a total Cronbach's alpha of 0.968 was obtained. Table 1 lists the Cronbach's alpha and the minimum correlations for each of the variables in the scale

Table 1: Cronbach's alpha coefficients and minimum correlations for each variable. (Elaboration by authors)

Variable	αCronbach	Correlations
Thermal environment and lightning	0,855	0,419
Mental load	0,789	0,366
Psychosocial aspects	0,855	0,538
Safety standards at work	0,879	0,450
Salary	0,898	0,401
Individual and work group: Hierarchical level	0,965	0,430
Individual and work group: Technical level	0,931	0,433
Training and research	0,841	0,418
Individual and work group: Organizational level	0,881	0,388
Mental ability	0,803	0,401

Factorial Analysis

In order to evaluate impact of working condition on QWL, it was applied an exploratory factor analysis: principal components analysis with VARIMAX rotation. The result obtained from the factor matrix was satisfactory with a KMO = 0.934 and Bartlett's sphericity test was significant. To do so, factors that did not generate a significant impact in assessing QWL conditions were discarded. The study was started with 30 factors and only 10 were significant. The factorial structure was represented by 63 items scaled in 4 groups for work conditions variables, and 6 groups for QWL variables.

The following are the latent variables obtained from the reduction in the context of the analysis of working conditions:

- Thermal environment and lighting: physical conditions that set up the employee's work environment encompasses temperature and luminosity. Hence, it is necessary to evaluate how these factors impact the employee's performance, while facilitating or hindering the

levels of productivity. For this factor was obtained a Cronbach's alpha of 0,855 and a correlation of 0,419. These values show the relevancy of the thermal environment and lighting from the employee's perspective.

- Mental load: it is considered as those opportunities that employee has to create active breaks during the working day, since this allows him/her to rest or create relationships with his/her co-workers. For the individual, it is important to have this spaces that allow recreational leisure, since the Cronbach's alpha was 0,789 and the correlation was 0.366.
- Psychosocial aspects: seeks to determine how much acceptance is given to the employee for the contributions attributed to the company, and the relationship between peers. For this factor was obtained a Cronbach's alpha of 0,855 and a correlation of 0,538.
- Occupational Safety: it provides the conditions that employees require according to law, and regarding their occupational safety and health conditions. For this factor was obtained a Cronbach's alpha of 0,879 and a correlation of 0,450. These values must be evaluated since they indicate that employees respond positively when it is provided working conditions that ensure their protection in working hours.

Similarly, the variables to be considered in the analysis of the QWL were:

- Individual and work group - Hierarchical level: relationship between individual and his/her superiors or persons in charge, which allows the optimal execution of the organizational goals. It is determined by a Cronbach's alpha of 0.965 and a correlation of 0,430. These indicators show that employee demands a kind relationship with superiors or subordinates to perceive an enjoyable work.
- Individual and work group - Technical level: participation and communication that the individual has in his/her work environment by performing his/her functions and responsibilities. It justifies a Cronbach's alpha of 0,931 and a correlation of 0,433, from which it is concluded that the execution of the work in terms of work groups generate greater result when there is harmonious relationship.
- Individual and work group - Organizational level: it contemplates how the employee is related to the company's policies and his/her knowledge of each one, to make constructive the difficulties that may arise. It has a Cronbach's alpha of 0,881 and a correlation of 0,388. It is showed that this variable has a significative relevancy since every employee should be informed about his/her organizational context.
- Salary: perceived by employees as the remuneration received for a job performed. The result was a Cronbach's alpha of 0,898 and a correlation of 0,401. This indicates that salary is perceived as a good stimulant, so it must be correctly estimated to generate a substantial positive impact.
- Mental ability: it includes the competences that the individual has to carry out their daily activities. Therefore, it entails assuming roles of responsibility. The Cronbach's alpha was 0,803 and the correlation was 0,401, which indicate the relevance of studying the employee's mental abilities in the development of their tasks based on the assessment of competencies.
- Training and research: indicates the promotion of new knowledge and the culture of inquiry to try to find solutions or alternatives to common problems of the area. It obtained a Cronbach's alpha of 0,841 and a correlation of 0,418, which shows that it has a significant impact to enable the employee to progress in his academic training.

Table 2 and Table 3 present the resulting factor structure for the Working Conditions variables and for the QWL variables, respectively. Significant factor loads were found in accordance with the reliability analysis previously discussed.

Table 2: Exploratory factor analysis: principal components analysis and VARIMAX rotation for working conditions variables. (Elaboration by authors)

Item	F1: Thermal environment and lighting	F2: Mental load	F3: Psychosocial aspects	F4: Occupational Safety
The temperature in the work area is pleasant	0,85			
Ventilation and air conditioning equipment in the workplace are sufficient	0,85			
The clothing I use is adequate, relative to the temperature in the workplace	0,70			
The sources of hydration in my workplace are sufficient	0,58			
The lighting level is adequate for the activities I do in my job	0,48			
During the working day I have time to make active breaks		0,80		
I may be momentarily absent from the job without a replacement		0,74		
The spaces and times available to establish communication and relationship with my other colleagues are adequate		0,65		
The breaks or rest time are sufficient to avoid fatigue during my workday		0,67		
The company promotes and contributes to good interpersonal relationships			0,53	
The company promotes and contributes to teamwork			0,58	
I feel that I am recognized for the work			0,49	
When I do a good job, I receive the respective recognition			0,60	
In the company there is the regulation of hygiene and labor safety and this one is applied according to the established by Law				0,70
The company has programs of promotion and prevention in subjects related to occupational health and safety				0,72
I constantly pay attention to the safety regulations established by the company				0,75
I pay attention to the safety regulations and apply them as established by the company				0,64
The company provides the necessary personal protection elements to carry out my activities in a safe				0,58
The company responds quickly to situations where the safety of its workers is compromised				0,57

Table 3: Exploratory factor analysis: principal components analysis and VARIMAX rotation for QWL variables. (Elaboration by authors)

Item	**F5:** Hierarchical level	**F6:** Technical level	**F7:** Organizational level	**F8**: Salary	**F9:** Mental ability	**F10:** Training and research
The supervision and daily instructions of my immediate boss allow me to perform my activities better	0,69					
I feel the freedom to express my opinion in the company	0,49					
I clearly know the management planning of my boss	0,81					
My boss allows me to be proactive	0,86					
My boss gives me feedback on the activities performed	0,83					
My boss takes into account the suggestions and innovative ideas I have about the development of my work	0,81					
I have open communication with my immediate boss	0,87					
My boss motivates me to do my job better	0,87					
My boss shares with the team the achievements of his management	0,84					
I am heard by my boss in an eventual labor problem	0,85					
I feel support and solidarity from my boss	0,87					
The team leader maintains order and contributes to the performance of the designated activities	0,59					
My immediate boss is competent in his work	0,69					
I am happy to carry out the activities that they entrust to me		0,51				
In the organization we are able to solve problems in work teams		0,48				
I am willing to listen and collaborate with any team member when I need it		0,71				
I consult the different opinions of the working group to make decisions		0,66				
I feel support and confidence from co-workers		0,59				
I express myself well from my co-workers		0,79				
I establish fellowship, cooperation and solidarity with my colleagues		0,84				
I acknowledge the achievements of my colleagues within the company,		0,78				
I feel an important member in the company		0,46				
I expressed good company with other people		0,55				
I enjoy my co-workers		0,74				
I know who to turn to for conflict resolution			0,45			
They inform me in a timely manner of the organizational changes in the company			0,66			
They inform me in advance of an eventual error, the product of my work			0,72			

In the organization the difficulties are discussed constructively			0,64			
Disciplinary rules are applied objectively			0,68			
I receive my remuneration at time				0,52		
I feel that my salary is adjusted to my professional profile				0,86		
My salary is competitive in the sector				0,8		
I feel that my salary is in line with my job responsibilities				0,86		
I consider that my salary is enough to satisfy my basic needs				0,79		
I am satisfied with the possibilities of wage increases				0,47		
I develop activities that are related to my labor competencies					0,71	
I apply my knowledge and skills in the development of the programmed activities					0,69	
The degree of mental ability required to perform my duties is high					0,75	
I have the ability to receive more responsibilities or functions in my position					0,64	
I have equal opportunities to grow professionally in the organization						0,69
I have the opportunity of promotion as a stimulus for my job performance						0,79
The activities developed in my work are related to my profession						0,65
I have the possibility to rotate to other areas of work						0,63
I have the possibility to work in other places (external to the company) that allow me to interact with other cultures.						0,6

Correlation Analysis

Correlation is a measure of the strength of the relationships between each of the variables, thus, in order to assess the magnitude and significance of the associations between the different variables of the study, we calculated the Pearson correlation coefficients. The results exhibit positive relationships with respect to p-value less than 0.01 (see Table 4).

Table 4: Pearson Correlations Coefficients – Working Conditions Variables and QWL Variables (Elaboration by authors)

Variables	F1	F2	F3	F4	F5	F6	F7	F8	F9	F10
F1. Thermal environment	1	0,171**	0,383**	0,478**	0,244**	0,333**	0,240**	0,369**	0,188**	0,238**
F2. Mental load		1	0,424**	0,174**	0,137*	0,273**	0,233**	0,181**	0,146**	0,228**
F3. Psychosocial aspects			1	0,409**	0,283**	0,310**	0,341**	0,313**	0,319**	0,439**
F4. Occupational Safety				1	0,352**	0,332**	0,201**	0,361**	0,232**	0,215**
F5. Hierarchical level					1	0,289**	0,413**	0,324**	0,156**	0,232**
F6. Technical level						1	0,512**	0,197**	0,370**	0,307**
F7. Organizational level							1	0,201**	0,399**	0,229**
F8. Salary								1	0,169**	0,272**

F9. Mental ability									1	0,244**
F10. Training and research										1
**. The correlation is significant at the 0.01 level (bilateral).										
*. The correlation is significant at the 0.05 level (bilateral).										

The relationships found suggest:

- With the correlation coefficient of 0,413 for the hierarchical level, can be deduced that when good relations are carried out and these are in favor to the constructive development of both the individual and the workgroup, it is executed a coupled work that makes prosper all departments of a company.
- For technical level and its relationship with thermal environment, a correlation of 0,333 was obtained which reflects a positive impact of physical conditions, such as comfortable temperature and lightning, in participation and communication of employee. Optimal conditions should be provided to obtain a good technical perception.
- When Occupational Safety conditions are appropriated, the satisfaction level in variables such as psychosocial aspects and salary, is greater (r = 0.409 and r = 0.361, respectively).
- Finally, the better the training and research opportunities within the organization, the more the employee's mental state increases (r = 0,439).

Analysis of the impact of working conditions on the Quality of Working Life

The evaluation of a model to estimate the impact of the variables of working conditions on the variables of QWL, begins in the exploration of different regression models. The correlation analysis previously discussed demonstrated the existence of positive relationships between the variables associated with working conditions and variables associated to QWL. Figure 1 presents the conceptual schema of regression analysis.

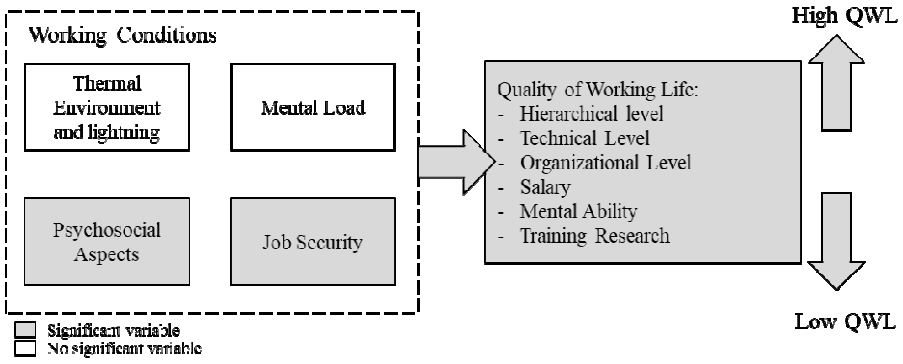

Figure 1: Conceptual frame evaluation model of the impact of working conditions in the perception of QWL. (Elaboration by authors)

The first step was to categorize the dependent variable as a dichotomous variable with levels low (0) and high (1) to achieve a better fit to binary logistic regression models. The number of final cases included in the analysis was 333 participants who had complete measurements in the study. To calculate the logistic regression model, it was used Wald's stepwise forward method, which contrasts the input based on the significance of the scoring statistic and contrasts the scoring based on the probability of the statistic. At each step, it revalues the coefficients and their significance, being able to eliminate from the model those that do not consider statistically significant. The last step of the study generated the model shown in Table 5.

The variables Occupational Safety and Psychosocial Aspects are those that impact the QWL of employees linked to companies in the health sector. The multivariate analysis suggests that both variables are significant at a level lower than 0.001. In addition, the Hosmer-Lemeshow test allows to maintain that there is enough statistical evidence to affirm that the obtained model fits well with the initial data of the sample (Chi-square: 12.43; Significance: 0.133).

The model explains between 32.5% and 58.9% of the QWL and obtained a global classification percentage of 92,2%. There was evidence of weakness in the prediction of a low QWL. The predictive value of low QWL was 58,7% while the predictive value of high QWL was 97,6%. Therefore, there is a risk that 41,3% of the times a worker's QWL is rated positive, even though their working conditions do not support this assertion. However, the sensitivity of the model is not impaired in the other scenarios in which it is applied. The model predicts well the QWL of the workers, especially when they present working conditions related to S Occupational Safety and Psychosocial Aspects from which a high QWL is perceived. The omnibus test for the proposed binary logistic regression model is significant at a level lower than 0,01. Considering these results, the model obtained is said to be acceptable.

Table 5: Regression Model for QWL variable (Elaboration by Authors)

Included variables	B	T.E.	df	Sig.	Exp(B)
Occupational Safety	0,072	0,21	1	0,001	1,075
Psychosocial Aspects	0,188	0,30	1	0,000	1,207
Constant	-6,685	1,114	1	0,000	0,001

The model is represented by Equation (1). When the probability tends to one, the perception of the quality of working life of workers linked to companies in the health sector will be positive. In this equation, the variables X and Y are Occupational Safety and Psychosocial Aspects, respectively.

$$P(QWL = 1) = \frac{e^{-6,685 + 0,072\,X + 0,188Y}}{1 + e^{-6,685 + 0,072X + 0,188Y}} \quad (1)$$

Discussion

The coefficients of the variables of working conditions show that Occupational Safety and Psychosocial Aspects positively affect Quality of Working Life. The second one does more than the first. The significance of these coefficients and of the constant was verified through the Wald statistic, determining that they are significant (see Table 5).

Quality of working life includes all policies, programs and measures that are taken to preserve the body and soul of an employee and produce their satisfaction and gratitude to the organization (Mejbel & Almsafir, 2013). Therefore, companies must ensure that the physical, mental and social conditions that occur are catalysts of their well-being.

Several studies have addressed the issues of QWL and its interaction with factors such as commitment to work (Farid, Izadi, Ismail, & Alipour, 2015), burnout and overload (Patlán, 2013), work performance (Rastegari, Khani, Ghalriz, & Eslamian, 2010), organizational culture (Valizadeh & Ghahremani, 2012), among others. The research of Mejbel et al (2013) reported that the main drivers of QWL are the systems of remuneration, benefits and compensation, professional development and communication. As a result it can be said that the QWL construct is multidimensional and structurally is composed of individual factors, the work environment, the work itself and the organization and the socio-labor environment (Patlán, 2016), from which it is explained its impact and interaction with the different elements adjacent to the employee, work and organization.

For the health sector, research has focused primarily on studying the QWL of nursing staff from the perspective of psychosocial risk (Arenas & Andrade, 2013), its consequences on patient care (Romero, Mesa, & Galindo, 2010), its intention to leave (Lee, Dai, Park, & Mccreary, 2013), among others. A conclusion from this literature is that the QWL of workers in the health sector requires special analysis since these employees are subjected to factors of work stress and burnout that are detrimental to a positive QWL (Rodríguez-Marín, 2010). According with Moradi, Maghaminejad, & Azizi-Fini (2014), assessing and improving the QWL would improve performance and reduce staff burnout linked to the health sector. In fact, these same authors report that a poor QWL in the medical support staff can cause problems such as job dissatisfaction, emotional exhaustion, burnout and rotation at work; which together could negatively affect the quality of care provide to patients.

The aim of this research was to study the impact of working conditions on the perception of QWL in 333 employees linked to health sector companies in the city of Barranquilla, Colombia. Form this, it was observed that the relationship between the two dimensions supports the continuation of the analysis of the implications of the work factors on the employee's perception of subjective conditions, job satisfaction, compensation and vocational development. Correlation analysis presented allows to consider that thermal environment and lightning are related with Occupational Safety. In the health sector, workers are exposed to risks such as physical, chemical, biological, postural, confined and inadequate space and inadequate lightning (Rodríguez-Marín, 2010); which must be controlled through Occupational Safety Plans.

The mental load has a moderate positive correlation with the variable of psychosocial aspects. Cañón & Galeano (2011) addressed the issue of psychosocial aspects and their relationship with QWL, determining that job satisfaction, intrinsic motivation and managerial support are essential in the health sector. However, the results show that the mental load and psychosocial aspects are perceived by the worker as an intra-organizational aspect related to times of care and rest, work climate and interpersonal relationships. These statements are consistent with the revision of Rodrígez-Marin (2010) regarding the high demands of work and difficulties in personal relationships for workers in the sector.

The regression analysis proposed in this research was used to show that Occupational Safety and Psychosocial Aspects are independent variables that positively influence the perception of QWL. This study demonstrated that the mechanisms offered by companies to work as a team, promote good interpersonal relationships, make recognitions; establish regulations, promotion programs, prevention and care in occupational safety and health issues; as well as the willingness of the worker to take advantage of these mechanisms, translate into a perception of high QWL.

In this sense, employees of the health sector demand to work in organizations in which the promotion of teamwork and the recognition of their own efforts are part of the organizational culture in benefit of their psychosocial conditions. Arenas et al. (2013) argue that diseases caused by work-related stress and associated with psychosocial aspects are the main concern at the public health level. The impact generated by the psychosocial aspects of work is responsible for behavior, emotions and commitment with which health workers face the workload and provide qualified service for the benefit of social welfare.

In addition, the results of this investigation show the imperative need to intervene strategically work safety conditions in the sector. The exercise of public health is subject to occupational risk factors, hygiene, medical care, legal advice, among others; which must be operated in accordance with the law, unions and workers' expectations. In this sector, employees perceive that the QWL is positively influenced when Occupational Safety conditions are favorable. The above agrees with the conclusions obtained in the study of Abd et al (2013) since it has been demonstrated that the conditions of occupational safety have an important role in the QWL. The research of Martinez-Buelvas, Oviedo-Trespalacios, & Luna-Amaya (2015) also states that Occupational Safety is a factor that makes the perception of QWL high when companies comply with the guarantees given by law.

Finally, QWL is defined as a multidimensional concept that is constructed from the complexity of the worker within the technical, hierarchical and organizational plane; his/her conformity with the salary earned, his/her mental ability and the training and research opportunities he/she have within the organization. QWL is positively influenced by the assurance of guarantees regarding safety and psychosocial well-being. Creating a high QWL for workers can improve their productivity and increase their job satisfaction (Abd et al, 2013). Also, it can allow the employee to feel motivated, committed, competent, cheerful, productive, safe, etc. (Platán, 2012, quoted by Patlán, 2016). Therefore, it should be made efforts to establish strategic policies and programs that will improve the quality of working life of employees in the sector, in order to improve collective well-being.

Kravchenko V. V., Peter the Great St. Petersburg Polytechnic University, St. Petersburg, Russia, kravchenko_vv@spbstu.ru

Abstract

Development of tourist industry is one of the key directions of economic policy in Russia. In order to define the main development prospects of this industry in Russia the author conducted a regional analysis of the hotel infrastructure, as an inseparable part of tourism industry, for the year 2016. The analysis was carried out based on the results of the algorithm, which was developed and applied by the author to rank federal subjects of Russia depending on the values of two coefficients: the level of room occupancy and level of room sufficiency in a region. A conclusion was made about the development potential of tourism industry depending on the state of the hotel infrastructure.

Keywords: economic policy in tourism industry, room occupancy at the region, level of room sufficiency in a region, hotel infrastructure.

Introduction

Today the Russian Federation is pursuing state policies in terms of contributing to the development of tourism industry and domestic tourism. In particular, the following ones are implemented: state program of the Russian Federation "Development of culture and tourism" for the years 2013-2020, "Tourism development strategy in the Russian Federation for the period until 2020", Federal target program "Development of domestic and inbound tourism in the Russian Federation (years 2011-2018)" and a number of other federal and regional programs for tourism industry development in the RF.

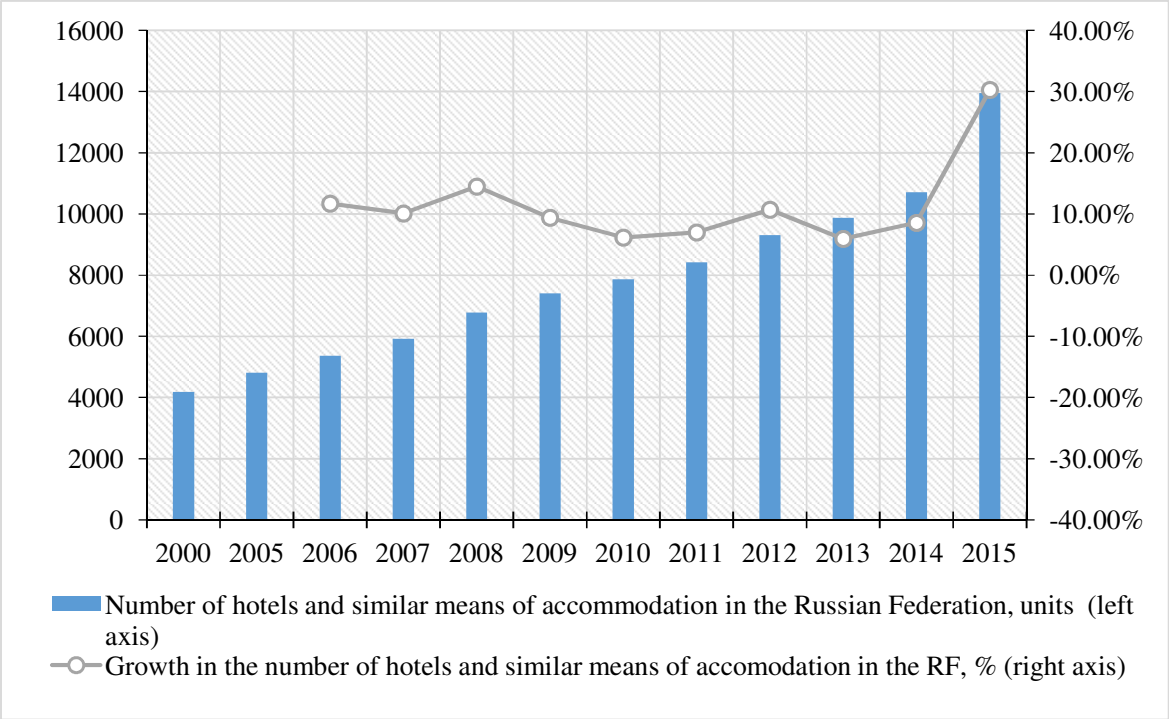

Fig. 1: Dynamics in the growth of the number of hotels and similar means of accommodation in the RF in the period from 2000 to 2016

In 2000-2015 the number of hotels and similar means of accommodation grew in the Russian Federation (see Fig.1). This growth was caused by the development of the service sector in the country, growing demand for accommodation services and legalization of the existing means of accommodation. A growth equal to 30.2% in 2015 is mostly related to the fact that the Republic of Crimea and the city of Sevastopol became the members of the Russian Federation.

So, in the context of the declaration about the need to develop domestic and inbound tourism and under the conditions of the constantly growing number of hotels and similar means of accommodation, the author finds it reasonable to analyze the level of room sufficiency in the category "Hotels and similar means of accommodation" of the RF regions over the year 2016 and conclude if the volume of the hotel infrastructure as well as the intensity of its utilization in the RF regions is adequate.

Literature Review

According to N.V. Pogorelova (2011), tourism infrastructure represents an organizational and economic system of interrelated companies and enterprises which ensure (material and sociocultural) conditions necessary for reproducing a tourist product, e.e. for performing utility functions in servicing tourists. Thus, the hotel infrastructure is an integral part of the tourism infrastructure of the city and region, since it directly ensures such a utility function of tourist services as accommodation of the users of these services.

Many researchers believe that the hotel structure in the RF is not developed enough. Thus, a team of authors - Barashok I. V., Ovcharenko N. P., Rudenko L.L. (2014) emphasize that even though the hotel infrastructure has been developing over the last two years, most cities and regions lack means of accommodation with affordable and qualitative conditions of stay. Consequently, the authors conclude about the need to grow the hotel base to meet the needs of potential customers. This

statement is supported by Khorev A.S. and Nikolskaya E.Yu. (2015), who also mark out the weak development of the tourism infrastructure and poor provision of regions with means of accommodation of mid and economy categories with the level of comfort satisfying modern standards.

Moreover, the following problems, common for the hotel sector in the RF are identified: not working competition mechanisms in the hotel services market (including unbalance of the prices and quality of hotel services), lack of trained personnel, lack of well-considered marketing policy among hotel management teams in the regions, low level of support to the hotel sector provided by regional authorities (Horev, A. S., & Nikol'skaja, E. Ju., 2015).

Thus, based on the reviewed literature it can be concluded that the development level of tourism infrastructure is directly dependent on the level of hotel infrastructure, as its constituent. Today researchers agree that in the RF this constituent of tourism infrastructure has not been developed enough, both quantitatively and qualitatively.

Metodology

Step 1. The data was downloaded from the Rosstat database for the year 2016 by the following performance indicators: population size of the federal subject, the hotel room capacity in the group "Hotels and similar means of accommodation", number of nights spent in the "Hotels and similar means of accommodation" for the year.

Step 2. Based on the obtained data, two indicators were calculated: the level of hotel room sufficiency in the RF subject and the level of hotel room occupancy in the RF subject. Both indicators were calculated by the group: "Hotels and similar means of accommodation", which include the following accommodation objects: hotels, furnished rooms, motels, boarding houses, hostels and other hotel-type organizations. The group is constructed based on the obtained data

The coefficient of hotel room sufficiency is calculated in the following way:

$$K_{\substack{hotel\ room \\ sufficiency}} = \frac{\substack{The\ hotel\ room\ capcity \\ in\ the\ RF\ subject}}{\substack{Population\ size \\ in\ the\ RF\ subject,thous.people}}, (1)$$

The coefficient of hotel room occupancy or hotel room use is calculated in the following way;

$$K_{\substack{hotel\ room \\ occupancy}} = \frac{\substack{Nights, \\ spent\ in\ the\ region\ per\ year}}{Number\ of\ beds\ in\ the\ means\ of\ accommodation*365}, (2)$$

Step 3. A five-point grading scale is used to grade the level of hotel room sufficiency and the level of hotel room occupancy for every federal subject. The correlation of the coefficient values and grades is presented in Table 1.

Table 1 : The correlation of the coefficient values and grades

The value of the hotel room occupancy coefficient	The value of the hotel room sufficiency coefficient	Equivalent grade by a five-point grading scale
1	[10;+∞)	5
[0.9;1)	[9;10)	4.5
[0,8;0,9)	[8;9)	4
[0.7;0.8)	[7;8)	3.5
[0.6;0.7)	[6;7)	3
[0.5;0.6)	[5;6)	2.5

[0.4;0.5)	[4;5)	2
[0.3;0.4)	[3;4)	1.5
[0.2;0.3)	[2;3)	1
[0.1;0.2)	[1;2)	0.5
[0.0;0.1)	[0;1)	0

Step 4. Calculation of the mean value.
Step 5. Grouping of the regions by the obtained mean value and analysis.

Table 2: The correlation of mean values and characteristics of the groups corresponding to them

Mean value by the federal subject	The group the subject will be referred to	Characterization of the group
[4;5)	1	The development level of the tourism infrastructure is high and the occupancy is close to maximal. Tourism is one of the leading industries in the federal subject. Option close to ideal.
[3;4)	2	The development level of the hotel infrastructure is high, but the hotel room occupancy is average Tourism is one of the leading industries in the federal subject.
[2.5;3)	3+	The development level of the hotel infrastructure is good. In case of system support and well-devised promotion strategy, transfer to group 2 is possible, mostly due to a larger hotel room occupancy and/or investing in construction of the hotel infrastructure.
[2;2.5)	3	
[1.5;2)	4+	The hotel infrastructure is averagely and poorly developed in comparison to the world level. The hotel room sufficiency and occupancy are not enough to ensure an average term growth of the tourism sector. Long-term investment and promotion of these regions are necessary.
[1;2)	4	
[0.5;1)	5+	The development level of the tourism in the federal subject is lower that the mean level in the country and considerably lower in comparison to the developed tourist centres of Europe. The tourism infrastructure can only develop in the region provided there are long-term investements and system suport on the part of the state.
[0;1)	5	

Conclusion

Based on the conducted analysis it is found out that despite the stable growth in the number of hotels and similar means of accommodation, the degree of hotel room sufficiency and occupancy in the regions remains unsatisfactory (see Fig. 2). The average level of hotel room sufficiency in the country in 2016 was 2.97 rooms per 1000 people, and the occupancy level– 0.36. In most federal subjects, the hotel room sufficiency is lower than 5 beds per 1000 people, living in the region and the occupancy does not exceed 40%. Moreover, even St. Petersburg and Moscow, being leaders of the tourism industry in the country, show relatively weak results. Thus in 2016 in St. Petersburg the coefficient of hotel room sufficiency was 4.04 with the occupancy coefficient equal to 0.53, whereas in Moscow they are 3.85 and 0.53 correspondingly. Furthermore, as of the year 2011, in Paris the coefficient of hotel room sufficiency was equal to 8 and in London to 12.

The most advanced regions in terms of the hotel infrastructure availability are Krasnodar Krai, where the coefficient of hotel room sufficiency is 13.3, the Republic of Altai– 8.68, the Republic of Crimea

– 13.1 and Sevastopol – 13.37. In terms of the hotel room occupancy, other leaders in the country are North Ossetia – Alania – 0.88, Kaliningrad region – 0.59 and Krasnodar Krai – 0,43.

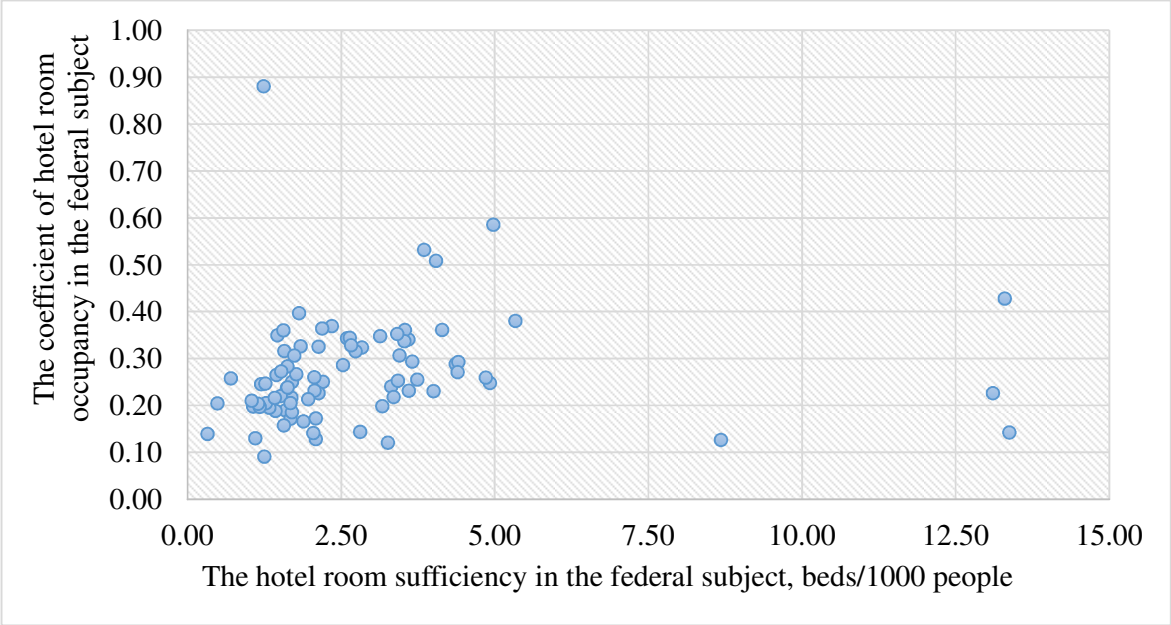

Fig. 2 : The grouping map of the federal subjects based on the hotel room occupancy and sufficiency indicators for the year 2016.

Table 3: Grouping of federal subjects accoding to the obtained mean values

The group the subject refers to	Federal subjects
1	-
2	Krasnodar Krai, the Republic of Crimea
3+	Sevastopol
3	Moscow, St. Petersburg, Kaliningrad region, the Republic of Altail, the Republic of North Ossetia - Alania, the Republic of Khakassia
4+	12 federal subjects
4	28 federal subjects
5+	33 federal subjects
5	2 federal subjects

The result of grouping of the federal subjects are presented in Table 3. This data can be used to work out development strategies for tourism industry in these subjects, transfer better experience from more successful subjects and determine the development level and intensity of use of the hotel infrastructure in the subjects. The existing potential can be exploited under the following conditions: state support of the policy of domestic tourism development, insurance of market pricing mechanisms to foster supply, corresponding to the existing financially reliable demand, including potential one, and to the modern vision of comfort stay, provision of the economy with the sufficient quantity of well-qualified staff.

The main limitation of the obtained results is a moderate number of indicators used for ranking. In further research, the author plans to widen the number of performance indicators and present a more detailed analysis, in particular, dynamic analysis of the hotel infrastructure development in the RF

subjects.

Abstract

In this paper, the authors consider the tariff policy of St. Petersburg from the position of two participants in transportation: authorities and passengers. The study includes a comparative analysis of the size of subsidies allocated for passenger transport by urban transport, the cost of travel and the share of travel costs in major cities of the Russian Federation and the world.

Keywords: financing, tariffs for transport, fare, share of travel expenses.

Introduction

Problems on the roads force sometimes all citizens, not only without cars but also with them, to use public transport that is why access to public transport is one of the most urgent topics of any large city nowadays. Thus, it becomes obvious that fare in urban transport affects all segments of the population.

Today, three parties are involved in the organization of passenger traffic in urban transport: authorities, which organize traffic control and tariff regulation, carriers, who carry out the transport, and passengers, who are active consumers.

The purpose of this work is to a comparative analysis of the cost of travel and diversity of tariff menu in cities of the Russian Federation and the world.

Tasks:

1. Detailed study of funding passenger transportation by urban transport in Moscow, St. Petersburg and Nizhny Novgorod in 2017.
2. Conducting a comparative analysis with the identification of deviations in St. Petersburg from other cities in question of fare in Moscow, St. Petersburg and Nizhny Novgorod in 2017.
3. The allocation of the share of travel expenses for residents of Moscow, St. Petersburg and Nizhny Novgorod.
4. Analysis of the cost of one-time tickets and daily tickets in various cities around the world in 2017.
5. The allocation of the cost of travel for residents of London, Helsinki and Lisbon.
6. Determination of positions in the tariff menu of other cities not represented in St. Petersburg.

Review of the literature

The statistical data of the Online Library of the Organization for Economic Cooperation and Development were used in writing this work (2017). It is through them the authors have analyzed the

average wages for 2016 in such cities of the world as London, Helsinki, Lisbon and the statistical services of the regions of the Russian Federation (Territorial authority of the Federal State Statistics Service in Moscow; Administration of the Federal Service of State Statistics by city Petersburg and the Leningrad region; Territorial body of the Federal State Statistics Service for the Nizhny Novgorod region). Based on data on the average wages of them it has become possible to calculate the share of monthly expenses of citizens for public transport.

The authors have given special attention to the normative legal acts of the Russian Federation regulating the formation of the budget of the regions of the country, as well as the approval of the fare.

Domestic experience was considered on the basis of a number of legislative documents of those regions that were taken by the authors as a basis for a comparative analysis of the cost of travel (Order of the Tariff Committee St. Petersburg; Order of the Tariff Committee St. Petersburg; Department of transport and development of road and transport infrastructure of Moscow).

The international experience of the cost of travel is considered on the basis of electronic resources of foreign countries (The Metropolitano de Lisboa; Helsinki Region Transport; Transport for London. Fares & payments). For example, these sources indicate not only the cost of a one-time trip, but also the cost of travel on electronic tickets is available.

The results of the literature review has showed that the problem of forming a tariff menu in the Russian Federation is not sufficiently developed in the normative literature.

Problem

In 2017, new travel documents were introduced in St. Petersburg, allowing citizens and visitors of the city to choose the most convenient and economical way for them. It was in 2017 when students of St. Petersburg had the opportunity to choose travel documents for a month (only land transport, only the underground or a unified ticket), and tourists - when purchasing temporary travel documents, which enable them to plan their travels around the city with the least costs.

Since 2017 new types of travel documents have become effective in St. Petersburg. They are monthly registered combined (tram, trolley, bus) ticket for students, monthly underground ticket for students, daily unified (tram, trolley, bus, underground) ticket (from 1 to 7 days), unified (tram, trolley, bus, underground) ticket for 90 minutes.

According to the information received by the author in the study tariff menus in various cities of the Russian Federation, ticket as “a ticket for 90 minutes” is only available in Moscow [9], St. Petersburg [5] and Nizhny Novgorod. A daily ticket is also available to residents of Nizhny Novgorod [12]. Thus, in the authors' opinion, it is expedient to consider the tariff policies of Moscow, St. Petersburg and Nizhny Novgorod as a comparison of the cost of travel in large cities of the Russian Federation, (tab.1.1 and 1.2).

The choice is based on social level of development of these cities, including the number of inhabitants, the complexity of the transport infrastructure, including the presence of the underground, and territorial distinctiveness. In the process of analysis, the Central, North-Western and Volga federal districts of the Russian Federation are considered.

Table 1.1 : Comparative analysis of passenger transportation subsidies in St. Petersburg, Moscow and Nizhny Novgorod in 2017

City	The budget of the subject of the Russian Federation, billion rubles.	The amount of subsidies for transporting passengers from the budget, billion rubles.
Moscow	1 977,00	90,00 (4,5% of budget)
St. Petersburg	554,00	28,00 (5% of budget)
Nizhny Novgorod	133,2	2,10 (1,58% of budget)

Table 1.2 Comparative analysis of the cost of travel in St. Petersburg, Moscow and Nizhny Novgorod in 2017

Travel Documents	Ticket price in 2017, rub.			Variance of the ticket price in St. Petersburg from Moscow,%	Variance of the ticket price in St. Petersburg from Nizhny Novgorod,%
	Moscow	St. Petersburg	Nizhniy Novgorod		
Monthly unified ticket	2 550,00	2 900,00	2 300,00	13,72%	26,09%
One-time fare for the underground	55,00	45,00	28,00	-18,2%	60,71%
One-time fare for ground transportation	55,00	40,00	28,00	-27,3%	42,86%
Electronic wallet (land transport)	35,00	31,00	26,00	-11,43%	19,23%
Electronic wallet (underground)	35,00	36,00	26,00	2,86%	38,46%
Monthly unified ticket for students	-	1 035,00	1150,00	-	-10%
Monthly ticket for students by underground	380,00	550,00	600,00	44,74%	-8,33%
Monthly ticket for students to land transport	250,00	485,00	600,00 (tram/ trolleybus)	94,00%	-19,17%
Monthly unified ticket for schoolchildren	-	515,00	920,00	-	-44,02%
Monthly ticket for schoolchildren by underground	380,00	-	500,00	-	-
Monthly ticket for schoolchildren to land transport	250,00	-	500,00 (tram/ trolleybus)	-	-
Ticket for 90 minutes	65,00	70,00	40,00	7,69%	75%
Ticket for 1 day	210,00	180,00	120,00	-14,29%	50%
Ticket for 3 days	400,00	340,00	350,00	-15,00%	-2,86%
Ticket for 7 days	800,00	680,00	-	-15,00%	-

Based on the information in tables 1.1 and 1.2, the following conclusions can be drawn: Moscow's budget is 3.6 times higher than the budget of St. Petersburg, while the amount of subsidies allocated for passenger transportation for 2017 in Moscow (90 billion rubles) (Law of the City of Moscow, 2016) 3.2 times the amount subsidized by urban passenger transport in St. Petersburg (28 billion rubles) (Law of St. Petersburg, 2016). The smallest share of subsidies from the budget allocated for passenger transportation by urban transport is in Nizhny Novgorod (1.58%).

The amount of subsidies for transporting passengers from the budget of Nizhny Novgorod is only 2.10 billion rubles (1.58%) (Law of the Nizhny Novgorod, 2016). Therefore, the cost of a one-month unified ticket for students is much higher than the cost of Moscow students for both types of public transport (by 520 rubles) and higher than in St. Petersburg (by 115 rubles). However, the fare for a ticket for one day is 120 rubles, while the highest price of this ticket was fixed in Moscow -210 rubles.

Thus, with a sufficiently high funding of urban passenger transport in Moscow, the cost of travel on tickets is slightly lower there than in St. Petersburg and Nizhny Novgorod.

The monthly single ticket in Moscow in 2017 costs 13.72% lower than in St. Petersburg (the difference in absolute value is 350 rubles). The ticket for students on the underground is 170 rubles lower, but the cost of tickets for schoolchildren in aggregate (380 rubles for the underground and 250 rubles for land transport) exceeds the total cost of a similar ticket in St. Petersburg by 115 rubles.

Besides, with a significant difference in the cost of tickets for 90 minutes (10 rubles), fare for daily tickets is more profitable in St. Petersburg (20 rubles per 1 day, 60 rubles - 2 days and 120 rubles - 7 days).

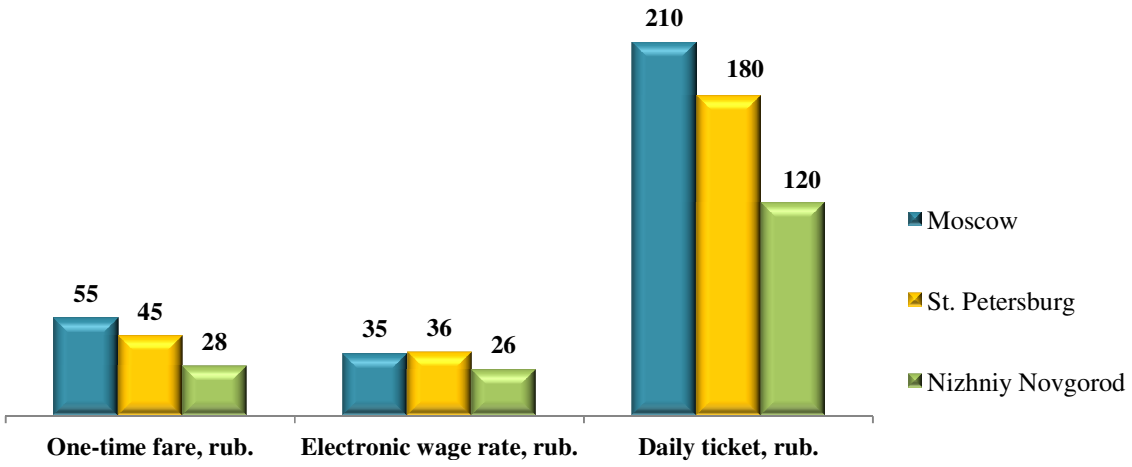

Fig.1.1 The fare for underground in Moscow, St. Petersburg and Nizhny Novgorod in 2017

Figure 1.1 shows comparative data on the cost of travel in the underground in 2017 in various cities of the Russian Federation. According to the provided information, the cheapest daily ticket belongs to

Nizhny Novgorod (120 rubles), while the most expensive one belongs to Moscow, respectively, the cost of a daily ticket in St. Petersburg can be considered one of the lowest.

The discount for fare on a travel document in relation to a one-time tariff in Moscow is 36.4%, which is 13.9% more than in St. Petersburg (20%). This is due with the size of the subsidies allocated from the budget of the constituent entities. However, at the same time, the tariff policy of St. Petersburg can not be considered unprofitable.

Based on the comparative analysis, the authors made a decision on the representation of the average nominal wage of residents of Moscow (Territorial authority of the Federal State Statistics Service in Moscow), St. Petersburg (Administration of the Federal Service of State Statistics by city Petersburg and the Leningrad region) and Nizhny Novgorod (Territorial body of the Federal State Statistics Service for the Nizhny Novgorod region) in April 2017 and the allocation of a monthly share of the costs of citizens for travel in urban transport for a monthly single pass (Table 1.3).

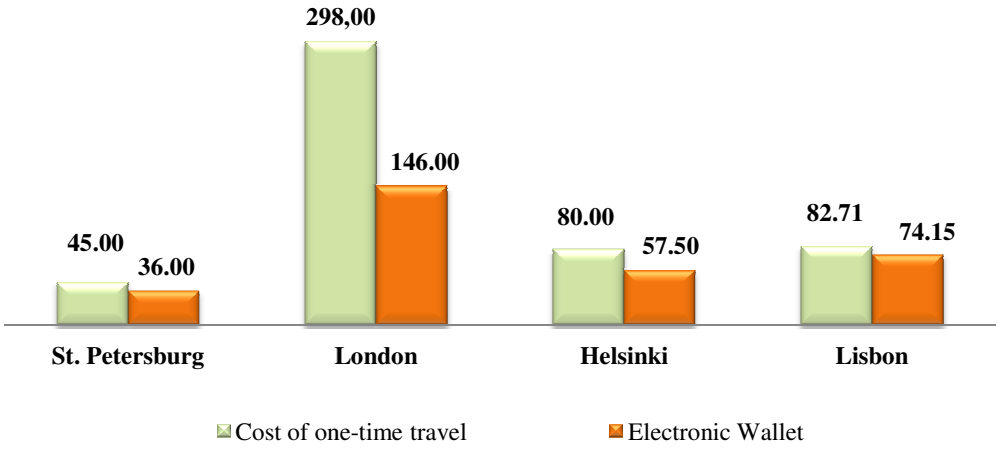

Table 1.3 Share of the costs of citizens of large cities of the Russian Federation for travel in urban transport in 2017

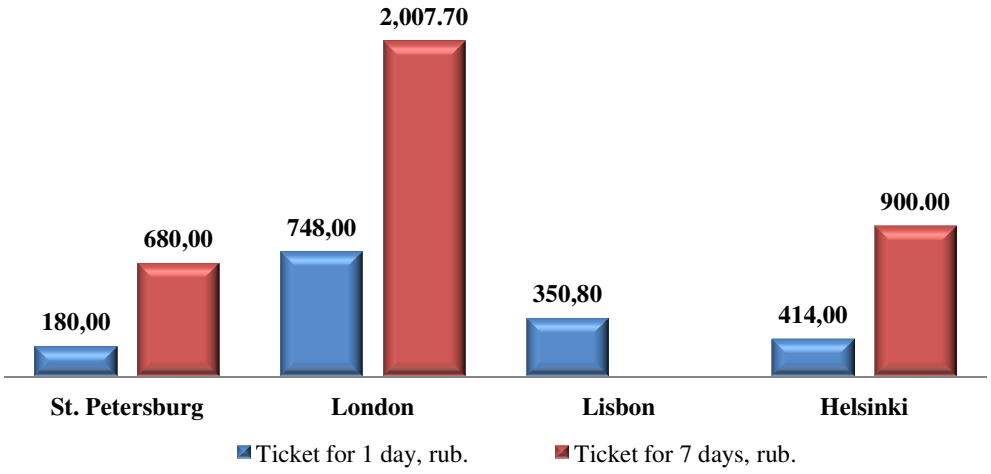
Index	Moscow	St. Petersburg	Nizhniy Novgorod
Average nominal wages, rubles.	86 759	53 261	30 865
The cost of a unified travel document for a month, rub.	2 550	2 900	2 300
Share of expenses for travel,%	2,94	5,44	7,45

Based on the data presented in Table 1.3, it can be concluded that the share of travel costs is much lower in Moscow. At the same time, residents of Nizhniy Novgorod have the largest share of travel costs (7.45%).

Based on the results of the study, the authors decided that it is necessary to consider the cost of travel in major cities of the world and determine the share of travel costs not only for residents of cities of the Russian Federation, but also for foreign citizens.

Based on the foregoing, a comparative analysis of the cost of one-time tickets for land transport in St. Petersburg and various cities around the world in 2017 (Fig. 1.2) and a comparative analysis of the cost of daily tickets in various cities around the world in 2017 (Figure 1.3).



*** The cost in rubles is indicated by purchasing power parity**

Fig. 1.2 Comparative analysis of the cost of one-time tickets for underground in various cities around the world in 2017

In accordance with the information presented in Fig. 1.2, the highest unified tariff is presented in London (298.00 rubles.), further - in Lisbon (82.71 rubles.) and a one-time trip to Helsinki (80.00 rubles.). The discount for trip on a travel document in relation to a one-time fare in St. Petersburg is 20%, which is less than in London (104.1%) and Helsinki (39.13%), but more than in Lisbon (11.54 %).

However, an analysis of purchasing power parity showed that a one-time trip to St. Petersburg is one of the most economically accessible cities in all.

In addition, the authors conducted a comparative analysis of daily tickets in various cities around the world in 2017. Based on it is possible to determine what the cost of new tickets in St. Petersburg in other cities in the world, as well as to assess how far the cost of travel for this type of ticket is available for residents of the city and its guests.

*** The cost in rubles is indicated by purchasing power parity**

Fig.1.3 Comparative analysis of the cost of daily tickets in various cities of the world in 2017

Based on the data presented in Fig. 1.3, we can conclude that the highest price for travel on daily tickets is offered in London (748.00 rubles per day and 2 007.70 rubles per week).

The cost of the train in St. Petersburg remains the most socially-oriented among all cities considered by the authors, amounting to only 180.00 rubles for a day ticket and 680.00 rubles for the whole week ticket.

It is important to mention that for giving an objective assessment of the amount of fare in foreign countries it is advisable to identify the monthly share of travel costs in London, Lisbon and Helsinki (Online Library of the Organization for Economic Cooperation and Development. OECD iLibrary). However, given the availability of official data on the average wage in statistical offices of other countries only for 2016, it makes sense to indicate the share of travel costs.

Table 1.4 Share of travel costs for residents of major cities in the world in 2016

Index	London, GBP	Helsinki, euro	Lisbon, euro
Average monthly salary in 2016	2 845,2	3 434,1	1 381,2
The cost of travel by e-wallet per month	234**	54,70	36,20
Share of travel costs per month,%	8,2%	1,6%	2,62%

** counting on 2 subway journeys and 2 trips by land transport per day.

Thus, on the basis of the data presented in Table 1.4, it is concluded that the largest share of travel costs is borne by residents of London (8.2%), the lowest is by residents of Helsinki, with an average

wage of which it is only 1.6 %. However, even at such a low level of travel costs, the residents of Helsinki favor the abolition of fare for public transport (Most residents of Helsinki favor free urban transport).

Statement

While studying the nonresident and foreign experience of forming the tariff scale, the authors took into account the fact that the St. Petersburg tariff menu can rightly be considered one of the most diverse in the world, as today all the major travel tickets are available to the all citizens and visitors.

Problem solution

Based on the results of the analysis, the following conclusions can be formulated:

1. The amount of subsidies allocated for transporting passengers for 2017 in Moscow (90 billion rubles.) is 3.2 times the amount funded by urban passenger transport in St. Petersburg (28 billion rubles.). However, the smallest share of subsidies comes to Nizhny Novgorod, it is only 1.58% (2.10 billion rubles).

2. With a rather high subsidization of urban passenger transport in Moscow, the cost of travel tickets is slightly lower than in St. Petersburg and Nizhny Novgorod, and sometimes even higher. Thus, the monthly unified ticket in Moscow in 2017 costs 13.72% less than in St. Petersburg, but at the same time the cost of travel tickets for schoolchildren in the aggregate significantly exceeds the total cost of a similar ticket in St. Petersburg (115 rubles).

The share of travel expenses is much lower for citizens of Moscow (2.94%) than for residents of St. Petersburg (5.44%). At the same time, residents of Nizhny Novgorod (7.45%) have the largest share of travel costs.

3. The highest fare for a one-time ticket is presented in London (298.00 rubles.), the next one is in Lisbon (82.71 rubles.) and the cheapest in Helsinki (80.00 rubles).

An analysis of purchasing power parity showed that a one-time trip to St. Petersburg is in effect one of the most economically accessible cities in all.The most expensive whole- day tickets are offered in London (748.00 rubles for the day and 2 007.70 rubles for the week). Fare in St. Petersburg remains the most socially-oriented among all cities considered by the authors, amounting to only 180.00 rubles for a day and 680.00 rubles for 7 days.

4. The largest share of travel costs in foreign capitals of the world is born by residents of London (8.2%), the least - residents of Helsinki, with an average wage level, which is only 1.6%. In the Russian Federation, Moscow accounts for the smallest share (2.94%), followed by St. Petersburg - 5.18% and Nizhny Novgorod - 7.45%. In comparison with the cities of the Russian Federation, Moscow residents bear a smaller share of the cost of travel after city residents in Helsinki and Lisbon (2.94%). At the same time, residents of Nizhny Novgorod spend a large part of monthly incomes (7.45%) on travel, rather than residents of Moscow, St. Petersburg, Helsinki and Lisbon, but less than residents of London (8.2%).

5. There is the lack of a monthly ticket for the underground in the tariff menu of St. Petersburg. Only monthly tickets for a land type of transport (bus, tram or trolley bus by choice) are presented.

Conclusion

The authors' position is the need to introduce a working monthly ticket for the working people on the underground, the same as for students. This approach will allow residents of the city, traveling exclusively in the metro, to save money on travel without purchasing a unified monthly ticket or an electronic wallet called "Podorojnik".

Also the author considers the most interesting and potentially popular in St. Petersburg a unified ticket for 365 days, presented in Moscow and allowing Moscow residents to save about 1 517 rubles per month or 12 400 rubles a year.

Based on the conducted research, the authors adhere to the position according to which St. Petersburg is on the top level of accessibility of public transport in accordance with the proportion of the costs of citizens to travel among the major cities of the Russian Federation and the world considered. At a fairly low cost of travel, the share of costs remains stably high, second only to London.

From the point of view of the authorities, the subsidies allocated from the budget of St. Petersburg allow compensating the incomes for carriers that fall due to transportation of passengers on travel tickets. They do not cover the inter-tariff difference (the difference between an economically justified tariff and a one-time tariff for the population), since in 2017 specially approved a high one-time travel, oriented more likely not to residents, but to tourists of the city.

On the other hand, passengers have the opportunity to purchase travel documents profitable for themselves, taking into account individual needs and financial possibilities (from a one-time ticket to a "Plantain" ticket or a daily ticket), but are forced to spend a significant part of monthly incomes on public transport.

The tariff menu of St. Petersburg, in comparison with the proposals of other major cities in the world (London, Helsinki, Lisbon), seems to the author to be sufficient and diverse. However, the cost of travel, according to the presented tariff policy of the city, as a result of the analysis, can not be considered economically expedient for citizens in the same way as for the budget of St. Petersburg. In other words, in St. Petersburg, the process of subsidizing and tariff formation needs to be further improved in order to achieve a balance between the interests of such participants in passenger transport as authorities and passengers.

A Study on the Impact of Taxation on the Business Environment in the EU

Țibulcă Ioana Laura, PhD. – Bucharest University of Economic Studies, Bucharest, Romania, tibulca.laura@gmail.com

Abstract

In any modern economy the business environment will be affected by taxation. The goal of this study is to look at the impact taxation has on the business environment in the European Union using business confidence as a measure for the expectations entrepreneurs have regarding the future evolution of the four major sectors of the economy: the services sector, the retail sector, the construction sector and the industrial sector. The tax burden will be used to measure the level of taxation and the impact of fiscal policies different EU countries implement. The research was done using quarterly data for the period between 1985Q1 and 2016Q3 collected from all 28 EU Member States. Several regression models were estimated which lead to individual conclusions for each Member State. These conclusions show the various effects that changes in the tax burden can have on the business environment.

Keywords: tax burden, business confidence, taxation, European Union, confidence index

Introduction

Taxation has an undeniable impact on our day to day life. If this statement holds true for people, it is equally true for companies. However it is much more difficult to pinpoint the influence taxation has on the business environment. The current study is an attempt to analyse the relationship between the business confidence index and fiscal pressure.

The business confidence index is calculated by the European Union and the OECD based on the answers managers of companies give to questions that are part of business confidence surveys. The goal is to see what the managers believe is the current state of their company and what their expectations are for the future. The confidence index calculated for a certain sector reflects the expectations of the economic agents that are active in that sector of activity regarding the evolution of that particular sector. In order to see if the expectations of managers are influenced by possible changes in taxation, I have decided to use the tax burden as a quantifiable taxation measure. The tax burden I used is calculated for different categories of taxes. Thus I have taken into account, separately, income taxes, taxes on production, sales and imports, and social security contributions.

This study is structured into three sections. The first section deals with the literature review and it contains an overview of other research previously done on this topic of interest. The second section deals with the research methodology I used throughout the entire research process. The third section contains a presentation of the results I obtained as a result of the analysis as well as the interpretation of the research results. This last section is followed by the conclusions of the research and by the references used. A more extensive presentation of all the results can be found in the tables included in the annexes.

1. Literature Review

Previous research regarding business confidence is sparse and most of the existing studies focus more on the theoretical, methodological and descriptive side of calculating various business confidence indices. The main original element of the current research is relating business confidence to taxation by using the tax burden and various business confidence indices. As far as I know, this has not been done previously.

The tax burden has been the focus of financial researchers for many decades. Different approaches towards measuring the fiscal pressure are presented, amongst others, by Musgrave and Thin (1948), Atkinson (1980), Devarajan, Fullerton, and Musgrave (1980), Auerbach and Rosen (1980), Kiefer (1984), Atrostic and Nunns (1991), Metcalf (2006). While the opinions regarding ways of measuring the tax burden have evolved and expanded, the fiscal burden has remained in the limelight of debates and research studies as a means of evaluating the impact of different fiscal policy decisions on the social and business environment.

Business confidence has also been an issue of great interest amongst researchers. Collins (2001) used the Granger Causality to analyse the relationship between business confidence surveys and stock market performance. His conclusion was that business confidence surveys are not a predictor of stock market performance, but that stock market performance is a predictor of business confidence surveys.

One of the main issues of interest regarding business confidence is exactly what business confidence reflects and what does a change in business confidence mean. Silverstone and Mitchell (2005) used panel data analysis on a company level to determine exactly what changes in microeconomic and macroeconomic variables are anticipated by changes in business confidence. Their conclusion was that the variables associated to business confidence change over time and, moreover, business confidence means different things to different companies. Herein lays one of the limitations of using business confidence indicators in any analysis: these indicators are constructed based on answers that reflect the personal view of the manager who answered the survey questions. Therefore, they contain a good dose of subjectivity. However, this can also be seen as one of the advantages of using business confidence indicators; sometimes a manager's perception can be more important than the actual truth because any decision the manager makes will be based on that perception.

This study aims to analyse the relationship between taxation and business confidence indices. I will analyse data from the European Union Member States and estimate regression models with the different business confidence indices as a dependent variables and the different types of tax burden as independent variables.

2. Research Methodology and Database

The research database contains quarterly information for the dependent and independent variables I used in the regression models. I collected information for each variable for each of the 28 EU Member States. The initial time period was 1985Q1 to 2016Q3. However, not all the Member States provided information for the entire time period and this is the reason why the number of observations differs from one Member States to the other. I do not believe that the difference in number of observations has an impact on the relevance of the research results because for many of the Member States it is to be expected that the time period will be shorter. For countries that only became EU Member States in 2004 or later, I can only consider relevant to the research on tax convergence the tax and business confidence information that they provided during the period when they were undergoing negotiations to become part of the European Union. Therefore, a shorter time period actually leads to more relevant results in the case of the Member States that I mentioned above.

The research method I used is regression model estimation. In order to shed some light on the influence that taxation has on business confidence, I estimated a series of regression models based on equation (1).

$$CI = \alpha_0 + \alpha_1 * DTR + \alpha_2 * ITR + \alpha_3 * SSC + \varepsilon \qquad (1)$$

where CI is the confidence index, DTR is the direct tax burden, ITR is the indirect tax burden and SSC is the social security burden.

A description of the variables used in the regression models can be found in Table 1. The tax burden is used as a proxy for the fiscal system of a Member State of the European Union. I considered three major types of tax burden, each corresponding to one of the major types of taxes: the direct tax

burden (DTR) calculated as direct taxes collected as a percentage of the GDP, the indirect tax burden (ITR) calculated as indirect taxes collected as a percentage of the GDP, and the burden due to social security (SSC) calculated as social security contributions collected as a percentage of the GDP. The database contains information for each of these three major tax groups, on a quarterly basis, for the period between 1985Q1 and 2016Q3. The data was extracted for the Eurostat online database.

Table 1: Description of variables

Independent Variables	
Name of Variable	*Description of Variable*
DTR	direct tax burden; calculated as direct taxes collected as a percentage of the GDP
ITR	indirect tax burden; calculated as indirect taxes collected as a percentage of the GDP
SSC	burden due to social security; calculated as social security contributions collected as a percentage of the GDP
Dependent variables	
Name of Variable	*Description of Variable*
ICI	industrial confidence index; business confidence index calculated on a national level for the industrial sector
CCI	construction confidence index; business confidence index calculated on a national level for the construction sector
RCI	retail confidence index; business confidence index calculated on a national level for the retail sector
SCI	services confidence index; business confidence index calculated on a national level for the services sector

The dependent variables in each regression model are the business confidence indices for different sectors of the economy: the industrial sector (ICI, industrial confidence index), the construction sector (CCI, construction confidence index), the retail sector (RCI, retail confidence index) and the services sector (SCI, services confidence index). These indices are calculated and reported by each Member State on a monthly basis. They are calculated using the OECD methodology based on business confidence surveys. These surveys contain multiple choice questions that the managers of companies that are active in a certain sector of the economy have to answer. The questions are aimed not only at the current state of the company, but also at what the expectations of the managers are for the future. Many of the questions ask the respondent to anticipate what the evolution of the company or the market will be in the short term (the next few months). One of the limitations of the business confidence indices comes from the fact that, though the general principles and the methodology the surveys are built on are the same, the questions and the answer choices are not standardized. However, the business confidence surveys are considered to be a good way of seeing how those involved in a certain activity anticipate the evolution of their business sector (Collins, 2001).

The data for the four business confidence indicators (ICI, CCI, RCI and SCI) that I used in this analysis was also taken from the Eurostat online database. As the data was provided on a monthly basis, I calculated a simple arithmetic average for each three months to convert the monthly data into quarterly data which could be related with the quarterly information regarding taxation.

I conducted a country-based analysis for each of the 28 EU Member States. Therefore, for each Member States, four regression models were estimated using OLS. In other words, I estimated a regression model for each of the four business confidence indicators (ICI, CCI, RCI and SCI). Some of the models were adjusted and validated, others were rejected as inappropriate. A more extensive view on the results of this research is presented in the next section of the paper.

3. Research Results

Using the database previously described, I estimated multiple regression models for each Member State of the European Union. For each EU Member State, I estimated 4 regression models using the same explanatory variables (DTR, ITR and SSC) in each model. But for each estimated model I changed the dependent variable starting with the ICI in the first estimated model, followed by the CCI, RCI and SCI respectively. Thus, I estimated 110 regression models in total for the EU Member States. Not all the regression models were validated and some were adjusted in order to be validated. We only estimated 110 regression models and not 112 because Luxembourg did not provide information for either the retail confidence index (RCI) or the services confidence index (SCI) and, therefore, those regression models could not be estimated.

The research on the impact of taxation on business confidence in the industrial sector in the European Union (please see Annexes, Table 3) resulted in the validation of regression models for 10 of the 28 Member States (the Czech Republic, Greece, Croatia, Italy, Lithuania, Luxembourg, Slovenia, Slovakia, Finland and Sweden). It should be noted that for some of these countries adjustments were made in order to validate the regression model.

The analysis conducted regarding the impact of the tax burden on business confidence in the construction sector (please see Annexes, Table 4) resulted in the validation of regression models for 8 of the 28 Member States (Bulgaria, Denmark, Germany, Croatia, Italy, Hungary, Poland and Slovenia). After analyzing the impact of taxation on business confidence in the retail sector (please see Annexes, Table 5) I validated the linear regression models for 7 of the 28 Member States (the Czech Republic, France, Cyprus, Latvia, Slovenia, Slovakia and Finland). For Ireland, Denmark and Malta there were too few observations for the estimation to have any accuracy. Of all four confidence indicators, for the RCI I found the fewest validated regression models.

As a result of analyzing the impact of taxation on the confidence of companies in the services sector (please see Annexes, Table 6), I validated 8 of the models, those estimated for Denmark, Germany, Latvia, Hungary, Austria, Poland, Slovenia and Slovakia. For Luxembourg I could not estimate the regression model because data for the SCI was not available for this country. Also, there were too few observations for Denmark and Croatia to be able to give any scientific and economic value to the results of the estimations.

Table 2: Estimation results – adjusted and validated models

Note: *significant at 1%; ** significant at 5%; ***significant at 10%

In order to have a more detailed analysis on the impact of the tax burden on business confidence, I will continue with a presentation of the estimation results of the adjusted validated regression models of each Member State. The results are summarized in Table 2.

One result that I expected to find was an indirect relationship between the business confidence indices and the different types of tax burden. And my expectations were fulfilled in the case of most Member States for which I validated regression models. However, the results vary from one country to the other; therefore I will comment on the results obtained for each Member State in turn.

In *Bulgaria*, the indirect tax policy has a direct and positive impact on business confidence in the construction (CCI). In spite of the small value of the R^2 coefficient, which was to be expected, I can conclude that an increase in indirect taxation can lead to an increase in business confidence in the

construction sector. This result can be attributed to the fact that the managers might see an increase in indirect taxation as a guarantee that direct taxation will not be increased. Also, managers might expect to be able to shift the additional indirect tax burden onto their clients and not be affected by the increase in indirect taxation.

For the *Czech Republic*, I can conclude that indirect taxation positively influences business confidence in the industrial sector (ICI). The positive value of the coefficient that determines the indirect tax burden is relatively large (43.443) and it is significant at a 10% level. This leads to a considerable influence that the indirect taxation has on business confidence in the industrial sector. Business confidence in the retail sector (RCI) is negatively influenced by the social security policy. An increase in social security contributions would lead to larger tax expenses for the company, which would cause a decrease in business confidence for the retail sector in the Czech Republic.

In *Denmark*, the social security policy negatively impact business confidence in the construction sector (CCI), while direct taxation has a positive impact on the same sector. The result for social security contributions was to be expected, but the outcome of the research for direct taxation is surprising. An increase in direct taxation leads to an increase in business confidence in the construction sector. This positive impact of direct taxation also appears when the services sector is analyzed. But for the business confidence in the services sector I also find a negative impact of indirect taxation. Therefore an increase in direct taxation is seen as favourable by the managers, while an increase in indirect taxation is seen as unfavourable. The explanation for this perception might be due to the fact that Denmark is one of the northern countries of Europe, where most of the tax income comes from direct taxation. Therefore, managers might be used to high direct taxation, but might perceive increases in indirect taxation as bad signs.

Most of the research results for *Germany* are as I expected: an increase in indirect taxation leads to a decrease in business confidence in the services sector (SCI), while an increase in social security contributions leads to a decrease of business confidence in both the construction sector (CCI) and in the services sector. The conclusion for direct taxation is, however, similar to that presented for Denmark: direct taxation positively influences business confidence in both the construction and in the services sectors. Another noticeable result is the fact that the model for the services sector in Germany is the only one where all three types of tax burden Ire retained in the final validated model. For the services sector, taxation accounts for almost 26% of the perception of managers regarding the future development for their sector of activity.

The research results for *Greece* show a positive impact of direct taxation and a negative impact of indirect taxation on business confidence in the industrial sector (ICI). The impact of indirect taxation is almost double that of direct taxation, which is not surprising in a country that relies mostly on indirect tax revenues. However, all conclusions regarding Greece must be considered with caution because for this country only 34 observations were available and this might have a negative impact on the results.

In *France*, there is a negative impact of the social security policy on business confidence in the retail sector (RCI). For this country, on the one hand I have the largest number of observations for any of the EU Member States (118 observations); on the other hand, the value of R^2 is only 4.6%, which means that less than 5% of the managers' confidence in the retail sector is based on taxation.

According to the research results, in *Croatia*, there is a negative impact of direct taxation on business confidence in both the industrial (ICI) and in the construction sectors (CCI). In spite of the high level of the R^2 coefficient for both models, any conclusion for Croatia should be drawn with considerable reservations due to the very small number of observations available for this EU Member States (only 10 observations).

In *Italy* there is a negative impact of the social security policy on business confidence in both the industrial (ICI) and the construction sectors (CCI). However, the impact is much more pronounced in the industrial sector than it is in the construction sector. What is surprising about the results for Italy is the positive impact of direct taxation on business confidence in the construction sector. This result

is similar to the results obtained for the construction sectors in Germany and Denmark. Still, the impact of direct taxation on business confidence in Italy is much less pronounced that in Germany or Denmark.

The research for *Cyprus* leads to a significantly negative impact of indirect taxation on business confidence in the retail sector (RCI). This means than even the slightest increase in indirect taxes will lead to a severe decrease of business confidence in this sector. The regression model has a R^2 coefficient of 0.35 and the research was conducted on sufficient observations, which lends credibility to the conclusions.

The results for *Latvia* show a negative impact of the social security policy on business confidence in the services sector (SCI). However, there is also a positive impact of indirect taxation on business confidence in the retail and services sectors (SCI). The explanation for these results might be similar to that previously discussed for Bulgaria. The managers might see this as the lesser of two evils (an increase in indirect taxes is preferable to an increase in direct taxes) and they might think it will be possible to shift the additional tax burden to the end-consumer instead of bearing it themselves.

Direct taxation has a negative impact on business confidence in the industrial sector in *Lithuania*. Even if the coefficient that determines the direct tax burden is significant at a level of 10%, the value of R^2 is only 8%. This value is acceptable for this study, but it shows that the influence of direct taxation on the perception of managers in the industrial sector is nevertheless limited.

In *Luxembourg*, the research results showed a strong negative impact of the social security policy on business confidence in the construction sector (ICI). Also, direct taxation has a positive impact on business confidence in the construction sector. This result is similar to those obtained for Denmark and Germany. The value of the R^2 coefficient is 19%, one of the largest for all the validated models, which leads to the conclusion that managers in Luxembourg consider taxation important when making predictions about the future of their company and their business sector.

The research results for *Hungary* revealed a negative impact of the direct taxation policy on business confidence in the construction sector (CCI). However, when I analyzed business confidence in the services sector (SCI), the estimations showed a positive impact of the social security policy. This means that an increase in social security contributions could lead to an increase in business confidence in the services sector in Hungary. This result is even more revealing when linked to the fact that the services sector accounts for more of the Hungarian GDP than any of the other sectors of the economy.

When it comes to the results I obtained for *Austria*, I could only adjust and validate one regression model. This showed a negative impact of direct taxation on business confidence in the services sector (SCI) in Austria. Therefore an increase in direct taxes could lead to a decrease of business confidence in this sector of the economy. However, it must also be noted that R^2 is only approximately 5%, which means that direct taxation only accounts for a small part of the variations in business confidence in Austria.

The data for *Poland* lead us to conclude that an increase in direct taxation could cause a decrease in business confidence in the services sector (SCI). Furthermore, the results also showed a positive impact of the indirect tax policy on business confidence in the construction sector (CCI). This is similar to the findings for Latvia, the Czech Republic and Bulgaria. The explanation might be similar: managers of companies in this sector prefer increases in indirect taxation to those in direct taxation.

Slovenia is the only European Union Member State for which I could reach conclusions for all the four sectors of the economy that I included in this analysis. The social security policy has a negative impact on all the four sectors. Therefore, any increase in social security contributions could lead to a decrease of business confidence in the industrial, construction, retail and services sectors in Slovenia.

The results for *Slovakia* were somewhat surprising: direct taxation has a negative impact on the confidence of managers in the industrial sector (ICI), but it has a positive impact on business confidence in the retail (RCI) and services sectors (SCI). This type of result underlines the

complexity of any tax policy decision. The same tax measure can be seen as a positive signal by the companies in one sector, but it might be perceived as unfavourable by other sectors of the same economy.

The research conducted on data collected from *Finland* showed a positive impact of indirect taxation on business confidence in the retail sector (RCI). This is a similar result to that present for Latvia, for the same sector of activity. As Finland relies mainly on direct taxation, perhaps managers perceive increases in indirect taxation as a signal that the direct tax burden will diminish in the future because it is being shifted to the indirect taxes.

Business confidence in the industrial sector (ICI) in *Sweden* is negatively linked to indirect taxation. The data from Greece showed the same connection for the same business sector. The value of the coefficient that determines the indirect tax burden is quite large, but this is outbalanced by the small value of R^2, less that 5%.

The overall conclusion for the European Union is that, in spite of the fact that changes in taxation levels clearly impact business confidence, I cannot establish any rules that would be valid in all the Member States. Each change in the tax burden impacts every Member State in a unique way. The only conclusions that can be drawn are for each Member State individually and not for the EU as a whole.

Conclusions

In the current study I tried to establish if managers take tax policy into consideration when anticipating the evolution of their company and of their business sector. In order to answer this research question I used regression model estimation based on business confidence indices for the industrial, construction, retail and services sectors as Ill as tax burden information for direct taxation, indirect taxation and social security contributions.

The analysis was conducted for all the current 28 Member States of the European Union. However, the results pointed to different conclusions for different countries, therefore I have no single answer for the entire European Union. I can only reach conclusions for certain groups of states and, sometimes, for only one Member State.

One group of Member States is that where, according to the results, taxation does not influence managers' perception of their business environment. This group includes: Belgium, Estonia, Ireland, Malta, the Netherlands, Portugal, Romania, Spain and the United Kingdom. I believe that there can be two possible explanations for these results: either the tax legislation is very stale, with few changes and therefore it is unlikely to cause any surprising changes in the business environment; or the opposite is true: the tax legislation is very unstable and the changes are so frequent that the managers cannot anticipate them in any way.

For all the other Member States that were not included in the first group I could reach conclusion regarding the influence of tax policy on business confidence for at least one of the sectors that I included in the analysis. In most cases an increase in taxation would lead to a decrease in business confidence: a higher direct tax burden would have a negative impact on business confidence in Croatia, Lithuania, Hungary, Austria, Poland and Slovakia; an increase in indirect taxes would negatively impact business confidence in Denmark, Germany, Greece, Cyprus and Sweden; higher social security contributions could diminish business confidence in the Czech Republic, Denmark, Germany, France, Italy, Latvia, Luxembourg, Slovenia and Finland. As an overall conclusion, the social security tax burden seems to have the greatest impact on business confidence in European countries.

The research results also showed that in some of the European Union Member States, taxation has a positive impact on business confidence in certain sectors of the economy. The dependent variables (business confidence indices) are based on qualitative data provided by the managers of companies that are active in a certain sector. Therefore, sometimes managers perceive increases in a particular

type of tax burden as favourable or perhaps they only consider it to be the lesser of two evils (e.g. the manager would rather have an increase in the indirect taxes that have one in direct taxes).

There is a clear need for more extensive research on the influence of taxation on business confidence, with more clear-cut conclusions and using a variety of research methods. The study has barely scratched the surface of establishing and describing the relationship between the tax burden and the perception of managers regarding the future evolution of their company and their business sector.

Experimental Studies of Taxpayers Behavior in Russia: Taking Into Account Regional Differences in the Level of Shadow Economy

Dmitrii Y. Fedotov, Doctor habil. (Economics), Associate Professor, Baikal State University, 11 Lenina str., Irkutsk, 664003 Russia, E-mail: fdy@inbox.ru

Natalia V. Pokrovskaia, PhD, Associate Professor, St. Petersburg State University, 7/9 Universitetskaya nab., St. Petersburg, 199034 Russia, E-mail: n.pokrovskaya@spbu.ru

Abstract

The article focuses on assessing the differences between Russian regions in terms of shadow economy level, these are important to take into account when studying such phenomena as behavior of taxpayers, tax compliance and tax evasion. The purpose of this article is to find differences in the level of the shadow economy between the regions of the Russian Federation and to specify their impact on the methodology for carrying out experimental studies into the behavior of taxpayers. Experimental study methods of behavior of taxpayers have been widely used since the second quarter of the 20th century, but most of the described tax experiments relate to European countries and the USA, which have a relatively high level of tax compliance and tax discipline. The study of the behavior of taxpayers in countries with a different level of tax discipline, in particular in Russia, may be of interest. To take into account the differences in the scale of tax evasion and the level of the shadow economy in different regions of Russia, a methodology was developed to measure the size of the shadow economy in the regions on the basis of a comparison of statistical and tax reporting data. The data presented show the heterogeneity of the Russian regions in terms of shadow sector share, as well as the heterogeneity of entrepreneurs and the population of different regions in their tendency to evade taxes. These circumstances should be taken into account when conducting tax experiments in various regions of the country.

Keywords: tax experiment, tax compliance, tax evasion, behavior of taxpayer, shadow economy.

Introduction

Studies of taxpayers' behavior, factors influencing tax compliance and tax evasion occupy an important place in modern studies on taxation (Nevzorova et al. (2016)). At the same time, the central methodology of such a studies is tax experiments that have been actively developing since the last quarter of the 20th century.

Experience of tax experiments in Russia is rather scarce. At the same time, the potential for studying the specifics of taxpayers' behavior and honesty in terms of tax morale in Russia is quite vast and can have its application, among other things, in certain aspects of tax incentives (e.g. Koroleva, 2016: Balandina et al, 2016, Troyanskaya, 2017), including regional level (Pinskaya 2016). At the same time, it is conditioned by the scale of the shadow economy not least of all. It should be noted that the shadow economy (boundaries of which often remain blurred - Bykov et al., 2015) is an indispensable attribute of modern society. There is economic activity in every country that is banned or does not get official registration by authorities it yet exist. As can be seen from the data presented in Fig. 1, the shadow sector has bee revealed in the economies of the most economically developed countries of the world, yet to a smaller degree than in the developing countries.

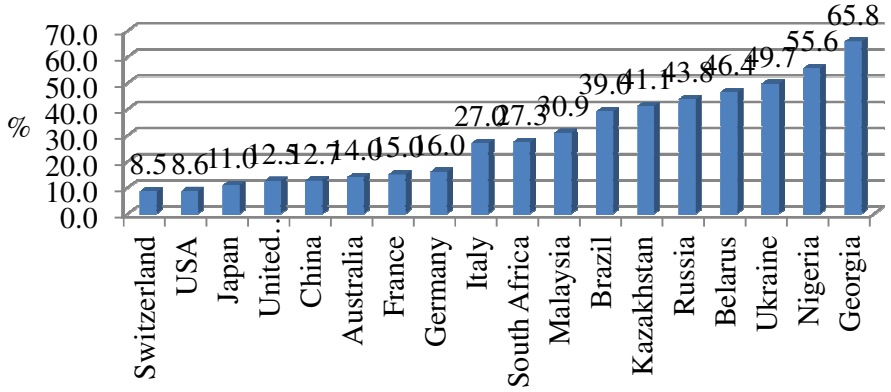

Fig. 1: Weighted average size of the shadow economy in 1999-2007, % of GDP (Schneider et al., 2010)

Schneider et al. (2010) note, that in almost all studies it has been ascertained that the overall tax burden is among the main causes for the existence of the shadow economy. At the same time, the direct connection between the size of the shadow economy and the tax burden is not obvious, which does not exclude the possibility of finding another characteristic of the tax system or even the system of public finances as a whole that affects the scale of the shadow economy. In particular, it is rather unagruable that there is a connection between shadow economy and tax evasion, and tax experiments can indirectly help to reveal the motivation to the latter.

Even though the effects of shadow economy and tax evasion are studied for the state as a whole, including such studies for international comparisons (e.g. Bykov and Frotscher (2016)), in our opinion, regional peculiarities of the analyzed phenomena can be of considerable interest. The thing is that conducting tax experiments is complicated because of different habits in terms of tax evasion in large countries, characterized by heterogeneous population and economic entities. The results of tax experiments in countries such as Russia and countries similar in their regional differences will be distorted if differences in the scale of tax evasion and the accompanying differences in the level of the shadow economy that exist in different regions of the country are not taken into account. In particular, the results of tax experiments conducted in regions with a high level of shadow economy will be unrepresentative in regions with a low shadow economy. Therefore, in order to increase the reliability of the results, tax experiments should be simultaneously conducted in regions with different levels of the shadow economy, and the obtained data should be adjusted taking into account regional differences in population's tendency to evade taxes.

The purpose of this article is to find differences in the level of shadow economy among Russian regions and to specify their impact on the methodology for carrying out experimental studies into the behavior of taxpayers.

Studying Taxpayers' Behavior in Experiments

In the second half of the 20th century, there was a significant development of studies into economic behavior under conditions of instability, a comprehension of the adequacy of the basic premise about the rationality of economic subjects. This also becomes reflected in the studies of taxpayers' behavior. In the early 1970s, theoretical models of rational behavior of taxpayers arise, the beginning of which is associated with classical works by Allingham and Sandmo (1972), as well as Yitzhaki (1974), which are soon supplemented by experimental studies of this subject, in particular, in the tax experiment that has become classic (Freidland, Maital and Rutenberg (1978)) and subsequent ones.

Modern literature extensively describes the methodology and results of various tax experiments aimed at studying the behavior of taxpayers and elucidating the factors, causes and motivations of tax evasion and tax compliance. Experiments can be combined according to different criteria. First of all,

with respect to subjects and objects studied in experiments. From this point of view, it is possible to separate experiments that consider the payment of personal and corporate taxes (it is important that the decisions taken by people are modeled anyway, therefore some researchers do not make corresponding differences). Within the framework of this article, we consider experiments related to the payment of personal income tax.

The implemented experiments are summarized in reviews and meta-studies compiled on various parameters. A. Roth in Handbook of Experimental Economics (1995) suggest experiments' classification according to "how they were motivated and to whom they were intended to be persuasive: "Speaking to Theorists", "Searching for Facts", "Whispering in the Ears of Princes". The category "Speaking to Theorists" includes experiments designed to test the predictions of well-articulated formal theories, and to observe unpredicted regularities, in a controlled environment that allows these observation to be unambiguously interpreted in relationship to the theory. They are part of dialogue between experimenters and theorists. The category "Searching for Facts" includes experiments studying the effect of variables about which existing theory may have little to say. Often these experiments are motivated by earlier experiments and are designed to isolate the cause of some observed regularity, by varying details of the way the experiments were conducted. Such experiments are part of the dialog that experiments carry on with one another. The category "Whispering in the Eras of Princes" deals with the dialogue between experiments and policymakers. These experiments might be motivated by the kind of question raised by regulatory agencies, about the effect of changes in the way some market is organized".

Togler (2002) summarizes more than 100 sources containing information on tax experiments from the categories "Speaking to Theorists" and "Searching for Facts" with main focus is on the social and institutional factors. Conclusion of this review was that holding the probability of penalty, the fine rate and taxpayer's risk aversion constant, social and institutional factors systematically matter. Tax morale and tax compliance experiments have impressively shown that many taxpayers seem to have a more refined motivation structure than that assumed by traditional economics.

Mascagni's review (2017) aims to update Torgler's review. 86 sources represent more experiments in the category "Whispering in the Ears of Princes". Moreover, Mascagni's review is contrasted with Torgler's review in the nature of the experiments: field experiments versus lab experiments.

While the general requirements for experiments in the economy were formulated at the beginning of their active use (Smith, 1992), the advantages and disadvantages of laboratory experiments (the most frequently studied are students in artificial situations; about using student subjects in experimental research in more detail see Marriott, 2014) and field experiments (real subjects who are not informed of participation in the experiment, in a real environment, but under controlled conditions) are discussed a lot. In A. Kireenko's review (2015), which represents the main trends in the development of experimental methods in taxation, it is noted that the main criticism of laboratory experiments is related to the interpretation and generalization of their results, namely, that laboratory experiments are conducted in an artificial environment that is free from external factors; in contrast to the real situation, negative behavior does not bring financial losses to the participants; the behavior of students used as a convenient experimental environment may not correspond to the behavior of real taxpayers; most significant experiments can be costly and time consuming. It is noted that due to the use of the real environment, the results of field experiments are of greater credibility and value, but their procedure becomes complex and very expensive, therefore field experiments are more rare.

The review by Hallsworth (2014), like Mascagni's review, is more focused on field tax experiments. The above chronology begins with an experiment conducted in 1967 in the USA, the next one followed in 1996, the remaining analyzed 21 experiments were conducted from 2001 to 2014. Thus, the investigation of tax behavior begins with laboratory experiments and is further supplemented by field experiments.

The experiments provided an opportunity for extensive meta-analysis of their results, in particular Blackwell (2007), based on the regression of the results of 20 experiments carried out from 1978 to

2006, including 54,588 observations (the smallest number of observations in the described experiment was 74 (Togler, 2003), the largest was 13,440 (Beck et al., 1991)), with subjects from the United States, Central America, Europe and Israel, came to the following conclusions: raising either the fine rate or the probability of audit will increase tax compliance; increasing the return received upon a public good increases tax compliance; no clear results as to the impact of raising the tax rate on tax compliance.

Hoffman et all (2017) present meta-analyses of survey studies which take into consideration the relationships between tax compliance and age, sex, education as well as income taking into account geographical regions. Results of meta-analyses support the hypothesis that older taxpayers are more compliant than younger ones; women tend to hold higher tax compliance than men; individuals with lower education tend to be more tax compliant than highly educated taxpayers; income is to be negatively related to tax compliance. Although the examined sociodemographics correlate significantly with tax compliance their predictive power is limited for age and sex, and negligible for education and income.

The study Hoffman et all (2017) highlights that the analysis of the results included a large number of countries. However, in the twentieth century description of tax experiments largely dominated by Europe and the USA (e.g. Zhang et al., 2016; Lefebvre et al., 2015; Alm et al 2017). Only in recent years, the general results included in comprehensive tax books (e.g. Kirchler, 2007) are complemented by a study of tax behavior in low- and middle-income countries, allowing researchers to draw a more global picture than ever before (see Mascagni). Tax behavior can become an important characteristic of financial systems (Lvova, 2016).

As for Russia, it is interesting that the reviewed sources contain information about local field experiments, but not the laboratory ones (at the same time, there are separate studies devoted to the perception of various aspects of taxation, e.g. Lvova et al., 2016). Conducting tax experiments, according to the "classical" methods implemented in various countries, can have a high value both for studying taxation in Russia and for characterizing the national specifics of tax compliance and tax evasion. We agree that carrying out experiments in Russia may be of interest for comparative analysis, since most of the described tax experiments concern countries with a traditionally high level of tax compliance and tax discipline. It may be interesting to compare the results of similar experiments in countries with a traditionally low level of tax compliance (Kireenko, 2015). The results of tax experiments can be applied in various aspects of taxation in Russia, e.g. for personal income tax studies and so on.

At the same time, experimental methods in taxation have one more fundamental, albeit obvious, difficulty, i.e. creating an adequate methodology. Actually, the improvement of experiments' methodology explains their rapidly growth and diversity. An important aspect of conducting a tax experiment is the representativeness of the selection being studied, which is of crucial importance for Russia territories of which have significant socio-economic differences. The advantages of conducting a tax experiment in several regions are obvious. However, this raises the question of the comparability of the data obtained, what implies the forming groups of regions or cities (Pashkus et al., 2015) with similar characteristics. In this case, the directions of the analysis can be, on the one hand, the joint examination of data in different regions with testing their homogeneity or their comparison with the results of other regions and the identification of their differences. Due to the strong negative correlation between the size of the shadow economy and the degree of the tax morale (Alm and Togler, 2005), we suggest using the indicator of the size of the shadow economy as a characteristic of regions for conducting tax experiments.

Calculation of the shadow economy in Russian regions by the tax method

There is a keen interest of researchers to study the causes and measure the scale of shadow economy. To date, economics has developed a significant number of methods for measuring the size of shadow economy. It should be noted that studies devoted to the assessment of shadow economy at the regional level are much less common than similar studies on a national scale.

The fact is that traditional methods of measuring shadow economy size at the regional level are not always able to provide a reliable data about the phenomenon due to the limited sources of information, and in some cases, a fragmented approach to the choice of the object of research.

In order to overcome these limitations of shadow economy research at the regional level, we developed a methodology for measuring the size of shadow economy in Russian regions on the basis of a comparison of statistical and tax reporting data. This methodology is described in more detail in Fedotov et al., 2016

Official information published by the Federal State Statistics Service (Rosstat) and the Federal Tax Service (FTS) is sufficient to identify the shadow share of gross regional product (GRP) in all Russian regions. We compared the aggregate GRP and its components, measured by Rosstat, to the size of the tax base for some taxes published by the Federal Tax Service, which in turn is a legal component of the GRP of the country's regions. The discrepancy between the data of national accounts and the indicators of tax reporting makes it possible to reveal the unobserved share of the GRP of a particular region of the country. A comparative analysis of these indicators was carried out for the period 2011-2015. Similar studies were conducted by O'Higgins (1989) in the UK in the previous century, however, not in the regional context but with regard to national indicators.

As an indicator measuring the size of shadow economy, we chose the share of shadow economy in the gross regional product of every region of the country. The gross regional product is calculated by the production method as the difference between output and intermediate consumption. At the same time, Rosstat, analyzing the structure of GRP from the point of view of generating income, identifies three components forming the GRP: payroll fund, gross profit and net taxes on production. In this connection, the calculation of GRP can be carried out by the following formula [1].

$$GRP = W + P + T_{prod} \quad [1]$$

GRP – gross regional product;

W – wages of employees (excluding hidden wages and mixed incomes), i.e. legal wage (without the shadow one), but increased by the amount of contributions for compulsory social insurance funds;

P – gross profit of the economy and gross mixed incomes;

T_{prod} – net taxes on production, which include property tax of organizations, transport tax and land tax paid by legal entities, license fees.

Of the three components of the GRP, the first (wage) and the third (taxes on production) are accounted for by Rosstat in its legal value. Wage (W) includes only the officially paid aggregate payroll for each subject of the Russian Federation, excluding the shadow salary paid in "envelopes" and other informal incomes. And the value of net taxes on production (T_{prod}) Rosstat calculates on the basis of the actual amount of tax revenue included in this group.

The only part of the GRP, containing the informal economy's results of the Russian regions according to the Federal State Statistics Service, is the gross profit of the economy and gross mixed incomes (P), which together represent:

1) legal profit of enterprises;
2) hidden profits of enterprises (including financial performance of the informal economy and officially unregistered enterprises);
3) hidden wages and other mixed incomes received informally.

Therefore, we get the value of shadow economy of each region of the country by subtracting its legal component from the gross profit amount. We determined the size of legal profit of enterprises on the basis of the size of tax base, based, in its turn, on corporate profit tax, presented in the Report on the tax base and the structure of accruals on corporate profit tax (Form No. 5-P), compiled and published by the Federal Tax Service. The aggregate tax base for corporate profit tax is the total amount of profit received in the reporting year by the organizations of the region for which they reported to the tax authorities. The amount of profit that is not included in these data refers to the shadow results of

the organizations of the region. The data obtained allowed us to calculate the value of shadow economy in every Russian region using one of the two interchangeable formulas [2] and [3].

$$GRP_{shad} = \frac{P - P_{tax}}{GRP} \times 100$$ [2]

где, GRP_{shad} – share of the shadow economy in the GRP of the region,%;

P_{tax} – legal profit included in the tax base for corporate profit tax;

GRP – gross regional product;

GRP_{shad} – share of the shadow economy in the GRP of the region,%;

P_{tax} – legal profit included in the tax base for corporate profit tax;

W – employees' remuneration;

T_{prod} – net taxes on production;

$$GRP_{shad} = \frac{GRP - W - T_{prod} - P_{tax}}{GRP} \times 100$$ [3]

где, GRP_{shad} – share of the shadow economy in the GRP of the region,%;

GRP – gross regional product;

W – employees' remuneration;

T_{prod}– net taxes on production;

P_{tax} – legal profit included in the tax base for corporate profit tax.

The results of calculating the size of the shadow economy in the subjects of Russia are given in Tab. 1.

Prepared by the authors on The electronic supplement to the collection "National accounts of Russia in 2011-2016" URL: http://www.gks.ru/wps/wcm/connect/rosstat_main/rosstat/en/statistics/publications/catalog/ doc_1135087050375 ; Report on the tax base and structure of corporate profit tax accruals (Form No. 5-P) - URL: http://www.nalog.ru/rn38/related_activities/statistics_and_analytics/ forms /.

As can be seen from data in Tab. 1, Russian regions vary significantly in terms of the level of shadow economy. If in the Magadan Region in 2015 the shadow sector amounted to 13.7% of GRP, it reached 76.6% in the Republic of Dagestan. The difference of regions according to the level of the shadow economy is illustrated in Fig. 2 where regions are grouped by the value of this indicator.

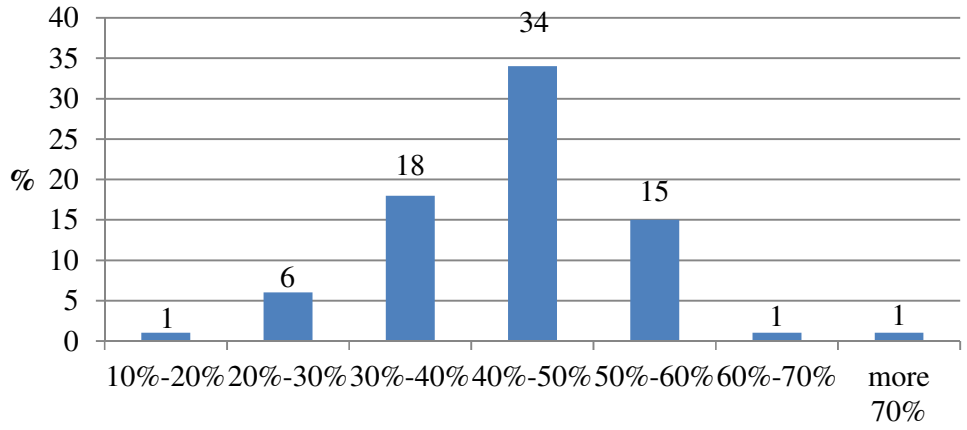

Fig.2: Distribution of Russian regions by groups depending on the level of the shadow economy in 2015

The data presented reveal the heterogeneity of the Russian regions in terms of shadow sector share, as well as the heterogeneity of entrepreneurs and the population of different regions in their tendency to evade taxes. These circumstances should be taken into account when conducting tax experiments in different regions of the country.

Conclusions

The revealed differences in the shadow economy in Russian regions are of great importance for the experimental analysis of tax compliance, tax evasion, tax morale and, in general, the taxpayers' behavior. Differences in the level of the shadow economy in regions should be taken into account when interpreting the results of tax experiments that study the behavior of taxpayers. Since opportunistic tendencies of taxpayers, revealed by tax experiments, can be caused not by objective behavioral characteristics of the population of the whole country, but by specific socio-economic conditions that have developed in certain regions of the country. In particular, the tendency towards tax evasion and the high level of shadow economy in the North Caucasus regions of Russia are to a large extent stipulated by weak economic development and low living standards of the population of these regions. "Withdrawal into the shadows" and tax evasion is a certain way to "make ends meet" and ensure the profitability of local enterprises. This is the manifestation of the social function of the shadow economy, which, according to Peruvian scientist Hernando de Soto (2002), is to ensure employment in a poorly developed economy.

Abstract

The authors have analyzed the major steps in the investment process of banks, typical mistakes investors make in terms of this process, and developed methods for hedging relevant risks by complex introduction of innovative financial instruments into the portfolio (coupon bearing federal loan bonds (OFZ-PK) and federal loan bonds with indexed face value (OFZ-IN)) and by using algorithms for flexible investment horizon of other innovations.

Key words: Investments, bank, portfolio, risks, instruments

Introduction

In Russia, commercial banks are historically strong players on the stock market. By using instruments of the stock market, they form investment portfolios not only to obtain profit, but also ensure the most important and one of the main indicators of their activity – paying capacity via liquidity of their investment portfolio (security portfolio).

Today the specific weight of securities in the asset structure of a bank amounts to, on average, from 15 to 40% [1], depending on the specifics of the bank activity and its investment policy. In turn, a number of aspects concerning the theory and practice of bank portfolio investment management should be further developed and improved. Primarily, it is about accounting the normative requirements for banking and real time operation mode on open markets.

Investment activity of commercial banks in most publications is seen as a purely auxiliary tool of active operations, mainly aimed at maintaining the liquidity of banks and ensuring minimal returns on investment assets.

This approach can be seen as reasonable in the periods of relative stability of economic systems. However, in the periods of high volatility of the main parameters of national economies and crisis phenomena of global nature, even such a conservative investment strategy of banks can prove to be inefficient.

This situation, being the superposition of global economic processes starting from 2008, and political aspects, which started to aggravate at the end of 2013 – beginning of 2014, jointly resulted in the need for revising the tools and, to a large extent, methodology of investment operations of Russian banks.

Methodology (basic algorithm) of investment process

The following fundamental works by western economists should be mentioned in the context of the subject of this paper: G. Alexander, H. Markowitz, W. Sharpe, J. Mossin, J. Tobin, J. Lintner, R. Merton, M. Scholes, Z. Bodie, A. Keynes, E. Peters and among Russian economics – V Barkhatov, N. Berzon, A. Burenin, V. Milovidov, A. Shapkin, A. Abramov, V. Kazakov and other authors.

An investment process in its classical interpretation represents a decision taken by an investor about the securities in which investments are made, the amount and time of investment. The next procedure, including five steps, is the basis of the investment process:

The first step – formalization of investment policy - includes determination of the investor's goals and volume of invested money. The goals of investment must be formulated given both yield and risk.

The second step of the investment process, known as stock market analysis, includes investigation of individual types of securities (or groups of securities). One of the goals of such research is to determine those securities which seem to be wrongly evaluated at the present moment.

The third step of the investment process – formation of the security portfolio – includes determination of particular assets for investment and proportions for distribution of the investment capital between assets.

The forth step of the investment process – revision of the portfolio content – is related to the repetition of the three previous steps. I.e. after a while the goals of investment and/or quotation prices of securities may change and the current portfolio will not be optimal any more. The decision about portfolio revision depends also on the amount of transaction costs and expected yield growth of the revised portfolio.

The fifth step of the investment process – portfolio efficiency evaluation – includes regular assessment of the obtained yield and risk parameters the investor collides with. Herewith it is necessary to use appropriate yield and risk parameters and the relevant standards ("reference" values) for comparison.

No doubt, the abovementioned classical approach to the content and sequence of the investment process steps is based on generalized experience of several generations of stock market players and, in particular, its bank subset. However, core changes in the field of finances, banking and capital markets happening over the last decades and related to the complexity and globalization of the world economy urgently call for using innovative techniques, algorithms and tools of investment operations.

Russian researchers, being residents of the developing economy with all its peculiarities are, undoubtedly, interested in learning the specifics of the transitional period, especially in the conditions of global crisis phenomena. Thus, in particular, O.G. Bakatanov (2008) suggests adding the generally recognized structure of portfolio management with a step of portfolio management tactics management, which follows the formation of investment policy and precedes the step of direct financial analysis.

Portfolio tactics is formulated in the context of the chosen strategy and contains specific ways and methods to form the portfolio. It implies maximum detailing.

Portfolio tactics must contain the following elements:

- security information analysis methods,
- portfolio risk management technology,
- a decision-making model for asset purchase and sale.

The importance of portfolio tactics identification as a separate category in the theory of security portfolio management is in the fact that it is the portfolio tactics which is the core of the portfolio management process and a guarantee for achievement of investment goals. Moreover, the use of the category "portfolio tactics" allows fining a new and more efficient way to solving such important problems of the theory of portfolio management as investment risk assessment and portfolio management efficiency.

Adequate risk measurement of investments in the security portfolio seems to be the key moment in forming an efficient investment strategy. Even though different approaches to risk assessment have been elaborated, the issue of risk assessment of investments in the security portfolio must be worked out further. The existing methods of risk assessment do not fully consider some specific features of stock markets. Such specific features include short-term and long-term trends in price movement and the existence of various phases in market movement – periods of high volatility and price instability and, vice versa, periods of low volatility and reduced activity of investors.

Therefore, risk assessment in the conditions of emerging markets must be closely related to the investment goals of the investor and his investment horizon.

Risk assessment under the conditions of emerging markets and by using traditional methods results in unreasonably high estimates. For this reason, many big portfolio investors are really conservative about investing on emerging markets and limit themselves to short-term investment operations (in more detail this problem is looked into below in this paper in reference to OFZ-PK and OFZ-IN). Thus, investing money on emerging financial markets for quite long periods allows a portfolio investor to obtain all benefits from high returns on investment into financial assets of these markets and be exposed to risks which are considerably lower than commonly believed in the international investment practice.

The aforementioned is topical primarily for investors who practice conservative and moderately conservative investment strategies or strategies implying that the positions in the portfolio sustain for quite a long time, which is very common for banks as security market players. Thus, investments in the condition of developing markets on short-term investment horizons call for elaborating an active strategy for investment portfolio management.

Investment portfolio management and typical mistakes of investors

There are several most common and well-known mistakes made by investors in relation to risk. However, many investors will still make them and break the main investing principles. The main principles of long-term investing include:

- time value of money;
- sectoral diversification;
- impossibility of discrete market analysis.

Investors, as a rule, know about these principles, but regularly break them, especially in times when volatility of markets is increasing, which, in turn, make them commit one or several common (typical) mistakes listed below.

1. Volatility, forming multidirectional market vectors, decreasing the criticality level of investors' assessments.

Rather than be worried about short-term volatility, a long-term investor should concentrate on the risk which is hardly noticeable – risk of losing control over long-term goals due to excessive attention paid to short-term volatility.

2. Active search for ways to invest with minimal risk.

Every investor wishes to work with the lowest risk. However, to search for a type of investment with the lowest risk is the same as to search for the best type of a mutual fund. Everything depends on the specific goals of the specific investor.

3. Empirical calculation of the exact time for particular operations on the market.

Investors know that attempts to determine specific time for operations on the market often fail. The majority know that even very experienced professionals cannot successively foresee the market movement. But still many try to project a "lucky" moment on the market and often without any grounds.

4. Sale of assets in case of possible market decline.

In case financial markets suddenly transfer to a negative trend there is always a result. In such a case there is no need to be waiting for a sudden fall in the value of investment in order to sell assets. Otherwise, there is danger of a limited view of the market due to one's own losses. Moreover, as soon as money is lost and an asset is sold, there is no more chance to derive profit from further movements of the markets while according to a long-term assessment.

5. Purchase of "hot assets"

Only very few assets consequently appear to be productive, especially if only short-term production is considered.

One of the reasons is that as soon as a "hot asset" has been defined by market players, it will experience the pressure of investors' excessive financial means.

Another factor includes shifts on the market itself. Conditions (usually temporary ones), favorably affecting any of these types of assets in a short-term period, will, most probably, change faster than the asset will find its way to "retain" them in its market parameters.

Change in Investment Paradigm

As it was already mentioned at the beginning of this paper, at the formation stage of cumulative economic and political crisis manifestations (including the decline in the sovereign credit rating of Russia), bank investments into state bonds with fixed yield have acquired a negative dynamics, both in terms of falling yield and negative reassessment of the balance-sheet value of investment portfolios.

Dynamics of the main market parameters is given in Fig. 1:

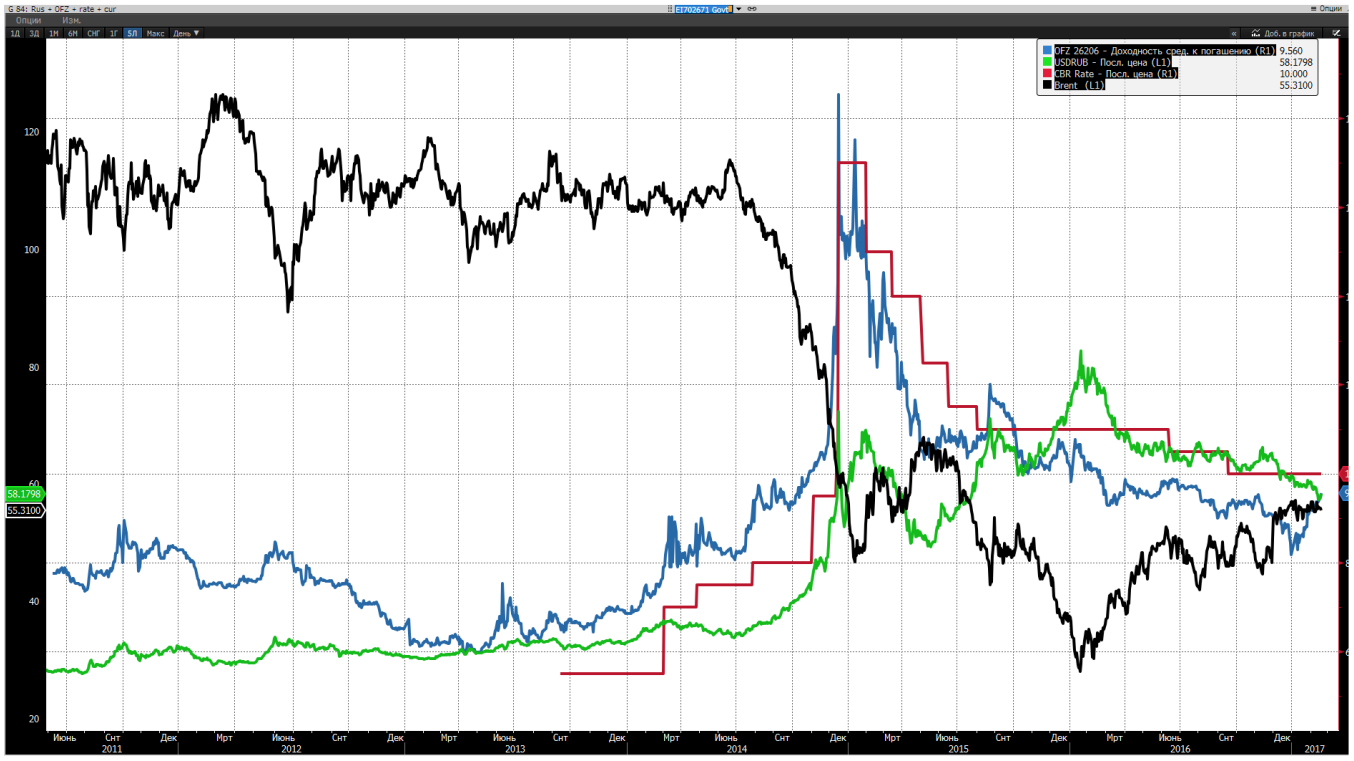

Fig.1: Dynamics of the key parameters of the Russian economy (September 2011 – February 2017)

Further development of events for every certain bank was individual, depending on the combination of several factors – general condition of the bank, specific weight of the investment portfolio in the total amount of its assets, personnel qualification, pressure on the bank exerted by the client base and its moods, decisiveness of executives and their mutual understanding with the bank's owners.

At that period, the simplest and so the most common operation algorithm of banks was to transfer a part of investments from the trade portfolio ("securities for resale") to the portfolio of "securities sustained until redemption"[1]. Nevertheless, this method resulted in the loss of the total returns on investment of the portfolio and, in addition, immobilized some amount of resources in government liabilities, without giving the bank a chance of a local maneuver for redistribution of money in the instruments with relatively high returns on investment at a certain time period (of cause, in case the level of risk was acceptable for such instruments).

In addition, the processes considered were significantly accelerated by ruble devaluation (with the excursion of fluctuation amplitude of RUR/USD pair up to 50 rubles per one US dollar over the period from June 2014 to July 2015 with absolute historical maximum of the exchange rate on December 16, 2014, equal to 80.1 rubles per one US dollar[2], on the same day the exchange value of ruble to euro reached the amount of 100.74 rubles per one euro).

Thus, the sustainable investment strategy of most universal banks proved to be insufficiently flexible and, as a consequence of this drawback, not very efficient.

[1] In terminology of regulatory documents of the Bank of Russia
[2] The next historical maximum falls on 20.01.2016 and amounts to 80.773 rubles per USD

Symmetrical Response

It should be mentioned that the reaction of specialized state institutions (the Ministry of Finances and the Bank of Russia) to this situation proved to be prompt and timely. The solution suggested to the Russian banking system had the necessary "technological" effectiveness.

In the early 2015, the Minfin issued new securities - federal loan bonds with variable coupon (OFZ-PK), whose rate was calculated based on the values of the RUONIA rate (**Ru**ble **O**ver **N**ight **I**ndex **A**verage), and federal loan bonds with indexed face value (OFZ-IN), where the face value was indexed daily in reference to the consumer price index (CPI) [1,2].

Here, undoubtedly, some comments are needed about the mentioned innovation tools and the base used in their construction.

General principles of RUONIA are the basis for defining the amount of Accumulated Coupon Income (ACI) of OFZ-PK [1,2]:

1. The indicative specific rate of one day ruble credits (deposits) called RUONIA reflects the value assessment of an unsecured loan on "overnight" conditions by a standard borrower from the number of Russian banks with a minimal credit risk.
2. RUONIA is calculated by the Bank of Russia according to the technique developed by the selfSRO "NFA" [7] jointly with the Bank of Russia based on the information about deposit deals made by the leading Russian banks from RUONIA list between each other during the entire day.

…

5. The calculation excludes the deals with signs of inconsistency or non-marketability.

Indexation of OFZ face value

OFZ-IN are the only bonds in Russia which have an "integrated" protection from inflation. For the first time they became available for market players in July 2015. The protection mechanism is implemented via determination of the current amount of the bond face value, which is indexed daily depending on the achieved level of inflation changes. Thus, if inflation has increased by some percentage, the OFZ-IN face value gets increased by the same size, herewith bond coupons are fixed and amount to 2.5% of the face value.

The level of inflation is calculated based on the Consumer Price Indes (CPI), which is updated and posted daily on the web-site of the Minfin of the RF according to the data from Rosstat.

However, the face value is recalculated not at once but with a 3-month delay. For example, if by the end of January, the CPI has increased by 2%, the OFZ-IN face value will increase by 2% only by the end of April. OFZ-IN are issued by the Ministry of Finances of Russia (Minfin) and the general emission agent is the Bank of Russia.

Parameters of primarily purchased OFZ-IN [5]:

1. Date of issue (or date of purchase) – July 17, 2015.
2. Date of redemption – August 16, 2023, i.e. total circulation period is 8 years.
3. For indexation of OFZ-IN face value, the consumer price index is used. It is published by the Minfin of the RF according to the data from Rosstat. For the date of purchase, the CPI was equal to 487.8 points. The value of the CPI affects the face value of OFZ-IN with a 3-month lag. I.e. if today the CPI has grown by 1%, the face value of OFZ-IN will grow by 1% only in 3 months. The following formula is used to recalculate the face value:

Face value		Face value		Consumer Price Index (CPI)
of	=	of	*	of current period
current period		previous period		CPI of previous period

On the date of issue the face value of OFZ-IN amounted to 1000 rubles. Now it is bigger (due to inflation growth), but on the date of redemption, the minimal value of the face value cannot be lower than the initial amount of 1000 rubles. I.e. if by the end of the circulation period, inflation should reduce dramatically (down to deflation) and the face value of OFZ-IN according to the formula will be lower than 1000 rubles, the redemption will still be carried out at 1000 rubles, but not at a lower value.

4. The coupon rate is fixed and equivalent to 2.5% per annum. The coupon is paid once every six months. The above interest is allocated on the newly indexed face value, i.e., first, depending on the CPI, the face value of a bond will be determined (according to the formula above) and then, given the obtained value, the coupon payment will be calculated. The exact schedule of coupon payments is presented in the table below.

Calculate the face value of OFZ-IN for the end of March 2017. For January 31, 2017 the face value was equal to 1100.51 RUR. As mentioned above, the CPI is taken with a 3-month lag, so to calculate the face value in March, the value of the CPI valid by the end of December 2016 will be used, i.e. 537.8 points. By the end of November 2016, the CPI was equal to 535.7 points.

- Inflation for the considered period amounts to +0.39% ((537.8/535.7)*100%-100%).
- The face value of OFZ-IN for 01.04.2017 = 1104.91 RUR = (1100.51 RUR*(537.8/535.7))
- The accumulated coupon yield = 2.88 RUR

Thus, indexed OFZ protect the investor from all risks related to inflation growth. However, there are moments when it is not profitable to purchase these securities. It implies the following. If the investor expects growth in inflation risks, i.e. there are real pre-requisites for a great increase in consumer prices, the purchase of OFZ-IN is reasonable. It will protect the capital from depreciation and, in addition, gives some premium (in the form of a 2.5% coupon). If, contrarily, the level of consumer prices is expected to decrease, it is inadvisable to purchase OFZ-IN, since the face value will fall following the decreasing inflation. In such periods, it is better to consider alternative instruments as investment vehicles.

Comparison of investment efficiency in federal loan bonds with variable coupon (OFZ-PK) and federal loan bonds with indexed face value (OFZ-IN)

It is necessary to analyze the ratio of such factors as the key rate (KR), inflation, RUONIA rate and the difference between RUONIA and KR. On Fig. 1 choose, with some allowance, the range of values of these parameters in the period when market volatility was maximal – from September 2013 to January 2016.

For easier analysis, the target values are presented in the form of two graphs (Fig.2).

Since the coupon of OFZ-PK depends on the *average* rates of the RUONIA over 6 months, the second of the presented illustrations is more informative. It clearly shows that the peak of average inflation is primary in relation to the peak of average rates, i.e. the accumulation of coupon yield of OFZ-PK lags behind the rate of inflation (it is important for correct modelling, see also item 8 below). It should be also noted that the RUONIA follows the key rate precisely (apart from short-time deviations), so for modelling it is enough to consider only the key rate. Before the shock of the mid-end 2014, the rates were a little lower than inflation. It can be assumed that with the transfer of

the Central Bank to inflation targeting, the rate will be insignificantly higher than inflation (after inflation arrives at the target parameters of the Central Bank) – it is also important for the model.

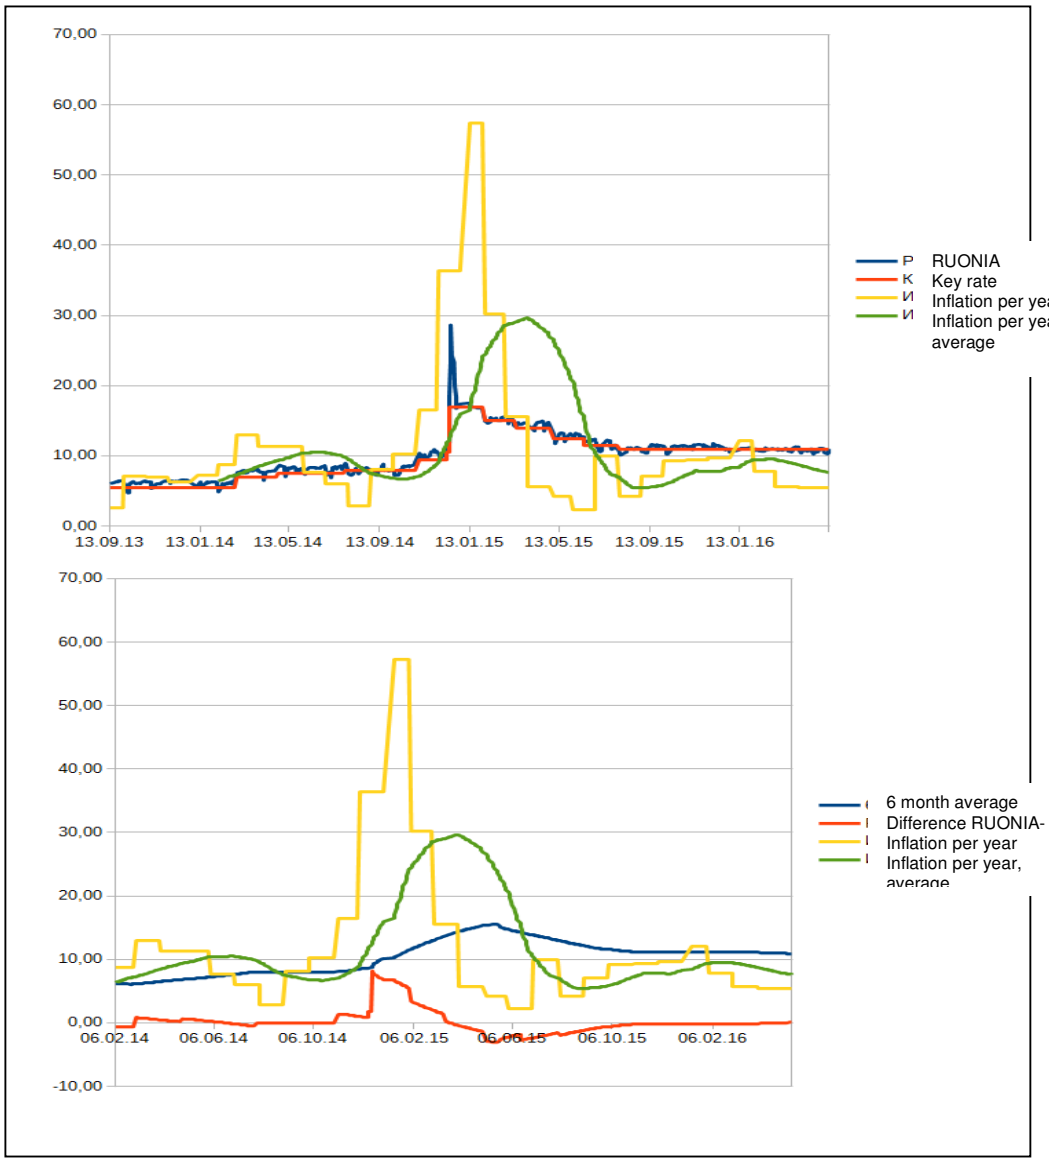

Fig. 2: Comparative dynamics analysis of the selected economic parameters

For variation analysis of the dependences considered, a support model has been developed. It is based on comparison of discounted cash flow (DCF) without reinvestment and with reinvestment. Logical price relation of OFZ-IN and OFZ-PK is calculated separately (if > 100%, then OFZ-PK must cost more than OFZ-IN, if < 100%, then OFZ-PK must cost less than OFZ-IN). In addition the DCF for bonds is calculated at the price of 100%, so in the last two periods OFZ-PK demonstrated negative cash flows (in the model considered, variable parameters are only the values of inflation and rate, values are average annual for the relevant period.).

Intermediate conclusions:

1. The main contribution in the DCF and the difference in the DCF is brought by the rate inflation ratio. The higher is the rate over inflation, the bigger is DCF for OFZ-PK. In case of "normal" rates (1-1.5-2 % greater than inflation), OFZ-IN have an advantage over OFZ-PK (which is so much more significant the smaller the difference is).

2. This advantage is especially noticeable in case coupons are reinvested. OFZ-IN are just incomparably much more profitable, especially in case of long periods.

3. Today OFZ-PK are traded more expensively than OFZ-IN, although the model demonstrates that they should be cheaper than OFZ-IN, given that the rate will lower in future. There are several possible explanations of this inconsistency:

a) Big market players do not believe in fast and sustainable reduction of rate. If the rate is considerably higher than inflation, this price is reasonable.

b) OFZ-PK prices will go down as the rates begin to decline and will come to a "normal" relationship with OFZ-IN prices.

c) Big market players use insignificantly deep analysis and, correspondingly, a short projection horizon, i.e. they live for the day and for the nearest future or do not reinvest, but just immobilize money resources for 6-12 months and remove coupon payments from the market.

At this state, it is reasonable to conclude that investors, interested in allocating money resources for 5 years or more, should reinvest from OFZ-PK in OFZ-IN right now, when the market proposes super-attractive prices for that.

4. Big and super-big investors, including professional market players (first of all, banks), who have access to cheap funding, with the instruments being investigated, can make operations according to the hedge-fund method – keep short position to OFZ-PK versus long position to OFZ-IN. However, here it is important to analyze in detail the periods of investment in order to avoid paying more for the raised money than the potential return on investment will be.

5. OFZ-PK become more preferable than OFZ-IN at the moment of "economic shocks" of the following main types:

a) Inflation shocks. The rates rise after inflation quite operatively and grow bigger than inflation and fall in a slower way (see Fig. 1 and 2).

b) Liquidity shocks. It is possible that the rates will grow not because of inflation, but because of tension in the interbank lending market (for example, as in 2007-2008, when in 2008 inflation insignificantly exceeded the level of 2007 (by 1.5% per annum) and the interbank lending rates grew exponentially at the same time.

Taking into consideration the probability of such situations, it is reasonable to implement a "back and forth" investment algorithm with a regular "withdrawal" from OFZ-IN and further investment in OFZ-PK (in the period when economic shocks are diagnosed) and then make a backward movement (reformation) of the portfolio.

6. The investor may choose between OFZ-IN and OFZ-PK, given the investment goals. Situations when coupons are removed and when they are reinvested are cardinally different. In case of coupon reinvestment, inflation bonds (OFZ-IN) are much more profitable. In case coupons are removed, OFZ-PK are more profitable.

7. It is possible to insure from shocks by combining OFZ-PK and OFZ-IN in the portfolio. If the market forecast is negative, it is possible to add OFZ-PK in the portfolio, so as to get additional returns on investment in case of shock. The ratio between OFZ-PK and OFZ-IN must be selected given the expectations of the inter-bank rate, from 100% OFZ-IN (in a relatively calm period) to 100% OFZ-PK (when there are grounds to expect market disasters). However, the investor must be utmost careful, because if the forecast does not come true, it will lead to the reduced resulting returns on investments.

8. An active investor at the moment of shocks can reinvest from OFZ-IN in OFZ-PK and back again. Or choose between purchase of OFZ-PK and OFZ-IN, given the existing conditions and nearest future projections. For this it is important to monitor carefully the interbank lending, inflation and analyze the comments of the Central Bank and Minfin, since the peak of average inflation does not coincide with the peak of average rates – here you get opportunities for making extra profits.

9. Conservative investors, in our opinion, should keep the bond part of the portfolio 100% in OFZ-IN. Shocks and risks are relatively short-term phenomena, whereas inflation is a factor of constant pressure on the market. According to the DCF model, in case of very long periods OFZ-IN with reinvestment considerably outride OFZ-PK (and bonds with fixed coupon).

Final Conclusions and Discussion

The most common concepts of capital market operation and security portfolio management, which have been elaborated in the western economic theory, are applicable in the conditions of developing and highly unstable markets with big limitations. In particular, the hypothesis of efficient markets and linear pricing paradigm of market assets, common for the western academic circles distort the real processes on stock markets. For this reason, all theoretical models worked out on this foundation, such as MPT and CAPM cannot fully satisfy people on the ground of the financial market. In application to developing markets, linear concepts are seen as even more inefficient in comparison to developed markets.

Formation of a security portfolio and its management in the conditions of highly unstable markets call for other approaches to the asset management process and risk assessment which more clearly reveals the processes happening on the developing capital markets.

The investment strategy in the conditions of unstable market must be selected given the investment horizon of the investor. Money investment for a short period in the conditions of unstable markets is associated with a significant risk. This risk reduces a lot in case of long-term investment (from 1 year).

If passive strategies are used in the conditions of instable markets, investment risk reduces considerably provided the investor has a “flexible” investment horizon, i.e. the investor can prolong the period of investment if the market situation is unfavorable and wait until security price quotations rise.

Risk assessment of non-receipt of the planned yield allows making a conclusion that with the established level of planned yield, the risk of non-receipt of the planned yield is changing insignificantly in case the investment horizon changes. The level of risk reduces if the investment horizon is long (more than 5 years).

In case the investor has a “flexible” investment horizon, i.e. when in case of unfavorable conditions, the period of investment can be prolonged, it is reasonable to assess risk with a lower degree of forecast reliability (80-90%). Such an approach will allow assessing risk in a less conservative way and form a more profitable strategy.

If investment portfolios, formed in such a way, have ,in their content, innovative financial tools, whose constructions have residentially integrated additional protection factors from manifestation of market or economic environment volatility, it will allow investors and professional market players (primarily, banks) to hedge their own investment risks efficiently in the conditions of unstable economy.

The methodological approaches stipulated in this paper can be applied in practical work of professional stock market players – primarily banks, investment and management companies, institutional investors.

Abstract

The paper aims to assess the effectiveness of measures to improve the organization of road network (using the example of controlled intersections), determine the indicators for evaluating the effectiveness of controlled intersections, establish the role of BI systems in such tasks, and describe the project for developing a BI application for analysis of road network organization at a controlled intersection before and after optimization. The possibilities of using business analysis technologies in evaluating activities to improve the organization of controlled intersections are illustrated by a project of developing a BI application for municipal administrations. Qualitative positive effects from the implementation project both for the company-developer, and for municipal administrations are considered.

Keywords: controlled intersections, road network, BI-systems, Qlik Sense, data analysis.

Introduction

The organization of non-stop traffic is a key component of the socio-economic development of cities and regions. Actively developing technologies in the field of transport modeling and design allow solving many transport problems: optimization of traffic and pedestrian flows, public transportation, traffic management, optimization of traffic light facilities, and justification of investments in the construction of transport infrastructure. However, less attention is paid to comparing the actually obtained optimization results with the planned ones. [1] The decision makers of optimization projects, namely the heads of municipal transport administrations and their deputies, do not have the opportunity to receive operative and reliable information about the situation in the city, including what elements of the road network require immediate optimization and increased attention. A large flow of information passes through them, often in paper form, which needs long time periods to be processed. This often leads to data loss.

Effective management of the transport situation is currently impossible without full IT support of processes at all levels: from the collection of primary data on the road situation and the regulation of road infrastructure facilities to the management decisions support. In this regard, the development of intelligent transport systems and their individual components is experiencing a period of rapid development and represents a great potential for research in this field. [2-4] The intelligent transport system (ITS) provides integration of existing and prospective information and control systems in transport, automation and centralization of the processes of collecting, transmitting and processing data on the functioning and current status of all components of transport systems into an integrated hardware and software system, exchange this information, its delivery, both to the participants of the transport process, and to the managing structures, and the use in automatic and automated mode while optimizing all transport processes. [5]. Due to the complexity of its structure, the development of ITS contributes to the solution of a wide range of problems, which are typical for transport systems of modern cities. [6-8] The global goal of ITS development in a city can be seen as development of a system for monitoring and managing the city's transport system in real time to improve the quality of transport services for the economy and the population, reduce transportation costs, improve environment and safety.

Road and transport management in Russia is a traditional point of government-level focus, as the territory of the country is big and roads are the key factor of effective domestic communications. A number of federal-level projects, including state project [9] are being run at the moment. Developing and creating of ITS and its elements is regulated and supported by the number of adopted state standards [5, 10-15].

At the moment there is a wide range of software for modeling traffic at intersections, calculating delay, queue length, bandwidth and other characteristics. Also there is software that has predictive capabilities based on both static and dynamic models. These are products like HCS 3.0, PASSER V-09, SIDRA INTERSACTION, Synchro, OSCADY PRO, PTV Vissim, PTV Optima, TransInfo - Traffic Platform.

Despite the wide variety of software products for developing transport models, calculating and planning indicators, and designing road network parts, there is no solution for senior management that directly decides on the optimization of particular road network parts. Often, the decision makers of transport infrastructure development projects do not have a clear idea of its current state. There is no full understanding of which objects require special attention and which should be optimized as a matter of urgency. It is also not possible to evaluate the effectiveness of measures taken to improve the effective functioning of the traffic in general sorted by districts, cities, years or other indicators [16]. As a result, the development of transport systems is slowing, and people's lives are put at risk, problems are difficult to track, and therefore they are often left without attention.

The decision-maker should be provided with a fairly simple tool that would allow the large volumes of information received from various poorly interconnected sources to be presented in a single environment and in a form convenient for analysis and subsequent well-reasoned decision making. That is why BI-systems are an integral part of modern ITS [17].

Decision support systems have a variety type of instrumentation tools. However, the most topical solution for the top management are business intelligence systems, or BI-systems. They represent a repository of extracted relevant information from an operational database designed for actual data analysis. Their key feature is the ability to combine unstructured data in large volumes from a variety of sources into a single system, process it in a specific way, and present it in a form that is convenient for evaluation and analysis.

In order to solve the problem of poor knowledge of the top management on the state of road traffic management, it will be advisable to develop a business intelligence application that would assess the effectiveness of traffic management before and after optimization of road network parts. The road network consists of a number of elements and it makes sense to use separate applications for each of them, since the evaluation of the efficiency of traffic management optimization projects devoted to different elements of the road network has its own calculation features. Since controlled intersections make up a higher percentage of road network and have a high concentration of traffic accidents, main attention should be paid to assessing the performance of this particular element. To solve such a problem, it is necessary to develop an application that will be able to demonstrate how efficient the optimization of the elements of the road network turned out to be, and also on their basis will make recommendations for further improvement of the road network elements or their totality. Given the fact that such an application should become an assistant to senior management in the process of decision making, it would be most appropriate to use the capabilities of BI-systems that exist to solve similar problems [18].

The BI application was implemented on the basis of a company that for many years has been engaged in transport modeling and traffic planning at the sites of the road network and has the necessary tools to fill the existing gaps in the analysis of transport infrastructure. The paper describes main stages of the BI application development project.

Research Methodology

Complex Analysis of Road Traffic Management on Controlled Intersections

The road network is a system of transport and pedestrian connections between the elements of the city's

structure assigned for the organization of transport and pedestrians traffic, laying of utility systems, landscaping and capital improvement [4].

Elements of road network can be classified according to the type of traffic [19]:

1. Transport traffic:
   - road or street sections;
   - fly-over intersections;
   - gyratory intersections;
   - controlled intersections;
   - non-controlled intersections.
2. Pedestrian traffic:
   - sidewalks;
   - controlled crosswalks;
   - non-controlled crosswalks.

Controlled intersection's main characteristic is the establishment of the traffic sequence by the means of a traffic light or a traffic policeman [20]. Controlled intersections are places of greatest concentration of traffic accidents. This is due to the fact that because of the large number of so-called conflict points, the traffic becomes difficult. Providing the necessary conditions for fast, safe and convenient traffic of vehicles and pedestrians on the controlled intersections is a key task of traffic management.

To ensure road safety and reduce the number of road accidents, the following means are used: road signs, road markings, traffic lights, road barriers and guiding devices. However, the main tool that provides a consistent pass of vehicles and pedestrians across the intersection is the traffic light. Regulation of traffic through traffic lights allows identifying and eliminating the most dangerous conflict points.

However, the existing measures for the traffic management on certain elements of the road network may fail to achieve optimum effect and require further optimization. Following actions can be typified as traffic management optimization measures [21]:

- partial reconstruction of individual elements of the road network (re-planning of intersections, construction of safety islands, equipment of bus stops);
- installation of road signs, traffic lights, road markings, safety fences;
- implementation of automated traffic management systems;
- change in the timetable for the movement of scheduled passenger transport;
- various traffic restrictions (speed, entry for certain types of vehicles).

The basis for the traffic management development measures is data on the current state of traffic organization and information on the intensity, composition of traffic and pedestrian flows, service levels and other information on road traffic. This information is collected in the process of periodic surveys of traffic by organizations, responsible for optimizing the traffic organization.

Identification of places with concentration of accidents, areas with limited capacity, where delays in transport and pedestrian flows are noted, are carried out based on the data of traffic accidents statistics, traffic police information on violations of the Russian Federation traffic rules, and assessment of the capacity of individual road network elements. The work on the identification of black spots should be regularly carried out by traffic police units responsible for a specific territory or road. Investigation of road accident clusters and assessment of capacity should be carried out by the traffic police or an

organization entrusted with the implementation of traffic optimization projects. Depending on the task assigned, the project is developed for a local road network element (intersection, a section of the street) or for a city (urban area), city road or city highway as a whole.

Only a specialized project organization can manage such traffic optimization projects. The assignment for designing usually is developed by an appropriate subdivision of the local administration with the participation of a traffic police unit servicing that territory or road.

Efficiency evaluating methods for traffic management on controlled intersections

Evaluation of the traffic management efficiency on controlled intersections is the first and fundamental stage in the design of [4]:

- site plans;
- comprehensive transport schemes;
- local area development plans;
- comprehensive traffic schemes;
- traffic management plans.

In addition, the efficiency of design solutions should also be evaluated. In this regard, an important aspect is the choice of indicators that allow to assess the efficiency of traffic management. At the moment, there is no unambiguous opinion in Russia how to classify the criteria for estimating road network and to calculate them. Two different approaches are used to evaluate road network: the application of particular criteria and the use of integral criteria. First, we will consider the particular criteria classified by the tasks of the traffic management plans. They are presented in Table 1.

Table 1: Classification of road network estimation criteria based on traffic management plans

Traffic management plan point	Criteria
Traffic management state value	– Time spent on movement over the road network – The total vehicle run over the road network – Environmental characteristics (transport noise, air emissions) – Conflict loading of road network – Stability of road network operation
Identification of road network bottle-necks	– Speed of communication over the road network – The indirectness of transport connection over the MAC – Environmental characteristics – Places of concentration of road accidents (as a result of statistics analysis) – Stability of road network operation

Traffic management plan point	Criteria
Using network methods for traffic management	– Mobility plans – Road network traffic routes – Traffic load of road network – Dislocation and characteristics of traffic flows attraction objects – Throughput of main streets and roads – Intensity of pedestrian traffic – Intensity of vehicle traffic within the assumed pedestrian zone – Provision of parking places – Volume of transit traffic – Vehicle speed – Characteristics of consignees and consignors – Intensity of vehicle movement – Intensity of traffic and distribution of transit flows – Qualitative composition of transit flows

The above road network criteria can be combined into 4 groups:

- economic indicators of the traffic management state value;
- road safety indicators;
- indicators of environmental safety;
- indicators of the sustainability of road network operation.

In addition, particular criteria for assessing the road network state can be characterized by the elements of road network and the traffic types. Detailed classification is presented in Table 2.

Table 2: Classification of particular road network criteria based on network elements

Traffic type	Road network element	Evaluation criteria
Traffic flow	Road/street section	– Traffic capacity – Traffic speed
	Fly-over intersections	– Traffic capacity
	Gyratory intersections	– Traffic capacity – Number of vehicles waiting – Average delay – Total delay
	Controlled intersections	– Traffic capacity – Number of vehicles waiting – Percent of stopped vehicles – Average delay – Total delay
	Non-controlled	– Traffic capacity – Number of vehicles waiting – Percent of stopped vehicles – Average delay

Traffic type	Road network element	Evaluation criteria
		– Total delay
Pedestrian flow	Sidewalks	– Traffic capacity – Traffic speed – Pedestrian density
	Controlled crosswalks	– Average delay – Que length (territory occupied by pedestrians)
	Non-controlled crosswalks	– Traffic capacity – Average delay – Que length (territory occupied by pedestrians)

In contrast to the particular criteria, there is an integral criterion, represented by the level of service. Let us consider in more detail the particular and integral criteria for estimating traffic management at controlled intersections.

Under the traffic capacity of any element of the road network, including the controlled intersection, it is customary to understand the maximum possible traffic intensity in the area under consideration. In the HCM 2000 manual, traffic capacity is defined as the maximum sustained movement rate at which a traffic or pedestrian flow crosses a certain section of the road under a particular control mode, geometric intersection features and other specific traffic conditions. The traffic lane capacity at a controlled intersection to be measured in number of cars per hour (cars / h).

There are theoretical, practical and design capacity to be distinguished. Theoretical traffic capacity is calculated for a horizontal section of the road, assuming that the intervals between vehicles and the uniform composition of the transport stream are constant, that is, they consist only of cars. Practical traffic capacity corresponds to the capacity of road network elements having the worst conditions in comparison with the reference section. Design traffic capacity characterizes an economically viable number of vehicles that the road can skip in a unit of time in the analyzed conditions under the existing traffic management scheme.

The indicator of the average delay of one vehicle is widely used as a criterion for optimizing traffic at a separate intersection. This indicator is closely correlated with such indicators as traffic intensity, queue length, total delay, parameters of the regulatory regime.

Based on the average delay, the queue length and the total delay are determined. The total delay is defined as the delay of all vehicles for the analyzed period on the considered road network or its separate element. The total delay is more suitable for the economic evaluation of the traffic management efficiency in the whole road network or an urban area, while the average delay mainly characterizes the efficiency of servicing a single vehicle.

The number of vehicles in the queue on the road network section or its length in linear units is the definition of the queue length. Using this indicator, one can judge the degree of the road network saturation. A term “supersaturated road network” stays for the situation where the queue of vehicles at one intersection causes congestion at neighboring intersections.

As an integral indicator of the level of service of vehicles at controlled intersections, it is customary to use the value of the average delay. Table 1.3 represents which means of average delay correspond to certain levels of service and how they are interpreted.

Table 3: Controlled intersections service levels

Service level	Description	Average delay		
		May A, Tidvell J.E.	Sutaria T., Hampreys J.E.	HCM
A	Delay is absent or small	≤15	≤12,6	≤5
B	Slight controlling cycle, good coordination	≤30	≤30,1	5,1 – 15
C	Increased duration of controlling cycle, reasonable coordination	≤40	≤47,7	15,1 – 25
D	Significant duration of controlling cycle, reasonable coordination	≤60	≤65,2	25,1 – 40
E	Significant duration of the controlling cycle, poor coordination	>60	≤82,2	40,1 – 60
F	The traffic conditions are unacceptable for most drivers, the intensity at road access exceeds the capacity of the intersection	—	—	> 60

In the HCM 2000 manual, the so-called "regulatory delay" is used as a measure of service level at controlled intersections. It is defined as the delay that occurs as a result of slowing or stopping vehicles and is calculated as the difference between the time spent in driving without regulation.

In Russia, to assess the safety of traffic on the road network elements, it is necessary to identify places where traffic accidents are concentrated, also called accident clusters. The accident cluster is a homogeneous and limited to length part of the road network, characterized by a statistically stable level of accidents. Areas of traffic accident concentration are determined on the basis of accident data for a period of not less than 3 last years and a relative accident rate. The focus of road accidents in cities is a section of road network that does not exceed 400 meters, where three or more accidents occurred during the year.

Evaluation of the road traffic optimization projects is a task of business intelligence, which requires the collection, processing and analysis of large volumes of raw data. Implementation of such a task is practically impossible without using the capabilities of modern BI technologies.

Results

Development of BI Application for Evaluating the Organization of Controlled Intersections

The paper describes the project of BI application development for evaluation the organization of controlled intersections of the road network. The objectives of implementing a BI application are:

3. To increase the effectiveness of managerial decision making on the optimization of transport infrastructure facilities.
4. To aggregate data on the state of the transport system elements and optimization projects of the road network sections.
5. To provide a user-friendly and intuitive interface.
6. To simplify reporting.
7. To provide an instant analysis of the characteristics of adjustable intersections before and after optimization.

To develop such an application, it needs to:

- Identify the data sources from which information will be extracted;
- Identify key concepts, their characteristics and relationships between them;
- Transform the data for further processing;
- Formulate the basic requirements for the application functionality;
- Work out application scenarios;
- Develop application windows;
- Identify software and technical characteristics;
- Describe the order of work in the application;
- Formulate the positive effects of using the developed application.

The application should answer the following questions:

- Number / percentage of optimized road network areas by years;
- List of sites with the highest / lowest rates (per year);
- Determination of how many high / low sites have been optimized over the past year, two, etc.;
- Determination of the ratio of costs for optimization and performance indicators;
- Number of road accidents by sites and years (identification of places where traffic accidents are concentrated and the safest areas);
- Changes in indicators by years for a single site.

The implementation of the application was carried out in several stages:

Stage 1: Conceptual modeling.

To implement the application and solve the tasks, it was decided to identify 3 entities that reflect the key concepts of the subject domain:

1. Intersection. Element of the road network, which is analyzed. It consists of two intersecting streets, which can have an X-shaped or T-shaped intersection. The intersection also indicates the location, namely the area and the city. If optimization was carried out, the fact of optimization, the date, the cost of implementing the project and who was appointed as the executor is indicated.

2. Measurements before optimization. As indicators of the effectiveness of traffic management, the following private and integral indicators were selected: throughput, queue length, number of road accidents and service level. This entity reflects the values of the listed indicators for adjustable intersections before optimization, which are fixed each week.

3. Measurements after optimization. This essence reflects the values of traffic performance indicators for controlled intersections after optimization, which are recorded every week.

In the ITS database, the characteristics of the adjustable intersections are not divided into data before and after optimization. In this connection, in the application it is necessary to load these data in parts. This means that the measurements will be divided into two lists according to the date criterion. By the project completion date, optimization for a particular site will be divided into two parts. This procedure is necessary for the correct and complete presentation and analysis of data in the BI system.

Stage 2: Infological modeling of the database.

The relationships that emerged between these entities were defined:

Intersection - Measurements before optimization: the intersection can have many dimensions before optimization, in turn each measurement refers directly to one intersection, hence, the 1: M link.

Intersection - Measurements after optimization: the intersection can have many dimensions after optimization, in turn each measurement refers directly to one intersection, hence the 1: M link.

Step 3: Normalize the data.

Data was normalized to the fifth normal form.

Step 4: Datalogical Design

The next stage in the design of the application's information base is the implementation of the physical model based on the infologic data model. For each relationship obtained as a result of the design of the data model, tables were created by setting the basic properties of the relationship attributes - 6 tables in all.

Step 5: Develop a conceptual application model

The conceptual model of the database describes the objects of the domain, their attributes and the relationships between them in the volume in which they are to be directly stored in the database of the system. At this stage, the physical model of the database was designed by means of ErWin Data Modeler.

Step 6: Identify the data sources

Data on road traffic performance indicators for the application can be obtained from the local points of the traffic police or the traffic control center, if there is one in the city. As a rule, such statistics are collected by these objects. The information is stored in databases or knowledge bases of intelligent transport systems.

- Data on the state of the street-road network are collected from various devices:
- detectors of traffic flows;
- automatic road weather stations;
- a stationary and rotary camera;
- points of detection of high-speed modes.

Information on projects to optimize the objects of the road network can be obtained from local authorities, which initiate these projects. There you can get information about the composition and structureof the road network.

For the test version of the application, the data from various sources was collected in an .xls file, in which the information is stored as "directories". Directories are filled in analogy with the generated tables of the conceptual data model. There are 6 directories: City, Area, Intersection, Synthetic key, Measurements before optimization and Measurement after optimization.

Step 7: Description of application scenarios

The application scenario can be described by the following sequence of actions (in the project described in the eEPC ARIS notation):

The application is launched by the user locally or in the cloud.

The process of extracting data on the main characteristics of traffic flows at the controlled intersections of the MAC from the database of the ITS used and data on completed optimization projects stored in an .xls file is started.

The data is loaded and the previously created graphic objects are populated or updated on the application sheet.

The user selects the necessary values in the filter fields, after which the filtered information is displayed on the graphs.

Having obtained the required information, the user analyzes it and takes the necessary administrative decision.

Step 8: Select the application implementation tool

At the moment, the most current information on the state of the world market of analytical reporting systems is provided by the consulting company Gartner in the form of graphical reports called "magic quadrants". Based on Gartner's estimates for BI systems, as of 2017, software products were selected as leaders in business intelligence: Qlik, Tableau, and Microsoft Power BI. The most important criteria are chosen when choosing a system: speed of implementation, price, availability of a free version, interactive visualization, data integration, visual deepening into data, integration with GIS, modeling and analytics, development environment. As the most suitable BI platform, Qlik Sense was chosen, which has a powerful tool for visualizing data and generating analytical reporting. From an integration point of view, Qlik Sense allows you to load data from various sources, whether it be databases of corporate information systems up to user files in Excel format.

Step 9: Downloading Data

After the .xls test data has been loaded, a data model is automatically generated in Qlik Sense.

Step 10: Developing Data Marts

A Qlik document can use one or more sheets on which objects are placed. These sheets are called data marts. At each data window there are blocks of information that are not directly related to each other, but are united by a common idea. Also mandatory attribute of the showcase are the fields by which the desired values are selected. For the created application 4 sheets were created:

1. Data of an adjustable intersection.
2. Statistics of adjustable intersections.
3. Comparison of the characteristics of adjustable intersections.
4. Geographical information.

For each data showcase, the following were described:

- a set of graphical elements for analysis;
- a set of fields underlying the measurements and measures of graphic objects;
- the purpose of each graphic sheet object.

The developed application was tested using test data, the errors were not found. The application was provided with a user's instruction.

It is necessary to separately evaluate the positive effect of the implementation of the developed application for the company-developer and for city administrations [22]. The effect for the developer company is described as follows:

1. Profit from the introduction of additional functions, installation of necessary software and technical components;
2. Priority in the queue for obtaining projects for the optimization of sections of the road network for specific urban sites.

The city administration will receive the following benefits, which will improve the current transport infrastructure:

1. Increase the effectiveness of decision-making;
2. Decrease in decision-making time;
3. Increase the volume of information used for decision-making;
4. Improve the quality of information;
5. Increase in the likelihood of the results of the analysis;
6. Increase of quantitative information in comparison with qualitative information.

Conclusions and Discussions

Within the framework of the project described in the paper, the issue of applicability of BI-tools for analyzing traffic efficiency at a controlled intersection of the road network before and after optimization was examined. The paper defines the indicators that assess the effectiveness of the operation of adjustable intersections, and describes the stages of the project to develop a BI application that includes the selection of a specific tool for implementing the application. Also, the qualitative positive effects from the implementation both for the company-developer and for city administrations were considered. Analytical reporting provided by the developed application will allow improving existing methods of optimizing the elements of the road network, and will also help to use the experience more effectively when designing new road objects. The developed application can become one of the components of the BI system within the IT architecture of the city road network management system. [17]

The further research in the field of BI systems application for decision making support in the road network management can be the development of similar applications for other types of road network elements, as well as their integration within the framework of a single ITS.

Abstract

This research is based on to identify the impact of online reviews on customers' dining decision. Five independent variables (credibility of website, number of reviews, physical environment, perceived risk, and visuals on website) have been used to identify their impact on the dependent variable (customers' dining decision). Non-probability and convenience sampling has been adopted in this research to gather the data. A close ended questionnaire of 5 point Likert scale was adopted in this survey. A total of 720 respondents were included in the questionnaire survey. With the help of SPSS software, various tests like Reliability, regression analysis and correlations were run and in the end, it was found that number of reviews, perceived risk, and visuals of website are main factors which affect a lot on customers' mind while making a dining decision.

Keywords: Customers' dining decision, Credibility of website, number of reviews, perceived risk.

1. Introduction

1.1 Background

In today's era of increased technology, internet has proven to be a vital mode of communication for everyone else. The availability of various online reviews has made people more aware about what is happening around them, how they are living in. With time people have started relying more on online reviews prior to make a purchase decision. This medium has given a platform to all those people who want to exchange information, share their experiences about a certain product/service has grown a lot as compared to traditional Word-of-mouth. With the numerous numbers of apps, it has become a lot easier for marketers to connect with their customers and reach out to masses just a few clicks away. Nowadays people do not only talk to each other, but also get to know about current affairs and unknown realities.

When it comes to having a dinner at any restaurant we always ask others about their experience of dining in that restaurant. We are afraid to go to a new place at first. And always prefer to read online reviews. People have many types of fears like (taste of food quality, dining environment, customer service etc).

From last few years, many companies have now realized that how much "word-of-Mouth" matters in making a consumer's perception about a certain product/service and how much consumer talks may affect a possible purchase intention. While consumers speak with each other, they get an idea that whether buying a certain product would help them or not? Is this the right choice they are making? People's intentions are interrupted after reading online reviews about a certain product/service.

Looking at this trend, advertisers have also started using these online forums to improvise their advertisement techniques. Not only customers, but advertising personnel are also using these online

forums for their business expansion. Without any doubt, social networking websites are the biggest forums for such purposes. Earlier the word of mouth used to happen when one person heard from the other and then they pass it over to the other, but in this era of advanced technology and electronic media has completely turned its canvas towards a different direction.

It is estimation that internet users are more than 900 million around the world and the flow of information is increasing every year. It has been established that people are very much dependent on their peer's opinions when it comes to making a purchase decision. Many researches have been made which proves that word-of-mouth is considered more credible as compared to advertisements. When it comes to electronic word of mouth people tend to have vast platform to express themselves and their opinions are reached out to masses. Online reviews are also long lasting meaning that they don't just disappear and can be found by simply scrolling down the pages. There are many factors which effect on online reviews such as the quality of the review (i.e. is it from a reliable source or just fake).

1.2 Scope of the Study

We always take a second opinion when we decide to go to a restaurant for dine-in, and for that we always check Facebook or other social websites where we can read people's reviews about a place and make our decision based on its judgement. So, this research will be about how much these reviews help or affect us on the way of our decision making.

1.3 Objective of the Research

The main objectives of this study would be how reviews on social media may help or affect your decision of dining in that restaurant. This research may also help in finding out what factors may affect customers in making reviews like the pleasant environment, food quality, customer service, food price, food quantity, cleanliness, aroma, location of the place, serving time etc.

1.4 Research Question

1. What is the impact of online restaurant reviews on our dining decision?

1.5 Hypotheses

H1: There is no impact of credibility of website on customers' dining decision.

H2: There is no impact of quantity of reviews on customers' dining decision.

H3: There is no impact of perceived risk on customers' dining decision.

H4: There is no impact of visuals on website on customers' dining decision.

H5: There is no impact of physical environment on customers' dining decision

1.6 Theoretical framework

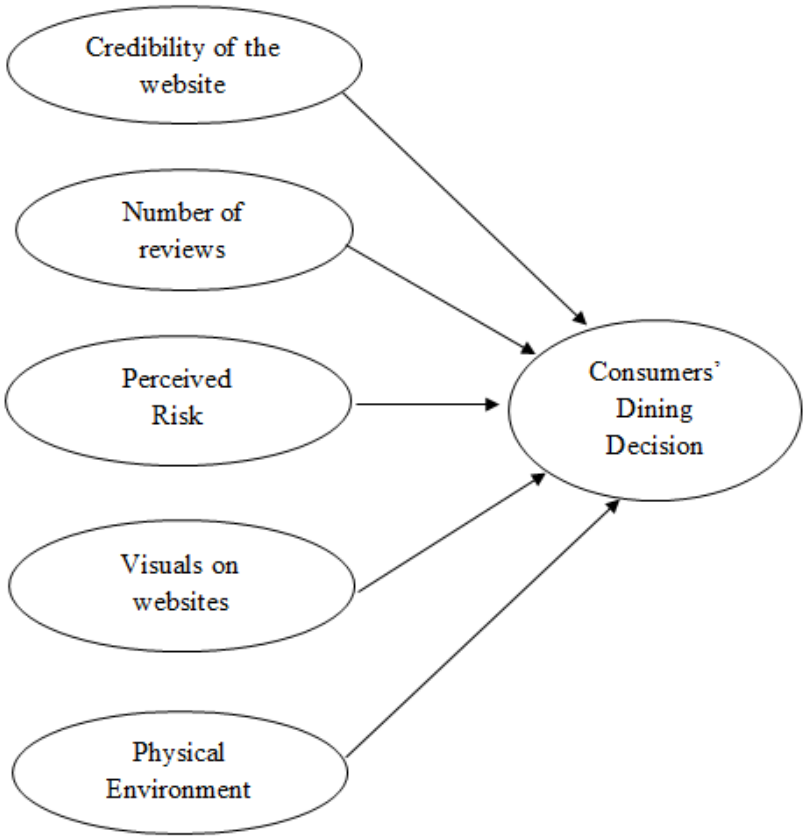

Figure1. Conceptual framework

This framework explains that customers' dining decision is dependent on these five variables which are credibility of website, number of reviews, perceived risk, visuals on website and physical environment. The framework is opted from (kim & lennon, 2013).

2. Literature Review

The reputation of an online retailer plays a vital role as an external source and influences a lot in generating consumer responses and their purchase decisions apart from the quality of website. (Kim & Lennon)

In another research, it is stated in their article that trends of unprofessional reviewers who share their experiences of various subjects is giving a tough time for experts. Internet has become a convenient forum for all such amateur reviewers and has now become a challenge for journalists because consumers have started relying more on such un professional reviews. Thus, the quality and credibility of the website and its reviews is deteriorating day by day.

(Watson, Morgan, & Pamela)
It is discussed in an article about what are the factors of customers' satisfaction through IPA (Importance–Performance Analysis). Their research showed a clean environment and proper customer service can make a restaurant famous and more likeable for customers. In general, quality

of food, customer service and a pleasant environment are those core areas which force customers to make positive reviews about a restaurant. (Liu & Jang, 2009)

Another study was conducted to identify the effects of review quality on customer's purchase intentions. The research also included that how these effects differ depending on product's type (high-quality and low quality products). Products which require an experience for evaluation like video games may influence customer's purchase decision by positive high quality reviews.
(Lee & Shin, 2014)
Researchers found that negative EWOM may decrease reviewer's interest but if the they see any response from restaurant's owner then this negative impact may be contracted because no response at all may leave interested readers in utter state if confusion and would decide not to visit that restaurant anymore. Once they see any constructive response from restaurant's management then there are chances that that specific negative review might not cause any damage. (Evans, et al., 2012)
Previous researches have also found that online reviews mainly rely on customer's perception about a product/service. (Dobele & Ward, 2002)

Another research has mentioned in their article that the information provided in online reviews may help others in making their purchase decisions especially in experience goods because these goods are difficult in assessing and such reviews on internet may help in other customers in evaluating the product through different ratings and narratives on websites. They also discussed that if the identity of the reviewer is disclosed then it may affect the quality and credibility of the review. (Kiran & Vasantha, 2015)

In one study researchers adopted The Elaboration Likelihood Model (ELM) method to find out how EWOM influences on consumer's purchase intention and found that high quality of reviews may positively influence people. It also supported the fact that the quantity of online reviews also pushes consumers into buying that product. Furthermore, results of this research suggested that people who tend to purchase high involvement products may opt "central route" per ELM and they emphasize more on the quality of the argument and people planning to purchase low-involvement products may rely more on "peripheral route" which is emphasizing more on the quantity of the reviews. The Elaboration Likelihood Model was constructed by (Petty & Cacioppo, 1986) which helps in comprehending the usefulness of persuasive communication. This model suggests that people may perceive information of online reviews in two routes that is the central route and the peripheral route. People who tend to think through central route may involve in cognitive assessment of online arguments and then form an attitude towards a product/service. On the other people who follow peripheral route might be impressed simply by the physical attractions of the website and the number of reviews. (Lee S. H., 2009)

A research was conducted to find out the impact of website quality on customer's purchase intention. The study was based on Mehrabian and Russell's Stimulus-Organism-Response model to test that customer's purchase decision is not only based on internal factors like online environment, colors, graphics, navigations etc but also on external factors like the reputation of online stores and its company may play a vital role in forcing a customer to make his mind into purchasing that product from that online store. (kim & lennon, 2013)

A research found that in this era females are more inclined towards online shopping and are more familiarized by various trends on internet as compared to men. Their results also show that negative reviews may have a strong negative impact on people especially on females because they perceive that the negative analysis of a product in a review is more useful as compared to a positive review. These negative reviews may save consumers from the perceived risk in their minds and ultimately effecting negatively on purchase decision. (Lee & Bae, 2011)

A research was conducted to find out the effect of review type and number of reviews on consumers. Their results showed that consumers examine and analyze a review on the level of their expertise and their cognitive ability. The research was hence concluded that people who are new to shop from online stores may make their purchase decision simply by looking at the quantity of reviews. On the

other hand, people who are experts in this field will involve in more reasoning and analyzing of various reviews and their types before making up their minds.
(Park & Kim, 2008)

It has been mentioned in a research that restaurants are mainly based on few important and core aspects which are fine dining, quick customer service, quality of food and separate family halls. It has been emphasized that quick service quality as the main differentiator with your competitors which helps restaurant owners making their place in a market and competing with competitors. (Dutta, Parsa, Parsa, & Bujisic, 2014)

It has been discussed in a blog that statistics show a direct relation between online restaurant's reviews and its revenues. Nowadays people especially social media users go out for dining very often and they are very addicted to posting pictures of their food and sharing experiences on social media. This creates an opportunity for restaurant owners to make sure that their chefs should work on food presentation because it's important that the presentation of food should be attractive and photogenic. This will lead other people to select your restaurant because many people are looking for places not only with great taste but also offering aesthetically pleasing environment. (Storms, 2014)

It is stated that many people have a psychology to feel the touch of a product before purchasing it. This feel-effect may demotivate many potential customers from purchasing goods online because they are not able to feel the product and evaluate its quality. Looking at this aspect, many advertisers have now given this option that people may share pictures which will help others in evaluating products because there is a lot of difference in reading a review of a product and visually looking at it. Another researcher also supported this view and said that sharing reviews along with pictures may increase people's confidence into purchasing that product provided there is no deceiving. (Alba, et al., 1997) (Chatterjee, 2001)

In this new era of SNS companies focus on how to communicate with their customers and SNS has made it possible. Facebook fan pages are the most convenient and highly used platform where various brands and their consumers meet and exchange information.
(Ahn, Kwon, & Sung, 2010)
Since restaurant pages are highly searched by users on Facebook has led many food companies to reach out to potential customers. Through such pages, companies can easily get to know what people are expecting from them and what their current position is in the market. These Facebook fan pages also creates a bond of trust between the brand and its consumers. (Lee, Xiong, & Hu, 2012)

Facebook fan pages are built up of both consumers and brands. Information which a brand shares is further enriched with reviews shared by various users of that brand. A researcher suggested that information presented on Facebook pages help users to evaluate and make better judgements about products. (Hsu, 2012) (Flavián & Guinalíu, 2006)

A research revealed results that the expectations of people about EWOM may vary from forum to forum. EWOM on forums which are sponsored by marketers are more reliable and authentic because the information shared here are from experts and professionals belonging to specific fields. On the contrary EWOM on consumer sponsored forums are more realistic and strong. When a consumer is looking for information on such forums administrator's identity influences their perception. (Liu, Dong, & Burnkant, 2013)

Previous researches show that this internet based feedback is an emerging mechanism which not only involves computer science but it includes various fields such as electronic marketing, social science, sociology, management science and psychology. This research further shows that EWOM are different than traditional WOM both on consumers and marketers end. For marketers, this can be helpful in building brand image, acquire and retain customers and build brand loyalty. Contrary to this on customer's end the information in EWOM is very helpful in making purchase decisions. (Dellarocas , 2003)

A study conducted from 2000 consumers showed that EWOM trend is based on various motives such as want for socializing, desire for various incentives and boost their self-esteem are main factors of EWOM practices. (Hennig-Thurau, Gwinner, Walsh, & Gremler, 2004)

Past research shows that consumers planning to purchase products which are expensive and are high involvement may indulge themselves in the depth of information as compared to inexpensive or low involvement products. (Heikkinen & Tudoran, 2012)

Researchers suggested through their research on quality of travel website that purchase intention is very much based on the quality of website. The quality of website may be enhanced by various website displays, website outlook, icons and web patterns which not only beautifies a web page but also encourages people to purchase. (Bai, Law, & Wen, 2008)

3. Research Methodology

Research methodology is the chapter which describes how are we going to further extend this study to reach out to our desired results. This chapter include methods which we are going to opt for this research. Since this is a quantitative research so we will collect data through a survey questionnaire.

3.1 Data

The main sources of collecting data would be primary and secondary. Primary data will be gathered from questionnaire whereas, secondary data will be obtained from different articles and websites. The tool of data collection for this research is a close-ended questionnaire. The questionnaire will consist of 5-points Likert Scale, i.e. from (1 as lowest to 5 as highest). This questionnaire will be circulated on social media (mainly Facebook) and in Hamdard University (HIMS) campus.

3.2 Variables

After establishing a literature for this research, we have selected following variables which are also used in various other researches to find out the impact of online reviews on customers' dining decisions.

3.2.1 Dependent Variable

1. Customer's dining decision

3.2.2 Independent Variables

1. Credibility of the website, (Kim & Lennon)
2. Quantity of reviews. (Lee S. H., 2009) (Park & Kim, 2008)
3. Perceived Risk (Lee & Bae, 2011)
4. Visuals on websites (Storms, 2014)
5. Physical Environmental (Liu & Jang, 2009)

3.3 Sampling Techniques

The main sampling technique which we will be using in this research would be non-probability sampling. In non-probability sampling samples are selected in a way that individuals from the population are not given equal chances of selection. Furthermore, we have selected convenience sampling to be used for collecting data because circulating questionnaires on Facebook and within

the University is more convenient for us. The sample size for gathering empirical data is of 720 Pakistani customers.

3.4 Model

Statistical tool helps us to quantify the data which has been collected in a research. The aim of analyzing data is to discover useful information and come to conclusions which may further help in making decisions.
This research is a causal research which shows us the impact of online reviews on customers' dining decisions so we will be using regression and correlation analysis for analyzing the collected data.

4. Result and Discussion

4.1 Descriptive Statistics

Table 4.1.1: Gender

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	FEMALE	397	55.1	55.1	55.1
	MALE	323	44.9	44.9	100.0
	Total	720	100.0	100.0	

The above table shows that in this survey there were 397 female respondents and 323 male respondents.

Table4.1.2: Age

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	15-25 years	313	43.5	43.5	43.5
	26-35 years	139	19.3	19.3	62.8
	36-45 years	143	19.9	19.9	82.6
	46-55 years	92	12.8	12.8	95.4
	56-65 years	33	4.6	4.6	100.0
	Total	720	100.0	100.0	

The above table shows that out of 720 respondents 313 people are from the age group of 15-25 years. 139 respondents are associated with the age group of 26-35 years, 143 respondents are from the age group ranging from 36-45 years, 92 respondents were from the age group of 46-55 years and only 33 respondents belonged from the age group of 56-65 years.

Table4.1.3: Income

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	Below 15,000	261	36.3	36.3	36.3
	15,001-30,000	155	21.5	21.5	57.8
	30,001-45,000	126	17.5	17.5	75.3
	45,001-60,000	113	15.7	15.7	91.0
	Above 60,000	65	9.0	9.0	100.0
	Total	720	100.0	100.0	

The above table shows that majority of people (261) involved in this survey have their income level of below 15000, 155 respondents have their income level of 15,001-30,000, 126 respondents have their income of 30,001-450,000 and only 65 respondents have their income level above than 60,000.

Table4.1.4: Designation

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	Non-executive	244	33.9	33.9	33.9
	Officer	113	15.7	15.7	49.6
	Lower management	146	20.3	20.3	69.9
	Middle management	157	21.8	21.8	91.7
	Top management	60	8.3	8.3	100.0
	Total	720	100.0	100.0	

The above table shows that majority of people (244) involved in this survey are not employed, 113 respondents are officers, 146 respondents belong to lower management, 157 respondents belong to middle management and only 67 belong to top management in the organizations.

Table4.1.5: Education

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	Matariculation	207	28.8	28.8	28.8
	Intermediate	98	13.6	13.6	42.4
	Graduate	212	29.4	29.4	71.8
	Masters	161	22.4	22.4	94.2
	Other _____	42	5.8	5.8	100.0
	Total	720	100.0	100.	

This table shows that 207 respondents involved in this survey have completed their matriculation, 98 respondents have passed intermediate. the highest group of people (212) involved in this survey are graduates and 161 respondents have completed their masters.

4.2 Inferential Statistics

4.2.1 Reliability analysis

Table.4.2.1 Reliability statistics

Variables	Items	Cronbach's Alpha
CDD	3	.854
COW	3	.854
NOR	3	.862
PE	3	.905
PR	3	.891
VOW	3	.840

The reliability test for this research was conducted through SPSS software. reliability for each variable is mentioned in above table and it can be observed that each variable has its Cronbach's value higher than 0.88 showing higher internal consistency.

4.2.2 Correlation Analysis

Table**4.2.2: Pearson correlation**

		COW	NOR	PE	PR	CDD	VOW
COW	Pearson Correlation	1	.729**	.566**	.532**	.524**	.472**
	Sig. (2-tailed)		.000	.000	.000	.000	.000
	N	720	720	720	720	720	720
NOR	Pearson Correlation	.729**	1	.704**	.618**	.610**	.509**
	Sig. (2-tailed)	.000		.000	.000	.000	.000
	N	720	720	720	720	720	720
PE	Pearson Correlation	.566**	.704**	1	.722**	.654**	.547**
	Sig. (2-tailed)	.000	.000		.000	.000	.000
	N	720	720	720	720	720	720
PR	Pearson Correlation	.532**	.618**	.722**	1	.783**	.630**
	Sig. (2-tailed)	.000	.000	.000		.000	.000
	N	720	720	720	720	720	720
CDD	Pearson Correlation	.524**	.610**	.654**	.783**	1	.734**
	Sig. (2-tailed)	.000	.000	.000	.000		.000
	N	720	720	720	720	720	720
VOW	Pearson Correlation	.472**	.509**	.547**	.630**	.734**	1
	Sig. (2-tailed)	.000	.000	.000	.000	.000	
	N	720	720	720	720	720	720

**. Correlation is significant at the 0.01 level (2-tailed).

The above table of correlation shows the relation between Perceived Risk and Customer's Dining Decision. The Pearson value is near to 1 which means that there is a strong relationship between these two variables. The positive value of Pearson means if the value of one variable increases the other will also increase simultaneously. The 2-tailed value is significant at the level of 0.01 level which means that those variables are statistically significant.

4.2.3 ***Regression***

Table 4.2.3.1 :Model Summary

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate
1	.849[a]	.720	.718	.717
2	.849[b]	.720	.719	.717
3	.848[c]	.719	.718	.717

a. Predictors: (Constant), VOW, COW, PE, PR, NOR
b. Predictors: (Constant), VOW, PE, PR, NOR
c. Predictors: (Constant), VOW, PR, NOR

The value of R in above table shows simple correlation and R square explains us that how well dependent variable can be explained by independent variables. The value of R is 0.849 whereas, the

value of R square is 0.720 which is very close. Thus, it indicates that there is no error in sample selection.

Table 4.2.3.2 : ANOVA[d]						
Model		Sum of Squares	Df	Mean Square	F	Sig.
1	Regression	945.332	5	189.066	367.730	.000[a]
	Residual	367.099	714	.514		
	Total	1312.432	719			
2	Regression	945.318	4	236.329	460.280	.000[b]
	Residual	367.114	715	.513		
	Total	1312.432	719			
3	Regression	943.955	3	314.652	611.409	.000[c]
	Residual	368.477	716	.515		
	Total	1312.432	719			
a. Predictors: (Constant), VOW, COW, PE, PR, NOR b. Predictors: (Constant), VOW, PE, PR, NOR c. Predictors: (Constant), VOW, PR, NOR d. Dependent Variable: CDD						

The above ANOVA table shows us the sig value of 0.000 which is less than 0.01 concluding the model's significance at 99% confidence interval. We have used backward model regression and the final F-value is 611.409 which is significantly higher than our sig value, rejecting our null hypothesis.

Table 4.2.3.3: coefficients statistics						
Model		Unstandardized Coefficients		Standardized Coefficients	T	Sig.
		B	Std. Error	Beta		
1	(Constant)	.197	.090		2.199	.028
	COW	.005	.031	.005	.171	.865
	NOR	.110	.035	.108	3.165	.002
	PE	.048	.030	.053	1.623	.105
	PR	.437	.031	.443	13.963	.000
	VOW	.362	.026	.368	14.016	.000
2	(Constant)	.201	.087		2.319	.021
	NOR	.113	.029	.111	3.848	.000
	PE	.048	.030	.053	1.629	.104
	PR	.438	.031	.444	14.012	.000
	VOW	.362	.026	.369	14.136	.000
3	(Constant)	.196	.087		2.256	.024

	NOR	.135	.026	.132	5.153	.000
	PR	.460	.028	.466	16.383	.000
	VOW	.366	.026	.373	14.330	.000
a. Dependent Variable: CDD						

The above table show those variables which highly affect the dependent variable i.e. Customer's dining decision. Since we have used backward regression; in first place the model included 5 independent variables i.e. Credibility of the website, Number of Reviews, Physical Environment, Perceived risk, and visuals on website, gradually eliminating Credibility of website and physical environment in next two models as they were insignificant. The final model predicts NOR, PR and VOW to be significant variables impacting more on Customers' dining decision.

4.3 Hypotheses Assessment

Table 4.3.1: Hypothesis Assessment summary

H.No.	Null Hypotheses	t	Sig Value	Status
H1	There is no impact of credibility of website on customer's dining decision.	.171	.865	Failed to Reject
H2	There is no impact of quantity of reviews on customer's dining decision.	5.153	.000	Rejected
H3	There is no impact of perceived risk on customer's dining decision.	16.383	.000	Rejected
H4	There is no impact of visuals on website on customer's dining decision.	14.330	.000	Rejected
H5	There is no impact of physical environment on customer's dining decision.	1.629	.104	Failed to Reject

4.4 Discussion

The result of this research shows how customers' dining decision gets affected by various variables like, credibility of website, number of reviews, perceived risk, physical environment, and visuals on website hence rejecting our Ho hypothesis i.e. "there is no impact of online reviews on customer's dining decision". Its backward regression model has predicted that number of reviews, perceived risk and visuals on website have a significant impact on customer's dining decision. This research has shown that visuals on website are impacting a lot on customer's dining decision which is backed up by a research which has been conducted in past has indicated in his study that various pictures of food very much attract people. Tempting food pictures may trigger people to select that restaurant and the results can practically be implicated for all restaurant owners that they should work on the presentation of food because good presentation attract eyes in the first place. (Storms, 2014)

Second result shows that number of reviews are also affecting a customer's dining decision. Eating outside is not a very high involvement procedure in which a customer spends a lot of time in evaluating options so they may go by the quantity of reviews on websites rather than quality of reviews. The result is further supported with a research which established through its results that according to Elaborated Liklihood Model (ELM) customers select "peripheral route" when they are not highly involved in making a purchase decision. Since in this survey most of the respondents belong to the age group of 15-25. So, it is clear that youngsters have a habit of dining in restaraunts

oftenly so, they are not highly involved in making a decision and would prefer to dine-in in different restaraunts getting attracted by the number of reviews. If we see the result of correlation it is clear that the value of Pearson Correlation of Perceived risk if 0.783 which states that customer's dining decision is highly correlated with the amount of risk which a customer may experience. (Lee S. H., 2009)

This research has also indicated that credibility of the website is not statistically significant on our dependent variable i.e. customer's dining decision because nowadays people are providing fake reviews, many unprofessional reviewers can post on various websites thus the quality and standard of websites are declining day by day. It has been discussed in a research that due to the increase of amateur writers on internet, the credibility of websites are negatively being affected and people are the value of professional reviews is not worthy anymore. (Watson)

5. Conclusion, limitations and recommendations

This research shows that customers' dining decision is based on three main variables which are number of reviews, perceived risk, and visuals on website. People usually go by the number of reviews when they are not highly involved into the decision process. We always decide and select that option in which we have the lowest amount of perceived risk because of the fear of something might bad happen people always prefer a look on reviews about that product. Third most factor which attract people eyes are visuals of food and restaurants. Attractive pictures may attract and force people into making a purchase decision.

5.1 Limitations

With some restraints, there were some obstacles towards effective and precise research work. The study was only restricted to the area of customers' dining decision. Limited number of only five independent variables were used in this research, so this study is very confined and the results may not be applicable on a large scale. The data was collected only through social media due to financial constraints and because it was more convenient.

5.2 Recommendations

This research can also be further conducted to find out the impact of Electronic word of mouth on customers' purchase decision of various products. Variables like customer service, taste of food, etc can be used to conduct this research in depth. Many restaurant owners can apply results of such researches to improve their weak areas of business.

Abstract

At present, the heads of organizations have come to realize that the leading positions for their companies allow us to occupy not only the use of high technologies, but also the personnel, which is the basis of any organization. It is exactly how much the organization's personnel is interested in accomplishing the tasks set, with what enthusiasm they start to work and the way they show their attitude to the company are key factors in the effective operation of the company. The problem of staff involvement is relevant. Many foreign and Russian companies are aware of the importance of involving staff in the activities of the organization, which is due to the direct relationship between the involvement of staff and the performance of the organization. The purpose of this article is to investigate the indicators of staff involvement and develop recommendations for improving the toolkit to increase the involvement of staff in the organization. In the article proposes recommendations for improving the involvement of staff, measures were developed to improve the development of factors of staff involvement - remuneration and recognition. The practical importance of this article consists in the possibility of using the developed recommendations on improving the toolkit for increasing the involvement of personnel in the organization's activities in the practice of functioning of commercial organizations with similar characteristics of the personnel.

Keywords: personnel management, staff involvement, tools to increase staff involvement

Introduction

Scientific and practical interest in the concept of "involvement" can be traced from the end of the 20th century - the time when a radical restructuring in the world economy began to take place, and changes in the public consciousness that influenced the structure of the organizational system began to occur.

The concept of "involvement" is a qualitative characteristic of the personnel, which consists in a benevolent attitude not only to the leaders, but also to the organization as a whole, acceptance and division of the goals, principles, mission, acting in the organization; understanding the importance of their contribution to the activities and development of the organization; the desire to grow and develop together with the organization through the manifestation of initiative and the introduction of innovations; continuous reciprocal dialogue at the level of leader-subordinate.

The important things in understanding the role of staff involvement in the activities of the organization are the results of research on the impact of involvement on the financial and economic performance of the organization. Thus, numerous studies show that the total return on investment with an involvement of 60% is more than 20%, the value of the company's shares grows by more than 12%, the increase in sales per employee increases in the year to 27 000 USD, the profit per 1 employee in Year increases to 3 800 USD, profitability from work with clients increases by 15-20%.

Tools and Methods

J. Hellevig in his researches noted, the formation and development of the involvement of the personnel in the organization are influenced by general and individual factors of involvement. A similar point of view can be found in Russian researchers. Thus, according to the Russian scientist V.N. Belkin, the analysis of the factors of employee involvement must be carried out at two levels:
- at the level of the organization (division) - the organizational level;
- at the level of each employee - an individual level.

In order to ensure the formation and development of staff involvement, good intentions and real interest are not enough. The process of creating an involvement is a systemic process in which all levels of the organization's employees participate: managers, mid-level managers, ordinary employees. According to practitioners, the effective tools for developing involvement are:

1. Development and implementation of an adaptation program for new employees, which will allow you to quickly learn about the history of the company, its goals, objectives, values, corporate culture and basic programs that enable you to develop and become an active member of the team. Heads of the organization should care about the initial impression of new employees – it should not be negative, especially they should care for the best employees - those who have many proposals from other employers.

2. Weekly spreading general information in all units in the company. You can talk about the ongoing actions, about the events held and planned - every employee must constantly be aware of the company's events.

3. Conducting conversations, ongoing interviews. These methods of involvement are an alternative to the exit interview. Many large companies believe that it is necessary to conduct the current interview not only with the employees involved (it allows managers to find out what keeps them in the company), but also with middle-staff and those who show low rates (allows the manager to notice early signs of problems).

4. Regular (optimally - monthly) holding meetings of top management executives with employees of departments, where existing problems and ways of their solution are discussed.

5. Participation of employees in project teams in various areas of perfection of processes, products, etc.

6. Participation in bright, significant projects of the company. In order to increase the involvement of the staff, most modern companies include their employees in the work on bright projects. The opportunity to participate in such projects inspires them and motivates employees, which in the future leads to increased involvement and improvement of the company's business performance.

7. Involvement of the personnel through the organization of competitions between teams in production, teams, as well as the promotion of winners.

8. Encouraging the best employees. D. Robinson believes that the involvement of the personnel can be achieved by creating an organizational environment in which positive emotions are present. For example, this is the environment in which employees are encouraged. This increases organizational efficiency, reduces staff turnover and improves staff health.

9. Assisting the leaders of their subordinates in professional development by delegating tasks, transferring existing knowledge, learning by example.

10. Training and development of employees - for this there must be effective internal training programs, if necessary; you can pay for training from external service providers.

11. Development of individual development plans. Creation of individual development plans, which reflect the personal and professional goals of employees, leads the way to increased involvement and improvement of market indicators.

Drawing up personalized development plans makes it possible to identify careers and academic interests of the best, and also to determine what actions the employees themselves and their leaders should take to achieve the goals. In the individual development plans it is recommended, besides training and programs, to include the following activities: rotation; virtual learning resources; co-teaching or mentoring by the senior manager or the first person of the company.

The presented research is based on approaches to the involvement of staff as satisfaction of needs (V.Kan, 1990). In these works, involvement as a full involvement in the performance of the work role, in which the employee directs his cognitive, emotional and physical energy to perform work tasks. Involvement as the antithesis of burnout (Maslach, Leiter, 1997). The components of involvement (high energy level, enthusiasm, sense of effectiveness) are determined through contrasting burnout components (exhaustion, cynicism, inefficiency). Investigation of the interaction of "satisfaction - involvement" (Gallup Model, 2002). Multidimensional approach to involvement (A. Saks, 2006). The theoretical significance of the presented article is that the presented conclusions and conclusions, formulated as a result of the conducted research, can find application in scientific works, studies, scientific dissertations.

Formation and development of staff involvement requires readiness for changes to all participants in this process. From the HR manager, it requires the ability to persuade, to join interests, to disclose and fix the benefits of the result of involvement.

There are various options for assessing involvement, the most common is conducting periodic written and oral interviews with the organization's employees. The involvement of staff should be studied at least 2 times a year. Research and evaluation of the effectiveness of the measures taken to increase the level of involvement are conducted for the first time at the end of the fiscal year. The analysis of the data shows how successful they were. After that, they develop a budget for the next year to implement a new plan of activities. At the end of the first half of the year, a second survey of employees is conducted. After studying the data received, adjustments are made to the plan.

As a rule, Russian organizations are invited by consulting organizations that have experience of such work to investigate the involvement of personnel.

Specifically for the diagnosis of the involvement of staff, the researchers created and implemented the following methods to measure the involvement of staff (Table 1).

Table 1: Basic methods for measuring the involvement of staff.

Name	**Indicators**
Gallup Method [http://www.gallup.ru]	A questionnaire that includes 12 questions that measure involvement through the indicators of inclusion, satisfaction and enthusiasm.
Shaufeli and Becker's method	Questionnaire, which includes 17 questions. Identification of results on the scale of involvement: vigor, devotion, immersion (absorption) activity.
E.A. Scriptunova's method	It assesses the involvement in completing corporate tasks, involvement in the work process, interest in the work as a whole, initiatives and focus on increasing the efficiency of their work and company development. The methodology for assessing the level of involvement is based on the algorithm of formation of involvement.
May, Gilson and Harter's methods [http://www-01.ibm.ru;	Their methods are based on the work by W. Kahn. This technique evaluates 3 components of involvement: cognitive, emotional, physical.

http://www.haygroup.com/ru]	
Saks's methodology	The methodology is designed to measure two types of involvement: involvement in work and organizational involvement.
Aon Hewitt's methodology [http://www.axesgroup.ru]	The questionnaire (counting about 70 questions) allows you to assess the level of involvement and employee satisfaction with 14 factors that affect involvement: brand attractiveness, top management, direct manager, career opportunities, training and development, performance management, reward and recognition, Interaction, independence, work content, conditions for success, respect and recognition, talent management and selection, balance of work and personal life. In turn, 14 factors are divided into 6 groups: people, work, career, remuneration, company activity, quality of life of workers.
Towers Watson's methodology [http://www.towerswatson.ru]	This methodology measures 3 factors: attachment to the company, the desire to apply additional efforts and achieve more; an atmosphere that is conducive to productive work and contributes to the improvement of labor performance; individual working conditions.

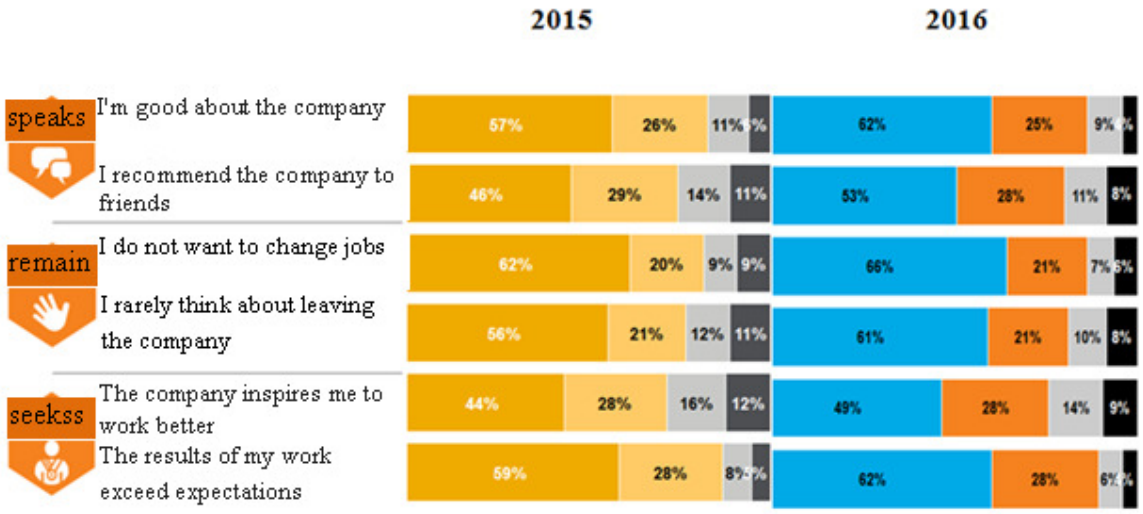
Evaluation of the implemented methods allowed to conclude that it is necessary to use the presented methods of Aon Hewitt and taking into account the specifics of the enterprise under investigation.

Results And Discussion

Let's consider the implementation of the toolkit for staff involvement in Russian enterprises. In Russia, large enterprises annually (for example, Rostelecom - the largest representative of the market of telecommunications) conduct research on the involvement of staff. These surveys help to get feedback from employees, which allows to understand how the personnel assess the situation in the company, how satisfied they are with the company and motivated, to identify the main factors affecting the involvement of staff, and to identify the necessary changes that will lead to increased effectiveness.

Most often, the study of the involvement of staff is carried out with the help of external providers. For example, the services of AXES Management, which is a representative of Aon Hewitt in Russia, are very popular. In the research of involvement, AXES Management closely cooperates with the international leader of HR consulting Aon Hewitt.

The results of the survey of the indicators of the level of involvement for the years 2015 - 2016 in large Russian companies are presented in Figure 1. Figure 1 shows that in 2016, as compared to 2015, there is an increase in the involvement of the personnel in Russian companies. Authors interviewed 30% of staff of branches Rostelecom in regions of the central Russia.



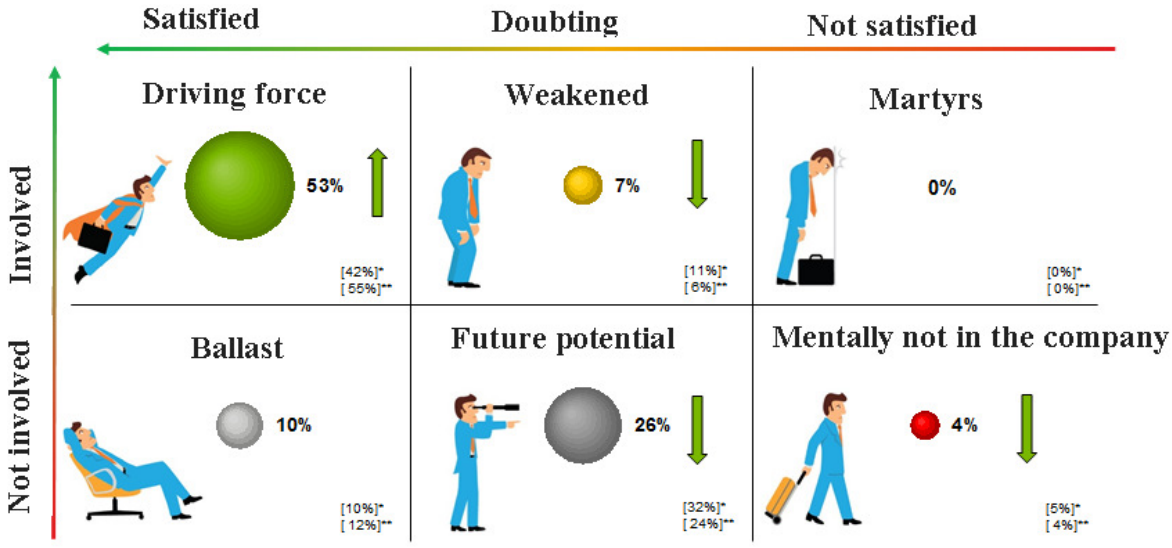


Figure 1 : Results on indicators of involvement.

In order to take into account the priorities of staff involvement, authors suggest to conduct an annual segmentation of employees in relation to the company, in which the following categories of employees are assigned: "Driving Force", "Weakened", "Martyrs", "Ballast", "Future Potential", " Mentally is no longer in the company. " The first three categories of personnel refer to the employees involved, and the next three categories to the unaffiliated employees. Results of inspection of 30% of staff of branches Rostelecom are presented on Figure 2. Authors investigated the involvement by means of a method of questioning and online – questioning.

* results of segmentation for 2016

** ideal indicators for the large enterprises

Figure 2 : Results of segmentation of personnel in Russian companies

Let us consider in more detail the characteristics of each category of personnel and the results of the research obtained. "Driving Force" are employees and managers who carry the bulk of the burden, and do it voluntarily and with pleasure. Such employees as a whole at the time of the 2016 survey amounted to about 53%. This is 11% higher than the result of last year. Employees from the category "Weakened" are involved in the work, give companies all the strength. At the same time, there are spheres in their working life that they are not completely satisfied with. Such employees in 2016 were 7%.

Compared with last year, the percentage of the personnel in this category fell by 6%. "Martyrs" are employees who are 100% involved in the work in the company, but at the same time everyone is not satisfied. At the time of the survey, such employees were not found in 2016. "Future Potential" demonstrates low involvement, and there are areas in which these employees are not happy. According to the consultants of the company, Hewitt, it is the employees of this group who can in the future replenish the ranks of the people involved in the company or in the company in the event that the actions of HR-service and company management aimed at this group will be temporary and effective. Such employees in 2016 were 26%. Compared with last year, the percentage of the personnel in this category fell by 6%. "Ballast" is a category of the personnel who are completely uninvolved in their work, but at the same time everyone is happy. They can be very loyal employees who work in the same company for years, occupying the same position (or even moving along the career ladder), but they do not put forward any ideas for the implementation of which they could take, do not take responsibility and in the performance of their work they never show special dedication. At the time of the survey in 2016, there were 10% of such employees. Compared to the previous year, the percentage of this category of personnel remained unchanged. "Mentally no longer in the company" is a category of the personnel that is not involved and there are no such spheres of working life in the company, which employees of this category would be satisfied with. There were 4% of such employees, which is 1% lower than the result of 2015.

Let's consider the results of the study of the level of involvement of the personnel in 2016 compared to 2015, which are reflected in Figure 3.

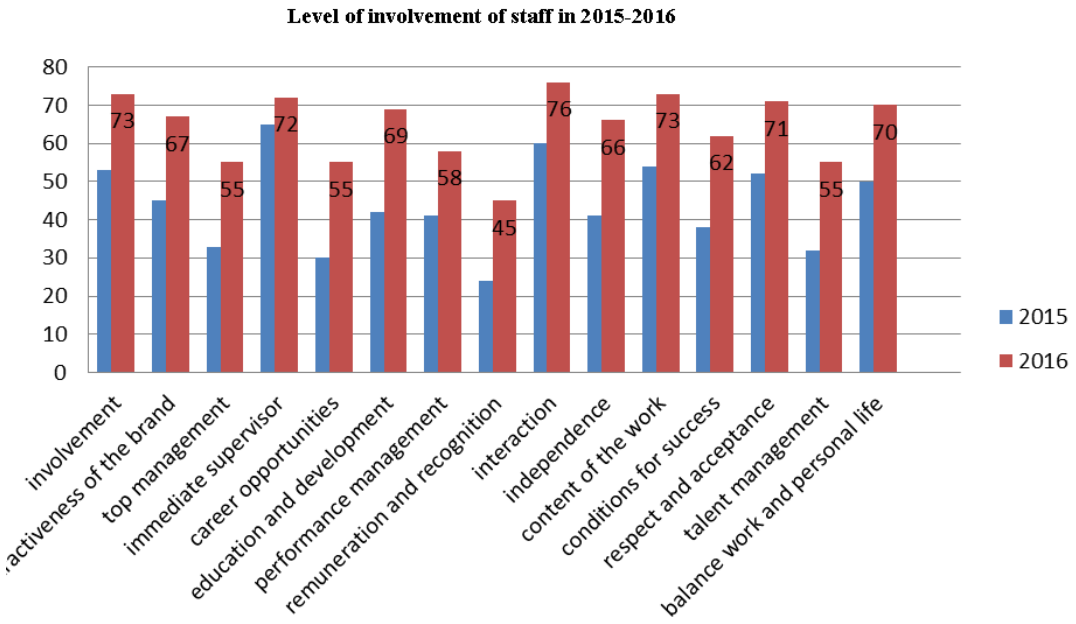

Figure 3 : Level of involvement of staff in 2015-2016.

As we can see from Figure 3 in 2016, the level of involvement has increased by 20% compared to 2015. This indicates that special measures are being implemented and they are aimed at changing the established positions of things that have contributed to the involvement of personnel in the changes taking place in the life of companies. Also, such an increase in the level of involvement indicates that employees are not indifferent to their work, and they are ready to exert additional efforts to help achieve the goals set by the company.

The analysis of the priorities of staff involvement in large Russian enterprises conducted by the authors of the article showed that, compared to 2015, in 2016 priorities have changed with which it is necessary to work in order to increase involvement:

1. *Remuneration and recognition.* The staff want to see how their contribution to the work relates to their level of wages (understanding the wages system, awareness of the system of individual bonuses), and also want to understand how the company shares financial success with them.

2. *Top management.* Employees want management to be accessible to them and interact with them.

3. *The attractiveness of the brand.* Personnel are very interested in the brand of the company, in particular: the implementation of promises given to employees, as well as the company's external and internal brand.

4. *Conditions for success.* Employees want to see effective work management, successful intra-organizational cooperation, as well as a rationally constructed organizational structure and business processes.

Conclusions

As recommendations for improving the involvement of staff, measures were developed to improve the development of 4 factors of staff involvement. "Remuneration and recognition" - involves working with material and non-material motivation of personnel, as well as the need for staff to understand the system of motivation, an objective balance of tasks and opportunities for their implementation, active application of the system of individual bonuses for personnel results of their activities. The main goal of this factor of involvement is that the employee is aware of the rules of being paid; he considers remuneration for his work fair; he has an opportunity to influence his income in one way or another. To increase the involvement of staff in this factor, the following activities are proposed for implementation:

1. Implementation of the program of bonuses and benefits, based on the type of "cafeteria" it

Will help to eliminate the main drawback of the traditional system of additional payments, when costs influence everyone, and privileges are given to the elite; to evade the "equalization" in the provision of benefits; link the provision of benefits with individual performance; individualize the motivation due to the fact that each person can independently choose the most attractive services for him.

2. Implementation of the program "Recognition". The "Recognition" program is a set of actions that are aimed at assessing the manifested qualities of employees in the performance of their immediate duties, as well as evaluating their efforts in the performance of assigned tasks, public recognition of these qualities and efforts with the delivery of the appropriate attributes of recognition and symbols of achievement.

"Top management" - involves work on building communication between employees and top management. The main goal is to inform the management of the company about the main problems of employees; to be interested in the well-being of employees; to arrange an open and sincere communication with employees. It is important for employees that the management is accessible to

them and interacts with them. To increase the involvement of staff in this factor, the "Days of Informing" project is proposed to be implemented for the purpose of delivering the most relevant and up-to-date information about the company, explaining the main activities, and also for feedback from employees.

"Attractiveness of the brand" is aimed at increasing the attractiveness of the company's brand not only as an employer, but also as a socially responsible organization. The main goal of this involvement factor is that the staff understands that the company is respected, and employees are assured of the success of the company, its reliability and sustainability. In order to increase the attractiveness of this factor, the following projects are proposed for implementation:

1. "Conditions for success" project, which assumes that the company provides opportunities for self-fulfillment and contributes to the achievement of the goals of employees. The main goal of this factor is that the employees are happy with the development of their career and understand that their career growth depends on the results of their direct work.

2. Holding a modular training program "Master of Communications". This program will give key employees the tools, knowledge, skills that will allow them to work more efficiently.

Abstract

Despite the fact that almost nine years have passed since the beginning of the global financial crisis of 2008, the world economy has not reached a stable development path. Within the framework of the article it is shown that the crisis has a regular character, caused by the cyclical nature of the development of the world economy. The basis of the methodology is the analysis of the dynamics of the International Monetary Fund data, including the MSCI World integral index, reflecting the global tendency of the stock market, macroeconomic, demographic indicators, money supply indicators, etc. As a result, it was revealed that the current state of the world economy speaks about the formation of a period of transition to a new technological order, which, first of all, is determined by energy supply. The authors concluded that any technological base depends on new energy, which should significantly differ in energy efficiency. This is justified by the fact that capitalist development requires the growth of energy intensity of products, volumes of energy consumption. The efficiency of new energy resources is determined by the assessment of energy costs for extracting energy resources, the quality of energy resources, and the costs of extraction. It is obvious that the transition to a new technological order will be determined by the growing interest in biofuels, shale oil and gas. However, the energy efficiency of these fuels is low, and in recent years there has been no transition to a new energy resource.

Keywords: economic crisis, cyclical economic development, new technological ways

Introduction

2008 is characterized by the global financial crisis. By years 2010-2011 most countries had already "reported on overcoming" the consequences of that crisis. The main tool for combating the crisis was the so-called "quantitative easing" undertaken by the leading central banks of the world. In particular, the Federal Reserve, the European Central Bank, the Bank of England and the Bank of Japan - all carried out a quantitative easing policy with varying success. And apparently everything looks pretty good, especially judging by the indicators of the stock markets.

For example, the integrated index MSCI World, reflecting the global tendency of the stock market and including 1,650 shares of companies around the world, is at historic highs (Fig. 1). The situation is the dame with the indicators of individual countries. In particular, the US S & P 500 index, uniting the shares of the 500 largest US companies, is almost 60% higher than the peak pre-crisis 2008 values. And even the Russian market, despite all sanctions and counter-sanctions and the economic recession of recent years, exceeded pre-crisis levels (Fig. 2).

This study is based on the statistics of the International Monetary Fund (http://www.imf.org), as well as such portals as Investing (http://investing.com/), Finam (http://finam.ru).

Figure 1 : Dynamics of the MSCI World Index

Figure 2 : Dynamics of the MICEX index

The presented graphics and figures actually confirm the growth of the financial market and stagnation of the real sector. At first glance, the situation is paradoxical. But, obviously, this has already happened in history. All this is described by the theory of cyclical economic development, which is not very popular nowadays and which is most often associated with N.D. Kondratiev and his successors. In its economic basis, this study considered the current crisis through the prism of the limitations of the model of capitalist production described by A. Smith, K. Marx, and J. Schumpeter. The authors used theoretical ideas of J. Kitchin, Juglar, S. Kuznets, J. Arrighi, L. Badalyan - V. Krivorotova, V. I. Pantin, S. Y. Glazyev.

Results and Discussion

If we try to look at the real sector, we'll see that the economic growth of most of the largest economies is at the level of statistical error. For example, if you analyze international transport of resources, it turns out that they are at an extremely low level. In particular, the Baltic Dry Index is at levels close to historical lows (Fig. 3).

Figure 3 : Baltic Dry Index

The index reflects the cost of transporting dry goods on 20 main sea routes. The content of the index reflects the level of business activity. Moreover, we can say that the index is a leading indicator in its essence, since economic growth requires an increase in the volume of resources, and this increases the volume of their transportation. A similar situation is with the prices for oil, aluminum, copper, nickel and other metals (Fig. 4).

Low prices for oil can somehow be linked to the "shale revolution", but nothing like this happened with prices for metal.

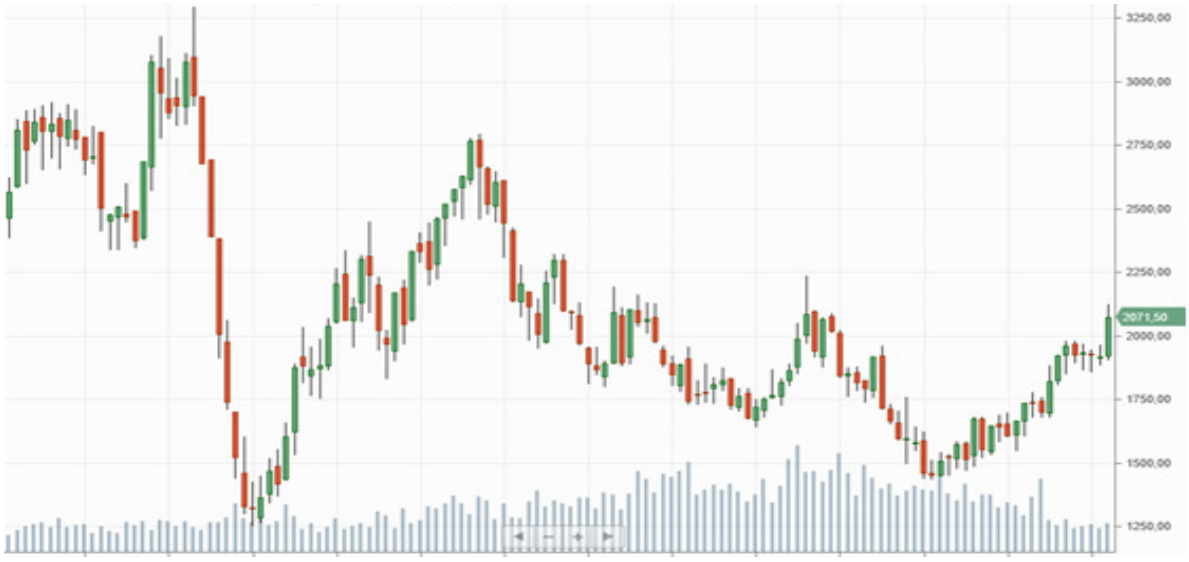

Figure 4 : Dynamics of prices for aluminum and nickel

Finally, we illustrate the situation by means of macro statistics. Let's consider the GDP indicator. For a cross-country analysis, a more correct estimate can be obtained on the basis of the Gross Domestic Product by purchasing power parity (PPP GDP later) (Table 1).

Table 1: GDP dynamics in PPP of leading world economies and PPP GDP growth rate

Country	Subject Descriptor	Units	1995	2000	2005	2010	2015	2016	2016/1995
Brazil	GDP based on PPP	Current international dollar, billions	1306,756	1579,824	2046,98	2803,368	3216,167	3141,335	240,4%

The source: http://www.imf.org/external/data.htm

At first glance, the growth of the world economy is obvious. However, let's look at the dynamics of GDP growth (Table 2).

Table 2: dynamics of the growth rate of GDP by PPP by the previous year

Country	Subject Descriptor	2000	2005	2010	2015	2016
Brazil	Rate of a gain (to previous year)	6,8%	6,5%	8,8%	-2,7%	-2,3%
China	Rate of a gain (to previous year)	10,9%	14,9%	12,0%	8,1%	8,1%
France	Rate of a gain (to previous year)	6,2%	4,9%	3,2%	2,4%	2,5%
Germany	Rate of a gain (to previous year)	5,5%	4,1%	5,2%	2,6%	3,1%
India	Rate of a gain (to previous year)	6,3%	12,8%	11,6%	9,1%	8,2%
Indonesia	Rate of a gain (to previous year)	7,4%	9,1%	7,7%	6,0%	6,4%
Japan	Rate of a gain (to previous year)	5,1%	4,9%	5,5%	2,3%	2,3%
Russia	Rate of a gain (to previous year)	12,6%	9,8%	5,8%	-1,8%	1,1%
United Kingdom	Rate of a gain (to previous year)	6,1%	6,3%	3,2%	3,3%	3,1%
United States	Rate of a gain (to previous year)	6,5%	6,7%	3,8%	3,7%	3,0%

The source: http://www.gks.ru/wps/wcm/connect/rosstat_main/rosstat/ru/statistics/publications/

Let's pay attention to the fact that since 2010 GDP growth rates of all countries have begun to fall, which in a compartment with a share of these economies, suggests that the global economy is slowing and this slowdown has a systemic (fundamental) reason. At the same time, we draw attention to the fact that after the years 2008-2009, there were no external signs of a crisis in the world economy. The situation is explained by the regular cyclical development of the economy.

More interesting explanation of the cyclical nature of the world economy can be gleaned from the theory of "technical and economic cenosis" by L. Badalyan - V. Krivorotov. The availability of the resource base and technology for its development form one or another socioeconomic structure (in

other words, the cenosis). Population growth at this technological level of resource development is gradually limited to a certain extent. As we approach it, the cenosis accumulates structural imbalances that result in wars, migrations, and the destruction of the social sphere. Such imbalances, arising as the population grows, are called Malthusian scissors. As a result of solving the problem of the Malthusian scissors, the techno-economic prices are being destroyed and the human population is "thin out". Then a new cenosis is formed on a new technological level.

The first signs of a new cenosis appear at the stage of financial expansion of the previous cycle of capital accumulation. Its very formation takes place at the initial stage of material expansion, when the technological structure is being formed. The latter is the basis for a new material expansion and determines the structure of the new cenosis. In general, in the development of the new cenosis, the development of "non-extinction," (the territories that were not in demand earlier because of the lack of technological access to them), is of great importance. For example, the development of steam engines and railways contributed to the fact that Britain (from the beginning in the metropolis and then the colonies) was able to master significant areas that were previously not in demand. The same story was repeated in the USA in the middle of the 20th century, when "inappropriateness" was "embroidered" with a network of highways.

On the basis of the new technological order in the material sphere, capital accumulation takes place according to the "D-T-D" scheme before the super-accumulation crisis, which begins to destroy the technical and economic cenosis. It must be said that the new techno-economic price is a skeleton of the future scheme of capital accumulation.

As it has already been mentioned, the new technological order is born during the period of the previous mode of action, mainly in the phase of its decline. The transition to a new technological order takes about 10 years. This period is characterized by the growth of a new technological order. At this stage, at the beginning, the fading effect of the old technological order on the world economy outweighs the positive impact of the new technological order. However, with the flow of capital, the positive impact of the new way outweighs and the stable economic development begins. As mass development of technologies of a new technological structure grows, growth slows down, which leads to the maturity phase. This gradually leads to a decrease in the rate of return on invested capital, which in the future will lead the technological order to decline. The decay itself can last for a long time.

Conclusions

Obviously, within a certain period there is a formed configuration of the world economy. However, this forms the limit of economic growth. Even if we consider a single global economy, its size has limits. The growth of scientific and technological progress and the increase in the level of the division of labor processes are interrelated. However, within the framework of the formed scientific paradigm there are also limits. The transition to a much higher level of division of labor requires radical changes in technology (in S. Glazyev's terms "technological change"). When the technological paradigm is replaced, the world economy is "reset": a new configuration of the world economy is being formed, production processes are being developed at a new technological level, the structure of the division of labor is changing, etc.

Without this, the world economy has a certain limit, and the economy is in a systemic (structural) crisis. Now, the timing of the crisis is not important for those who occupy a dominant position in the world economy. It is important only that the way out of it is possible on the basis of a new technological paradigm. Without this, the world economy will remain in a state of "technological stalemate", which has been more noticeable since the mid-2000s. In recent years, manufacturers of electronics, cars, household appliances do not offer new products. These are the same products, but with a new design, improved ergonomics and a bunch of small "improvements" ("upgrades").

Finally, it is worth mentioning one more aspect. Any cycle assumes a new technological base. However, any technology starts not with the mode of production, but with the energy. It is obvious that it is possible to sow and harvest crops with the help of a horse and a tractor. Of course, the

performance will be different (different technological levels). However, energy supply will be different. Thus, any technological base depends on new energy. And there are a number of explanations.

First, the logic of capitalist development leads to a reduction in the volume of labor and, on the contrary, an increase in the use of capital. This is well analyzed by K. Marx. In other words, the capital intensity of production is growing. However, any equipment requires energy, therefore, the energy intensity of the products also increases.

Secondly, with the growth of the reproductive circuit, the volumes of energy consumption, whose energy sources are limited, also grow. Gradually, readily available sources are exhausted, which leads to higher energy prices, higher production costs and, ultimately, lower rates of return.

Thirdly, the choice of a new energy resource is associated with the technological capabilities of its extraction, processing and transportation, which means that the economy should be used. Fourthly, the transition to a new energy resource is due to the fact that it is more efficient compared to the previous resource, which is associated with an increase in the energy consumption of the world economy.

The issue of energy efficiency is quite complicated. A certain idea about this can be obtained on the basis of the EROI (energy return on investment) indicator (sometimes called EROEI - energy returned on energy invested), which is the ratio of the amount of useful energy (suitable for further use) to the amount of energy spent on obtaining such energy resource . It is difficult to obtain an accurate estimate of the index.

1. The main problem is the estimation of energy inputs for extracting energy resources. The fact is that these costs are seriously different. Here, the location of the energy resource is important, as well as the technology used to extract it. This leads to the fact that even at neighboring deposits, the EROI indicator may differ significantly.

2. Quality of energy resources. It is obvious that the quality of energy resources influences the energy output. Naturally, certain standardization is possible. But since all energy resources are natural objects, and natural conditions are different, energy resources themselves will differ. This is clearly visible thanks to hundreds varieties of oil.

4. The indicator changes significantly in time. This is due to two circumstances. Firstly, the extraction of a new energy resource begins with readily available deposits, and it is necessary to move to more difficult areas. This, on the one hand, reduces the dynamics of EROI. But, secondly, the production technology is optimized (it gets cheaper), which, on the contrary, leads to an increase in EROI. However, since the resource has limited volumes, it is possible to cheapen production due to technological improvement only in a limited time frame.

5. Finally, the validity of the estimates is important. As a rule, you will not find open primary ("raw") numbers, you will see only the results. Often they are quite contradictory, and without "raw" estimates, it is impossible to verify the nature of the discrepancies.

In other words, only an approximate estimate based on the EROI indicator can be obtained.

However, this is not crucial for the transition to a new technological order.

Indeed, the new technological structure implies a new energy resource significantly different in energy efficiency. This is to ensure a reduction in production costs and to meet the sharply increasing energy needs at a new technological level. All this leads to an increase in the rate of return at this stage (at the beginning of a new technological cycle). In this case, as a rule, resources with the highest EROI are first used, if possible. As resources are depleted, they use resources with a lower EROI. However, this increases energy costs, the specificity of which lies in the fact that they "characterize" any product. The higher the degree of processing, the more energy is used in the technological process. The fall of EROI to some critical values makes the use of energy resources not

advisable. It is obvious that the energy efficiency of oil and gas has fallen significantly. For example, for the US, the indicator fell from 100 in 1930 to 14.5 in 2005.

The decline in EROI on a global scale (not in relation to companies and deposits) leads to a global economic crisis. Incidentally, the logic of this approach can be applied to the explanation of the rise and fall of individual countries. Taking into account the initial thesis about the systemic crisis of the world economy and the idea of a cyclical world economy, we can find the way out at a new technological level. The latter requires a new energy resource. However, recent years have not been marked by a transition to a new energy resource. It is obvious that the surge in interest in biofuel in the early 2000s. is hopeless, because its EROI at the initial stage is critically low. The situation with shale oil and gas is more complicated.

Evaluation of the Feasibility of Applying Reduced Social Contribution Rates in Special Economic Zones in Russia

Elena Iadrennikova, Ural Federal University named after the first President of Russia

B.N. Yeltsin, Ekaterinburg, Russia, elena.yadrennikova@mail.ru

Abstract

Special economic zones (SEZ) have seen widespread implementation in international practice and act as one of the instruments used to stimulate economic development of a country as a whole, specific regions, and areas of national economy, which is especially relevant in conditions of crisis and slowed economic development. This article considers the types of special economic zones in use in the Russian Federation and studies taxation preferences afforded to residents (participants) of Russian SEZs. Special attention is given to the investigation of preferences in wage fund taxation, in particular the amount of income tax and the rates of insurance contributions to the wage fund applied by SEZ contributors in Russia. The article will analyze indices of the activity of different types of Russian SEZs, identify problems in their performance and make conclusions about their productivity. It will also look at the feasibility of applying reduced tariffs on social contributions for different types of special economic zones, including industrial/development zones, technical/innovation zones, and recreational and touristic zones, depending on the cost structure typical for each type of SEZ. Finally the article will draw conclusions about which types of SEZ are most justified for implementing reduced tariffs on social contributions and about the perspectives of the long-term development and improvement of SEZs in Russia.

Keywords: Special economic zone (SEZ), taxation, rates of insurance contributions to the wage fund, taxation preferences, cost structure.

Introduction

Special economic zones are widespread in international practice. According to 2015 data from the UN Industrial Development Organization (UNIDO), there were around 4,500 SEZs operating in 140 countries, which employed over 65 million people (Economic zones in the ASEAN, 2015).

Thanks to its economic appeal, special economic zones are used by both developed and developing countries. However, the most impressive results on SEZ usage can be observed specifically in their implementation in developing economies. Their use facilitated the modernization of China, Malaysia, Mexico, Taiwan, and South Korea among others. For example, in Malaysia 90% of output in the electronics industry is produced in SEZs (Morgachev, 1992). The appearance of SEZs on a large scale in China not only attracted foreign investment, but also served as a catalyst for economic reform throughout the entire country (Farole and Akinci, 2011; Ji et al, 2017; Alder et al, 2016).

The development of SEZs throughout the world and in the Russian Federation occurs under the influence of international tax competition, which is aimed at stimulating the flow of foreign capital into sovereign tax jurisdictions by using favorable tax rates and tax regimes. The final goal of the international tax competition process is the strengthening of the competitive advantages of a country by the creation of effective infrastructure, clusters of certain branches of national economy, which in the end leads to growth in national income and the increase of tax revenue (Maiburov et al, 2010). Special economic

zones have a number of peculiarities, which include special customs zones, simplified investment regimes, decreased administrative barriers and preferential treatment with taxation.

In the Russian Federation, special economic zones began active development at the start of the 1990s, as the years 1990 and 1991 saw the opening of 11 of such zones in Russia, totaling 1 million sq. km (7% of the country's territory) and 13% of the population (18.5 million people) of the country. Currently more than 40 special economic zones of different types are in operation in Russia, all of which were founded between 1999 and 2016. Study of existing tax preferences, the results of SEZ performance and the cost structures typical of different types of SEZ allowed for the creation of an evaluation of the feasibility of applying reduced rates of social contributions in the wage fund in SEZs in Russia.

1 Research Methods

Various theoretical and empiric research approaches were used in the writing of this article. Research was carried out with the use of theoretical methods such as analysis, synthesis, generalization and classification. The classification of current SEZs in operation in the Russian Federation revealed the fact that several types of Russian SEZs overlap in their range of activities and have similar legal regimes for the implementation of entrepreneurial and investment activities. Analysis of current SEZs in Russia demonstrated a rather low level of performance on the part of the country's SEZs, especially taking into account budget losses due to tax losses.

The empiric methods used include observation and comparison and were used for the measurement of basic economic tendencies and the comparison between types of SEZs in order to identify the varieties of special economic zones in which the application of reduced tariffs on social contributions in the wage fund is more feasible.

2 Results and Discussions

2.1 Classification of special economic zones in Russia

Currently there are a few types of special economic zones in the Russian Federation, which are classified in table 1.

Table 1: Classification of special economic zones in Russia

Types of SEZ	
1. Special economic zones created in accordance to the federal law No. 184-FZ from 29.05.2015 "About special economic zones in the Russian Federation"	
• Industrial/development zones	SEZ Alabuga, SEZ Lipetsk, SEZ Tolyatti, SEZ Titanium Valley, SEZ Moglino, SEZ Kaluga
• Technical/innovation zones	SEZ Tomsk, SEZ Zelenograd, SEZ Dubna, SEZ Saint Petersburg, SEZ Innopolis
• Recreational and tourist zones	SEZ Baikal Harbor, SEZ Biryuzovaya Katun' (Altai Krai), SEZ Valley of Altai
• Port SEZs	SEZ Ulyanovsk-Vostochnyy, SEZ

	Soviet Harbot (Khabarovsk Krai)
2. Special economic zones created under separate federal laws	
• Special economic zone in Magadan Oblast • Special economic zone in Kaliningrad Oblast • Free economic zone on the territory of the Republic of Crimea and the City of Federal Importance Sevastopol. • Free port of Vladivostok	
3. Innovation centers	
Skolkovo Innovation Center	
4. Territories of leading socioeconomic development created in accordance to federal law No. 473-FZ from 29.12.2014	
In 2015-2016 18 of such regions were created in various regions in the Russian Federation	

Note that SEZs in Magadan and Kaliningrad Oblasts, the Republic of Crimea, territories of advanced socioeconomic development, and the free port of Vladivostok were created by a territorial principle in which preferential treatment is given to residents that exist within a defined territory. Some examples of SEZs created by this territorial principle include small states such as Lichtenstein, Luxembourg, Cyprus, Malta, and the Caribbean Basin countries among others. The remaining SEZs in the Russian Federation, as well as the Skolkovo Innovation Center, were founded on the cluster, or point, principle, which dictates that a group of neighboring interconnected companies of a separate branch and organizations tied to them are provided certain advantages under certain conditions (Kirillova, 2014). SEZs of similar type are widespread in the United States, China, South Korea and many other countries.

2.2 Taxation benefits in Russian SEZs

Widespread use of special economic zones in modern practice of government economic regulation can be attributed to the fact that the use of this form of economic activity organization provides economic interest on the side of both the government and bodies carrying out economic activity, which include individuals and legal entities that do business in special economic zones. SEZ-provided tax benefits are one of the tools used that make participation in special economic zones attractive for tenants and investors.

Because of the various regulatory potential of different taxes and fees and their varying significance in terms of their share in the total amount of tax payments in the worldwide practice of SEZ regulation, the most common tax instruments are (Maiburov et al, 2017): corporate income tax; value added tax (with regard to import VAT); turnover tax; import customs duties; capital gains tax; property taxes (land tax, real estate tax); transport tax, etc.

Although much more rarely, benefits to individual income tax (Ambroziak, 2016) and social contributions to the wage fund are still implemented.

Tax benefits provided by the Tax Code of the Russian Federation for special economic zones can be split into two categories.

1. Tax benefits provided for tenants/participants of all types of SEZ:

1.1. A decreased tax rate on profit established by federal subjects of the Russian Federation with respect to tax credited to the budget of the subjects (the duration of these benefits can be various and is applied by the law of the individual subject);
1.2. Exemption from taxation organizations' property (for a period of 10 years from the date of property registration);
1.3. Exemption from land taxation for resident organizations of SEZs (for a period of 5 years from the moment the company receives rights to a plot of land).

2. Tax benefits provided for SEZ tenants of only certain types:
2.1. Application of a special coefficient (≤ 2) to the main depreciation rate for the residents' own depreciable fixed assets in industrial/developmental zones and recreational and touristic zones;
2.2. Exemption from VAT on services in port-based SEZs;
2.3. Setting a 0% rate for corporate profit tax to be credited to the federal budget for residents of technical/innovational and recreational and touristic zones;
2.4. Reduction of or exemption from transport tax (established by the law of the subject of the Russian Federation) for industrial/development zones, technical/innovation and recreational and touristic zones and free ports;
2.5. Lowered rates of insurance contributions to the wage fund for all varieties of SEZ, except for ports and SEZs in Magadan and Kaliningrad Oblasts.

Thus, the tax preferences provided for various types of SEZ in the Russian Federation correspond to the world practice of tax regulation in special economic zones and are attractive to SEZ residents/participants.

2.3 Preferences in labor taxation in Russia's SEZs

We will take a more detailed look at the advantages that tenants/participants of SEZs in the Russian Federation receive in income taxation paid by individuals.
Note that preferences in personal income tax for tenants/participants of SEZs are not provided by legislation of the Russian Federation. This can be explained by the fact that the application of a basic rate of personal income tax (13%) in Russia is in and of itself one of the lowest income tax rates among both developed and developing countries. Besides this, the tax rate does not depend on the level of income received, since there is an absence of progression in personal income tax. This all testifies to the high competitive positions and attractiveness of the Russian tax system in terms of taxation of individuals' incomes and without the establishment of additional preferences for personal income tax in special economic zones.

Rates of social contributions on the cost of labor in Russia are at a rather high level, totaling 30%. A comparison of the amount of social tax on the wage fund in various tax jurisdictions according to worldwide-tax.com shows that many developed and developing countries, including the US, Indonesia, Mexico, India and the UK are more competitive in this parameter (the maximum rate of social taxes and fees in these countries range from 5.7% to 25%). As a result, concessions on social contributions of employers for the wage fund are provided to increase the attractiveness of SEZs in the Russian Federation. For organizations and self-employed individuals that are tenants (participants) of special economic zones and/or provide wages for individuals that work in SEZs of certain types, legislature of the Russian Federation provides reduced rates of insurance contributions for retirement, medical and social insurance (Table 2).

Table 2: Rates of insurance contributions paid by businesses distributing payments to individuals employed in various SEZs in Russia

Categories of payers			
1. Organizations and self-employed individuals distributing payments to individuals employed in technical/innovation, industrial/development, or recreational and tourist SEZs			
Name of fund	Rate size in different years, %		
	2011-2017	2018	2019
Pension Fund of the Russian Federation	8.0	13.0	20.0
Social Insurance Fund	2.0	2.9	2.9
Federal Compulsory Medical Insurance Fund	4.0	5.1	5.1
Total:	14.0	21.0	28.0
2. Organizations and self-employed individuals having tenant/participants status in a special economic zone in the Republic of Crimea and the federal city of Sevastopol, the free port of Vladivostok or a territory of advanced socioeconomic development			
Name of fund	Rate, %		
Pension Fund of the Russian Federation	6.0		
Social Insurance Fund	1.5		
Federal Compulsory Medical Insurance Fund	0.1		
Total:	7.6		
3. Organizations that are participants in the Skolkovo Innovation Center project			
Name of fund	Rate size, %		
Pension Fund of the Russian Federation	14.0		
Social Insurance Fund	0		
Federal Compulsory Medical Insurance Fund	0		
Total:	14.0		

Note the following observations.

1. The most significant preferences for the amount of insurance contributions are provided for the free economic zone of the Republic of Crimea, the free port of Vladivostok and the territories of leading socioeconomic development (with the total tariff reaching 7.6%). The mentioned SEZs were created rather recently—between 2014 and 2016—and are at the beginning stage of their development. Therefore analysis of the results of these areas' activity is currently not possible. However, judging by the size of the preferences provided to residents/participants, it is these zones that possess the upmost attractiveness to potential investors, and it is in these zones that the rate is set as the main driver of economic development in various regions of the country. At the same time, the legislature has limited the time for the use of lower rates by payers to 10 years.

2. Organizations that are participants in the Skolkovo Innovation Center project pay insurance contributions only to the Pension Fund of the Russian Federation in the form of a 14% rate. For these participants there is also a limit for the use of lower tariffs, 10 years.

3. For organizations and individual entrepreneurs that carry out payments to individuals working in industrial/development, technical/innovation and recreational and tourist zones, the total amount of the insurance contribution for a seven-year period (2011-2017) was set at 14%. Therefore tangible benefit for these types of SEZs by the size of the tariff, which affects their attractiveness for residents and investors, will only be valid through 2017.

4. Tenants of port SEZs as well as SEZs in Magadan and Kaliningrad Oblasts do not have concessions on the size of insurance contributions.

Note that in the Russian Federation there is already successful experience with the application of reduced social contributions for separate categories of payers. In particular, a reduced rate that totals 14% (such rates are currently set for industrial/development, technical/innovation and recreational and tourist zones and the Skolkovo Innovational Center) for a period of several years is applied to Russian organizations active in information technology (development, implementation, adaptation, modifications and support programs for computers and databases) when they provide income to individuals. The provision of such incentives in total with benefits to profit tax for several years has lead to the IT sector's fast rate of growth in the Russian Federation. As a result, the volume of sales and the amount of taxes paid has increased many times, many jobs have been created and currently IT is one of the fastest export-oriented sectors in the economy. Thus, in this case the provision of concession on social contributions has had a significant effect on public revenues, many times exceeding losses in state off-budget funds from the reductions of the standard rate.

2.4 The viability of the application of reduced rates of insurance contributions in SEZs

We will take a look at how justified the applications of reduced rates of insurance contributions depending on the type of SEZ. We will focus attention on SEZs created in accordance with federal law No. 184-FZ "About special economic zones in the Russian Federation", since the majority of them has rather significant concessions on social contributions and many of them have been in existence for several years, which allows for an analysis of the results of their activity.

For the period of 2006 through 2015, special economic zones attracted 472 investors (tenants) to Russia. From this total number of residents, 79 (or 18.6%) were investors who used foreign capital from 29 countries. These foreign investors chiefly came from the United States, Japan, China, Germany, France and Italy. By the end of 2016, the number of residents of the Russian Federation's SEZs reached 500. The results of their activity as of 01 Jan 2016 are given in table 3.

Table 3: Performance of SEZs in the Russian Federation as of 01.01.2016. (Russia. Special Economic Zones, 2016)

Indicators	Type of SEZ				Total
	Industrial/ development zones	Technical/ innovation zones	Recreational and tourist zones	Port SEZs	
1. Number of residents	135	264	63	10	472
1.1. By percentage of total SEZ residents, %	28.6	56.0	13.3	2.1	100.0
2. Amount of declared investment, billions of rubles	338.1	174.2	58.8	16.5	587.6
2.1. By percentage of total					

SEZ investment, %	57.5	29.7	10.0	2.8	100.0
3. Investments implemented by residents of SEZs, billions of rubles	139.451	38.99	1.654	0.513	180.608
3.1. By percentage of total SEZ investment, %	77.2	21.6	0.9	0.3	100.0
4. Share of implemented investments as a percentage of declared investments	41.2	22.4	2.8	3.1	30.7
5. Tax payments of residents to the federal and regional budgets (accumulated total), millions of rubles	12 351	8 593	65	15	21 024
5.1. As a percentage of total tax payments, %	58.7	40.9	0.3	0.1	100.0
6. Number of new working places	9 315	8 727	465	19	18 526
6.1. As a percentage of the total number of new working places, %	50.3	47.1	2.5	0.1	100.0

Source: Russia. Special Economic Zones (2016). *Annual report 2015*. [Online], [Retrieved August 1, 2017], http://www.russez.ru/, author's calculations

From the data from Table 3 the conclusion can be made that the most dynamic development among SEZ development in Russia is observed among the industrial/development and technical/innovation zones, and these are the most attractive for investors. These zones represent 28.6% and 56% of the registered tenants of SEZs, respectively. The amount of investments declared by the tenants totals 587.6 billion rubles, or an average of more than 1 billion rubles per resident. The amount of investment implemented comes to 180.608 billion rubles, or 30.7% of the declared sum. At the same time, the amount of budget investments in the creation of infrastructure totals 118 billion rubles, which puts the residents' investments at 1.5 times more than allocated by the budget. In terms of the amount of declared and implemented investments, the leaders are the industrial/development zones. This can be explained by the specific features of this SEZ type and the existing requirements for tenants regarding the size of investments in activity agreements.

In the 10-year period tenants of SEZs created 18.5 thousand job positions (of which 97.4% were created by industrial/development and technical/innovation zones). Over the course of their existence tax payments to the budget have slightly exceeded 21 billion rubles (a 99.6% share of which was generated by industrial/developmental and technical/innovational zones), which is 1/6 of the amount of budget funds invested in SEZ infrastructure. The activity of recreational and tourist and port-based SEZs is practically unseen, as evidenced by the following data: 73 residents of these zones invested a bit more than 2 billion rubles in their business, created a total of 484 jobs and paid only 80 million rubles in taxes. This could be explained by the fact that tourist zones and free ports appeared in Russia not long ago and are still in the process of formation.

In total the results of SEZ activity for the given period are positive. However, taking into account that the results are taken from a ten-year period (2006-2015), their level of efficiency is low and begs the question of their feasibility of their creation and further development. This is even without taking into account tax revenue shortfalls and other mandatory payments that were not received by the state budget as a result of tax and customs incentives provided to SEZ tenants. It can be noted that providing tax benefits to SEZ

residents has not produced a tangible economic effect. This may be due to institutional factors such as a low level of tenure security and a high level of shadow economy, corruption, etc. As in the situation with low tenure security, no foreign investor will take tax benefits as a convincing argument for investment in such a country (Maiburov et al, 2017; Cizkowicz et al, 2017). Additionally, in the coming years the effectiveness of SEZ activity will increase, since a number of large companies in SEZs are just being built or are just launching production, and the results of the activity of SEZ tenants will significantly improve in three to five years as the enterprises reach full production capacity.

2.5 The feasibility of applying reduced rates of insurance contributions for various types of SEZ

When discussing feasibility of applying reduced tariffs for various types of SEZ, the area and specific features of their activity should be taken into account. We will focus on types of SEZs whose tenants are entitled to reduced rates of insurance contributions (industrial/development, technical/innovation, and tourist zones).

Industrial/development SEZs are created with the aim of manufacturing and/or processing of products (goods) and their subsequent implementation. The advantages of this type of SEZ include the location of production in close proximity to the resource base, access to available infrastructure and basic transport arteries. The location of production in industrial/development zones allows for the increase in competitiveness of production on the Russian and international market due to lowered costs.

The main activities of residents of industrial/development zones include: machine building; automobile and car component manufacturing; petrochemicals; production of power equipment and alternative energy systems; production of medical equipment; instrument manufacturing; production of construction materials; production of home appliances and consumer goods.

Technical/innovation SEZs carry out innovation activities, the creation, production and implementation of scientific and technical products; the creation and realization of programs for computers, databases, and informational systems; and the provision of services in innovation and maintenance of these products. The locations of these SEZs in large scientific and educational centers with rich scientific histories and recognized investigative schools provide additional opportunities for the development of innovation business, the manufacturing of high tech products and output into the Russian and international market.

Recreational and tourist SEZs are created for the development of tourism in the Russian Federation, the construction of use of facilities for the tourist industry, the development of health resort facilities, medicinal rehabilitation and rest. Recreational and tourist zones are created to provide tenants with engineering infrastructure in hard-to-reach places that cannot be developed by forces of individual investors alone.

The study of the structure of costs for the creation of products (services) by types of activities that are typical for different types of SEZ (Table 4), allows us to draw the following conclusions.

Table 4: Cost structure for manufacturing, labor and services for some types of economic activity in the Russian Federation in 2015 (Statistics Russia, 2017), %

Type of activity	Types of cost					Total
	Material costs	Labor costs	Social contributions	Depreciation	Other	
1. Economic activity in industrial/development SEZs						
✓ Production of machinery and equipment	63.3	19.1	5.4	3.3	8.9	100.0
✓ Production of						

electrical and optical equipment	62.6	20.2	5.7	2.8	8.7	100.0
✓ Production of vehicles and equipment	69.2	13.6	3.9	3.1	10.2	100.0
✓ Chemical production	72.6	9.6	2.7	5.3	9.8	100.0
2. Economic activity in technological/innovation SEZs						
✓ Scientific research and development	48.6	26.8	7.0	3.0	14.6	100.0
3. Economic activity in recreational and tourist SEZs						
✓ Restaurant and hospitality business	46.2	21.6	6.1	4.1	22.0	100.0
✓ Health and social services	29.0	37.1	10.2	4.9	18.8	100.0

Source: Statistics Russia (2017). *Russian Statistics Annual Report.* [Online], [Retrieved August 2, 2017], http://www.gks.ru/bgd/regl/b16_51/IssWWW.exe/Stg/03-14.doc, author's calculations

For the type of activity carried out in industrial/development zones, the cost structure is characterized by a predominance of material expenses (62.7-72.6%), while the share of labor costs, and by extension, social contributions, is relatively low (9.6-20.2% and 2.7-5.7%, respectively). As a result the application of reduced rates by tenants of this SEZ type does not have a significant effect on the reduction of costs and the increase of competitiveness of products. At the reduced rate of 14% the amount of costs reduces to 1.4-3.0%, and at the 2018 level of 21%, only 0.8-1.7%.

In the cost structures of activities carried out in technical/innovation and recreation and tourist SEZs, the share of labor costs and social contributions is much higher (21.6-37.1% and 6.1-10.2%, respectively). Therefore, for these types of SEZ, the effect from using reduced rates of insurance contributions is considerably higher. The reduction in costs for the production of innovative hi-tech products and tourist services may amount to 3.3-5.4% in 2017, and from 1.8% to 3.1% in 2018. Thus the application of a reduced rate of insurance contributions is more justified and feasible for these SEZs.

When considering the question about the effectiveness and feasibility of providing tax concessions to participants of SEZs, including in social contributions, one must consider that the use of tax benefits lead to violation of the principle of fairness in taxation. This is because of the fact that in supporting some territories and types of activities, the government must increase the tax load on other taxpayers. This is where China is deserving of attention in its establishment of special economic zones. Thanks to a weighted and consistent policy in this area, China has managed to bring itself to a leading economic position in the world in the period of a few decades. The essential characteristic was the fact that production facilities in the country's SEZs were oriented on export and not on the supply of goods, labor, and services to the domestic market, thereby not undermining the basis for fair competition in the country (Goncharenko, 2016).

Experience of the functioning of SEZs in the Russian Federation shows that SEZs are mainly focused on attraction of local investors, which is seen in the low share (18.6%) of tenants of the country's SEZ that use foreign capital. At the same time the sales vector of goods produced in SEZs is directed mainly at Russia. For example, in SEZ Kaliningrad, which is unique in its proximity to the general European market, the direction of development on international labor cooperation and the export of Russian goods and services to Europe, the development of logistics should have become a main priority for the SEZ. However, unfortunately, it does not have (Ivanova et al, 2015). Thus, Russian SEZs' orientation of output mainly on the domestic market creates a prerequisite for the appearance of horizontal tax competition between the country's regions and violates the principle of taxation fairness.

Conclusion

Tax preferences currently granted to residents/participants in Russia's SEZs are quite adequate and attractive. However, an analysis of their activity has shown a low level of efficiency, especially taking into account losses to the budget from cut taxes. The reason for this can be institutional factors of the Russian economy, including a low level of tenure security and a high level of shadow economy and corruption.

Comparative analysis has shown that the most feasible and justified use of reduced rates of insurance contributions to the wage fund are in technical/innovation and recreational and tourist SEZs, taking into account the cost structure for these areas of activity.

Currently SEZ activity is largely focused on the domestic market, which creates a prerequisite for horizontal tax competition between regions of the country. To increase of efficiency of SEZs in the Russian Federation, it is necessary to attract investors, including foreign ones, with the general prospects of development of the Russian economy. The main factors to contribute to the development of SEZs in Russia should become the condition of infrastructure, the protection of invested capital, and the simplification of administrative procedures concerning entrepreneurial activities. At the same time, products and services produced by SEZs should largely become more export-oriented.

Integration of Soldiers to the Labour Market In Visegrad Group Countries

Kristýna Binková, University of Defence, Brno, Czech Republic, kristyna.binkova@gmail.com

Miroslav Krč, University of Defence, Brno, Czech Republic, miroslav.krc@unob.cz

Abstract

Integration of soldiers to the labour market after the termination of their military service is the topic of this article. It deals with the issue of provided benefits associated with preparation of soldiers for a so called second career in the Visegrad Group states - Czech Republic, Poland, Hungary and Slovakia. Its aim is to describe national approaches of each country and compare them. The method of analysis of scientific literature, semi-structured interviews with employees of Ministry of Defence of each country and analysis of statistical documents were used.

Keywords: Soldier; second career; labour market; Visegrad group countries

Introduction

A person's career starts when he enters the labour market. In the role of an economically active person in the labour market, he concludes contracts and agreements, through which he carries out his profession, through which he forms his social and economic position in society. Opinions about the career concept are different and there are many of them. For some people, a career means a way of meeting basic economic needs, for some people a social status. At present, it is typical that many individuals' careers consist of multiple positions and are characterized by frequent changes and high mobility. The reason for this is the dynamism of the labour market, i.e. increasing competition, constant technological change, and new trends, the initiative of an individual, or the inevitable change of career resulting from the nature of professions. One of these professions is professional soldiers.

After the termination of military service, a "critical" period, during which it's decided about the nature and methods of soldier's adaptation in the civilian sector, begins. Poor adaptation leads to signs of negative consequences of job loss. But they can be avoided by successful start of a second career, in the shortest possible time. A second career can be defined as the next stage in the career path or in the new profession as a result of the voluntary or necessary termination of previous career. The armed forces are part of the labour market and must, therefore, fight for potential employees and seek out the best candidates for the military profession. They are a specific employer who does not have the equivalent in a civilian economy, and therefore should show an interest in former employees being successful also in civilian economic life.

The Visegrad Group, also called the Visegrad Four, or V4 is a cultural and political alliance of four Central European states – the Czech Republic, Hungary, Poland and Slovakia, which was formed in 1991 as a response to the consequences of the fall of totalitarian regimes in these states, for cooperation in a number of areas of common interest within the framework of pan-European security and economic integration. The following chapters will outline how individual members of the Visegrad group help their members of armed forces to integrate to the labour market after the termination of their service, in order to facilitate their transition to a second career, to encourage placement at civilian employers, to alleviate the negative social and psychological impacts and, last but not least, to strengthen organizational culture.

1 Overview of the issue

A professional soldier is a citizen who performs military service as a job for the nation. The employment relationship of a professional soldier is terminated by the expiration of the period for which he / she has been negotiated, or by other, statutory reasons. Soldiers leaving the military do not reach the statutory retirement age in most cases. They belong to relatively young population, most often at the age of 40, that are often at the peak of their professional career at the end of their military career and with the potential to work for another 15-30 years (Vigoda-Gadot, Baruch & Grimland, 2010). Since soldiers want to maintain a certain standard of living even after leaving the service, they try to integrate to the labour market and achieve a second career in a new, civilian job (Levinson, 1978). However, practice shows that ex-military servicemen experience serious difficulties with integration to the civilian labour market after leaving the army, and that selection of a new profession can take up to a disproportionately long time (Wing, Wolf, London & Wilmoth, 2009).

The army environment is hierarchical, based on strict rules and high division of labour. It is therefore compensated by paternalism that provides most basic living needs such as steady income, housing, or medical services (McCarthy, 1992). In the "civilian world", with a completely different culture, principles and habits, with greater autonomy (Zarecky, 2014), they often feel needless (Anderson, Goodman, 2014) and don't know how to act independently (Higate, Richard, 2001). Many of them cannot even cope with this so-called intercultural transition (Black, Westwood & Sorsdahl, 2007) several years after the termination of military service (Doherty, 1983, Ullmann 1971).

Soldiers have skills that are very little applicable in civilian environment, and after about 15 years of service, it is not very realistic for them to return to the field they have studied. They also have a problem with identifying of so-called transferable skills (Felder, 2008; Simpson & Armstrong, 2010). Their techniques of self-presentation are ineffective, and the difference between military and civilian terminology does not contribute to the problem. Employers do not understand the qualities of job seekers with military experience, and therefore underestimate them (Becker, 1957). Former soldiers belong at the labour market to disadvantaged groups.

The integration process and satisfaction of soldier during his / her integration to the civilian environment depends on many factors according to the authors. In confirmation or refutation of hypotheses of the impact of these factors on the process of soldier adaptation in the civil sector, however, researches do not take a single opinion. On the contrary, a clear positive impact had, according to previous research, early preparation for a second career, the individual's social capital, the perception of organizational policy in new job (Vigoda-Gadot, Baruch & Grimland 2010), perception of the labour market (Baruch & Quick, 2007), or personal satisfaction (Cauly, 1987).

2 Approaches to solving the issue – theory

Vigoda-Gadot, Baruch & Grimland (2010) noted: “Good retirement preparation will allow the retirees to better understand second career reality.” The preparation will affect expectations from the new organization and will enable retirees to overcome difficulties and frustrations in their new career workplaces. Fuller & Redfering show that second career planning was the only factor which had significant effect on retirement adjustment; those who adjusted well were those who had planned well. According to McNeil (1983), it is important to start planning at least one year before the termination of service. Studies show that planning and consistent preparation for a second career is the only factor that demonstrably facilitates career change. Individual responsibility and soldiers' activity is crucial, but the assistance of the state and organizations is necessary and increasingly important nowadays (Wolpert, 2000).

Figure 1 depicts a situation where a soldier at point t_1 leaves the armed forces and his income curve $y_{armforce}$ and becomes unemployed for periods t_1 to t_{1+x}. Then he has the opportunity to return to his original qualification obtained at point t_0 with a return to the y_{civ} curve which he would have been on if he did not enter the armed forces or he can reach the reception curve lying somewhere between the $y_{armforc}$ curve and the y_{civ} curve. The reason why the armed forces must try to compensate the drop of income of former soldier is not just the effort of a good image of the armed forces, i.e. the competitiveness at the labour market, but also the prevention of the escape of former soldiers whose military qualification has no civilian alternative in the form of a y_{civ} curve, or whose return to original civilian profession is problematic, to illegal activities. The environment of organized crime gives them a great opportunity to apply the special skills gained in military service and possibly to return to the course of their income given by y_{amforc} curve or even higher.

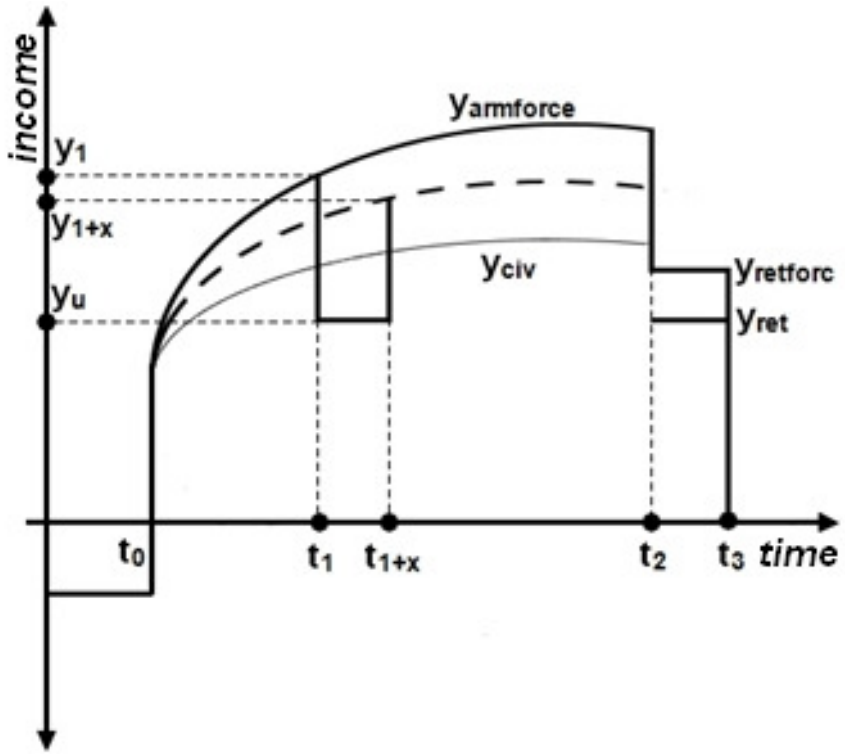

Fig 1: Income of soldier over time

Source: Pernica (2007)

According to Pernica (2007), there are three ways to limit the consequences of the former soldier's economic downturn. The first option is to offset a portion of the difference between former $y_{armforc}$ income and unemployment income, or income in civilian employment corresponding to the initial qualification of soldier in the form of retirement benefits or other benefits provided to former soldiers after termination of service. This option is called the social security for soldiers.

Another way to reduce soldier's drop of income is to enable him to obtain a qualification during the duration of service to be able to continue without major problems even in the next economic life. Further training of military personnel is even part of personal marketing. There is no cheaper advertising than a

good name in the labour market. Qualification can be made at the beginning of the service, during or at the end of the service as replenishment, incensement of qualification, or as a re-qualification.

A third way to limit the income impact of a professional soldier after the termination of service is to economically stimulate him to voluntarily leave the service by stopping the growth of soldier's income. This measure is particularly suitable for the most qualified military personnel. The interpretation of Figure 1 is that the soldier would not be interested in extending the contract at a time when the difference between the $y_{armforce}$ curve and the y_{civ} curve would increase significantly. The tool of this policy is the salary rules linked to the career order.

3 Approaches to solving the issue – practice of Visegrad Group Countries

For the notion of how powerful armies of the Visegrad Group countries are, and how important the problem of the outflow of professional soldiers is, the following table shows size of armed forces and outflow of soldiers from armed forces in 2016.

Table 1: Size of armed forces and outflows of soldiers from armed forces in Visegrad group countries in 2016

Country	Size of armed forces	Outflow from armed forces
Czech Republic	23 184	842
Poland	106 000	4 844
Hungary	19 871	800
Slovakia	12 333	660

Source: Authors' own elaboration

In all countries, the lowest decrease was recorded in the lower ranks, the most frequent reasons were the expiry of the defined period of the contract and the filing of the application for dismissal. The average age of soldiers terminating the service was 35-40 years.

In Czech Republic, a professional soldier serves for a fixed term period in the range from 2 to 20 years, which can be prolonged. Soldier must be released if he / she has reached the retirement age according to a special legal regulation. The length of military service in Poland lasts from 18 months to 6 years, with the total length of service for a soldier not exceeding 12 years. 3 months before the expiration of a certain period, soldiers may apply to extend the contract or to change it for an indefinite period. In Hungary, soldiers serve at least for a period of 3 years, which can be extended up to a maximum of 20 years. As in Poland, soldiers who meet the necessary requirements may apply for the status of a professional soldier and serve for an indefinite period of time, most notably until the age of 60. In Slovakia, the military service is based on his rank ranging from 1 year to 17 years or he or she ends up by reaching the statutory age limit, which is 55 years in all grades.

3.1 Integration of soldiers to the labour market in Czech Republic

Military retirement pay. The soldier is entitled to a retirement allowance if his/her service lasted for at least 15 years. The basic amount of the service allowance is 15% of the average monthly gross salary but no more than 55%. A soldier whose service lasted for 15 years and is also entitled to a severance pay at the amount of quadruple of the average monthly gross salary. The maximum severance pay is six times

the average monthly gross salary. A soldier whose service lasted at least 2 years is entitled to pay in the amount of 2 average monthly gross salaries. With more years in the service, the pay is increased to a maximal amount of eighteen times of monthly gross salary (Act No. 221/1999 Coll).

Military education system. Specialized training of the Defence Department in terms of usability for the second career is supported especially by the Military High School and the Higher Technical School of the Ministry of Defence in Moravská Třebová, the University of Defence and the Headquarters of Training - the Military Academy in Vyškov within their fields of study and courses. Language training in the department is focused on meeting the language skills requirements set out in accordance with the STANAG 6001 Standardization Agreement (Koncepce přípravy, 2011)

Retraining. This is a benefit for professional soldiers whose service lasted at least 5 years. Retraining is granted to soldiers on the basis of their application in the form of short-term courses. Their duration must not exceed 3 months and must end at the latest on the last day of service. Courses offered by the Ministry of Defence every year, last on average from 3 to 4 weeks. However, it is difficult for a professionally trained soldier to retrain to a different expert for such a short period of time. Moreover, courses focus only on the basic knowledge and skills needed to perform the profession in which the soldiers retrain. However, this is not in line with labour market requirements. There is no competitive advantage for soldiers and the success at the labour market is not very realistic (Bednář, Simbartl, Drábek, 2016)

Job opportunities in state companies of defence sector. VOP, LOM Prague, the Military Forests and the Farms of the Czech Republic and Volareza are state companies of defence sector that offer jobs to soldiers who terminated the service. Most often these are technical jobs, air mechanics, or chefs (Benefity pro válečné veterány, 2017).

Leave of absence. For the purpose of job searching before the termination of service, the soldier is entitled to a 2 day leave per month during the period of three months before the expiry of service (Decree of the Ministry of Defence No. 263/1999 Coll.).

Summary of the interviews: Employees of the Ministry of Defence agreed on the view that the retraining system requires changes. They have stated that it is important to educate soldiers for longer period of time, already since recruiting and direct them in preparation for a second career in civilian fields related to their military expertise. They also expressed the importance of obtaining feedback on the retraining courses and using the latest educational trends, such as e-learning. About 20% of soldiers terminating the military service are interested in retraining courses every year, and this percentage needs to be increased. A team of experts is taking steps towards change, but it is in the state of negotiations.

3.2 Integration of Soldiers to the Labour Market in Poland

Military retirement pay. If soldiers' service lasted for at least 25 years and if they have reached the age of 55 years they are eligible for military retirement pay. The basic amount is 60% of the average soldier's salary. This amount increases each year by 3%, but maximally up to 75%, which the soldier receives after 30 years of service (Emerytura, 2017).

Military education system. One form of support is a military education system. In Poland, soldiers can acquire knowledge and skills potentially applicable in the civilian sector by studying at military universities: War Studies University, Polish Air Force Academy, Military Technical Academy, Tadeusz Kosciuszka Military Academy and Naval Academy.

Counselling. The soldier may have individual consultations with experts, offering him the opportunity to meet employers, personalists selected by companies or other people who have successfully undergone a career change.

Seminars. Soldier can participate in up to 3-day seminars on the theme of retraining opportunities, start-ups, job opportunities, labour market adaptations, job search methods, rules of writing a CV and motivation letter, interviewing techniques, and employment law issues.

Training. Part of preparation for the second career is training, i.e. retraining and other courses, which are paid up to the amount that is given by: the percentage of the lowest basic salary in force as of the first day of the calendar year in which the person requires retraining, the number of years worked in active service and the date of termination of service.

Job search assistance. A soldier looking for a new job can apply for job search assistance at the appropriate military unit. He /she is provided with a wide list of vacancies within his / her place of living, which takes into account his / her needs, qualifications and requirements.

Reserved jobs in the public sector. A soldier, whose service relationship was terminated for reasons defined by law and whose service lasted for at least 10 years, has a priority in applying to positions in the area of national defence in the public sector.

Internship. Upon a decision of the Minister of Defence and with the consent of the commander of a military unit, the soldier can apply up to 6 months of internship before termination of service if it is necessary for obtaining employment in the civilian sector.

Other forms of support. Professional Activation Centers also offer business start-up assistance and organize job fairs that employers are invited to, to establish contacts for future cooperation with soldiers (Rogoń, 2017).

Summary of the interviews. The core of the integration of soldiers to the labour market is a system based on the cooperation of specialized institutions, so-called Professional Activation Centres that are in eight cities. A team of employees regularly visits military units and institutions and teaches soldiers about the possibilities of preparation for a second career. The centres provide professional counselling or seminars, personally, by telephone and online, individually and in groups. A total of 9 438 attendees participated in the year 2016. This year centres also established contacts with a total of 451 employers and received 1 273 job offers for soldiers. A total of 2 693 retraining took place, 1 256 soldiers took part in the internship, and 27 job fairs were organized. The system of integration of soldiers to the labour market is very sophisticated in Poland.

3.3 Integration of soldiers to the labour market in Hungary

Military retirement pay. In the year of 2012, the benefit of military retirement pay was cancelled.
Military education system. One form of support is the education system, the National Public Service in Budapest, which offers its military students the opportunity to gain the status of a professional soldier after five years of study, as well as knowledge in other areas of public administration (Jobbágy, 2016).
Reserved jobs in the public sector. In addition to financial compensation, the soldiers are offered an advantage in the form of preferential occupation of vacancies in two state-owned enterprises. These are the Hungarian State Railways and the Hungarian Post Office. Soldiers also have the option to transit to a police or fire-fighters, but another form of support for soldiers to integrate into the labour market does not currently exist.

Other forms of support. Until the end of 2016, soldiers who were not able to perform their military service for psychological or physical reasons not caused by their fault were provided financial compensation. Even this benefit was cancelled since January 2017. Soldiers have only the right to apply for a financial contribution to the National Public Employment Foundation for a maximum of 90,000 Forints to cope with the career change period (Kovács, 2016).

Summary of the interviews. Some forms of integration of soldiers into the labour market in Hungary existed in the past. Now there is a trend of cancelling these forms of support, and according to the interviews, this is mainly due to a significant reduction of the dismissal of soldiers for organizational reasons. Most outgoing soldiers leave for retirement, so the motivation for implementing a system of preparation of soldiers for a second-career is not too high. Therefore, no change is planned in the near future.

3.4 Integration of soldiers to the labour market in Slovakia

Military retirement pay. The retirement benefit is provided to soldiers for one to three years, depending on their length of service (at least 10, not more than 25 years) in the amount of 1% of the average monthly salary. The severance pay in the amount of half the average monthly salary is provided to soldiers whose service lasted for at least 13 years, and the amount increases with every additional year of service. If the military service of a soldier lasts at least 25 years, he / she is entitled to a so-called retirement pension, which is 37.5% of the average monthly salary. This percentage increases with further years of service (Act No. 328/2002 Coll.).

Military education system. Soldiers can acquire knowledge for a second career in the study programs of the Academy of Armed Forces Gen. M. R. Štefánika.

Counselling and seminars. Soldiers may also undergo a preparation for further employment during the notice period, which is aimed at developing soft skills in finding a new job. This training within 6 hours is provided by military psychologists at units every 2 months. This training is carried out in accordance with the Directive of the Ministry of Defence of the Slovak Republic on the performance of psychological activities. Its content is structured mainly in preparation for an interview, writing of a motivation letter and cover letter, the possibility of finding employment in the civil labour market, or the diagnosis of a suitable profession for individuals. The specific content is adjusted according to the preferences of the soldier and the psychologist. Information on outplacement is also provided by the Department of Psychological and Sociological Activities of the Personnel Office of the Armed Forces (Štammová, 2016).

Military training. In §80 of Act No. 346/2005 Coll. On State Service of Soldiers of the Armed Forces of Slovak Republic, retraining was defined and the conditions for its provision were specified. Those were the reasons for termination of employment, further specified in the law, and the length of service for at least 5 years. Retraining was provided at the cost of the state with the possible participation of a soldier. However, in the last amendment to the Act, we cannot find any mention of retraining.

Other forms of support. Soldiers are allowed to prepare for the transition to a civilian profession at their own expense during the period of notice. In practice, this is a leave in the scope of preparation for a new job, with maximal length to 30 days. In addition, soldiers are entitled to a leave from work used for searching for a new job, in the scope of half of a day per week.

Summary of the interview. The defence sector of Slovakia focuses mainly on seminars and counselling. Retraining courses have been cancelled for unspecified reasons. Because of the relatively low number of soldiers released annually, changes are not expected in the near future.

4 Comparison and Discussion

Based on the information provided by individual Visegrad Group countries, we can conclude that Poland has the most sophisticated system of integrating soldiers to the labour market, providing a range of diverse benefits. It is the only country that provides job-seeking assistance, allows internships in civilian

organizations, organizes job fairs, and also helps in starting a business. Assistance with the integration of military personnel into the labour market is a logical continuation of the personnel policy of the Polish armed forces. It is perceived as a duty of the state towards its soldiers and represents one of the strategies of preserving the prestige of the military profession and the quality of recruitment.

At a similar level, though with another benefit mix, is Czech Republic and Slovakia. The strengths of the integration of soldiers to the labour market in Czech Republic is its military education system, the career training of professional soldiers, comparable in their content to similar managerial courses in the civilian sphere, as well as language training. The retraining system has several weaknesses. Especially the length that is too short for a soldier to retrain to an expert with a completely different professional orientation than his / her military one. A significant weakness of retraining courses is also their focus on basics of professions and therefore inconsistency of the content of the courses with the requirements of the labour market. Retraining course itself cannot prepare a soldier for new conditions and a second career. In the Czech Republic, there are no consulting activities to assist soldiers with getting to know the labour market or with searching for a job. On the contrary, in Slovakia, career counselling and career seminars are organized, but the benefit of retraining courses is no more provided.

The least benefit in terms of preparation for a second career of soldiers is provided in Hungary. As the only one of the analysed countries, it does not provide military retirement pay and from other benefits, it only provides reserved jobs in some public institutions. The situation is illustrated in the following table.

Table 1: Benefits related to assistance with integration of soldiers to the labour market provided by the Visegrad Group countries

Benefits	Czech Republic	Poland	Hungary	Slovakia
Military retirement pay	x	x		x
Military education system	x	x	x	x
Counselling		x		x
Seminars		x		x
Training	x	x		
Job search assistance		x		
Reserved jobs	x	x	x	
Internship		x		
Job fairs		x		
Business start-up assistance		x		

Source: Authors' own elaboration

Conclusion

Based on the study of scientific literature analysing the transition from military service to civilian employment, the implications for human resource management can be deduced. Human resources management is more than ever the most important area of assuring capabilities of the armed forces. Due to the negative demographic development and the aging of the population, as well as the drop in

education in the technical fields, the armed forces face difficulties in replenishing the units by qualified personnel. Therefore, it should be in the interest of creating comfortable conditions for leaving the armed forces, which would have a significant effect on recruitment.

All analysed countries provide some support for professional soldiers during the transition to a second career. However, Poland has the most elaborate system of integration of soldiers to the civilian sector, which can be a good example for defence sectors of Czech Republic, Slovakia, and Hungary in terms of potential adaptation to domestic conditions. Research shows that soldiers are very sensitive to the correctness of layoffs and are significantly affected by the procedures that are used. The impact of the clarity and adequacy of the explanation of the reasons for the dismissal as well as severance, counselling and other services and benefits associated with facilitating the period of transition to the second career is significant.

It is necessary to change access to the occupation of a professional soldier as a lifelong profession, to inform soldiers of this fact as soon as they enter the army and to involve them in preparation for the transition to the civilian sector as soon as possible during their active career. Effective planning is a key aspect of integration to the labour market. Studies show that planning and consistent preparation for second career are the only factors that demonstrably facilitate a career change. The individual responsibility and activity of soldiers are crucial, but the assistance of the state and organizations is essential and increasingly important.

raul.mata@udem.edu

Abstract

The presence of economies of scale allows industries and companies to have better profits. In the present study, the translog cost function of a manufacturing company in Mexico is estimated during the period January 2013 to September 2016. The elasticity of production with respect to cost is found to be 1, where increases in production lead to increases in the same proportion in costs. From this result, we analyze some aspects in which the company could improve this situation, for example, to change its accounting to the costing method ABC.

JEL classification: D22, D24, L21, M21.

Keywords*:* Economies of Scale, Manufacturing, Costs.

Introduction

According to a recent report by JP Morgan and IHS Markit (2017) on the sensitivity of the market, Mexico contributes 1.5% to the world manufacturing production, currently occupying the number fourteen place globally. This report also mentions that in the following years an increasing trend in world production is expected, and this is beneficial for the country. In Mexico, the manufacturing industry has taken an important role in the economic development since the last decade, and has positioned to the country as a leader of certain sectors. This industry has directly and indirectly participated in a large number of economic activities: generation of jobs, transferring of technology, and generation of investments. According from the Manufacturing Industry Monthly Survey (EMIM, 2017), during the period 2016-2017, in Mexico the employment of this sector registered an increase of 3.5%, while the value of production increased by 16%; however, a major concern that could reduce growth in this sector are its costs, as according to the Center for Public Finance Studies (CEFP, 2016) since the end of 2014, the average costs in this sector have increased, presenting an annual growth of 5.62% in June 2016.

For this reason, it is important to analyze the productivity and efficiency of companies in the manufacturing industry. One of the key indicators for this analysis is the determination of economies of scale, which, unlike the reduction of costs due to technological changes, is presented when there is a reduction of costs given a proportional increase in production. Although economies of scale have become a topic of study in various industries such as oil, steel, electric power, airlines, and financial, in an environment like the current one it is important to generate analyses on how companies can take advantage of economies of scale and become more efficient, providing added value to the industry of each country.

According to a report by HSBC (2016), the mechanical metal sub-sector has a value of 7 billion dollars annually in Mexico, and is made up of 23,120 companies of which 20,100 are microenterprises. The company analyzed in this study is a Mexican subsidiary of one of the largest machinery manufacturers in Japan, which belongs to this sub-sector and serves as an international provider of engineering solutions.

The hypothesis to prove is whether this company, given its structure of costs and production, incurs economies of scale for one family of products of greater sale in Mexico, being the period to be

analyzed from January 2013 to September 2016. Once the presence of economies or diseconomies at scale is determined, an analysis will be performed to determine the causes of this result and provide some suggestions.

The present work makes the following contributions to the literature: initially, it is an article that uses the translog cost function applied to one of the families of products of this company, and secondly, it analyzes the existence of economies or diseconomies of scale in its structure of production, which has not been done in Mexico at the company level.

The remainder of this study consists in five additional sections. In the first section the literature review is presented; then the methodology is described, followed by descriptive statistics. The results are found in the fourth section and in the fifth section the conclusions are found. Finally the references are presented.

1.-Literature Review

In the last decades, the efficiency of production costs has been analyzed in several industries, such as the electric energy industry. Christensen and Greene (1976), in their pioneering study of economies of scale, analyzed electric power companies in the United States by estimating a translog cost function to determine if economies of scale exist in the structure of their production. The authors used a cross-sectional database for the years 1955 and 1970 for 114 companies. The authors found that the decline in the cost of producing electricity in these years was not due to economies of scale but to technological changes in the industry. They concluded that public policies designed to promote competition in this industry do not interfere with economies of scale, so they established that it is not efficient for the production of electric power in the United States to reduce the number of companies.

Clark and Speaker (1994) used data from the income statements and balance sheets of 402 commercial banks in the United States for the year 1989. They estimated a translog cost function to determine if there are economies of scale in the banking industry. The authors found statistically significant evidence that any bank, regardless of the size or products it markets can achieve greater efficiency through economies of scale by increasing the size of its production, which means that its costs would decrease. The authors suggest that small banks should increase the size of their institution in terms of the products they offer (such as deposits and loans), thus improving the efficiency of their productivity.

In a study by Stratopoulos, Charos and Chaston (2000), 25 companies from the US steel industry were analyzed during the period 1990 to 1992. The authors used a translog cost function for their estimation; they used financial ratios as a proxy variable for the prices of the factors of production. The authors found that the profitability of steel companies is inversely related to operational efficiency, that is, as the company becomes more efficient, indicators such as net income and their respective financial ratios are lower.

Another branch of the same banking industry in which this type of efficiency analysis is carried out is that of microfinance institutions. Hartarska, Shen and Mersland (2013) used a panel database for 69 countries during the period 1998 to 2010, obtained from the MicroBanking Bulletin (MBB). The sample contains 989 observations. The authors evaluated the efficiency of the industry through the estimation of the translog cost function to determine if there are economies of scale in the production of microfinance institutions, as well as the elasticity of substitution of the inputs used in this industry (labor, financial capital, and physical capital). The results indicate that the inputs used are inelastic substitutes, that is, that a great change in the price of one is needed to be replaced by another. It was found empirical evidence that microfinance institutions, regardless of the type of products they manage (loans or investments) can generate significant savings in their costs through the expansion of their production.

Recently Bitzan and Peoples (2016) analyzed information on the costs of 61 companies belonging to the United States airline industry, according to the type of service they offer: low-cost and full-service airlines. They used data from the period 1993 to 2014 to decompose changes in costs and

identify which percentage is due to productivity, firm size, technological change, and changes in input prices (such as labor, capital, aircraft fuel and cargo equipment). The authors estimated a translog cost function and found that full-service airlines have experienced decreases of 10% in their average costs, while in low-cost airlines it has increased by 8.5%. As for the decomposition, it was found that for full-service airlines, the increase in the amount of cargo equipment, due to a merger or acquisition, further contributes to the decrease in average costs above the increase in the size of the company. On the other hand, the increase in average costs in low-cost airlines is mainly due to the technological changes used to imitate full-service companies and thus become more competitive.

2 Methodology

A traditional approach to measuring firm efficiency measured as the presence of economies of scale, as well as estimating the price elasticity of its inputs, involves estimating a function of benefits or costs. In the case of this company, it is more convenient to estimate the cost function rather than the profit function, because in some of the products the company has some market power, its prices being non-competitive, while the price of the inputs if it is determined by the market (Varian, 1984).

Economies at scale exist in the company if an increase in production results in a less than proportional increase in total cost (keeping everything else constant). The most common way of expressing economies of scale (EE) is as follows:

$$EE = 1 - \frac{\delta lnC}{\delta lnY}. \qquad (1)$$

Thus, economies of scale are calculated as 1 minus the derivative of the logarithm of costs relative to output. If the result is positive, it would indicate that the company operates under economies of scale, that is, it has increasing returns to scale; while if the result is negative, there would be diseconomies at scale, where an increase in production results in a more than proportional increase in costs (decreasing returns to scale), and finally if the result is equal to 0, there would be yields constants at scale.

The translog cost function to be estimated will take into account the 21 models of one of the company's most sold products during the period from January 2013 to September 2016[1], the initial estimation method being Ordinary Least Squares (OLS). The translog cost function to be estimated will be the one used by Bitzan and Peoples (2016), where each variable normalizes with respect to its mean, in order to obtain the first order conditions to obtain the elasticities evaluated in the mean. The function is defined as follows:

$$ln\left(\frac{C}{\bar{C}}\right) = \alpha_0 + \alpha_Y ln\left(\frac{Y}{\bar{Y}}\right) + \frac{1}{2}\gamma_{YY}\left(ln\left(\frac{Y}{\bar{Y}}\right)\right)^2 + \sum_i \gamma_i ln\left(\frac{P_i}{\bar{P}_i}\right) + \frac{1}{2}\sum_i \sum_j \gamma_{ij} ln\left(\frac{P_i}{\bar{P}_i}\right) ln\left(\frac{P_j}{\bar{P}_j}\right) + \sum_i \gamma_{Yi} ln\left(\frac{Y}{\bar{Y}}\right) ln\left(\frac{P_i}{\bar{P}_i}\right) + \ln V_i \qquad (2)$$

Variables are defined as: C is the actual total cost[2], Y is the quantity produced, Pi are the input prices: raw materials (M), labor (L), real freight cost (F), actual plant operation cost[3] (P) and administrative cost (A).

We suppose that $\gamma_{ij} = \gamma_{ji}$ and that the error term has a normal distribution with zero mean and constant variance.

According to economic theory, a homothetic production structure is restricted to being homogeneous[4] if and only if the cost elasticity with respect to production is constant (Green, 1998). For the translog cost function, the constraints to be homothetic and homogeneous are described as follows:

$$\sum_i \alpha_i = 1, \quad (3)$$

$$\sum_i \gamma_{Yi} = 0, \quad (4)$$

It is also required that the function be symmetrical in the substitution of inputs:

$$\sum_i \gamma_{ij} = \sum_j \gamma_{ij} = \sum_i \sum_j \gamma_{ij} = 0. \quad (5)$$

In order to find the best model to determine if the company operates with scale economies, or scale diseconomies, in addition to Model A (equation 2), we will additionally estimate 3 econometric models that incorporate the aforementioned constraints: Model B imposes the restriction of homogeneity, model C imposes homotheticity restriction and finally model D imposes the constraint of unit substitution elasticity.

The results obtained from the four models (A-D) present problems of multicollinearity, since the costs of the inputs are related to each other, for which it is necessary to obtain the equations of the participation of the cost of each input. To obtain these equations, it is first necessary to obtain the demand function of the factors of production, which is obtained by differentiating the function of costs with respect to the prices of the inputs. According to Shephard's Lemma this function is described as follows:

$$\frac{\delta C}{\delta P_i} = X_i \quad (6)$$

In the logarithmic form it would be as follows:

$$\frac{\delta lnC}{\delta lnP_i} = \frac{P_i X_i}{C} = S_i \quad (7)$$

S_i indicates the participation of the cost of input i in the total cost. Using the translog cost function, we can estimate the cost-sharing equation as follows:

$$S_i = \alpha_i + \gamma_{Yi}\, lnY + \sum_j \gamma_{ij} lnP_j. \quad (8)$$

When all the equations of the inputs involved are obtained, a system of equations formed by equation (2) and (n-1) cost sharing equations (equation 8) will be obtained to avoid perfect colinearity[5]. To improve the efficiency of the parameters, the estimation method will be that of Seemingly Unrelated Equations (SUR) (Green, 1998).

3. Descriptive Statistics

In order to determine whether the company operated under economies of scale or diseconomies of scale, we proceeded to estimate the translog cost function taking into account the 21 models of one of the products of which the company has the largest sale in Mexico during the period of January 2013 to September 2016. The translog cost function will be initially estimated using the Ordinary Least Squares Model.

Table 1 presents the descriptive statistics. The average total cost of the period analyzed is $26,223 dollars (base 2010 = 100) with a standard deviation of $ 22,160.6, this standard deviation is presented since the costs vary according to the weight of the model, which ranges from 25 kilograms to 1.5 tons. Production, on the other hand, presents an average of 32 units and a standard deviation of 49.

Regarding the participation of the inputs in the cost, it is important to mention that the company is an assembly company and belongs to the manufacturing industry, it is specific to the metal-mechanical subsector. Its production is carried out with the work of the operators (hours of labor) with minimal robotic intervention, the sample indicates that the participation of this input in the cost is only 2%. Raw material costs represent on average 61% of the total cost. The remainder consists of freight costs, plant costs and administrative costs and will be considered as the part of the variable costs of the technological change.

Table 1. Descriptive Statistics

Variable	Mean	Standar deviation
Total Cost ($)	26,223.0	22,160.6
Production	31.9	48.8
Participation of the inputs in the cost		
Raw material	0.611	0.067
Labor	0.020	0.014
Freight	0.061	0.011
Plant cost	0.058	0.013
Administrative cost	0.250	0.068

Source: Own elaboration with data of the company.

4.Results

The following table shows the results obtained from the four models. The results of Models B and C indicate that, because the corresponding parameters (specified in equations 3 and 4) are not significant, none of the constraints is consistent with the firm's data. In the case of the constant substitution elasticity constraint (Model D) we find that the coefficients involved in equation 5 are not significant, which was an expected result, since in the case of this company the production process is manual and costs depend largely on the price of raw materials.

The results indicate that the estimation of the translog cost function shows a good overall adjustment, with an R squared of 99%.

It is found that if the price of raw materials increases by 1%, the total costs of the company increase by 0.95%, while if the administrative costs are decreased by 1%, the total costs would be reduced by 20%. Costs that are less than proportional are labor costs and plant costs, having a coefficient of -0.26 and -0.13 respectively. As expected, the only input that has a direct effect on output is labor. There is also complementarity in labor costs with administrative costs.

From equation (1) we find that the coefficient of lnY is 1.00 and replacing it in the formula EE is 0, which indicates that this company operates with constant economies of scale so doubling the production requires double the costs.

The ideal for any company is to operate under economies of scale, which means that the total cost begins to decrease as production increases. According to Pindyck and Rubinfeld (2013), there are 3 possible ways in which a company could operate with economies of scale: the first is that if the company operates on a large scale, workers could specialize in the activities in which they could to be more productive, for this, at least in the short term, the space of the factory and the machinery should be adequate for the workers to do their work effectively. In the case of this company, the use of machines is minimal, so it will be analyzed that the number of employees is appropriate given the physical space and also their productivity. According to the theory of production, there are an optimal number of workers that minimize costs and this occurs at the point where the marginal product must be equal to the average product.

Graph 1 shows the relationship between the total monthly production and the number of employees of the company in the period of time analyzed.

Source: Own elaboration with data of the company.

Graph 1. Production and number of employees

The graph shows that there is a linear relationship between production and the number of workers, so that as the number of workers increases, production will increase at a constant rate. This makes sense since being a company with minimal machinery intervention; its main factor of production is labor, so its capacity is not limited. In economic terms, the average product per worker is equal to the additional production that is generated by hiring an additional worker.

To obtain the average and marginal product of this company, the total production function will be estimated, that is, without considering the type of model to which the product belongs. The period

considered is from January 2013 to September 2016. It will be taken into account that as there are no workers, there will be no production, so a model without a constant will be considered:

$$y = \beta L + \varepsilon \qquad (6)$$

Variables are defined as: y is the total production of the company; L is the number of workers. It is assumed that the error term has a normal distribution with zero mean and constant variance.

The results are presented in Table 5. For each extra worker, the production increases by 17 units on average. We conclude that the marginal product and the average product are equal, and the number of employees is optimal.

The product is made in three different assembly lines, divided according to the weight of the product and classified in small (from 25 to 60 kilos), medium (from 60 to 350 kilos) and large (from 400 kilos to 1.5 tons). In the case of this company if workers perform repetitive tasks in each line of assembly is very likely to learn from accumulated experience how to perform their work quickly and efficiently, which in theory their costs should decrease with experience. To analyze if this is the case of the company, the following learning curve will be estimated for the period from January 2013 to September 2016.

$$\ln C_t = \alpha + \beta \ln n_t + \delta \ln y_t + u_t \qquad (7)$$

Variables are defined as: C is the actual total cost in month t, n is the cumulative production in month t, and y is the production in month t. It is assumed that the error term is distributed normally with zero mean and constant variance. The results are shown in Table 6:

The results indicate that the parameter of unit cost elasticity with respect to cumulative production is -0.025, and indicates that for every 1% accumulated production increases, the total cost only decreases

0.025%. This would be an area of opportunity for the company, where technology intervention should be considered in terms of automating some processes that reduce costs.

According to Pindyck and Rubinfeld (2013) the second reason why a company can operate with economies of scale is that the management of a company may be able to negotiate the price of inputs for the advantage of operating higher volumes or for an efficient management of its costs. In the case of the company, the raw material is bought from a subsidiary company so there is no negotiation, since prices are determined by the market. In terms of cost efficiency, it was found that this company uses a standard or traditional cost system also known as the traditional cost absorption system. This system is a costing technique employed that seeks a way to distribute indirect costs (Skoda, 2009). Today many companies use this methodology because of their simplicity and good results, and focuses on the distribution of indirect costs (such as consumables, maintenance, depreciation, electricity, water, gas, etc.) using hours of labor or machine time, however, some of the operations can be "punished" at high costs due to this cost distribution. The traditional unit cost perspective used in standard costing is counterproductive because it tends to direct managers' attention to actions at product unit level to consider a price increase, for example, or to reduce direct labor, the materials or the processing of the machines (Cooper and Kaplan, 1991).

What is proposed to analyze whether management of the company is effective is to compare the current cost method with another method of cost taking into account the level of production of the year 2016 to determine if the company is more profitable to consider a new form of cost which gives more analysis and a perspective focused on seeing the processes individually rather than in general, as does the traditional cost system. Specifically, it will compare the rate of return on sales between both methods of costing. The proposed cost method is Activity-Based Costing (ABC). This method was developed with the purpose of improving the use of accounting information, providing management with a more complete picture, such as determining which product is the most profitable and which ones are the areas of opportunity that require supervision (Tsai, et al., 2009).

Among the main characteristics of the ABC model is the identification of the manufacturing activities and the management of consumption resources of each product. According to Tsai et. al. (2009) in the ABC model, the hierarchy of the company's activities is composed of the following categories: unit-level activities (according to the product service unit, for example machining, finishing); activities at batch level (according to batch of products or services, for example configuration, programming); activities at product level (made to benefit all units of a particular product or service, for example product design); and activities at the facility level (according to the manufacturing facility or service, for example, plant protection and management).

The form in which the mentioned categories will be taken into account will be to divide the models that are within a same line of assembly. In the company there are 3 assembly lines according to the weight of the model, which are classified as mentioned above in small (from 25 to 60 kilos), medium (from 60 to 350 kilos) and large (from 400 kilos to 1.5 tons).

It will begin with the calculation of the standard or traditional costing, for which hourly costs are used. The company calculates the total annual total cost of labor, the total annual cost of plant costs, and the total annual cost of administrative and selling expenses, each of these items being then divided by the total time to be spent to be required for annual production. First, to calculate the cost of annual labor, only the basic salary of the operators will be taken into account, without any provision or extraordinary payment, then the calculation is based on the total number of operators for their annual base salary; Second, for the costs of the plant, all its consumables are calculated on an annual basis to be able to operate. This data involves the finance department, maintenance, production, materials, quality, engineering, continuous improvement and plant management. Finally, to obtain the administration and sales expenses, the finance department meets with the department of marketing, sales and human resources to determine this expense, since it is the departments that contribute intangible resources to the organization and, therefore, independent rate for them.

Once the mentioned costs are obtained, it would be necessary to obtain the total time that will be required for the annual production. Table 7 shows the times required for each model.

Table 7.- Times required for each model

Model	Time (Hours)	Model	Time (Hours)	Model	Time (Hours)
A	1.47	H	14.23	O	23.42
B	1.93	I	14.32	P	19.34
C	2.39	J	20.46	Q	12.79
D	4.91	K	26.51	R	22.99
E	4.94	L	24.99	S	46.90
F	5.68	M	35.64	T	33.06
G	7.04	N	18.12	U	26.38

Source: Own elaboration with data of the company

Then, the required time of each product is multiplied by its volume in the year (in this case 2016) and the results are summed to obtain the total amount of available hours of this year, the formula is presented in the equation:

$$Ttotal^{6} = \sum t_i * Q_i \qquad \text{i = model} \qquad (8)$$

The result is 61,495.07 hours available.

Once the process is completed, the company determines the hourly costs for each model i of labor, plant costs and administration and sales expenses according to formulas 9 to 11. With this methodology, they make sure that the cost incurred annually is distributed and covered in each salable unit:

$$MO = \frac{\sum Maintenance\ expenses\ MO_i}{\sum t_i * Q_i} \qquad (9)$$

$$Plant\ OH = \frac{\sum Plant\ OH_i}{\sum t_i * Q_i} \qquad (10)$$

$$SG\&A = \frac{\sum SG\&A_i}{\sum t_i * Q_i} \qquad (11)$$

Derived from these calculations will obtain the costing rates for the models:

Table 8.- Costs according to the Traditional model (TAC) ($ per hour)

Assembly line	MO	Plant OH	SG&A
Model i	$ 2.00	$ 6.51	$ 25.52

Source: Own elaboration with data of the company

Considering the ABC model, the costs were distributed based on the production per assembly line (j) and the required times of each product:

$$MO = \frac{\sum Maintenance\ expenses\ \ MOj}{\sum t_j * Q_j} \qquad (12)$$

$$Plant\ OH = \frac{\sum Plant\ OHj}{\sum t_j * Q_j} \qquad (13)$$

$$SG\&A = \frac{\sum SG\&A\ j}{\sum t_j * Q_j} \qquad (14)$$

j is the assembly line according to the size of the model (small, medium and large line).

The same operations were carried out for each of the groupings, obtaining the costs presented in Table 9.

Table 9.- Costs according to the ABC model ($ per hour)

Assembly line	MO	Plant OH	SG&A
Small	$ 2.43	$ 5.78	$ 22.61
Medium	$ 1.36	$ 5.85	$ 22.29
Large	$ 2.72	$ 19.84	$ 83.52

Source: Own elaboration with data of the company

In order to analyze the difference of apportioning costs between all the models (Traditional Model) and the costs grouped according to the assembly line (ABC Model), we will compare the rate of return on sales[7] obtained for which will be taken into account the sales in 2016 and each of the costing methods. Table 10 presents the results.

Table 10.- Rate of return on sales

Assembly line	TAC	ABC	Difference
Small	10.8%	14.0%	3.1%
Medium	14.1%	18.4%	4.3%
Large	48.3%	34.2%	-14.0%

Source: Own elaboration with data of the company

The results indicate that for models that are manufactured in small and medium assembly lines, considering ABC costing would be beneficial, whereas for large assembly line models it would be the opposite, as these show little sales compared to the other models, and have very high costs, which are amortized using the traditional methodology.

The area of opportunity in this regard, is that the company usually sets its prices based on their costs plus a percentage of utility, so the price of large models would be below what it should be.

The third reason a company can operate with economies of scale is that the company must have flexibility in the use of inputs and thus organize its production process more effectively. According to the results obtained in Table 4, it is observed that there is very little substitution between labor and freight (-0.075) and between labor and administrative cost (-0.057). These results indicate do not present area of opportunity.

5.-Conclusion

The results indicate that given its cost and production structure, in 21 of the models of one of the best-selling products in Mexico during the period from January 2013 to September 2016, the company in this study operates with constant returns to scale.

The elasticities are evaluated in the average value of the sample and indicate the raw materials have a more than proportional effect because if their price increases by 1%, the costs of the company would increase by 0.95% and if the administrative costs are decrease by 1%, total costs would be reduced by 20%

According to Pindyck and Rubinfeld (2013) there are 3 reasons why a company can operate with economies of scale, which were analyzed to find the areas of opportunity for the company to reduce costs as production increases. It was found that in two of the three reasons the situation could be improved: the first is that by analyzing the relationship between the number of workers and production, it is found that the average product is equal to the marginal product, that is, the company operates with a number of efficient workers; however, the learning curve indicates that for every 1%

that accumulated production increases, the total cost only decreases 0.025%, this may be due to staff turnover, however, given the existing technology, certain processes could be automated to improve efficiency. The second reason is that the management of a company could be more effective when using the costing method ABC, which consists of identifying the manufacturing activities and the management of consumption resources of each product according to the assembly line and not in a general way as it does with the traditional costing system. It is found that with the ABC system, the rate of return in the small product line would be 14% compared to 10.8%, and the medium is 4.3% higher when compared to traditional costing.

As mentioned, the manufacturing sector has experienced sustained growth in Mexico, so that this company, as well as the many that belong to this sector, must take advantage of technological and administrative resources of the way in which they operate in the day to day, and thus lower their costs as they increase their production, in other words, operate with economies of scale.

Endnotes

[1] Corresponds to the latest available data provided by the company
[2] Base 2010=100
[3] Includes maintenance, spare parts, consumables (water, electricity, gas), depreciation, quality, etc.
[4] For a fixed level of production, the total cost must increase proportionally when prices increase
[5] $\sum_i S_i = 1$. The equation that will not be taken into account will be S_L the participation of the cost of labor.
[6] *Ttotal* refers to the total time of labor hours available
[7] The rate of return is obtained by dividing the profit on sales.

The Rural Area, Land Fund and Restitution of Agricultural Land Property In Romania After 1990

Tiberiu Iancu
Banat University of Agricultural Sciences and Veterinary Medicine, Timisoara, Romania, e-mail address iancutiberiu10@gmail.com

Silvius Stanciu
„Dunărea de Jos" University of Galati, Romania, sstanciu@ugal.ro

Abstract

Romania's rural development experienced a complex evolution after the change of the political regime in 1990, being influenced by the national policies regarding the land fund field and land retrocession to former owners. The process of land investiture of the Romanian farmers was ambiguous, sinuous and difficult to apply. Land property and agricultural land property restitution constituted a process running for over 20 years, which is still not concluded. The paper analyses the evolution of the land fund and agricultural land property law after the 1990's, as well as the rural environment with regard to agricultural land. After the land retrocession law came into effect and was applied, starting with the year 1996, the percentage of privately owned land fund started to increase, reaching over 73.6% in 2007, a constant value up to the present day. The evolution was much more accelerated in the case of private agricultural land, which registered a rapid increase reaching 72 % in 1997 and over 93% in 2014. Deficiencies of the national legislation favoured unsystemised retrocessions, sometimes without complete supportive documents, which generated injustices and abuses, punished in some cases by national and international fora. The fragmentation of agricultural land, also due to the defective system of land realottment of the Romanian farmers, affected the performance of the national agicultural production and favoured the alienation of Romanian land. Measures undertaken by Romanian officials in the field of agricultural land were dictated by social criteria, economic pressure, unprofessional adherence negotiations or momentary political interests.

Keywords: agricultural land, rural, restitution, Romania

Introduction

With a total surface of 238 thousand km^2, representing almost 6% of the total European Union surface and a population of about 19 million inhabitants (circa 4 % of the European population) Romania is the second new European Union member state in terms of size, after Poland. The Romanian territory possesses a generous natural potential, with agricultural land of good quality soils, rich in land and human resources. Up to the present, these advantages observed a limited influence in generating a significant development and restructuring in agriculture and in rural areas. The reconstruction of property right on agricultural and silvan land constituted a difficult pocess in Romania, which is still not concluded. In many cases, land restitution has resulted in damage to a territorial delivery. The structures and functions of the Romanian rural area and restitution of the property right, generated social tensions and conflicts, manifestated at the territorial organization and urbanism organization. The greatest pressure at the level of land areas was felt into the territorial organizations ownership in the vicinity of urban areas, where the high value of lands was determined by the high prices and the great real estate pressure (Rusu et al, 2011). The demarcation of the land for retrocession to the old locations was made by the municipal councils of the administrative-territorial units on which the land is located, the restitution claims being

submitted to the offices of the territorial-administrative organizations. An analysis of the rural development and land restitution could not be achieved without the present territorial organization, focusing on towns, communes and villages.

Short Literature Review

Ienciu, Tudorascu and Oprea (2014), in an analysis regarding the porperty right in Romania, highlight the importance of technical topographic and cadastral expertise, in a complex paper including complex working stages carried out with adequate equipment, in difficult conditions, for the reconstruction of the agricultural property right. Gavrilescu, (1993), performs an analysis of Romania's transition to a market economy, refering to the agri-food production, mentioning the fact that it will be a complex long-term process. Van Meurs (1999), carries into effect a comparative study regarding rural policies during the inter-war, communist and post-communist period in Romania. The author concludes that, in Romania, there was always a tendency for strict state control of the agricultural production, rural environment and property right, no matter the political regimes succeeding each other during the entire 20th century. Romanian political leaders have always opted for the application of short-term solutions to social problems of the rural environment, imposed by political and social pressures, neglecting a parallel approach to the economic and technical aspects necessary for the modernization of the agricultural production. Brooks and Van Meurs (1994), based on surveys carried out in 1991 in România, describe transitional models linked to agricultural land property, comparing individual farms and private property. During the analysed period, homesteads registered a slower reaction in developing competitive markets. However, agricultural associations seemed to be even less receptive to market stimuli, compared to private farmers, slowing down the agricultural sector evolution towards a market economy.

Prosterman and Rolfe (1999), in their research regrding the development of agricultural land markets in Lithuania, Poland, and Romania analyse the legal base of agricultural land transactions, in the context of a potential adherence to the European Union. For each of the analysed countries, agriculture plays an important role in the national economy, and agricultural land represents a resource and porperty right for one- fifth of the population. At Romania's level, the authors underline less ethical aspects of agricultural land acquisition, on the basis of ex-property presumptive rights.

Mihalache and Croitoru (2011), carry out an analysis of the Romanian rural environment, highlighting evolutions as well as involutions, during a research achieved with the help of European funds, in order to promote a specific form of inclusion of persons from the rural environment on the labour market, by supporting training, professional reconversion and entrepreneurial spirit development programs, depending on the target group characteristics. Istudor and Popescu (2016), during a work meating dealing with agricultural policies, land market and property relations in agriculture, which reunited specialists of the Romanian agri-food economy field, perform a complex analysis of the agricultural land situation, major tendencies of alienation to foreign investors and of the national agricultural policies, incoherent, unadapated and inefficient in promoting the national agricultural section.

Material and Method

The research method was that of secondary data collection, published in statistical databases, magazines, magazines, newspapers, books, online portals and other sources. Data-based research has become more and more widespread. As Johnston notes, secondary data analysis is flexible and can be used in many ways, being an empirical exercise and a systematic method based on well-defined procedural and evaluative steps (Johnston, 2014).

The data refering to the approach of the Romanian land fund and rural environment issue were selected from specialty literature, public reports of Romanian bodies in the field (the Ministry of Agriculture and

Rural Development, the National Authority for Property Restitution, the National Institute of Statistics), relevant national legislative regulations, in effect in Romania. The data were processed, graphically represented and interpreted. For an optimal interpretation, where found, the obtained results were compared to relevant data from scientific literature.

The Romanian Rural Area

According ot Law 350/2001 regarding territorial organisation and urbanism, respectively Law 351/2001 regarding the approval of the National Territorial Organisation Plan, from an administrative point of view, at a NUTS 5 level, Romania's territory is organised in 320 localities (of which 103 municipalities, the most important towns), which form the urban area, and 2,861 communes, which constitute the rural area (figure 1). The commune includes one or several villages comprising rural population, and it is organized according to economic, socio-cultural and geographical conditions.

The villages, the smallest administrative-territorial unit, where the mayor office resides, are the commune villages. There are about 13,000 villages in Romania with a slight decrease in the analyzed period.

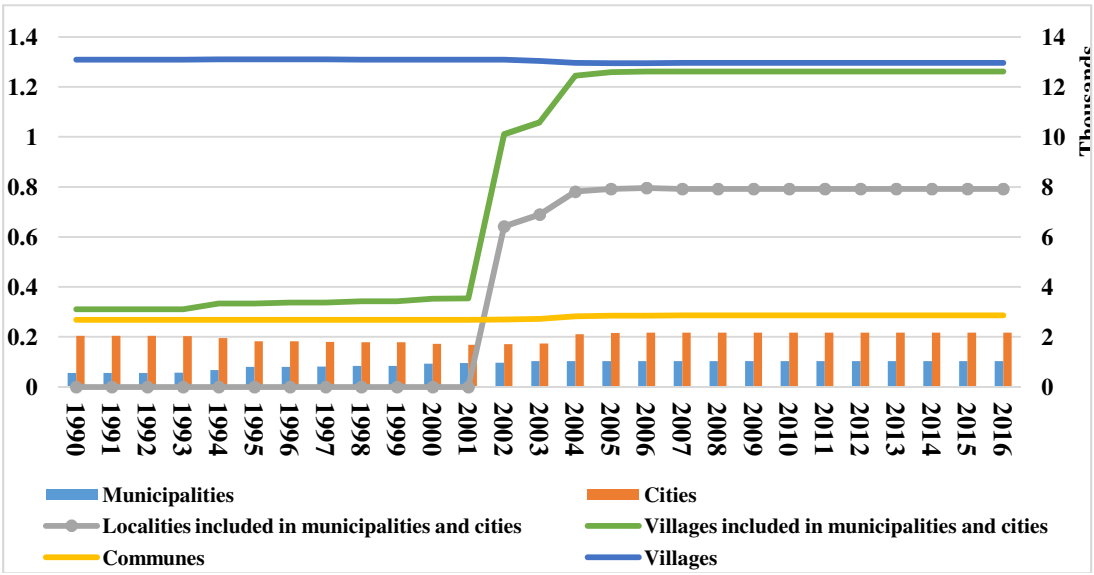

Figure 1: Locality distribution in Romania, on categories

Source Authors, by using NIS data (2017)

Communes are generally formed by several villages, with no administrative responsability. In 2016, in Romania there are 12,957 villages (Management Authority for the National Program of Rural Development AMPNDR, 2012). In order for a commune to become a town, a specific law must be approved. Towns and communes are grouped in counties (NUTS3 level), with administrative functions. The 42 counties are grouped in 8 development regions (NUTS2), with no administrative functions. The rural space represents an extremely complex concept, which generated a great diveristy of opinion regarding its definition, scope and components.

According to Bold, Buciuman and Drăghici's definition (2003), the rural includes activities developing outside the urban, and has three essential components: administrative communities (made up of relatively few members with mutual relations), pronounced poulation and collective services scattering, the special role of agriculture and forestry. Although, from an economic point of view, agriculture and forestry

occupy an important place, the rural sense is larger than agricultural or silvan, comprising other activites as well, such as rural specific industry; handcrafts, productive services refering to agricultural production and non-productive ones specific to the rural population.

After the restitution of the land properties, there is no significant evolution of the number of communes or villages in Romania. An important change can be observed in the evolution of localities included in municipalities and cities, the number of which increased by 400% between 1990 and 2016. A possible explanation of this evolution can be found in the return of agricultural land in the vicinity of towns to owners who have been converted into habitable areas.

Rural areas in Romania cover 87.1% of the country territory, encompassing 47.2% of the population, and 8.98 million inhabitants in 2011 (National Insitute for Statistics NIS, 2017). The Organization for Economic Cooperation and Development (OECD) considers rural settlements those areas, in which the density represents less than 150 inhabitants/km^2. According to this criteria, only the capital and some counties (Ilfov, Prahova, Iași) may fall under the category of urban spaces. The OECD methodology for the rurality notion allows comparisons with other member states. According to territorial distribuition, Romania's populaiton rurality level is much more pronounced than that of other Eu countries, where rural settlements are less populated and at a lower scale, generally considered as an alternative to urban concentrations. Many rural communities contribute in a small way to economic growth, but preserve their social structure and traditional way of life. In relation to the Eurostat data from 2012, citated by AMPNDR (2012), circa 45.5% of the Romanian population resides in rural areas, 43.9% in intermediary regions and10.6% in urban areas. In the context of a continuous demographic decline, the share of urban population in the total population continued to rise to the detriment of the rural population (figure 2).

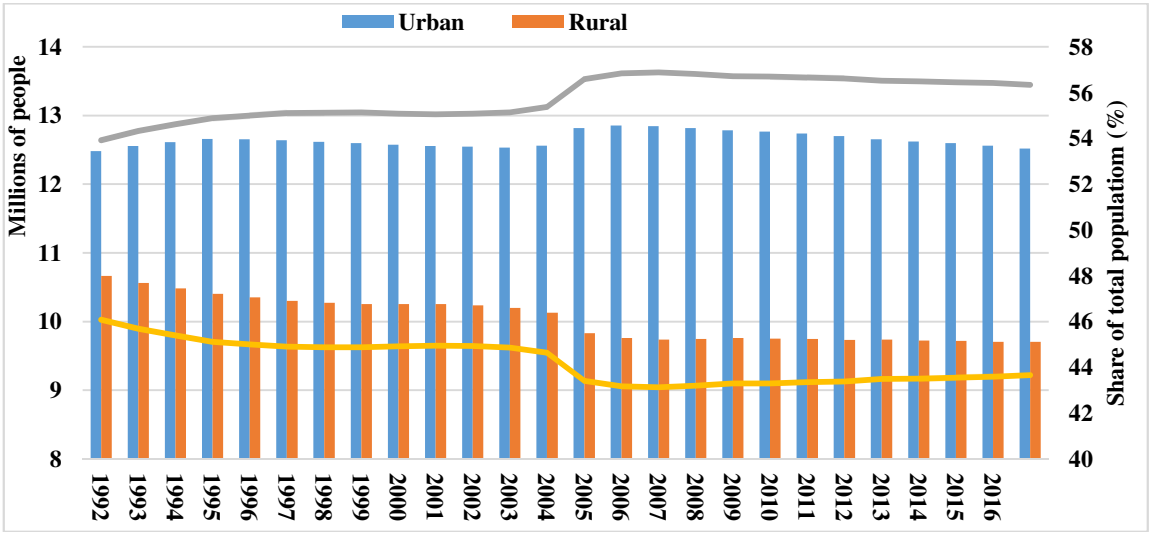

Figure 2: Romania's rural and urban population

Source Author, by using NIS data (2017)

Based on the demographic analysis, it can be seen that the restitution of agricultural land has not led to a revival of the rural population, as expected.

After the change of the political regime in Romania, changes took place in all areas of the economic, social and political life. Based on the measures destined for rural programs developed in Romania, four stages can be outlined in the development of the rural area. The first measure, during the post revolution period, was that of agricultural and forestry land retrocession to former owners, by applying the Land

fund law 18/1991, augmented by the Law 1/2000, followed by the measures undertaken during to Romania's European Union pre-adheration stages, activities towards the integration in the EU structures, and, at present, by the national rural program for the period 2014-2020.

The increase of the competition within the rural sector calls for some actions leading to the economic performance growth and market access for farms, by gaining access to the proper agricultural surfaces, modernizing and restructuring production, increasing the volume of quality agricultural production, or continual stimulation of the processing and commercialization unit modernization. Modernizing and developing the processing sector insures, on one hand, the maintenance of working places and, on the other hand, the creation of new working places (AMPNDR, 2017).

An important influence on the development of the rural environment is that of agricultural land property. Agriculture, the activity that basically defines the rural environment, is facing major problems, given by the large number of agricultural exploitations and the overwhelming percentage of those with no legal personality, wich operate on a 5 hectare surface, and are considered to be the great structural disadvantages of the Romanian agriculture.

The Restitution Of The Private Property Right On Agricultural And Silvan Land In Romania

The restitution of the private property right on agricultural and silvan land in Central and Eastern European countries aimed at creating a private agricultural and silvan sector and rural area market economy. Most ex-communist counries approached the issue of property retrocession in an open, decissive manner, right after the change in political regime and transition to a market economy. Thus, in Albania, Bulgaria, Hungary, Czech Republic and former East Germany, nationalized real estate retrocession laws were adopted before the end of 1993, in Croatia in 1996, and in Makedonia in 1998. Although in Romania, the issue of retrocession of abusive overtaken property was adressed right after the revolution, the problem is far from being resolved.

The world of the Romanian village underwent a continual transformation process after the inter-war period, which led to a change in terms of rural locality specific, as well as the population demographic, occupational and value coordinates. The traditional village went through important structural modifications during the communist regime.

The collectivization process, the massive unrbanization and industrialization of the ′50s-′70s radically transformed the economic activity, life style and customs of Romania's villages, leading to the disappearance of a traditional form of social life organization (Mihalache and Croitoru, 2011).

After the revolution from 1989, The Romanian rural environment entered a new evolution stage, characterized by a ruralization of the country, economic difficulties and the increase in rural heterogenity. The first years after the revolution represented a process of re-rualization of the country, the rural environment and agriculture representing a refuge for population segments affected by the economy restructuring. The urban-rural migration, the de-industrialisation, the overall agricultural employment of the rural population, the practice of subsistance agriculture on a large scale are specific processes for this stage.

During the last 25 years, politicians elaborated a series of laws, governement decisions and other normative acts, in the attempt to reinstate the rights of property nationalization victims of the communist era. The laws regarding land restitution and distribution were accompanied by laws regarding new organization forms in agriculture.

The process started in 1990, when the members of agricultural cooperatives gained property rights over a surface of 0.5 hectares – an increase of the traditional 0.3 hectares lots of the homesteads. This restitution was not based on a principle or law, people working the land just gained a property right for the extra surface, thus commencing the land transfer toward the private sector.

The main legislative norms, issued after the change in political regime in Romania towards the restitution of the land fund property right, were Law 18/1991 and Law 1/2000, later augmented by Law 247/2005, HG 1095/2005, HG 890/2005 and HG 240/2006, respectively Law no. 165/2013. The regulations regarding the restitution of the property right are also specified by Law 10/2001, with ulterior modifications and additons.

The main objective of the Land Fund Law no. 18/1991 was the restitution of private porperty rights regarding agricultural and silvan land. The new Land Fund Law from 1991 lay the foundation for a dual land reform mechanism, based on property right restitution to former owners whose land had been expropriated by the state after the 6th of March 1945, when the first communist regime came into power, and the restitution of land usage rights for those individuals whose land had been administered for years and decades by cooperatives and state farms (World Bank, 2007)

The law adressed cooperative members who brought land to the agricultural production cooperative or from whom the cooperative overtook land, as well as their heirs (Romanian Parliament, 1991). By issuing the law 18/1991, the Romanian peasents were reinstituted with the porperty right over limited surfaces of their land, that is for only 10 hectares, in locations decided by the commissions responsible for the application of the law. These provisions generated abuses of the commissions, who distributed the land as they liked, and a long series of trials.

The second undergoing of land property restitution was regulated by Law no. 1/2000 for the restitution of property rights on agricultural and silvan land, requested in accordance with the provisions of the Land Fund Law no. 18/1991 and Law no. 169/1997, also called Law Lupu (Romanian Parliament, 2000).

According to the regulations of Law no. 169/1997 (a part of the legal project initially proposed by PNTCD representative Vasile Lupu, and adopted with modifications three years later), the owners had to right to request restitutions of up to 50 hectares of agricultural land per family and 30 hectares of forest per family, the actual retrocession being postponed until an ulterior modification provision of the Land Fund Law. However, the law did not command the restitution of the initially owned land. Moreover, according to Digi24 (2017), instead of clarifying the situation, the Law 1/2000 introduced new difficulties in the retrocession process, especially with regard to the problem of restituting the former properties in the same locations. The regulations allowed the mayorhall commissions to decide what and where to restitute. In addition, the lack of cadastre in Romania deepened the problem, according to the former minister of agriculture, Achim Irimescu, mentioned by the quoted source.

The Law 400/2002 refered to the reduction of formalities, but allowed a rapid land investiture of thousands of people only based on lists from 1945 as well as the occurrence of uncertain retrocessions, complaints at CEDO and penal dossiers. According to Horațiu Raicu, general secretary at Agrostar, quoted by the afore mentioned source, a situation was created in which surfaces that had to be restituted became much larger than the ones owned in 1947.

In 2005, Law 247 came, which stated that forests and constructions pertaining to agricultural and silvan land were to be restituted in full, and owners on whose land investments had been placed were to be compensated.

Starting with Law 18 in 1991 until 2007, 11 laws and emergency edicts were adopted in order to regulate the land property, and the bureaucracy prevented many Romanians from getting their rights (DIGI24, 2017).

The legislation was ulteriorly augmented by Law no. 165/2013 regarding the measures for the conclusion of the resttution process, in nature or by equivalent, of the real estate property overtaken in an abusive way during the Romanian communist period. The measures were anounced by the government at the end of 2012, the law coming into effect in May 2013. For a unitary application of the law, the National Authority of Property Restitution ANRP elaborated HG no. 401/2013, which established the procedure for land restitution in the state private and public sector, as well as the procedure to capitalize it in cash the points received as a result of the compensation decision. Starting with October 2013, ANRP began to issue payment titles for the approved dossiers before Law no. 165/2013 came into effect.

A major change operated at the level of the retrocession law referd to the fact that former owners could be compensated with other goods as well, a possibility introduced by Law no. 368/2013, published in the Government Gazette, 1st Part, no. 819 from 21st December 2013 and coming into efect on the 24th of December (Oprea, 2014). Although the law foresaw as resolving deadline the 1st of January 2016, this deadline was postponed until the 1st of January 2017, when the land the local commissions were supposed to use for the finalization of the restitution process, still not restituted to the former owners, would be included in the National fund of agricultural land and other real estate (entitled the National Fund), administered by the Agency for State Property, and will be subjected to point capitalization in accordance with Law no. 165/2013.

According to public data presented by ANRP (2017) refering to the dossiers for the establishment of property right constituted in accordance with the land fund laws, as a result of the decisions taken on the level of county commissions, the Secretariate of the National Commission for Real Estate Compensation (C.N.C.I.), during 1991-2013, 30,356 dossiers were registered, constituted in accordance with the land fund laws. Among these, 21,954 dossiers were resolved, other 5,010 dossiers passing the analysis stage, and, after adding the requested documents, they will be introduced on the agende of C.N.C.I. for the issuance of the decision for compensation/partial validation/invalidation.

A number of 3.200 dossiers was sent back to the local authorities by the Secretariate, either before the occurrence of Law no. 165/2013, for documentation completion, or after the Law no. 165/2013 was issued, at the request of the dossier holders, in order to benefit from restitution in nature. For the complete dossiers, the Secretariate of C.N.C.I., comprised by A.N.R.P. councilors, proposed/will propose to the Commission compensatory measures. As for the other dossiers, with the approval of C.N.C.I, the councilors requested/will request documents which should clearly state the quality of the owner for the requested real estate property, at the date it was taken over by the state; the quality as an heir of the former owner (in the case of the owner's death); the proof of abusive property overtake by the state; the location of the reclaimed property, in order to establish its value in accordance with the notary grid.

The graphical representation of the status of the restitution requests for agricultural and silvan land at a national level is rendered in figure 3. According to the data presented below, over 70% of the filed dossiers have been resolved until the present moment.

After Law no. 165/2013 was issued, the dossiers constituted in accordance with the land fund laws were processed in the strict order of their registration. Until the moment of this documentation, according to public records, all dossiers registered until 30.06.2017 have been analysed.

The land fund property move after 1990 resulted in relatively consecutive start-ups, although without coherence relations, motivated or supported by scientific or strategic criteria. Actions in the field of the land fund market set out ulteriorly and during different periods as compared to the first post December

agrarian reform from 1991. Thus, Istudor and Popescu (2016), mention that the scond agrarian reform, from 2000, took place belatedly, after the enactment of the main actions on the land fund market - land association, leasing and sail.

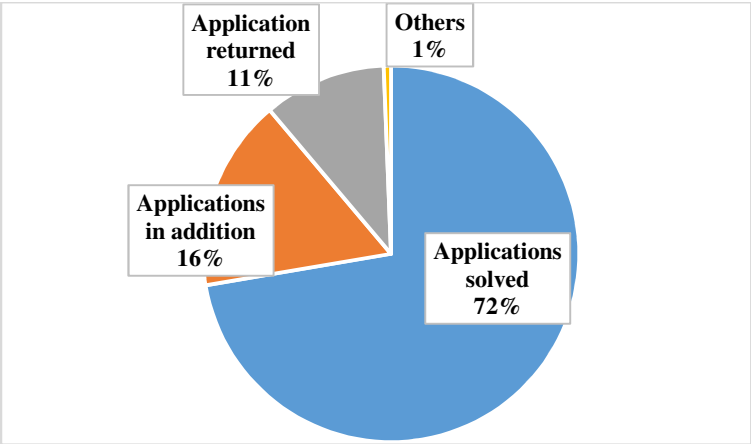

Figure 3: Agricultural land retrocessions resolved on September 1st, 2017
(according to Law 165/2013)
Source Authors, by using ANRP Data (2017)

According to Istudor and Popescu (2016), the restitution of land fund property after 1990 has been inadequate, the main limitations in configuring a durable property regime being the volatile relationing to historical truths; accepting documents for land fund property right restitution based on land measurement units without public homologation/updating; differencial management, by historic regions, of the land fund property; accepting proof with witnesses, because of the lack of public records for the individual restitution of land fund property; deficiencies determined by modifcations occuring in the agricultural landscape and the territorial locality structure; landmark dissolution between individual properties during the communist era, which made lot realignment on old placements almost impossible; occurrence in the legal text of the possibility to restitute land fund property under the formula "usually in the same location", which determined the reactivation of the land fragementation degree from periods anterior to cooperativization; restitution of land fund property only in physical dimensions, and not under the aspect of abstract traits, respectively the natural and economic land value.

These deficiencies in the restitution of land fund property took place on the backgound of preemptory slips, while attempting to solve unbalances caused by decisions based on the social market economy, while, in the Western European area, economic policies based on the neo-liberal doctrine applied. The absence of specific financial instruments which should help stimulate the local entrepreneurship (credits, interests, guaranties, etc.) for land aquisition, affected the position of Romanian entrepreneurs on the land fund market, whose investment capacity was situated under the potential of their EU correspondents.
Romania possesses a land fund surface of 23,839,071 ha, represented according to national statistic data by 14,630,072 ha agricultural land, tillable land 9,395,303 ha, pastures 3,272,165 ha and 1,556,246 ha hayland, in 2014 (figure 4).

Agricultural land represents over 61 % of the total national land fund. On the agricultural category, tillable land predominates (66%), followed by pastures (23%) and hayland (11%), according to the geographic conditions specific to the relief of our country.

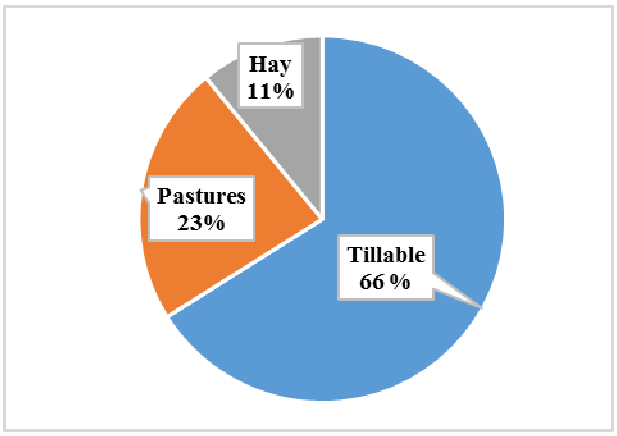

Figure 4: Distribution of the national agricultural surface on land categories
Source Author, by usind NIS Data (2017)

From the point of view of property form, in 2014 over 72% of the total land fund pertains to private property, the rest pertaining to the state (figure 5). The evolution of the land transition from state to private property observed o few main benchmarks. The period 1990-1995, when property title reinstitution represented an incipient process, is characterized by the lack of private land property, showing an insignificant percentage when compared to the state property.

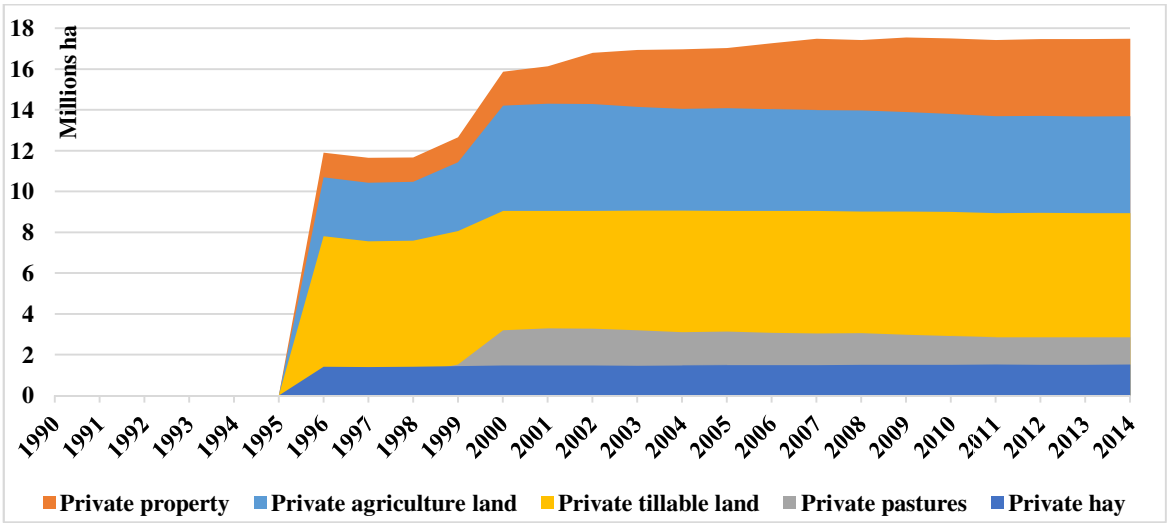

Figure 5: The land fund surface after years and usage, on private property
Source Author, by usind NIS Data (2017)

After the legislation regarding land restitution came into effect and was applied, starting with 1996, the private property percentage started to increase, ranging from 49.94 % in 1996, to 68% in 2000, respectively 73.6% in 2007, a value relatively constant until the present day. The evolution was much faster in the case of private agricultural land, which quikckly registered a 72% percentage in 1996, reaching over 93% in 2014 (figure 6).

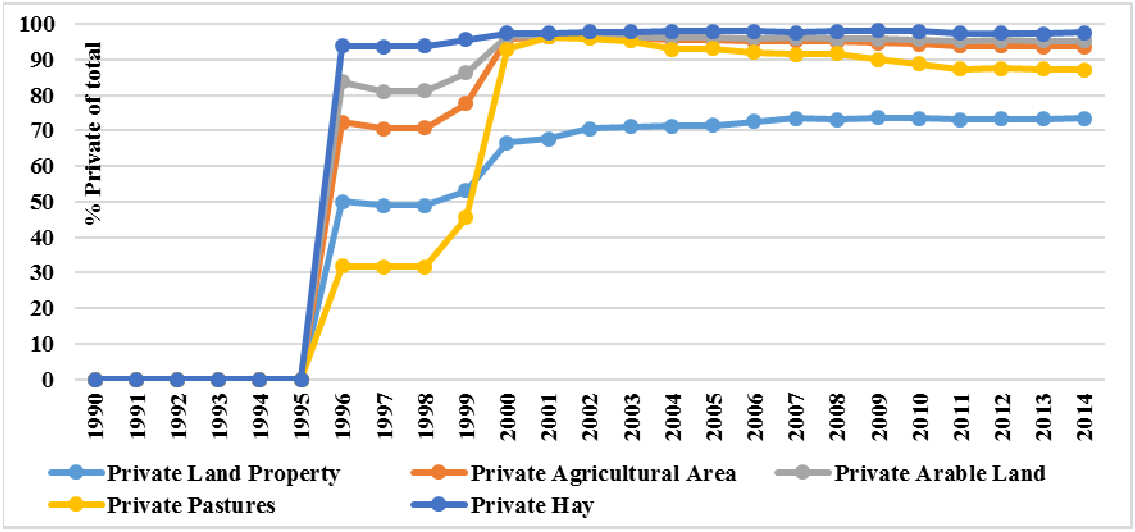

Figure 6: Percentage evolution of private property on land categories

Source Author, by usind NIS Data (2017)

The slowest privatisation process was registered in the case of pastures, whose retrocession percentage started out with 31% in 1996, only reaching 92 % in 2000.

Starting with 2000, the private percentage evolution resembles that of the other agricultural land categories, which achieved a retrocession percentage of over 90%, maintained relatively constant during 2000-2014.

Conclusions

Restitution of land fund property, especially that of agricultural land, represented a difficut process in Romania, devopled during a period of over 20 years, which is not yet concluded. Legal deficiencies favoured unsystemized retrocessions, in some cases without complete supporting documents, generated injustices and abuses, sometimes punished by national and international legal fora. The lack of unitary policies on land restitution without affecting land ownership, accompanied by permissive legislation, has facilitated the fragmentation and acquisition of land by foreign investors.

Until 1995, the restoration of the property was an incipient process.Thus, in the first five years since the change of the Romanian political regime, the private land property represented an insignificant percentage of state property. Since 2000, private property has become a majority with agricultural land. Demographic data have shown that there is a correlation between the return of farmland and development of the rural population, which continued to decline in the period 1990-2017.

As with the majority of situations registered during the last century, Romanian officials did not establish eficient ways to encourage associative forms in Romanian agriculture, protection measures for the local capital and for the growth of economic peformance in the agricultural sector, the decisions taken in the land fund field being dictated by social criteria, internal or international economic pressures or momentary political interests.

Abstract

Although it has been introduced a long time ago, social entrepreneurship as a concept has still not been adequately addressed in theory and practice within the East European educational system. In this paper, we analyze the current state of social entrepreneurship in South East European (SEE) universities' and colleges' course syllabi and compare it with the best world practice i.e. US and UK universities. First, we explore previous surveys on social entrepreneurship education conducted in the East European Countries, the US and the UK. Next, we conduct a content analysis of syllabi (targeting both topics and pedagogical approaches) across East European Universities which will allow us to reach an unbiased conclusion on the current state and perspectives of social entrepreneurship education in the SEE region. Our research conclusion was based on the survey results, and at the level of 2% presence in academic syllabuses of SEE universities are very disappointing and showed a serious delay in contemporary entrepreneurship education in contrast to the US.

Keywords: *Social entrepreneurship, Social entrepreneurship education, Syllabi*

1. Literature Background of Social Entrepreneurship Surveys

1.1. ***Introduction***

Entrepreneurship as a concept, career choice or academic education in all post-communist and transition societies has lagged behind West European countries and the US for a variety of reasons. The introduction of entrepreneurship into the academic curricula of the South East European (SEE) countries mostly started in the 21st century with a small number of pioneers in the field. In contrast, US universities saw its introduction in the mid 50's. According to Fayolle (2000), entrepreneurship education at the university level is a rather recent phenomenon in France where it was also introduced in the 1990's. The situation is even worse at our observed research context, i.e. the SEE countries. Not only has entrepreneurship education been introduced rather late, but there is also an evident lack of academic papers regarding the content, approaches, teaching methods and/or the outcomes of entrepreneurship education. Moreover, no research on the presence of Social entrepreneurship (SE) education in the SEE has been conducted yet.

SE as a part of the curriculum was first introduced many years ago. AshokaU and Harvard University introduced SE to the US educational system in the 1970's (Fiet, 2001). Since then, the number of public and private initiatives involved in training and educating people to be more entrepreneurial has multiplied on both sides of the Atlantic (see, for example, Fayolle, 2000).

In the SEE countries, particularly post-communist and transition ones, entrepreneurship and especially SE is still insufficiently included in the society. Furthermore, it is not clear how the Croatian legislation tackles opening and running social enterprises. Although there has been improvement, owing to the Croatian accession to the EU, progress feels slow. Indeed, in 2015 the European Union (EU) commission in its report did not reveal the exact number of existing social entrepreneurs or social enterprises or the existence of a specific legal form designed exclusively for social enterprises in Croatia. When Croatia joined the European Union, the National Strategy for the Development of Social Entrepreneurship was launched in 2015 which, with the adopted legislation, helped a bit those who plan(ned) to be(come) social entrepreneurs.

Hoogendoorn et al. (2011) notice that the majority of research in the field of social entrepreneurship has focused on the definition of social entrepreneurship itself, and with an extensive literature review of the field of social entrepreneurship we discovered many definitions (see Brock et al., 2008; Peredo and McLean, 2006; Tan et al., 2005; Dess, 1998).

Business education for social entrepreneurship is an emerging area of both study and practice (Peredo and McLean, 2006). The review of academic literature shows that there is an evident lack of surveys on entrepreneurial education, and particularly on social entrepreneurship education curricula in the SEE which is the main purpose of this paper. Our paper is organized as follows: 1) literature review of social entrepreneurship education; 2) identifying key educational topics in social entrepreneurship education; 3) identifying key pedagogical and teaching methods used in social entrepreneurship education; 4) collecting social entrepreneurship curricula from the selected SEE countries; 5) content analysis of the collected curricula; 6) presentation of survey results and recommendations.

1.2. Entrepreneurship and Social Entrepreneurship Surveys

Many previous studies explored the effect of entrepreneurial intentions as a subfield within entrepreneurship research (Langer et al., 2016; Linan and Fayolle, 2015; Kruger et al., 2005; Lee and Wong, 2004; Reilly and Carsrud, 2000; Weihe and Reich, 1991; Hills and Welsch, 1986; Shapero 1984; Shapero and Sokol, 1982). Most of the researches focused on Ajzen's (1991) theory of planned behavior (TPB), which was identified as the best predictor of the respondents' future entrepreneurship behavior (Salamzadeh et al., 2013; Iakovleva et al., 2011; Engle et al., 2010; Kruger et al., 2000). Recently Rajh et al. (2016) used the TPB to explore entrepreneurial intention of students in the SEE countries and concluded that the respondents from Bosnia and Herzegovina exhibited a higher level of the entrepreneurial intent. Shaw and Carter (2007) explored the difference and the similarities between the for-profit and non-profit entrepreneurship and found that contemporary practice is similar in most of the topics.

The authors of social entrepreneurship academic papers use several important milestones in the introduction of the term social entrepreneurship: 1) in the 18th century UK industrialist Robert Owen started to protect employees through broader social context of education and inclusion (Shaw and Carter, 2007; Perić and Delić, 2014); 2) the term was introduced in the 1980's by Bill Drayton (Perić and Delić, 2014; Cukier et al., 2011); 3) it was additionally promoted by Muhammad Yunus, the Nobel Peace Prize winner from India (Perić and Delić, 2014; Cukier et al., 2011).

As a new concept in academia and the practice, SE is insufficiently surveyed (Brock and Steiner, 2009). The situation is the same in the SEE countries - entrepreneurship is insufficiently surveyed, (Perić and Delić, 2014). Cukier et al. (2011) conducted content analysis of 567 unique articles from 1987 to 2008 and revealed patterns in researches and confirmed very limited empirical data on the topic, confirming the need for a more rigorous empirical research. Hoogendoorn et al. (2011) confirmed that socially motivated entrepreneurs are less likely to survive the earliest levels of the entrepreneurial engagement. Furthermore, highly educated individuals are more likely to become social entrepreneurs. Austin et al. (2006) conducted a comparative analysis of commercial and social entrepreneurship. Vidović (2012) conducted multiple case studies and interviews with relevant actors in the supportive system, aimed to provide insights into the basic features, aspects, and roles of social entrepreneurship

Wu et al. (2013) conducted Web based survey of the content, learning and teaching methods, professional specialties of the teachers, and grading of the curricula. Salamzadeh et al. (2013) investigated awareness, intentions/support, and the contextual elements among higher education students in the University of Tehran, in order to find the gap(s) in social entrepreneurship education in Iran. Vidović (2012) found that there is an evident lack of SE education in Croatia, where there is not any full program or single curricula and SE was rarely included in general entrepreneurship education, on some universities.

Many authors agree on the manifestation of social entrepreneurship (Salamzadeh et al., 2013; Perić and Delić, 2014; Singer et al., 2011) proposed by Peredo and McLean (2006:64) in situations when an individual (or a group):

1. aim(s) at creating social value, either exclusively or at least in some prominent way;
2. show(s) a capacity to recognize and take advantage of opportunities;
3. create(s) that value ("envision");
4. employ(s) innovation, ranging from outright invention to adapting someone else's novelty, in creating and/or distributing social value;
5. is/are willing to accept an above-average degree of risk in creating and disseminating social value tolerates the risk; and
6. is/are unusually resourceful in being relatively undaunted by scarce assets in pursuing their social venture.

Wu et al. (2013) analyzed the contents of social entrepreneurship education, teaching methods, professional specialties of the teachers, and grading of the curricula. Wiley and Berry's (2015) paper reviewed 16 syllabi for courses taught in US schools of public affairs and administration, largely from schools ranked in the top 30 nationwide. Elmes et al. (2012) examined social entrepreneurship for the academic year 2010-2011 syllabi of selected US and UK universities.

2. Social Entrepreneurship Education

Drucker (2008) sees entrepreneurs as people who are committed to the systematic practice of innovation, not as specific personality. Kuratko (2004) supports the idea that entrepreneurship can be taught and learnt. McMullan (1998) emphasizes the importance of entrepreneurship education. First entrepreneurship course was introduced and offered at Harvard University in 1947 and social entrepreneurship courses were introduced in the late 1990s primarily at business schools, with Stanford, Harvard, Berkeley, Duke, and Georgetown University business schools, among others (AshokaU, 2014) leading the way. Chen et al. (1998) revealed a correlation between students' entrepreneurial intentions and the number of management courses taken by non-management students, while Varela and Jimenz (2001) saw entrepreneurial education initiated by universities as a very important factor.

According to Garavan and O'Cinneide (1994), major challenges of entrepreneurship are appropriate syllabi and training programs. Fayolle (2000) interviewed directors of French business schools and revealed that the introduction of entrepreneurship programs mostly results in 1 – 3 start-ups per year, if the school kept a record of postgraduate success. He also sees a longer history of the entrepreneurship education as an important factor for success. Except education, some other studies (e.g. Salamzadeh et al., 2013) reveal lack of experience and knowledge (63.7%) as a reason for not starting a social enterprise. It is worth mentioning that the real challenge for entrepreneurship education lies within the development of the first two dimensions, i.e. learning for entrepreneurship, rather than learning about entrepreneurship (e.g. Gibb, 2002; Honig, 2004). As a response to the previously mentioned observation, Pache and Chowdhury (2012) emphasized the need to move away from educating 'about' entrepreneurship to eventually educating 'for' entrepreneurship (Kirby, 2004; Fayolle, 2006; Kozlinska, 2011).

There are scholars who argue whether or not social entrepreneurship should be taught as a distinct field and whether it fits into the larger picture in the area of management studies (Austin et al., 2006).

Elmes et al. (2012) surveyed social entrepreneurship curricula from the perspective of place as pedagogical method, proving that an on-site approach enriches education in terms of creative thinking and leveraging the lack of resources. There is no agreement on the best way to teach entrepreneurship to students (Kuratko, 2005; Fayolle et al., 2008) and there has been limited research which has articulated the teaching proficiency associated with attending to both social and commercial focus.

2.1. Key Educational Topics in Social Entrepreneurship Education

The extensive literature review has revealed that some educational topics are typical for social entrepreneurship syllabi no matter in which country the syllabi are proposed. Most common topics are: 1) *social mission/need* (Kumar Sinha et al., 2014; Brock and Steiner, 2009; Alter, 2007; Dees, 1998); 2) *resources allocation* (Brock and Steiner, 2009; Mair and Marti, 2006); 3) measuring *outcomes* (Willey and Berry, 2015; Brock and Steiner, 2009; 4) *opportunity recognition* (Brock and Steiner, 2009; Dees and Anderson, 2003; Shane and Venkataraman, 2000; Timmons, 1999); 5) *sustainable business model* (Willey and Berry, 2015; Brock and Steiner, 2009; Hamel, 2000); 6) *innovation* (Nian et al., 2014; Worsham, 2012; Brock and Steiner, 2009; Austin et al, 2006; Haugh, 2006; Light, 2006; Mair and Marti, 2006; Alvord et al, 2004; Dees and Anderson, 2002); and 7) *social impact* (Brock and Steiner, 2009). Willey and Berry (2015) also found some other topics to be dominant in the SE curricula such as: defining SE, marketing, management, finance, and fundraising.

Fayolle (2000), for example, revealed the importance of pedagogical objectives as influencing factor on students' attitudes towards entrepreneurship. When teaching is structured around clearly identified economic objectives and is focused on the creation of new businesses and employment (the case of seven schools), the rate of new business start-ups among each years' graduating class is between 4 and 5%, as compared to less than 2% for schools favoring purely educational objectives.

2.2. Pedagogical Teaching Methods Used In Social Entrepreneurship Education

Fayolle et al. (2006) noticed the lack of research regarding educational outcomes. Dickson et al. (2008) in their analyses of studies published between 1995 and 2006 found that there is a positive correlation between entrepreneurial education and successful entrepreneurial activity.

The course instructors have a range of options of using lectures, suggested readings, case studies, and biography assignments to facilitate students to develop into social entrepreneurs and the collective use of these pedagogical techniques aids them to analyze social issues from a broader context (Smith and Woodworth, 2012). Dilts and Fowler (1999) tried to show that certain teaching methods (traineeships and field learning) were more successful than others in preparing students for an entrepreneurial career.

It is evident from previous studies that some pedagogical methods are dominant in the proposed social entrepreneurship syllabi such as: 1) *lectures* (Krishna et al., 2015; Nian et al., , 2014; Wu et al., 2013; 2015, Brock and Steiner; 2009); 2) *discussions* (Krishna et al., 2015; Nian et al., 2014; Wu et al., 2013; Brock and Steiner, 2009; Solomon, 2008); 3) *case study* (Krishna et al., 2015; Nian et al., 2014; Wu et al., 2013; Brock and Steiner; 2009); 4) *hands-on projects (interviews/shadowing),* (Krishna et al., 2015; Nian et al., 2014; Brock and Steiner; 2009) 5) *writing a business plan* (Krishna et al., 2015; Nian, Bakar and Islam, 2014; Brock and Steiner; 2009); 6) *providing expertise* (Krishna et al., 2015; Nian et al., 2014; Brock and Steiner; 2009); and 7) *volunteering in organizations* (Krishna et al., 2015; Nian et al., 2014; Brock and Steiner; 2009). In some form, service learning may be included in the curricula - Elmes et al. (2012) introduced a place where education is performed with sponsors as pedagogical method in terms of mentors or role models. Regarding the abovementioned pedagogical methods, it seems that many authors agree that experience should be included in the syllabi in different forms e.g. volunteering in organization, traineeship or service/experiential learning as an important ingredient in SE education.

3. Research Methodology

3.1. Research design and collecting social entrepreneurship syllabi for the SEE universities

In a modest effort to contribute to the social entrepreneurship educational landscape, we address the following specific research questions: 1) existence of SE syllabi at the SEE universities; 2) content of SE syllabi; and 3) pedagogical methods used in SE syllabi, with limitation of our research on the following countries: Croatia, Serbia, Bosnia and Hercegovina, and Montenegro.

In AshokaU's (2014) worldwide survey, research results reveal that only 6% of public schools have SE in its curricula. The existence of SE syllabi in educational institutions is a prerequisite for raising awareness and acquiring knowledge about the possibilities of SE, and encouraging the development of an SE eco-system. However, we need to agree with Robinson and Haynes (1991), the quality of entrepreneurship course offerings remains to be proven in terms of allocation of resources and formalization of course content, or the impact of entrepreneurship education on starting a new business. From the perspective of more developed countries, in the United States there were more than 148 institutions offering courses related to social entrepreneurship in the year 2011 (Kim and Leu, 2011).

For the purpose of this research we selected several SEE countries, namely Bosnia and Herzegovina, Croatia, Montenegro, and Serbia. Although they have been in the transition process since the 1990s they are still struggling with the perception of entrepreneurship as a career choice. Furthermore, despite the growing interest and popularity of social entrepreneurship in academia, politics or economy there is still an evident lack of surveys (Rajh et al., 2016; Perić and Delić, 2014; Vidović, 2012) on entrepreneurship in those countries. With our research, we fill the gap by providing theoretical background on social entrepreneurship education, pedagogical methods, and development of social entrepreneurship syllabi in those countries. Entrepreneurial education can certainly help to resolve the problems of low entrepreneurial activities by being the needed promotion tool (Rajh et al., 2016).

Finally, we do not know of any previous studies, which try to explore the content of SE syllabi in the SEE and pedagogical methods used similar to the one we are planning to conduct. It is only evident from previous studies that some pedagogical methods and some educational topics are dominant in the proposed SE syllabi. Therefore, in this study our efforts will be devoted to drawing attention to those observations.

3.2. Content analysis of the collected syllabi

The World Wide Web presents researchers with a powerful tool for the collection of data and the Web-based survey provides researchers with an efficient and valid method to code the data compared with costs associated with conventional surveying methods. A Web-based content analysis method was applied in order to show how social entrepreneurship is taught in SEE.

This study followed the steps of traditional approach in Web-based content analysis; McMillan (2000) suggested these five steps, (1) The researcher formulates a research question and/or hypotheses. (2) The researcher selects a sample. (3) Categories are defined for coding. (4) Coders are trained, code the content, and the reliability of their coding is checked. (5) The data collected during the coding process are analyzed and interpreted. It is evident from previous researches that some pedagogical methods are dominant in the proposed social entrepreneurship syllabi.

3.3. Research Question and Survey Results

Previous studies revealed as the most presented topics in the syllabi of SE the following topics: social mission (100%), resource allocation (80%), measuring outcomes, opportunity recognition, sustainable business model, innovation (60%), and finally scaling impact as last represented in only

33% of syllabi (Brock and Steiner; 2009). Furthermore, Brock and Steiner (2009) found service/experimental learning and guest speakers in 75% and 30% of syllabi respectively.

Our main research question examined the level of development of the SE syllabi at universities and colleges in the SEE, in line with a well-known practice in terms of educational topics and pedagogical methods. The following seven topics of each selected SE syllabi were surveyed: social mission, resources allocation, measuring outcomes, opportunity recognition, sustainable business model, innovation ad scaling impact, and pedagogical methods.

The main research objective was to analyze the current state and perspectives of the social entrepreneurship education within the selected South East European countries' educational system. For that purpose, a sample was selected – business schools and faculties, both public and private from the republics of Croatia, Bosnia and Herzegovina, Serbia, and Montenegro. These selected countries of SEE are characterized by common heritage principle and a nearly century-old history of living in one state. Moreover, these countries have similar language (once Serbo-Croatian, after the breakup of Federal Republic of Yugoslavia and formation of independent states, took different standard forms – Croatian, Serbian, Bosnian, and Montenegrin which are mutually understandable). The first step of the Web-based survey was to identify relevant institutions - business schools and faculties. For that purpose, official web pages of ministries of education (four ministries respectively) were contacted. Only accredited institutions entered the sample so a total of 106 business schools and faculties, both private and public were analyzed. It should be mentioned that far more business schools are operating in selected countries at the moment but are not all recognized by the relevant ministry of education. Together the selected countries have just under 16 million inhabitants, so 106 business-oriented higher education institutions are rather a lot. The distribution of institutions by country is given in Table 1.

Table 1: Distribution of business schools and faculties by country.

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	BH	26	24.5	24.5	24.5
	CRO	35	33.0	33.0	57.5
	MNE	5	4.7	4.7	62.3
	SRB	40	37.7	37.7	100.0
	Total	106	100.0	100.0	

Source: Research results.

It can be seen that the majority of institutions are either from Serbia (37.7%) or Croatia (33%). Just under quarter of institutions in the sample are from Bosnia and Herzegovina and only 5 institutions operate in Montenegro. Nearly half of the institutions (47.2%) are publicly held while 52.8% are privately held.

Then, the orientation of institutions was identified. Two systems of business-oriented programs can be identified in the selected countries - academic and professional. Academic programs are offered exclusively by faculties (180 ECTS credits are assigned for the undergraduate university degree and 300 ECTS credits for the graduate university degree) while professional programs are offered by faculties and business schools (180 ECTS credits assigned for the professional undergraduate degree and 300 ECTS credits for the professional graduate degree). Out of 106 institutions that entered the sample, a total of 76 (71.7%) offer academic programs and 30 (28.3%) offer professional business-oriented programs.

Next, we analyzed if a specialization in entrepreneurship is offered. Out of 106 faculties and business schools, 15 (14.2%) offer a major in entrepreneurship on the undergraduate study level, 15 (14.2%)

offer a major in entrepreneurship on the graduate study level while only 4 (3.8%) offer a specialization in entrepreneurship on the postgraduate level.

The following step of our study was to identify whether social entrepreneurship course is offered and for that purpose 106 faculty and business school's curricula were analyzed. Only 2 faculties (both from the Republic of Croatia) offer a social entrepreneurship course: one on the undergraduate study level and the course is offered as a compulsory one, the other on the graduate study level and the course is offered as elective. Out of these 2 courses, only one syllabus is transparent and available through the web page (it is complete but available only in Croatian version). Course outcomes are outlined as follows:

- To analyze and quantify social entrepreneurship outcomes,
- To analyze the demands of social entrepreneurship on local, regional and national levels,
- To discuss collaboration opportunities between profit and non-profit sector,
- To understand the differences between social and traditional entrepreneurship and the differences between social entrepreneurship and humanitarian work as well,
- To propose social ventures,
- To apply techniques of creative thinking in idea generation,
- To evaluate one's own resources using effectuation theory,
- To evaluate social ventures by developing a business plan.

Teaching methods include lectures and case studies while the final grade is obtained by the exam grade and the assignment (business plan) grade. Suggested reading is in Croatian (only 5 titles) and includes two PhD thesis, two academic papers and one book published by the Government of the Republic of Croatia (NGO department).

Since we were more than encouraged by our findings, we took a step back to investigate the current state of general entrepreneurship education within curricula of business schools and faculties in the selected countries.

Table 2: Institutions offering general entrepreneurship course

BH					
		Frequency	**Percent**	**Valid Percent**	**Cumulative Percent**
Valid	No	2	7.7	7.7	7.7

	Yes	1	20.0	20.0	100.0
	Total	5	100.0	100.0	

Source: Research results.

As it can be seen from Table 2, a vast majority of business schools and faculties in Bosnia and Herzegovina have general entrepreneurship course in their curricula (92.3%), and situation in Croatia is similar (80% of analyzed institutions have a general entrepreneurship course). There is a slightly bigger proportion of higher education institutions not offering general entrepreneurship course in Serbia (32.5%) while in Montenegro 80% of business schools and faculties do not have general entrepreneurship course in their curricula.

Next level of analysis was to determine the number of courses directly connected to entrepreneurship and the results are given in the table below.

Table 3: Number of courses directly connected to entrepreneurship

BH					
	N	**Minimum**	**Maximum**	**Mean**	**Std. Deviation**
Number of connected courses	26	1	4	1.54	.761
Valid N (listwise)	26				
CRO					
	N	**Minimum**	**Maximum**	**Mean**	**Std. Deviation**
Number of connected courses	35	1	33	4.54	5.873
Valid N (listwise)	35				
SRB					
	N	**Minimum**	**Maximum**	**Mean**	**Std. Deviation**
Number of connected courses	40	1	12	2.20	2.377
Valid N (listwise)	40				
MNE					
	N	**Minimum**	**Maximum**	**Mean**	**Std. Deviation**
Number of connected courses	5	1	4	1.80	1.304
Valid N (listwise)	5				

Source: Research results.

As it is evident from Table 3, the number of courses offered by the analyzed higher education institutions, which are directly connected to entrepreneurship, varies from minimum 1 to maximum 33. On average, business schools and faculties from the selected South East European countries offer 3 (mean value 2.79) courses directly connected to entrepreneurship. Having this in mind, our finding that only 2 institutions offer social entrepreneurship course (0.02% of all business schools and faculties in the sample) turns out to be even more disappointing. The reason the maximum number of courses (33) is offered in the Republic of Croatia is the fact that the field of entrepreneurship can be studied from undergraduate through to the PhD level, whereas in other analyzed countries only undergraduate and graduate programs are available.

As the main objective of this research was to investigate the current state and perspectives of social entrepreneurship education in the selected South East European countries, we can conclude, drawing from the presented results, that social entrepreneurship education is not adequately positioned within the analyzed curricula.

4. Recommendations, Discussion and Conslusion

The aim of this paper was to reveal the state of the art in the field of the SE education in SEE. In this survey, content analyses protocols were followed. Although the topic is more than hot in entrepreneurship education, there is an evident lack of the SE syllabi in the SEE education systems. Moreover, we can clearly notice there is a lack of introductory entrepreneurship courses. Our next step, directed to exploring pedagogical methods in SE syllabi, proved to be unnecessary as it did not reveal any representative results regarding it at this point of time. Overall, we found disappointing results on the level of introduction of SE syllabi in the SEE higher education systems.

The polygon of our research, i.e. the selected SEE countries, was definitely our first research limitation, even though when we started this research process we could not even imagine that the introduction of SE was thus neglected. We are very sure that SE as a part of entrepreneurial education will enter the next level during the process of EU accessions for three of the four observed countries.

Silvius Stanciu,
"Dunărea de Jos" University of Galati, Romania, sstanciu@ugal.ro

Abstract

The paper aims to describe and analyse the consumption of fish and fish products in the Republic of Moldova. The results of the study can be extended and complemented in order to correspond to the national level. The traditional consumption of fish in Moldova is based mainly on catches made from natural water bodies or on the production from domestic aquaculture. A significant part of the fishery products present on the food market of the Republic comes from imports, the national sector being quite modest lately. The research was made in Cahul City, with a population of about 40,000 inhabitants, representing 1% of the republic population, on a sample of 400 persons, respectively about 0.1% of the total national population. The research shows that there are favourable conditions for increasing the national consumption of fish and for developing the domestic production, given the consumer preferences for indigenous fish species. The development of the national fisheries sector is possible and necessary in view of the natural resources available on the national territory At the same time, proper fishery production can lead to rational consumption, can cause changes in the consumer mentality and attitudes and can positively influence the health of the population. We consider the work to be useful for the academic environment, due to the scientific results obtained, for the business environment for the potential development directions of the market, as well as for the officials from the Republic of Moldova for the restoration of the national fisheries sector.

Keywords: fish, consumption, strategies, Republic of Moldova

Introduction

The fish has been part of the diet of the Romanian population since ancient times. The tradition of fish consumption continues on the national territory throughout the ages, with freshwater fish being the basic food for the population of the Romanian countries. The fisheries sector has an old tradition in Moldova and since the time of Stefan cel Mare there has been a well-developed system of ponds producing fish for consumption (The Gazette of Agriculture, 2009). In the popular gastronomy, freshwater fish was considered ordinary, inexpensive and easy-to-buy food, being frequently consumed especially by the low-income population.

The modern aquaculture of the Republic of Moldova was established in 1945. In the post-war period, almost 30,000 ha of fish-farming reservoirs were created, of which the 12,000-hectare ponds accounted for only 40% of the total. Later on, the fish pond culture became one of the main forms of aquaculture production in the republic. The Moldovan territory has a considerable natural fish potential. Thus, the rivers, lakes and other wetlands cover 95,000 ha (or 2.8% of the country), but only a small part, representing 7.5% of the natural aquatic potential, is exploited in the fisheries. At the national level, only five fish farms with indigenous capital are mentioned as significant for their production level (Zubcov et al, 2013). The vast majority of fish farms carry out an extensive system activity based on the culture of the pond in a polyculture system. Practicing polyculture fish farming is aimed especially at the growth of the carp, the phytophagous species and some species of predators such as the pike, the zander and the European catfish.

In recent years, rivers and lakes have been drained or water has been used in industry, resulting in the pollution and disruption of the biological and aquatic balance. Many species of high economic value fish, such as the shale, the carp, the plaice or the rapacious carp are in danger of extinction in the national waters and the sturgeon can virtually no longer be found (Zubcov et al, 2013). The Moldovan fishing specialists believe that the situation could be saved by building artificial breeding centres of valuable species for the maintenance and development of the natural basins in the Republic of Moldova (Usatîi et al, 2015).

The demands of the Moldovan fish market have evolved over the last period. Thus, from a consumption mainly based on indigenous fishery products, the preferences of the population started to focus on imported products, a tendency especially due to the permanent reduction of the domestic production. At present, there are over twenty enterprises active in the import of fish, processing and wholesale supply, large-scale fish import processors (Curcubet, Domanciuc and Tîmciuc, 2016).
On the market, fish products can be purchased fresh (live or fresh fish), preserved by cold (chilled or frozen fish) or processed (salted, smoked, sterilised), with specialised stores or specially designated areas in markets for the marketing of fishery products**.**

Short Literature Review

Compared to the Republic of Moldova, where there was no national program for the assessment of fish consumption, a series of studies on fish consumption and fish products were conducted in Romania at the national level. For example, the Romfish Study (2013), conducted during 2011-2013, aimed to highlight the consumption trends among the Romanian population. The research was based on a survey based on a multistage cluster, consisting of 800 respondents, with a probability selection of individuals at a tolerable error level of 3.5% and a probability of 95%. The sample was validated on the basis of INSSE 2009 and the Population Census in 2002 (Romfish, 2013). The survey found that 65% of Romanian respondents consume fish because they consider that "eating fish is an important part of a healthy diet", 27% because they think "fish is one of the few foods containing omega 3" and 25% of respondents because they appreciate that fish meat "is a dietetic meat". Nearly 19% of respondents believe that the best fish is the trout, 15% think that the best fish is the carp and only 11% of the interviewed people prefer the salmon. Of the total verified sample, the opinions on the evolution of fish consumption at the national level are balanced. Thus, 36% of respondents said that over the last year the fish consumption has decreased, while 35% of respondents consider that it has increased;

Zubcov et al (2013) presents details of the total production of catches in the natural waters of the Republic of Moldova between 1991 and 2010. The researches aimed especially at the analysis of catches in natural water reservoirs. The highest value of the catch yield was 177 tonnes in 1991 and the lowest quantity of 7 tonnes of fish which was caught in 1998.

The team of researchers directed by Curcubet et al (2016) stated that the per capita biological norm for fish consumption recommended for the Republic of Moldova has an average value of 20 kg/year, while the real consumption of the population reaches only half of this quantity, estimated at 11.9 kg/year. The study concludes that there is a need to increase the national consumption of fish by at least 1.5 - 2 times, so that at least the consumption standard recommended by nutritionists is attained. In addition, the research assessed the correlation between the promotion of aquaculture products on the domestic market and the evolution of the purchasing capacity of the population. The authors recommend, as measures aimed to increase the consumption of indigenous fishery products, to have the price of the indigenous products reduced, mainly on the basis of optimizing production costs and increasing production volumes, to diversify the supply of products produced by the national sector and also to take protectionist measures based on the introduction of special taxes for raising the price of mariculture products. In order to increase the productivity of the national aquaculture sector, researchers carried out a comparative analysis of the adaptation of carp breeds to the national culture conditions. The reduction of the production losses aimed at the use of genetic methods for the prevention of infectious diseases, created and specifically approved to increase the resistance of the cyprinid species to various limiting growth and reproductive factors.

Materials and Methods

Information on fish and fish consumption in the city of Cahul, the Republic of Moldova, was obtained through a market study conducted by the authors of the article. In this direction, a survey based on a questionnaire consisting of a set of 9 open questions was used, applying the CATI survey methodology. The target was represented by 400 questionnaires filled in by the respondents. The SMARTQUEST methodology was used for sampling, which recommended a minimum sample size of 381 respondents for a statistical population of 40,000 inhabitants, as Cahul has, in order to obtain conclusive results. The research was carried out at a tolerable error of 5% and at a probability level of 99%. The proportion of the respondents by gender was balanced (50% of women and 50% of men), respecting the male-female ratio in Cahul. The respondents' age was between 25 and 65 years of age. 2,000 questionnaires were distributed, using the face-to-face direct interview method (500 questionnaires), the mailing method (500 questionnaires), and 1,000 questionnaires were sent via the Internet (email or social networking). The average response rate was 28% (560 completed questionnaires received, of which 280 were direct interviews, 60 postal questionnaires and 220 questionnaires filled in via the Internet). Of the 560 completed questionnaires, 400 were validated. The data collected from the survey were ordered, statistically processed and presented graphically. The results obtained were compared with other data from the literature for an appropriate interpretation.

Summary Data on Fishery Production and Consumption of Fishery Products in the Republic Of Moldova

Current information on the Moldovan fishery sector was collected from the database of the National Bureau of Statistics of the Republic of Moldova, NBS (2013). According to the official statistics, the results achieved by the national economy in 2013 were very good, being materialized in the GDP Gross Domestic Product of 73.3 billion lei. Between January and September 2014, the GDP per resource categories increased by 19.5%. The largest increase was recorded in agriculture, forestry and fishing-fishery (36%), with a contribution of 11% to the GDP growth and 3.7% to the increase of the Gross Added Value (GAB).

According to the data provided by NBS (2017), the Moldovans registered an average annual consumption of fishery products between 11.7 and 16.9 kg/inhabitant during 2006-2016. The evolution of fish consumption in the Republic of Moldova registered an upward trend during 2006-2016, with slight fluctuations between 2009-2011 and 2014-2016 (Figure 1). In the top of the average annual consumption of the fishery products per capita at the European level, Moldova occupies positions higher than Romania, which registered an average of only 5 kg per capita in 2014; than the Czech Republic, with 9.5 kg or Poland, with 12 kg/capita being overtaken by Belgium with an average consumption of 25 kilograms of fish per year, Croatia, 20 kilos, France (35 kilos), Germany (14 kg), Greece (20 kg), Italy (25 kg) or Spain (42 kg). Icelanders consume most fish in Europe, with an average of 90 kilograms/year/resident and the Portuguese, approaching a consumption of 60 kg of fish per year per resident (Iancu, 2014).

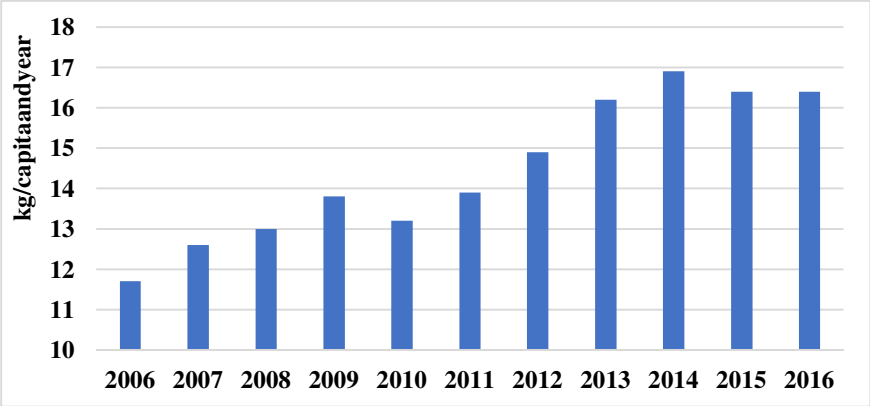

Figure 1: Fish and fish product consumption (kg/capita and year)

Source: Own research, based on the data from the National Bureau of Statistics of the Republic of Moldova, (2016)

The small number of aquaculture farms and the low production of fish farming do not allow the Republic of Moldova to export fish and fish products to other countries. Internal fishery production cannot cover entirely the domestic market, the domestic consumption being dependent on imports from Ukraine, Russia or the European Union. In 2016, the Moldovan imports of fish, crustaceans and molluscs increased by 21.8% as compared to 2015.

The Purpose of the Research

The fishery consumer survey is conducted in order to obtain additional information from the consumers in the city of Cahul about food consumption patterns related to fish consumption. It was assumed that consumers are well-informed, for whom their health and the health of people around them are very important. The paper was based on a survey which, in its turn, was based on a questionnaire interview. Questions were addressed to people who are in charge of purchasing household food and who had purchased fish or fish products in the previous three months. The target is a future consumer education company to promote the consumption of domestic fishery products and the increase of the domestic production, with a reduction in import dependency. The results obtained can be extended to the regional level of the Republic of Moldova, respectively at the national level.

Presentation of the Analysed Area

The town of Cahul is situated on the banks of the Prut River, on the border with Romania. The total area of the municipality is 3,415 ha, of which 2,000 ha of agricultural land and 37 ha of aquatic basins. The city has two small flowing water courses - the Frumoasa River, with a length of 9 km, and the Cotihana with a course of 7.4 km, but the main source of supply of lakes in the area is the Prut River, which flows nearby. The local fish production is estimated at .... tonnes/year

The city has a population of 40,000 inhabitants according to the population census in 2016. The gender share is 51.9% women and 48.1% men; the average income per capita is 5000 Moldovan lei. In terms of the level of education, 42% are people with secondary education, 32% are people with higher education and 26% are people who have completed their compulsory education.

The city has a grocery market with 2 fish areas specially designed for fish sale, a fish shop for fresh fish and fish products and a market for live fish. There is also a supermarket (Fourchette) in the city, with a special area for the sale of fishery products. The fishery products, represented by frozen fish, semi canned or canned fish, can also be purchased from the food stores in the city districts.

Although there are commercial areas specially designed for fish sale, there are fishermen or producers who prefer unfair selling methods (street trade or directly from means of transport).

The offer of fishery products on the Cahul market is generally represented by native fish species (Carp, the Bighead Carp, the Silver Carp), fresh fish (the Carp, the Crucian Carp, the Bighead Carp, the Silver Carp, the Pike, the Zander, the Bream), dried fish from the domestic production, marketed at the stall in the agro-food market and imported fish (fresh, fillet, frozen, smoked) marketed at grocery stores or at the Fourchette Supermarket.

Evolution of Fish Consumption in the City Of Cahul, the Republic of Moldova

According to the data presented in Figure 2, it has been noticed that over the past few years there have been no major changes in fish consumption for 35% of respondents, while for 29% of the consumers interviewed, the consumption has fallen due to high prices or other causes. For some 15% of consumers there has been an increase in the consumption over the last few years. 21% of consumers do not know how/want to answer this question.

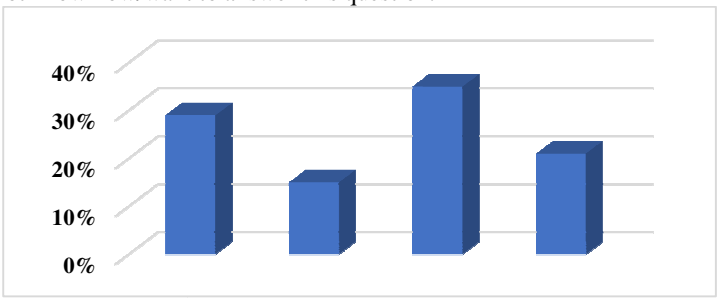

Figure 2: Fish consumption in the Cahul City, Republic of Moldova
The source: Own research.

Considering the low share of consumers who have appreciated the increase in fish consumption, we believe that concerted national efforts are needed to increase the consumption of fishery products in the Republic of Moldova, given the benefits of a fish-based diet and a better use of the potential of the national aquaculture.

Purchase and consumption of fish and fish products

To the question "Where did you last buy fish?" most of the respondents (60%) replied that they bought fish/fishery products from specialised stores (fishmonger's). Almost a quarter of the sample (28%) bought fish in the supermarket, while 9% of the respondents bought fish occasionally from the corner shop. Only a minority of respondents (3%) purchased the products directly from the producer's farm (Figure 3).

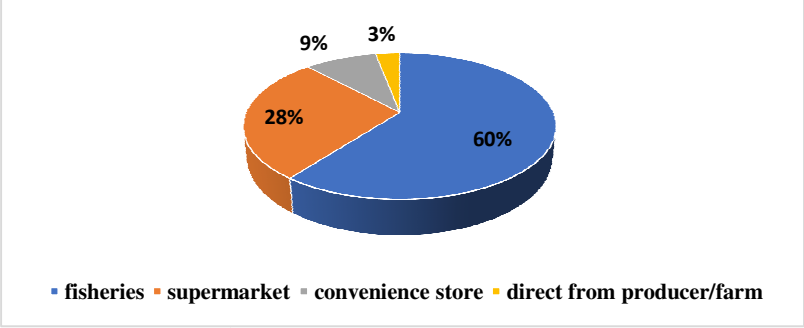

Figure 3: Types of stores for purchasing fishery products. Data for the last purchase
The source: Own research

It can be noticed that the most accessible and preferred places for purchasing fresh fish by the consumer are the specialized shops - the fishmonger's and the supermarket, where the products have adequate sales spaces, as exposure and storage conditions are concerned. The Moldovan consumer is confident in the purchase of fresh fish from specialised commercial premises where there is a control of the officials on the products/producers, the products are fresh and there is a minimum guarantee of quality.

Frequency of consumption

To highlight the consumption frequency of fishery products, the question "How often do you eat fish?" was used. According to the answers received, almost a quarter of the respondents (24%) consume fish once a week or 2-3 times a month (21%). The rest of the respondents rarely consume fish (17% only once a month and 17% less than once a month), while 8% of respondents do not consume fish at all. No respondent consumes fish daily, the diet of the inhabitants of Cahul being relatively diversified (Figure 4)

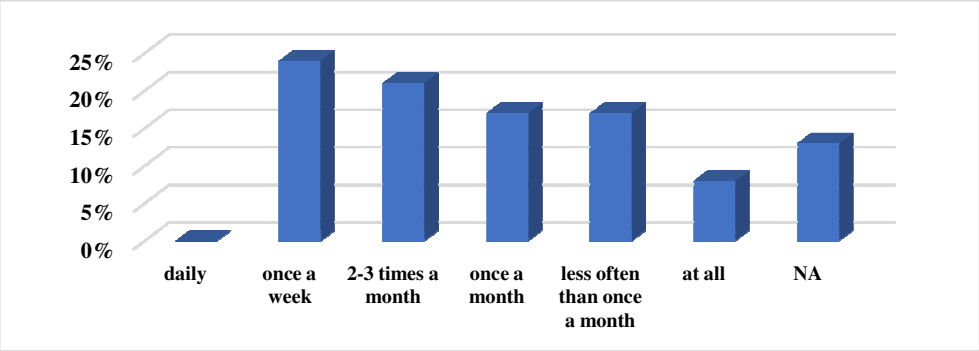

Figure 4: The purchasing frequency of fish and fishery products

The source: Own research

Types of fish commonly purchased

Figure 5 illustrates the consumption of fish and fish products by category. According to the answers received, half of respondents prefer fresh fish and if they can even alive (11%). The other respondents often buy frozen fish (21%), canned fish (9%) or smoked fish (5%). A reduced share of 4% of consumers buys only roe. Food consumption habits are influenced by culture and traditions, being transmitted from one generation to the next.

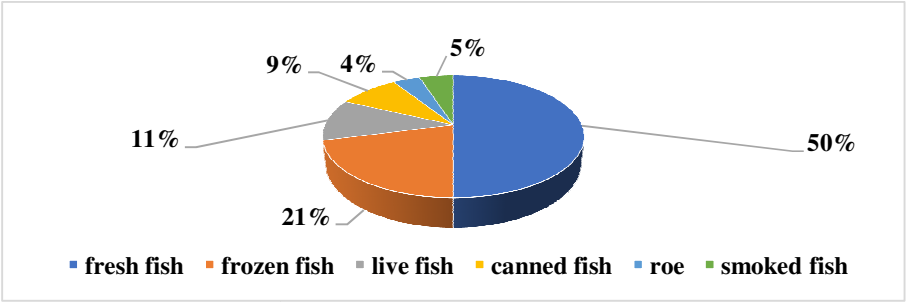

Figure 5: Preferences, habits for a certain type of fish/fishery products

The source: Own research

In the Republic of Moldova fish is consumed less than in other countries. As some consumers claim, the demand for fish and fish products on the market has declined considerably due to high prices.

The quantity of fish at a purchase

Figure 6 shows the average amount of fish purchased by Moldovan consumers in Cahul. In most cases consumers buy about 2 kg of fish per purchase (43% of respondents). Otherwise, the quantities purchased are generally based on family size or tradition, with 3kg bought by over 22% of respondents, or over 3kg by 15% of those interviewed. Quantities of fish below 1 kg are purchased by only 2 % of consumers, especially elderly people.

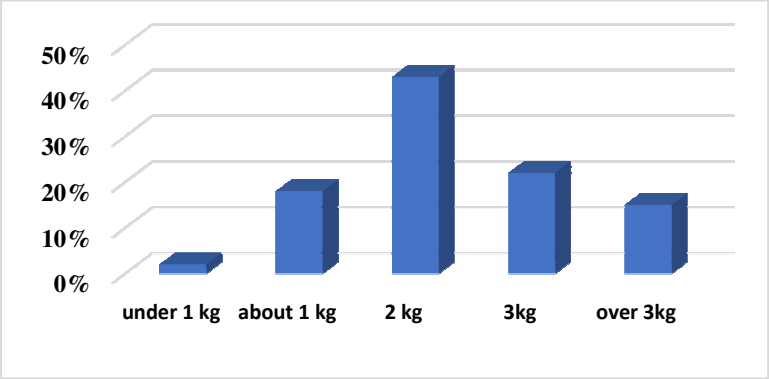

Figure 6: The average quantity of fish for a purchase

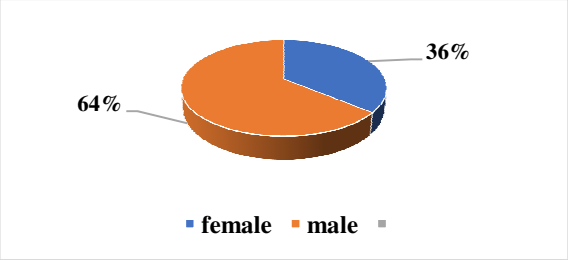
The source: Own research

Consumer Preferences for the Respondents' Gender

The largest consumers of fishery products are men, representing 64% of the interviewed sample, while female respondents represent only 36% of the frequent fish consumers (Figure 7).



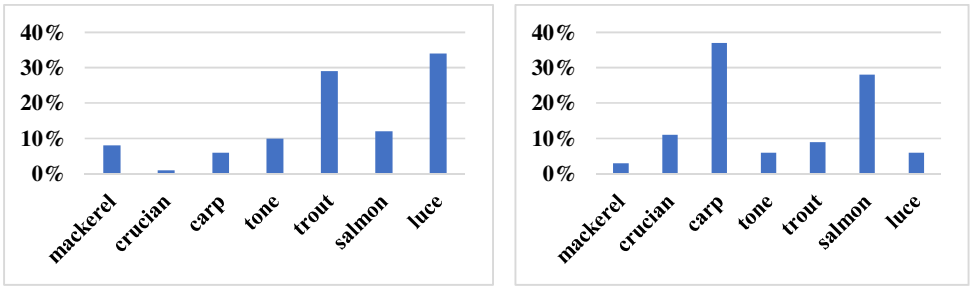


Figure 7: The weight of consumption preferences of fish and fish products by the respondents' gender

The source: Own research.

The species of fish preferred by consumers according to the gender of the respondent

Women generally prefer fish with fewer bones, such as zander, trout, salmon and mackerel. Men do not have special preferences for boneless fish species, often consuming domestically produced fish, the most preferred species being the carp, the salmon or crucian carp (Figure 8).

a) species of fish preferred by women b) species of fish preferred by men

Figure 8: Consumption preferences according to gender

The source: Own research

Consumption of Fish by Age

According to the respondents, it was observed that the interviewed consumers in Cahul had a slight increase in fish consumption with the aging, with the largest consumers being between the ages of 48 and 58 years (figure 9).

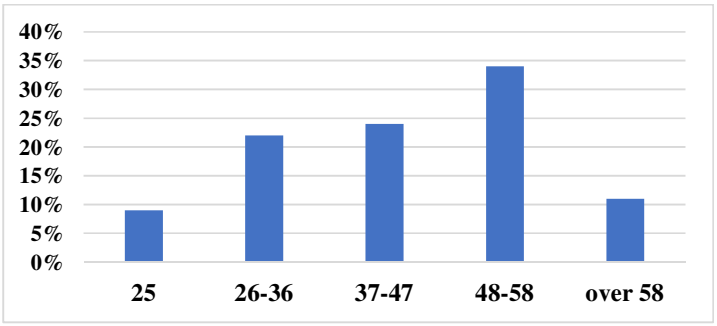

Figure 9: Fish consumption by age categories

The source: Own research

For respondents over the age of 58, a decrease in fish consumption has been observed, probably due to low incomes.

Conclusions

The research implied a market analysis in order to obtain additional information on the consumption of fish and fish products. Based on this questionnaire, information has been collected and solutions have been addressed that will influence the consumer's choice of fish products in the future. The development of production is possible by developing and implementing various new technologies and by expanding the range of fishery products available on the market of Cahul, the Republic of Moldova. Consumers in the city of Cahul prefer primarily fresh or live fish, which must be correlated with the natural resources of the region, rich in lakes, ponds or rivers (the Prut River). The average amount per purchase is about 2 kg of fish. Families in the city of Cahul have an average of 4-5 members, which limits the quantity purchased, and the availability of fresh fish on the market only requires the purchase of a single meal. The main fish consumers are men who prefer native species (carp, zander and crucian carp), while women prefer fish species without bones or less bones (sturgeon, catfish or trout) or fillet fish from the market, without bones (salmon). The age at which most fish is consumed in Cahul, the Republic of Moldova is 48 and 58 years. In most of the completed questionnaires we can see the preference for domestic fish production.

The consumer reaction has a direct impact on the supply and demand of fishery products on the market. According to the market survey carried out, it can be noticed that the interest of the consumers in the consumption of fish and fish products in Cahul town has declined lately, mainly due to the high prices and the low income of the inhabitants. Only a small part of the respondents has a direct link between the promotion and consumption of fishery products. Although it is said that advertising is the soul of trade, it seems that the Moldovan consumer is not so influenced by an excessive promotion of products on the market. This should have an impact on producers or traders, who should not allocate high budgets to the promotion of fishery products with low or unlikely effects. For developing the private sector, the Government of the Republic of Moldova must mobilizes funds from its and from foreign partners. Entrepreneurs benefiting from various grants, subsidies, credit schemes, are able to develop their business, to increase significantly the quality and the ability to export local products, thus becoming more competitive by creating new jobs. External development partners for the Republic of Moldova for the fisheries sector could be BERD, the World Bank, Austria, Switzerland, Norway, Turkey, but the main donor being EU.

It is recommended to create a national strategy to support the Moldovan fisheries sector, based on the protection of the natural fishery, to increase the share of aquaculture, to develop and implement modern technologies that will lead to the diversification of indigenous fishery products on the market and to the consumption demand. It is necessary to maintain a permanent communication between fish farmers and consumers, because correct and timely information from producers stimulates the production and directs it towards certain products demanded by the market.

The study is part of a wider research on fish consumption in the Republic of Moldova, which aims to increase domestic consumption and domestic fish production, with a reduction in import dependence, whose weight on the market of the country has increased significantly lately.

Knowledge Management Based on Expert Systems

Cezar Braicu, Hyperion University, Bucharest, Romania, cezar_braicu@hotmail.com

Abstract

Knowledge management rests on information systems such as Decision Support Systems (DSS) and Expert Systems (ES). This paper focuses on ES, described as formal systems based on Well Formed Formulas (WFF), axioms and inference rules. The basic axioms gathers explicit codified knowledge like regulations, codes, processes, copyrights and patents into a knowledge database, the first component of the ES. The valid well formed inference rules are evaluated by forward chaining (if…then patterns) by the inference engine, the second ES component. Those two united components forms a deductive apparatus fueled by the organization intellectual capital.

Keywords: knowledge management, expert systems, predicate logic, rules of inference, well formed formula.

Introduction

Current technologies, the spread of internet connections, on the one hand and the limited resources (financial, natural, human), on the other hand determined the modern managers to use efficient tools in order to make decisions in real time, based on scientific knowledge management models. Over the past decades, changes have also been made in organizational management, both in managerial thinking and managerial practice. According to the new theory, the organization is a system of elements in strong interaction with the environment. Choosing the right model is not easy, but with the support of AI (artificial intelligence) had been developed inference engines that guide the managers in juggling with more and different types of variables. Expert Systems (ES) are the result of scientific research in AI in the struggle to catch the rule-based knowledge representations. ES has been used with success in the management decision support for a long time. ES are used to make it more efficient human resource management needs, production resources need, marketing (promotion and distribution) activities, accounting, finance, nutrition care process, intelligent energy-efficient green buildings etc. The managerial decision must thus maximize the effect / effort ratio to lead to greater economic effects on the total resources used.

Literature Review

It is believed that Panini is the father of the formal systems, writing his masterpiece between the 5th and the 6th century BC. Ashtadhyayi is a treatise on Sanskrit grammar in eight chapters that is generative, meaning that it is capable of expressing a potential infinity of well-formed Sanskrit sentences starting from a finite symbolic inventory. The grammar in Ashtadhyayi seems like an idealized mathematical model that reduces the logical structure to its essentials. Panini's great work was compared with Turing's Automata, making complex use of meta-rules, transformations, and recursions.(Fig.1)

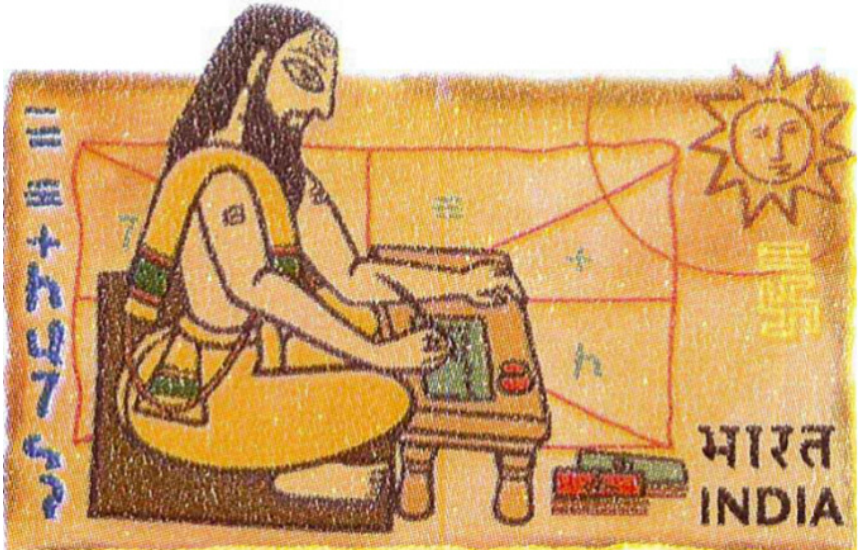

Fig.1: Panini stamp, [Satyavedism]

As Wagner observed diagnostic expert system applications continue to be the most popular [Wagner 2017]. Very efficient ES had been the result of finding solution on synthetic type problem domains such as design and planning. The spread of ES in decision making is studied by Wagner in a complex analyze on 311 ES case studies dating from 1984 through 2016 (Fig.2).

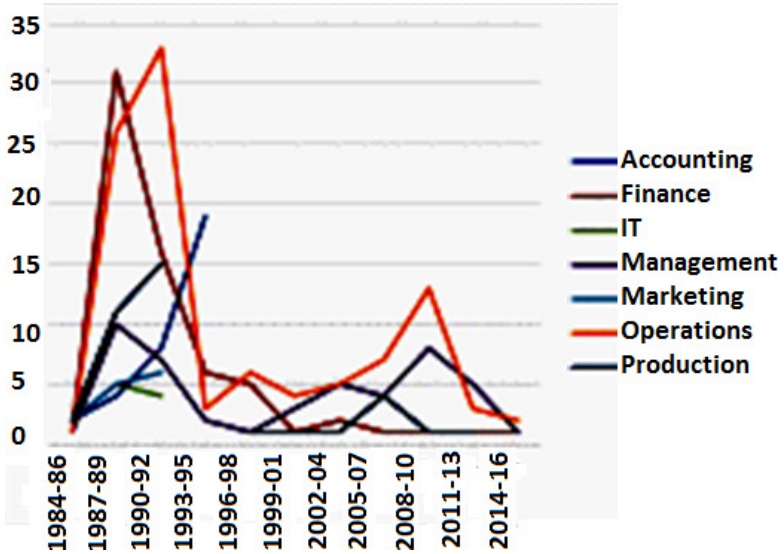

Fig. 2: ES evolution from 1984-2016 in different activity domains [Wagner 2017].

An example of tools to experts in real enterprise environments, either for evaluation of employees towards an optimal job assignment and vocational training or for recruitment processes based on a competence model (Professional, Innovative and Social competence tree) is presented in [Bohlouli, 2017].

An example for nutrition care process and planning is presented by [Cioara, 2017]. An inference engine is developed over a taxonomically organized knowledge base, providing mechanisms for evaluating defined rules for aging behavior of the elderly in the short and long term, in order to identify unhealthy food patterns and to detect the early establishment of malnutrition. The system provides personalized intervention plans covering nutrition education, diet prescription and food ordering

An intelligent energy-efficient outdoor lighting control system for green buildings based on ES is described by [Atis, 2016]. It contributes to the reduction of carbon dioxide emissions by using more conservation of electric energy and daylight more efficiently. During the evaluation period an average of 33% conservation was achieved in energy consumption.

AI technologies expand continuously over new fields of research from machine learning based on neural networks to image recognition based on hundreds of raw pictures of the given target, as may be seen in the picture bellow (Fig.3):

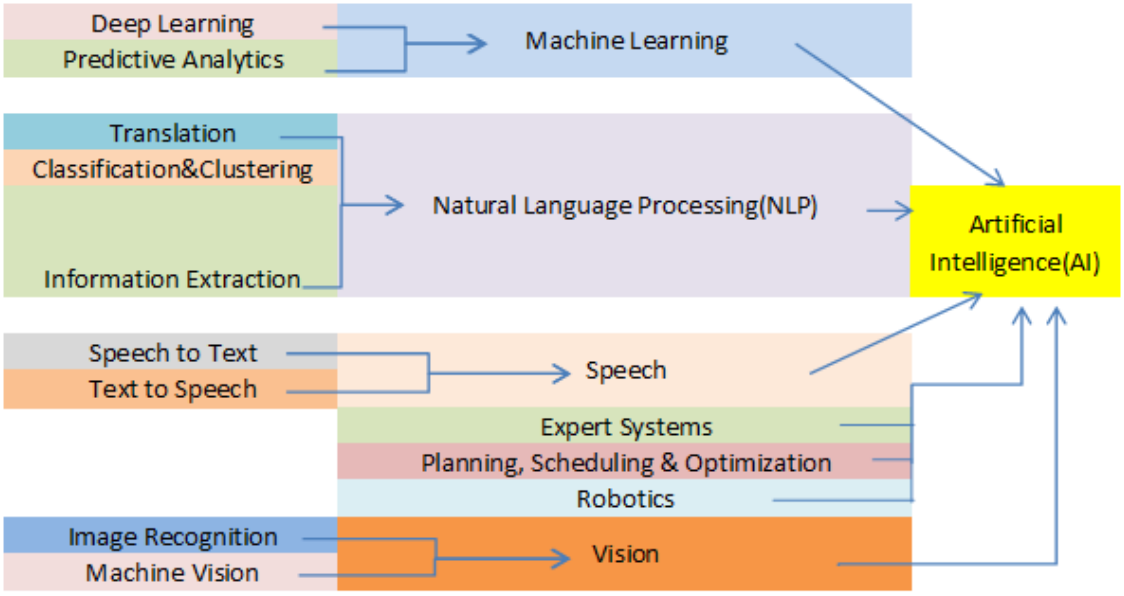

Fig.3: Artificial Intelligence: How will it affect legal practice – and when? [Martin, 2016]

The CommonKADS is the best known methodology for building knowledge-based systems and shows how knowledge analysis and knowledge-system development can be used as techniques within an overall knowledge management approach (Fig.4).

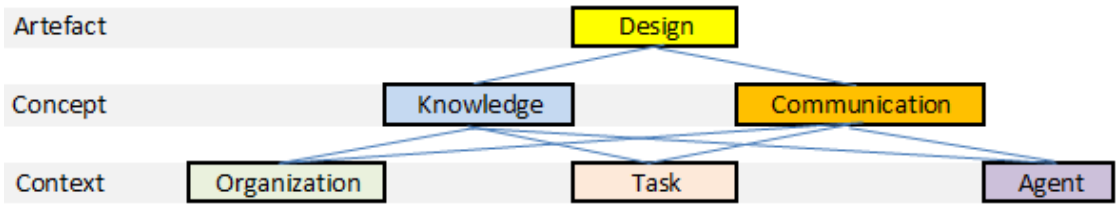

Fig. 4: CommonKADS Model Set, [Fensel, 2010]

CommonKADS uses UML notations wherever possible, in particular class diagrams, activity diagrams and state diagrams. [https://commonkads.org/]

Case study

The aim is to build a forward chaining inference engine based on predicate logic and implemented with lambda expressions. We focus on querying a knowledge base as the second subsystem of an expert system. To emphasize the importance of our research, we employ lambda expressions to implement a complex logical rule (teachers that have salary higher than their own chair's salary) and a method of grouping entities that share common features (like a hand of cards).

Inference engine by forward chaining of rules

An ES consists of a knowledge base and an inference engine. Any formal system relies on a finite alphabet, a grammar, a set of axioms, and rules of inference.

A knowledge database is a set of basic axioms corresponding to domains and tuples in the base relationships plus inference rules. Inference consists in evaluating Boolean expressions corresponding to the knowledge base relations and tuples. Inference rules are based on some basic axioms, for example:

Mother	Daughter
Ana	Maria
Maria	Ioana

If Mary is Ana's daughter and Joanna is the daughter of Mary, then Joanna is Ana's niece (or Ana is Joanna's grandmother) or

```
Grandmother = MX.Mother unde MY.Mother = MX.Daughter
```

These rules can be expressed in predicate logic as follows:

```
MOTHER_FOR(Ana,Maria)

MOTHER_FOR(Maria,Ioana)
```

An inference engine is a AI tool that parse logical rules (chaining) against a knowledge database to obtain new information. After [Eisenberg, 1997], rules denote constraints that enable procedures to seek new assertions or to validate a hypothesis. In forward chaining, rules are processed moving from if patterns towards then patterns.

A rule of inference can be formulated as follows:

```
GRANDMOTHER_FOR(Ana,Ioana)=MOTHER_FOR(Ana, Maria) AND MOTHER_FOR(Maria,Ioana)
```

or parameterized as follows:

```
GRANDMOTHER_FOR(x,z)=MOTHER_FOR(x,y) AND MOTHER_FOR(y,z)
```

Other rules can be expressed as follows:

PARENT(x,y) AND MALE(x) => FATHER(x,y)

PARENT(x,y) AND FEMALE(x) => MOTHER(x,y)

PARENT(x,y) AND PARENT(z,y) => STEPBROTHER(x,y)

PARENT(x,z) AND ANCESTOR(z,y) => ANCESTOR(x,y)

The axiom schemata and the rules of inference form a **deductive apparatus**. We must ensure that each line of derivation is merely a syntactic consequence of the lines that precede it.

WFF or the grammar of the formal system is constructed out of logical operators, for example:

non	-φ
and	(φ & ψ)
or	(φ | ψ)
If…then	(φ -> ψ)
If and only if	(φ <-> ψ)

For the basic axioms in the table below we follow the following inference rules, after [Vardi, 2006]:

Professor	**Department**	**Chair**
Ionescu	Math	Iosipescu
Popescu	Informatics	Iamandi
Radulescu	Math	Iosipescu

¬Professor (Popescu, Math, Iosipescu) => "The statement that Popescu is working at the Chair of Mathematics led by Iosipescu is false"

(Professor(x, Math, Iosipescu) ∧ Professor(z, Math, Iosipescu)) => "x and z are colleagues at the mathematics department headed by Iosipescu".

∃y.Professor (y, Math, Iosipescu) => "Someone from the mathematics chair led by Iosipescu"

∃y.∀x.Professor (x, y, Iosipescu) => "All professors in the chair led by Iosipescu"

Implementing inference of rules in Java 8

The Missing Parts in Java 8 jOOλ [Github, 2016] improves the JDK libraries, adding tuple support, function support, and a lot of additional functionality around sequential Streams. jOOλ knows a Sequential (Seq) interface that extends Stream and adds a variety of additional methods to. Let's see the

example bellow that displays the teachers who have the higher salary than the head of the chair after the fallowing logical query: t1.name ((Teachers (t1) ∧ Chairs (t2) ∧ Teacher s(t3)) ∧ ((t1.chair = t2.chair) ∧ (t2.name = t3.name) ∧ (t1.salary > t3.salary))):

```
Chairs.add(new Chair("Iosipescu","Math"));

Chairs.add(new Chair("Radulescu","CS"));

Teachers.add(new Professor("Georgescu","CS",5000,1999));

Teachers.add(new Professor("Iosipescu","Math",3000,2004));

Teachers.add(new Professor("Radulescu","CS",7000,2000));

Teachers.add(new Professor("Marinescu","Math",6000,1998));

System.out.println(Seq.seq(db.Teachers)

    .sorted((p1, p2) -> Long.compare(p1.salary, p2.salary))

    .flatMap(v1 -> db.Chairs.stream()

        .filter(v2 -> Objects.equals(v1.dept, v2.dept) && db.Teachers.stream()

            .anyMatch(t -> v1.salary>t.salary && t.name.equals(v2.name)))

        .map(v2 -> tuple(v1.name, v2.name)))

    .format());
```

The special method named flatMap() is very similar to map but expects the function received as an argument to return a functor. The result is the following, meaning that Marinescu has a greater salary then Iosipescu, the head of the chair (Fig. 5):

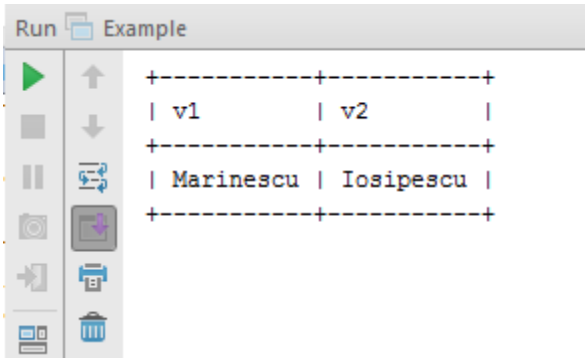

Fig.5: Intellij IDEA logical query result

For returning groups of more than two identical elements we can use the following syntax (Fig. 6):

```
Seq.seq(hand).groupBy(i -> i).values().stream().filter(u -> u.size() >=
2).collect(Collectors.toList()).forEach(System.out::println);
```

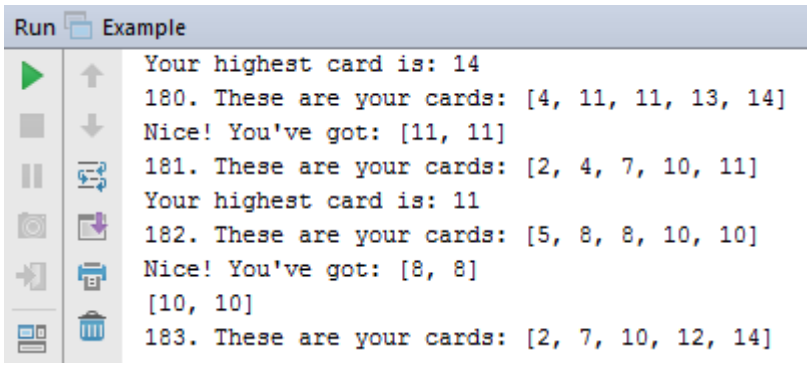

Fig. 6: Result window showing groups of identical elements

The source code as well as the model of the knowledge base can be found here: https://github.com/radubm1/test1/blob/master/Example.java

Conclusions

Since the formalization of logic (XIX century), many scientific domains are reformulating their base axioms accordingly to logical formal laws (Mathematics, Natural Language Processing, Logical programming, etc.). Fueled by the revolution of AI tools, automation of reasoning finds through logic a new horizon from where the boundary between the human brain and the computer seems dimmer than ever. Now it is the time when the art of management and particular the knowledge management should embrace fully the AI technologies to reach the level where the human error is just history.

Legal Provision of the Quality of the Results of Construction Works: Theoretical and Practical Problems

Vorontsova Elena Vladimirovna, Department of Financial Law, Constitutional, Civil and Administrative Proceedings FSBEI HPE «South-West State University», Kursk, Russia, proskyrinae@mail.ru

Vorontsov Andrey Leonidovich, Department of Administrative and Labor Law FSBEI HPE «South-West State University» Kursk, Russia, vorontsov.a.l@mail.ru

Annotation

The aim of the work was to analyze the problems of normative definition of the concept "quality of the result of construction work", taking into account the significance of this definition for regulating relations in the field of construction activities. In addition, much attention was paid to the problem of the legal fixing of the criteria for this quality, as well as consideration of legal guarantees ensuring the quality of the result of the work.

The study was based on comparative characteristics of the content of regulatory documents governing construction activities and the analysis of doctrinal points of view. At the same time, the methods of logical substantiation, linguistic (linguistic) interpretation, formal-legal method were used.

The content of normative sources, jurisprudence, the diversity of opinions of scientists, lead to a conclusion about the uncertainty of the very concept of "quality" in relation to construction works. The article suggests the author's version of the definition of the "quality of the result of construction works", as well as the criteria for the quality of the result of construction work, which the authors propose to fix by law.In their opinion, this will allow to overcome the existing conceptual uncertainty and will contribute to improving the quality of construction works.

The practical significance of the suggestions made by the authors is that in the event of the normative fixing of the quality criteria of the result of construction works proposed by them, the legal guarantees for its provision will increase substantially. The conclusions drawn by the authors are intended for entrepreneurs and lawyers practicing in construction activities. The results of the research will contribute to streamlining the legal regulation of relations in construction.

Keywords: construction works, result of works, quality, quality of the result of works, quality assurance

Introduction

Since the second half of the 90's.the last century, Russia is experiencing a kind of "construction boom." And if the end of the XXth century was noted, for the most part, by the unprecedented scope of individual housing construction, the first fifteen years of the twenty-first century are characterized, besides, by a significant increase in the construction of industrial facilities. The introduction of a huge number of those and others even more actualized the problem associated with the quality of the result of construction work, especially in connection with the massive attraction of low-skilled labor from the countries of near and far abroad.

However, as regards the quality of buildings and structures resulting from construction activities, a number of issues arise in the legal plan, primarily related to the definition of the very concept of "quality" in relation to construction works, or "the quality of the result of the work", as more appropriate in view of that, that similar works are carried out, as a rule, on the basis of the contract of the building contract.

In addition, the question «what are the parameters of this quality and what acts should they be installed?»is not completely clear.

And, finally, what are the legal guarantees for ensuring the quality of the result of the construction works and, accordingly, what compensation (corrective) mechanism in this case can be envisaged?
In order to regulate contractual relations in construction, the answers to these questions have a clearly expressed practical significance, nevertheless neither the legislator nor the judicial practice allows them to form a completely definite opinion on them. There is also no intelligible concept in doctrinal sources.

Results and Discussion

1. Problems of normative definition of the concept "quality of the result of construction work"

If we turn to the explanatory dictionary, then the concept of "quality" appears as "a set of essential features, properties, features that distinguish an object or phenomenon from others and give it certainty; this or that property, a sign that determines the dignity of something" (S.I. Ozhegov, N. Yu. Shvedova, 1995, p. 265).

In turn, specialized legal literature treats quality as "the ability of an object to serve its intended purpose" (V.F. Yakovleva, 1954, p. 56), "suitability for its intended use" (A.V. Ivanov, 1990, p.19).
For the legal formalization of the quality of services, the following circumstances make the complexity difficult: the creative nature of the service as an activity; direct evaluation by the consumer; the consumption of a service often occurs at the time of its provision; significant variability of individual customer requirements (E. Vorontsova, A. Vorontsov, 2016, p.869).

Based on such definitions, K.S. Maulenov formulated the legal concept of construction quality as "the ability of an object to satisfy public needs, for which the constructed object is intended" (K. S. Maulenov, p.3). However, in our opinion, this definition is too general and cannot be included in the Civil Code of the Russian Federation as normative, since it does not take into account all the factors underlying the legal value of the quality of the result of construction work.

In contrast to the above definition, the legal constructions of other authors are built on the account of several such factors. In particular A.Kh.Berbekov identifies four factors that, in his opinion, are the necessary criteria for assessing the quality of the result of construction work: 1. The result of the work performed is related to the technical parameters (characteristics, properties) that are presented to this type of work based on its subject nature and requirements, stipulated in technical norms (technical regulations); 2. the result of the performed works should not damage the environment and do not violate the rights and legal interests of other persons; 3. the result of the work performed must comply with the terms of the contract and the requirements of the law, and in the absence of such conditions - the customs of business turnover or other commonly presented requirements; 4. The result of the work must be capable of operation within the period specified in the law or by the contract (A. Kh. Berbekov, p.33).

On the basis of the unity of these factors, the concept "quality of the result of work" of the contractor was formulated, and the author proposed to introduce it in art. 721 Civil Code of the Russian Federation. However, in our opinion, some of the criteria for assessing the quality of the construction work performed by him do not meet the requirements of objective certainty, i.e. more simply, duplicate each other in meaning. So, the requirement not to violate the rights and legitimate interests of other persons, in our opinion, is obvious, it is supposed to be obligatory to comply with the requirements of the law. This can be said with respect to the requirement not to damage the environment (in terms of its compliance with Chapter VII of the Federal Law of 10.01.2002 No. 7-FZ "On Environmental Protection"). In addition, not to damage the environment as a duty logically follows from the need to match the constructed object with technical requirements (requirements of technical regulations) regarding the safety of the facility for life, human health and the environment (Article 7 of the Federal Law "On Technical Regulation").

As it seems to the authors of this article, the essential characteristic of the concept "quality of the result of construction works" can be reduced to three main indicators:

1. the result of the work must correspond to its intended purpose (that is, in this way, should corresponds to public needs);
2. the result of the work must comply with the terms of the contract (ie the result should correspond to the construction works reflected in the customer's interests);
3. The result of the work must comply with the mandatory requirements of technical regulations (technical requirements).

It seems that these components can be used as the basis for the normative definition of the "quality of the result of construction works", which, in our opinion, is worthy of placing in §1 "General provisions on the contract" of Chapter 37 of the Civil Code of the Russian Federation, and also in Art. 1 (Basic concepts used in this Code) of the Urban Development Code of the Russian Federation.
In view of the foregoing, we believe that the normative definition of the term "quality of the result of construction work" may look like this: these are the results of construction work, determined by the degree of its compliance with the intended purpose of the facility, the terms of the contract, mandatory technical requirements.

In the above definition, we deliberately used the expression "mandatory technical requirements" in place of the current technical regulations, thus creating, as we see it, a certain legal perspective for the use of this rule. The fact is that the practice of using in the construction of technical regulations has shown that they are far from being fully able to provide the required quality (necessary consumer properties) of the result of construction work. At present, loud enough voices are heard for returning to acts of technical regulation (like GOSTs, SNiPs), which very accurately determined the mandatory (normative) criteria by which it was possible to compare the results of completed construction work with the indicators that acted as a reference. In case of returning to the previously used system of technical rationing, it will not be necessary to introduce changes to the Civil Code of the Russian Federation, because the acts of technical rationing contain, in fact, mandatory technical standards (let's call them, for example, the maximum tolerances or something else: the comment of the authors).

At the same time, currently used technical regulations are fully covered by the term we proposed.

Legal criteria for the quality of construction works and legal guarantees for its provision: systemic problems of the Russian legislation

Responding to the first question we raised regarding the definition of the concept of quality of construction works, we touched in part the second question, which concerning the acts setting parameters of this quality. Indeed, the current legal framework for regulating relations in construction is far from perfect. Parameters of the quality of construction works, previously established by the system of acts of technical regulation in the form of building norms and rules (SNiP), GOSTs and technical conditions, with the introduction of technical regulations lost their mandatory importance. We can say that the legislation on construction as a result of the renewal has lost its integrity. A single normative array of building standards has "grown" according to technical regulations, which did not delay to affect the quality of construction works. From the memory of Russian citizens, tragedies in water parks and shopping complexes, caused by violations of technical norms during construction work and resulting in human casualties, have not yet erased.

Technical regulations contain technical terms that often do not receive their normative decoding. The content of these terms can only be judged by using the appropriate technical vocabularies, but the terminological interpretation presented in them is not official, and therefore provides an opportunity for subjective discretion.
In addition, in various laws there is a diversity of concepts, which also does not contribute to the normal organization of relations in construction activities. So the Civil Code of the Russian Federation uses the concept of "technical documentation", and in the Town Planning Code of the Russian Federation - "project documentation". To regard them as identical from a legal point of view

is not possible, since the concept of project documentation in normative acts receives its detailed disclosure regarding its structure, content, training rules, etc., unlike the concept of "technical documentation".

Thus, for today we do not have unambiguous normative parameters of the quality of the result of construction works. In this case it is worth, perhaps, to agree with O.G. Ershov, who, having conducted an analysis of the documents establishing technical requirements, came to the conclusion that "the legal regulation of relations in construction at the present time cannot be ensured either by construction norms and rules or technical regulations. There is reason to believe that the process of developing technical regulations will not bring the expected results because of the lack of opportunities for legal technology (O.G. Ershov, 2007, p.60). "

The lack of regulatory criteria for the quality of the result of construction works directly affects the legal guarantees for its provision. Sometimes quite difficult to correlate the customer's complaints that have occurred, guided by the requirements of previously acting technical regulations (which in their essence reflected the actual achievements of construction equipment in terms of reliability, safety, etc.) with the standards of the current technical regulations that guided the performer construction works. The problem also arises when the contractor recognizes the presence of shortcomings in the facility. On a contractual or non-contractual basis, it is obliged to eliminate them, if the demand to eliminate these deficiencies was announced after the termination of the construction contract.

The lawmaker tried to increase the responsibility of the executor of construction works by setting a requirement for the participation of persons who performed the work in a self-regulatory organization (Chapter 6.1 of the Town Planning Code of the Russian Federation). The possibility of exclusion from this organization, as well as the obligation to make contributions to the compensation fund, should, by its intention, induce executors of construction works to ensure proper quality. However, exclusion from a self-regulatory organization does not at all mean compensation for the damage suffered, and the size of the compensation fund, which limits the responsibility of the executor of works (Article 60 of the Town Planning Code of the Russian Federation), can also cover the incurred losses far from full.

It seems that a significant contribution to the development of additional legal guarantees for the quality of the result of construction work could be made by the legal centers of large construction corporations, as well as by the legal departments of higher educational institutions that have an architectural and construction faculty.

Conclusion

The significance of the issues raised in this article is not limited to the construction industry alone. Uncertainty of many basic concepts, contradictoriness and legality of legislation - are characteristic features of the Russian legal system, which, despite all the measures taken, is still very far from perfect.

As for the construction industry, the problems of legal ensuring the quality of the result of construction work determine, in our opinion, the vector of the entire development of this industry and not only, taking into account the significance of construction activities for the development of other spheres of public life. It is obvious that the current legal mechanism for ensuring this quality cannot fully cope with its functional role. To implement this role it is hampered by its own technical and legal imperfection, the elimination of which requires the coordinated work of the Russian legislator, legal academic circles and representatives of the construction business. At the same time, the lack of coherence between the interested parties leads to a limited legal capacity of the proposed legal mechanisms to ensure the quality of the result of construction work. In the opinion of the authors of the article, the way out of this situation lies in the plane of changing approaches to norm-setting activities in the construction sector, where the gap between the aspirations of representatives of the scientific community trying to present a unified scheme for the legal regulation of the quality of construction works and the aspirations of representatives of the construction industry, which are

determined by the practical needs of their activities. In this regard, it is necessary to initiate more often joint scientific and practical conferences and other events designed to coordinate the positions of all interested parties.

Acknowledgment

We express our deep gratitude to the organizers of the conference for the opportunity to speak on the very topical issue of Russian law.

Abstract

Social innovation and social entrepreneurship are key elements in the development of modern societies. Whereas setting up a business and managing it towards success is commonly seen as a difficult task, the start of a social business may be even more challenging, considering its special features. This paper presents the main barriers identified by: to be managers and managers of social organizations and experts/lecturers in the field of social economy and social entrepreneurship, and other social economy stakeholders, when undertaking the mission of setting up a social enterprise. Data was collected in four European countries under the Erasmus+ Project Social Entrepreneurship Support Europe (SES-EU)[i] using questionnaires. A total of 183 stakeholders answered about the main reasons that could lead them to question the start-up of a social enterprise. The analysis was conducting based on Kruskal-Wallis H-test, the Dunn's test for post hoc comparisons and Spearman Correlation Coefficient. The findings reveal that, although realities are different across countries, the main barriers faced by social entrepreneurs tend to have a common ground. The other similarity identifies is the lack of a common framework for social enterprises. This lack represents the main challenges to overcome. Our research and results are of considers particular relevance for governments and other entities promoters of social entrepreneurship, since it points out the key areas of concern, to which special attention should be given in order to boost start-up of social enterprises.

Keywords: Barriers; Start-up; SES-EU; Social Enterprise.

Introduction

Social Entrepreneurship and Social Innovation have become important key concepts to develop solutions for current social issues, which are not entirely addressed by the government, and public sector. As societies and governments face a multitude of challenges, namely social, cultural, economic and environmental (Haugh 2005; Braga *et al.* 2014), demanding solutions, social innovation are changing paradigm as a possible solution. Encouraging interested people to set up their own organization in order to respond to social needs and to deliver better social outcomes. Societal innovation and social entrepreneurship play, indeed, an important role in our society and economy.

The process of responding to a societal problem involves a number of stages, from the identification, evaluation and exploitation of opportunities, to the creation of social value (Certo & Miller 2008). The fundamental novelty of a social entrepreneur is not focusing solely on profits, but on achieving the social aim (Austin, Stevenson & Wei-Skillern 2006). While a business entrepreneur focuses his/her attention on the economic return or profit, a social entrepreneur mission is always essentially social (Austin *et al*. 2006). Societies may see further the social results such as mutual benefits emerging from values created by people leading a social enterprise. Although social entrepreneurs may create social impact in their personal daily-life or even in the companies where they work. Considering the importance of the value, they create, it is important to understand all the process of creating such organizations.

According to Nabi and Holden (2008) the definitions for entrepreneurship highlight the importance to start up an enterprise. The authors critically emphasized the entrepreneurship not only representing the way to create an enterprise, but to translate entrepreneurial intentions into entrepreneurial activity. Despite the differences in the missions of traditional and social entrepreneurs, some difficulties when establishing social businesses might be the same (Silva, Amorim & Dias 2015).

However, there might be other additional issues of special relevance for social entrepreneurs. From the innovative and creative society point of view, the need to fulfill the gap between reality and start up an enterprise implies and requires a consensual model to qualify entrepreneurs to risk and start their own business.

Social Enterprises and their Barriers

At the heart of the social innovation and entrepreneurship movement in Europe, many initiatives took place, many of them as a response to the pressures of youth unemployment (European Commission 2014b). Social economy approaches are considered as a key pillar of societies, regarding their importance to achieve the wellbeing of the people and communities. The social enterprise movement leads to the emergence of a diversity of initiatives that address social, cultural and environmental challenges (Bikse *et al*. 2015). The last decades have been marked by a significant increase in the number of social enterprises as one of the ways to answer that proposed challenge (Bikse *et al*. 2015; Silva *et al*. 2016).

Individuals and organizations that propose innovative solutions to societal challenges typically promote social entrepreneurship. Usually this type of entrepreneurs are highly motivated towards addressing community problems and lead the identification of several possible answers (Zahra *et al*. 2009). Simultaneously, social entrepreneurs accept risks and actively seek for the necessary resources and partners to start-up their projects (Abu-Saifan, 2012).

However, social companies have just recently started to be recognized by governments and policy makers, and there is still a lot to do in what concerns their credibility among citizens and communities. Supranational entities, such as the EC or the Organization for Economic Co-operation and Development are, nowadays, aware of the added value of the social enterprises and the social economy as a whole. The European Commission (EC), has set inclusive guidelines and funding for the promotion of social entrepreneurship and to support social entrepreneurs in achieving success (EC 2013). It seems to be still difficult to set up a social enterprise in most countries – since its conceptual framework and legal status is still under development. Therefore, social entrepreneurs may face other challenges in setting-up, developing and scaling the activities of their companies besides the traditional ones, dealing with different barriers.

Hypotheses Derivation

A number of barriers are identified in the literature as the main challenges for social entrepreneurs including: the mobilization of human and financial resources, bureaucracy, the fact that it is something innovative, communication and time management, the process of decision-making and lack of credibility or inexperience in the area (Braga *et al*. 2014).

With this study, it is intended to understand, on one hand, if the barriers identified are transversal to the managers / owners of social economy enterprises; experts / lecturers in the field of social economy, entrepreneurship and management; individuals interested in setting up the social economy enterprise and VET organizations and social entrepreneurship stakeholders. As we are dealing with these heterogeneous groups, from different backgrounds, the first hypothesis (H1) is "There are differences regarding the groups of interviewees regarding the barriers in starting-up the social enterprise". On the other hand it is expected to find differences among the countries in this study, where the second hypothesis (H2) is placed as “There are differences concerning the countries in this study regarding the barriers to starting-up a social enterprise”.

It is known that poor access to funding is also highlighted as one of major concerns for social entrepreneurs to start their business (Karaphillis 2010; Kendall *et al*. 2016; Martins *et al*. 2004;

Rykaszewski *et al*. 2013). This may be similar to the difficulties faced by smaller companies to access funds in capital markets, and their dependency of external sources of finance (Martins *et al*. 2004). The lack of an established and clear framework for social entrepreneurship has also major impact in the funding issue, since it is difficult for social entrepreneurs to identify funding options for the social sector. Given the lack of framework, social entrepreneurs submit applications for other public funds, but the formulation of their applications is always a challenge, since it is more difficult for them to fulfill the requirements of such financing models.

The process of creating a social enterprise is strongly influenced by cultural and social context. The absence of knowledge regarding the role, services and mission of social enterprises, both by societies and even by the appropriate institutions, is certainly a great barrier to the development of social business (Martins *et al*. 2004). The access to social and business networks have a huge impact in the successful process of start-up social enterprises, increasing the sector opportunities dealing with social issues (Bikse *et al*. 2015).

According to this, two research questions arise. The first question, "Is there a relation between the barriers to start-up a social enterprise and the key factors to success towards implementing a social entrepreneurship idea?". To test this research question we formulate three hypotheses (H3, H4 and H5):

H3: Contextual resistance and barriers affect the ability to identify adequate instruments and sources of funding.

H4: Lack of knowledge about the concept of social entrepreneurship influences the leadership and negotiation skills of the social entrepreneur.

H5: Lack of knowledge about financial instruments and sources of funding influences familiarity with other experiences of social entrepreneurship and other business models.

The second question, "Is there a relation between the barriers to star-up a social enterprise and the key elements in the qualification of the people involved in social entrepreneurship initiatives?". To test the research question two hypotheses (H6 and H7) were formulated:

H6: Contextual resistances and barriers affect the ability to work autonomously and develop initiatives.

H7: Technical competences in the business specialty domain of the social entrepreneur are associated with lack of knowledge about the concept of social entrepreneurship.

This study aims to understand the main barriers, identified by a group of social economy stakeholders, to establish a social enterprise and investigate the relation between these identified barriers and the key factors to success towards implementing a social entrepreneurship idea and the key elements in the qualification of the people involved in social entrepreneurship initiatives.

Methods

The present article addresses the identified barriers building on evidence collected in the context of the European Project SES-EU, which was conducted in five countries, namely, Cyprus, Italy, Poland, Portugal and Romania[ii]. The Project aims to contribute to the development of critical competences in the social entrepreneurship domain, through the creation of tools, which support such apprenticeship.

The research work relies on the evidence collected from four different groups of informants, managers/owners of social economy enterprises; experts/lecturers in the field of social economy, entrepreneurship and management; individuals interested in setting up a social economy enterprise and VET organizations and social entrepreneurship stakeholders involved in the ERASMUS+ Project SES EU. The study involved the application of questionnaires that were prepared within the scope of the SES-EU project, allowing for the collection of 183 responses obtained via online and by face-to-

face application in four European countries: Cyprus, Italy, Poland and Portugal. In order to find the key difficulties to establish a social enterprise, the 183 respondents were asked to score a list of 7 items identified in literature as key barriers. They were asked to consider their impact in their hypothetical decision to give up. The list of options had 11 key factors for the successful implementation of a social entrepreneurship idea and 8 core elements in the qualification of the people involved in social entrepreneurship initiatives, using a Likert type scale to classify from 1 (extremely unlikely reason/totally irrelevant) to 5 (extremely likely reason/ absolutely necessary).

Sample Characterization

Among the 183 questionnaires collected, it was possible to count answers from 58 managers/owners of social economy enterprises, 27 experts/lecturers in the field of social economy, entrepreneurship and management, 62 individuals interested in setting up a social economy enterprise and 36 VET organizations and social entrepreneurship stakeholders. Most of the answers were collected by Poland (35.3%), followed by Portugal (28.3%), Cyprus (20.1%) and Italy (16.3%). The ages of the inquired individuals range from 22 to 64, with an average of 40 years old. The majority of the individuals holds a higher education degree, in particular, bachelors and master degrees. The average length of professional experience is approximately 14 years, which suggests relevant experience. The main business areas of the social enterprises established, or intended to be established by respondents, are agriculture, tourism, education, health and other areas connected to services.

Statistical Analysis

In order to test the differences between more than two groups regarding answers to ordinal variables the statistic non-parametric Kruskal-Wallis H test was used (Corder & Foreman 2009; Cohen 1988; Siegel 1975; Sprent & Smeeton, 2001) and Dunn's test was used when focusing on multiple comparisons. The correlation between ordinal variables was executed by using the Spearman correlation (rho). The significance considered was .05 (Howell 2013).

Results

Identified Barriers

The results show that the major barrier is the "1-Lack of knowledge about financing instruments and sources" (M=4.06, SD= 0.98, Md=4), followed by "2-Contextual resistance and barriers (e.g. regulations, norms, culture, etc.)" (M=3.89, SD= 1.08, Md=4) and a "3-Lack of understanding about the concept of social entrepreneurship" (M=3.89, SD= 1.15, Md=4). The barrier "4-Aversion to risk" shows up immediately after (M=3.85, SD= 1.11, Md=4) and so does "5-Lack of managerial experience" (M=3.64, SD= 1.27, Md=4). Lastly, "6-Lack of technical knowledge about product processes, etc." (M=3.45, SD= 1.13, Md=3) and "7-Lack of qualified and motivated staff and volunteers" (M=3.44, SD= 1.19, Md=3).

Differences concerning the four groups of interviewees regarding the barriers in starting-up a social enterprise

It is possible to observe there is no statistically significant differences between the four groups of participants and the barriers that were studied: 'Lack of managerial experience' ($H_{(3)}$=2.87, p=.412); 'Lack of understanding about the concept of social entrepreneurship' ($H_{(3)}$ = 5.53, p =.137); 'Aversion to risk' ($H_{(3)}$ = 4.34, p =.227); 'Lack of technical knowledge about products and processes'($H_{(3)}$ = 2.77 , p =.429); 'Lack of knowledge about financing instruments and sources'(H(3) = 3.45, p =.327); 'Lack of qualified and motivated staff and volunteers' ($H_{(3)}$ = 7.68, p =.053); 'Contextual resistance and barriers (e.g. regulations, norms, culture, etc.)' ($H_{(3)}$ = 2.62, p=.454). Therefore, we will focus on the four groups as a whole.

Differences concerning the four countries in this study regarding the barriers to starting-up a social enterprise

It is possible to observe that, there is statistically significant differences regarding the most expressive barriers in at least one of the four countries which take part on this study: '5' ($H_{(3)} = 10.99$, p =.012), '3' ($H_{(3)} = 21.37$, p < .001), '6' ($H_{(3)} = 11.12$, p = .011), '7´ ($H_{(3)} = 18.69$, p < .001) and finally ´2' ($H_{(3)} = 10.89$, p = .012). On the other hand, there are no statistically significant differences concerning the barrier ´4´ ($H_{(3)} = 3.25$, p = .354) and the barrier ´1´ ($H_{(3)} = 2.28$, p = .516).

In order to understand these differences, the Dunn's test for post hoc comparisons was used (see the Table 1).

Table 1: Differences between countries regarding the barriers

Barriers	Country	Mean Rank	Dunn's test	*p*
2 – Contextual resistance and barriers (e.g. regulations, norms, culture, etc.)	Italy	74	z=2.78	.033
	Cyprus	108.78		
3 - Lack of understanding about the concept of social entrepreneurship	Portugal	73.78	z=2.75	.036
	Cyprus	103.82		
	Portugal	73.78	z=3.80	.001
	Poland	109.39		
	Italy	71.72	z=-3.39	.004
	Poland	109.39		
5 - Lack of managerial experience	Portugal	79.87	z=2.89	.023
	Poland	107.28		
6 - Lack of technical knowledge about products and processes	Portugal	77.19	z=2.98	.017
	Poland	105.59		
7 – Lack of qualified and motivated staff and volunteers´	Portugal	79.75	z=3.10	.012
	Poland	109.40		
	Italy	66.32	z=-3.80	.001
	Poland	109.40		

Considering this scenario, Portugal and Poland are the countries which most differ in number of barriers among themselves. The divergence are when it comes to the lack of managerial experience, the lack of understanding about the concept of social entrepreneurship, the lack of technical knowledge about products and processes and the lack of qualified and motivated staff and volunteers, Portugal is considered to be the country that gives less importance to the barriers and Poland the one that recognizes their greater importance, even when compared to other countries.

Linking Social Enterprise Barriers with the Key Factors to Success towards Implementing a Social Entrepreneurship Idea

The major factors contributing to the successful implementation of a social entrepreneurship idea are described in Question 4 of the questionnaire (Appendix).

As a means to understand which of these conflict with the barriers previously mentioned, it was possible to see that there is a statistically significant correlation (rho=.420, N=182, p<.001) between 'Ability to identify adequate financing instruments and sources' and 'Contextual resistance and barriers (e.g. regulations, norms, culture, etc.)'. This correlation is positive and moderate and it demonstrates that, the more detailed identification of adequate financing instruments and sources there are the more difficult to clarify in this topic, since there is a more prevalent contextual resistance and barriers. In other words, for the effective success of the idea of social entrepreneurship which is the core of the social enterprise it is mandatory to identify adequate financing instruments and sources – and, in order to accomplish this, it is necessary that contextual resistances and barriers such as norms, regulations, cultural issues, among others, are clearly defined.

Concerning this issue, the study found a statistically significant correlation (rho =.411, N=183, p<.001) between the factor 'Leadership and negotiation skills of the social entrepreneur' and the barrier 'Lack of understanding about the concept of entrepreneurship'. This correlation is positive and moderate and it allows to conclude that in order for the social entrepreneur to best perform their leadership and negotiation duties – which are crucial to the success of their enterprise – the entrepreneur needs to master the concept of social entrepreneurship, which urgently requires a consensual definition in the European countries being studied.

There is also a statistically significant correlation (rho =.475, N=183, p<.001) between the success factor 'Familiarity with other social entrepreneurship experiences and business models' and the barrier 'Lack of knowledge about financing instruments and sources'. This correlation is positive and moderate and it allows us to explain that in order to recognize other social entrepreneurship experiences and business models there needs to be knowledge regarding financing instruments and sources.

Barriers of Starting-Up a Social Enterprise and Key Elements in the Qualification of People Involved In Social Entrepreneurship Initiatives

Another important result are the key elements the entrepreneur needs to improve in order to overcome the barriers of starting-up a social enterprise. According to the elements used (Question 5) it is possible to observe a statistically significant correlation (rho =.410, N=183, p<.001) between 'Ability to work with autonomy and to develop initiatives' and the barrier 'Contextual resistance and barriers (e.g regulations, norms, culture, etc.)'. This correlation is positive and moderate. It is only possible to work with autonomy and to develop initiatives if the context allows that to happen due to the absence of contextual barriers. In other words, the less resistance and barriers there are, the more initiatives will be developed, as well as a rising autonomy of social entrepreneurship.

It was still possible to observe a statistically significant correlation (rho =.405, N=183, p<.001) between 'Technical competencies in the business specialty domain' and the barrier 'Lack of understanding about the concept of social entrepreneurship'. This correlation is positive and moderate and demonstrates that when there is a good understanding of the concept of social entrepreneurship, the social entrepreneur will be more apt to develop technical competencies in the business specialty domain.

Discussion

According to the EC (2014a), there seem to be external and internal inhibiting factors that influence both the start-up and the development and growth of a social business. The present paper presented the barriers faced by social entrepreneurs when undertaking the challenge of establishing a social business.

The biggest barrier identified by the interviewees when it comes to starting-up a social enterprise is the 'lack of knowledge about financing instruments and sources', followed by the 'contextual resistance and barriers (e.g. regulations, norms, culture, etc.)' and the 'lack of understanding about the concept of social entrepreneurship´. These barriers have a huge potential to discourage social entrepreneurs to start-up a social enterprise. All these barriers are consensual among the different parts involved in the study, so the results did not meet H1. People involved in traditional business were out of the scope of this study.

When we analyze the barriers taking into account the reality of each different country, we are able to understand that only the barriers 'Aversion to risk' and 'Lack of knowledge about financing instruments and sources' are present across-the-board, i.e, in all four European countries. After this analysis it was verified that the results go towards H2, since the countries differ among them in 5 of the 7 barriers under study. Portugal and Poland are the countries, which demonstrate a contrasting number of barriers between each other. Portugal is giving less importance to these barriers and Poland is the country, which gives the most importance to these. Literature studies highlight the differences between these two countries, being one of the causes presented the evident geographic

separation between the two countries has always affected the possibility of a close relation between them (Almeida 1992). According to Delgado (2014), from 2008 to 2013, the evolution of the Portuguese and Polish economies denote how the two countries are in different stages of economic maturation and European integration. They also have reacted to the international crisis of 2008 in a very different way. However, both countries are converging to the same point, respectively, into international accounting norms (Alves & Antunes 2010).

When we raise the first question of investigation, we realize that there are barriers that clearly oppose to the success of the implementation of an idea of social entrepreneurship. As the results go towards H3, it was possible to understand it is mandatory that contextual resistances and barriers such as norms, regulations and cultural issues be overcome so that there is a successful way to identify adequate financing instruments and sources for a social enterprise.

On the other hand, and once the results achieved go towards H4, the 'lack of understanding about the concept of social entrepreneurship', the third barrier which worries the participants the most, meddles with the social entrepreneur's leadership and negotiation skills. Being a leader is central in the business world and the leadership style is one of the decisive factors that induce an individual to undertake. It is known that this skill deals with the person's preferences, necessities and personality traits (Souza, 2014), nevertheless, external influences, as the lack of understanding about the concept of social entrepreneurship can also interfere with leadership skills.

Another important aspect is that in order to have knowledge about financing instruments and sources, there needs to be a familiarity with other social entrepreneurship experiences and business models, thus the results go towards H5. Some authors report that the financial success of a company depends largely on the expertise of its entrepreneurs and on the knowledge they bring from the companies where they have been before (Aldrich & Yang 2013; Eesley & Roberts 2013; Shepherd *et al.* 2009). According to Silva and collaborators (2016), another factor that constitutes a constraint to the familiarity with this type of business is the fact that specific legal framework does not exist and consequently the European social enterprises are bounded to other existing legal forms.

In addressing the second issue of this study that focuses on the relationship between barriers and core elements in the qualification of people involved in social entrepreneurship initiatives, it is apparent that the contextual resistances and barriers of the context affect the ability to work autonomously and develop initiative, so the results go towards H6. "Social entrepreneurs often need freedom and independence to implement their visions of how to solve a social problem and/or stimulate social change" (Lumpkin *et al.* 2013:776). According to these authors autonomy can be influenced by the presence of multiple stakeholders and access to resources.

Additionally, the results of the present research offer support for H7. The social entrepreneur will be more apt to develop technical competencies in the business specialty domain, when there is a good understanding of the concept of social entrepreneurship. Probably after understanding exactly what a social enterprise is, the entrepreneur may be concerned about his or her own competency in business. The concept of social entrepreneurship lacks a rigorous definition and after a long time of conceptual exploration with important contributions there is no excuse for not having a clear definition of this concept to be used as the basis for future developments and research (Braunerhjelm & Hamilton 2012).

The results of the study constitute an alert to the institutions with responsibilities in the area of entrepreneurship and/or social entrepreneurship, which should take actions to support and provide guidelines to future social entrepreneurs concerning financing.

Given the implications of a lack of conceptual and legal framework, it seems to be evident that governments and policy makers should make decisions regarding this issue, facilitating the process of establishing a social enterprise, as well being able to scale up the activity later on. In fact, the creation of a legal form and clear policies would be of major importance not only for would-be social entrepreneurs but also for already established social entrepreneurs. A clear and transparent framework would also lead to a greater understanding and acknowledgement of the importance of the social sector by communities, in general, which would contribute to deconstruct any preconceived notions and other cultural barriers. A guidebook for public entities and governments to support social

entrepreneurs would be of great importance to promote this type of entrepreneurship and assure the creation of organizations which represent an added value to communities and their quality of life.

According to our opinion, this topic requires more coverage and understanding – otherwise, generic programs and measures that are less effective might be prescribed. This study should be seen as a first approach towards a guidance which needs further development. The definition and the framework of this type of society should have a set of European guidelines in order to promote their dissemination and implementation.

Appendix

Questionnaire

Project Social Entrepreneurship Support Europe-SES EU

Project Number: 2014-1-PL01-KA202-003633

http://www.ses-project.eu/en/

This questionnaire is structured in to three parts.

The first part aims at understanding what competences you consider to be critical for developing your role as a social entrepreneur. The second part is focused in listening to your perceptions about the needs for education and training whose offer you consider that need to be improved. Finally the final part includes questions that aim to characterize your academic and professional profile and your motivations for engaging in social entrepreneurship.

Part I: Critical Competences of Social Entrepreneurs

Question 1

We first would like to know what you think are the main areas where social entrepreneurs need support and training for the effective start-up of a social enterprise.

Please rate the provided statements about knowledge and competence areas using a scale from 1(Not at all relevant) to 5 (Extremely relevant).

Knowledge and competence areas		1	2	3	4	5
Sales and marketing						
Financial planning						
Organizational development						
Leadership and human resources management						
Operations management						
Laws and regulations						
Measuring impact						
Business and strategic planning						
Recruiting and working with volunteers						
Community engagement						
Presentation skills						
Social media						
Fundraising						
Developing the people and culture of organizations						
ICT Tools						
Foreign languages						
International markets						
Other (please specify)						

Question 2

Do you believe that the education and training for social entrepreneurs in the aforementioned areas should differ from that traditionally provided to other entrepreneurs (e.g. technology start-ups, etc.)?

Please indicate how much you you agree with the statement "The education and training offer for social entrepreneurs should be different that the one provided to other entrepreneurs…." for the various knowledge and competence areas. Use a rating from 1(Totally disagree) to 5 (Totally agree).

Knowledge and competence areas		1	2	3	4	5
Sales and marketing						
Financial planning						
Organizational development						
Leadership and human resources management						
Operations management						
Laws and regulations						
Measuring impact						
Business and strategic planning						
Recruiting and working with volunteers						
Community engagement						
Presentation skills						
Social media						
Fundraising						
Developing the people and culture of organizations						
ICT Tools						
Foreign languages						
International markets						
Other (please specify)						

Question 3

Please indicate to what extent each of the following reasons would lead you to question the idea of starting up a social business.

Please use a rating from 1 (Extremely unlikely) to 5(Most likely) to classify each reason.

Reasons that may lead to question the startup of a social business		1	2	3	4	5
Lack of managerial experience						
Lack of understanding about the concept of social entrepreneurship						
Aversion to risk						
Lack of technical knowledge about products processes, etc.						
Lack of knowledge about financing instruments and sources						
Lack of qualified and motivated staff and volunteers						
Contextual resistance and barriers (e.g. regulations, norms, culture, etc.)						

Question 4

What do you consider are the key ingredients for the successful implementation of a social entrepreneurship idea?

Please rate the factors indicated in the table below using scores from 1(Totally irrelevant) to 5 (Extremely relevant)

Factors for successful development of social entrepreneurship ideas		1	2	3	4	5
Academic (technical) qualifications of the social entrepreneur in the social business area						
Management competencies and qualifications of the social entrepreneur						
Ability to identify adequate financing instruments and sources						
Relational and contact network of the social entrepreneur						
Innovative character of the social entrepreneurship idea						
Previous work experience of the social entrepreneur						
Leadership and negotiation skills of the social entrepreneur						
Personality of the social entrepreneur						
Availability of motivated volunteers and collaborators						
Ability of social entrepreneurs to develop a detailed a business plan						
Familiarity with other social entrepreneurship experiences and business models						
Other (please specify)						

Question 5

What do you believe are core elements in the qualification of the people involved in social entrepreneurship initiatives?

Please attribute a rating from 1 (Totally irrelevant) to 5 (Absolutely necessary) to classify the need for specific education and training for the social enterprise phases identified below.

Preferred training models		1	2	3	4	5
Ability to work in teams						
Awareness and sensitivity to societal needs						
Ability to work with autonomy and to develop initiatives						
Flexibility and adaptation ability						
Working experience						
Technical competencies in the business specialty domain						
Institutional commitment						
Communication abilities						
Other (please specify)						

Part II – Education and Training Needs in Social Entrepreneurship

Question 6

Please let us know your perceptions about the existing education and training offer in the knowledge and competence areas that may be required for setting up social businesses.

Complete the following table indicating your perception about the availability of education and learning offers for the stated knowledge and competence areas using a scale from 1(Not at all existing) to 5 (Extremely relevant).

Knowledge and competence areas		1	2	3	4	5
Sales and marketing						
Financial planning						
Organizational development						
Leadership and human resources management						
Operations management						
Laws and regulations						
Measuring impact						
Business and strategic planning						
Recruiting and working with volunteers						
Community engagement						
Presentation skills						
Social media						
Fundraising						
Developing the people and culture of organizations						
ICT Tools						
Foreign languages						
International markets						

Question 7

Please rate the importance of obtaining specific education and training for different phases of social enterprise development. Please attribute a rating from 1 (Totally irrelevant) to 5 (Absolutely necessary) to classify the need for specific education and training for the social enterprise phases identified below.

Social enterprise development phases		1	2	3	4	5
Inspiration and diagnose of social needs and opportunities						
Selecting and structuring and of ideas for social enterprises						
Prototyping and piloting social entrepreneurship ideas						
Achieving sustainability of social entrepreneurship initiatives						
Scaling and disseminating social entrepreneurship initiatives						
Promoting effective social impacts of social enterprises						
Assessing results and impacts of social entrepreneurship initiatives						

Question 8

What was your awareness about the existing offer of education and training for social entrepreneurs? Please rate the following statements using scores from 1(Absolutely false) to 5 (Absolutely true).

Awareness statements		1	2	3	4	5
I can easily identify several existing programs of education and training for social entrepreneurs						
I am familiarized with the syllabi and contents of existing program of education and training						

for social entrepreneurs						
I have attended some social entrepreneurship training						
I know people who have attended some social entrepreneurship training						
I'd privilege the use of the Internet for finding information about existing programs of education and training for social entrepreneurs						
I'd privilege the use of the knowledge of my friends and acquaintances about existing programs of education and training for social entrepreneurs						
I'd privilege searching for information about programs of education and training for social entrepreneurs in specific publications and newsletters						
I'd privilege searching for information about programs of education and training for social entrepreneurs with specific institutions (e.g. business schools, associations, etc.)						

Question 9

Which factors would motivate you to enroll in programs for social entrepreneurs? Please rate the following options using scores from 1(Absolutely false) to 5 (Absolutely true).

Reasons for enrolling in social entrepreneurship programs		1	2	3	4	5
Updating and recycling knowledge in my academic and professional area						
Acquisition of new knowledge and competencies						
Specialization in a specific area						
Performance improvement						
Other (please specify)						

Question 10

Which type of training model would you prefer? Please use a rating from 1 (Extremely unlikely) to 5(Most likely) to classify each reason.

Preferred training models		1	2	3	4	5
General (classroom/workshop) training						
Individual consultancy to entrepreneur/manager						
Training-action programs in the enterprise						
Out-door training						
Internships						
On-line/e-learning						
Other (please specify)						

Part III – Characterization of the Profile of social Entrepreneurs

Now, please let us know some things about you, your background and your motivation for social entrepreneurship.

Question 11

What is your main academic background?

_____

Question 12

Can you describe the type of working experience you had before enrolling in the development of a social business idea? (e.g. business owner, technician, etc.)

_____

Question 13

Can you please indicate the length of your professional experience? (e.g. in years)

_____

Question 14

What is the main business area of your social enterprise/idea? (e.g. agriculture, tourism, healthcare, etc.)

_____

Question 15

Please indicate your age: _____

Question 16

Gender_____

Question 17

Please indicate to what extent each of the following statements describe your profile and your path into social entrepreneurship.

Please rate the following options using scores from 1(Absolutely false) to 5 (Absolutely true).

Statements		1	2	3	4	5
I've collaborated in a social enterprise before developing my own business idea						
I've enrolled in specific training for social entrepreneurs						
I've enrolled in generic entrepreneurship training						
I had a good previous education and training in business and management						
I've applied to competitions on social entrepreneurship ideas						
I know, and I'm acquainted with a large number of other social entrepreneurs						
The area of my social enterprise is very much aligned with my previous academic background						
It was easy to find collaborators and volunteers with adequate qualifications for working in a social enterprise						
The social enterprise is my main occupation and means of subsistence						

Question 18

In which development phase would you say is currently your social enterprise/idea?

Please rate the following options using scores from 1(Absolutely false) to 5 (Absolutely true).

Social enterprise development phases		1	2	3	4	5
Inspiration and diagnose of social needs and opportunities						
Selecting and structuring and of ideas for social enterprises						
Prototyping and piloting social entrepreneurship ideas						
Achieving sustainability of social entrepreneurship initiatives						
Scaling and disseminating social entrepreneurship initiatives						
Promoting effective social impacts of social enterprises						
Assessing results and impacts of social entrepreneurship initiatives						

Thank you very much for your time!

Resource Productivity in a Circular Economy

Luminta Pistol, Spiru Haret University, Bucharest, Romania, luminita_pistol@yahoo.com,

Rocsana Bucea-Manea-Tonis, Spiru Haret University, Bucharest, Romania, rocsense39@yahoo.com

Abstract

Nowadays the companies face the challenge of very high competition, expensive and insufficient resources, employee demoralization due to the effects of economic crises, expensive technologies. Besides all these problems the companies has to answer the need of disruptive changes and radical innovations in the management and production activity. A business development model should be sustainable on long term and has to take into account the environment protection. Thus emerge the idea of reducing cost by recycling and reusing the wastes, having a systemic perspective.

This paper aims to get a perspective on resources consumption and productivity of the economical agents analyzing the data published by Eurostat in Environmental Data Centre on Natural Resource. The result of data analysis is a regression model that weights the factors that influence the resource productivity.

Keywords: indicators in circular economy, resource productivity, regression

Introduction

Considering the lack of resources, the high cost of implementing green management models, the high cost of technologies and the low productivity in the added value chain the European Union (EU) is now agreed on important items that go towards circular economy (CE). CE relinquishes conventional economic model 'take-make-dispose' into a newest one 'prevent-reuse-recycle-recover-dispose" pattern [Pistol, 2017] in order to mitigate the risks of a new economical global crisis. CE should not become another buzzword in the sustainable development discourse.

There are more that 100 definitions for CE [Kirchherr, 2017], but it is obvious that the focus is on economic prosperity, with the concern on environmental and waste control. A low consideration is granted to social issues. "However, CE must be understood as a fundamental systemic change instead of a bit of twisting of the status quo to ensure its impact." The twist is to obtain economic growth by making more performing products that can be used for a longer time, instead of producing, selling or offering services to increase the companies' revenues. These products should be rather maintained then replaced. [Amui, 2017] "CE suggests keeping materials available instead of disposing them, and thus closing the loop of materials within the product lifecycle, in order to reduce resource usage and energy demand". [Ritzén, 2017]. "Expectations for the circular economy are articulated as: (1) a perfect circle of slow material flows; (2) a shift from consumer to user; (3) growth through circularity and decoupling; and (4) a solution to European renewal". [Lazarevic, 2017]

The article presents a regression model that explains in what extend the factors such as *new technologies for lowering carbon dioxide levels and air purification* or *improving buildings, ensuring efficient mobility* have facilitated the increase in resource productivity.

Literature Review

'Most of the methodologies developed so far measure resource efficiency on the basis of the environmental burden of the resource relative to the value of output. However, the key point of circular economy is keeping resources within the economy when products no longer serve their functions so that materials can be used again and therefore generate more value'[Maio, 2017].

The circular economy approaches are unlikely to make further energy efficiency savings disproportionately harder to achieve. Circular economy approaches have the potential to make significant energy savings that are complementary to other energy efficiency measures and equivalent to their potential. [Cooper, 2017]

In Jul-2017 Eurostat published an interesting data-source regarding essential elements of circular economy, called: ***Environmental Data Centre on Natural Resource***. [Eurostat, 2017]. The report presents elements on carbon dioxide evolution, management of waste, the urban population exposure to air pollution, pollutant emissions from transport – Nox and so on. It also had been allocated a section for research and innovation in the circular economy field. The data collected allow creating a perspective on resources consumption and productivity of the economical agents. It also identifies the week points in the implementation of the Roadmap to a Resource Efficient Europe.

The data source contains three categories of indicators, for the year 2000, 2005, 2010-2016, for EU-28, and for each country in EU:

- lead (resource productivity)
- dashboard (material, land, water, carbon)
- theme-specific indicators (turning waste into a resource, supporting research and innovation, getting the prices right, biodiversity, safeguarding clean air, land and soils, addressing food, improving buildings, ensuring efficient mobility).

Unfortunately Eurostat does not provide data for all these indicators for the period under review. Thus it had been extract only few of them to design a model, such as. *Resource productivity (RP), Carbon (C), Safeguarding clean air (SCA)* and *Improving buildings, Ensuring efficient mobility (IB).* The model aim is to weight how resource productivity is influenced by the new regulations and implementation of ecological technologies, methods and management. Other indicators that might influence *resource productivity* are related to Eco innovation.

Eco innovation became in important issue in the circular economy statement and is measured on the base of 16 sub-indicators from five thematic areas: eco-innovation inputs, eco-innovation activities, eco-innovation outputs, resource efficiency outcomes and socio-economic outcomes. The data source offer information for Eco innovation index [EII, 2016], as a average, in 2014-2015 (Fig.1). In the figure below we may see that the leads of eco innovation in Europe are Germany, Luxemburg, Finland and Denmark (EII almost 140). At the opposite pole there are counties such as Bulgaria (EII 40), Hungary (EII 60) and Romania (EII 70). The north countries are the engine of innovation, probably because they have more financial resources. The average of EII was constant, approximately 100 for the yeas 2013-2016. The lack of data for the year 2000, 2005, 2010-2013 urges us to exclude the index from the conceived economic model.

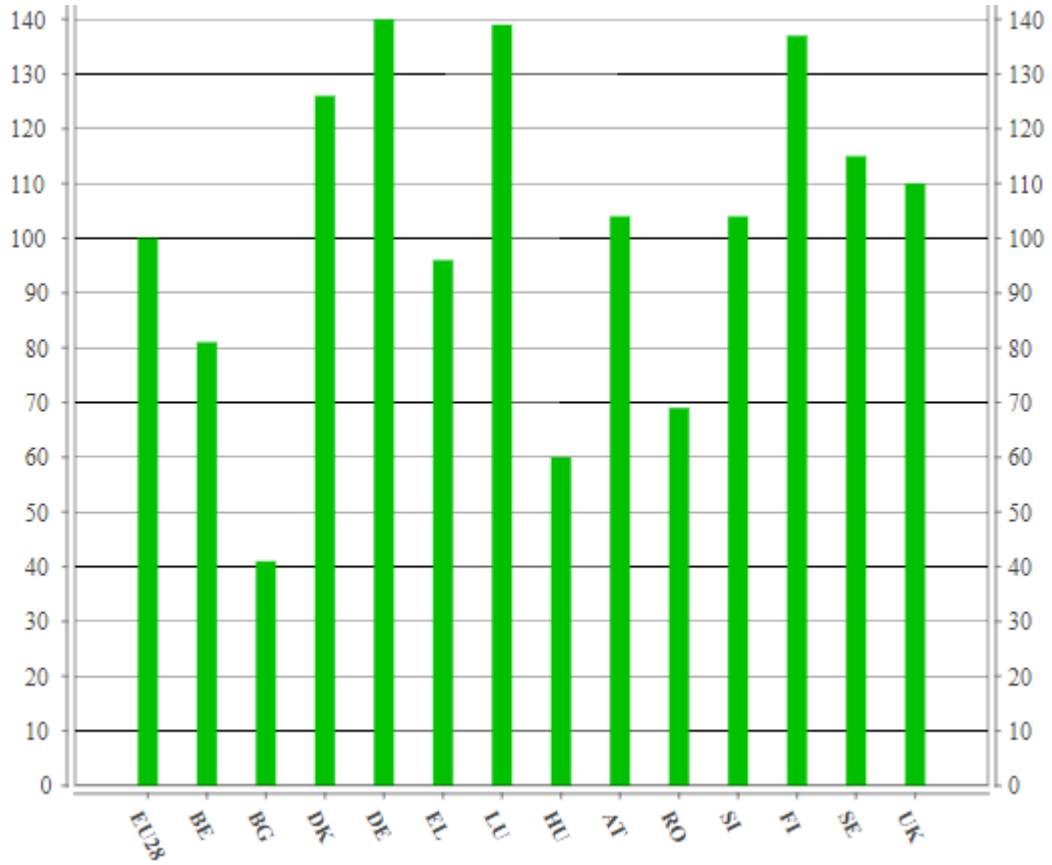

Fig.1: Eco innovation index for EU28

Research Methodology

Following the study of specialized literature and restrictions on access to data, we decided to study the evolution of resource productivity in the competitive environment of the CE. It had been designed a regression model that weight how *Carbon (C), Safeguarding clean air (SCA)* and *Improving buildings, Ensuring efficient mobility (IB)* can influence *Resource productivity (RP).*

The first step of the analysis is the studying the correlation between variables using the Pearson coefficient. This coefficient highlights the strong and positive correlation between carbon emissions - C and resource productivity (0.915 out of max 1), and between safeguarding clean air (SCA) and resource productivity - RP (0.958). This means that the more increase the first value of first variable, the more increase the second variable and at the same pace. A similar correlation can be seen between safeguarding clean air - SCA and carbon emissions (0,81). We notice that current production methods are harmful to the environment: the higher the production, the higher the carbon emissions and the more polluted the air. (Tabel 1).

Table 1: Correlation between variables (Pearon Coefficient)

Person	*RP*	*C*	*SCA*	*IB*
Resource productivity (RP)	1			
Carbon (C)	0.915994993	1		
Safeguarding clean air (SCA)	-0.958542183	-0.810805	1	
Improving buildings, Ensuring efficient mobility (IB)	-0.011940728	0.385972	0.196523996	1

The second step of the analysis: using Microsoft Eview, it had been designed a regression model, through *Least squares method.* At the beginning it had presumed that the null hypothesis is true, which asserts that the value of the coefficients of the variables will be zero (H0: coefficients = 0). The alternative hypothesis (H1) asserts the opposite of the null hypothesis: coefficients are different from zero. In other words, we start from the hypothesis that the mentioned factors (C, SCA, IB) have the value of coefficient 0, so they do not influence the resource productivity (RP).

Table 2: Regression Statistics and Coefficients – Least Squares

Dependent Variable: PRODUCTIVITY
Method: Least Squares
Date: 10/14/17 Time: 11:39
Sample (adjusted): 1 8
Included observations: 8 after adjustments

Variable	Coefficient	Std. Error	t-Statistic	Prob.
IB	-0.031610	0.003314	-9.537790	0.0002
C	0.153724	0.005982	25.69801	0.0000
SCA	0.023687	0.003833	6.179719	0.0016

R-squared	0.993618	Mean dependent var	1.838500
Adjusted R-squared	0.991065	S.D. dependent var	0.220099
S.E. of regression	0.020805	Akaike info criterion	-4.627275
Sum squared resid	0.002164	Schwarz criterion	-4.597485
Log likelihood	21.50910	Hannan-Quinn criter.	-4.828201
Durbin-Watson stat	2.494027		

The role of determining the multiple **R-squared** coefficients is to indicate the meaning of the relationship of the observed values with the ones predicted by applying the regression model to the Resource productivity. Table 2 shows that R-squared is 0.99 and since its value is close to 1, demonstrates that the relationship between observed and predicted values is strong. This observation confirms the consistency of the model.

The R-squared coefficient of this model is 0.993, indicates that 99% of the *Resource productivity (RP)* variance is determined by the variation of causal variables *(Carbon - C, Safeguarding clean air - SCA , Improving buildings, ensuring efficient mobility -IB)* and only 1% of this influence can not be explained by the model. As R-squared takes values closer to 1, the regression model better adjusts the data in the sample. In this case, the value of 0.993 demonstrates the validity of the model, which means that the variables C, SCA and IB influence RP (Table 2).

Also, the **Adjusted R-squared** value (0.993) is almost equal with the value of R-squared (0.991), which proves that the influence of the independent variables (C, SCA and IB) is significant to explain variance of the dependent variable (RP) and allows the extension of the proposed regression model to the entire population surveyed. In this case, the variance of the dependent variable decreases with the difference between the two coefficients (0.993 - 0.991 = 0.002). This difference can be seen to be below 1 (Table 2).

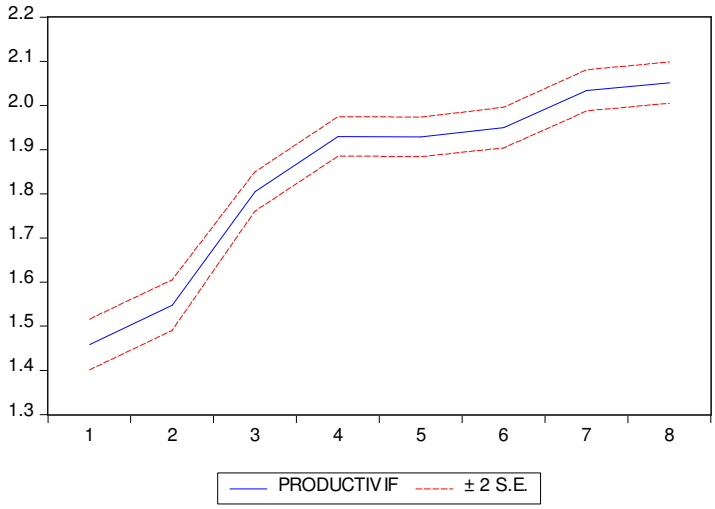
The validity of the model is reinforces by the fact that the variation explained in the regression model (**S.E. of regression** 0.02) is greater than that of the residual variables (**Sum squared resid** 0.002)

The simplest test to highlight error self-correction is the **Durbin-Watson** test. In this case the D_W value is 2.49, included in the [2, 4] interval. The conclusion is that is no self-correction between errors.

The **Akaike criterion** (AIC) is often used in model selection for non-nested alternatives—smaller values of the AIC are preferred [Eview, 2017].. In the analyzed case AIC is very small (-4.62).

The **Schwarz Criterion** (SC -4.59) and **Hannan-Quinn Criterion** (HQ -4.82) are alternatives to the AIC that imposes a larger penalty for additional coefficients and have similar interpretation.

In order to be able to interpret the statistical significance of the regression model, it is necessary to apply Fisher test. The **Fisher** test generated validates the model and stands that the independent variables (IB, C, SCA) greatly contributes to the predictive power of regression. This statement is based on the fact that **Prob.** (the significance threshold of the model) is 0.00 for all independent variables, less than the sensitivity threshold of 0.01 (Table 2). It may be summarizes that the model correctly adjusts the data series. The probability as F test value to be due to hazard is less than 0.01.



The regression equation for the model is:

$$\textbf{Resource productivity (RP)} = 0.15*C + 0.02*SCA - 0.031*IB + \varepsilon$$

Particular attention must be paid to the estimated coefficients of the regression equation (Table 2). For all independent variable (IB, C, SCA) the null hypothesis must be rejected because the significance threshold is Prob. = 0.00 <0.01. With a 99% probability and a small standard error of 0.0033, IB coefficient is -0.031. With a 99% probability and a small standard error of 0.0593, C coefficient is 0.15. With a 99% probability and a small standard error of 0.0038, SCA coefficient is 0.02.

In conclusion, the alternative hypothesis is accepted. It stands that C, SCA, IB, has the coefficient different from 0 and influences RP. The increase in resource productivity is associated with increase in Carbon emissions (C) and harming clean air (SCA). Improving buildings indicator and ensuring efficient mobility (IB) led to a decrease in productivity due to high costs.

The third step of the analysis is a forecast of resource productivity variable (fig.1). If the current trend is maintained, for the next years, it is predicted a constant increase of resource productivity. This is good news, but the unpleasant side is that increase of resource productivity is associated with increase of environment pollution. Steps have been taken to reduce pollution and protect the environment, but their share in the current context is lower, as it might be seen in the regression model (table 2).

Forecast: PRODUCTIVIF	
Actual: PRODUCTIVITY	
Forecast sample: 1 9	
Adjusted sample: 1 8	
Included observations: 8	
Root Mean Squared Error	0.016448
Mean Absolute Error	0.013311
Mean Abs. Percent Error	0.708298
Theil Inequality Coefficient	0.004445
Bias Proportion	0.000145
Variance Proportion	0.004544
Covariance Proportion	0.995311
Theil U2 Coefficient	0.126646
Symmetric MAPE	0.707390

Fig.1: Resource productivity forecast

Conclusions

Because human race extended the resource consumption above the limits making many negative footprints, they have to come up with solutions to reestablish the equilibrium. This solution seems to be CE. The companies of our century are increasingly aware of the need to adopt the eco trend. However, the cost of adopting the new economic model, of the CE is not easy to be paid, because of financial, structural, operational, attitudinal and technological barriers.

The results of the analysis made in this paper indicate that the new technologies, methodologies and managerial methods make their mark on the resources productivity. Of all the variables analyzed, it had been observed that the implementation of new technologies for lowering carbon dioxide levels and air purification have facilitated the increase in resource productivity. And the improving buildings indicator, ensuring efficient mobility, has led to a decrease in productivity due to high costs. In this respect, it is recommended to adopt new innovative models and technologies that promote sustainable development.

The model should be further developed with new variables such as: *turning waste into a resource, supporting research and innovation, getting the prices right, biodiversity, reducing land and soils footprint, addressing food, improving buildings, ensuring efficient mobility*, etc. Insufficient statistic data were provided by Eurostat.

Pointing to the future Innovation in management and technologies should offer better perspectives for both productivity and environment protection.

Developing Entrepreneurship Education within Universities: The Italian "Contamination Lab" case

Giustina Secundo, Giuseppina Passiante, Maria Andriulo

Department of Innovation Engineering, University of Salento, Lecce, Italy,
giusy.secundo@unisalento.it; giuseppina.passiante@unisalento.it; mariandriulo@hotmail.it

Abstract

The focus of this research is to present a particular typology of entrepreneurial projects in the field of Entrepreneurship Education. The article describes the operational model of the "Contamination Lab" an innovative Laboratory aimed at developing an entrepreneurial mindset, creativity and innovation at University of Salento (Lecce, Italy) according to the learning strategy of the Entrepreneurship Education. The laboratory involves all the University's students with different backgrounds (Business, Humanities, Social science, Science, Engineering , Biology, arts etc..) through an innovative extra-curricular learning program to create an entrepreneurial awareness, mindset and capability. The final value is to grow in effectiveness and contamination of ideas, knowledge and skills within the University and the local Entrepreneurship Ecosystem according the Quadruple Helix model (Carayannis and Campbell, 2009).

Keywords: entrepreneurship education, entrepreneurial mindset, case study, quadruple helix.

Introduction and Background

In the entrepreneurial economy developing entrepreneurial capacity, competence and attitude to transform new ideas, technologies and inventions into products and services to create economic and social value through innovative business models (Allen 2009; Ratinho et al. 2015) becomes the real concern. This needs to be addressed in education, teaching and learning (Lamine et al. 2016; Henrekson and Rosenberg 2001) as a key competence to be developed by highly skilled human capital (Global Innovation Index, 2017; European Union, 2006; European Union 2016). Thus, equipping human capital with an entrepreneurial mindset could be considered as an important antecedent for developing technology entrepreneurship (Elia et al., 2017; Secundo et al, 2017): it represents the skill helping the citizenship, students at all levels of education, young entrepreneurs and start-upper to be creative and confident in whatever they undertake (European Commission, 2008) in order to react to business uncertainty, ambiguity and complexity (Gibb 2005). The entrepreneurial mindset, can be defined as the capacity to think creatively, strategically, analytically and reflectively; the confidence in one's abilities, the ability to collaborate, the well-developed communication skills and understanding of the current business context (Pollard and Wilson, 2014).

The literature claims that an entrepreneurial mindset can be developed (Kuratko 2005) and shows how schools, higher education and academic education are the most fertile ground to create this, above all university (INSEAD, WIPO, 2014). Particularly, in the academic education, Education Project Programs (EPP) are increasingly being established in an effort to equip students with the knowledge and competence needed to create economic value, but above all to create an entrepreneurial awareness (Duval-Couetil, 2013). In the last years, scholars highlighted the role of

Science and Technology Entrepreneurship Education (STEE) in promoting more entrepreneurial mind-sets in the field of advanced technologies has flourished in the academic community through a large number of initiatives (Fayolle 2008; Cassia et al. 2014; Lamine et al. 2016; Passiante and Romano 2016). In this context, University plays a fundamental role for promoting technological change and innovation (Bramwell and Wolfe 2008; Elia et al. 2017) as well as for creating favorable environments for entrepreneurship cultural development (Kirby 2004).

The entrepreneurship education has received a significant increase also within the Italian Universities even if the scholars found two problems related to the lack of effectiveness and the achievement of the desired goals. Firstly, most of the entrepreneurial education courses are present in business schools and department; secondly, the organization of courses did not innovate much traditional teaching methods (Iacobucci, Donato, Micozzi, 2012). The research shows that the real challenge is the shift from education "about" entrepreneurship to education "for" (Kirby, 2004) and "through" entrepreneurship; the approaches and methodologies to create places for entrepreneurial skills development is the shift from "traditional methods" to "innovative methodologies" (as simulations, meeting with entrepreneurs, project works, etc...) where the interactions of University' students with Industry, Institutions and Civil Society are encouraged in sustaining the Quadruple Helix Model (Carayannis and Campbell, 2009).

Against this premises, there is still the need to understand in practices which are the processes for developing an entrepreneurial mindset. With the aim to cover this gap, this paper describes a framework to understand the learning processes characterizing the entrepreneurial mindset development for innovative entrepreneurship within Italian University.

Methodology: Case study

The paper adopts a case study methodology (Eisenhardt, 1989) aimed to analyze the processes to create an entrepreneurial mindset and skills in the university's students. The case study analyzes the phases of design of an innovative EPP related to entrepreneurial education at University of Salento (Lecce, Italy) aimed at instilling in students with different background and enrolled in undergraduate, graduate and post graduate studies an entrepreneurial mindset , creativity and innovative ideas. The project named Contamination Lab of University of Salento (hereafter "CLab@Salento") has been successfully evaluated by the Italian Ministry of University and Research – MIUR. The project has been ranked third among the 25 projects submitted by the Universities located in the South of Italy; Just 7 projects will receive funds from the MIUR. The project has a duration of three years (starting on September 2017) and will organize 6 editions of an innovative EPP. The preliminary phase of design and organization of the learning and experimentation activities started in the month of September 2017. The launch of the entrepreneurship program is scheduled on November 2017 and will involve 40 students.

Preliminary Findings

This section is aimed to describe the design phase of the "CLab@Salento" a laboratory of "contamination" which involves university students from different faculties and high school students. The operational model of "CLab@Salento" can be described in five components (figure 1): 1) the programs' aim and final impact; 2) the program basic value; 3) the learning path to develop entrepreneurial mindset; 4) the stakeholders involvement in the learning strategy; and 5) the entrepreneurial mindset assessment.

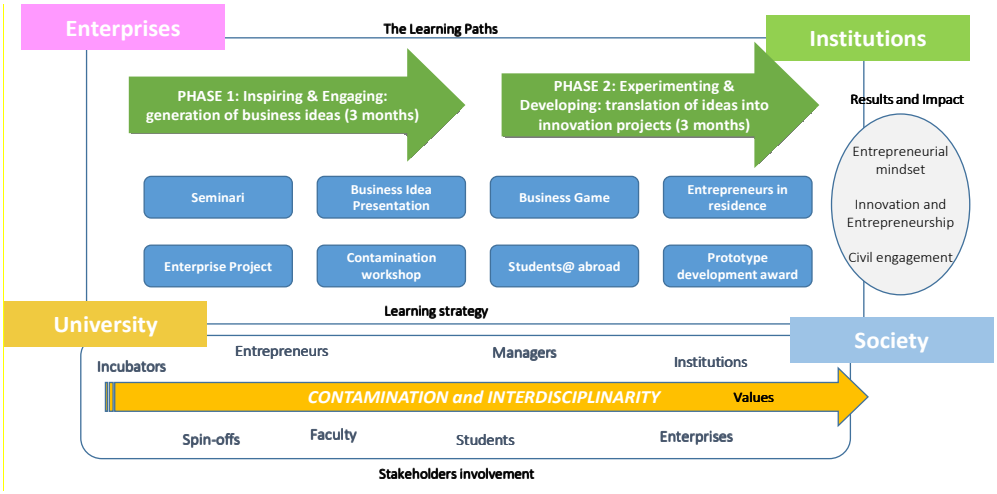

Figure 1: The Contamination Lab "CLab@Salento" Learning & Experimentation model

The program aim and final impact. The project aim is to create a virtual and physical laboratory to develop and diffuse in the University students an entrepreneurial mindset and awareness, creativity, innovation and entrepreneurial and business culture; develop "spirit of initiative and entrepreneurship", understood as the ability to translate ideas into actions; develop entrepreneurial awareness with models of learning with strong interdisciplinary connotation; integrate managerial and scientific skills for the analysis of business opportunities; develop team building skills and profitable contamination between different scientific areas. Three "pillars" in which University of Salento is involved will be taken in consideration: *smart technologies* (nanotechnologies, robotics, innovative materials, digital economy & banking, new digital tools), *bio-economy* (bio-based industries, biotechnologies, blue growth, green chemistry, etc..), *cultural and creative industries* (tourism, storytelling, cultural heritage valorization, empowerment, …). This aim will be achieved using innovative learning methodologies based on the contamination of different background, interdisciplinary teams, project-based learning activities guided by different local and international stakeholders. The final impact for the University is to achieve the third mission aim through the creation of a permanent laboratory for the diffusion of innovation at local level. The final result for the enterprise and companies participating to the activities is to develop innovative projects in collaboration with student and corporate entrepreneurship in the form of new product, services and processes. Finally, the impact for the civil society is the involvement of the institutions for the generation of social innovation and knowledge transfer.

The program basic value: includes the Interdiscipilinarity and the Contamination. The first one is related to the diversity in the students' composition: the Laboratory is a place where the sharing and collaboration among ideas of students of different degrees (from high school to doctorate) and various disciplines; the second one is the Contamination among students, between students and teachers, with the other contamination laboratory already active in Italy, with the world of entrepreneurial innovation, with the territory, with the school world, with Europe and the rest of the world. In the process of contamination, all the actors of the entrepreneurship ecosystem of the territory interact to implement a profitable contamination of ideas, knowledge and skills both for the spread of entrepreneurial culture and for the development of the territory.

The learning path to develop entrepreneurial mindset. The learning path lasts 6 months and it includes two phases (both of which lasts for 3 months). *Phase 1: Inspiring & Engaging* aimed to the development of entrepreneurial awareness and to the generation of business ideas. The learning

strategies mainly concern: *Business Idea Competition*: ideas created by students and selected to start the creation of interdisciplinary teams; *Enterprise Project Idea*: businesses present innovative ideas to be developed by interdisciplinary team; *Contamination Learning Workshops*: teachers, entrepreneurs and students discuss on selected issues; *Entrepreneurs in Residence*: entrepreneurs share their experiences in workshops. The core contents of this phase are: Communication and team building, Innovative entrepreneurship; Technological foresight; Creative thinking; Business Model Canvas; Arts and Creativity for Business; Innovation and territory empowerment.

Phase 2: Experimenting & Developing is characterized by the translation of ideas into innovation projects etc. The initiatives will mainly concern *Students@abroad*: students are selected for travelling to an international or national center; *Business Game*: on-line simulations; *Prototype development Award*: activities including the study of project feasibility and the development of prototype. The core contents of this phase are: Project Management, Design Thinking, Digital Enterprise, IPR: intellectual Property right, Communication 2.0, Business Plan and rapid Prototype development.

The stakeholders involvement in the learning strategy. The stakeholders involvement is very important for entrepreneurial learning strategy. They includes university faculty and all the actors of the Entrepreneurship ecosystem, as the regional institutions, entrepreneurs, managers, local companies, national enterprises, International Centers on Entrepreneurship and Innovation, European Universities and citizenship (Secundo, del Vecchio, Passiante,2015) which can contribute providing seminars, developing innovative projects proposed to the students.

The entrepreneurial mindset assessment. This section regards the short- and long-term impact monitoring indicators grouped by impact areas. They refer to the knowledge acquisition and theory background, the ability to apply the concept, the capacity to generate new value (Kim, 1993) and the capacity to contaminate. In particular, the indicators are related to: Relationship and Impact in territory; Interdisciplinarity; Context; Innovative Enagagement; Entrepreneurship; Training; University Contamination; Institutional and Industrial Contamination; Internationalization.

Conclusions

This paper provides a descriptive framework to show how is possible to create entrepreneurial mindset in the academic and university field, analyzing all the processes to develop (Duval-Couetil, 2013). Future research will be aimed to describe more in deep the “CLab@Salento” operational model discussing the phases of monitoring and assessment of the planned results for students and for all the stakeholders involved into the projects.

Abstract

In Romania, the taxpayer is obliged to calculate, declare and pay the contributions to the State Budget. The accounting information provided by the economic entity is very important for the state institutions because based on it they determine the fiscal policy, calculate the national income and other statistical indicators. This paper discusses the dynamics of the fiscal deficit of the Romanian Budget on the 31-st of December 2014 as compared to the same period in 2015 and 2016. We have chosen these three years because we wanted to identify the effects of reducing fiscal pressure on the level of State Budget collecting system, given that from October 1st 2014 - the employer's social insurance contribution was reduced by 5 percentage points and from January 1st 2016 VAT has fallen from 24 to 20 percentage points, and now (2017) at 19%; the research has been done on the basis of the data offered by the Romanian National Agency for Tax Administration (NAFA) on 200 companies considered as large business taxpayers. The results of the research present the level of unpaid taxes of these companies in the context of reducing fiscal pressure, the ways of collecting debts as well as the impact of uncollected debts on certain fields of activity in the public sector.

Keywords: accounting information, fiscal deficit, State Budget

Introduction

The way of organizing the society implies putting some funds at its disposal in order to fulfil its functions. Gradually the in kind incomes are replaced by monetary revenues which take the form of compulsory installments. To assure the level of returns necesary to the State and in order to mobilize and track them there has been funded a specialised agency called Revenue Office. The Revenue Office is defined as „the State Agency which establishes taxes and tolls and goes after those who do not pay up their taxes."

This paper observes the situation of the fiscal deficit correlated with the large business taxpayers and the impact of uncollected debts on the State Budget. Despite the taxpayers have a series of ways to pay up debts still they cannot pay their exigible debts and they find themselves in the position of not being able to pay all their taxes.

The state revenues have greatly diminished because of uncollected fiscal taxes and implicitly the quantity of goods and public services offered to the citizens has also decreased. A sector affected by the lack of budgetary funds is the health sector, thus hospitals are deprived of high quality medicine, equipment, medical asssistance. In many cases doctors do not have performance equipment to cure the patients in best conditions and a great number of care units do not have the European hygiene standards. Loans have been made because of uncollected funds and depending on the tax refund period the State overburdens the following generations who will have to pay back.

The Research Methodology

The research method consisted in reviewing the approaches of the specialty literature, articles and special studies published in national and international magazines. We followed a detailed approach of the dynamics of the budgetary fiscal deficit by collecting the data needed for a comparative study regarding the evolution of the Romanian fiscal deficit in the last 3 years.

I. Dynamics of the fiscal deficit of the Romanian State Budget in relatition to the large business taxpayers

Accounting information must allow both existing investors and potential ones to identify, measure, clarify, evaluate all operations and activities of an entity. Without a doubt, one of the most important products that a bookkeeper offers is the accounting information. This enables managerial decisions and appropriate investment for existing and potential investors as well, according to the reaserch made by Vătăşoiu C.I. (2010). Domnișoru S. (2011) mentioned that accounting information are part of the treasure of knowledge and of investigation of the issuing entity and of interested parties.

In the reaserch made by Andone I., Tabără N (2006) accounting information, the result of a system of principles and rules, relatively homogeneous, remains the „ace" from his sleeve, of different groups of users, providing a high degree of credibility in relation to other sources of information on the organization.

Fiscal debts represent property rights resulting from the relations of fiscal rights. From the foregoing relations we observe both the content and the amount of tax debts which represent determined rights consisting in:

a) The right to levy taxes, contributions which are considered revenue budget, the right to refund the value added tax, the right to tax refunds, contributions etc. known as main fiscal debts.
b) The right to ask for penalities for delays known as accessory fiscal debts (see also bonds).

Law stipulates that the internal revenue service is endowed to ask for the annulment of a debt and to excuse the indebt to pay a bond in the debtor's place.

Fiscal debt and correlative financial bind are both possible in case of a tax base that generates them. Fiscal deficit as well as correlative fiscal bind occur in case of a tax base that generates them. Taking into account that the Romanian fiscal system is a declarative one and implies voluntary action of each tax payer to estimate, declare and pay the due taxes. The present study is based on the data offered by the Romanian National Agency for Tax Administration (NAFA) which has to provide resources for public expenditures by collecting and managing taxes and contributions owed to the State Budget.

State Budget Deficit is formed by:

- tax on profit,
- VAT,
- income tax,
- excise duties,
- other taxes,
- interests and penalties.

On the 31-st of December 2014 and on the 31-st of December 2015 and 2016 the Romanian National Agency for Tax Administration published the lists with the unpaid fiscal debts of the large business taxpayers. From those lists it results the following:

❖ **Unpaid fiscal debts of the large business taxpayers on the 31-st of December 2014**

On the 31-st of December 2014, the unpaid fiscal debts of the large business taxpayers amounts to **4.018.099.606** lei. As can be seen in table no. 1 this amount represents the sum of the following obligations:

Table 1: Unpaid fiscal debts of the large business taxpayers on the 31-st of December 2014 - the amount expressed in lei- 1 euro at 31-st. Of December 2014 = 4,4821 lei

Nr. Crt	Obligation	Amount
1	Tax on profit	21.691.818
2	V.A.T	1.116.963.840
3	Income tax	237.206.985
4	Excise duties	65.906.388
5	Other taxes	209.403.370
6	Interests and penalties	2.366.927.206
	TOTAL	**4.018.099.606**

(Source: own interpretation after the published list of NAFA)

From the data showed in the table we can observe that in 2014 the level of interests and penalties owed by large business taxpayers is very high, namely 59%. Debts from V.A.T are second in place in the top of unpaid bonds, namely 28%. The tax on wages as well as taxes called „other taxes" contribute with sums representing 11% of the total debts owed to the State. In the budget structure we also find revenues obtained from excise duties which in this case represent 1,6% and the tax on profit which contributes with only 0,4% of the total of unpaid debts.

❖ **Unpaid fiscal debts of the large business taxpayers on the 31-st of December 2015**

On the 31-st of December 2015, the unpaid fiscal debts of the large business taxpayers amounts to 2.538.327.435 lei. As can be seen in table no. 2 this amount represents the sum of the following obligations:

Table 2: Unpaid fiscal debts of the large business taxpayers on the 31-st of December 2015 -the amount expressed in lei- 1 euro at 31-st. Of December 2015 = 4,5245 lei

Nr. Crt	Obligation	Amount
1	Tax on profit	18.441.154
2	V.A.T.	500.754.712
3	Income tax	195.608.637
4	Excise duties	188.235.872
5	Other taxes	151.417.262
6	Interests and penalties	1.483.869.798
	TOTAL	**2.538.327.435**

(Source: own interpretation after the published list of NAFA)

From the data showed in the table we can observe that in 2015 the level of interests and penalties owed by large business taxpayers is very high as well, namely 58%. Debts from V.A.T are second, namely 20%. The tax on wages, 8%, as well as taxes called „other taxes", 6%, contribute with sums representing 14% of the total debts owed to the State. In the budget structure we also find revenues obtained from excise duties which in this case represent 7% and the tax on profit which contributes with only 1% of the total of unpaid debts.

❖ **Unpaid fiscal debts of the large business taxpayers on the 31-st of December 2016**

On the 31-st of December 2016, the unpaid fiscal debts of the large business taxpayers amounts to 1.043.710.209 lei. As can be seen in table no. 3 this amount represents the sum of the following obligations:

Table 3: Unpaid fiscal debts of the large business taxpayers on the 31-st of December 2016 -the amount expressed in lei- 1 euro at 31-st. Of December 2016 = 4,5411 lei

Nr. Crt	Obligation	Amount
1	Tax on profit	162.408.307
2	V.A.T.	484.773.198
3	Income tax	25.225.525
4	Excise duties	12.877.826
5	Other taxes	82.818.793
6	Interests and penalties	275.606.559
	TOTAL	**1.043.710.209**

(Source: own interpretation after the published list of NAFA)

From the data showed in the table we can observe that in 2016 the V.A.T. level is high, namely 47%. Debts from interests and penalties are second in place in the top of unpaid bonds, namely 26%. The tax on wages, 2%, as well as taxes called „other taxes", 8%, contribute with sums representing 10% of the total debts owed to the State. In the budget structure we also find revenues obtained from excise duties which in this case represent 1% and the tax on profit which contributes with 16% of the total of unpaid debts.

Having this database, in the next figure, Figure nr.*1 The dynamics of the unpaid fiscal debts*, we can see the dynamics of the unpaid fiscal debts of these 200 comapanies, in relation to the State budget in the years subject to the analysis:

- the amount expressed in lei –

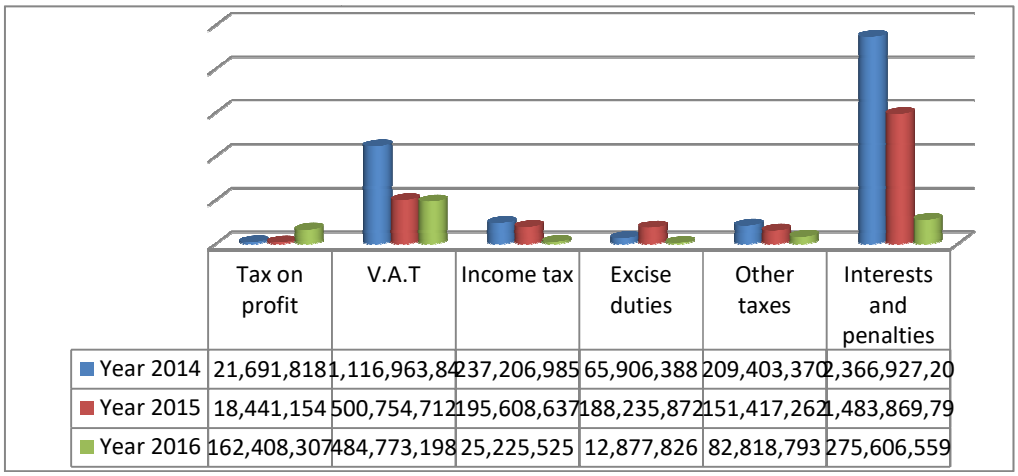

Fig. 1: The dynamics of the unpaid fiscal debts
(Source: own interpretation after the published list of NAFA)

Comparing the values registered on the 31.12.2016 with those registered in the same period of 2015 and 2014 we can observe that the level of unpaid debts of the large business taxpayers has greatly diminished. If in 2014 the debts of the large business taxpayers reached **4.018099.606** lei, in 2015

they dropped to **2.538.327.435** lei and in 2016 the dropping trend amounted the sum of **1.043.710.209** lei.

In the joint figure we can observe that from 2014 and up to 2016 the sums coming from VAT, income tax, other taxes as well as those coming from interests and penalties dropped each year. In exchange in 2016 compared with 2014 the sums coming from the tax on profit have significantly increased from 21.691.818 lei, the debt registered at the end of 2014 up to 162.408.307 lei debt registered on the 31.12.2016. The excise duties situation is opposed to that registered in the case of tax on profit. Thus if in 2014 the companies' debts due to the State reached the value of 65.906.388 lei and in 2015 the values of those debts compared to the previous year have almost tripled and by the end of 2016 the values dropped to 12.877.826 lei.

Generally the drop in debts of the large business taxpayers in 2016 compared to the previous 2 years represent a favourable difference in the actual economic context. The State has fewer uncollected debts from the large business taxpayers in 2016 compared to the same period of 2015 and 2014. Does this imply a more eficient way of collecting debts or has the activity of the companies diminished each year?

II. Means of collecting the taxes needed for public financing

To collect debts due to the State, the fiscal code stipulates the following possibilities: payment, compensation, reimbursement, debtor's insolvability, commissioning payment, enforcement, allowances and assignment of debts.

To underline the means of collecting the taxes needed for public financing we made an analysis of the 200 companies. Using the annual charts we can percentualy analyse the most used method for paying up debts.

- **Year 2014**

In 2014 the State deficit reached the value of **4.018.099.606** lei and represented the sum of restant debts of 200 companies considered large taxpayers. From the total of 200 companies, most of them are in the position in which the enforcement has started (80% of cases). In figure no. 2 Means *of paying up debts due to the State Budget in 2014,* we observe that means of collecting the debts predominates in most cases. 35 companies (17,5%) are waiting for an answer at their request for compensation and 5 companies (representing 2,5% of the 200 companies) benefit of allowances.

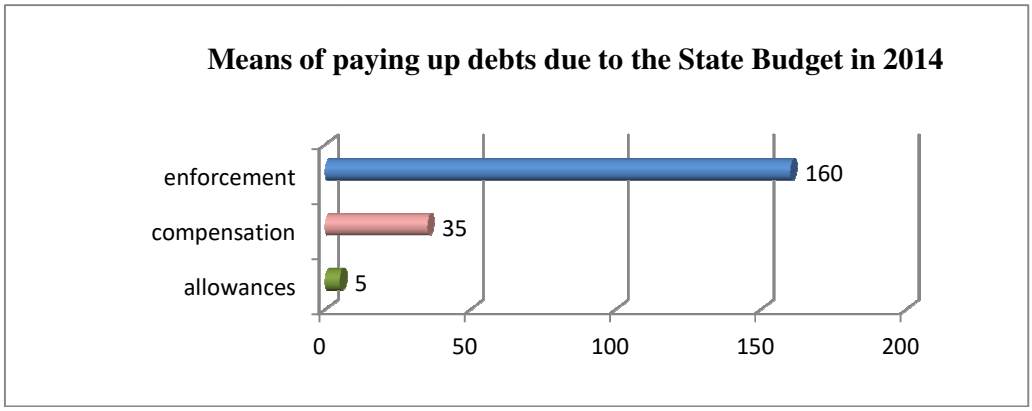

Fig.2 : Means of paying up debts due to the State Budget in 2014
(Source: own interpretation after the published list of NAFA)

❖ **Year 2015**

In 2015 the State deficit reached the value of 2.538.327.435 lei and represented the sum of restant debts of 200 companies considered large taxpayers. From the total of 200 companies, most of them are in the position in which the enforcement has started (100 companies, namely 50%), as can be seen in the figure no.3 *Means of paying up debts due to the State Budget in 2015*. 40 companies (20%) are waiting for an answer at their request for compensation, 60 companies (representing 30% of the 200 companies) are in insolvency.

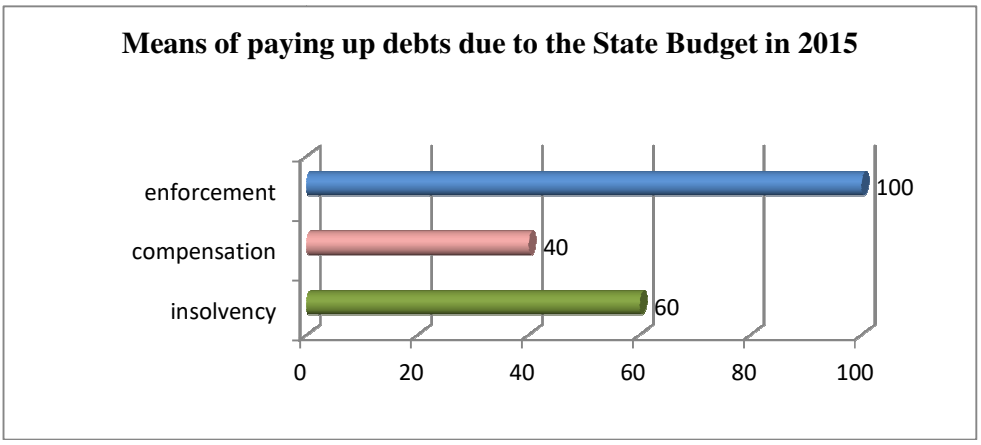

Fig. 3 : Means of paying up debts due to the State Budget in 2015
(Source: own interpretation after the published list of NAFA)

❖ **Year 2016**

In 2016 the State deficit reached the value of **1.043.710.209** lei and represented the sum of restant debts of 200 companies considered large taxpayers. From the total of 200 companies, most of them are in the position in which the enforcement has started, as we can observe in figure no.4 *Means of paying up debts due to the State Budget in 2016,* that means of collecting the debts predominate in 60% of the cases (120 companies). 50 companies (25%) are waiting for an answer at their request for compensation and 30 companies (representing 15% of the 200 companies) are in insolvency.

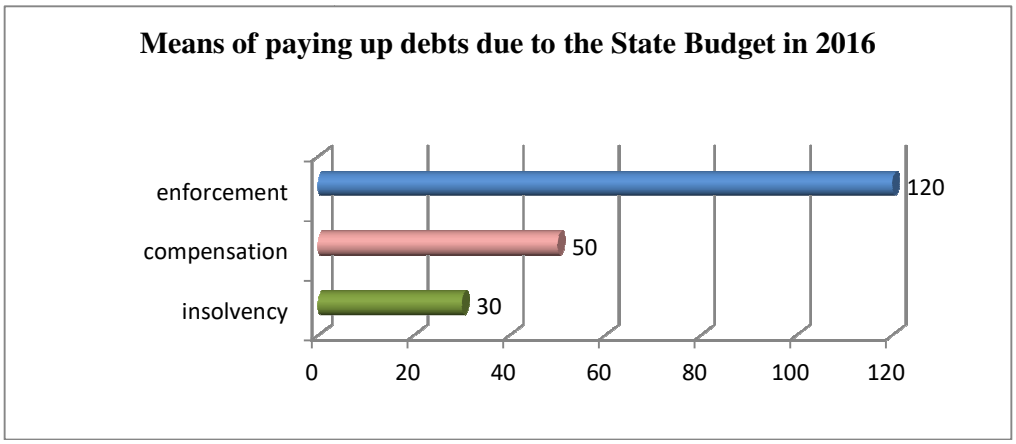

Fig. 4 : Means of paying up debts due to the State Budget in 2016
(Source: own interpretation after the published list of NAFA)

As far as can be seen from the charts, the most common mean to collect debts to the State Budget is by enforcement. But an important question remains, what happens, however, in the situation when instead of outstanding amounts, the State notes that are auctioned a stapler and a printer found at companies with huge debts to the State Budget?

Conclusions

Causes and effects of uncollected debts

Even if there are numerous ways of collecting debts, the lack of resources, the lack of available funds to pay debts block the collecting process.The biggest loss comes from the annual debts which are prescribed and cannot be collected as well as from the intrinsec loss generated by any uncollected fiscal debt which is added to the financial burden that hinders the citizens.

We may say that the effects generated by contributions and taxes payable by physical entities and juridical entities are linked to their reactions towards collecting taxes. Generally the attitude regarding taxes is not one of acceptance but an attitude of refusal of paying fiscal debts. Because of uncollected debts, the State is obliged to appeal to measures as foreign loan. In addition to the loans that have already been made from Romanian banks, the State has asked for the support of the International Monetary Fund. This loan has been conditioned by some clauses as adopting the unique wage law, cutting the budgetary jobs, cutting bonuses and incentives as well as wage freezein the budgetary sector for a certain period of time.

Allocation and effective use of public finances represent two of the most important issues for public authorities since making public expenditures is conditioned by using the resources came from taxes.

The authorities give the resources specific usages as sustaining expenditures which are consuming resources like those serving for collective utilities which cannot be obtained individually as: expenditure related to public order or purchases made for the good functioning of pubic institutions. From economic point of view these expenditures do not produce revenues but they consume resources which need to be permanently refunded. In addition to those traditional state expenditures there are other expenditures which need only advanced resources. They include investments in economic entreprises or subsidizing private companies. The result of these expenditures is focused on durable goods and economic services which can be recovered and can also be income generating. A concrete example in this case is the minimis aid offered by The Romanian Government to stimulate investements of small and medium companies and to create new jobs. Besides these expenditures, there are expenditures made with the educational system, the health system and with culture. They have a mixed character and they are financed both from public and private sector. Dual funding of expenditures represent an objective necessity taking into account that they are intended for expensive areas that demand for bigger and bigger budgetary funds. Thus the State assumes the budgetary resources, it finances primary expenditures following that high-quality services are supported in part by beneficiaries.

As it can be seen the collection of state debts is particularly important for "the good" of the whole society because otherwise the unpaid debts of entities will affect all industries and there is a risk of affecting the following types of expenses: social-cultural or defense expenditures

It can be said that symbolically the economic system can be compared to a circular chain which may break at the weakest link . Therefore there is a priority in supporting an intense economic activity which could generate jobs and by horizontal development it should lead to increasing the number of taxpayers, increasing the amount of wages owed to the state as high or substantial profits resulting in improved productivity. With countless unemployed and socially assisted persons the Stae is growing weak and increasingly impoverished. Instead the State can be strengthen by a policy of supporting the private economic sector which has demonstrated over time its ability to absorb labor and generate revenue to the budget. It goes without saying that the State should participate by paying on time the commitments negotiated with operators so that they could be able to pay taxes, fees and contributions at maturity.

Abstract

Nowadays, multimedia document sharing networks, in particular images, have become very popular. They enables to host a massive amount of data stocked in the databases. Therefore, the discovery of the most relevant images, which respond to the users' needs, constitutes a challenge for researchers. Thus, many research studies have been focusing on improving the images annotation process. In fact, an effective annotation helps to facilitate and optimize the images research process.

In this context, we suggest in this paper an annotation approach dedicated to the socio-tagged images. The suggested approach consists of constructing and inferring a set of semantic rules that specifies the different semantics of an image according its semantic facets pattern. These rules are presented via the logic of predicates. Experimental studies are performed on a collection of 25.000 socio-tagged images shared in *Flickr* service and the evaluation results demonstrate the effectiveness of the suggested approach.

Keywords : Socio-tagged Images, Domain Ontology, Semantic Facets Pattern, Semantic Rules, Semantic Annotation and Inference Processes, Enriched Ontology.

1. Introduction

Previously, the information research process has treated only text documents. Nevertheless, with the progress of the multimedia technologies and the emergence of the Web 2.0, the concept of document cover other content types such as image, video and audio. Accordingly, the mass information available on the web, in particular the images, has grown exponentially especially with the popularity of the social networks. Hence, the research process of the most pertinent images has become an extremely difficult task that requires adequate discovery methods adoption. In this context, we distinguish two research methods:

- **The Content-based Image Retrieval** (*CBIR*)**:** which is used to look for images based on their visual characteristics, such as shape, texture, and color (Kumar 2010).
- **The Text-based Image Retrieval** (*TBIR*)**:** which is based on the return of potentially relevant images compared to a textual research query described by a user (Zhang & al., 2005).

Nevertheless, most users prefer to use the textual queries because of semantic gap between the visual image features and the human concepts (Smeulders & al., 2000). Therefore, the images should be annotated in order to facilitate the text-based research task. The annotation process consists in associating a set of keywords to an image which will be the focus of research queries. However, the content of the annotation might represent a problem. Indeed, it is necessary in the context of images to define the description level (visual content, semantic content, etc.), the used vocabulary (structured or unstructured) and according to what facets (temporal, spatial, taxonomic, etc.).

On the other hand, the traditional methods of images retrieval are relied on manually or semi-automatically images annotation. However, the intervention of human operators during the annotation process is expensive, laborious and time-consuming task. Hence, it is recommended to automate the images annotation process.

In this context, we are interested in our work in the annotation of the images shared on social networks. In fact, these images are frequently associated with a set of tags that are introduced by the social community. However, these tags are often ambiguous because they are voluntarily introduced by amateur photographers who are not domain experts. So, they do not constitute an effective solution enabling to describe the images content by a specific and complete vocabulary. Therefore, we must concentrate efforts on automating the annotation process of the socio-tagged images by their semantic content based on a pre-defined description pattern.

The outline of this paper is organized as follows : Section 2 presents some research works dealing with the annotation of image-type documents. Section 3 presents the general architecture of the proposed approach. Section 4 presents an overview on the adopted modeling technique of the socio-tagged images semantic facets. Section 5 details the annotation and the inference processes and presents the extension of the used ontology. Section 6 presents the general algorithm of the annotation process. Section 7 presents the experiments carried out and the obtained results. Finally, we conclude this paper while suggesting some future perspectives.

2. Related works

During the recent decades, there has been extensive research in aiming to improve the images annotation and consequently to optimize the research process. These studies can be classified into two broad categories : visual content-based images annotation approaches and textual content-based images annotation approaches.

2.1 Visual Content-based Images Annotation Approaches

With the evolution of computer vision technologies, the visual content-based images annotation techniques have become very prevalent. The aim of this type of approaches is to attribute to an image a set of keywords. These keywords can be related to the visual objects of an image (*low-level features*) or to its semantic content (*top-level features*).

The annotation based on the *low-level features* of images depends essentially on objects recognition which appears in the images. The objects recognition can be often performed by the region-based segmentation technique. Thereafter, an identifier is assigned to each recognized object. The objects identifiers can be chosen from an unstructured vocabulary (Von Ahn & al., 2004 ; Von Ahn & al., 2006) or from a structured vocabulary such as ontologies (Adebayo & al., 2016 ; Preece & al., 2016 ; Lingutla & al., 2014). Although these approaches have enabled to reduce the semantic gap problem by providing a better description of the images' visual content, they are considerate subjective and may not accurately describe images content. In fact, the recognition of activities and events which appear in the images are quite negligible.

As an alternative, the oriented-semantics annotation approaches have originated. Indeed, the approaches based on the *top-level features* of images enables deducing the image's semantics in term of its visual characteristics (regions, objects, etc.) (Wang & al., 2013 ; Zomahoun & al., 2013) or in term of the spatial relationships that exist between the objects which appears therein (Ayadi & al., 2013 ; Wang & al., 2010). Though these approaches have provided considerable testing in order to generate and infer semantic descriptions for images, the expression of the semantic content of images remains partial because it is not based on a specific semantic model or pattern. In fact, some approaches have successfully described the spatial semantic content of images, however, other semantic facets such as the taxonomic, temporal and qualifying facets have been ignored.

Finally, the visual content-based images annotation techniques rely often on a semi-automatic annotation. Nonetheless, human intervention is evermore considered time consuming, tedious and laborious. Consequently, this technique is not considered effective for annotating the big collections of images.

2.2 Textual Content-based Images Annotation Approaches

The collaborative potential of the World Wide Web has not only offered the possibility to share images, but also to associate them to free textual descriptions called tags. However, the users' tags can be ambiguous, disturbing or missing (Wang & al., 2006). So, they do not make a reliable solution to annotate the images. Wherefore, multitudes research studies have carried out considerable efforts to refine the initial keywords associated to the images by automatically completing the missing tags and rectifying the noise-corrupted ones. In fact, the social images tags refinement will be able to improve the images indexing quality. In this context, some works have been based on the calculation of the semantic relationships score between the keywords and the others have been based on the richness of the structured vocabulary of external resources such as the domain ontologies.

Indeed, numerous web portals, like *Flickr* and *Delicious*, help the users to manually annotate their shared images with freely chosen tags. Due to the limits of these tags, several research studies have focused on their refinement. In this context, we can mention the annotation approaches based on semantic similarity measures (Mousselly-Sergieh & al., 2014 ; Quattrone & al., 2011) and the annotation approaches based on semantic relationships measures (Xu & al., 2014 ; Feng & al., 2016 ; Ksibi & al., 2012). These annotation approaches are purely automatic and they can be applied to annotate large collections of images. However, they are not considered effective to express the semantic content of the images because they are approximately based on static calculations unfounded on a logical reasoning.

As an alternative, a new type of approaches emerged. The main aim of these approaches is to ensure the refinement of the social tagging information based on a domain ontology in order to generate more pertinent annotations (Im & al., 2015, Im & al., 2013 ; Jeong & al., 2013 ; Liu & al., 2010 ; Jin & al., 2005). Though this type of approaches has solved the automating semantic annotation of the big collections of images problem, the expression of the semantic content of these images is considered fractional because it is not based on a predefined semantic model or pattern.

2.3 Synthesis

To synthesize, multitude research studies have carried out considerable efforts to improve the images annotation process. However, the problem of automating annotation of the big masses of images by their semantic content is not yet solved. In this context, we suggest in this paper an automatic annotation approach that is oriented towards the description of the images' semantic content. Our solution is based on a structured vocabulary, in particular a domain ontology, and a semantic facets pattern on the basis of which the semantic content will be described. Indeed, it is important that the semantics are managed on the basis of a predefined model or semantic pattern. In this example, these images are tagged with the word "*Tomate*". Thus, the semantics that can be generated are : "*Monument attraction*" and "*Festival event*". The annotation guided by a model or a semantic pattern may be a solution to resolve this conflict.

Table 1: Example of description of the images' semantic content based on a semantic facets pattern

	Semantic pattern	Generated semantic
	*Type of the attraction :*	Monument attraction
	*Type of the event :*	Festival event

3. General Approach

The automatic images annotation process is a rich study field. Its goal is to develop a set of methods that can predict, for any image, a set of relevant keywords from an annotation vocabulary. The predicted keywords can be used to suggest the semantic content of images. Thus, our work focuses on the automatic annotation of images shared on the social networks by their semantic content. The new generated information can be used to facilitate and optimize the future research system of images. The approach that we suggest is composed by three processes that can be presented by the following figure :

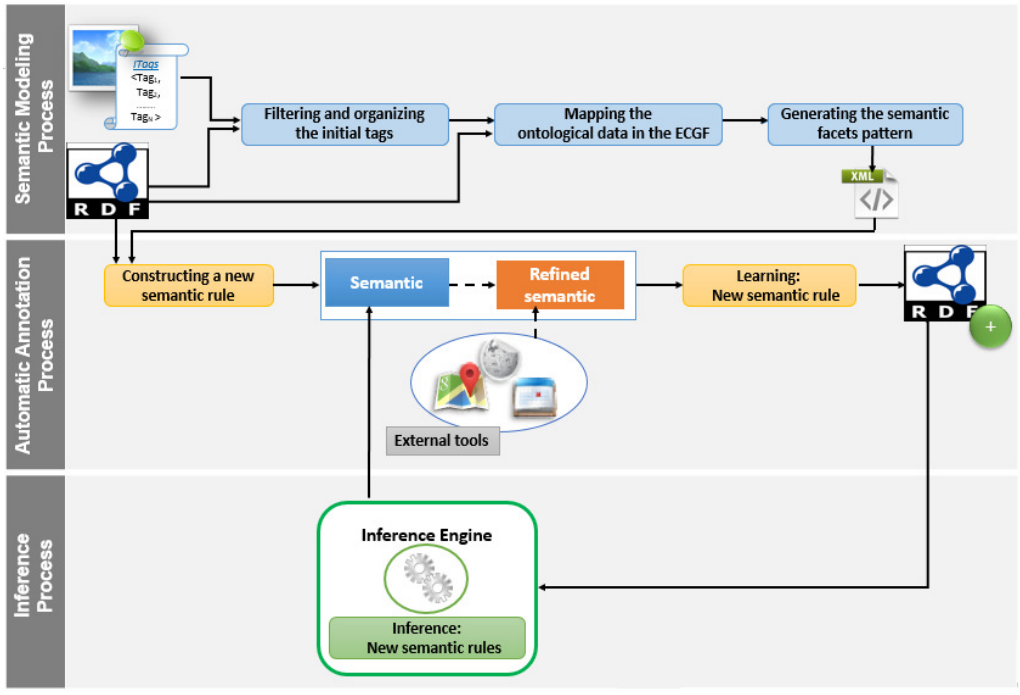

Fig 1: General architecture of the socio-tagged images modeling and annotation system

The general architecture of the proposed modeling and annotation system of the socio-tagged images can be descripted as follows :

- **Semantic Modeling Process :** It consists in treating the initial images' tagging information and projecting them on the adopted ontology in order to generate a semantic pattern. This pattern enables to identify the different semantic facets of an image based on which its semantic content can be described.
- **Automatic Annotation Process :** It consists in defining a set of semantic rules, enriching the adopted ontology by these rules and annotating new images based on the enriched ontology. Thus, the principal aim of this process is to know the structure of these rules.
- **Inference Process :** It consists in automatically generating new semantic rules. Indeed, the inference process can be defined as an action, which enables a human or a machine to widen its knowledge.

4. Overview of the Semantic Modeling Process

The images shared on the social networks are associated with a set of keywords that they are assigned to them by the social community. However, these tags do not constitute an implicit and an effective solution for annotating this type of images. Thus, our solution consists in annotating the socio-tagged images based on their semantic content. Nevertheless, a better description of the semantic content of an image requires defining, in the first step, these different semantic facets. Thus, the main aim behind of the modeling process is to generate a semantic pattern that enables to presents the different semantic facets of an image that makes a basic support for the semantic annotation process. Therefore, in our previous work (Bouchakwa & al., 2016), we have firstly classified the tags associated with socio-tagged images. These tags often express "who" and "what" and can be seen according to several views :

- **The structural view :** It presents the set of objects constituting the image and which are noticeable in the real world (towers, monuments, etc.).
- **The behaviour view :** It presents the activities carried out by the characters (sports, adventure, etc.).
- **The event view :** It presents the unfolding events in the image (festivals, parties, etc.).

Moreover, the concepts of each view can have a spatial and a temporal contexts ; likewise, they can have a set of specifications that characterize them and a set of taxonomies from which they are derive. Thus, we defined four facets from which the different concepts can be seen :

- **The temporal facet :** It allows to indicate the epoch of construction of the historical objects and the unfolding season of the events and activities.
- **The spatial facet :** It allows to indicate the location of the visual objects and the unwinding location of the events and activities.
- **The qualification facet :** It allows to describe the nature or the specifications of an object, an activity or an event that distinguishes them from other objects, activities and events.
- **The taxonomic facet :** It allows to indicate the type of a visual object, an activity that unfolds or an event.

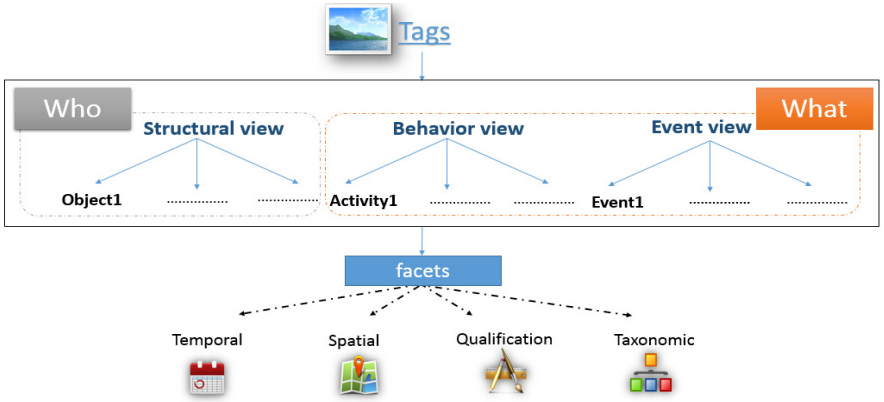

Fig. 2: General view of the different semantic facets of an image

Thereby, the images' tagging information can be used to define the semantic pattern that presents the different semantic facets of these images. Our solution is approximately based on a domain ontology following three steps :

- **Filtering and organizing of the initial tags :** It consists in projecting each tag attached to an image on the approved ontology in order to verify their membership. Thus, the tags that are contained in the ontology as classes or instances are considered as domain concepts and they will be the subject of our work.
- **Mapping the ontological data using the Extended Conceptual Graphs Formalism :** It consists in moving from the abstract level of an image towards its conceptual description level. Indeed, the conceptual description level of an image is obtained by the mapping of the ontological data, in particular the semantic relationships and the specific properties of the filtered and organized tags, on the extended conceptual graphs formalism *ECGF*. Subsequently, the various conceptual models will be drown into the same graph. It should be noted that we have extended the formalism of the conceptual graphs defined by (Sowa 1984) so that it enables to presents the concepts and the conceptual relationships as well as the conceptual features.
- **Generating of the semantic pattern of an image :** It consists in deducing the corresponding semantic pattern from the conceptual description model of an image. This pattern enables to identify the different semantic facets of such an image and helps to describe its semantic content for the future annotation system. For example, we can deduce from the start and the end date of an event its unfolding season. As we can deduce from the GPS data of a monument the location of this historical object. Also, we can deduce from the taxonomic relationships of an activity its taxonomic semantics and so on.

Figure 3 illustrates an example of the semantic facets modeling process of a socio-tagged image.

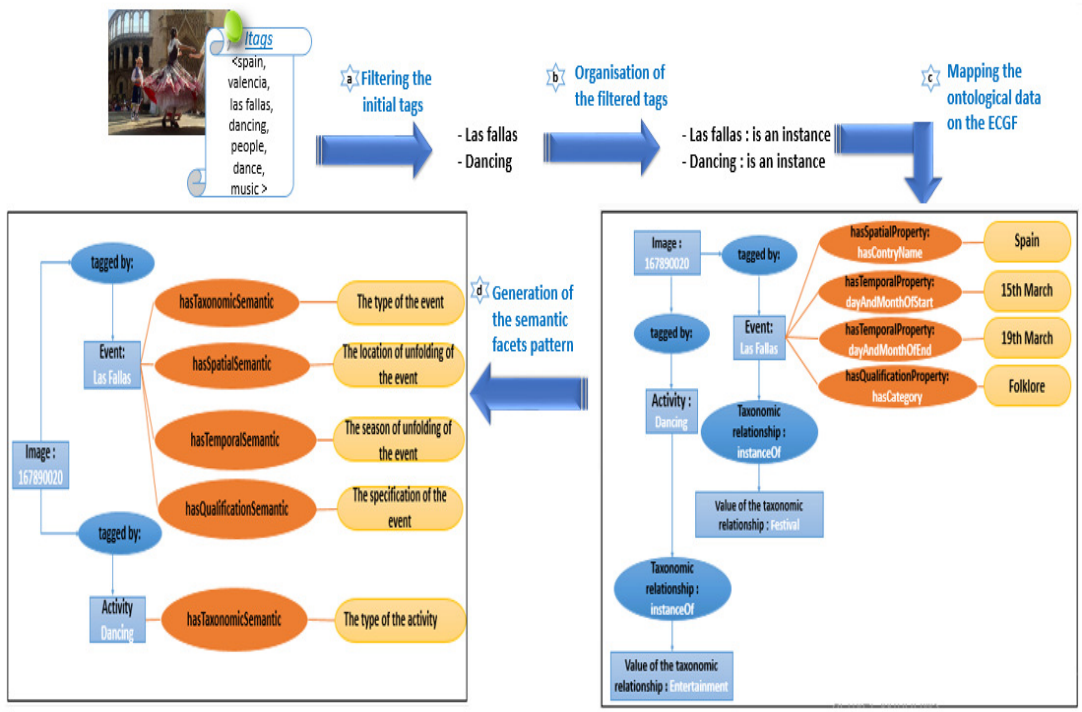

Fig. 3: An example of the semantic facets modeling process

The generated pattern is saved in XML file as presented below :

```
<?xml version="1.0" encoding="ISO-8859-1"?>
  <image id="167890020">
    <TaggedBy Event="Las Fallas" Type="Ontological_Instance">
      <hasTaxonomicSemantic> The type of the event </hasTaxonomicSemantic>
      <hasSpatialSemantic> The location of unfolding of the event </hasSpatialSemantic>
      <hasTemporalSemantic> The season of unfolding of the event </hasTemporalSemantic>
      <hasQualificationSemantic> The specification of the event </hasQualificationSemantic>
    </TaggedBy>
    <TaggedBy Activity="Dancing" Type="Ontological_Instance">
      <hasTaxonomicSemantic> The type of the activity  </hasTaxonomicSemantic>
    </TaggedBy>
  </image>
```

Fig. 4: An exemple of the semantic facets pattern saved in XML file

5. Automatic Annotation and Inference Process

The aim of the semantic annotation process consists in assigning a set of keywords to the images in order to facilitate their research afterwards. Indeed, this process is based on the construction of the semantic rules that enables to express the images content according to the tags associated with them. Subsequently, an inference process allows to generate new semantics based on the suggested inference rules. In the following subsection, we detail the suggested semantic and inference rules.

5.1 *Automatic Annotation Process*

The automatic annotation process is composed of the following steps :

5.1.1 The research of the semantic rules step

The annotation process begins with the search for the ontological semantic rules that can be applied according to the image's tags. Following a positive result, the retrieved semantic rules will be applied in order to annotate the image. A negative result means that no semantic rule found. Consequently, we move to the construction of a new semantic rule.

5.1.2 The construction of the semantic rules step

In order to provide a better interpretation of a socio-tagged image by its semantic content, we define a set of semantic rules. These rules allows to deduce the qualification, spatial, temporal and taxonomic semantics for an image. They can be formulated using concepts, relationships, instances and their properties extracted from ontology. Thus, if we consider that :

- **IB** : Base of the ontological instances
- **CB** : Base of the ontological concepts
- **PB** : Base of the ontological properties
- **PVB** : Base of the ontological properties values
- **RB** : Base of the ontological relationships
- **SRB** : Base of the ontological semantic rules

These rules can be presented via the logic of predicates as follows :

Semantic Rule 1. For a tag *t* which appears as an instance *o* on the adopted ontology *On*, this rule allows to deduce the qualification, spatial or temporal features of the visual object, the unfolding activity or event according to the ontological properties. Thus, if we consider that :

- *t* : is a tag associated with an image and its value is equal to the ontological instance *o* ;
- *o* : is an ontological instance ;
- $\{c_1, c_2, \ldots, c_{n-1}, c_n\}$: is the list of the ordered superclass of *o* ;
- *p* : is a property value that characterizes the instance *o*.

The generated semantics from this rule allows to provide a *qualification, spatial or temporal description* to the first superclass c_1 of the instance *o* through his property value *p*. Formally, this rule can be described with the general form as follows:

$$
\begin{aligned}
&\forall\ \text{IValue} \in \text{IB}\\
&\forall\ \text{InstanceOf} \in \text{RB}\\
&\forall\ \text{PValue} \in \text{PVB with PValue is a property value of IValue}\\
&\forall\ \text{P} \in \text{PB with P is a property of IValue}\\
&\forall\ \text{CName}_1 \in \text{CB with CName}_1 \text{ is the first superclass of IValue}\\
&\forall\ \text{x} \in \{\text{Qualification, Temporal, Spatial}\}\\
&\exists\ \text{x_SR}_1 \in \text{SRB}/\\
&\quad \mathbf{x_SR_1} = (\text{IValue, P, PValue}) \wedge (\text{IValue, InstanceOf, CName}_1) \rightarrow (\text{PValue} \oplus \text{CName}_1)
\end{aligned}
\qquad (1)
$$

It is necessary to mention that we should divide this rule into two sub-rules : the *simple rules* and the *complex rules*. In the structure of the simple rule, we use a single ontological property while in the structure of the complex rules we use more than an ontological property. The complex rule are particularly used to derive the locations that are indicated by **GPS** coordinates or the seasons that are indicated by two dates (the start and the end dates of an event for instance). The generated semantic by these rules will be refined in the next step.

Semantic Rule 2. This rule allows to generate a taxonomic semantics based on the taxonomic relationships of the tag *t* which appears as an ontological instance *o*. Thus, if we consider that :

- *t* : is a tag associated with an image and its value is equal to the ontological instance *o* ;
- *o* : is an ontological instance ;

- $\{c_1, c_2,..., c_{n-1}, c_n\}$: is the list of the ordered superclass of *o*.

In fact, the instance *o* is connected to its first superclass c_1 with the relationship "*instance-of*" and the superclass c_1 is connected to the superclass c_2 with a relationship "*is-a"*. Thus, c_1 is a specific type of c_2 and c_2 is a general type of c_1. Hence, we can add to the superclass c_2 a *taxonomic description* according to his subclass c_1. Formally, this rule can be described as follows :

$$\begin{aligned}&\forall\ \text{IValue} \in \text{IB}\\&\forall\ \{\text{CName}_1,..., \text{CName}_N\} \in \text{BC}/\ \text{CName}_1 \neq \text{CName}_{N-1} \text{ and } \text{CName}_1 \neq \text{CName}_N\\&\forall\ \{\text{ISa, InstanceOf}\} \in \text{RB}\\&\exists\ \text{Taxonomic_SR}_2 \in \text{SRB}/\\&\quad \textbf{Taxonomic_SR}_2 = (\text{IValue, InstanceOf, CName}_1) \wedge (\text{CName}_1, \text{ISa, CName}_2)\\&\qquad\qquad \rightarrow (\text{CName}_1 \oplus \text{CName}_2)\end{aligned} \quad (2)$$

Semantic Rule 3. Likewise, the application of this rule allows to generate a taxonomic semantics based on the taxonomic relationships of the tag *t* which appears as an ontological concept c_i. Thus, if we consider that :

- *t* : is a tag associated with an image and its value is equal to the ontological concept c_i ;
- c_i : is an ontological concept ;
- $\{c_{i+1}, c_{i+2}, c_{i+3,}, ..., c_{N-1}, c_N\}$: is the ordinate list of the superclass of c_i.

In fact, the class c_i is connected to the class c_{i+1} with the relationship "*is-a"* and c_{i+1} is connected with c_{i+2} by the same relationship ; then c_{i+1} is a specific type of c_{i+2} and c_{i+2} is the general type of c_{i+1} (with $1 \leq i \leq n$-2). Hence, we can add to c_{i+2} a *taxonomic description* according to his subclass c_{i+1}. Formally, this rule can be described as follows :

$$\begin{aligned}&\forall\ \text{ISa} \in \text{RB}\\&\forall\ \{\text{CName}_1,..., \text{CName}_N\} \in \text{CB}\\&\forall\ \text{CName}_i \in \{\text{CName}_1,..., \text{CName}_{N-2}\}\\&\exists\ \text{Taxonomic_SR}_3 \in \text{SRB}/\\&\quad \textbf{Taxonomic_SR}_3 = (\text{CName}_i, \text{ISa, CName}_{i+1}) \wedge (\text{CName}_{i+1}, \text{ISa, CName}_{i+2})\\&\qquad\qquad \rightarrow (\text{CName}_{i+1} \oplus \text{CName}_{i+2})\end{aligned} \quad (3)$$

5.1.3 Grammatical refinement step

The application of the semantic rule SR_i according to a tag t_i associated with a socio-tagged image *I* allows to generate a set of semantics carrying the content of the image. Therefore, the adopted grammatical form for the generated semantics is as follows :

$$\text{Adjective_Name} \quad (4)$$

With :

- *Name* : refers to an ontological concept.
- *Adjective* : is a property value that expresses a qualification, spatial or temporal characteristic of the ontological concept or a concept that indicates the type of its super-concept.

However, the application of x_SR_1 rule allows to generate semantics which are presented by the concatenation of a property value p_k of the tag t_i and the first superclass c_1 of t_i. But, the properties may have different types in the ontologies. For example, for the ontological instance *o* that corresponds to the tag t_i, we can have a set of properties such as the spatial features that can be indicated directly by the name of the country or presented by the GPS coordinates. In order to refine the obtained results, we use different external resources such as the GPS conversion tools that transform the GPS coordinates by the country name of the location.

For example, if a tag "*TowerBridge*" is an instance of the ontological concept "*Bridge*" and its location is indicated by the properties that indicate its latitude and its longitude, the corresponding spatial semantic rule and the grammatical refinement are expressed as follows :

Tag : Tower bridge
Qualification_SR$_1$:
(TowerBridge, *InstanceOf*, Bridge) ∧ (TowerBridge, *hasLatitude*, 51°30′20″) ∧ (TowerBridge, *hasLongitude*, 0°4′32″)
Generated semantic :
51°30′20″_0°4′32″_Bridge
Refined semantic : London Bridge

5.2 *Inference Process*

The inference process allows to generate a new semantics by defining new semantic rules. Its principle is based on the front chaining. Thus, three inference rules were proposed :

Semantic Inference Rule 1. For a tag *t* which appears as an instance *o* in the adopted ontology *On*, this rule can be described with the general form as follows :

$$
\begin{aligned}
&\forall\ \{ISa, InstanceOf\} \in RB\\
&\forall\ \{CName_1,\ldots, CName_N\} \in CB\\
&\forall\ CName_i \in \{CName_1,\ldots, CName_{N-1}\}\\
&\forall\ \{x_SR_1, SR_4\} \in SRB \text{ with } x \in \{Qualification, Temporal, Spatial\}/\\
&\quad \mathbf{x_SR_1} = (IValue, P, PValue) \wedge (IValue, InstanceOf, CName_i) \rightarrow (PValue \oplus CName_i)\\
&\quad SR_4 = CName_i \rightarrow CName_{i+1}\\
&\exists\ x_SR_5 \text{ a new Rule}/\\
&\quad \mathbf{x_SR_5} = (IValue, P, PValue) \wedge (IValue, InstanceOf, CName_{i+1}) \rightarrow (PValue \oplus CName_{i+1})
\end{aligned}
\tag{5}
$$

Semantic Inference Rule 2. For a tag *t,* which appears as an instance *o* in the adopted ontology *On*, this rule can be described with the general form as follows :

$$
\begin{aligned}
&\forall\ \{ISa, InstanceOf\} \in RB\\
&\forall\ \{CName_1,\ldots, CName_N\} \in CB\\
&\forall\ CName_i \in \{CName_1,\ldots,CName_{N-2}\}\\
&\forall\ \{Taxonomic_SR_2, SR_6, SR_7\} \in SRB/\\
&\quad \mathbf{Taxonomic_SR_2} = (IValue, InstanceOf, CName_i) \wedge (CName_i, ISa, CName_{i+1})\\
&\qquad\qquad \rightarrow (CName_i \oplus CName_{i+1})\\
&\quad SR_6 = CName_i \rightarrow CName_{i+1}\\
&\quad SR_7 = CName_{i+1} \rightarrow CName_{i+2}\\
&\exists\ Taxonomic_SR_8 \text{ a new Rule}/\\
&\quad \mathbf{Taxonomic_SR_8} = (IValue, InstanceOf, CName_{i+1}) \wedge (CName_{i+1}, ISa, CName_{i+2})\\
&\qquad\qquad \rightarrow (CName_{i+1} \oplus CName_{i+2})
\end{aligned}
\tag{6}
$$

Semantic Inference Rule 3. For a tag *t,* which appears as a concept *c* in the adopted ontology *On*, this rule can be described with the general form as follows :

$$
\begin{aligned}
&\forall\ \{ISa\} \in RB\\
&\forall\ \{CName_1,\ldots, CName_N\} \in CB\\
&\forall\ CName_i \in \{CName_1,\ldots, CName_{N-2}\}\\
&\forall\ \{Taxonomic_SR_3, SR_9, SR_{10}\} \in SRB/\\
&\quad \mathbf{Taxonomic_SR_3} = (CName_i, ISa, CName_{i+1}) \wedge (CName_{i+1}, ISa, CNam_{i+2})\\
&\qquad\qquad \rightarrow (CName_{i+1} \oplus CName_{i+2})\\
&\quad SR_9 = CName_{i+1} \rightarrow CName_{i+2}\\
&\quad SR_{10} = CName_{i+2} \rightarrow CName_{i+3}\\
&\exists\ Taxonomic_SR_{11} \text{ a new Rule}/\\
&\quad \mathbf{Taxonomic_SR_{11}} = (CName_i, ISa, CName_{i+2}) \wedge (CName_{i+2}, ISa, CName_{i+3})\\
&\qquad\qquad \rightarrow (CName_{i+2} \oplus CName_{i+3})
\end{aligned}
\tag{7}
$$

5.3 Examples of illustration

In these examples, we annotate the socio-tagged images by applied the necessary semantic rules and inference rules.

Example 1

Socio-tagged image	Ontological description	Semantic rules description	
	"*BattleOfTheOranges*" is an instance of the ontological concept "*Festival*" which is in turn a sub-concept of "*Event*", and the value of its property "*hasCategory*" is "*Fruit*"	**Qualification_SR1 :**	(BattleOfTheOranges, *InstanceOf*, Festival) ^ (BattleOfTheOranges, *hasCategory*, Fruit) Generated semantic : Fruit Festival
		Taxonomic_SR2 :	(BattleOfTheOranges, *InstanceOf*, Festival) ^ (Festival, *is-a*, Event) Generated semantic : Festival Event
		Inference rules description	
		Qualification_SR5 :	**Implicit_SR4 :** Festival → Event (BattleOfTheOranges, *InstanceOf*, Event) ^ (BattleOfTheOranges, *hasCategory*, Fruit) → Fruit Event

Example 2

Socio-tagged image	Ontological description	Semantic rules description	
	"*Rafting*" is an instance of the ontological concept "*Riding*" which is in turn a sub-concept of "*Adventure*" and "*Activity*"	**Taxonomic_SR2 :**	(Rafting, *InstanceOf*, Riding) ^ (Riding, *is-a*, Adventure) Generated semantic : Riding Adventure
		Inference rules description	
		Taxonomic_SR8 :	**Implicit_SR6 :** Riding → Adventure **Implicit_SR7 :** Adventure → Activity (Rafting, *InstanceOf*, Adventure) ^ (Adventure, *is-a*, Activity) → Adventure Activity

Example 3

Socio-tagged image	Ontological description	Semantic rules description	
	"*Football*" is an ontological concept and it is a sub-concept of the concept "*TeamSport*" which also is a sub-concept of the concept "*Competition*" and "*Event*"	**Taxonomic_SR3 :**	(Football, *is-a*, TeamSport) ^ (TeamSport, *is-a*, Competition) Generated semantic : TeamSport Competition
		Inference rules description	
		Taxonomic_SR11 :	**Implicit_SR9 :** TeamSport → Competition **Implicit_SR10 :** Competition → Event (Football, *is-a*, Competition) ^ (Competition, *is-a*, Event) → Competition Event

5.4 *Enrichment of the adopted ontology*

Ontologies are used to model the concepts of a given domain. It is a formal explicit description of the knowledge domain by concepts (classes), properties of every concept describing attributes (facets) and relationships between concepts. Our work proposes a semantic annotation process of the socio-tagged images guided by a domain ontology. Therefore, to annotate this type of images, we used **TOURING** (Saeedi 2010) ontology that presents the used concepts in the tourism domain. Formally, this

ontology is presented by $\boldsymbol{On}$: ($\boldsymbol{C_{On}}$, $\boldsymbol{R_{On}}$, $\boldsymbol{X_{On}}$, $\boldsymbol{I_{On}}$, $\boldsymbol{P_{On}}$, $\boldsymbol{TP_{On}}$) where: $\boldsymbol{C_O}$, $\boldsymbol{R_{On}}$, $\boldsymbol{X_{On}}$, $\boldsymbol{I_{On}}$, $\boldsymbol{P_{On}}$, $\boldsymbol{TP_{On}}$ are respectively the set of concepts, the relationships between the concepts, the axioms, the instances, the properties, and the types of the properties that can be a string, an integer, a GPS (north and east), a date, etc.

Considering the semantic rules and the semantic description that result following their application, our approach consists in the integration of the semantic rules within the ontology by indicating their types. Thus, the formal definition of the ontology can be expanded as follows $\boldsymbol{On}$: ($\boldsymbol{C_{On}}$, $\boldsymbol{R_{On}}$, $\boldsymbol{X_{On}}$, $\boldsymbol{I_{On}}$, $\boldsymbol{P_{On}}$, $\boldsymbol{TP_{On}}$, $\boldsymbol{Rg_{On}}$, $\boldsymbol{Rf_{On}}$) where $\boldsymbol{Rg_{On}}$ is a set of rules and $\boldsymbol{Rf_{On}}$ are the facets of these rules. For example, the annotation of the image in below based on the generated semantic facets pattern can be presented as follows :

Tag : Diving
Facet name : The type of the activity
Taxonomic_SR : (Diving, *is-a*, Adventure) ∧ (Adventure, *is-a*, Activity)
Generated semantic : Adventure Activity

The extract of the RDF of the enriched ontology is presented by the Figure 5.

6. Socio-tagged Images Annotation Algorithm

The following algorithm presents the progress of the semantic annotation process with :

- ***HasSemanticRule*() :** allows to verify according a tag *t* if it exists in the ontology a set of applicable semantic rules.
- ***HasProperties*():** allows to specify according a tag *t* (which appears in the ontology as an instance) if a tag *t* has a set of properties in the ontology.
- ***BuildQSR1*(), *BuildSSR1*(), *BuildTSR1*(), *BuildSR2*(), *BuildSR3*() :** allows to build respectively the rules : *Qualification_SR1*, *Spatial_SR1, Temporal_SR1*, Taxonomic_SR2 and Taxonomic_SR3.
- ***ExcuteSR*() :** allows to apply a semantic rule and to enrich the ontology with the multimedia data information.
- ***FacetOfSR*() :** allows to specify the type of a rule based on the semantic facet pattern. For example, the facet « *hasQualificationSemantic* » is assigned following the application of the rule *Qualification_SR1* and the facet « *hasTaxonomicSemantic* » is assigned following the application of the rule *Taxonomic_SR2*.
- ***RefineGrammar*() :** allows to apply the necessary grammatical rafinement for the generated semantic following the application of the x_RS_1 rule.
- ***EnrichmentOntology*() :** allows to add a new semantic rule at the base of the ontological semantic rules by indicating its facet.
- ***TreatInferredRules*() :** allows to run any inferred rule, to specify its facet and to enrich the ontology.

Algorithm : Automatic annotation of the socio-tagged images

Input :

Vector ITB [] : Chain // *Set of tags indicated in the semantic facets pattern as an ontological instance*
Vector CTB [] : Chain // *Set of tags indicated in the semantic facets pattern as an ontological concept*
Vector PVB [] : Chain // *Base of ontological property value of an instance*

```
1 : Begin
2 :   for (each i in ITB) do
3 :     if HasSemanticRule(i) = true Then
4 :        ExecuteSR()
5 :     else
6 :        if HasProperties(i) = true Then
7 :          for (each SpatialValue in PVB) do
8 :                BuildSSR1(), RefineGrammar(), FacetOfSR(),
9 :                EnrichmentOntology(), TreatInferredRules()
10 :         end for
11 :         for (each TemporalValue in PVB) do
12 :            BuildTSR1(), RefineGrammar(), FacetOfSR(),
13 :            EnrichmentOntology(), TreatInferredRules()
14 :         end for
15 :        for (each QualificationValue in PVB) do
16 :           BuildQSR1(), RefineGrammar(), FacetOfSR(),
17 :           EnrichmentOntology(), Treat Inferred Rules()
18 :         end for
19 :      else
20 :         BuildSR2(), FacetOfSR(),
21 :         EnrichmentOntology(), TreatInferredRules()
22 :      end if
23 :    end if
24 :  end for
25 :  for (each j in CTB) do
26 :     if HasSemanticRule (j) = true Then
```

```
27 :        ExecuteSR()
28 :      else
29 :        BuildSR3(), FacetOfSR(),
30 :        EnrichmentOntology(), TreatInferredRules()
31 :      end if
32 :    end for
     33    End
```

7. Experimental Evaluations

In order to endorse the efficiency of the approach that we suggest, we have implemented a called prototype "*Tourism-Annotizer*" enabling to perform two principal functions. Indeed, this prototype enables to modeless the semantic facets of a collection of images initially tagged by social community. Subsequently, these images are automatically annotated by the application of the necessary semantic rules. Since there are no a specific pre-prepared collections for each interest domain, we conducted this work by the construction of a test collection of images related to the tourism filed and extracted from the social network *Flickr*. Then, we carried out a series of experiment to evaluate our modelization and annotation approach of socio-tagged images.

7.1 *Construction of a test collection*

With over billions of images and millions of users, *Flickr* is a social media service that it is rapidly evolved in recent decades. The most important reason for this attention on *Flickr* may be because it is based on the principle of tagging. In addition, *Flickr* provides of the developers a PHP API (FlickrPHP) that is available for no-commercials use.

In this context, and in order to construct a tourism images collection, we used the model provided by the RI work of (Ellen 2001 ; Chris & al., 2000). In terms of implementation, we have constructed the test collection in two steps as follows :

- Firstly, we collected n = 180 photo queries that illustrate popular tourist attractions (eg bridges, churches, historic monuments, etc.) to ensure their identification later on, by a large number of users. They are also chosen to fit in the spatial neighborhoods of other images and vice versa.
- Secondly, each photo-request is loaded on the web interface that we have developed to extract socio-tagged photos from the free database of *Flickr*. The coordinated location of each request-image was automatically extracted from its format. In addition, the web interface allows to introduce the radius of the photos recovery as well as the maximum number of photos to download (for exemple, in Figure 6, a distance of 5 km and a maximum number of 50 images have been chosen).

As a result, we ended up with a collection that contains 25,000 separate images and 15,562 unique tags.

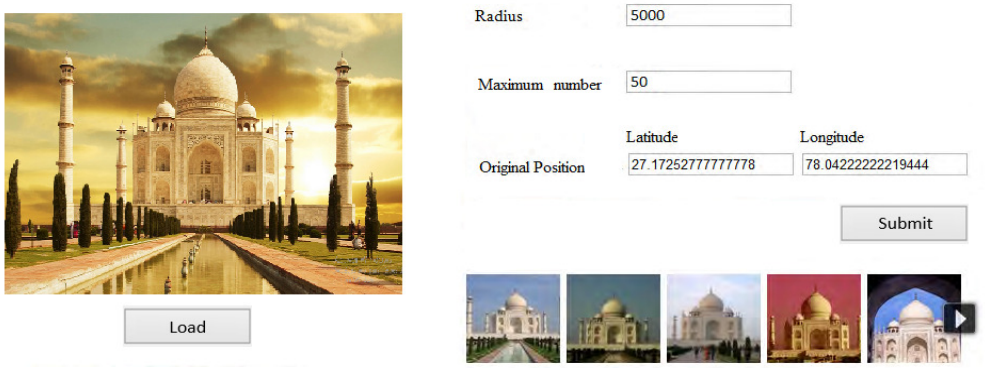

Fig. 6: The web interface developed to extract the test images collection

7.2 *Implementation of the prototype test "Tourism-Annotizer"*

The prototype "*Tourism-Annotizer*" is constituted by tow interfaces: (*i*) an interface allows to brows the test images collection and to generate for each image its corresponding semantic facets pattern that will be saved in the XML file and (*ii*) an interface for automatically annotating the modeled images.

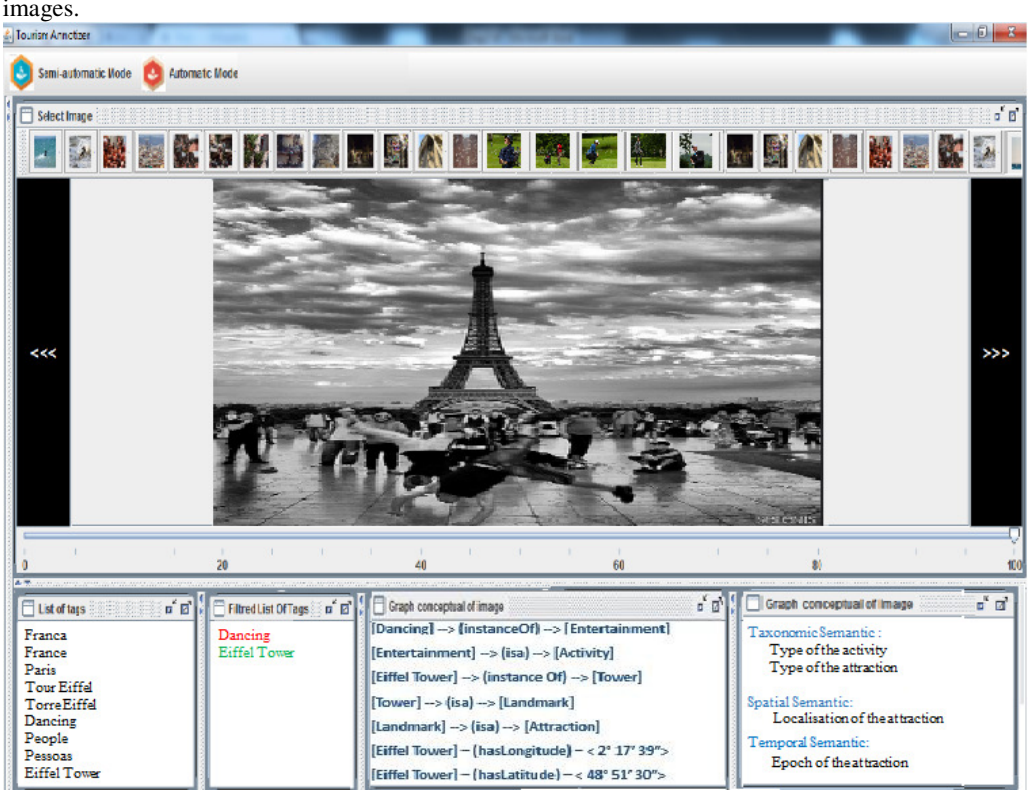

Fig. 7: Modeling interface based on the ECGF

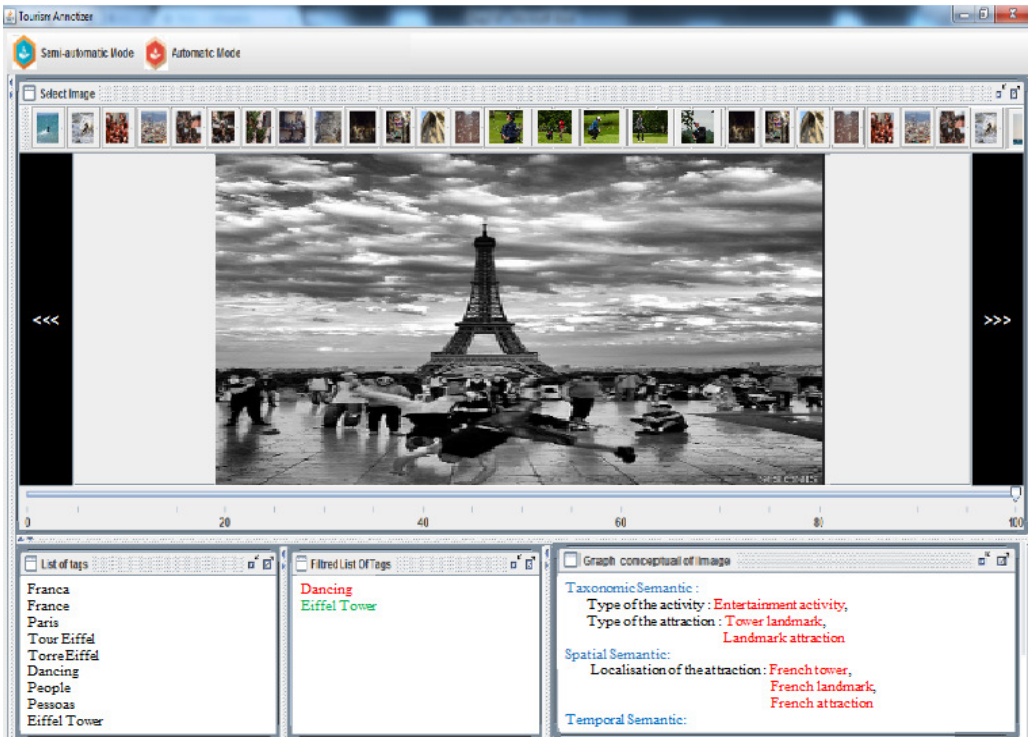

Fig. 8: Annotation interface based on the semantic facets of patterns

7.3 *Evaluation of the semantic modeling process*

In order to evaluate the results of the semantic modeling process, we have followed the method of (Im & al., 2015) for testing the big collections of data. Indeed, this method consists in selecting from each 1000 images of the test collection 100 sample images. These images will be considered as exemplary images and will be the object of the tests that will be carried out. In addition, our test procedure was guided by the technique of (Ricardo & al., 1999) intended for the results performance test in the IR systems.

In our context, experts in semiotics have concluded the relevance of the generated semantic facets for each test image and recommended the missing semantic facets. Subsequently, we measured the performance of the suggested modeling process results using precision and recall which have computed as follows :

$$Precision = \sum_{k=1}^{n} \frac{\text{Number of relevant semantic facets for a test image k}}{\text{Number of semantic facets proposed automatically for a test image K}} \quad (8)$$

$$Recall = \sum_{k=1}^{n} \frac{\text{Number of relevant semantic facets for a test image k}}{\text{Number of semantic facets proposed by the expert for a test image K}} \quad (9)$$

The results of the evaluation are of the order of 0.861 for the precision and 0.743 for the recall. Figure 9 shows the quality of the modeling process in 2500 sample images divided into five groups of 500 images each.

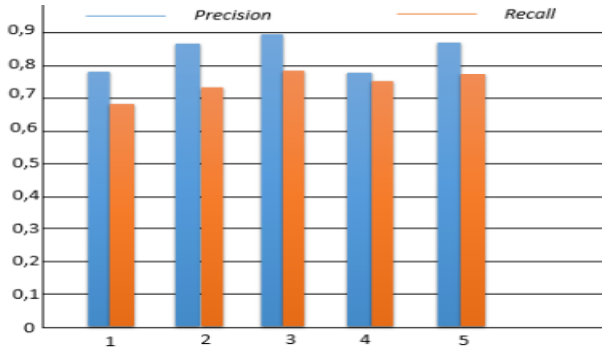

Fig. 9: Evaluation results of the semantic modeling of the socio-tagged images

These results motivated us to use the obtained semantic facets as support for the annotation process.

.

7.4 *Evaluation of the automatic annotation process*

Using the same method proposed by (Ricardo & al., 1999) to evaluate the performance of IR systems, we have presented the images previously modeled by semiotic experts and associated with their a set of semantic annotations suggested by our annotation system to domain experts. The domain experts have confirmed the relevance of the generated annotation compared to the defined semantic facets and recommended the missing semantic annotations. To evaluate the performance of the annotation process results we used the measures defined as follows :

$$Precision = \sum_{k=1}^{n} \frac{\text{Number of relevant semantic annotation for a test image k}}{\text{Number of semantic annotation proposed for a test image K}} \quad (10)$$

$$recall = \sum_{k=1}^{n} \frac{\text{Number of relevant semantic annotation for a test image k}}{\text{Number of semantic annotation proposed by the expert for a test image K}} \quad (11)$$

Figure 10 show the evaluation results carried on the groups of images that we modeled earlier.

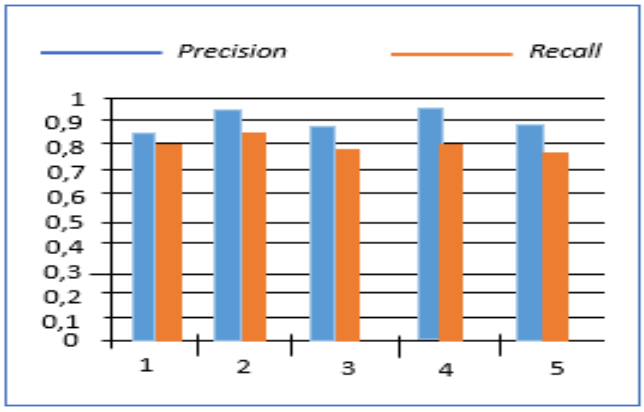

Fig.10: Evaluation results of the semantic annotation of the socio-tagged images

Indeed, the results are quite satisfactory with the average precision is high. It is a whole in the order of 87,2%.Secondly, the average recall is a little lower but it is also satisfactory compared to the results of domain experts. It is a whole in the order of 79,7%. Thus, notice that the "*Tourism-*

Annotizer" can be successfully and easily used to annotate the socio-tagged images by their semantic content.

8. Conclusion And Future Works

In this paper, we suggest to annotate the images shared on the social networks by their semantic content, according to the tags associated with them. In the first step, we have defined the semantic facets pattern based on the content of a collection's images. Thereafter, we have built a set of semantic rules which are characterized by their type. These rules are expressed by the logic of predicate. The application of any semantic rule generates a semantic that will be associated with the image. An inference engine is implemented to create new semantic rules and consequently to generate new semantic results. Thus, the initial adopted ontology will be enriched with the notion of typed semantic rules. Finally, and in order to test the suggested approach, we have developed a modeling and annotating socio-tagged images prototype. The results of the evaluation have been satisfactory.

Our future work will consist, in the first step, to reformulate the initial request sent by the user by applying the corresponding semantic rules in order to implement a semantic search system, and in the second step, to classify the annotated images using new technologies of the processing big data.

Résumé

La réalité observée de la situation actuelle des établissements d'enseignement supérieur au Maroc est marquée par une mise en place progressive d'un certain nombre des pratiques d'évaluation. Ces pratiques sont loin de constituer un véritable système de culture d'évaluation de la performance. D'autre part, ces systèmes sont fortement orienté recherche, ce qui n'est pas sans conséquence sur les autres activités et surtout celle de l'enseignement et la formation.

L'objet de cette article est relative à l'analyse de l'impact de cette orientation recherche des systèmes d'évaluation à profil unique centré sur les publications, sur la performance globales des établissements d'enseignement supérieurs.

Mots clés : logique d'évaluation, performance individuelle et collective, régulation, réglementation.

Abstract

The observed reality of the current situation of higher education establishments in Morocco is marked by the gradual introduction of a number of evaluation practices. These practices are far from being a true system of performance evaluation culture. On the other hand, these systems are highly research-oriented, which is not without consequence on other activities and especially that of education and training.

The purpose of this article is to analyze the impact of this focus on single-profile evaluation systems centered on publications, on the overall performance of higher education institutions.

Keywords: Evaluation logic, individual and collective performance, regulation

Introduction

Depuis la fin du siècle dernier l'enseignement supérieur au Maroc a fait l'objet de réformes continues. Ces reformes ont impacté son « mode de gouvernance », « l'architecture des formations » et « les contenus des enseignements », ces réformes sont régies par les textes de la Loi 01-00 portants sur l'organisation du secteur de l'enseignement supérieur et par les orientations de la Charte Nationale d'Education et de Formation. Ce processus de réformes a imposé progressivement à la communauté universitaire des exigences nouvelles, un changement des valeurs collectives mais aussi un changement de sa propre représentation avec la prééminence d'un modèle anglo-saxon, davantage centré sur des relations contractuelles interinstitutionnelles et intra institution et qui implique plus d'autonomie et plus de responsabilisation des acteurs, ainsi la mise en place progressive d'une nouvelle gestion dont l'évaluation de la performance constitue l'un de ses piliers.

Dans ce contexte, quelques pratiques d'évaluation ont progressivement pris forme (l'auto-évaluation, l'accréditation, les classements internationaux), elles sont l'œuvre des instances de la tutelle ministérielle ou sous l'impulsion des Présidents d'universités, Conseils universitaires et d'autres forums de gouvernance, et les classements internationaux. Jusqu'à présent, ces pratiques restent insuffisantes pour doter les établissements universitaires marocains d'un véritable système de culture d'évaluation de la performance. Par ailleurs, ces pratiques semblent aussi souffrir de l'absence de l'unité de la logique de leur mise en place, car elles ont été établies par les acteurs universitaires à partir de leur capacité à problématiser la performance universitaire et aussi suivant les rapports de force entre les acteurs. En plus, les acteurs sociaux, des établissements universitaires public, confrontés aux contraintes nationales et internationale ont tendance à vouloir démontrer qu'ils sont performants ; avec cette question récurrente sur le choix entre l'option l'élitisme et la sélection ou celle de l'inclusion et de l'intégration. Au deuxième niveau le statut de l'étudiant ; client ou usager, se pose avec acuité. Il n'est pas rare de relever même dans la littérature qui ne fait que l'exégèse des textes des reformes du système universitaire marocain de constater l'absence de réponse claire à ces questionnements fondamentaux. Les pratiques d'évaluation observées flottent entre les exigences d'une « régulation contrôle »[i] multicéphale imprécise et changeante et qui est représenté au niveau national à la fois par le ministère et les hauts conseils, et parfois par la présidence des universités et leurs conseils ou par les instances locales de chaque établissement, conseil ou départements. Elle peut être aussi d'origine internationale lorsqu'il s'agit de vouloir imposer des normes inspirée par les pratiques de classement. Pour ce qui est de la « régulation autonome », elle domine les pratiques d'évaluation elle est aussi dominé par des individus ou des groupes informels d'individus, elles profitent du caractère spécifique de chaque établissement d'enseignement supérieurs. Qui sont d'ailleurs considérées par certain comme « bureaucratie professionnelle » et de la faiblesse la « régulation contrôle ».

Dans ce contexte globale, l'objet de cet article est de montrer comment les systèmes d'évaluation ont provoqué l'intérêt des individus plus vers des activités de recherche. Cette orientation n'est pas sans conséquence sur les autres activités et surtout celle de l'enseignement. En définitive, notre question centrale est relative à l'impact de cette orientation recherche des systèmes d'évaluation à profil unique et centré sur les publications, sur la performance globales des établissements d'enseignement supérieurs dans leur hétérogénéité.

Pour essayer d'apporter des éléments de réponse, la suite de cet article sera agencée en trois temps. Après avoir présenté le contexte global du système d'enseignement supérieur au Maroc[ii] (partie 1), nous allons présenter une analyse théorique sur les logiques d'évaluation de la performance individuelle (partie 2), et enfin, pour conclure nous allons relever dans la littérature les contradictions de l'évaluation dans les universités**.**

I. Contexte Globale De L'université : Réglementation Et Régulation De L'évaluation

Trois aspects fondamentaux caractérisent la mission des universités: l'enseignement, la recherche et les services à la collectivité. Elle se réalise de façon large et comprend des dimensions académique,

sociale, politique, culturelle et économique. Cette mission contribue de façon générale au développement des personnes et de la société. En outre, avec la mondialisation et l'harmonisation des systèmes d'enseignement supérieur, l'université est confrontée à un changement de paradigme, celui-ci ne concerne pas seulement l'enseignement mais l'ensemble du positionnement de la sphère universitaire dans son environnement et la façon dont l'université se doit de trouver sa place et de remplir les missions qui lui sont assignées. Par ailleurs, la mise en place des processus des réformes génère des conflits :

- Le premier niveau de conflit tient à la relation entre les organismes de tutelle et l'université en tant qu'institution. La question centrale porte sur la réalité de la liberté de manœuvre laissée aux établissements.

- Le second niveau tient aux résistances organisationnelles du niveau intermédiaire que sont les composantes (les Unités de Formation et de Recherche, Départements par exemples).

- Le troisième lieu de résistance se situe au niveau des acteurs, utilisateurs et metteurs en œuvre des réformes.

Dans ce contexte a été progressivement implanté des pratiques d'évaluation au niveau individuel, institutionnel, il a aussi été prévu la création d'une instance nationale d'évaluation et ceux sur la base d'un arsenal juridique.

Ainsi, la Loi 01 - 00 stipule :

- ***Article 8***: ... Baser l'acquisition des modules sur des évaluations régulières ...;
- ***Article 77***: Évaluation régulière du système de l'enseignement supérieur, portant sur sa rentabilité interne et externe, et touchant tous les aspects pédagogiques, administratifs et de recherche...;
- ***Article 78*** : Auto-évaluation des établissements;
- ***Article 79***: Création d'une instance nationale d'évaluation et un observatoire pour l'adéquation des enseignements supérieurs à l'environnement économique et professionnel.

Par ailleurs, la Charte nationale d'éducation recommande:
- ***Article 80*** : Asseoir le cursus des étudiants sur l'évaluation…;
- ***Article 103***: Création de l'agence nationale d'évaluation et d'orientation;
- ***Articles 127 et 129***: Deux types d'évaluation pour la recherche scientifique : interne et externe;
- ***Article 137(a):*** Critères d'évaluation pour la promotion et la gratification des enseignants;
- ***Article 155***: Évaluation des administrations centrales;
- ***Article 157***: Évaluation de l'ensemble du système éducatif.

La politique d'évaluation administrative des enseignants titulaires de l'enseignement supérieur, concerne l'avancement dans la carrière dans le cadre du même grade (de A à C) ou lors du passage du grade de Professeur Assistant au grade de Professeur Habilité, et de celui de grade de Professeur Habilité à Professeur de l'Enseignement Supérieur.

L'avancement dans la carrière dans le cadre du même grade est assuré par une commission composée des membres de la commission scientifique et des chefs de département qui délibèrent sur la base d'une grille remplie par le candidat. Cette grille retrace les travaux de recherche, les activités d'enseignement et les responsabilités dans des activités locales et internationales.

Pour le passage du grade de Professeur Assistant à grade de Professeur Habilité, et de celui du grade de Professeur Habilité à Professeur de l'Enseignement Supérieur, une commission délibère sur la base d'un examen qui s'appuie sur des grilles d'évaluation des travaux de recherche et des activités d'enseignement réalisés par le candidat et d'un entretien conduit sous forme d'un exposé et d'une discussion (Kaaouachi A. 2010).

Dans ce dispositif, la pratique du Ranking est présentée de façon explicite dans la promotion dans le même grade et elle est implicite dans l'ensemble du dispositif.

Ce dispositif réglementaire mis en place progressivement n'a pas pu combler le déficit de performance réelle et perçu. Il semble aussi négliger la logique de l'évaluation dans son expression la plus simple, pour le moins qu'on puisse dire, le dispositif réglementaire n'a pas convenablement favorisé une régulation satisfaisante.

La régulation c'est un processus complexe, selon les dictionnaires français est l'action consistant à régler, à assurer le bon fonctionnement des systèmes, notamment de systèmes biologiques.
La régulation et la règlementation sont deux notions différentes mais liées. Si généralement on peut penser que la réglementation permet la régulation (Keynes par exemple prônait l'intervention de l'État comme agent de régulation de l'économie de marché). La déréglementation constitue aussi un mode de régulation (Hayek défendait la déréglementation la plus totale pour laisser le marché faire cavalier seul).

Maroy Demailly (2004)[iii] distinguent plusieurs niveaux à l'origine des régulations: le niveau international, national, intermédiaire, local…et la manière dont elles s'articulent; les acteurs source de régulation, autrement dit les acteurs hégémoniques ou susceptibles d'hégémonie : l'État, le marché, les professions établies, les syndicats, les usagers, l'opinion publique, les experts…. Selon Lacoumes Simard (2011)[iv], les instruments utilisés pour produire, légitimer, imposer les règles peuvent être normatifs (viser directement l'orientation des pratiques) ou systémiques (favoriser, grâce à un certain nombre de supra-règles structurelles, qui jouent sur les jeux d'intérêts, l'émergence de certaines normes des conduites). L'ensemble de ces éléments et leur articulation définit un mode, une configuration particulière de régulation.

Par ailleurs, J. D. Reynaud (1988) considère la « Régulation » comme la capacité à produire des règles. « Règles » est employé au sens large et recouvre aussi bien le domaine de la règle juridique à ses différents niveaux (loi, règlement) que de la règle morale, de la norme formelle que de la norme informelle. Raynaud distingue aussi trois grands types de régulation, les « régulations autonomes », produites par les collectifs de base et les « régulations de contrôle », émises par les supérieurs hiérarchiques et/ou les responsables politiques, les tenants du pouvoir, et les « régulations conjointes » : systèmes institutionnalisés, coopératifs, et donc relativement stables, de combinaison des deux premiers types de régulation.

Enfin, les modes de régulation organisent les rapports d'hégémonie entre les acteurs qui peuvent prétendre à être coproducteurs de l'action, le Ranking comme mode de régulation constitue un exemple.

II. Logique D'évaluation De La Performance Individuels

Les transformations survenues dans le domaine de l'enseignement supérieur ont affecté non seulement les établissements, mais aussi les acteurs. En fait, avec l'évolution des systèmes d'accréditation et des classements universitaires à l'échelle internationale, les établissements d'enseignement supérieur ont adapté leurs systèmes d'évaluation en fonction de ce nouveau contexte. L'accent mis sur ces institutions est passé d'un rôle de développement à un rôle de jugement, où les mesures quantitatives sont devenues d'une importance primordiale dans l'évaluation des activités universitaires (Bogt et Scapens, 2012).

Le classement des universités est devenu un outil puissant de l'évaluation des établissements d'enseignement supérieur, mais il se concentre principalement sur la performance des activités de recherche. En conséquence, l'utilisation de leurs mesures sur la performance individuelle amène les acteurs à développer un plus grand intérêt pour les activités de recherche.

En effet, l'évaluation est le support qui oriente les actions des acteurs dans l'organisation, c'est-à-dire que les acteurs essaieront d'être performants dans le cadre des actions qui seront évaluées par l'organisation. Elle aura donc un impact important sur la performance globale de l'organisation et aussi sur la performance des acteurs, notamment en les aidant à déterminer leurs priorités d'où l'importance pour les universités de compléter leur système d'évaluation de la recherche par celle de l'enseignement et celle de l'implication dans les tâches administratives.

Pour qu'un système d'évaluation puisse bien fonctionner, il doit permettre aux objectifs des acteurs et ceux de l'institution de se rejoindre afin d'évoluer ensemble.

Bien que les classements universitaires indiquent qu'ils se concentrent également sur ces deux dimensions de l'enseignement supérieur, la recherche semble avoir gagné en importance, tant au niveau organisationnel qu'au niveau individuel.

D'un autre point de vue, les acteurs influent sur le développement de leur environnement par leurs actions. Ils définissent leur propre réalité à travers la compréhension qu'ils ont sur leur environnement. Ils appréhendent que leurs actions ne soient évaluées que si elles sont reflétées dans leur performance. En conséquence, ils apprennent à agir en fonction de ce que mesurent les systèmes d'évaluation.

Dans cette perspective, l'évaluation est un outil stratégique au service des établissements d'enseignement afin d'atteindre leurs objectifs, puisque les systèmes d'évaluation constituent un moyen de coordination entre d'un coté les objectifs et les intérêts individuels des enseignants-chercheurs (volonté d'être reconnus dans leur discipline, d'enseigner des cours qui les intéressent, etc...), et de l'autre coté les objectifs institutionnels.

III. Contradictions De L'évaluation Dans Les Universités

Le système d'évaluation est dominé par le nombre de publications, ce système ne encourage pas les individus à diversifier leurs activités, sauf par exemple pour leurs heures obligatoires des cours d'enseignement. Évidemment, le choix de concentrer l'évaluation sur les publications n'est pas totalement irrationnel puisque les classements internationaux les considèrent comme étant une mesure crédible de la production des enseignants-chercheurs (Thiétart, 2009). L'évaluation dans les universités ne prend pas en compte les trois dimensions du métier, ce qui crée, pour utiliser l'expression de Dejours (2003), des tensions entre le prescrit et le réel que les enseignants-chercheurs doivent apprendre à gérer. Par conséquent, les enseignants-chercheurs seront plus intéressés par les activités de recherche aux dépens des autres activités de l'enseignant-chercheur. Ainsi, en évaluant de manière équitable les différentes activités de l'enseignant-chercheur, cela permet une orientation équilibrée des activités des acteurs et en définitif, une adéquation entre leurs objectifs et intérêts individuels avec ceux de leurs institutions, afin d'éviter des effets pervers.

Dans cet esprit, il s'agit de mettre en correspondance ce qui est nécessaire dans le cadre d'objectifs institutionnels et ce qui est important pour que les mécanismes d'évaluation individuelle répondent à ses objectifs, en évitant des effets pervers » (Pras et al, 2010). Bref, l'importance que les universités donnent à la recherche se fait aux dépens des autres dimensions et est à la base du problème de l'évaluation dans les universités. Dans ce sens, cette contradiction montre l'écart entre ce qui est évalué et ce qui est vraiment vécu/demandé (Thiétart, 2009). Autrement dit, les systèmes d'évaluation actuels ne favorisent pas l'adéquation entre les objectifs personnels et les objectifs institutionnels. Puisque les enseignants-chercheurs auront logiquement tendance à s'investir plus dans les activités leurs permettront d'avance dans leur carrière.

« L'efficience d'un système d'évaluation se mesure à sa capacité de "générer les bonnes pratiques", c'est-à-dire à canaliser les ressources d'attention et de réflexion vers l'accomplissement des missions fondamentales de l'organisation. Une centration trop exclusive sur l'évaluation de la seule recherche au détriment des autres dimensions aura nécessairement pour effet d'affaiblir ces autres dimensions » (Eraly, 2011).

Par ailleurs, le système qui est à la base destiné à motiver les enseignants-chercheurs à publier dans les meilleures revues crée souvent le résultat inverse. Ce qui engendre les conséquences suivantes, tout d'abord les enseignants-chercheurs se concentrent plus sur les revues moins classées pour obtenir des points suffisant pour leur prochaine évaluation. Ce qui peut obérer la qualité de la recherche et qui explique la démultiplication observée des nombres des revues males classées. Toutefois, l'existence d'un classement des revues facilite la délibération leurs des évaluations de promotion. Une autre conséquence de cette quantification de l'évaluation est que les instances chargés de

l'évaluation s'en remettent quasi totalement au jugement des rédacteurs puisque ce sont eux qui permettent ou non à un enseignant-chercheur d'être publié, d'obtenir ses « points » bibliométriques, d'augmenter son « capital scientifique » et d'accéder à une promotion. Il y a donc une forme d'« externalisation » des pouvoirs d'évaluation vers les comités de lecture (Walery, 2011). Par conséquent, dans ce système, les instances d'évaluation traditionnelles se transforment progressivement en acteurs passifs.

Les établissements d'enseignement supérieur étant classés ainsi en fonction de leur capacité à « faire publier » leurs enseignants-chercheurs, plusieurs stratégies sont mises en place, lesquelles reposent sur des injonctions institutionnelles dont le système d'évaluation est la clé. C'est un système de type punitions/récompenses: cela n'est pas sans influencer nécessairement leur processus de recrutement et créer un biais vers la sélection d'enseignants-chercheurs plutôt chercheurs qu'enseignants (Durand et Dameron, 2011).

En guise de conclusion, les systèmes déséquilibrés d'évaluation amènent les enseignants-chercheurs à privilégier les critères « individuels » au détriment de collectif. Ainsi, « ils ont tendance à ne penser qu'à leur carrière « individuelle » et à publier pour ajouter une ligne de plus dans leur CV » (Deetz, 1995 ; Courpasson et Guédri, 2007). Finalement, la perversité du système d'évaluation ne peut etre contré que par le sens de devoir, de l'éthique et voir même des considérations morales. L'éthos professoral est un qualificatif qui trouve amplement sa place pour décrire cette situation.

---

[i] J. D. Reynaud (1988) considère la « Régulation » comme la capacité à produire des règles. Règles est employé au sens large et recouvre aussi bien le domaine de la règle juridique à ses différents niveaux (loi, règlement) que de la règle morale, (formelle ou informelle). Raynaud distingue aussi trois grands types de régulation, les « régulations autonomes », produites par les collectifs de base et les « régulations de contrôle », émises par les supérieurs hiérarchiques et/ou les responsables politiques, donc les tenants du pouvoir, et les « régulations conjointes » : systèmes institutionnalisés, coopératifs, et donc relativement stables, de combinaison des deux premiers types de régulation.

Abstract

Traditional corporations handle their decision-making process according to a goal consisting in the generation of economic value, that is to say, the maximisation of the company value for the shareholders, maximisation of the economic added value, maximisation of profit, and so forth. Nevertheless, in recent years, a set of organisations that do not prioritise the creation of economic value have appeared, although they are not non-profits. Indeed, they pursue the generation of economic value, but at a level that guarantees their long-term viability. At the same time, their main objectives are not linked to this economic value, but are linked to the generation of positive social value or to the reduction of negative environmental impact. These "new" organisations, commonly referred to as hybrid organisations, need a tool to assess the social and environmental impacts they are generating, in order to guide their decisions concerning the goals they have set in these fields.
In contrast to the accounting area, there is no generally accepted method to quantify the social or environmental impacts of a project, an activity or an organisation. Therefore, deeper research is required in this line. In this paper, we analyse the items that the matrix of the Common Good Balance Sheet (MCGBS) requires for its calculation and classify them according to their relevance for assessing social and environmental impacts. This allows us to evaluate whether these items (and, ultimately, the MCGBS) can be used as a means to quantify the social or environmental impacts generated by an organisation.

Keywords: Social Impacts, Environmental Impacts, Economy for the Common Good, Impacts Assessment

1. Introduction

Firms, institutions, organisations and governments are showing a growing interest in the effects of their actions. Nowadays, however, everybody accepts that these effects go beyond the economic impacts and an evaluation of the social and environmental impacts is also required. Indeed, a large number of institutions have developed initiatives to assess the social impact of their actions, which is proof of how important this issue is for organisations. The diversity of the approaches used by organisations nevertheless highlights the huge complexity involved in this kind of assessment.

An organisation's efficiency is usually measured through a range of specific indicators, related to its scope and mission. This specificity undermines comparability of the information and can diminish its usefulness in decision-making processes.

The aim of this paper is to study the information available to economic organisations and, through the common good balance sheet (CGBS), analyse its value as a means to assess the social and environmental impact of their activities. To this end, we analyse the items used by the common good

matrix (CGM) to elaborate the CGBS and then rank these items according to their usefulness to measure the social and environmental impacts. By so doing, we can determine to what extent these items (and, ultimately, the common good balance sheet – CGBS) can be useful as a means to assess the social and environmental impacts generated by the organisation.

We have structured our paper in the following way: after the introduction section, the social and environmental impacts and their assessment are defined in the second section. In the third, we show the main features of the balance sheet of the economy for the common good. Subsequently (in sections 4 to 6), we classify the indexes depending on the information they provide about social, environmental or mixed impacts. The last section summarises the main conclusions of the paper, shows its limitations and proposes future research lines.

2. Social And Environmental Impacts

Over the last few years, a growing interest has been observed in the assessment of social and environmental impacts generated by both governmental organisations and private firms. It is assumed that these impacts go beyond the accounting results to cover wide areas with a large number of stakeholders involved. One definition of social impact is that provided by Eccleston (2011:172), who claims that it is linked to the effects on the human population of any private or public action that modifies the way people live, work, act, relate and organise in order to satisfy their necessities and help them in acting as members of society. These effects also include cultural impacts that imply changes in the rules, values and beliefs that guide and streamline their knowledge of themselves and of their community.

The methods currently used to assess social impacts are still in an early stage of development. Ebrahim and Ragan (2010) classify the main methods of assessment of social impacts in terms of the different approaches employed. According to these authors, we can distinguish between methods that estimate the expected return, experimental methods, logical methods, strategic approaches, participative methods, relation-based methods and experimental approaches. They also say that those responsible for organisations are facing increasing pressure to demonstrate the impact of their activities on society. This pressure has been exacerbated by the specific budgetary requirements for organisations to make the impacts of their actions public in order to attract new funding (Lyon et al 2010, Chapman et al 2010). In this regard, in the Social Economy Report (2008) and the proposal for a "Regulation of the European Parliament and of the Council on the European Social Entrepreneurship Fund", the European Commission recommends the need for organisations to develop instruments to measure and compare the impact of their investments. In this sense, Diaz et al (2012) state that social impact assessment will be a key element, both in the search for the improvement of social and economic efficiency and in providing different stakeholders with adequate mechanisms of evaluation of the fulfilment of the organisation's social objectives. This need has also directly influenced the rating agencies of non-profit entities in the United States, which in recent years have renewed the rating parameters based purely on financial indicators, tending towards the development of social indicators (Charity Navigator et al 2009).

The interest in sustainable growth in recent years has not only led to concern about the social impacts of the organisations' actions, but has increased the amount of attention paid to environmental impacts. This interest was boosted in 1987 with the publication of the Brundtland Report, where the concept of sustainable development was introduced for the first time, taking into account its three aspects: economic, social and environmental. Sustainable development has since been fostered by successive reports published by the UN World Commission on Environment and Development.

The increasing concern for sustainable growth over the last few years has led to a growing interest in not only social but also environmental impacts. The first studies on the impacts that human actions leave on the environment (Environmental Impact Assessment, EIA) can be dated back to the USA in the late 1960s and introduced the first controls and instruments to evaluate the repercussion of human actions. One definition of impact assessment can be found in Abaza et al (2004), who claim that this assessment refers to the evaluation of the repercussion of a higher project or action that affects the natural and artificial environment. The definition that the International Association for Impact

Assessment (IAIA) provides for EIA relates it to the process (undertaken before relevant decision-making and commitments) of identification, forecasting, evaluation and mitigation of the biological, social and other effects that stem from development proposals (see Vanclay, 2015). Eccleston (2011) claims that EIA can be defined as the accumulated results of a project or activity that generate changes in the environment or ecosystem over time and space.

As for social impacts, nowadays there is no method that can be used by itself for environmental impact assessment, given the variety of firms and the different kinds of actions that can generate an impact. The different methodologies for environmental impact assessment can be classified, among others, into matrix methods (such as the Leopold method), Odum's optimum pathway matrix, modelling methods or simulation techniques, and indicator methods. This last group evaluates environmental impacts through previously established indicators, to which a weighted value is assigned and a final score is set for each of them. Therefore, the MCGBS can be classified within this group of methods.

The two most widely used methods of impact assessment are Social Audit Accounting (SAA) and Social Return on Investment (SROI), the latter having received more attention in the literature (Emerson, 2003; Gair, 2002; Arvidson et al, 2009; Nicholls et al, 2012; Lingane and Olson, 2004). SROI attempts to express the social value generated by the activities carried out by entities in monetary values, based on cost-benefit principles (Flockhard, 2005; Arvidson et al, 2010; Millar and Hall, 2012). Unlike the CGBS method, it adapts itself to the project to be analysed and the interest groups will vary depending on the project. However, carrying out the CGBS is aimed at all the stakeholders that make up society. Other differences between the two methods are that the CGBS can be adapted to apply to organisations, enterprises and municipalities, and SROI is an instrument that applies to particular projects. Accordingly, an organisation can apply the CGBS to the set of all its activities and the SROI to each of them separately, so the first method will give us an overview of the performance of the entity and the SROI will offer a partial view of each of these actions.

Derived from the above and from the temporal point of view, the CGBS covers the activity of the company throughout the same period in which, in accordance with Spanish legislation, companies are required to draw up their accounting and financial reports, that is to say, an accounting year, which usually coincides with the calendar year. The SROI may cover different periods other than a year because the projects analysed by this method can have different durations (greater or less than a year). Thus, if some kind of comparative study were to be carried out between the two methods, it would be advisable for the projects analysed by SROI to also have a duration equal to one calendar year.

On the other hand, the SAA method uses quantitative and qualitative analyses, as well as ratio analysis to measure the activities carried out by the enterprise. It is an internal organisational system implemented by the company and moderated by an independent external evaluator. In contrast, the CGBS does not need interventions from outside the firm to carry out its evaluations. Another point on which the two methodologies coincide is that they are both standardised models, and so comparisons can be made between companies that adopt these methods. This implies that it is possible to show an image of the joint situation of the sector to which these companies belong. Both methods can also be applied to all kinds of organisations (profit and non-profit) and to municipalities. Furthermore, the SAA method, like the SROI, is carried out through several successive stages, although the CGBS does not need the calculations of the indicators to be ordered sequentially.

The SAA system could be placed within the orbit of the analyses based on the Triple Bottom Line[i] as it incorporates the study of commercial and financial, social and community, and environmental and society areas. This is similar to the CGBS, which incorporates indicators related to the social and environmental field into the CGM, the economic-financial field being covered by the annual accounts of the company.

When it comes to choosing the most appropriate method it is necessary to determine in advance whether the study will be directed towards the fundees or investors or whether it is focusing on stakeholders' accountability. On the other hand, and given that both the SAA and the CGBS are

methodologies that include environmental aspects, according to Gibbons and Dey (2011), the principles and application of SROI should also meet the demands of the Triple Bottom Line, including social and environmental as well as economic aspects, in order to provide verifiable and complete information about the company's activity.

3. The Common Good Balance Sheet

As regards changes in the economic model, one of the most comprehensive and innovative approaches is the Economy for the Common Good, which comprises instruments like the Common Good Balance Sheet and Matrix, which many firms have adopted in recent years. The CGBS is based on a series of indicators that make up the CGM. This is a flexible instrument that has been continuously evolving to adapt itself to the social and environmental situation since it was created five years ago. As a result, several versions have been released to date. Table 1 shows version 4.1 of this matrix:

Table 1: Common Good Balance Sheet (Matrix 4.1)

VALUE / STAKEHOLDER	Human dignity	Cooperation and Solidarity	Ecological Sustainability	Social Justice	Democratic Co-determination and Transparency
A) Suppliers	**A1: Ethical Supply Management** Active examination of the risks of purchased goods and services, consideration of the social and ecological aspects of suppliers and service partners 90				
B) Investors	**B1: Ethical Financial Management** Consideration of social and ecological aspects when choosing financial services; common good oriented investments and financing 30				
C) Employees, including business owners	**C1: Workplace quality and affirmative action** Employee-oriented organizational culture and structure, fair employment and payment policies, workplace health and safety, work-life balance, flexible work hours, equal opportunity and diversity 90	**C2: Just distribution of labor** Reduction of overtime, eliminating unpaid overtime, reduction of total work hours, contribution to the reduction of unemployment 50	**C3: Promotion of environmentally friendly behavior of employees** ctive promotion of sustainable lifestyles of employees (mobility, nutrition), training and awareness-raising activities, sustainable organizational culture 30	**C4: Just income distribution** Low income disparity within a company, compliance with minimum and maximum wages 60	**C5: Corporate democracy and transparency** Comprehensive transparency within the company, election of managers by employees, democratic decision-making on fundamental strategic issues, transfer of property to employees 90
D) Customers / Products / Services / Business Partners	**D1: Ethical customer relations** Ethical business relations with customers, customer orientation and co-determination, joint product development, high quality of service, high product transparency 50	**D2: Cooperation with businesses in same field** Transfer of know-how, personnel, contracts and interest-free loans to other business in the same field, participation in cooperative marketing activities and crisis management 70	**D3: Ecological design of products and services** Offering of ecologically superior products/services, awareness raising programmes, consideration of ecological aspects when choosing customer target groups 90	**D4: Socially oriented design of products and services** Information, products and services for disadvantaged groups, support for value-oriented market structures 30	**D5: Raising social and ecological standards** Exemplary business behavior, development of higher standards with businesses in the same field, lobbying 30
E) Social Environment: Region, electorate, future generations, civil society, fellow human beings, animals and plants	**E1: Value and social impact of products and services** Products and services fulfill basic human needs or serve humankind, society or the environment 90	**E2: Contribution to the local community** Mutual support and cooperation through financial resources, services, products, logistics, time, know-how, knowledge, contacts, influence 40	**E3: Reduction of environmental impact** Reduction of environmental effects towards a sustainable level, resources, energy, climate, emissions, waste etc. 70	**E4: Investing profits for the Common Good** Reducing or eliminating dividend payments to extern, payouts to employees, increasing equity, social-ecological investments 60	**E5: Social transparency and co-determination,** Common good and sustainability reports, participation in decision-making by local stakeholders and NGO's 30
Negative Criteria	Violation of ILO norms (international labor standards) / human rights -200 Products detrimental to human dignity and human rights (e.g. landmines, nuclear power, GMO's) -200 Outsourcing to or cooperation with companies which violate human dignity -150	Hostile takeover -200 Blocking patents -100 Dumping Prices -200	Massive environmental pollution -200 Gross violation of environmental standards 200 Planned obsolescence (short lifespan of products) -100	Unequal pay for women and men -200 Job cuts or moving jobs overseas despite having made a profit -150 Subsidiaries in tax havens -200 Equity yield rate >10 % -200	Non-disclosure of subsidiaries -100 Prohibition of a works council -150 Non-disclosure of payments to lobbyists -200 Excessive income inequality within a business -150

Source: https://www.ecogood.org/en/common-good-balance-sheet/common-good-matrix/

Although the CGBS encompasses topics beyond those related to the environment, on analysing the social effects of the firms' actions, one could consider them as a kind of EIA, since it involves an evaluation of the activities that negatively affect the environment. Therefore, this paper focuses on classifying the items in the MCGBS (Table 1) into those related to the social area, those regarding the environmental field, and those that could belong to both areas and hence cannot be separated.

4. Common Good Balance Sheet: Social Impacts

In practice, the measurement of social impact is often confined to just a series of individual indicators. As a result, the information provided does not reflect a global vision and is segmented and biased, as it fails to offer a common view of the different facets of social impact (Díaz et al, 2012). Therefore, it is necessary to analyse and determine which methods for measuring social impact are more suitable for different types of organisations, with the aim of reducing the gap that exists between the information that is currently disseminated by organisations about impact assessment and the different existing models.

Taking the CGM as an instrument for measuring impacts (see Table 1), and ignoring the way enterprises that adhere to this movement record the score when they attempt to implement the CGBS[ii], in the following sections the impacts will be classified in the three groups referred to above.

The indicators of the CGM which may be directly related to the social area are:

C EMPLOYEES, INCLUDING BUSINESS OWNERS
C1 Workplace quality and affirmative action
C1.1 Employee-oriented organisational culture and structure
C1.2 Fair employment and payment policy
C1.3 Occupational safety and workplace health promotion including work-life balance / flexible work hours
C1.4 Affirmative action and diversity

The need to achieve equality between all the people in the company and their full development as individuals is valued , with special attention given to their health. Hence, it is important to avoid the imbalances between different groups such as people with disabilities, migrants, the long-term unemployed, minorities, and so on, and to promote gender equality.

C4 Just income distribution
C4.1 Income divergence in the company
C4.2 Minimum income
C4.3 Transparency and institutionalisation

The wage differences between workers are increasing and this difference, according to Social Medicine, engenders sick societies, which suffer greater inequality and higher crime rates. To solve this issue, it would be advisable to establish a fairer distribution of the workers' income from the performance point of view.

D CUSTOMERS/ PRODUCTS/ SERVICES/ PARTNERS

D1 Ethical Customer Relations

D1.1Total extent of ethical customer relations measures (ethical marketing + sales)
D1.2 Product transparency, fair pricing and ethical selection of customers
D1.3 Extent of customer co-determination / joint product development / market research
D1.4 Extent of customer co-determination / joint product development / market research

In today's society there is a danger that the customer will be seen as a means to obtain an end, that is, as a way to increase profits by using advertising to encourage compulsive and unsustainable purchasing, when purchases should be thoughtful and rational.

D2 Cooperation with businesses in same sector

D2.1 Disclosure of information and passing on of technology
D2.2 Passing on of personnel, contracts and financial resources; cooperative market participation
D2.3 Cooperative marketing

The aim is to encourage cooperation rather than competition among companies, because this is considered to be the way to achieve a higher return.

D4 Socially oriented design of products and services

D4.1 Facilitation of access to information / products / services for disadvantaged customer groups
D4.2 Structures worthy of promotion are supported by sales policies

The level of social responsibility is evaluated from the customers' point of view. This is achieved by considering whether there are facilities that make access by disadvantaged consumers easier, since these have to be a reference for the production of goods and services.

E SOCIAL ENVIRONMENT: REGION, ELECTORATE, FUTURE GENERATIONS, CIVIL SOCIETY, FELLOW HUMANS, ANIMALS, PLANTS

E2 Contribution to the local community
E2.1 Achievements
E2.2 Effects
E2.3 Intensity

It is considered that the company can act as non-monetary contributor to the community, in a similar way to how an individual could, by trying to cover some of its deficits. This could be done through donations, foundations, etc.

N NEGATIVE CRITERIA

N1 Violation of human dignity
N1.1 Violation of ILO norms/human rights
N1.2 Products detrimental to human dignity and human rights
N1.3 Outsourcing to or cooperating with companies which violate human dignity

Companies must ensure compliance with current regulations on human rights and standards issued by the International Labour Organisation.

N2 Non-cooperative behaviour
N2.1 Hostile takeover
N2.2 Blocking patents
N2.3 Dumping prices

In relation to mergers and the acquisition of companies, this should not involve a hostile takeover, and individuals belonging to the company should be able to intervene in the acquisition agreements. With regard to the actions of companies concerning the innovation of products or processes, patents will not be used to hinder other companies from developing innovations that can modify the business *status quo* in the markets (defensive patenting). The application of dumping is also considered a negative strategy.

N4 Socially unjust behaviour
N4.1 Unequal pay for women and men
N4.2 Job cuts or moving jobs overseas despite having made a profit
N4.3 Subsidiaries in tax havens
N4.4 Equity yield rate > 10 %

There should be no gender inequality with regard to wages, and so if a company has been convicted in relation to this matter, or reliable proof of such inequality can be demonstrated, the company will receive a negative score. Dismissal of workers when the company is making a profit, business transfers and closures, and the existence of any kind of relationship with tax havens will also be considered negatively (due to the possibility of tax evasion). Further examination will also need to analyse the firm's situation as regards capital gains.

5. Common Good Balance Sheet: Environmental Impacts

Environmental impact is the effect of any human activity on the natural landscape, climate, and so forth. Environmental impacts produced by business activity can have serious consequences (especially if we are talking about industrial companies) on the health of individuals (both people linked with the company and those who do not have a direct relationship with the enterprise), as well as on the quality of the air, on the recycling of waste, on pollution, and so on. In short, we are talking about effects on the quality of life.

The CGM indicators that are seen to be related to the environmental area are:

A SUPPLIERS

A1 Ethical Supply Management
A1.1 Regional, ecological and social aspects / superior alternatives are considered
A1.2 Active examination of impact of purchased products / services and processes for ensuring goal achievement and extent and form of procedure for verification
A1.3Active examination of impact of purchased products / services and processes for ensuring goal achievement and extent and form of procedure for verification

According to this indicator, companies should take into account the ethical conditions of suppliers and products, for example by assessing precarious working conditions, fair trade, tourism services, cleaning services, etc.

B. INVESTORS

B1 Ethical Financial Management
B1.1 Institutionalisation
B1.2 Ethical / sustainable quality of financial service providers
B1.3 Investments oriented to the common good
B1.4 Corporate financing oriented to the common good

Businesses should be made aware of the effects of the financial sector (especially potentially destructive effects). However, this awareness is a little weak. In consequence, the levels of both the demand and the supply of ethical-ecological or sustainable financial products are not very high.

C EMPLOYEES, INCLUDING BUSINESS PARTNER

C2 Just distribution of labour
C2.1 Reduction of normal working time

C2.2 Increase in proportion of part-time work models and use of temporary employment (with adequate pay)
C2.3 Conscious approach towards (life-) working time

The distribution of work in today's society is highly unequal: there are individuals working a large number of hours (overtime), while others do not do so at all. From the ecological point of view, this is highly inefficient and it would be desirable for society to share working hours out more equitably.

C3 Promotion of environmentally friendly behaviour of employees
C3.1 Nutrition during working time
C3.2 Mobility to workplace
C3.3 Organisational culture, awareness raising and in-house processes

By complying with the conditions of this item the aim is to raise awareness of the need to achieve ecologically sustainable development. To this end it is considered necessary to have an awareness based on fundamental rights such as food or mobility, as well as working conditions which guarantee truly appropriate behaviour by individuals.

D. CUSTOMERS/PRODUCTS/SERVICES/PARTNERS

D3 Ecological design of products and services
D3.1 In ecological comparison to P/S of competitors or alternatives, products / services have equal utility
D3.2 Sufficiency (see excursus below): active design for ecological utilisation and sufficient consumption
D3.3 Communication: active communication of ecological aspects to customers

It is widely accepted that the production of goods and services involves a consumption of resources that exceeds the reserves that are available. The aim is to promote efficiency in the use of productive factors, beyond the actions followed in this regard to date, which are sometimes insufficient (for example, the use of renewable raw materials). For an action in this respect with effective effects on real overconsumption, it would be necessary to make clients aware of their patterns of consumption, or even reduce it as much as possible (food consumption).

E SOCIAL ENVIRONMENT: REGION, ELECTORATE, FUTURE GENERATIONS, CIVIL SOCIETY, FELLOW HUMANS, ANIMALS, PLANTS

E3 Reduction of environmental impact
E3.1 Absolute impact
E3.2 Relative impact: In sectorial comparison, as far as the state of the art and legal requirements are concerned, the company lies …
E3.3 Management and strategy

Given the extent of the influence on the environment at both national and global levels, it is necessary for companies and sectors to reduce it. This could be reflected, for example, in water consumption, recycling, reuse of materials, reduction of emissions, etc.

N NEGATIVE CRITERIA

N3 Environmental degradation
N3.1 Massive environmental pollution
N3.2 Gross violation of environmental standards
N3.3 Planned obsolescence (short lifetime of products)

The objective in this case is to minimise the effects of the destruction of natural areas. An enterprise will be given a negative score if it can be demonstrated that the firm has been sentenced in relation to such aspects or even if it causes environmental burdens.

6. The Common Good Balance Sheet: Mixed Impacts

The relationship between social and environmental impacts is now fully accepted. For example, research by Rettenmaier and Hienz (2014) has revealed a positive trade-off between socio-economic and environmental impacts. Sinha Babu and Datta (2015) claim that both areas are intricately connected and, moreover, that environmental and social factors are correlated when analysing their effects on the well-being of individuals. Thus, the effects of the programmes and actions of companies and organisations affect both individuals and the environment and, in most cases, the effects are deeply associated with each other. As indicated by RHEAS (Spanish-speaking Network for Environmental and Social Assessment) "the social component has become one of the fundamental aspects of environmental assessment". In fact, this network states that "in Legislative Royal Decree 1/2008, Spanish national law specifies that the EIA will identify, describe and evaluate the direct and indirect effects of a project on human beings, cultural heritage and their interaction with the environment".

The CGM indicators that are considered as being possibly related to both the social area and the environmental field are:

D. CUSTOMERS/PRODUCTS/SERVICES/PARTNERS

D5 Raising social and ecological standards
D5.1 Cooperation with competitors and partners of the value chain
D5.2 Active contribution to raising legislative standards
D5.3 Range, content-related scope and depth

Companies should increase cooperation and the dissemination of information on social and environmental standards (political processes, lobbying activities, quality, etc.).

E SOCIAL ENVIRONMENT: REGION, ELECTORATE, FUTURE GENERATIONS, CIVIL SOCIETY, FELLOW HUMANS, ANIMALS, PLANTS

E1 Products / services meet a basic need or serve the development of human beings / the community / the earth and generate positive use
E1.1 Pr Products / services meet a basic need or serve the development of human beings / the community / the earth and generate positive use
E1.2 Ecological and social comparison of products / services with alternatives of similar final benefit

Individuals consume goods and services because they are useful to them, but this cannot be the sole objective of consumers. The effects deriving from the actual consumption of goods and services and whether this consumption is compatible with the environment and society should also be taken into account.

E5 Societal transparency and co-determination
E5.1 Scope of CG Report
E5.2 Type of co-determination and documentation
E5.3 Scope of co-determination and stakeholder integration

The company must provide all the stakeholders with information about its actions; in other words, it must be transparent about its participation in other companies, and how its actions affect both individuals and the environment (level of pollution, recycling, and so forth).

N5 Undemocratic behaviour
N5.1 Non-disclosure of subsidiaries
N5.2 Prohibition of a works council
N5.3 Non-disclosure of payments to lobbyists
N5.4 Excessive income inequality within a business

As was the case previously with the equivalent positive indicator (C5), this item is also considered to be of a mixed nature. Any action that involves in some way a decrease in transparency will be considered an increase in the negative aspects of the company. These actions will be related to aspects discussed above, such as actions which may result in tax evasion, actions which have effects on the environment, and actions with political implications resulting from relations with certain political parties or lobby groups.

A summary of the indicators of the CGM classification, in terms of the type of impact, is shown in Table 2:

Table 2: Impact Indicators Classification

		Social Impact Indicators	Environmental Impact Indicators	Mixed Impact Indicators
A. SUPPLIERS	A1		**X**	
B. INVESTORS	B1		**X**	
C. EMPLOYEES, INCLUDING BUSINESS PARTNER	C1	**X**		
	C2		**X**	
	C3		**X**	
	C4	**X**		
	C5			**X**
D. CUSTOMERS/PRODUCTS/SERVICES/PARTNERS	D1	**X**		
	D2	**X**		
	D3		**X**	
	D4	**X**		
	D5			**X**
E. SOCIAL ENVIRONMENT: REGION, ELECTORATE, FUTURE GENERATIONS, CIVIL SOCIETY, FELLOW HUMANS, ANIMALS, PLANTS	E1			**X**
	E2	**X**		
	E3		**X**	
	E4	**X**		

	E5			**X**
NEGATIVE ASPECTS	N1	**X**		
	N2	**X**		
	N3		**X**	
	N4	**X**		
	N5			**X**

Source: Author's own elaboration

7. Conclusions

In recent years, companies are detecting changes that are leading them to accept that their activity has impacts that have not only economic, but also social and environmental effects. However, there is no system for collecting and measuring information with a level of consensus analogous to that of economics or accounting and which allows us to consider the value of the social or environmental impact of a particular project or organisation, and which favours the comparability of information for decision-making. It should be emphasised that considerable progress has been made in recent years in the measurement of impacts other than economic ones, that is, the social and environmental impacts of the projects undertaken by organisations. At this point, the contributions made by the CGBS methodology are especially significant.

According to this work, and in the light of the results obtained and summarised in the previous table, it can be stated that approximately half of the indicators and/or sub-indicators in the CGM correspond to the social area (more specifically slightly more than 45%), the environmental aspect being considered in only one third of the indicators and sub-indicators of this matrix. Thus, aspects directly related to the quality of life of individuals and their improvement are widely represented in this tool, but the effects on the environment and surroundings are less abundant. This claim does not necessarily imply that the differences in the number of second level indexes indicate differences in quality, in the items or in the instrument itself, which is backed by the results obtained and the high degree of satisfaction with its use in many companies. For these reasons, it cannot be said that the environmental area is represented only precariously in the CGM.

On the other hand, it should be noted that this is a preliminary analysis, and it would be necessary to delve into this subject with a deeper, broader and more exhaustive study. One of the possible derivations of this work would be to carry out analyses at the individual level for each organisation, and another (which is now under way) consisting in classifying the impacts according to different criteria, some of which have been pointed out previously. For example, consideration could be given to the classification of the different indicators studied according to the different points of view in the environmental area, such as the nature of the impact, the cause-effect relationship, its extension, persistence, recovery, manifestation or its interrelation with other impacts. This will allow us to obtain concepts, principles, methodologies and practices that can become balanced and reliable instruments for a better social and environmental assessment. In this respect, it should be noted that this approach (and therefore the metrics involved) has recently received a boost from the regional government through Order 2/2017, dated 21 February, of the *Conselleria de Economía Sostenible, Sectores Productivos, Comercio y Trabajo* of the Generalitat Valenciana. This example shows the growing interest of public administrations in the promotion of policies aimed at creating social and environmental value.

[i] The term *Triple Bottom Line* was coined by Elkington in 1997, in the book "Cannibals with Forks...". The Triple Bottom Line measures the company's degree of social responsibility, the economic value and the environmental impact of an enterprise. Therefore, companies should include assessments about social and environmental aspects of their activities within their accounts to be able to measure the total cost of doing business.

[ii] Companies assess the impacts of their actions in the areas listed in Table 1 (more in five sub-areas that reflect the possible negative impacts) by awarding scores drawn from scales previously established. The scores reflect the level of compliance with the 22 indicators listed in the table above, (the items from A1 to E5, the negative ones, and the respective sub-indicators). The aim is to enable enterprises to assess their level of compliance, obtaining a final score. However, this is not the main objective of the evaluation of an organization from the point of view of the Economy of the Common Good. The calculation of the result of this tool is indissolubly linked to the report that will reflect the deficiencies, the objectives to be achieved in the future, and the way forward for it.

Using Scorecards and Benchmarking in Management and Development of Cities and Regions

Abstract

The topic of this paper is the practical application of selected strategic management, scorecard and benchmarking systems, in the field of public administration and especially in the development of municipalities and regions. The objective of the authors was to highlight the importance of applied strategic approach in municipalities and regions as one of the important topics in the sector over the past two decades. The authors reviewed the application of scorecards and benchmarking in real conditions of The Slovak Republic in period 2005 – 2016 that were framed and started by the reform of the public administration of the Slovak Republic (1995-2005). In this paper they present real life cases and researches in 40 cities in total, representing 42% of the urban population of Slovakia. The paper provides ideas and inspiration for the development of modern management practice not only in local and regional self-government but in public administration in general.

Keywords: Municipality, Regional Development, Scorecard, Benchmarking, Territorial Marketing

Introduction - concepts and approaches

Municipalities and *regions* are the target Entities - Management Objects, which the research was focused on. We perceive these as *territorial management* and thus do not perceive them as a mere administration of territorial - administrative units. Newer theories emphasize access through the paradigm of *functional urban regions*. According to these, cities should be seen as centers of "natural regions", consisting of municipalities in the belonging area of urban and regional centers. The expression *municipality* is derived from the Latin word *municipium*, which means "city with self-government". In English, the municipality means "a city or a district with its own local government, the governing body of such a town" (Hornby 1989). *Region* is a territorial unit defined according to the classification of statistical territorial units. (EUR-Lex 2017). *Euroregion* is a territorial cooperation body composed of representatives of socio-economic partners operating at the regional and local level of neighbouring countries, established for the purpose of cross-border cooperation. *Regional development* is a set of social, economic, cultural and environmental processes and relationships that are taking place in the region and which contribute to enhancing its competitiveness, sustainable economic development, social development and territorial development, and balancing economic disparities and social disparities between regions. It is a long-term "process with a qualitative change aimed at the long-term increase in the economic wealth of the territory as well as its competitiveness" (Cajka and Rysova 2008).

In the history of *regional science* a different position and role of space can be observed. In the original theoretical considerations, space appears as a *physical barrier* to the economic and social activities within it (Tvrdon 2013). Theories that arose in the 1950s and 1960s used space as an *abstract unit*, generally corresponding to the administration units. A radical change in the view of the role of the space took place in the 1970s. The space was conceived as an *economic resource* as a *separate production factor*. In the current regional growth theory, space is understood to be a "*cognitive space*" that can use information to identify and solve problems or has the ability to transform information and knowledge into innovation and productivity growth. According to Camagni (2004), *cooperation between local actors* is also important for this understanding. Sloboda (2006, p.6) presents a summary of basic theories of regional

development from the perspective of economic theory from which it is ideologically based. The significance of space exploration since the 1990s has continued and has risen in the 21st century. In addition to the onset of the global financial crisis after 2008, it also results from the increased interest of regional policy makers, especially in relation to The European Union regional policy.

Trends in Urban and Regional Management

Trends in urban and regional management are based on general trends in public administration, nevertheless are these at the same time characterized by some specificities. The general trends include the strategic approach application, the client orientation, and the value-based service orientation. A specific trend is the shift from the perception of cities and regions as territorial units to *urban regions* as natural spatial units. In the second half of the 1980s a reform approach was developed by academics ("New Public Management", "NPM"). In the 1990s NPM was increasingly accepted as a "gold standard for administrative reform" (Kapucu 2006). In the course of a later period, it has been criticized by some authors and faced a "competition" by the "Value for Money" ("VFM") approach. The founder of the concept of public value can be considered M. Moore (1995). According to him the role of managers in public sector organizations is to create public value. A summary and comparison of selected paradigms in the development of public administration management is processed by Flynn (2007) and other authors. The 20th and 21st centuries, however, especially the outbreak of the global financial crisis after 2008, has raised serious questions about the future of the world economy and hence of access to the public sector economy as a specific component of each state (Gregusova 2016a).

Under Slovak conditions NPM-based concepts have not even been implemented to a wider extent before some scepticism emerged. In any case the NPM principles have penetrated into the public administration in Slovakia, which in essence represents the management of public affairs (Peracek 2016) and have brought and still are bringing many benefits to it. Essential fact in the author's opinion is that both NPM and VFM emphasize client's approach and effective value creation. Filko, Kiss and Odor from Institute of Financial Policy (The Ministry of Finance of the SR) and from the Council for Budget Responsibility (an independent body for monitoring and evaluating the fiscal performance of the SR) have developed a study (2016), which was adopted as a government project (Adrian 2017). The authors of study emphasize three levels of change: (1) VFM is a philosophical change, (2) institutional reform and (3) gathering and accessing data and using modern analytical tools. They consider the three most important tools: "*spending review, cost-benefit analysis, and benchmarking*" (p.5-6).

Scorecards and Benchmarking In the Management & Development of Cities / Regions

The management of organizations in a constantly changing environment requires a certain set of "navigation" tools and indicators to assess the situation from different perspectives and to monitor how organizations achieve their set strategic goals. Balanced Scorecard ("BSC") is more than a management reporting system or performance measurement system. BSC links indicators with strategy, "translates" the organization's vision, mission and strategy into a comprehensible set of performance indicators that give top management a quick but complex view of the organization. BSC goals and indicators follow the performance of the organization from four perspectives: financial, customer, internal processes and learning and growth (innovation). Individual perspectives lead to selected areas and guide strategic thinking to find causal links between them (Kaplan and Norton 2006). For non-profit organizations and the public administration sector, the perspectives system is modified: at the top is a customer perspective, which is also referred to as a civic perspective in the case of public administration (Niven 2003).

A new understanding of the role of public administration in society is inevitably linked to the application of new methods of performance evaluation and quality of service provided by the public administration. With this aim it was in 2013 SR adopted act on the electronic form of execution of competences of the public authorities (e-Government Act), whose main task is to facilitate communication with public

authorities (Gregusova 2016b). One of the most commonly used methods is *benchmarking*. The word "benchmark" means: a standard, a comparative point, or a comparative indicator. Benchmarking is a method of systematic and continuous measurement, comparison and evaluation of its own effectiveness and quality compared to others. "Benchmarking is a process in which we are so modest that we admit that someone else is in something better and then we are so smart that we will find out how we can deal with them or even overcome them." (Niznansky and Rafaj 2016).

The benchmarking method considers the best practice as a standard. In the standpoint of the standard, the institution - the self-government, which performs the best results in the provision of comparative services, performs both in terms of quality and costs incurred. The OECD countries are familiar with the various practices associated with initiatives to implement benchmarking in public administration. One approach is the *bottom-up initiative* where municipalities and public service organizations join together to improve the performance and quality of services provided. Organizations set up their own benchmarking system, looking for suitable partners for benchmarking (e.g. Ontario Provincial Initiative). If the initiative comes from self-government or other public sector bodies, then it is itself interested in knowing and using better practice, and the method contributes to improving the performance of the lagging behind. The second approach is the introduction of *mandatory benchmarking by law*, creating a competitive environment and pressure while creating the possibility of systematic control of organizations (The United Kingdom). A positive attitude towards such an approach is the full implementation of and the provision of an overview of the quality of work of organizations. To improve the performance of the lag, the tenderer is primarily interested in the performance, but may not be interested in the organization itself (Niznansky 2013).

Research on the Use of Scorecard and Benchmarking In Municipalities

The use of scorecards and benchmarking in the cities of the Slovak Republic ("SR") has been the subject of our own qualitative research. The aim of the research was to find out the extent and the way of using scorecards and benchmarking in the management and development of cities in the SR. The monitored period was 2005 - 2016, i.e. from the implementation of the first stage of the municipal reform of the SR - decentralization, which took place in 2004 to the present. The research was conducted from January to April 2017. A structured questionnaire, prepared in Microsoft Excel, was sent by electronic mail to cities in Slovakia. The questionnaire included a combination of closed and open questions. The cities were addressed directly and with the recommendation of the Association of Municipal Economists, the Association of Local Government Managers and the Communal Research and Advisory Center ("KOM").

In the Slovak Republic, there are 2 883 municipalities with local government bodies, out of them 140 have status of city. The research was carried out on a portion of the base file by a selecting 100 cities in total. The analyzed cities were clustered to following size categories: up to 10 000 inhabitants; from 10 001 to 20 000 inhabitants; from 20 001 to 50 000 inhabitants and over 50 000 inhabitants. 40 cities in total, i.e. 40% of the selection file and 29% of the base file responded. Total number of inhabitants of the responding cities amounts to 1,215 million, i.e. approximately 42% of the urban population and about 22% of the total population of the SR.

Assumptions: Use of Scorecards in the Cities

The first group of questions focused on finding out about the existence and usability, scope, method and duration of the use of the Balanced Scorecard, as well as other systems of performance indicators in the Slovak cities. The questions were drafted in order to enable differentiation of the Balanced Scorecard from other types of scorecard systems A differentiator to differentiate the relevance of the Scorecard used by the city to the type Balanced Scorecard was a set of questions aimed at detecting whether:

- Scorecard indicators are divided into four causally linked perspectives
- A scorecard is linked to city strategy or other strategic documents

- Scorecard is linked to actions - performance measurement in an organization or employee remuneration based on performance indicators.

Following types of system indicators were anticipated:
Balanced Scorecard (BSC) - a comprehensive balanced system of indicators in the sense of its generally accepted definition.
Financial - Budgeting Scorecard - reduced to the financial perspective, or just a set of basic financial or budgetary indicators.
Multi-criteria Scorecard - a scorecard containing financial and non-financial indicators across multiple areas of the scope of the city but which does not meet the Balanced Scorecard criteria.
Particular scorecard - set of indicators applied to the selected area(s).
Scorecard of Economic and Social Development - "ESD Scorecard " was not identified in any of the studied sources. However, it reflects the terminology and legislative specifics of the SR. The Economic and Social Development Plan is a document that is close to the strategy by the means of content and definition. The cities are obliged to develop and elaborate their ESD plans by the law (Act no. 539/2008 Coll. of the Slovak Republic on Support for Regional Development).

Results and discussion: Used scorecard types in the cities of the SR

The use of the definition-complete Balanced Scorecard system was not found in a sample of 40 responding cities. Thirtysix cities, i.e. 90% stated that they were using some system of performance indicators (scorecard or some type of dashboard system). Four cities, i.e. 10% of responding cities stated that they do not use a system of performance indicators or provided no response in the Scorecard questionnaire section. This fact can be interpreted in the way that the cities do not use a system of indicators but from other sources (INEKO 2017) we have the knowledge that the basic financial indicators, e.g. debts, liabilities are being monitored.

A financial scorecard, based on performance, financing, or budget indicators is being used by twenty-one cities, i.e. about a half (52.5%) of the respondents. A significant majority, 85% of these cities also stressed that it is considered sufficient to regularly assess the financial and budgetary indicators. A multi-criteria scorecard was used by 6 cities (15%) from the survey sample. The average amount of areas of the multi-criteria scorecard was totalled at 15. By the end of 2016 the ESD Scorecard, conceptually closest to the Balanced Scorecard strategic system was used in 9 cities (22.5%). The average amount of areas of the ESD Scorecard totalled at 13 and was reported by the 90% of the cities. This finding confirms that the ESD Scorecard cannot be considered a Balanced Scorecard based on the criteria of monitored perspectives. The criterion for the inclusion to the type ESD Scorecard were the ties with the city's economic and social development plan. We identified all anticipated scorecard types but BSC. The hypothesis that the use of the Balanced Scorecard system will be detected in at least 2% of cities is rejected. A summary of the used scorecards in the Slovak Republic is given in Table 1.

Table 1: Applied type of scorecard and duration of the use

Use as at 2016	**All scorecards**					**SC ESD & Multicriterial SC**		
Scorecard type	**cities #**	**share %**	**years in use**	**cities #**	**share %**	**years in use**	**cities #**	**share (%)**
Financial	21	52,5	1 - 5	2	5	1 - 5	2	13,3
Multicriterial	6	15	6 - 10	17	42,5	6 - 10	9	60
ESD Scorecard	9	22,5	not indicated	17	42,5	not indicated	4	26,7
no scorecard	4	10	no scorecard	4	10	Total	15	100
Total	40	100	Total	40	100			

Source: Own questionnaire survey

By the means of a questionnaire survey, we have identified further characteristics related to the use of scorecards in the Slovak cities:

- period and time of use,
- used support of information systems,
- scope of use within the city, city office and city-based organizations,
- use of a scorecard purposefully, in a limited range and time, within a specific project
- knowledge / awareness of indicators systems by city managers and leaders
- intentions / plans to implement the scorecard in the next period (year).

A graphical summary of the use of scorecards in the cities of Slovakia is shown in Figure 2. Further outputs will be published at a later period.

Assumptions: Use of benchmarking in the cities

The second group of research questions was aimed at finding out about the existence, usability, extent, method and time of using the benchmarking method in the Slovak cities. The questions were drafted in a way, so that differentiation of following would be possible:

- *systematic benchmarking* - long-term, regular and multi-criteria comparison and learning from the findings
- *ad - hoc benchmarking* - partial, focus - or time - limited benchmarking activities where cities compare the selected data.

The subject and objective of the survey was as follows:

- engaging in benchmarking projects and initiatives during 2005 -2016
- current involvement in benchmarking projects by end 2017
- particular (time, purpose, scope, or content) limited use within a specific project
- ad - hoc use of benchmarking
- duration of use of benchmarking
- the number of areas / subareas and the number of benchmarking indicators
- way of performing benchmarking
- using software tool support.

Results and Discussion: Use of Benchmarking In the Cities

Experiences with the practical use of benchmarking in the period 2005-2016 indicated 82.5% of the 40 responding cities. Systematic, regular and in the long run used benchmarking was indicated by 75% of cities. Most of them (85%) performed this in the form of an active annual participation in a long-term Benchmarking Project of Slovak Municipalities ("BMU Project") (Niznansky and Rafaj 2016). Overall, 26 out of the 40 responding cities (65%) were involved in the BMU Project for certain time within period 2005 - 2016. Active participation means collecting and inserting values into the web portal, for computing 160 indicators in 15 areas, participating in methodical meetings and on-line access to the database, graphical outputs, and to annual publication. The project has been a catalyst for the development of benchmarking since 2005. Furthermore, 10% of cities used benchmarking on a regular basis outside the area of the BMU Project. Using benchmarking for single / ad-hoc purpose or in the specific project reported 7.5%. The impact of experience with the BMU Project on higher return rate of the survey was approximately + 25%.

Seventeen cities (52% of 31) with benchmarking experience used it longer than 5 years in the reference period 2005 - 2016, nearly a quarter used it 10 or more years. 42% of cities said they were using benchmarking for less than 5 years. 6% did not indicate usage time.

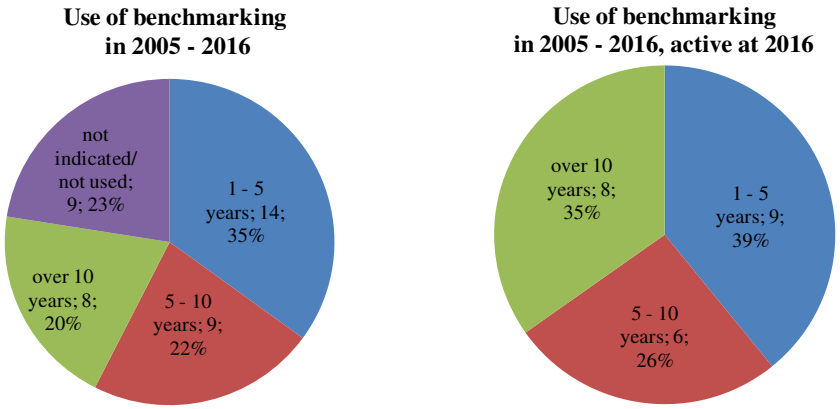

Fig. 1: Total duration of benchmarking usage

Source: Own questionnaire survey

Duration of use is shown in the graph in Figure 1. In a group of cities that actively used benchmarking to the year 2016, cities with benchmarking use 1 to 5 years (39%) are the most represented. Average duration of the use of benchmarking of active to the December 31, 2016 was 7 years. The share of cities that stopped using benchmarking is 39%, the average use in this group was 6 years. An important factor in the long life of benchmarking is the UMS and KOM initiatives that create "benchmarking culture" and quality service provision to "stimulate the demand" from cities.

Typical number of benchmarking areas amounts to 15. This was reported by 63% of the benchmarking cities. Within these, approximately 160 indicators benchmarked. This is a consequence of the fact that the BMU Project (BMU Project 2017a) has become the de facto benchmarking standard for cities. 10% of the cities have indicated less than 5 benchmarking areas. The most frequently mentioned areas of benchmarking application by respondents are shown in Figure 2. An interesting finding is that there is predominant use of benchmarking as a support for decision-making and there is no area of organizational improvements by benchlearning. Further research findings will be published at a later point in time.

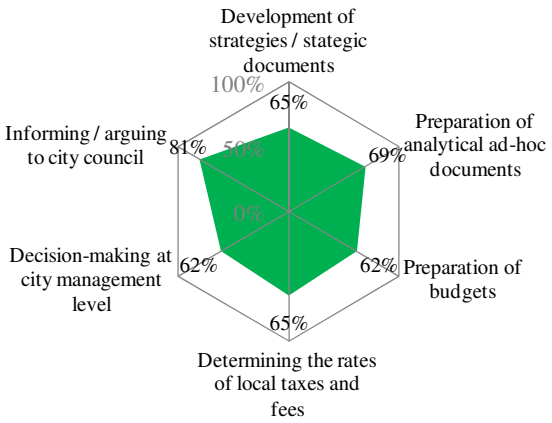

Fig. 2: Most frequently mentioned areas of benchmarking application

Scorecard for Benchmarking and Ranking Municipalities

In order to make it easier for municipalities to find their way around complicated decisions and to benchmark each other, a set of indicators can be used *Scorecard for benchmarking and ranking municipalities* in the SR. We present its possible form, which has also been tested in practice (Niznansky 2011). As a basis for the design of the scorecard for the ranking of municipalities, we used a set of indicators for the Benchmarking project of Slovak cities. The project took place in approximately 30 cities in Slovakia between 2004 and 2016. The cities compared each other in 160 indicators in 15 areas using a specially created web-portal for this purpose (BMU Project 2017b). The portal contains a database of 11-year data sets as well as a benchmark and trend visualizations.

When selecting indicators, we focused on areas that in our opinion, most affect the quality of life in the city. We consider such areas as: (1) Effective management; (2) Quality services; (3) Quality Environment; (4) Public finance and (5) Community safety. Selecting areas and indicators were based mainly on *brainstorming*. Ideas and suggestions were collected from experts from each participating city and from the project team. Furthermore, the *cause-effect diagrams* method from Balanced Scorecard designs was used. The selection of specific indicators for the Scorecard was carried out subsequently, after 6 years of data collection in the Benchmarking project. Selection was performed by combining expert choice and examining correlations of indicator. As an example, we present a summary of the analysis of the community safety indicators (Table 2).

Table 2: Correlation coefficients in the area of community safety

Indicator - correlation	# of traffic violations (penalties)	# of violations to city regulations	# of violations to law
Coverage with cameras	0,857	-0,955	-0,502
Patrolling city cops	0,847	-0,893	-0,367
Safety spending	0,718	-0,897	-0,734
Preventive events	0,706	-0,791	-0,420

Source: Database of Benchmarking project of Slovak cities (BMU Project 2017b)

In the survey sample of 34 cities, the productivity of city policemen and community safety shows an increasing tendency in the period 2004 – 2014 with increasing cameras coverage, number of patrolling city cops and safety spending. In the Community Safety area, following indicators were selected:

- City coverage with cameras (Number of cameras per $1km^2$)
- City coverage of patrolling city policemen (Number of policemen per $1km^2$)
- Share of city police expenditure on total city expenditures (Safety cost per citizen).

Analogously, other indicators of the Benchmarking and ranking scorecard of municipalities were selected. Consequently, we have defined the ranking of the city that we consider to be the best in this indicator. The evaluation is based on the sum of the achieved scores. The description and results of the ranking according to the above criteria setting can be found in the publication (Niznansky 2011).

Scorecard of the knowledge cooperation in metropolitan region

The overall goal of the TwinRegion project (TwinRegion 2012) - was the establishment and strengthening of cooperation in the metropolitan region of Vienna - Bratislava (TwinRegion) through greater involvement of the surrounding cities and towns. The Web-scorecard is supposed to support this goal insofar as it means a system of 450 indicators:

- showing existing collaborations and cooperation potential of the TwinRegion,
- representing best practices in different fields of cooperation
- provides the search of potential partners on various topics.

Thus, the figure of the Austrian and Slovak cities of TwinRegion in a Scorecard or a performance measurement system as a central base for the establishment of collaborations are understood. Below presented fields of cooperation were identified within the TwinRegion-study as areas of high potential for cooperation:

- Information and communications platforms
- Identity and marketing of the metropolitan region
- Education networks
- Coordination of regional development plans
- Development of the business location
- Innovative and sustainable use of resources.

The scorecard consists of three main parts: (1) Basic indicators for the regional framework; (2) Basic indicators for the cities; (3) Cooperation indicators of the selected cities to six domains.

Discussion

The goal of the Web-scorecard TwinRegion is not (only) to measure and compare the performance of the cities in the "Knowledge Sharing", but to provide structured information about the cities and their cooperation in 6 selected fields to support their mutual communication and interactive information exchange. The Scorecard offers to the cities interested new cooperation opportunities and potential partners the opportunity to present their own city for knowledge collaboration. In midterm perspective, the Scorecard should support the institutionalizing of cooperation at both political and (self)government level and promoting the co-operative strategies in the metropolitan region.

Benchmarking In Operational Program of the EU in the Slovak Republic

The most important funds with a significant impact on the development of municipalities and regions are The European Regional Development Fund, The Cohesion Fund and The European Social Fund. One of the cornerstones of the *outcome-oriented approach* in the 2014-2020 programming period is the performance framework. Under *The Partnership Agreement*, "Setting up a set of indicators correctly and effectively is crucial to successful implementation of the performance framework, which includes four steps" (Government Office 2014):

- *Selection of appropriate indicators*: selected indicators should be representative, realistic, verifiable and achievable;
- *Setting the values of the objectives* of indicators to be achieved by 2023. It is recommended to "perform a Value for Money analysis" and "use recognized quantitative or qualitative methods";
- *Selection of appropriate indicators for setting of partial targets*;
- *Setting the partial targets* to be achieved..

As an example, we select and generalize the experience from the successful practice of benchmarking in the Regional Operational Program ("ROP") in the 2007-2013 programming period and in the Environmental Quality Operational Program ("OP QE") for the 2014-2021 period, in which one of this paper authors participated. The data is drawn from public sources (ROP 2014, OP QE 2017).

An applicant-recipient of non-redeemable funds is required to maintain the principle of cost-effectiveness. On the project level, it means minimizing the costs necessary to implement the project while meeting the project objectives. On the program level, it is required to maximize Value for Money. Their common characteristic is the application of the benchmarking method to determine the reference values. Benchmarking has been chosen for reasons of objectivity and practical applicability. The benchmarking process will be demonstrated by an example of identifying the relative investment intensity of building a sewerage network. This was done on the basis of statistical analyzes of historical data from the projects implemented in 2007-2013. The population of the sample was 121 projects, of which 25 were expert selection according to defined criteria selected 25, fulfilling the "standard condition" (Table 3).

Table 3: Sample of OP Quality of Environment benchmark values

Project activity	Benchmark reference value
Gravitational sewer network	425,000 €/km
Gravitational sewer network+ water supply	480,000 €/km
Pressure sewer network	250,000 €/km
Pressure sewer network+ water supply	305,000 €/km

Source: Operation Program Quality of Environment (OP QE Call 2015)

The Regional Operational Program implemented in Slovakia throughout the 2007-2013 programming period can be perceived as an example of successful benchmarking practice. Benchmarks have been applied to assess economic efficiency in over 30 calls and over 2,600 evaluated applications. A sample list of ROP benchmarks is given in Table 4.

Table 4: Sample of ROP benchmark values

Measure	Benchmark reference values
2.1 Social Services Infrastructure	Resident place 15,000 – 40,000 €/client Non-resident services 1,000 – 1,500 €/m^2
3.1 Strengthening the cultural potential of the regions	30 – 100 € /user 1,500 – 3,200 €/m^2 floor square
4.2 Infrastructure of non-commercial rescue services	Rescue stations: 133,000 – 266,000 €/project Base stations: 332,000 – 730,000 €/project
5.1 Regional roads	166,000 – 498,000 €/km.

Source: Own processing of the author from public sources (ROP 2014)

As stated at The 7th European Summit of Regions and Cities (Bratislava Summit 2016), EU funds are considered an important means of regional development of the SR and a decisive source of its funding - they accounts for up to 80% of public investments. Provision of EU funding is a comprehensive system that also introduces systems of successful practice in municipalities and regions. They significantly contribute to the dissemination of know - how in the application of scorecards and benchmarks in the SR.

Benchmarking In Marketing Communication of Municipalities and Regions

The role of the *Territory Marketing* is to identify the needs of the target groups and provide them product offers in order to satisfy their individual perceptions and at the same time support the development of the territory (Olsavsky, 2014). The aim of the research focused on the *Benchmarking of Marketing Communication* in the municipalities and regions of Slovakia was to examine selected aspects of marketing communication on the sample of functional urban regions. The survey was carried out in 2017 on the data obtained by questionnaire survey in 2015 from a larger project of The Union of Cities of Slovakia ("UMS") (UMS 2017) in cooperation with the Communal Research and Advisory Center ("KOM") (KOM 2017).

In the survey data from the four functional urban regions of Slovakia were collected and analyzed. The sample of functional urban regions contains two pairs of comparators: two regions (R1-Trnava and R2-Trencin) have an urban, industrial character, with dynamic economic development after 2000. Two other regions (L1-Turcianske Teplice and L2-Gelnica) were of mountainous character, high forest share (60-70% of land area) and stagnant industry. They have the potential to develop tourism, but transport infrastructure is in an inconvenient state. Both forest regions have comparable natural and climatic conditions, population, but different demographic characteristics. Both of urban regions have comparable demographic characteristics and slightly difference in geomorphology.

The survey was conducted using a cloud-based questionnaire accessible to the respondents on-line, with telephone support. Seventeen questions, qualitative and quantitative, were addressed in the examined functional urban regions. These were answered by 40 - 45 municipalities, depending on the question. Qualitative questions were focused on: (a) Marketing message; (b) Marketing slogan; (c) Perceived competition of municipalities / regions; (d) Target groups; (e) Strengths on which the community builds its marketing strategy; (f) Used marketing tools; (g) Importance of marketing tools in terms of success; (h) Importance of marketing tools in terms of spending; (i) Areas of cooperation of the municipalities in marketing communications and other areas. In the post, we only show the answer to the question of "The importance of marketing tools in terms of success". Further results of the research were published (Rafaj and Strazovska 2017).

The community website is considered the most frequently used tool of marketing communication - used by over 90% of municipalities. According to Niznansky and Rucinska (2015), municipalities consider the website as an information board. The lowest share of municipalities with a website was in the L1 mountain region. Other most used marketing tools include brochures and flyers (60% of municipalities) and promotional items (50% of municipalities). Cultural, social and sports events are considered as an important marketing tool by 40% of municipalities. Surprisingly low was the use of social networks as marketing tools - only by single region. At the time of writing this paper (August 2017), a survey was conducted on the social networks use in the R1 region. Within two years, around half of municipalities started to use social networking and up to about 75% of municipalities (including unofficial profiles that contribute to community marketing). A summary of the answers to the survey on the use of marketing tools is given in Table 5.

Table 5: Use of marketing communication tools

Marketing tool - region	R1	R2	L1	L2	Total
Website	100%	100%	83%	92%	93%
Brochures and flyers	62%	75%	42%	50%	56%
Promotional items	15%	63%	58%	67%	49%
Events	31%	38%	8%	100%	44%
Information boards	31%	50%	0%	50%	31%
Local press / radio	46%	38%	0%	42%	31%
Video, multimedia	0%	13%	8%	0%	4%

Source: KOM, own data processing (KOM Data 2015)

A sample of successful practice of applying scorecards and benchmarking in city marketing will be complemented by selected outputs from the Benchmarking project of Slovak cities. Figure 3 shows the trend diagram of the share of promotion expenses of the cities in relation to the total expenditure of the cities. The sample includes the data of 32 cities in 2004 -2014.

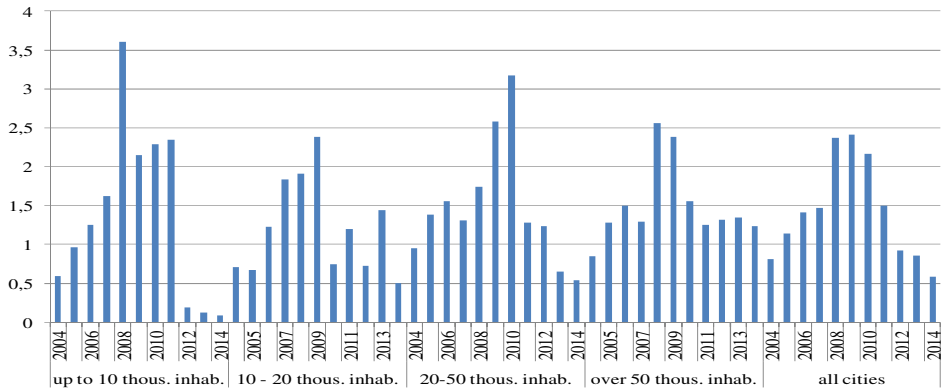

Fig. 3: Share of expenditure on promotion on total expenditure (%)

Source: KOM, own data processing (BMU Project 2017b)

Promotional spending grew in cities of all size classes until the beginning of global financial crisis. As a result, cities have moved on to more restrictive budgets since 2009, and marketing spending has fallen in all cities except for the cities with population of more than 50,000. The average value of marketing expenditures in 2014 amounted to 0.26% of the total budget. The promotion expenses in EUR per inhabitant show similar trend. In the entire sample of 32 cities, they have nearly tripled from an average of € 1.15 per capita to a maximum of € 3.20 per capita in 2008. The impact of the global financial crisis can be noted by the fall to € 1.7 per inhabitant 2013 and 2014, i.e. the initial level of 2005. In the sample surveyed in cities with over 50,000 inhabitants in 2014, they spent approximately € 2.90 per inhabitant on the promotion. The values in the sample show high scattering. Data include only directly charged promotion costs - do not include e.g. web costs, cultural events, etc.

Conclusion

Although the IMF and the OECD consider that Slovakia belongs to the most likely country among their members to carry out reforms, major regional disparities and a lack of government effectiveness persist (Adrian 2016). Slovakia's cumulative real GDP growth rate of 38% between 2004 and 2014 was the strongest of all 28 EU Member States (Eurostat 2015). In 1995 - 2005, the first phase of decentralization of public administration took place. As stated by the protagonists of the Value for Money concept (Filko, Kiss and Odor 2015) and of the public administration reforms in Slovakia (Niznansky 2005), The Union of Cities of Slovakia (UMS 2016), the application of scorecard indicators and their benchmarking appear to be one of the key success factors and transformation accelerators of public administration. In the paper we have presented a range of cases of application of scorecards and benchmarking in the development of cities and regions in Slovakia. The specificity of Slovakia is their use in the wider transformation of the social and economic system from a centrally planned regime to a liberal democracy with a market economy. In the short history of less than two decades, Slovakia has successfully applied scorecards in various areas. In Table 6 we summarize reflection of development trends by the scorecards and Benchmarks, as stated in this paper.

Table 6: Overview of scorecard and benchmarking use in Slovak Republic

Trend	Case described in paper (chapter)
From space as a physical barrier to cognitive space. Territorial Balanced Scorecard	Scorecard of the knowledge cooperation in metropolitan region
From administrative and bureaucratic approach to functional municipal regions	Scorecard for benchmarking and ranking municipalities
From financial / budget indicators to Scorecards,	Benchmarking (and Value for Money) in

Program Budgeting, NPM and VFM concepts	operational programs of The European Union
From marketing of places to integrated model of territory marketing / spatial marketing	Benchmarking in marketing communication of municipalities and regions / territories

Source: own processing of authors

The focus of this paper is the outputs of the research on the use of scorecards and benchmarking in the cities of the Slovak Republic. In the sample of 40 cities, representing 42% of the urban population of the SR, the system of financial and budgetary indicators (52%) is the prevailing type of scorecard, followed by the Scorecard of Economic and Social Development (23% of the cities). Benchmarking has been used around for about a decade in the cities of the SR. A high proportion, 80% of the responding cities stating systematic use of benchmarking, is also the result of the Benchmarking Project carried out by the Union of Cities of Slovakia in cooperation with the Communal Research and Advisory Center (BMU Project 2017a), initiated in 2005 by think-tank M.E.S.A. 10, supported by OSF.

The selected critical factors of success, verified under SR conditions, are:

- the interest of local and regional authorities and the involvement of professional association (Union of Cities, Association of Municipal Economists and Association of Municipal Managers)
- promotion, initiative, know-how transfer and leadership from think-tanks and non-governmental organizations and civic associations
- an obligation to create strategic plans of cities and regions, keep program budgeting in the SR legislation
- openness of the government sector to the application of new approaches, (e.g. Memorandum of Understanding between the Government Audit Office and the Department of Value for Money of the Ministry of Finance; starting in the autumn of 2016, the Value for Money initiative was rolled out in three additional sectors (education, environment and social issues))
- the transfer of Value for Money, indicators and benchmarking methodologies through the preparation and implementation of EU operational programs.

Although, apart from the example of the metropolitan region scorecard, we only provide Slovak Republic specific cases, examples of successful practice can be applied to other countries - not only in those in which the transformation of the economy or public administration and self-government is taking place. Vice versa, it is considered useful and appropriate to monitor the best practices of countries and regions that are champions of scorecards, benchmarking, value for money and functional municipal regions and transfer them to (not only Slovak) regions and municipalities.

Abstract

Each country applies their own rules and regulation and it is usually different when researcher compares one country to another. This paper intends to identify the takaful rules and regulations for Malaysia and Indonesia and to analyse the similarities and differences of takaful rules and regulations for both countries. In order to achieve these research objective, a case study on a leading takaful operator was undertaken. This study begins with the introduction of brief background of an ABC leading takaful operator. The main findings of this research include: Takaful rules and regulations of Malaysia and Indonesia are governed by Islamic Financial Services Act 2013 (IFSA 2013) and Undang-Undang No 40 (UU40) respectively; IFSA (2013) is a special Shariah compliance guidelines for financial services including takaful whereas UU40 focus on takaful and insurance service. The results of this research could provide a significant contribution to takaful operators in ASEAN countries especially Malaysia and Indonesia.

Keywords: Takaful rules and regulations, Comparative study, ASEAN, Malaysia, Indonesia

Introduction

Any organization around the world acknowledges the importance of rules and regulations to control mismanagement, increase the level of solvency and strengthen the position of the company. Therefore, each country applies their own rules and regulation and it's usually different when researcher compares one country to another. In some countries, the rules and regulations are governed by either government or independent agency.

In Malaysia, Bank Negara Malaysia (BNM) is a regulator and supervisor of the takaful operating system based on the principles of Islamic law which proves the importance of regulation in regulating takaful operators (Berkem, 2014). Meanwhile, in Saudi Arabia, SAMA (Saudi Monetary Agency), is the enforcement of the regulations issued in 2004 for small-sized insurers (Global Takaful Insight, 2014). Furthermore, Central Bank of Bahrain (CBB) is the ruling body for controlling the takaful industry in Bahrain to strengthen the solvency position of the firm, improve the efficiency of its business operations and at the same time safeguard the interests of all stakeholders or participants. This is seen as a healthy development and will enhance the financial sector, especially in the field of Islamic takaful industry (Ernst & Young, 2014).

At the present time, the practice of rules and regulations is based on the country itself. This is not in line with the requirements made by global financial regulators as a whole. Malaysia as a developing country with similarities to neighboring Indonesia, makes light-touch approaches that run periodically and gradually. At the same time, long-term regulatory principles are important events. Among them are minimum risks, creating stringent rules and maintaining high standards. However, in regulating the insurance industry in Malaysia there are some new things that change the approach. Among the new developments are the globalization and explosion of information technology, the concentration of the financial industry and the rise of consumerism (Majid, 2011).

However, the rule is an important basis and represents a milestone in the establishment of institutions and so on in their daily activities (Rosengard, 2007; Ya'u, 2013). Based on Ingram et. al (2011) if any regulation should be held, of course, the uncertainty can be reduced. On the other hand, if a regulation was not thorough and comprehensive, it probably will not be able to attract foreign investors to enter the takaful industry (Sukmana & Hidayat, 2014). This issue should be addressed by making improvements and enhancements regulations. Thus, the objective of this paper is to identify the takaful rules and regulations for Malaysia and Indonesia and to analyze the similarities and differences of takaful rules and regulations between both countries.

Literature Review

The establishment of the ASEAN Free Trade Area (AFTA) allows insurance companies from any member country to establish operations in another member country. The open market of insurance requires a set of minimum standards of rules and regulations to protect the industries from misconduct and unethical practices. ASEAN Insurance Training and Research Institute (AITRI) (2013) emphasized that it is important to build harmonized rules and regulations in the process of achieving an ASEAN Economic Community. It is hoped that deeper liberalization and integration of the insurance market will develop the financial infrastructure, harmonize the regulations as well as strengthen the national capacity.

The introduction of General Agreement on Trade and Services (GATS), requires the domestic company to have the ability to compete with world-class companies in the national market. In the context of the insurance industries, it is essential for the ASEAN countries to establish rules and regulations which an increased competitive advantage to the insurer and the insured.

The rapid growth of the Malaysia takaful industry contributes about 71% of ASEAN gross takaful contributions by country (Ernst & Young, 2014). Among the contributing factors to the progress are the enactment of Islamic Financial Services Act 2013 (IFSA 2013) and the support of Bank Negara Malaysia (BNM) as the regulator of takaful and insurance industries. BNM as the main regulator for insurance and takaful industry in Malaysia whereby it set the minimum capital requirement at RM100 million for the both life and non-life takaful operator. Simultaneously, all takaful operators are subjected to solvency regulation. In comparison to Indonesia, Malaysia has set a target capital available at the level of 130%. The perspective of policyholder protection under the Malaysia Deposit Insurance Corporation (MIDC) administers by the Takaful and Insurance Benefits Protection System (TIPS) which protects specific benefits under life and general insurance. Interestingly, foreign ownership is generally limited to 70% and the amount exceeding 70% must get the approval from BNM on case to case basis (Sivalap, Chucheep & Arunee, 2014).

Indonesia currently adopted Undang-Undang No 40 (UU40) for both takaful and insurance companies. The new act of UU40 covers the aspect of corporate governance, market conduct, consumer protection and licensing. The move is expected to reshape Indonesia takaful industry by spurring mergers as companies try to meet capital requirement for their expansion purposes. According to Sivalap, Chucheep and Arunee (2014), the regulator set the minimum capital requirement, the solvency regulation, policyholder protection and foreign ownership restrictions to protect the industry. Therefore, the Indonesia decided that the RBC solvency margin ratio of at least 100% and each takaful operator must form its own protection fund to protect the interest of participants. Additionally, in terms of foreign ownership restriction, the Indonesia's fixed that the foreign shareholders of the entity carrying Takaful activities are limited to 80% at the establishment of the company.

Based on the above discussion, the countries in ASEAN had a rules and regulations that provide by their own regulator to protect the takaful industry. The regulator is responsible for setting usually on a minimum capital requirement, the solvency regulation, policyholder protection and foreign ownership restrictions. This basically will open new opportunities in rapid growth market, especially in Malaysia and Indonesia.

Methodology

This research adopts Yin's (2003) definition of a case study as empirical inquiry that investigates a contemporary phenomenon within its real-life context when the boundaries between phenomenon and context are not clearly evident and in which multiple sources of evidence are used. This definition used to guide through the implementation of the research. Qualitative is chosen for this research since it attempts to get an in-depth opinion from participant. The objective of this research is to identify the takaful rules and regulations for Malaysia and Indonesia and to analyse the similarities and differences of takaful rules and regulations between Malaysia and Indonesia. Hence, single case study has been adopted in this research since it was more appropriate to the nature and context of this research in order to get a holistic view of the phenomenon under research.

This research uses a semi-structured interview process, non-participant observation and document analysis, where the researcher was the key instrument for data collection (Merriam, 2009). The Case Study Protocol and Implementation have been developed to express the nature of the interview and the interview questions as well as elaborate intricately on how the respondents are selected. Furthermore, content analysis has been chosen for data analysis. In content analysis, the researcher examines artifacts of social communication. Typically, these are written documents or transcriptions of recorded verbal communication (Strauss, 1987). Holsti (1969) defined content analysis as any technique for making inferences by systematically and objectively identifying special characteristics of messages. Content analysis is a powerful empirical method for analysing text and as a method that technical communicators can use in the research (Thayer, Evans, McBride, Queen & Spyridakis, 2007). It can also

expose hidden connections among concepts, reveal relationships among ideas that initially seem unconnected, and inform the decision-making processes associated with many communication practices.

The ways that the researchers choose to analyse data should stem from a combination of factors, which include the research questions, the theoretical foundation of the research, and appropriateness of the technique for making sense of the data.

Background Of The Case Study

An ABC is a leading wholesale provider of reinsurance, insurance and other insurance-based forms of risk transfer. Dealing directly and working through brokers, its global client base consists of insurance companies, mid-to-large-sized corporations and public sector clients. Their business from standard products to tailor-made coverage across all lines of business, the ABC leading Takaful operator deploys its capital strength, expertise and innovative power to enable the risk-taking upon which growth and progress depends. The ABC has operations across the globe. Their largest clients, too, have a global presence. Consequently, they are the only reinsurer with a client-centric model, that is with teams built around a client on a global basis. They reorganised office network makes them more competitive and effective, enabling them to focus on their core strengths and provide best-in-class service to their clients.

The company is committed to adhering to all applicable legal and regulatory requirements, the highest professional and ethical standards and its stated corporate values. They recognise that strong compliance provides a significant competitive advantage and is vital to securing sustainable profitable growth. Compliance assists the oversight and management bodies in discharging their respective duties to effectively identify, mitigate and manage compliance risk and encourage ethical behaviour. Ethics, integrity and compliance are integral components of the company culture and its successful performance.

Good corporate governance requires an effective system of mutual checks and balances among the top corporate bodies. The company able to fulfill this through a dual Board structure. The Board of Directors is responsible for oversight and the Executive Committee is responsible for managing operations. Their corporate governance principles and procedures are defined in a series of documents governing the organisation and management of the company. Their Board of Directors annually assesses the Group's corporate governance against recognised best practices. It receives updates on developments affecting corporate governance from selected jurisdictions and considers the relevant studies and surveys on corporate governance such as the Walker Report, a review of corporate governance in the financial services industry in the UK, for its assessment.

Findings

The findings are reported according to two research questions which are (1) What are the takaful rules and regulations for two ASEAN countries (Malaysia and Indonesia)? (2) How the takaful rules and regulations differs between two ASEAN countries (Malaysia and Indonesia)?

5.1 What are the Takaful rules and regulations for two ASEAN countries (Malaysia and Indonesia)?

Two participants involved in the interview were from ABC Company. They worked as a President and Client Manager for the general insurance and the family business. The research indicated that the current general takaful rules and regulations is IFSA 2013 in Malaysia and UU40 in Indonesia. They were further confirmed that the IFSA was on the administrative matters.

Leader X said:

> "We confirmed that the current general takaful rules and regulations is IFSA 2013 in Malaysia and Undang-Undang No 40 in Indonesia."

It was revealed that IFSA was an administrative rules and regulations for takaful operators to set up a business. However, in IFSA there was a special rules and regulations on Shariah compliance comparatively to UU40.

He also postulated that the researchers need to understand the regulatory structure of Malaysia and Indonesia. For example, in Indonesia the highest law is called *Undang-Undang Dasar*, there is only one document for the entire country. The *Undang-Undang Dasar* need to be discussed in the parliament. Based on *Undang-Undang Dasar, it has Peraturan Pemerintah* and its basically law and regulations choose by the president, and only the President can sign the *Peraturan Pemerintah*.

In Indonesia, Otoritas Jasa Keuangan (OJK) is actually Financial Service Authority (FSA) which supervise all the financial services banks and non banking. Whereas in Malaysia, BNM does all the supervisory functions including the monetary function. He also perceived that UU40 was more simple compared to IFSA 2013. The IFSA 2013 was quite thick because all the takaful rules and regulations were stated compiled of banking, takaful and money market. However, UU40 only discuss on the headlines for insurance and takaful and the explanation will be provided in the Peraturan Otoritas Jasa Keuangan (POJK).

Leader Y stated:

> "Even the Undang-Undang No 40, I think, is much thinner than the IFSA 2013."

Furthermore, they also suggested to compare chapter to chapter and also part to part of two acts to see in most areas they will be alike. Based on their perception, it was more appropriate to compare the Takaful Operational Framework (TOF) and Peraturan Otoritas Jasa Keuangan (POJK) rather than compare the IFSA 2013 and UU40. The reason behind was the IFSA 2013 and UU40 were referred to the basic and general policy of the takaful rules and regulations. The TOF and POJK will discuss on the practical part of takaful operation.

Leader X said:

> "So its mean here the perception on the operator's side when involve with issues of globalization and other factors, so we will refer to the TOF and POJK more compare to UU40 and IFSA because is based on the basic rules and very general."

5.2 Research Question 2: How the Takaful rules and regulations differs between two ASEAN countries (Malaysia and Indonesia)?

In order to address the second research question, the researchers designed questions related to differences between the two acts. They suggested to make a comparison with regards to the operational matters because it will find more differences such as the Takaful Operational Framework (TOF) and the Peraturan Otoritas Jasa Keuangan (POJK).

Leader Y stated:

> "I have the same comment with Mr. X because even in Malaysia we have Bank Negara Malaysia (BNM) at the top and we have Risk Based Capital (RBC), so for subsidiary we will have a lot of differences. So, depend on how deep you want to go, they might look at the different standard or guideline. For us, essentially, as a practitioner we do refer a lot to the Takaful Operational Framework (TOF)."

They further confirmed that there were a lot of differences regarding the operational parts of takaful rules and regulations. In Malaysia, the takaful operators were referred to the TOF as their main guidelines for operational framework. It applied same with Indonesian market, where they would follow the operational

parts based on the POJK and also the Surat Edaran Otoritas Jasa Keuangan (SEOJK). These were the immediate law which reflected the current operation of the takaful industry in Indonesia.

> Leader X said:
> "And same also in Indonesia, the practitioner will more on POJK and SEOJK. That's because the impact is an immediate on the operation. In our case also when we discuss on the law we refer to our legal person that keep an eye on the law."

Besides,the standard law for takaful rules and regulations like IFSA 2013 in Malaysia and UU40 in Indonesia, they also have the details of the law such as TOF in Malaysia and also the POJK in Indonesia. At the same time in Malaysia, they had Shariah guidelines in order to control the Shariah governance. In Indonesia, they also have the Dewan Shariah Nasional (DSN) to discuss on the Shariah compliance. Such guidelines also spell out the model and the separation of the fund. There was a difference between the BNM and Bank of Indonesia (BI). BNM would control all the financial institutions' activities in Malaysia. But in Indonesia, the Otoritas Jasa Keungan (OJK) was taken over the function of BI. In terms of similarities, the TOF in Malaysia was equal to POJK in Indonesia.

> Leader Y said:
> "So, in Malaysia, Bank Negara Malaysia is equal in Bank of Indonesia but BNM do all the supervisory functions not only do the monetary function. In Indonesia, they are not supervising banking anymore. Supervision function is taken over by OJK."

Discussion

The findings showed that the current general takaful rules and regulations is IFSA 2013 in Malaysia and UU40 in Indonesia. However, UU40 referring to takaful company and conventional insurance company was more simple and only discuss on the headlines for insurance and takaful because the further explanation of it will be provided in the Peraturan Otoritas Jasa Keuangan (POJK). Whereas, IFSA 2013 totally referred to takaful company covered all the takaful rules and regulations and also compiled of banking, takaful and money market. Inspite of making a comparison with regards to the general rules and regulations and more on administrative matters which referered to IFSA 2013 and UU40, it was suggested to compare the respected operational matters because it will find more differences such as the TOF from Malaysia and the POJK in Indonesia.

Conclusion

Takaful rules and regulations are very critical to ensure a sound takaful operations in ASEAN countries. Regulations could reduce mismanagement, increase the level of solvency and strengthen a company's position in the face of global competition. This is vital to ensure sustainability in takaful businesses. The findings of this research indicated that IFSA (2013) and UU40 are the most referred takaful rules and regulations for Malaysia and Indonesia respectively. Furthermore, IFSA (2013) is a Shariah compliance guidelines for Malaysian financial institutions and UU40 is the takaful and insurance guidelines for Indonesia.

They also further confirmed that there were a lot of differences regarding the operational parts of takaful rules and regulations for both countries such as their main guidelines for operational framework. However, since this is a case study based on a solely leading takaful company located in Malaysia, it is recommended to include more case studies to rectify this finding.

Acknowledgements

We would like to convey special thanks and appreciation to our sponsor, Universiti Sultan Zainal Abidin (UniSZA), Terengganu for providing the financial grant to this research. Our deepest appreciation also goes to the parties who participated in this research.

Computer Information Systems Persistent Struggles for Humanism: An Antithesis. Position and Reflective Paper

Nehemiah Mavetera, North West University, Private Bag X2046, Mmabatho, 2745, South Africa, Nehemiah.mavetera@nwu.ac.za

Abstract

Computerized Information Systems (IS) have successfully been used in organizations to improve the efficiency, speed and accuracy of doing repetitive tasks. However, organizations have added more expectations to their capabilities and now expect them to completely play the roles of humans. This has not been a complete failure, neither has it been a resounding success. This lecture raises some issues that require attention when designing IS if they are to completely replace humans in organizational roles. Besides incorporating the principles of romanticism in the IS design, methods should be found that allow the inscription of consciousness, freewill and interests among a plethora of other issues into the IS artefacts. This paper is grounded more in the philosophical arguments of IS-organizational relations.

Keywords: Information Systems, romanticism, ontology, Humanism

Introduction

Every organization survives by capturing, processing and sharing data and information amongst its workforce. These processes can be enabled manually or automatically. The state of these affairs is regarded as Information Systems (IS). Currently, many organizational systems are being automated, to make processes lean, efficient and effective. This automation has so excited people to the extent that IS, instead of playing an enabling role to humans, are now being touted to replace them in their roles. With this in mind, IS practitioners are currently battling to humanize these artefacts. An example prevalent in these sectors of IS are robotics.

The Information Systems Problem

The software development problem which has been extended to be the IS development problem, was coined a 'crisis' at the first NATO software engineering conference held in Garmish, Germany, 1968 (Randell, n.d.). Despite many reasons being cited as causes for the "crisis" (Baker, 2006; Brooks, 1987; Mullet, 1999) the problem that IS artefacts are not humans has not always been fully understood.

This problem has persisted for generations. Without some concerted effort and some stroke of genius, this may continue into the unforeseen future. We are provoked to ask several questions:

- What is the "IS Problem?'
- What are its origins?
- Why is it a problem?
- What do we do about it?

For a start, the IS problems have been inherited from its origins as a discipline. Information Systems as a discipline was an offshoot of the Computer Science discipline that also had its roots in the computer engineering discipline. As an engineering discipline and strictly bounded by the functionalist philosophical paradigms (Burrell & Morgan, 1979) where objectivity and order reigned supreme, IS developers conceived a 'reality space' where Russell and Wittgenstein had dwelt, grounded in the

thinking of "logical atomism." Logical atomism, according to Bertrand Russell (1872-1970), is the belief that all truths can be deduced from a layer of atomic facts. These atomic facts lie either in simple particles forming a pattern or in multiple simple particles lying in a relation.

With this thinking, the IS development and operational space was viewed to comprise of clearly ordered artefacts that could be arranged and re-arranged to construct different artefacts from the same atomic units as long as their original natural states were preserved. In short, bigger and complex organizational patterns could be built and defined using the simpler (atomic) ones as building blocks.

Essentially, the development of IS fundamentally negated and neglected the presence of people as components to the system. People, IS asserted, bring a certain degree of complexity in organizational IS. There has been limited success in some processes and total failure in others. What then are the issues required in humanizing IS? This paper highlights issues that need to be addressed in the quest of humanizing IS.

Focusing on the objectivity and orderliness of organizational reality, where atomic patterns could be identified, IS developers borrowing from their origins, adopted reductionist principles that were used in the engineering discipline to fashion their products. They argued that IS could be developed sufficiently enough using systematic methods. As Foucault (1987) accepted, "systematizing methods produces reductive social and historical analyses, and that knowledge is perspectival in nature, requiring multiple viewpoints to interpret a heterogeneous reality" such as an organization.

Also, the problem of these reductionist tendencies has seen IS artefacts being guided and controlled by algorithms that are inscribed as programmes. This was intended to ensure IS functionality. Since time immemorial, from its birth as computing machines, to gradual growth in information processing systems, IS as a discipline has grown from just ensuring functionality of systems, optimization of information seeking and storage to information meaning. These attempts looked at a fuller actualization of the humans (Cibangu, 2015). Is this attempt good enough in the 21st century? This paper critiques the grounding principles of IS development and the origins of gaps that still need to be closed for IS to approximate human praxis. An original IS, the level one, consists of people, technology and processes. These resources comprise the social, the natural and the artificial respectively.

As captured in Mavetera (2011), there must be a link between the natural, the social world together with the artificial world of human constructions for an effective mapping of the IS artefact onto the original being of the organizational system. There must be a theory that links these three elements (Gregor, 2006). Practice has shown that all but the social element of the original system are successfully mapped in automated IS. This gap needs to be addressed.

This calls for new ways of critical thinking and looking at the nature of organizations, which dictate the way IS products are to be fashioned in the future. How does one get a characteristically human IS product when the thinking behind its design negates the presence of humans in organizational information systems? What theoretical constructs are being considered and used in building IS products? Do these constructs consider the reality space where organizations dwell? This paper postulates that many theoretical constructs that are currently used in the development of IS artefacts are incapable of mapping them to the organization's life state. Organizations and hence their systems, just like humans, are romantic. As such, a paradox exists where a romantic view of the organizational system is force-mapped onto a mechanistic view of the IS artefact. Organizational life has an infinite number of life states that can be assumed at any one given time. This is because of the presence of humans. We would like to propose also that the IS representation of the organization maps only one life state out of the several possible and available. In its whole, an organizational system has a fluid existence that can be characterized as romantic, unlike the one static mapping of IS products that is mechanistic.

Can humans then entrust the running of their organizations, their lives, their activities to automated IS artefacts? Is there sanity in abrogating our life responsibilities to these artefacts? They aren't human but artefacts is the story that needs to be expounded in this thesis.

"There is a reason why computers have not yet become fervent natural language speakers (It's not a matter of processing power and never will be): we simply are not programming them correctly."

El Baze 2005.

El Baze's (2005) comment points to the fact that although developers can perfectly implement whatever they design, IS products fail because it is the design itself that is grounded on improper assumptions. IS product designs do not take cognizance of the central role played by people in organizational information systems. El Baze (2005) therefore logically laments that "we simply are not programming them correctly." Does this gap emanate from the techniques and tools that are used during the processes of requirements engineering? Is it a logical gap on what should be elicited, specified and later designed?

IS practices have gone so far that practitioners want to "engineer" the human mind, thinking, experiences, emotions, and beliefs. They seek to clone the human mind. This engineering mechanistic world view, based fundamentally on the functionalist paradigm as previously stated, regards the world as ordered, rational and unchanging. Monod (2007) strongly blames IS practitioners' unquestioning and faithful adoption and use of this rationality principle. Why should practitioners believe that the world can be reduced to discrete functional units that can be represented as rules and algorithms? How do we deal with knowledge and information possessed by people, which is mostly tacit and intuitive? IS practitioners therefore ought to adopt development paradigms that reject extreme rationalism and technological determinism. To address this, we must accept a world view that is voluntarist, messy, chaotic and subject to human interpretation. This is the relativistic stance. This also is the humanistic viewpoint required in automated IS.

In this paper, humanism is regarded as the belief in the value, freedom and independence of human beings. Humanism by its nature is fluid and ever-evolving, hence, the evolution that we have seen in humanity must extend and enrich IS design processes. The battle amongst IS professionals is to impart IS products with these humanist qualities. The argument so far suggests that IS design principles are grounded in the objective-ordered pair of the functionalist paradigm. Contrary to this, the lived organizational state lies along the continuum through to the neo-humanist paradigm. This has created a reality paradox.

Issues for Consideration in IS fashioning

The paradox identified above has revealed a major difference between the nature and representation of organizations using automated IS. People, information systems and the environment in which organizations exist can be considered holistically as a social group of actors interacting through networks. As Ngwenyama and Lee (1997) contend, being social involves the alignment of an individual's actions to both the organizational context and the other actors involved in performing a social action. All social interaction is governed by a social culture and this culture has to be observed when implementing organizational IS.

In addition, as complex systems, organizations have requisite variety (Rosenkranz & Holten, 2007:57). Requisite variety views organizational systems as possessing several possible states, in terms of "patterns of behaviour" or "number of manifestations." The intention when implementing IS has always been to holistically capture and maintain these patterns of behaviour (manifestations). However, contrary to this, all IS when designed tend to reduce the complexity of these organizational systems, thereby reducing their requisite variety. This process is regarded as the reductionist principle. Reduction in the possible behavioural states and hence, in the requisite variety of the original system. It is the contention of this

presentation that most information systems fail to provide value to their organisations because of this reduction in requisite variety. The question then remains, how can we have ISs that have as much requisite variety as the original organizational system?

Culture in Organizations

Another aspect that contributes to the requisite variety of organizational systems is culture. Organizational culture comprises the attitudes, experiences, beliefs and values of people in an organization. It also embodies the organisation's interactional behaviour with its stakeholders. All organizations are run within certain cultural and contextual boundaries. How do we, as IS practitioners, allow IS to capture culture? Culture is a very important element in defining organizational context.

Context-building amongst organizational actors is a process of weaving together the different situational understandings of different actors, establishing threads of common understandings and of inter-subjective knowledges within a network (Goldkuhl, 2002; Dilley, 1999). Contrary to what many people think, context is not a static phenomenon and is not a given. It is not self-evident in a situation but requires a constructive machinery to mould the varying situational meanings into a common understanding. Context, therefore, is an object of study that requires some analysis to arrive at an agreed and shared understanding. Furthermore, it is within the shared meaning of some situatedness that the said context resides. Organizational context is ever changing and amorphous.

This dynamism in context poses a big challenge to IS development if one has to capture the running context of an organization. IS practitioners scramble to find methods for identifying, capturing and communicating context? In a bid to address this, Mavetera (2011) proposed an ontology-driven approach and methodology for capturing and incorporating context into IS. To support the fluidness of organizations, another lens that can be used to critique organizations is the Theory of Organized Complexity.

The Theory of Organized Complexity

According to the Theory of Organised Complexity (Checkland, 1999:78), systems in general exhibit a general hierarchy of levels in which each higher level is more complex than the level below it. Each such higher level has emergent properties that are not found at lower levels. The emergent properties are a result of system formation, in which the whole exhibits characteristics that cannot be found in the individual sub-systems that combine to form it. Checkland (1999:78) notes that "neither a one level epistemology nor a one level ontology is possible" to describe the sum total of the subsystems. Hence, in a hierarchy of systems forming the whole, each level has different, distinct epistemological and ontological views. In other words, the views of the lower levels of the system can never be the same as those of the whole system. Put in another way, the behavioural characteristics of subsystems, when added together will generate a system whole that has behavioural characteristics completely different from those of its constituents.

The interaction of its components creates some emergent properties that are a by-product of the interaction and these manifest themselves in the whole as new characteristics. Rightly so, an aggregation of mechanistic components cannot have the same behavioural properties as the whole. The principles of systematicity and system formation that IS practitioners have depended upon to build products fail to preserve the natural that is encompassed in the romantic world view. In this sense, systematicity looks at the extent to which a system can be regarded as an ordered, hierarchical arrangement of components while system formation in turn looks at the ordered, organised building up of the whole system from its components.

With this state of affairs, Aristotle's maxim that the whole is equal to the sum of its constitutive parts is negated. When the whole is broken up, it loses its requisite variety by negating some other possible states. At the same time, when the system is reassembled from the parts, the theory of organized complexity explains the introduction of emergent properties that never existed in the original whole. This now constitutes a paradox, where one cannot holistically get an organizational whole from the products of its deconstruction, that is, the constitutive parts. Another lens that can be used to have organizational diagnosis is human activity system (HAS).

Human Activity Systems (HAS)

Human beings have never been predictable. Their behaviour is always changing. It is very difficult, if not impossible, to consider all contingencies in an a priori prescription of a human action (Suchman, 1987). Rationalization of human actions a priori or a posteriori overlooks much detail that is situated in the running context, such as the detail taken during a course of action in everyday life (Roque et al., 2003).

Furthermore, Roque et al. (2003) urge IS developers to guard against neglecting variability and independence during the development of IS products. They discourage any reliance on procedural and functional descriptions of organizations and individual roles as complete accounts of the social dynamics. This narrative, together with the TOC, argue for a change in our IS practices. The third lens discussed here is the Theory of Organized Activity (TOA)

The Theory of Organized Activity (TOA)

Like the human activity system (HAS), Holt (1997) developed the theory of organized activity (TOA) that is also based on human (organized) activities. An organized activity is a dependent variable of the social interaction of people in a particular setting. We would like to postulate that more often than not, IS technical component attempts to automate these organized activities. Looking at an IS as an activity system, Cordeiro and Filipe (n.d.) view the technical aspect of IS as playing a supporting role to the organizational human activity.

They describe the human action, that is, the action performed by a human actor, as comprising of interests and actors. These interests, together with the actors, are responsible for the actions. While humans can have interests, technical machines cannot have interests and, therefore, cannot be assigned any organizational responsibilities. This results in the technical aspects of IS being unable to perform actions (Cordeiro & Filipe, n.d.).

In short, although technological artefacts may be components of an organized activity, their failure to inscribe and exhibit interests places them at a disadvantage if they are to be assigned any responsibilities for an action. The development of IS product, a technical artefact, should therefore include ways that allow them to be assigned responsibilities. This is the notion of humanizing the technical artefact. This notion is expounded in the rest of this presentation.
The three theories of TOC, HAS and TOA, as discussed herein explain very important characteristics of organizations which should be incorporated into information systems. These three theories can be used as a basis for a conceptual grounding of romantic information systems.

The Principle of Romanticism

Romanticism can be described using Gasche's (1986) notion of anti-systematic thought. This is related to the anti-positivist notion described in Mavetera (2011). Romanticism argues for the negation of

systematicity and system-formation while, at the same time, allowing the concept of "the fragmentary …" (Gasche, 1986).

The paradox that faces IS practitioners emanates from the fact that one cannot tackle IS development project without breaking it up into manageable chunks. On the other hand, the whole cannot be reconstituted from these chunks. A development approach that reduces the gap between these two poles, one that is able to reintroduce the romanticism that existed in the original system in the developed systems, has thus to be found. By assuming the romantic world view, IS developers consider a holistic view and an acceptance of the organizational system, where culture and social context play a part in the execution of tasks. In the eyes of romanticists, "processes and change" are at the forefront of system "contemplation, understanding, interpretation and feeling" (Dahlbom and Mathiassen, 1997:501). In this view, change in organizational systems is taken as "unpredictable and beyond human control, the expression of hidden and unknowable forces" (Hirschheim et al., 1995:3).

The Romantic Systems Movement

Human problem-solving resides in the interpretive and neo-humanist paradigms. IS developers should not concentrate on tractability and objectivity. Such a move effectively distances and isolates the IS artefact from the complexities of everyday social changes. To build a system, the process of requirements engineering has to be followed. It is important to leverage the requirements engineering effort on the reasons why these are needed and gathered than on the specification of what the system must do (Yu, 1997). According to Roque et al. (2003), there is more to requirements than elicitation. Requirements are an everyday social construction, in which human and non-human actors participate. The requirements engineering process forms the basis upon which IS failures and successes can be measured.

While current IS development methodologies force organizational systems to embed their business rules, organizational culture, practice and their human aspect in the technological side of IS, it is necessary to liberate the human aspects of the organization from the bondage of technology by introducing romantic information software products.

What is a Romantic Software Product?

These are IS software products that are at the epicentre as building blocks of romantic information systems. Romantic information systems (RIS) are not only limited to the dictates of syntactic machine representations. They are also based on the romantic world view that considers the "world as a unitary organism" in sharp contrast to the rational and atomistic view of the mechanistic world (Tarnas, 1991:366-7). Mavetera (2011) is the first to coin these systems 'romantic information systems.' Romantic information systems can be viewed as having "gloried in the unbounded multiplicity of realities" (Tarnas, 1991:368) that are realised in organizations as a result of the subjectivity and the divergence in perspectives of the people found in them. Romantic systems accept the notion that "reality is constructed by the mind, not simply perceived by it, and many such constructions are possible [...]"

Furthermore, these systems capture and reflect all the possibilities in organizational life states (intentions) than to concretize a single life state only as a fact. The idea for romanticism in information systems is supported by Hohmann (2007:18), who calls for a "pluralisation of our culture and the humanization of technology." In his vision, he sees a future that demands technologies that stimulate creativity and inspire thoughts, thereby reconciling the "contradictions between technology and art" (p.18) that characterize the modern era. A conceptual framework for romantic information systems is characterised by Mavetera (2011) as one:

"… that allows the development of socially-constructed systems that capture and maintain the softer elements of organizational systems such as culture, social context, and semantics and to a certain extent pragmatics. These systems must be adaptive, dynamic, evolvable and innovative."
The whole romantic world view idea has to bring some intuition, tacit information and meaning into the IS product. This characterization may seem far-fetched, but existing literature like Weber (2003), Hohmann (2007), Yu (1995, 1997), Beynon et al (2008), Soffer et al. (2001), and Mavetera (2011), have already called for a romantic framework mentioned herein and several prototypes have been tested. The romantic IS cannot be conceived if practitioners cannot design IS artefacts that can be inscribed with the romantic characteristics as specified herein. This thesis as proposed in Mavetera (2010, 2011) introduces ontologies as artefacts to fill in this gap.

The theory of IS Ontology? A Brief Description

"Ontology makes knowledge visible and accessible and enables teams to share their knowledge and profit from experience."

Sheryl Torre-Brown (In-PharmaTechnologist.com, 2005)

Ontology is a word that originated from classical philosophy as a branch of metaphysics. It is referred to as the science of being (lower-case 'b') (Ruiz & Hilera, 2006) or as the study of existence (Hacking, 2002). As a study of essence, ontology started as a way of categorizing things and establishing the nature of their existence (Corcho et al., 2006). It also deals with issues such as how people perceive the world and with general issues of the nature of things as opposed to specific theories about particular things. Checkland (1999) holds that it is a concept that deals with the nature of the world or with what it contains. This definition does not look at the individual fragments of existence but at the general. As Hacking (2002:2) argues, ontology constitutes the thought study of "What there is." It should be noted that this term, 'Ontology' written with a capital letter 'O' has an uncountable reading (Guarino, 1998). A typical example is the statement 'Ontology is the study of existence' which, in this context, refers to a specific discipline of study. The philosophical ontology is "neither reducible to, nor identical with language or its formalism" (Zúñiga, 2001:188). However, the language can be used to describe this ontology.
In IS discipline, the term ontology has assumed a countable reading (Mavetera, 2011) allowing researchers and IS practitioners to assign it a linguistic definition that can inscribe romantic characteristics in the IS artefacts. This linguistic model definition is characterized in softer terms as a:
"…model of the world that comprises of syntax, semantics, pragmatics as well as the social context of that which is represented. Despite some unavoidable informal indeterminacy in the real world view, it should allow a shared, descriptive, both structural and behavioural modelling and representation of a real world view by a set of concepts, their relationships and constraints under the open world assumption" (Mavetera, 2011).
This characterization is very important to people who work in the softer fields of IT such as information systems. It is a characterization that allows behavioural and constructivist scientists to develop frameworks that guide the subsequent development of IT artefacts by design scientists. Examples of such ontologies are domain, method, process, intentional, social and status ontologies as explained in Mavetera (2011:144).

Context of IS as a Discipline of Specialization

A specialization can be regarded as the process of concentration on and becoming of an expert to a particular subject area or skill set. In this regard, our field of specialization is information systems (not capitalized) versus Information Systems (capitalized) referring to artefacts. As a discipline, Information systems looks at the essence, the practice, the methodologies, the ethical and legal issues guiding the fashioning and use of IS products by people and for people in organizations. The author has devoted most

of his career to improving the way IS products can enhance the way business is done. Most of this work has focused on the methodologies, the pillars upon which products are developed.

Knowles et al. (2015) advocated for new information system development methodologies that are grounded in "humanistic understanding of space, place, time, language and perception." Computing, sharing and presenting human experience has always been a problem that has confronted computing professionals and the Information Systems discipline. As stated in Knowles et al. (2015), moving away from the mechanistic dictates of current computing platforms to the conceived semantic, pragmatic and humanistic position requires a gradual transition process. This calls upon IS practitioners to be aware of their theoretical positionality and the sociotechnical implications of their methodological choices. In fashioning IS products, it has become necessary to relook at the paradigmatic choices. How can IS products be improved to incorporate human-like behavioral characteristics?

Hohmann (2007) and Beynon et al. (2008) advocated for the development of intuitive systems that are easily understood by humans, at the same time increasing the productivity gains from their use. Beynon et al. (2008) argued further that marrying intuition and software development has been made difficult because researchers and developers use frameworks that are inherited from the computer science discipline. These frameworks concentrate on "stable contexts of experience that can be engineered to exhibit law-like characteristics" (Beynon et al., 2008:4) and they do not allow some degree of freedom in cognition (Tarnas, 1991).

Just like the "biblical archetypes such as Exodus, the Chosen people, and the promised land," which did not stop playing an important role in the cultural imagination of the Christians, (Tarnas, 1991:108) this paper notes that the functionalist archetypes even with new revelations of positivist weaknesses have persisted in IS developers' minds and practices. This is one linking factor, particularly impeding the advancement of the romantic worldview in IS development. This problem has been persistent in the author's efforts to solve IS problems.

Contribution of Research to Body of Knowledge

Information Systems look at the social relations amongst tools, human actors and the social environment in which they co-exist. In 2002, the author published a paper that prescribed a framework for Land Registration Organizations (LRO) of South Africa and Zimbabwe to share their information with practitioners and the citizenry (Mavetera, 2002). This was based on the fact that e-systems were beginning to be pervasive and ubiquitous in the society and business environments. The framework aimed at reducing the costs of data sharing as well as increasing its access and availability to the citizenry. The information needed to be packaged in specific formats that would ensure all users get it in the same format. The research solved the problems of inefficiencies and government systems' bureaucracies. We envisaged a system that would replace these "blood lazy and inefficient" public servants, the humans. The system worked quite well in the laboratory but failed in the operational environment. Of the issues raised, some claimed the system lacked the flexibility of querying and customization to specific individual requirements.

In Mavetera and Kadyamitimba (2003), we attempted to improve the e-systems by introducing software agents, which would assume the role of a human principal to search, choose, collect and customize requirements. This system also hit a snag because, while humans are intuitive and have interests, these agent-mediated systems were not. As developers, we could not prescribe interests to mechanistic and artificial artefacts as software agents. Having noted that system failures are not because of the technologies that are used to design, build and implement them, the focus of our problem then changed.

Between 2000 and 2003, the research focused entirely on the design and development of systems that automated the work processes of information seeking and delivery in the electronic-business era

(Mavetera, 2000; 2002; 2003a & b; Mavetera & Kadyamitimba, 2003). An attempt was made to replace the human principal in these transactions of buying and selling with software agents. The processes, however, relied heavily on the syntactic matching capabilities of technologies that had grown in computing and storage capacity. This left a big gap in the effective and efficient operations of the Information Systems as enablers of business and complementary tools to human efforts.

It must be brought to the attention of the reader that organizational problems during this time now focused on semantic rather than syntactic issues. There was a realization that humans are more about sense-making and decision-making than finding similarities. This time the idea of semantic enabled ISs started developing and being researched. It was noted that information systems, despite their intended role to replace humans, had failed to completely eradicate human beings because humans are "more flexible, adaptable, and creative." Humans are better suited to respond to varying and unexpected situations.

The period 2004-2009 focused on the idea of e-systems that could semantically run business processes. These entailed the use of ontologies (Mavetera, 2004a & b; Shawa et al., 2008 &2009; Mavetera, 2007; Mavetera & Kroeze, 2009). During the period 2010-2013, the studies started graduating from previous studies and focused on enriching IS with human traits. Again the central theme and focus point was ontologies (Kroeze et al, 2010, 2011; Mavetera & Kroeze, 2010; Mavetera, 2011a & b).

The 2014-2017 period saw the research looking at missing human elements in IS that inhibit their capabilities. Consideration of culture in e-learning systems (Chukwuere et al., 2016a & b), e-government systems (Chikerema et al., 2016) are some of the products of these studies. All these researches have been grounded in the discipline of IS development and software engineering. Methodologies and frameworks for fashioning IS products were the central theme. The central theme of developing requirements engineering frameworks that consider the incorporation of tacit knowledge and human traits of intuition, freewill and choice making in the IS products is now the current focus.

Research into the Future

As we have consistently posited, technologists are advocating for the replacement of "human-decision makers and policy makers" with automated systems. These should measure and collect data, and make adjustments automatically to correct discrepancies. The idea is to position the role of technology as replacing humans instead of supporting them. However, as discussed in Robinson (2015) (which we will quote freely), there still exists human capabilities that cannot be replaced by or abrogated to IS artefacts.

Human capabilities that cannot be replaced by computers?

There has been a very long and arduous journey in academic and industrial research that has seen computers moving from simply automating processes to imitating the human capabilities of thinking (artificial intelligence) and decision making. Talking of intelligence, let us define it as the acquisition and application of knowledge and skills. While computers can take decisions based on information gathered, there are three things that computers have failed to do (Robinson, 2015). These are understanding, judgment and empathy. Human decision making and understanding do not rely solely on intelligence but also on experience and values. Human beings, apart from making decisions and being intelligent, are also capable of setting objectives. We can group these traits under understanding.

We can, however, fashion IS artefacts to be capable of acquiring experience. Can this, however, be compared with the ability to make judgments based on values like what humans do? Major questions still arise in human nature. What constitutes decision-making? Is it making choices? As Robinson (2015) questions, where do we find values that are learned through experience? In addition, where is empathy that is derived from shared values and experiences? (ibid.)

The Ghost Finally is in the Machine

For the sake of argument, let us assume that our technology will advance to the extent of being able to make judgments and decisions. Will the technological artefacts be able to possess free will? (ibid). This is an unavoidable capability of humans. Freewill is defined by Robinson (2015) as the "ability to set our own decisions bringing with it the responsibility to deal with their consequences." But our IS artefacts are based on classical physics and logic.

Let us bring this argument closer to home. Check information systems such as e-Natis and Hanis to name but a few that have been implemented by the Republic of South Africa. These are examples of several e-government systems that are being developed and implemented for public service delivery. How successful have they been in replacing the public servant of today? Judging through the lens of syntactic matching, semantic evaluation and pragmatic performance, they might have improved the way business is done. Can they make judgments and decisions too? Do they possess free will?

Rightly so, these systems can use a recorded occurrence to eventually inform the next event. Unfortunately, they do not have capabilities for conscious decision-making. Put simply, while computers can make choices, they cannot make judgments. Judgments are based on values and these values in turn emerge from human experiences of life (Robinson,2015). Hence computers cannot ascribe values because they cannot experience life. As can be deduced from the discussion on TOA, IS artefacts cannot have interests, they cannot be assigned responsibilities and hence cannot perform actions. Future research then has to enrich the IS artefacts with enough capabilities to address these gaps.

Summary and Conclusions

Ours is not a matter of being trapped in a paradigmatic pit and then cry for God to rescue us. IS practitioners are encouraged to move their practices to include other fields such as humanities (Kroeze et al., 2010), and to investigate how IS can espouse the human societal value system. This can not be investigated from the functionalist-positivist lens but an acceptance of the interpretive-and neo-humanist positionality of organizational systems should be cherished.
For now, IS are not humans but artefatcs. Maybe, they are artefacts not humans.

Abstract

This study is a descriptive research examining the relationship between the organization learning capabilities and its impact on the firm's performance. Although it is evident in the literature that organizations that are learning are also high performing organization, the researcher hardly found any empirical study in Pakistani perspective regarding this aspect of relationship between learning organization and its impact on performance. Based on Learning Organization Questionnaire developed by Watkins, K.E. and Marsick, V.J. (2003) scale will be used to measure learning capability of a sample from big five banks namely Habib Bank Limited (HBL), United Bank (UBL), Muslim Commercial Bank (MCB), National Bank of Pakistan (NBP) and Allied Bank Ltd. Financial data is also being obtained from these banks. Methodology we have used is survey method. Result of the study show that there is no relationship between learning capability and Return of Assets, however there is a moderate relationship between learning organization and Return on Equity.

Keywords*:* Learning organization, Return on Assets & Return on Equity.

Introduction

There is an increase interest in the concept of learning organizations; the potential driving force leading to this interest is globalization and the impact of knowledge as the foundation for developing competitive advantage. Managers and consultants as substantiated by the volume of literature dedicated to the topic (Goh & Richards, 1997), they have begun to realize the immense importance to manage their human resource in order to achieve sustainable competitive advantage.

Increasing competition and availability of choices has led to the idea that only those companies can sustain profitability that focus on continuous development and growth, for which, consistent learning is critical. This objective can only be achieved through building a learning organization (Garvin, 1993).

Peter Senge (1992) in his book the Fifth Discipline, sheds light on the characteristics of learning organization such as shared vision, challenging of mental models, team learning, system thinking and experimentation are the key features of learning organizations. Later on Garvin (1993) identifies a set of situations needed to construct a learning organization through a more applied and practical approach. There had been a growing body of literature that has made effort to illustrate organizational situation and management practices that learning organization possess (Goh, 1998; Goh & Richards, 1997).

The literature has implied that learning organization is highly competitive and effective as it has the capacity to experiment with new ideas making the organization innovative and creates new knowledge and then transfers the acquired knowledge to solve critical problems successfully (Mills & Freisen, 1992; Leonard-Barton, 1992). Though has been very few or rare empirical research rather than few in depth researches that attempts to associate organizational learning to performance effect that are implied

(Simonin, 1997). There has been very modest effort made to develop metrics and measures on this subject as a result there is no large scale empirical study. Recently, Goh & Richard (1997) made attempt to capture organizational situations and management practices through scale that can help in describing the characteristics of learning organization. Organizations that score high can be described to posses' strong learning capacity as specified by the subsistence of a set of organizational situations and management practices that encourages and assist organizational learning.

Purpose of Study

The aim of this research was to link organizational learning capability by measuring through survey the performance of big five banks of Pakistan. Before we further explain the research, the conceptual underpinning hypotheses about this research are:

Literature Review

There has been a confusion on the existing literature on learning organization, distinctions are made amid "the learning organization" and "organizational learning", among "practioners approach" and "academic approach" (Schon & Argyris, 1998), among "capability" and "normative" perspective (Dibella, 1995) and amid "organizational "and " individual" learning (Weick, 1991). This healthy debate generates an impression that the thought is not clearly understood neither it is practical in application.

This research captures a normative perspective on the learning organization concept. The researcher does not argue from learning perspective that organization and individuals behave like, however the researcher argues that organizational learning is associated with the actions and experiences of organizational members. Cook & Yanow (1993, p.375) defines organizational learning as" the studying of concrete structural and procedural arrangements during which actions of organizational members are understood to necessitate learning are pursued by observable changes in the activities pattern of the organization".

Mechanics of learning organization develop the basis to understand the concept of learning organization, with the purpose to understand its structure, procedures, policies and strategies that facilitate the member and organization to learn (Lipshitz & Popper, 1998). Therefore, we can view learning organization as those organizations that rationally adopt strategies and structure to persuade learning (Dodgson, 1993). These procedural arrangements and evident institutionalized structures or organizational systems illustrate the learning organization concept. It can be synthesizing that when organization adopts these procedures and structures have greater capability to learn.

To facilitate learning, an approach is required to identify those organizational mechanisms. So as to, what kind of procedures and management practices are associated to be learning organization? What structures support learning? These Procedures and structures can facilitate in defining the learning capacity of an organization.

To respond to these question, researcher conducted this study to test the measurement tool developed by Goh & Ryan (2002) to evaluate the learning capacity of the big five banks of Pakistan and to analyze, does group and individual learning be relevant to the achievement of organizations vision and performance goal and does internal conditions and management practices hinder or help this progression (Garvin, 1993; Mills and Friesen, 1992). The study conducted by Goh & Ryan (2002) assessed and identified a set of management practices and internal conditions that lead to assess the organization's learning capacity. The researcher will use the same model to assess the banks learning capacity.

Different orientations have been developed by the literature on learning organization as to how it can be built. DeBella (1995) recognized the normative perspective of learning organizations and illustrate this approach of orientation by stating that learning is an outcome of a collective activity that takes place

under certain circumstances or conditions and organizations need to identify the essential condition to permit and foster learning to take place.

To create learning organization, deliberate intervention is necessary to establish by leaders and essential internal condition for the banks to function in a learning mode. There has been an implicit supposition that there is an organization prototype that identifies a successful learning organization, which impacts the survival, long term performance and effectiveness of the organization. According to Garvin (1993), he states that to be competitive organizations need to vigorously manage learning progression to ensure that it happens by design rather than by chance. Distinct policies and managerial practices are accountable for the success of the organization as they structure the building blocks of learning organization.

Therefore, the researcher will test those conditions that are identified by Goh & Ryan (2002) to facilitate organizational learning or conditions and managerial practices that help an organization to become a learning organization. The supposition is that organizational learning does take place, but there are certain conditions and appropriate managerial practices are required for effective learning (Von Glinow, Ulrich & Jick, 1993).

Learning Organization Strategic Building Blocks

By examining the commonalities amid diverse explanation found in extensive literature review, the model anticipated by Watkins and Marsick (1993), which represent the action strategies, is presented below.

1**. Creating ongoing learning opportunities**

Today's organizations are more complex than yesterday's; earlier organizations were more like automated machines but the present organizations are more dynamic with continuous learning environment. The complete work environment is focused towards experimentation, continuous learning, and supportive environment.

2. **Promote Dialogue and Inquiry**

In the organization, information needs to be transparent, focused, clear and fast. Communication should be cross functional and within the sub-unit boundaries of the organization. The information spread and acquired needs to adhere with the organizational opportunities and problems; this has also been cited by most of the writers, specially the capability of the organization to transfer and impart knowledge across departments and to transmit knowledge from the stakeholders (Garvin, 1993; Shaw and Perkins, 1991).

3. **Encouraging Teamwork Dynamics**

In today's competitive world individuals work needs to be designed around work teams in order to accomplish organizational goals. Organizational systems and structures needs to foster problem solving culture and encourage teamwork in order to reduce dependency on top management and the teams should possess the expertise to work cross-functionally. Knowledge can be transferred and shared when employees work in teams and gets better understanding of individuals, their work, need and also enhanced information of how work takes place in different parts of the organization (Senge 1990, 1992).

4. **Institute Systems to confine and shared learning**

Problems and issues faced by organizations always present opportunities for experimentation. Organizational justice concept needs to be practiced by the organization, the climate should be as such

that fairness and transparency exist in rewarding employees, compensation system should be solely based on performance rather than attendance and seniority. Rewards should be designed in the parameters of risk taking and innovation, behavior that challenge status quo needs to be appreciated. This managerial practice is most consistently observed in the learning organizations. Innovative work processes and freedom to pursue novel work methods are supported and encouraged in the organization (McGill, Slocum and Lei, 1993; Garvin, 1993; Senge, 1990).

5. **Empowering People on the road of collective vision**

There has to be a clearly articulated purpose for each unit and for organization as a whole. There is a need for employees to understand the purpose of the organization and how their work contributes to the attainment of the organization mission. The organization needs to have individual and organizational goal integration in order to facilitate employees' commitment to the purpose and mission of the organizational. According to other researchers and Senge (1992) states that organizations should build a "shared vision" for the desired future as ambiguity in it creates tensions as individuals are not able to see the big clear picture of organizational existence. Individuals while working in the organization understands and know the gap between the current state and the desired state of the organization that hinders in the attainment of the vision and can strive to design activities that fulfill the organization vision (Mohrman and Morhman Jr., 1995).

6. **Connecting the organization to its environment**

Learning organizations are continuously interacting with its environment and recognize its reliance on its environment; they examine the environment and use the information received to regulate work performance. There is a healthy relationship between learning organization and the social, cultural and physical environment
(Watkins and Marsick, 1993).

7. **Offering Strategic Leadership for Learning**

Leaders in the organization needs to create a culture of egalitarianism and trust, they should be approachable, committed to the organizational goals and to the goals of learning. The organizational climate by the leader should be such that mistakes are treated as learning experiences and failures are treated as an integral part of the learning process. Specifically, the leaders have the responsibility to help the employees recognizing performance gaps and help employees to set goals that encourages the thirst of knowledge to solve and narrow these performance gaps.

Virtually all writes have mentioned leadership as a significant element to foster learning climate by open criticism, having tolerance for employee expression, being in quest of feedback, empowering employees, admitting mistakes, risk taking and helping employees make decisions (McGill, Slocum and Lei, 1993; Garvin, 1993).

The survey measured these above mentioned seven strategic building blocks on the big five banks of Pakistan.

Hypothesis Testing

Ho: There is no significant relationship between Learning Organization and Return on Assets (ROA).
H1: There is a significant relationship between Learning Organization and Return on Assets (ROA).

H0: There is no significant relationship between Learning organization and Return on Equity (ROE)
H2: There is a significant relationship between Learning organization and Return on Equity (ROE)

Methodology

Sample

The participants of the study I have chosen is about 50 respondents in number, who are senior human resource managers from the big five banks namely Habib Bank Limited (HBL), United Bank Limited (UBL), Muslim Commercial bank (MCB), National Bank of Pakistan (NBP) and Allied Bank of Pakistan.

Measures

Learning Capability is being measured using survey on learning organization that measures the five strategic building blocks of the learning organization, like Clarity of Purpose and Mission, Leadership Commitment and Empowerment, Experimentation and Rewards, Transfer of Knowledge and teamwork and group solving. The overall reliability of this scale was .93 (Cronbach's alpha).

For ***financial performance*** of the big five listed banks, data is being taken from Karachi Stock Exchange (KSE), Return on Assets (ROA) and Return on Equity(ROE) for a period of five years will be obtained through Compustat Database. These values will be averaged for the five time periods 2010, 2011, 2012, 2013 and 2014.The research was analyzed using SPSS.

Results

Table 1: Descriptive Statistics

	Mean	**Std. Dev**	**Total**
DLOQ	85.80	20.708	50
ROA	3.2740	2.77092	50
ROE	17.93	9.384	50

The findings suggest that there is no correlation found amid the big five learning organization and ROA. Examining the literature and research findings, it was found that there are certain factors that criticize the concept of learning organization. Finger and Wollis (1994) argues that learning organizations cannot take benefit from a learning organization without exploiting individuals working in an organization in favor of the organization. The emphasis according to him is organizational learning and not individual learning. The complexity of new knowledge and already exiting knowledge is also subject to organization politics and environment. In such environment it is extremely difficult to develop organizational loyalty before individual zeal for self-profitability.

Table 2: A Correlation between Dimensions of Learning Organization and Return on Assets

		ROA
DLOQ	Pearson Correlation	.032
	Sig. (2-tailed)	.826
	N	50

**. Correlation is significant at the 0.01 level (2-tailed).

Table 2 shows moderate correlation between Learning Organization and Return on Assets.

The second finding of the study shows moderate relationship between learning organization and Return on Assets (ROA), the possible reason could be the behavioral aspect, when shareholders actively participate in the functioning of the organization and want to improve their organization ROA, they lay emphasis in channeling the energy of their workers in the right direction by providing a clearly articulated purpose of the organization existence and make sure that the mission is clearly communicated and understood by the employees (Goh& Ryan,2002), shareholders understand the importance of motivated workers assuming that they possess the ability to identify gap between current state and desired state and when employees see the commitment of shareholders they stop cutting corners(Mohrman and Morhman Jr.,1995).

Table 3: A Correlation between Dimensions of Learning Organization and Return on Equity

		ROE
DLOQ	Pearson Correlation	.497**
	Sig. (2-tailed)	.000
	N	50

**. Correlation is significant at the 0.01 level (2-tailed).

Cronbach's Alpha	N of Items
.934	21

Table 4 depicts high reliability analysis i.e. .934 (Cronbach alpha) of the Dimension of Learning Questionnaire (DLOQ)

Discussion

According to Tsang (1997), learning organization is a structure of supreme organization that possesses the competence to flourish and to learn effectively. Progressively more literature and management research have focused on the advent of a "knowledge-based economy" (Drucker, 1993) and on the "learning organization" (Watkins and Marsick, 1993). Learning organizations all over the world are encouraged as in today's competitive world the business dynamics have changed. Initially organizations would be able to sustain their comparative advantage for multiple years. Technology, easy excess to information and globalization are some key elements which hinders organizations in maintaining their competitive position in the industry for a longer period. Due to globalization, investors also have diversified opportunities for investment. To attract investors, organizations need to achieve positive performance indicators. The organizations need to increase their profit to attract investors and solutions provided by several researchers for this problem is to create a learning organization.

The first findings suggest that there is no correlation found amid the big five learning organization and ROA. The complexity of new knowledge and already exiting knowledge is also subject to organization politics and environment. In such environment it is extremely difficult to develop organizational loyalty before individual zeal for self-profitability.

The individuals working in an organization continuously try to understand what is needed of them and how they can survive in the competitive internal environment of the organization. Dixon (1993), noted that organizations don't learn, people learn but at times individual learning is not being converted into organizational learning. From an individual's perspective, organizational job is only one sphere of their life. The other aspects of life might have different goals and objectives. Marsick and Watkins (1990) declared that individual learning does not lead to organizational learning and thus does not have an impact on organizational performance and profitability. The learning scores which are being assessed in the research can be individual learning score and does not reflect the organizational learning score.

According to Marsick and Watkins (1993) productivity is directly related to innovation. Thus only those individuals contribute to the organizations who are innovators. Paquette (1995) noted that most of the individuals hired by organizations are not innovators and do not have the capacity to learn continuously. Many empirical researches draw attention on the diminishing need of innovative individuals due to advancement in technology (Swardson, 1992). Also innovation increases cost which can reduce profitability in short run. Also many researches prove that not all innovations are profitable. The literature on learning organization promotes two types of facts: innovative and problem-solving or "detecting error" (Argyris, 1993). The problem-solving direction considers learning as persistently seeking liberty from obscurity (Prawat, 1993).

When the organization emphasizes to solve problem and product novelty, the learning is limited to technical knowledge (Habermans, 1984). At times the organizations lay more emphasizes on innovation leading to future present while letting go of current profitability. Also if organization emphasizes more on error detection then current profitability might increase but will cause future profitability to shrink. The individuals in an organization are often faced with dilemma of what to learn and where to concentrate. The organizations with high learning scores and lower profitability might be investing more on future profitability and neglecting present profits as opportunity cost. The need to continuously prove themselves as well as sow their loyalty to the organization might provide biased learning scores. Presence of learning organization and low profitability can also be due to political and economic condition of the country. High borrowing rate and cost of production can also be the reason of depressed profitability. Presence of learning organization and low profitability can also be due to political and economic condition of the country. High borrowing rate and cost of production can also be the reason of depressed ROA.

The second finding of the study shows moderate relationship between learning organization and Return on Assets (ROA), the possible reason could be the behavioral aspect, when shareholders actively participate in the functioning of the organization and want to improve their organization ROA, they lay emphasis in channeling the energy of their workers in the right direction by providing a clearly articulated purpose of the organization existence and make sure that the mission is clearly communicated and understood by the employees(Goh& Ryan,2002),shareholders understand the importance of motivated workers assuming that they possess the ability to identify gap between current state and desired state and when employees see the commitment of shareholders they stop cutting corners(Mohrman and Morhman Jr.,1995).

The shareholders do investment in the organization to promote culture that encourages egalitarianism and trust, team work and develop problem solving abilities in order to reduce the dependency on upper management. Teams are develop to work cross-functionally as in today's complex world it is difficult to accomplish organizational objectives individually (Senge, 1992; Garvin, 1993).The culture of the organization that has sustained due to the values and clear and focused communication of the owners, information shared is also cross functional, there is freedom provided to the workers to experiment with new ideas, encouragement and support is provided to the individuals who challenge the status quo (Slocum and Lei, 1993).

Conclusion

To conclude, the research finding revealed that there is no significant impact of learning organization on Returns obtained. The organizations with high learning scores did not have higher ROA. The findings are in precedence to the empirical evidences of the past. The individual learning does not ensure organizational learning. Also organization is not an absolute and stable structure. The individual constituting the framework is constantly changing, creating a shift in the organization. The individual learning is also often in conflict with organization's learning. Also accurate measurement of learning is complex due to critical self-reflection on individuals.

The findings of the study also revealed that when owners take interest in their organization and want to improve the ROE of their companies, the thirst drives them to build a culture which is the forerunner of learning organization and their commitment towards their company flourish.

The research only focused on the big five banks of Pakistan. In future, sample should be taken of different companies from all the sectors so that comparisons can be made within the industry to rule out factors which are pertaining exclusive to that sector. Also private sector should be included to note if the causal relationship has different effect on larger and smaller organizations. For future study it is recommended to view the relationship between learning organization and market capitalization.

Fig1 Conceptual framework of Dimension of Learning Questionnaire

***Source*:** Marvin Elie Mbassana, 2014**.**

Dimensions of the Learning Organization Questionnaire

The questionnaire below is the short version of the DLOQ, based on the above model. In this questionnaire, you are asked to think about how your organization supports and uses learning at an individual, team, and organizational lev From this data, you and your organization will be able to identify the strengths you can continue to build on and the areas of greatest strategic leverage for development toward becoming a learning organization.

Please respond to each of the following items. For each item, determine the degree to which this is something that i is not true of your organization. If the item refers to a practice that rarely or never occurs, score it a one (1). If it is almost always true of your department or work group, score the item as six (6). Fill in your response by marking the appropriate number.

No.		Rarely or Never (1 Almost Always (6				
1	In my organization, people help each other learn					
2	In my organization people are given tme to support learning					
3	In my orgamization, people are rewarded for learning					
4	In my organization, people give open and honest feedback to each other					
5	In my organization, whenever people state their view, they also ask what others think					
6	In my organization, people spend time building trust with each other					
7	In my organization, teams/groups have the freedom to adapt their goals as needed					
8	In my organization, teams/groups revise their thinking as a result of group discussions or information collected					
9	In my organization, teams/groups are confident that the organization will act on their recommendations					
10	My organization creates systems to measure gaps between current and expected performance					
11	My organization makes its lessons learned available to all employees					
12	My organization measures the results of the time and resources spent on training					
13	My organization recognizes people for taking initiative					
14	My organization gives people control over the resources they need to accomplish their work					
15	My organization supports employees who take calculated risks					
16	My organization encourages people to think from a global perspective					
17	My organization works together with the outside community to meet mutual needs					
18	My organization encourages people to get answers from across the organization when solving problems					
19	In my organization, leaders mentor and coach those they lead					
20	In my organization, leaders continually look for opportunities to learn					
21	In my organization, leaders ensure that the					

A Review of the Importance on the Need of Micro Medical and Health Takaful

Abstract

The overall aim of this paper is to discuss health care expenses incurred and borne by the government as well as the citizens. The development of Medical and Health Insurance (MHI) / Medical and Health Takaful (MHT) in Malaysia has also been reviewed accordingly in this study. Moreover, the issues and challenges raised in regard to the implementation of Health Takaful in Malaysia has been thoroughly assessed by focusing on low to moderate level individuals, specifically the hard-core poor, poor and low (B40), and moderate-income earners (M40). Therefore, the aims of the paper is to present the views of scholars on the importance of micro medical and health Takaful in daily life and to recommend framework of micro medical and health Takaful for poor people in Malaysia.

Keywords: Micro Medical and Health Takaful, Poor People.

Introduction

Malaysian Health Care Expenditure has been observed to rapidly increase on the average of 12-13% per year, with the assumption that it could exceed a total of RM20 billion by the year 2025. Previously in 2015, the government had allocated a higher budget amounting to RM23.3 billion for the purpose of providing free or almost free hospitals and clinics services to the Malaysian population. However, despite the huge allocations provided for healthcare purposes, those hospitals and clinics still having a few difficulties to accommodate and fulfil the needs of the population due to the lack number of personnel as well as medicines and supplies, which further leads the residents which include the poor to seek treatment from a health centre.

Meanwhile, in the year 2014, a high number of admissions and outpatient attendances represented by the amount of 86,237,051 patients managed to be recorded in 141 government hospitals, whereas only a total of 5,083,596 patients were found in the record of 214 private hospitals. Hence, this further indicates that most individuals are not able to afford the services provided by private hospitals due to the high cost of payment needed for personal which will cause more burden. One of the possible alternatives to overcome this problem is to buy health insurance; however, the existing health insurance is considered very expensive especially for the poor individuals in Malaysia. As a result, they will not even consider taking any health insurance scheme that can further prevent any future hospital costs. Therefore, it is deemed crucial to develop an affordable medical and health Takaful framework for the poor in order to provide them with a prompt access to medical and health services.

Literature Review

In spite of the efforts made to further understand medical and health care in society, the established studies have shown that an estimated total of 1.3 billion individuals worldwide do not have access to an affordable and effective health care. Meanwhile, more than 150 million individuals in 44 million households around the world are faced with the issue of direct financial helps every year. Other than that, recent evidence of the literature are mostly concerned with the need to validate the market penetration of medical and health insurance. According to Naseem Aliza (2012), only 11.9% to 15.7% of the whole Malaysian population have health insurance despite the high direct medical bills (Hima Gupta, 2007). Therefore, the issues that need to be addressed in this study include the number of people with health insurance as well as the reliability of medical and health insurance in providing adequate protection. It is very crucial for this scheme to be well designed and affordable. Furthermore, this scheme needs proper underwriting and effective controls, including the cost and procedure of claims that are burden free.

The importance of health care has led the underdeveloped and developing countries to introduce various insurance programs to the mass population, especially to those in the informal sector in order to achieve better accessibility of health care as well as financial protection. A few examples include the social health insurance in Africa, the National Health Insurance Fund in Tanzania, the law of national health insurance in Ghana, the New Rural Cooperative Medical Scheme (NRCMS) in China, and National Hospital Insurance Fund of State in Kenya (World Bank).

In light of this issue, India has also implemented micro insurance schemes that are mostly comprehensive by the International Labour Office which tend to put a major focus on the poor in the rural areas (ILO, 2005). In Malaysia, health care insurance offered before 1997 acted as a rider to a life insurance policy. However, life insurance companies were allowed to sell insurance policies and health care alone (stand-alone) after the upgrade of policy under the Insurance Act 1996. Hence, this further indicates that policyholder is allowed to purchase insurance and health care without buying a life insurance policy.

Generally, health insurance coverage are mainly categorized into two main groups which are the protection of health expenses and disability income protection (Treischmann et al., 2001). On top of that, it should be known that some of this coverage named as medical and health insurance are run by an insurance company. In this case, the insured is required to pay the premium to enable them to get protection on surgical and medical treatment as well as overcoming the loss of income due to accident or illness. Furthermore, it is important to note that the premium for this type of protection is expensive compared to other risk protection scheme, which is found to be extremely burdening especially for the low-income earners. Therefore, most of the poor families in developing countries such as Malaysia are left with no choice due to their inability to afford health insurance scheme despite their full awareness regarding the importance of preventing higher hospital costs (International Conference on Social Health Insurance in Developing Countries, 2005).

On top of that, it is believed that health insurance schemes in the health care will be able to produce healthy citizens among the low-income individuals. This is hoped to enroot to the aim of turning Malaysia into a developed nation by 2020, which indirectly contribute to the implementation of government's programme which tend to focus on the hard-core poor, poor and low (B40), and moderate income earners (M40). Apart from that, it is also very challenging to reduce the community's dependence on the government for healthcare purposes. Therefore, a method should be developed in helping the government to deal with this issue by allowing the interested stakeholders to partake in the contribution fee as part of their corporate social responsibilities initiatives.

3. Historical Background of Medical and Health Insurance (Mhi) / Medical and Health Takaful (Mht) In Malaysia

Similar to the function of conventional insurance in providing protection against disasters, Takaful serves as an alternative to insurance as a result of some insurance activities that are not in line with the Islamic Law (Htay, Sadzali, & Amin, 2015). The purpose of medical and health insurance/takaful is to cover the cost of private medical treatment which include the cost of hospitalisation and healthcare, provided that the insured are diagnosed with certain illnesses or involved in an accident. In this case, the cover could be on a stand-alone basis or as a supplementary contract to a basic plan (“Insuranceinfo,” n.d.).

In 1999, the Central Bank of Malaysia managed to identify MHI/MHT business as an emerging trend as well as an important sector for the future of insurance and takaful industry based on the facts that ageing population seem to require higher medical costs. In this case, the number of Malaysians aged 55 and above are expected to increase due to the increase of mortality rate for both males and females which are respectively recorded as 70 and 75 to 75 and 79 by the year 2020. Other than that, owing to the breakdown of extended family structure as well as caring family values expected and advocated by the government; hence, the old-aged parents may change in the near future. Therefore, it is highly recommended that healthcare insurance should be turned into one of the employment’s benefit to ensure employees’ loyalty and retention as well as for the purpose of personal income tax exemption (Abdul Rahman & Mohd Daud, 2010). In 1970s, the major industry players of MHI in Malaysia were foreign-based insurers such as American International Assurance, AETNA, and Prudential.

The above scenarios have resulted in a major change in 1999 with the establishment of the first national health insurance scheme known as SIHAT Malaysia. This scheme has attracted the subscription of several local insurance companies. SIHAT Malaysia is a new hospital and surgical insurance policy that incorporates a range of hospitalization plans which are able to cater to a wide segment of society (Abdul Rahman & Mohd Daud, 2010). Meanwhile, the Central Bank of Malaysia stated that the report on data collection and performance on MHT only started in 2003 which is the result of four Takaful operators being granted the licences to operate.

In Malaysia, there are Takaful operators and insurance companies that offer MHT/MHI. Apart from the hospitalisation and surgical insurance, dread disease or critical illness insurance is also considered as one of the main concerns of modern living healthcare. Generally, there are 36 critical illnesses covered by the insurance companies and Takaful operators. Table 1 below shows the most popular medical health insurance scheme offered by Takaful operators and insurance companies in Malaysia.The medical and health Takaful schemes provide a cheaper package amounting RM1,200 per year with a life time limit of RM650,000 based on the comparison between Takaful operators and insurance companies. On the other hand, an extremely expensive one-year premium payment provided by the insurance company is not affordable for the poor people despite the fact that lifetime coverage. However, the Takaful health insurance scheme of RM1,200 per year provided by TOA cannot be afforded by those with low income. This is evidenced by the market penetration for MHI and MHT recorded as 11.9% to 15.7% respectively of the population that possess health insurance (Naseem Aliza, 2012). Therefore, the micro medical and health scheme for the poor in Takaful Malaysia should be well developed.

Table 1: Comparison Table of the Medical Health Insurance Coverage

Takaful Operators /Insurance Companies	**Takaful Operators (TO)**		**Insurance Companies (IC)**					
	TOA	**TOB**	**ICA**	**ICB**	**ICC**	**ICD**	**ICE**	**ICF**
Annual premium (RM)	1,200	1,800	3,920	3,000	3,400	3,600	5,100	1,462

Issues and Challenges of Health Scheme in Malaysia

The National Key Results Areas (NKRAs) under the GTP have been identified to ensure the development of socio-economic growth of Malaysians. Hence, health care has been turned into one of the main priorities of this developing country based on the concern that the lives of most Malaysians are at low to moderate level. Specifically, the low to moderate level individuals are represented in terms of hard-core poor, poor and low (B40), and moderate-income earners (M40). According to the Economic Report 2015/2016, group B40 is described as those households with the monthly income of up to RM3,855,

while the M40 (40% medium income group) are those who earn between RM3,860 and RM8,319 monthly.

Meanwhile, the Eleventh Malaysia Plan (11MP) recorded that 60% of B40 and M40 are those who come from a level lower than the middle class, which further indicates that the government must give serious and critical attention to help improving socio-economic growth. Therefore, access to health care has become the number one priority, in which the government has taken an action to increase the average health spending to 12-13% per year. The high budget provided by the Ministry of Health for health services is different each year with the allocation of RM19.3 billion in 2012, RM22.1 billion in 2014, and RM23.3 billion in 2015. Meanwhile, the Ministry of Health has established a program known as Malaysian Healthcare Travel Council (HTC) to further promote Malaysia as a world-class healthcare service provider. In light of this, the government's determination is without doubt have been for the purpose of developing health care services that are easily accessible with doctor to patient ratio of 1 : 6332 at 355 hospitals (141 governments & 214 privates), 7,832 clinics with doctors (1,031 public & 6,801 private), and 2,075 community clinics run by paramedics (Community Clinics & 1Malaysia Clinics) (MOH, 2015). According to the report provided by Ministry of Health (MoH) in 2015, the number of admissions to hospitals and special medical institutions were 2,465,727 60,478 and 60,478, respectively. On top of that, higher outpatients attendances were found at hospitals with a total of 20,260,479 patients, followed by a total of 311,952 out-patients at special medical institutions, and 38,311,223 out-patients recorded at public health facilities (Ministry of Health, 2016). The percentage of total MoH allocation in the 2016 National Budget was only 8.62% which is equivalent to RM23,031,066,400, with the breakdown for operation and development amounting to RM21,430,802,000 and RM1,600,264,400, respectively. The facilities provided at the government hospitals are limited to only 134 hospitals and nine special medical institutions, which also minimizes the services that should be made available to the public. Hence, this indicates the inadequate amount of accessible healthcare services needed in the effort of coping with the total population that is almost approaching a total of 30 million. In the year 2015, Ministry of Health recorded a total of only 5,083,596 patients for both the admission and outpatient attendances at 214 private hospitals. These figures definitely reflect that most individuals are highly dependent on government hospitals due to the affordable and almost free treatment and services provided in comparison to private hospitals. Therefore, this may be the major reason that interferes with the development of health insurance in ensuring that effective health care is affordable for the majority of population.

The Importance of Micro Medical and Health Takaful

Micro medical and health Takaful scheme provides financial mechanisms for protecting and promoting good health by ensuring middle and low-income patients to have access to healthcare. In the absence of a micro medical and health Takaful scheme, many patients within this economic group are forced to rely on public hospitals. The shortcomings of public hospitals are twofold, namely long waiting period and low quality care (Zweifel 2005). The availability of the micro medical and health Takaful scheme will be able to promote early disease prevention and treatment before the disease becomes severe. Furthermore, the Takaful scheme can also provide benefits to both individuals and the whole community. The assurance of a proper healthcare will enable a family to be both productive and healthy.

In addition, the micro medical and health Takaful also proved to reduce poverty (Hamid, Roberts and Mosley, 2011) by preventing medical impoverishment among the rural population, whereby the poverty was reduced by 8.3-13.1% (Yip W, Hsiao, 2009) and higher storage. The poverty reductions were the results of risk management strategies, namely asset sales, reduced household savings, reducing consumption patterns and home loans. Apart from that, community participation in the scheme can also reduce the net health spendings, lower unofficial loans for medical costs, and increase in non-food

consumptions. Micro medical and health Insurance also changed the perspectives ofin the use of health, health seeking behavior or healthcare access (Habib, Perveen and Khuwaja, 2016). As a result, the overall country's economy will grow with a healthy society.

Conclusion and Recommendation

Developing countries such as Malaysia are composed of three classes of individuals, namely the rich, middle, and poor. It is without doubt that healthcare is very important to everyone; however, the priority of each group varies accordingly. In most cases, those individuals who expect better health care service without minding the high cost of treatment tend to choose the best and expensive insurance plan, whereas those who can only afford low-cost treatment will pick a plan that is cheaper.

Health insurance schemes are normally provided by the governments to its citizens, especially to those that come from low and middle-income populations. The formation of Micro Takaful Medical and Health Scheme is expected to assist policy makers to demonstrate their seriousness in terms of improving the welfare of the poor and those in informal sectors. Apart from that, it is also hoped to help those who are forced to spend their money on the out-of-pocket health expenses. Therefore, further studies need to be carried out in reducing the community's dependence on the government with the involvement of the interested stakeholders on the contribution fee as part of their corporate social responsibilities initiatives.

Preliminary Research Concerning the Fisheries Sector Potential of the Republic of Moldova

Mihaela Munteanu (Pila),
"Dunărea de Jos" University of Galati, Romania, mihaela_pila@yahoo.com

Silvius Stanciu,
"Dunărea de Jos" University of Galati, Romania, sstanciu@ugal.ro

Abstract

The paper aims at presenting and analyzing the natural water resources of the Republic of Moldova from the perspective of recovery for fishy production. As regards its total surface area, the Republic of Moldova has a significant natural fishy potential. Rivers, lakes and other wetlands cover 95,000 ha, or 2.8% of the country. Only 7.5% of the natural aquaculture potential is harnessed in the fishy area, with five autochthonous fish farms operating on the national territory. The vast majority of the fisheries operate extensively, based on pond culture in polyculture system. Although the national territory has significant natural resources, their exploitation is ineffective, the national food market depending on the imports of fishery products. A number of fish species from the natural environment are endangered, measures to protect them being necessary. At national level it is necessary to apply methods of Government support that encourage private initiative in the development of the fishing sector, mainly in the direction of an intensive exploitation by means of aquaculture. The access to European space pre-accession funds may represent a solution to revive the Moldovan fishy sector.

Keywords: aquacultural potential**,** strategies, fish farming, aquaculture, the Republic of Moldova.

Introduction

The Republic of Moldova is a small country located in South-Eastern Europe. The total surface area of the Republic is 33.846 km^2. In the North, East and South, it is bordered by Ukraine, and in the West by Romania. Compared to the relatively small surface area, the Moldavian territory is rich in water resources, such as ponds, rivers and lakes. The Moldovan waters are part of the Black Sea basin. The main rivers are the Dniester and Prut, which spring from the Carpathian Mountains and discharge into the Black Sea. At the South, on a small portion, the Danube represents the border between the Republic and Romania and Ukraine. There are more than 4,600 lakes in the Republic of Moldova, populated by various species of fish, of which the catfish, carp, bream, silver carp, bighead carp, grass carp and zander are of economic importance. Since fish stocks in the natural environment are limited, the aquaculture development, the understanding of aspects of reproductive biology of the different indigenous species of fish and their implementation in improvement and protection programs for the natural fish population are very important. Improvement programs must be adapted and applied depending on the species, resistance and environmental conditions, to allow an increase in fish performance. The increase in the share of aquaculture products represents a solution for the development of domestic consumption and for the reduction of the dependence of the national fish market on imports. The paper proposes an analysis of the existing data in the specialized literature, having as main objective the identification of viable strategies for the development of the Moldovan fishery sector. The increase in domestic fishery production, with the better exploitation of the potential natural habitats of the Republic of Moldova, could lead to the reduction of the dependence of the national market on imports and the revival of the consumption of domestic fish.

Short Literature Review

Data relating to the fishy potential of the Republic, the state of the environment, the existence and the use of the natural aquatic resources between 2009 and 2015 are presented in the statistical compilation „Natural Resources and Environment in the Republic of Moldova", drawn up by a team within the National Statistics Bureau, coordinated by Valcov (2016). The paper has been drawn up based on the reports submitted by the Moldovan economic operators to the national statistics, the reports containing information specific to the Ministry of the Environment and the National Agency for Land Relations and Cadastre. The monograph does not include information on the Transnistria area, a Moldovan territory located on the left side of Dniester River and Bender. The research of four indigenous breeds of crap provides useful information for the development of the national fishy sector, describing the resistance of these varieties at different infectious diseases, ways to increase productivity, the ability of the indigenous carp breeds to adapt to low water temperatures and to feed actively in different temperature ranges.

The Report of the Food and Agriculture Organization of the United Nations FAO (2017) on aquaculture in the Republic of Moldova carries out an analysis of the sector in the period 1990-2016. Until 1990, the use of intensive technologies of fish production allowed production to reach approximately 10.000 tons per year. The transition to a market economy and the difficulties arising in the organizational structure of the Moldovan food sector have led to the sharp decrease in the aquaculture production, reaching 1,042 tons in 1994. The 1994-2002 period has led to a slight increase in the quantities of fish caught, based on the production of the former State fish farms that have reached 1,643 tons in 2002, the fish produced largely coming from ponds. The estimates provided by the Moldovan fish farmers are, however, incomplete, data only covering approx. 50% of the national territory.

Bulat et al (2016), presents results of the study on the fish fauna from the Stanca Costesti Prut accumulation lake performed in 2013-2014 by a mixed team of the Zoology Institute of the Academy of the Republic of Moldova and the „Alexandru Ioan Cuza" University of Iasi, Romania. 1726 specimens from 29 different species of fish were analyzed, specific to the water basin in question. The study revealed the important fishy potential of the specified basin, the need for the involvement of the authorities of the two countries to improve the management of fish stocks and for better use and preservation of the natural biological potential.

An analysis of the use of the natural potential of the ponds in the central area of the Republic of Moldova for aquaculture in polyculture system was carried out by Lobchenko, Vedrasco and Billard (2002). The authors of the research obtained interesting results, highlighting the possibility of association in lakes of the increase in paddlefish (*Polyodon spathula*) with different species of sturgeon (*Acipenser baeri,* density 4300 ind./ha and paddlefish, density of 8300 ind./ha). Survival rates were 59% for Polyodon, at an average productivity of 432 kg/ha, and 77% for the *Acipenser baeri*to sturgeons, at a productivity of 174 kg/ha.

Rodríguez (2009), during a visit meant to monitor the management measures for the protected areas in the Republic of Moldova, presents the status of the indigenous flora and fauna, indicating the existence of 82 autochthonous fish species. In most of the aquatic basins, the number of commercially important fish species has declined (*Huso, Anguilla, Acipenser guldenstadi etc.).* At the time of the visit, the inspector specified that the status and evolution of the natural resources are not fully evaluated, being necessary to develop simple and robust monitoring systems and to implement them on a large scale.

Usatâi (2004) performs a study on the diversity of fish fauna in the catchment area of the Prut river. Research mainly focused on the lower Prut and the small rivers confluence areas, demonstrating the emergence of 37 species and subspecies of fish. Three species of fish (orfe, chop, little chop) are protected by law and are listed in the Red Book of the Republic of Moldova. Comparative analysis of fish species diversity in the water bodies assessed showed a great diversity in the middle and lower Prut. Ichthyologic studies conducted in the Prut river basin led to the identification of 44 fish species and subspecies belonging to 10 families.

Curcubet, Domanciuc and Timciuc (2016), in their work „Aquaculture of Moldova: Developments and Potential" perform an analysis of the aquaculture sector in Moldova, determining the status and prospective directions of development, the historical milestones in the development and the implications of the specialized education on sector development, the potential and the aquaculture development opportunity. Data on fish consumption in Moldova reflect the increased consumer demand, showing the methods for fish product cost reduction.

Materials and Methods

Information on aquacultural resources with fishy potential, namely the arranged fisheries and the production of the main fish product categories was collected from the FAO website. Information relating to the external trade of the Republic of Moldova in fishery products was obtained from the official statistics, presented by the National Commission for Statistics. The collected data were arranged, processed statistically and presented graphically. The results obtained were compared with other data from the literature, for a proper interpretation.

Issues on the Aquacultural Potential of the Republic Of Moldova

Climatic conditions in the Republic of Moldova are moderate-continental, the climate of the Republic being characterized by a mild, short winter and a hot, long summer with low rainfall. Therefore, the climatic conditions allow the widespread practice in the Republic of Moldova of the polyculture of carp and phytophagic fish, with the restocking of one of the predator fish species: zander, pike or European catfish, for the rational use of the biological production potential. Polyculture practice aims in particular at breeding carp, phytophagic species and some species of predators such as pike, zander, catfish. A major constraint for fish production increase is the difficulty of obtaining a good stock of biological material for breeding and pond spawn populating. According to Curcubet, Domanciuc and Timciuc (2016), the Moldovan fishy sector is one of the most developed areas of the national agriculture sector due to the economic activities carried out by specialized fisheries and individual fish farms. The freshwater native fish and the products offered come mostly from fish farming production and only 0.3% - 1.7% from the catches taken in natural water basins.

Rivers with fishy potential in the Republic of Moldova

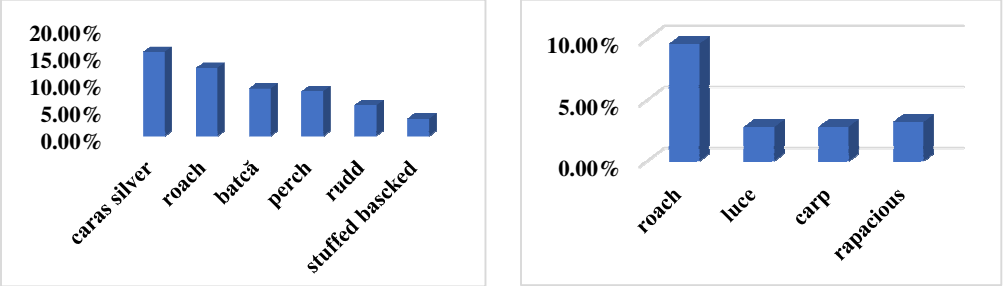
The main rivers with fishy potential in the Republic of Moldova are the Dniester, Prut, Raut, Bic and Botnar. The total length, water catchment areas and their share in the national territory are shown in Table 1.

Table 1: Rivers with fishy potential in the Republic of Moldova

Name of the water course	Total length (km)	Length on the Moldovan territory (km)	Total area of the water basin (km^2)	Water basin area in the country (km^2)
Dniester	1352	657	72100	19070
Prut	976	695	27500	7990
Raut	286	286	7760	7760
Bic	155	155	2150	2150
Botna	152	152	1540	1540

Source: Processing of the data from the National Statistics Bureau (2016)

Brief Overview of the Rivers In Terms Of Fishy Importance



The large rivers, the Dniester and the Prut River, play an important role in the life of the population of the Republic of Moldova, but smaller rivers, such as Raut, Bic and Botna, should not be neglected, due to their significant application in industry, aquaculture, agriculture and transport. Systematic

pollution with untreated wastewater from sectors that are harmful to fish, such as agriculture, zooculture, irrigation and household sector, led to a considerable reduction in the populations of economic valuable species, such as asp, carp, zander, little beluga, pike. The depletion of swamps for the passage of land in the agricultural field had negative effects on fish species, with the destruction of aquacultural areas important for valuable reproduction and development of the spawn. The development of accumulation basins, although beneficial in energy terms, affected the development of migratory species, such as the sturgeons, herring or Black Sea shad, which could no longer reach in the traditional reproduction places. Along with these factors, poaching and irrational fishing, in some causes hard to control in the waters representing the border areas, were other causes leading to the reduced fish population in the running waters.

The Dniester River

According to the data presented by the Directorate of Environmental Quality Monitoring (2017), the Dniester River originates in the Eastern Carpathians, in Ukraine, and flows through the homonymous harbor in the Black Sea. The upper sector of the Dniester River is located on the territory of Ukraine. Within the limits of the Republic of Moldova, the river encompasses the sector from Naslavcea to Palanca, where the border of the Republic of Moldova meets again that of the Ukraine. In the middle sector, it runs through narrow and deep valleys, with a width of 1.5-3 km and strongly inclined mountains. Downstream the town of Camenca, the meadow is flooded by the waters of Dubasari accumulation lake. A special role in the formation of the riverbed is played by the emersion of the hard rocks, which contribute to the formation of steep inclinations and crossover, most notably Cosauti (Soroca region), where crystalline rocks are visible in the riverbed. The main tributaries are the left ones (Camenca, Raut, Bic). The tributaries of the river may affect the regime of the river waters only in the spring, when the snow melts. The data provided by the National Statistics Bureau of the Republic of Moldova show that about 140 fish species were identified in the Dniester River in the middle sector (from the dam of the Novodnistrovsk accumulation lake to the dam of Dubasari accumulation lake) and the lower sector (from the dam of Dubasari accumulation lake to the sea). Ichthyologic investigations of the Dniester river are long-lasting, real fishy diversity being much larger than the known one, and without such knowledge the protection of aquatic resources may not be effective. Dniester continues to be the main source of electricity, irrigation, fish farming and leisure in the region.

As regards the economic importance, the Dniester river is considered a fishy basin of higher category, including more than 100 fish species that may be of interest to catch fishing: acipenserids (beluga, sterlet, sturgeon, starry sturgeon), cyprinids (carp, bream, barbel, little beluga), clupeids (mackerel), percids (zander, Zingel streber, Lynette), other species (trout, pike, catfish). In catchments, the most dominant species are presented in figure 1.

a) Small species (54.20% of total) b) Big species (18.4% of total)

Figure 1: Ichtyofauna of the lower course of Dniester River.
Source: Author, using data from Usatai, Saptefrati and Toderas, 10 noiembrie (2015).

The native fish fauna of the Dniester river has seen a significant decline of some fish species. Almost 50% of the fish species have never been found again or are found rarely (see figure). Thus, according to national statistics, about 9% of the species are endangered (EN), over 11% are vulnerable (VU)

and more than 20% of the species are rare (R) being encountered sporadically in the river waters. The increased attention paid to endangered fish species from the river has led to their inclusion in the Red Books concerning affected fish species from Ukraine and the Republic of Moldova, respectively in the list of the International Union for Conservation of Nature.

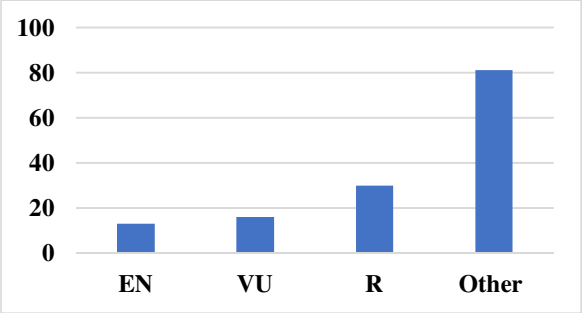


Figure 2: Fish species in the Dniester River
Source: Author, by using Usatâi et al. data (2015),

All endangered species require additional research and investigation and should mandatorily be included in the official documents relating to protection.

The Prut River flows into the Danube near Reni, in the east of the city of Galati and thus forms the border of Romania with the Republic of Moldova and partly with Ukraine. The Prut is the second river in length and importance, where approximately 44 fish species develops. The fish species are represented mainly by fish without economic value like the ablet (*Alburnus alburnus),* spined loach (*Cobitis taenia*), eel (*Misgurnus fossilis*), bitterling (*Rhodeus amarus*), bream, bleak, Black Sea shad, silver carp, asp, barbel, carp, pike, grass carp, balon's ruffe. The drainage regime is permanent. With the accession of the Danube waters, the Prut flows flooding the vast area of its meadow, which is partially swamped. This sector of the Prut river meadow represents a wonderful paradise of nature where a very rich aquatic animal world lives (fish, birds). In 2008, the cross-border project „A Living Legacy, the Prut" was drafted, performed by AquaTerra Ecologic Company in partnership with the Euribiont Public Association of the Republic of Moldova. The action was supported financially by the European Union and the Romanian Government. The project involved the research of various fish communities from the Prut river. The experts from the two organizations of the Republic of Moldova and Romania, together with the Water Quality Laboratory within the Directorate of Prut-Birlad Waters captured about 28 fish species through reversible electronarcosis. The fish were identified, measured and registered. The fish fauna of the river was thus identified, the species caught including also some species protected at European level.

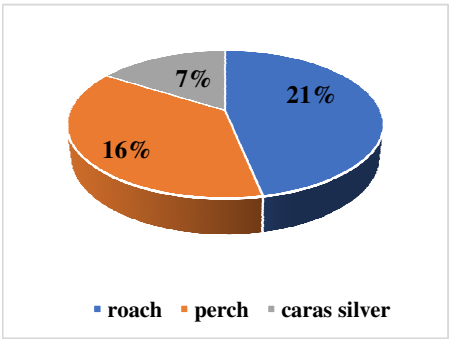
The Raut River it is the third largest river, with a length of 286 km. It is the only river that flows entirely in the Republic of Moldova and is the largest tributary of the Dniester river located in the central part of the country. Raut River ichtyofauna currently is represented by less valuable species in economic terms (69%), zingel, whitebait, bleak, spined loach, sculpin and low-value species (21%), silver carp, roach, perch, rudd, only 10% representing high economic value fish: zander, bream. About 7% are species coming from other stews.

The Bic River is a right tributary of the Dniester river. The capital of the Republic of Moldova, Kishinev, lies on the bank of Bic river. It has a length of 155 km. Ichtyofauna of the Bic river includes 28 fish species and subspecies grouped in 7 families (Cyprinids, Percids, Gobiids, Esocids, Gasterosteids, Signotids).

The Botna River originates near the village of Stejareni. It is 152 km long and flows into the Dniester river. Currently, 22 fish species of economic interest can be found in the Botna river basin: pike, bream, carp, bighead carp, zander, and with low economic value: bitterling, goby, frog fish, spined loach, silver carp.

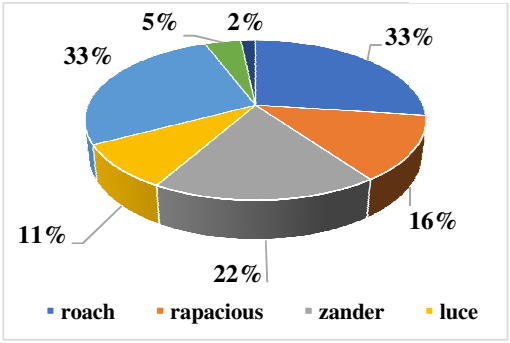
The total surface area of the water basins used for fish farming in the country is 20,507 ha. The main lakes with fishy potential in the Republic of Moldova are presented in Table 2.

Table 2 : Main artificial lakes in the Republic of Moldova



Lake name	Location (district)	Area (km^2)	Industrial fishy potential
Dubasari	Dubasari	67.5	Yes
Costesti – Stanca	Rascani	59.0	Yes
Cuciurgan	Slobozia	27.3	Yes
Taraclia	Taraclia	15.1	Yes
Ghidighici	Straseni	60.8	No – Tourist area

Source: Processing of the data from the National Statistics Bureau (2017)



Brief Overview of the Natural and Artificial Lakes In Terms Of Fish Importance

Most natural lakes are located in the valleys of the Prut and Dniester rivers. **The Dubasari Lake** is the largest in the Republic of Moldova, having a length of 125 km and a surface area of 6,750 ha. The lake has a variety of fish species, namely, on Dubasari dam segment (the lower course of the Dniester river) in the town of Vadul-lui-Voda, there are favorable conditions for natural reproduction and increase in the number of species. In order to develop the ichthyofauna, the Fishery Service, subordinated to the Ministry of the Environment, initiated the restocking with juvenile fish such as crap, grass carp, zinger, silver carp, with more than 39,400 kg of fish.

Dubasari accumulation lake ichtyofauna includes small species (Figure 3a) and big species (Figure 3 b).

a) Small species (43.8 % of total species)

b) Big species (26.9% of total species)

Figure 3: Dubasari lake ichtyofauna.
Source: Author, using data from Usatai et al. data (2015)

The Costesti-Stinca accumulation lake is located on the middle course of the Prut river. Scientific researches were made during 2004-2014 on Costesti-Stinca lake and about 27 fish species and subspecies were found (*Cyprinids, Percids, Silurids, Acipenserids, Esocids*).

The Cuciurgan Lake is located in the lower basin of the Dniester river, in the Southeast part of the Republic of Moldova. The lake is populated with about 30 fish species, such as carp, silver carp, zander, phytophage, bream, roach, two species of perch, pike).
The Ghidighici accumulation lake is the fourth largest lake is size after the Dubasari, Costesti-Stanca and Cuciurgan accumulation lakes, with a length of about 8.5 km. It is used as a tourist area in the city of Kishinev, with low fishy importance.

Most of the accumulation lakes built on the territory of the country are private properties today and are used as fish farms or tourist areas.

The Aquaculture of the Republic Of Moldova

According to the Government data from the official statistics, aquaculture production has reached in the year 2002 a value of 2,258 tons. Of this amount, the share of large fish farming enterprises was 1,643 tons and the share of the fish breeders was 615 tons. Government database includes both information concerning fish farming ponds and the production of natural ponds used in aquaculture. By comparison, FAO statistic data only include information on the production of the fish farming ponds. Figure 4 shows the evolution of the aquaculture production in the Republic of Moldova, according to the FAO statistics:

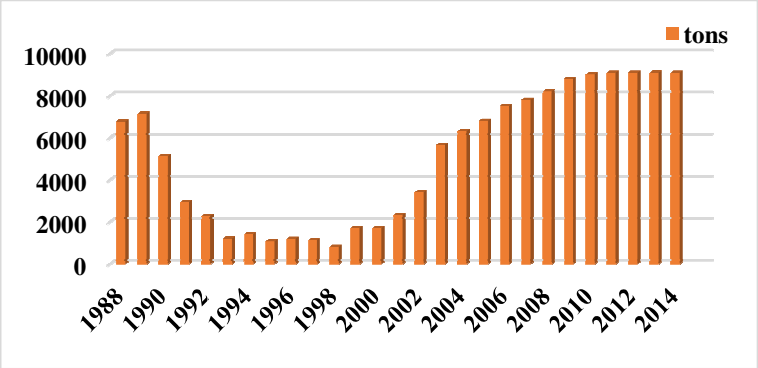


Figure 4: Total aquaculture production in the Republic of Moldova
Source: Author, using FAO Data (2017).

According to FAO statistics, fish production in 1990 was 7,141 tons, and, after 1992, there is a decline in fish production to about 2,935 tons. A slight comeback is noticeable in 2003, when production grew visibly to 3,408 tons. FAO data for 2015 announce a value of 9,080 tons for fish production in the country.

Currently, the Republic of Moldova is in a process of reorganization of the scientific and research institutes, including those dealing with aquaculture issues. In 2002, 139 farms were registered in the Republic of Moldova. In the 2003-2004 period, together with the Agency for Agricultural Consulting, more than 600 farmers were involved in the establishment and development of the capabilities for a more prosperous result. Forecasts show that, until 2010, production in these ponds will reach approximately 5,000 tons, and most of it will be consumed by the inhabitants of rural areas. Since there are 1,549 villages and settlements in the Republic of Moldova, and each rural settlement can provide over 2 tons of farmed fish per year, fish production growth may lead to a corresponding increase in fish consumption. The National Statistics Bureau (NSB) provides financial data related to economic activities for fishing and aquaculture, i.e. revenue accounts by economic activities in thousands MDL. Figure 5 shows the values recorded for the 2008-2013 period.

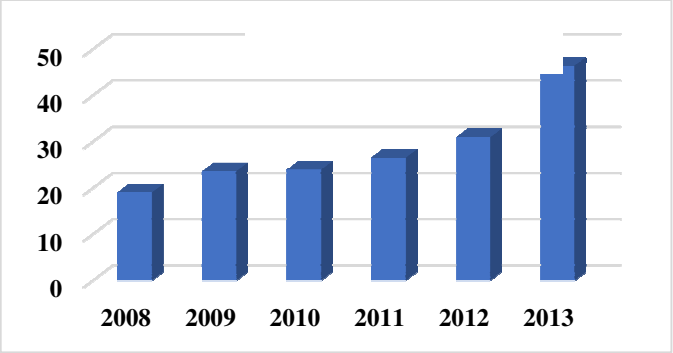

Figure 5: National accounts for fish farming and aquaculture (Mill. MDL)
Source: Author, using data from the National Statistics Bureau (2015)

Fishery products market in the Republic of Moldova

Trade balance of fishery products official transactions of the Republic of Moldova is represented in Figure 5. Data were collected from the official statistics, fishery products marketed illegally not being shown.

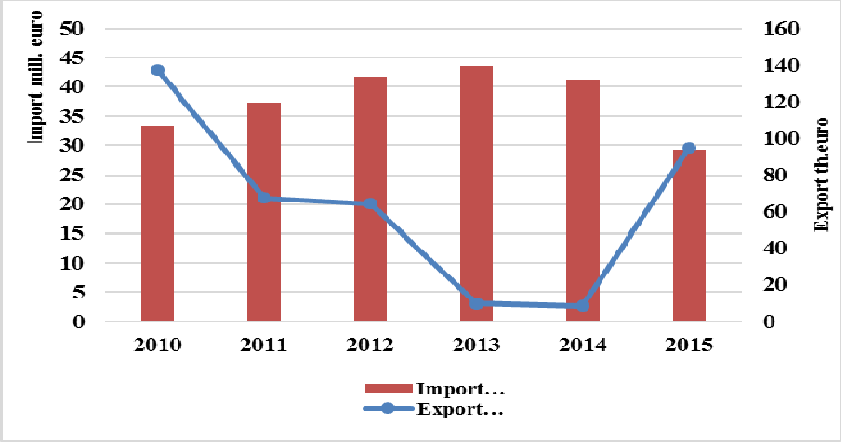

Figure 5: Fishery products trade in the Republic of Moldova
(Import Mill. of USD –Export Thousands of USD)
Source: Author, using National Statistics Bureau Data (2017)

The biological rate of fish consumption per capita is 20.0 kg/year, de facto fish consumption in Moldova represents 11.9 kg/year, of which approximately 3.0 kg of indigenous production, a fact that points to the need to increase fish consumption at least 1,5-2,0 times.

Economic operators in fishy field in the Republic of Moldova

As a business model in the fishy field in the Republic of Moldova, the following types of economic units are included:
• 1 state enterprise, consisting of a scientific and a production enterprise;
• 18 companies limited by shares (former state culture enterprises);
• 56 small to medium sized fish farms, which are included in the Fish Association.
• more than 100 small farms using ponds owned by them.
These enterprises carry out selection, reproduction and growth of fish and material storage for both their own farms and the farms of others.
A few words about the State enterprise and the most important companies/farms (5-6 altogether)

Development of research in the fishy field

There are only a few institutions for fishing and aquaculture in the Republic of Moldova:
• The Kishinev Branch of the State Enterprise for Research and Production Aquaculture of Water Bio-Resources –Moldova, of Bucharest, which is the successor of the Experimental Biological Station for Fishing (1945-1990) and the Scientific Research Station (1990-2007);
• The Zoology Institute of the Academy of Sciences of Moldova;
• The Fishery Association, which is subordinated to the Ministry of Agriculture and Food Industry;
• The Fishing Service, which is subordinated to the Ministry of the Environment;
• The Society of Hunters and Fishermen in the Republic of Moldova;
• Aquatir.

Governmental bodies involved in fishy activity

The Fishery Service in the Republic of Moldova makes an annual plan of action, achieving some objectives to reduce the negative impacts of human activity on the environment, in order to ensure fauna supervision.
- Organization and carrying out of supervision measures, as well as unannounced checks of enterprises that operate in the natural water fishing basins.
- Supervision, monitoring and survey of the works of deepening and cleaning of riverbeds from sand, gravel and various waste which would affect living flora and fauna in the Republic of Moldova.
- Organization and carrying out of actions together with the Department of Border Police in order to prevent poaching and illegal unregulated fishing.
- Monitoring water intakes, so that water from the natural pools may not be captured for other purposes: industrial, agricultural.

Programs / national or European funds allocated to the fishery sector

To access EU funds, there are restrictions at national level for foreign investors, legal entities or individuals that are not citizens of the Republic. Thus, they are required to be registered in the Republic of Moldova and to hold ownership of agricultural land. In many cases, to develop fish farms, it is necessary to build water tanks, hydro-technical installations or channels on private land, issues that hinder investment. In order to develop the private sector, the Government of the Republic of Moldova mobilizes funds from its partners and from foreign partners. Entrepreneurs benefiting from various grants, subsidies, credit schemes, are able to develop their business, to increase significantly the quality and the ability to export local products, thus becoming more competitive by creating new jobs. Various regional projects have been implemented at the national level within the PNUD company, in which small grants have been provided, which have been taken into account the physical-geographical particularities of the country, the Northern region having a hillier relief highlighted by the presence of lakes, small rivers and other geographic basins. By comparison, the Southern region is relatively poor in such natural resources. Small grant scheme has been developed in accordance with SGP – GEF. In 1994, GEF has invested 21,72 million dollars in the Republic of Moldova. In the Evaluation Report of the Country Portfolio 1994-2009, GED has fully supported the Small Grants Program in the Republic of Moldova. External development partners for the Republic of Moldova are BERD, the World Bank, Austria, Switzerland, Norway, Turkey, the main donor being EU.

Conclusions

The Republic of Moldova has a considerable potential represented by 95,000 ha of water surface. There are more than 2,500 km in rivers. There are over 4,600 lakes in the Republic of Moldova, naturally populated with a variety of freshwater fish species (catfish, crucian carp, carp, bighead carp, silver carp, zander, pike). The trend to diversify production by introducing new species of fish in the culture, thus increasing the consumption of indigenous fishery products. Nearly half of the fish species in the natural environment have no economic importance, and, of those with economic

importance, a large part is endangered. The existence of a high number of endangered species requires broad-based measures at national level to protect vulnerable fish species.

The European Union and FAO provide support to the Republic of Moldova in the development of this branch in relation to access to information and statistics, support with breeding material, developed by management programs, and the adaptation of various species to optimal quality conditions, with the recommendation of an environment compatible with the neighboring countries, respectively European. Local farmers must have patience, ambition and courage in acquiring non-refundable funds to support sustainable development of the fishing area.

The Production of Medicinal and Aromatic Plants – A Niche Business for the Romanian Agriculture

Tiberiu Iancu

Banat University of Agricultural Sciences and Veterinary Medicine, Timisoara, Romania,
iancutiberiu10@gmail.com

Silvius Stanciu

„Dunărea de Jos" University of Galati, Romania,
sstanciu@ugal.ro

Abstract

The current paper proposes an analysis of the Romanian production and trade sector for medicinal and aromatic plants. Romania possessesa rich natural potential, represented by over 800 plant specieswith medicinal potential, of which 283 with obvious therapeutic properties. Compared to other European states, the Romanian legislation in the field of medicinal plant based food supplements is not adequate for the progress registered by producers, since it must be adapted and correlated with the European regulations. The lack of efficient supportive measures by local authorities during 1990-2017 lead to the loss of an important competitive advantage on the international market in the field.The Romanian traditional knowledge and use of the medical potential of medicinal plants pertaining to the national flora positions our country on the 15th level in the world, outranking many European states. Production in the field is concentrated in a few counties, which occupy front positions when it comes to cultivated surfaces and medicinal and aromatic plant quantities harvested. The National Program for Rural Development2014-2020 offersimportant financing and business development opportunities to local farmers, in this niche segmentof agricultural production, obtaining important benefits for the Romanian economy, but governmental measures are necessary to promote and support Romanian agriculturistsin accessing European funds.

Keywords: medicinal and aromatic plants, agriculture, trade, Romania

Introduction

The purpose of the article is to analyse the Romanian market for the medicinal and aromatic plants as a potential niche for Romanian Farmers.

Romania's natural potential for producing and cultivating medicinal and aromatic plants is generous – of the 3.700 total of plant species growing in our country, the medicinal flora is represented by 800 species, of which 283 with proven therapeutic properties.

Medicinal plants have been used sinceancient times and are the basis of conventional medicine produced today.Considering the proven fact, that synthetized medicine can be harmful to the human body, triggering allergic reactions, addiction, intoxicationsandother unknown side effects, during the last years, a steady return to natural treatments was observed, especially to phytotherapy and other traditional treatment practices which thus came into the focus of current medical preoccupations.

If, during the 1980-90s, Romania was situated among the first five states in Europa regarding export and among the main seven regarding processing, during 1990-2007,the sector activity was reduced significantly, obtaining an annual production of2-3 tonnes. There ceased to be a correlation between agricultural and industrial activities regarding the product, and with the lack of great medicinal and aromatic plant consumers, the agricultural surfaces allotted to their cultivation diminished. Other causes for reducing the sector activity were the lack of local certified seed sources, the dissolution of Agricultural Research Stations or the important financial difficulties they encounter, the restriction of germplasm sources and growing costs for maintaining medicinal plant collections(Morărescu, 2015).
During 1990-2007,in Romania,the cultivation and processing activity for medicinal and aromatic plants did not represent a priority for the national agricultural policies, the development of this sector being mainly due to private entrepreneurs.Although medicinal and aromatic plant production and trade represents a relatively reduced segment of the Romanian agricultural activity, there are few data on national and local level in the field, the unofficial turn-over of this sector being estimated at circa 800-900 millionEuro.The demand is increasing, on the internal as well as international market. Although it encounters heavy competition from import products, mainly from the Asian area, the production of medicinal and aromatic plants can represent an opportunity for local agricultural farmers, to gain important benefits, considering the high efficiency of these crops while using small agricultural surfaces, and moderate initial investments.The cultivation of medicinal and aromatic plants, their processing and production of teas, cosmetics, pharmaceutics, and various food supplements became an interesting business for the Romanian business environment in recent years, a fact proven by the high number of natural product shops opened all over the country. The production and trade of medicinal plant cultivatedin thespontaneous flora has become a large economic activity, becoming an income source for producers, merchants and processors (Morărescu, 2015).

The population opts for natural products because of tradition, some acknowledged phytotherapy benefits, or advantages due to facile accessibility, with rare adverse effects, the lack of addiction, the use of natural products, perfectly assimilable which allow the association with other therapies and diets, attractive prices, compared to conventional pharmaceutical products. Today, a growing consumer segment resorts to natural treatments or various plant products for affection treatment, leading to a significant increase on international level and to opening new markets for Romanian producers. Medicinal plant cultivation may constitute an opportunity for the internal agriculture, since it requires modest funds and agricultural surfaces. What is more, a slight orientation towards ecologic production may be another advantage for the Romanian sector.

Relevant European and national legislation

Plant based traditional medicines have been officially recognized in the official European legislative framework for medicine starting with 2004, when the Directive regarding plant based traditional medicine came into force (2004/24/CE), which became part of the general European legislation foreseen in the Directive 2001/83/CE (Steinhoff, 2016). AtEuropean level, medicinal and aromatic plants and their productscan be used by consumers as medicine or food supplements, depending on use and legal situation. In order to facilitate the registration of certain plant based traditional medicines at European level, the Decision 2008/911/CE of the Commissionfromthe 21st of November 2008 established a list of plant based substances, productsandtheir mixturesto use in plant based traditional medicine,based on the scientific certification of theHerbal Medicinal Products Committee (HMPC). Applicantsmust prove beforehand the quality of the medicine they wish to register. Thus, according to the basic European directive in the pharmaceutical field, as medicine, phytosanitary products require approval in order to access the market. Documentation is required regarding the quality, safety and efficacy of plant based products, as well as the technical report of specialty experts. Phytosanitary medicine certification follows the general procedure established by the European Medicines Agency (EMA) for medicine.

Steinhoff (2005), states that European quality requirements for plant based medicine include quality criteria for raw materials (in accordance with the EuropeanPharmacopoeia, Good Agricultural and Collection Practices (GACP), Good Manufacturing Practices (GMP)and testing for potential contamination (microbiological purity, heavy metals, aflatoxins, pesticides). Regarding safety and efficacy evaluation, as a principle, pharmacological and toxicological examinations are required for all medicines, and efficacy has to be proven through clinical studies. For well-known active ingredient productsand a well-established medical use, the Directive 2001/83/CE foresees an option for the so-called "reference research".In the phytotherapeutic field, the European Scientific Cooperative on Phytotherapy (ESCOP), founded in 1989,constitutes theEuropean association for the national herbal medicine or phytotherapy associations across Europe, especially in their discussions with European medicines regulators (ESCOP, 2017). Romania, through the National Inter-Professional Organization of Associations in the Field of Medicinal and Aromatic Plants, is a member of ESCOP, alongside organisations in the fieldfromAustria, France, Germany, Hungary, Italy, Netherlands, Poland, Portugal, Spain, Switzerland, Turkey, and the United Kingdom.

ESCOP offersscientific studiesregarding the therapeutic use of medicinal plants, based on the most recent proofs and European top expertise.One of ESCOP's essential objectivesis the establishment of harmonized criteria for the evaluation of plant medicine. During the last period, sixty propositions were published regarding monographies about medicinal plant and their use, taking relevant scientific literature into consideration. The Herbal Medicine Products Working Party (HMPWP) proposed common criteria for the evaluation of plant medicine quality, safety and efficacy on European level and elaborated data bases, especially focused on the monography evaluation published by ESCOP.

According toSteinhoff, a new directive regarding the medicine used traditionally may lead to the change of the current legal framework, offeringmember states the option to establish their own registration system for traditionally used products, of sufficient quality and without proven prejudice.

In Romania, the general framework regarding the production, processingandmarket organizationfor medicinal and aromatic plants, the relationsbetween producers, processorsandmerchantsis established through the Medicinal and Aromatic Plant Law (Law 491/2003), and the Order 244/2005 regulatesmanufacturing, processingand commercialization of medicinal and aromatic plants used as such, partially processedor processed as pre-dosed food supplements. The national legislation in the field is completedby the Order 1228/2005 – for approvingtechnical norms regarding the commercialization of pre-dosed food supplements of animal and vegetal origin and/ortheir mixture with vitamins, mineralsandother nutrients, respectivelyby the Order 1946/2014 – for approvingthe Procedureregardingthe notification of finite products based on medicinal, aromatic plantsand bee products, which are notified by operatorsin the fieldand are registered as food supplements,products for internal or external use, except for cosmetics.

Law491/2003, the first to regulate this market, states that used medicinal and aromatic plantsmust occur in the national catalogue and book for medicinal and aromatic plants from the spontaneous and cultivated flora, or the official community catalogue or that of a European Union member state. The national catalogue and book for medicinal and aromatic plants from the spontaneous and cultivated flora is certified by order by the Ministry for Agricultural and Rural Development (MARD), the central public administration authorityin the field. The introduction on the market as well as the monitoring of medicinal and aromatic plant based finite products presentedas medicine/medical adjuvants (with propertiesfor the treatment or prevention of diseasesin humansoradministeredin order to re-establish, correct orchangephysiologic functions by carrying out a pharmacologic, immunologic or metabolic activity, or to establish a medical diagnosis), is accomplished in accordance with the legal provisions. What is more, the introduction of these products on the market respectsthe technical normsof productionand commercialization, elaboratedby theTechnical Committee for Medicinal and Aromatic Plants and Bee Products,the competent national authority in the field.The accordance with technical

production and commercialization norms for medicinal and aromatic plants, freshas well as processed, is established, under the law, by certifying bodies, accredited for this purpose.In order to be commercialized, medicinal and aromatic plants must be certified. In the medicinal and aromatic plant production,product quality is determined by the content of active principles, which is conditioned by ecologic factors, species zonation, crop technology, cultivar biologic value (population, variety, hybrid etc.), respectivelyby processing ways. Products obtained through the processing of medicinal and aromatic plants, with therapeutic indications, fall under the medicine category and are authorised to be introduce on the market by the National Medicine Agency. On market product monitoring is carried out by inspectors of the General Pharmaceutic Direction,Pharmacy and Medical Equipment Inspectionunder the Ministryof Health and inspectorsof the National Medicine Agency.Food supplements based on medicinal or aromatic plants are notified at the National Service for Medicinal and Aromatic Plants and Bee Products (SNPMAPS) under MARD.

During the parliamentary session due after the summer holiday, the national legislation might change in the field of food supplements. According to a law project debated by the Senate and enacted by the Deputy Chamber, the construction of a unitary legal framework is discussed for food supplements "commercializedas food products and presented as such", the implementationof some articles of the Directive 2002/46/CE, as well as carrying out the necessary legal framework for the application of Reg. (CE) 1925/2006 and Reg. (CE) 1161/2011.The project excludesfood supplements based on medicinal and aromatic plants (object of Law 491/2003, republished, which constitutesmore than half of the Romanian food supplement market) as well as any other authorities with limited attributes, but complementaryin the field of these productscontrol and monitoring (ANSVSA, ANPC, SNPMAPS/MADR, ANAD, ANAF, Customs), the Ministryof Health becoming the only competent authority in the field (Niculescu, 2017).

Materials and Methods

The information on the medicinal and aromatic plants production was taken from the MARD, from the European Medicine Agency (EMA) and from the official press releases of the County Departments of Agriculture. The National Institute of Statistics database was used for the data about agriculture areas and production. The relevant scientific information on the medicinal and aromatic plants production was taken from the site ISI Web of Knowledge and Google Academic and from the internal database of the "Dunărea de Jos" University of Galați, Romania. The data was selected, organised and statistically processed. The obtained results were graphically represented and compared with other relevant information form the domain-specific literature, for an adequate analysis. In order to assess the concentration degree, we used the methodology recommended by Săvoiu, Crăciuneanu and Țaicu (2010) on assessing market concentration and diversification by relying on the Gini-Struck Index. The calculation modality is presented in formula 1.

$$IGS=\sqrt{\frac{n\sum gi^2-1}{n-1}} \quad (1),$$

where - n represents the number of terms of the series under study

- g_i represents the weight factor of the agricultural area or crop production in the i county, related to the total authorized capacity (total agricultural area or crop production.

Registration of Medicinal and Aromatic Plant Based Products on European Level

The analysis regarding medicinal plant use worldwide, carried out under the framework of the Romanian-Bulgarian cross border projectMedPlaNet Project, code MIS-ETC 656 (2011), showed that it depends on the natural endowment of each country (total species number, due to specific geographic conditions), and especially on the local tradition in using natural alternative medicine.Thus, at a worldwide total of

422.000 plants, circa 72.000 are used medicinally, representing circa 17.05 % of the total. In the classification presented within the project,

China is in leading position, with a fund of 32,300 plant species, of which a number of4,941 species, representing circa 15.3%, are used medicinally. Romania occupiesthe 15th positionin the world classification, earned due to the relatively high number of medicinal plants used (figure 1).
Republic Korea, with 1,000 medicinal plants in use, representing 34.5% of a total 2,898 plant species occupies the first position with regard to usage percentage and knowledge of the pharmaceutical potential of their national plants.

By comparison, Romania possess a 3,700 plant species fund, of which 283 species are known for their proven pharmaceutical potential, representing only 7.6 % of the total. European Pharmacopoeia, adopted by all member states includes 98 plant species, a number which is growing due to international research and information exchange.

The European food supplement market, including medicinal and aromatic plants and their products, was worth 8.3 billion Euro in 2015, observing a significant growth as compared to the previous year, according to data from Euromonitor International, quoted by Mihalache (2016).

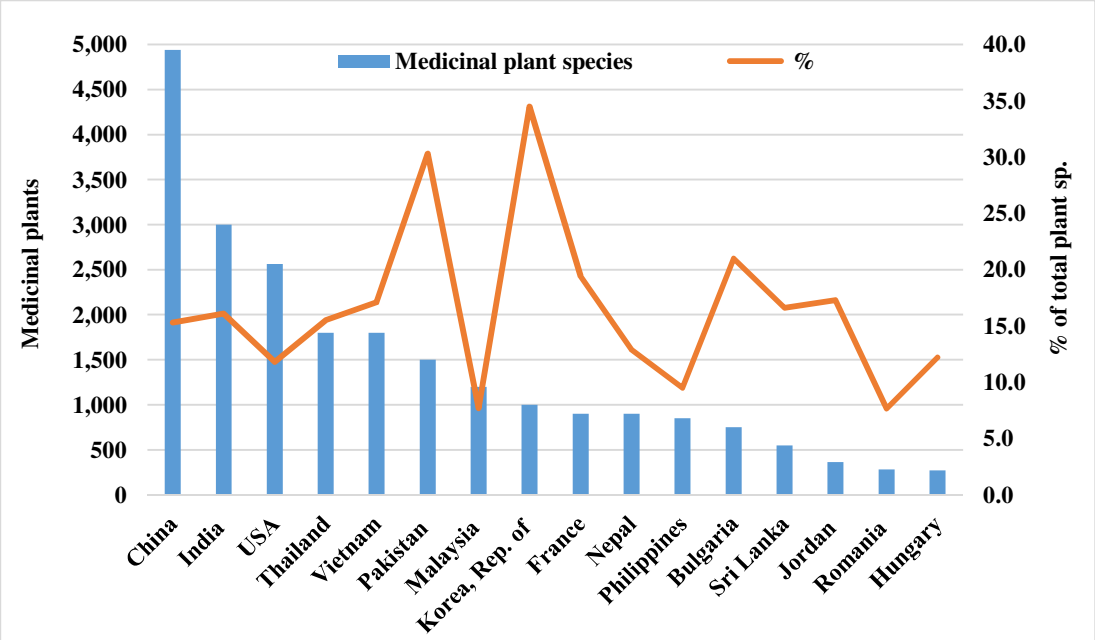

Figure 1: The global situation for the main producing countries of medicinal plants
Source: Authors, by using MedPlaNet Project data (2011)

Steinhoff (2016),observes that until the end of 2015, member stares of the European Unionapproved a total of 1,577 phytotherapeutic product registrations, most of them in the United Kingdom (344), Germany (263), Poland (197) and Austria (195). Of the 768 totalof commercialization authorizationsgranted to firms, most of them were located in Germany (278),followed by Austria (51), Poland (24), andthe Czech Republic (33).

According to data from the Herbal Medicinal Products Committee (HMPC) of the European Medicine Agency (EMA), 260 phytosanitary productsbased onplants/plant mixturesare prone to be evaluated depending on the foreseen effects on the health (figure2).

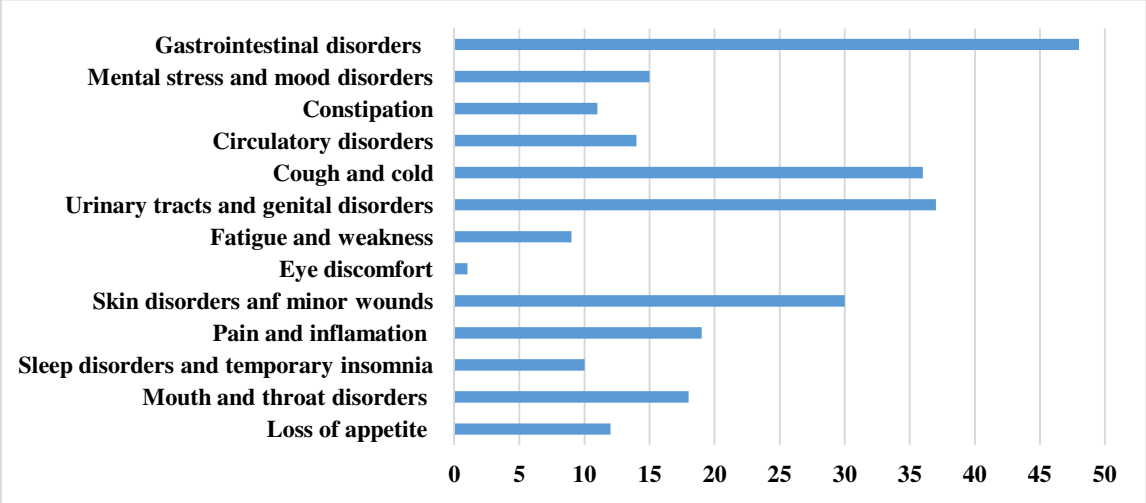

Figure2: Herbal medicines for human use based on therapeutic area

Source Author, by using EMA database (2017)

Each plant/mixturemay be in various evaluation stages. For each stage, a series of documents are associated with the substance, depending on the location of the evaluation process. The HMPC conclusions regarding the plant based substance at the end of the evaluation processcan be found in the final monography of theEuropean Union.HMPC can evaluate certain plant substances in combination. According to EMA (2017),the status of registered productscan be R (Rapporteur assigned), C (ongoing call for scientific data), D (Draft under discussion), P (Draft published), PF (Assessment close to finalisation/pre-final), F (Final opinion adopted). According to the datapresented infigure3,over 90% of the 190 registeredplants/monographiesobserved the Final opinion adopted (status F).

Registering Phytotherapeutic Products on a National Level

For the commercialization of plant based food supplements on the Romanian market, the national procedure requires for food supplements to be reported in accordance with order no. 244/401/2005toSNPMAPS Bucharest,orto Regional Centresof Public Health(CRSP) Timisoara, Iasi, BucharestrespectivelyClujNapocafor pre-dosedfood supplements of animal and vegetal origin and/ ortheir mixture with vitamins, mineralsand other nutrients notifiedaccording to Ord. 1228/244/63. Products for external use(medicinal and aromatic plant based supplements and bee products, in accordance with the provisions of law no. 491/2003 regardingmedicinal and aromatic plants, as well as bee products, republished, with ulterior changes and additionsand of Ord. no. 1946/2014 for approving the Procedure regarding the notification) are reported to S.N.P.M.A.P.S Bucharest.Of a total of 21,443 food supplements notified until December 2015, 18,122 productswere produced strictly from medicinal and aromatic plants, being reported toSNPMAPS Bucharest, while3321 pre-dosed/mixture supplements were reported to CRSP Timisoara (1,205), Iasi (237), Bucharest(38),respectivelyClujNapoca (1,841)(figure4).

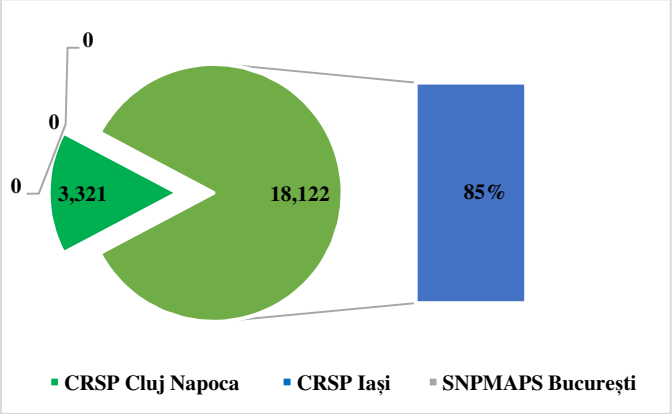

Figure4: Food supplements reported in Romania
Source Authors, by using SNPMAPS database (2017)

According to theEuromonitor study, quoted byMihalache (2016), the food supplement market in Romania hasobserved a spectacular evolution in recent years. Thus, during 2005-2015,the segment registered a worldwide growth of over 200%, with a maximum increase of 24% observed during 2010-2011, given the fact that during 2012-2014,in Central Europe,an averagegrowth of 8% was reported. At present, in Romania,there are over 18,000 natural products registered officially, intended to keep patients healthy, prevent disease or treat various affections. The study conclusions are that, in 2016, Romanians have bought natural products worth over 30 million Euro online, representing a 20 % increase as compared to the year before. A triple sum was cashed in at the counter, in pharmacies, hypermarketsandsmall neighbourhood shops, supported by a significant amount of commercials where potential healing properties are highlighted. However, consumers have no knowledge about how the products are manufactured, or about possible side effects or other aspects regarding these effects. Data revealed by the Romanian Patronageof the Food Supplement Industry, cited by Capital.ro (2016) show that food supplement publicity in Romania needs a unitary legal framework, correlatedwith the provisions of the European legislation in the field. In Romania, as well as in other EU member states, food supplement publicityis governed by the provisions of Regulation 1924/2006 of theEuropean Commissionand those of the Regulation 1169/2011 regarding statements referring tonutrition and health. At the level of self-

regulatingEuropean bodies, in 2015, from a total of circa 60,000 publicity complaints registered by EASA, approximately 180 dealt with food supplement publicity. In 2015,the Romanian Publicity Council received 121 complaints regarding 103 commercial communications, of which 18 referred to food supplement communication.

Producer groups and organizations established in Romania

Before 1990, in Romania, activitywasmonopolized by a single state capital company - Plafar. In 2016 a series private owned commercial companies were cultivating, processing and capitalizing medicinal and aromatic plants, forming numerous producer associations and groups. The main medicinal and aromatic plant producer and processor organizations from Romania, postedon the MARD site, arethe Patronage „Planta Romanica" (https://plantaromanica.wordpress.com), which reunites 25 firms (HofigalBucureşti, ExheliosTimişoara, Dacia Plant Sebeş etc.) and the NationalInterprofessionalOrganizationfor Medicinal and Aromatic Plants from RomaniaOIPMA (http://www.oipma.ro), reunitingeconomic agents in the field of medicinal and aromatic plants: the Professional Associationof Medicinal and Aromatic Plant Raw Material Producers,the Professional Associationfor Collecting and Acquiring Medicinal and Aromatic Plantsfrom the SpontaneousFlora, the Professional Association of Medicinal and Aromatic PlantProcessors, the Professional Association of Medicinal and Aromatic Plant Tea Producers, the Professional Association ofMedicinal and Aromatic Plant Tincture and Syrup Producers, the Professional Association ofMerchantsandSuppliersin the Field of Medicinal and Aromatic Plants, the Professional Association ofMedicinal and Aromatic Plant Food Supplement Producers, the Romanian Association of Phytotherapeutic Doctors, the Professional Association forResearch in the Field of Medicinal and Aromatic Plants (with member companies: Fares, Kalpo, Larix, Dacia Plant, Dobrogea Natural Farm, Radix, Santo Raphael, Rotta Natura,Vedda etc.).

Medicinal and Aromatic Plant Surfaces and Production in Romania

Following the selection and amelioration carried out at the Fundulea Research Station, 29 homologated varieties were registered (coriander, tarragon, fennel, lavender, mint, basil, thyme, poppy, Grecian foxglove, purple foxglove, chicory, camomile, artichoke, valerian, lesser periwinkle, marigold)in 2002. About 24 speciestaken over from the spontaneous flora were introduced to crops, relatively easily "domesticated", due to their remarkable ecologic plasticity; valuable populations from the point of view of active principle content (even local species) being identified in various geographic basins in the country (yarrow, angelica, belladonna, cumin, celandine, gentian, perforate St John's-worth, plantain, valerian, lesser periwinkle). Other 10 medicinal plant species which do not exist in the spontaneous florawere acclimated to crop conditions in our country (Grecian foxglove-*Digitalis lanata; Echinacea purpurea; yellow poppy – Glauciumflavum; bitter melon - Momordicacharantia, thyme – Saturejamontana*andothers). (Morărescu, 2015).

The most profitable medicinal plant crops in Romania have been in recent years those of lavender, sea berry, goji, chokeberry - aroniaanddog-rose. Medicinal plants are starting to be in great demand on the Romanian market, while already in great demand on the European market, due to the high number of requests by players of the pharmaceutical industry (Vlad, 2015).

The introduction of state support for medicinal plant producers by the Romanian Government lead to a positive evolution of cultivated surfaces and obtained production, with a maximum reached in 2010. The support came in the shape of direct payments (schema ofsingle payment per surface, redistributive payment, payment foragricultural practices beneficial for climate and environment, payment foryoung farmers, simplified schema forsmall farmers); national transitory support as foreseen by annual local budgets allotted to the Ministryof Agricultureand Rural Development, respectively state support for diesel

used in agriculture.The period 2010-2012 was characterisedbya substantial reduction of cultivated surfaces and accomplished production, which decrease to half of the amount produced in 2010.
During 2012-2016 cultivated surfacesand obtained productionreached 3-4 thousand ha and 4-5 thousand tonnes(figure5).

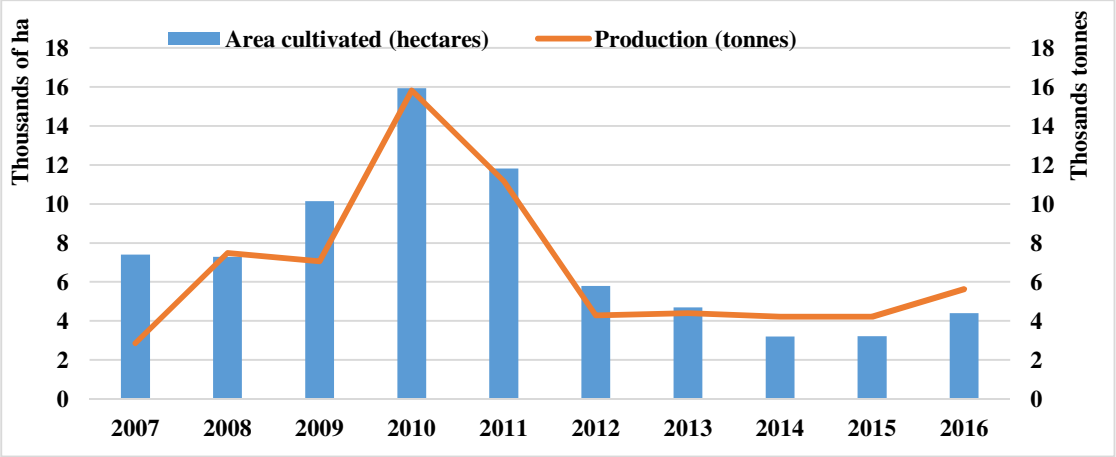

Figure 5: Medicinal and aromatic plant - cultivated area and productionin Romania
Source Author, by using MARD Data (2017)

Through the new National Program for Rural Development 2014-2020 a revival of the sector is planned, Romanian small farmers being able to get non-refundable financing of up to 100% for cultivating medicinal plants. Thus, in PNDR 2014-2020,financial measures have been planned, such as Measure 6 – Sub-measure 6.3. "Aid for the development of smallfarmers", non-refundable public aid up to 15,000 Euro, for an agricultural exploitation over a period of maximum five years, in two payments (75% – 25%).Other measures which can be accessed by the sector are Measure 11 "Ecologic agriculture", Submeasure 11.1. "Aidfor the conversion to ecologic agriculture methods, through payments for the conversion", grantedin a percentage of 100%; payments to sustain ecologic agriculture practices, or financing through Package 5 "Medicinal and aromatic plants" underSub-measure 11.1." (Morărescu, 2015).

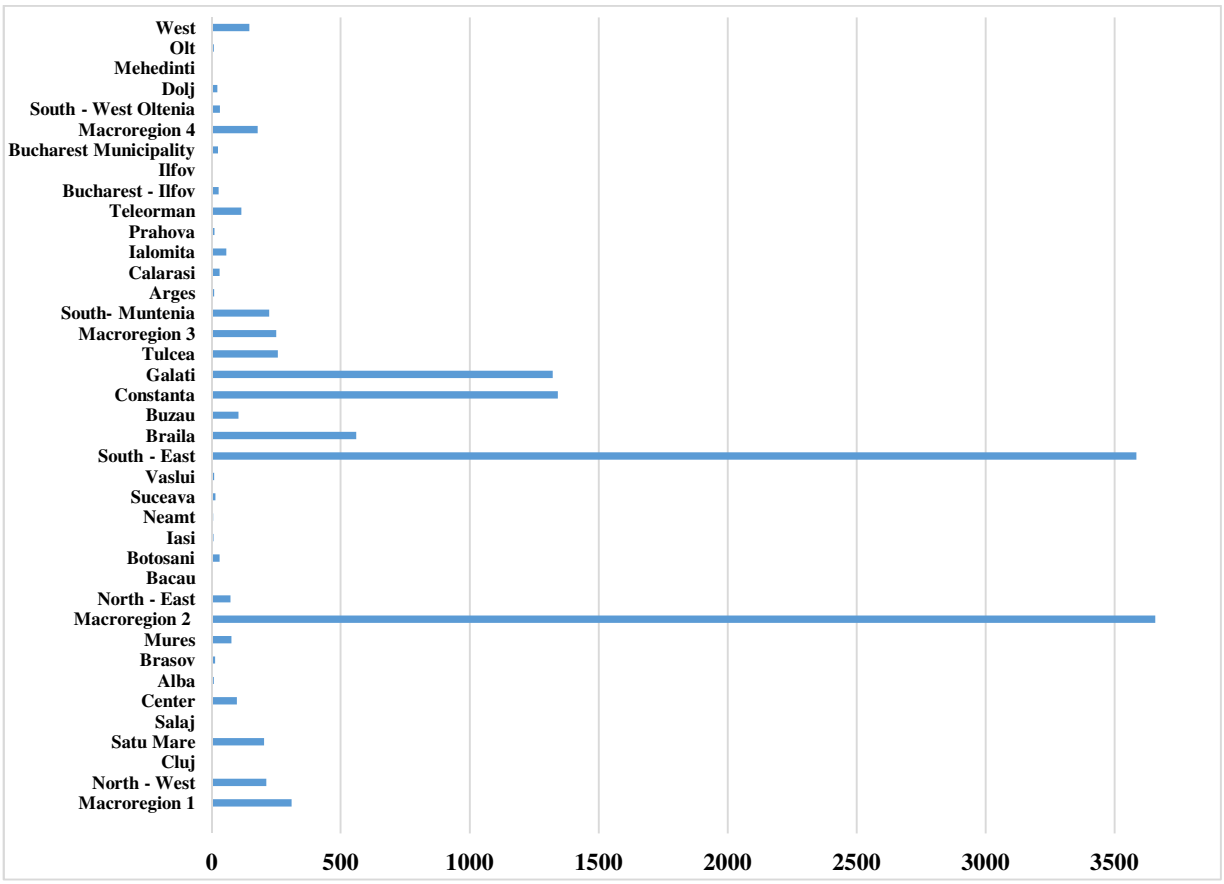

Figure 6: Distribution of medicinal plant cultivated surfaces in regionsandcounties

Source Author, by using NIS Data (2017)

The Concentration of the Agricultural Market for Medicinal and Aromatic Production in Romania

Assessment of the concentration degree of agricultural surfaces cultivated with medicinal/aromatic plants can be carried out using the method recommended by Săvoiu, Crăciuneanu and Ţaicu (2010), based on calculating the Gini Struck Concentration Index (IGS) and on the interpretation of the obtained result. The data presented in figures 4 and 5 have been processed statistically and interpreted. The results obtained by applying the mentioned methodology are presented in table 1.

Table 1: Specific parameters and the value of the Gini Struck Concentration Index (2016)

Indicator	Agricultural area (ha)	Production (tonnes)
Total	4,395	5,627
$\sum g_i^2$	2,085.028	2,183.81
n	27	27
IGS	46.531	47.6211
Concentration	**High**	**High**

Source Author, by using MARD (2017) and NIS (2017)

According to the results presented in table 1, we may notice that there is a high concentration degree of agricultural area distribution on counties. By comparison, the production presents higher values of the Gini Struck Index, proving a high degree of concentration in the Romanian counties.
The obtained results confirm a cursory analysis of NIS data, based on the comparison of surface and production distribution values in regions/counties. Thus, the South-Eastern Region,mainlycountiesConstanțaandGalațicover circa 80% of the total cultivated surfaces, respectively of the production obtained at national level (figure 7).

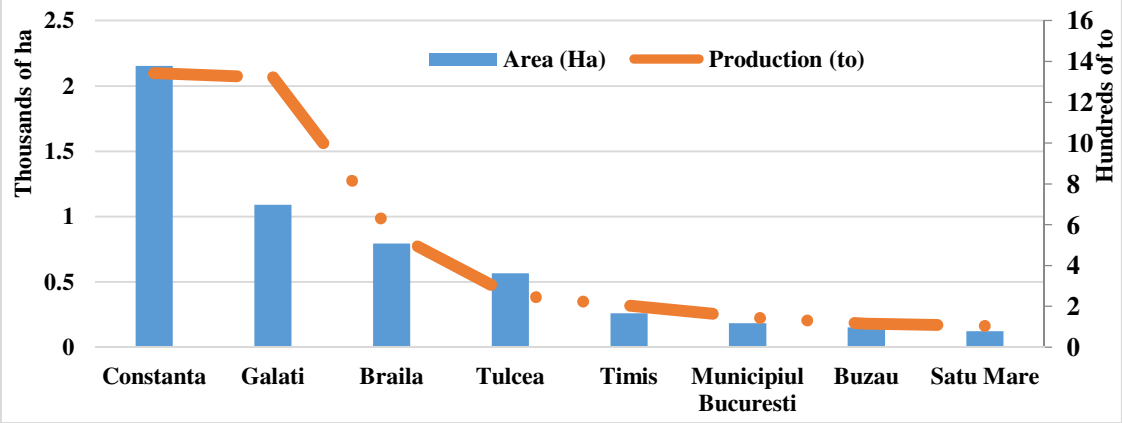

Figure7: Top counties cultivating/producing medicinaland aromatic plants
Source Authors, by using NIS data (2017)

According to the data presented graphically in figure 7, one may observe that a number of 8 counties, with agricultural surfaces allotted to the cultivation of medicinal and aromatic plantslarger than 100 ha achieve over 90% of the total production obtained at national level in 2016. One cannot make a direct correlation between relief forms or protected geographic areas and the production obtained, considering that the first 3 positions are occupied by counties in plain areas, with no ecologically protected regions,where a conventional agriculture is practiced.

Conclusions

The research highlighted a series of aspects we consider interesting for the national economy and for the internal business environment. Thus, Romania possesses an important natural potential for the medicinal and aromatic plant production, but it is not capitalized accordingly. Romania is ranked 15th in the world classification, due to the relatively large number of medicinal herbs used in traditional medicine.

National legislation is too permissive and does not sufficiently protect local producers, which face a fierce competition from import products. The national medicinal and aromatic plant production was significantly reduced after 1990 and represented substantial fluctuations during 2007-2016. There is a concentration phenomenon of the production and cultivated surfaces in the South-Eastern Region, which denotes a higher interest of local agricultural entrepreneurs in the development of business in the field. GSI values are very high, indicating a high concentration of the market and a rather difficult access to starting a new niche business.

The possible accession of funds by Romanian farmers, under the governmental support measures with European aidspecified in PNDR 2014-2020can lead to the revival of the system and to important benefitsfor the Romanian agriculture.

E-mail: vintilageorgeta@yahoo.fr

Abstract

This study takes into consideration a topic less study in the academic literature: the drivers of effective corporate tax rate (ECTR) in the Baltic financial markets. Using a sample of 40 listed companies from Estonia, Latvia and Lithuania stock exchanges we empirically tested the influence of profitability (ROA, ROE and ROIC), indebtedness and assets composition on ECTR. All the results were comparable with other well-known studies from the literature and seem to support the political cost theory. Additional we deployed other variables such as audit fees, R&D expenses, statutory rate and advertising expenses which highlighted characteristic of the Baltic companies. The results were explained from the perspective of corporate finance.

Keywords: effective corporate tax rate, firm characteristics, Baltic companies, panel data models

Introduction

The beauty of nature is driven by the evolution. But evolution itself is a continuous struggle for acquiring skills and dominant position. Similar idea can be applied to countries and financial markets. More often, the social gap between developed markets and the emerging ones is becoming almost conspicuous. There is a real endeavor for the emerging markets to obtain the status of developed market. There are many ways to study the emerging markets, and the social aspect is on interest not only for the financial analysts, but also for the broad public. Numerous factors differentiate the emerging markets from the developed ones, but in the present paper, as novelty, we focused on taxation from the Baltic stock exchanges in the context of corporate finance. The final goal for the European Union is strength by union and harmonized policies at all levels for member states, including taxation. But still there are gaps and disparities between West and East within the European Union. Estonia, Latvia and Lithuania were admitted as members in the EU in 2004 and all three countries are, in a way, interdependent all levels. With a similar history, and all three former communist countries, nowadays they represent an example of fiscal policies, but there are few academic papers about the effective corporate tax rate between these countries. Despite the fact that statutory tax rates represent taxation within the financial markets, the effective corporate tax rates (abbrev. ECTR) based on financial statements gives a proper insight on tax burden of a company. Taxation is a sensitive issue in attracting the investors and can influence a financial market and the 'developed/emerging' status. Baltic financial markets are considered emerging countries and in the present paper we set our goal to study their effective corporate tax rates from the perspective of corporate finance. The influence of the financial statements on the ECTR can be considered a starting point for new fiscal policies applied to reduce the gap from the Baltic countries and Western EU member states.

Our sample consists of Estonia, Latvia and Lithuania over the period 2000-2016, which is significant in the context of transition process to the free market economy. Being based on financial statements, the variables used includes drivers of ECTR such as indebtedness, asset composition and profitability. As a

novelty for a paper about the Baltic taxation, we included variables for audit fees and advertising expenses because these variables can capture the political power theory and also the impact of corporate governance on taxation. Corporate governance can be the link between fiscal policies within the European Union. We consider that size of the company is significant in the context of reduction of tax burden and Dyreng et al. (2017) proved that ECTRs have decreased over time (maybe as effect of transition process). The contribution of the article is in emphasizing the ECTR's influence factors as part of the new policies aimed at strengthening the EU markets. First, we contribute to the literature by adding a newer perspective on the ECTR from the Baltic region. Second, we illustrate the taxation of newer EU members and integration of the emerging stock exchanges. We found that the effective corporate tax rate from the Baltic region is influence by the classic drivers from the literature (indebtedness, asset composition, size) in line with the principles of accounting and tax deductions. The level of influence (R^2) recorded though a reduce value which means that there could be other drivers of ECTR in the Baltic countries. This can be attributed to the relative small number of companies included in the sample (only listed companies). Overall, proxies used indicate the presence of political cost theory and a diminished role of tax avoidance. Managers of the Baltic companies are more focused on the financial management than on the fiscal management. We consider that the political cost theory is due to the fact that each one of the three countries has a small population and it is more a 'solidarity cost' for the large companies.

The remainder of the article proceeds as follows. Section 2 provides a literature review. Section 3 reveals the sample and variables, along with the econometric methodology. Section 4 presents the empirical results. Section 5 is the conclusion.

1. Prior Literature and Hypotheses Development

Baltic region and its three countries, Estonia, Latvia and Lithuania, have an important role in the study of drivers of the effective corporate tax rate. All of them are similar, former communist states, but on the same time each one has its own characteristics ('idiosyncratic'). Alena et al. (2017) used cluster analysis for ECTR and observed that in each case the Baltic countries are grouped in the same clusters together with Bulgaria, Romania, Poland and Czech Republic. This cluster of the new acceding EU member states has the lowest level of ECTR among the European countries and is tax competitive.

The differences between Baltic States are important for the economist and for the financial analysts. Also, the influence factors of the ECTR based on the financial statements can be used as a benchmark for future fiscal policies necessary for the fiscal harmonization at the level of the European Union. The development gap between the EU member states is a matter of interest for the economists and it can be reduced through the channel of taxation. There are few papers on the academic literature about the Baltic countries and their effective tax rates.

Baltic stock markets are integrated on a single trading platform. Deltuvaitė (2016) used empirical analysis to study the Baltic stock markets and observed that these markets are related, but the Latvian market is more isolated. Brännäs and Soultanaeva (2011) empirically observed that Estonia and Lithuania are more affected by changes from the US and Western Europe and Latvia is influence by Russia. But for a better perspective of investors the three Baltic States decided to become one Baltic financial market and our main focus is on the Baltic stock market, and additionally on each stock exchange. Also, all three countries adopted fiscal policies designed to help the financial markets to get the emerging status and to become attractive for investors. Tax incentives have a significant impact on the effective tax burden and to attract investors. For example, according to Eurostat[1] in Lithuania the R&D expenses are deductible

[1] Taxation and Customs Union. Taxation trends in the European Union Data for the EU Member States, Iceland and Norway. Eurostat

even "[…] in a in a triple amount in the tax period when they are incurred" and the profit reported for tax purposes can be reduced with half of the value of expenses in "[…] incurred in the acquisition of investment asset". Thus, taxation is an important part in the process of becoming developed market. Statutory rates are the first info points about corporate taxation, but for the corporate finance perspective, the effective corporate tax rate has the accurate image about tax burden from a financial market. The gap between statutory rates and ECTR is another important aspect because shows how much tax deductions can be used with respect to the legal regulations. Dyreng et al. (2017) observed with empirical models that for the European countries, ECTRs and statutory rates decreased and the Baltic region are not an exception. Finkenzeller and Spengel (2004) studied the Baltic countries, among other new EU members from 2004, and they observed that these states compensate the tax incentives with tax rate reductions design to give advantage against the Western European countries. Following the study of Hanlon and Heitzman (2010), we place our study about effective corporate tax rate between taxation, corporate finance and accounting. We started from the idea that the Baltic stock exchanges are together emerging markets and new places for investing. The final goal was to study the drivers of effective corporate tax rates from the Baltic listed companies in the context of the relations between managers-shareholders and investors. The corporate income tax or effective tax rate has macroeconomic, microeconomic, politic and social impact.

1.1. Drivers of the ECTR Based on Financial Statements (academic literature)

2.2.1. The impact of profitability and size on the ECTR

There are countless computation formulas for the ECTR, but Devereux and Griffith (1998) developed the effective marginal tax rate and the effective average tax rate. The literature about the drivers of ECTR has at its core three categories of indicators based on financial statements: profitability, assets composition and indebtedness. Finkenzeller and Spengel (2004) considered that higher profitability makes the companies to search for location with lower statutory tax rates such as the Baltic region. Gupta and Newberry (1997), Lee and Swenson (2012), and Richardson and Lanis (2007) studied the drivers of effective corporate tax rates and one of the proxied used for profitability was the return of assets (ROA) which recorded a positive link with ECTR. Gupta and Newberry (1997) decomposed the formula of effective tax rate and have rewritten it with ROA included. Thus, they considered that an increase of the ROA will lead to an increased ECTR. But other authors such as Buijink et al. (2002) who studied European companies or Md. Noor et al. (2010), recorded a negative link between ECTR and return of assets. We consider that big and profitable companies are able to redirect their profitability and size in order to obtain lower levels of ECTR and thus, lower levels of tax burden. From this idea two theories derived in the academic literature: political power and political cost theories. Belz et al. (2015) obtained a negative link between firm size and the effective corporate tax rated, supporting the political power theory. In research papers political power is link usually with the firm size on the principle size is power. The opposed side of the authors see size as a weakness in front of the fiscal authorities.

Dyreng et al. (2016) considered that large companies are victims of their size and suffer from the political cost theory. With size comes visibility in front of the public authorities and society who demand good practices and that part of the profit of the companies to be shared with community.

We set as dual hypothesis for our empirical study the presence of both theories political power and political cost

H1: Presence of political power and political cost through negative/positive link between ECTR and profitability/ firm size

2.2.2 The impact of indebtedness on the ECTR

The Modigliani–Miller's theorem (1958) brought into the light the well-known link between indebtedness and taxation. The fact that interest expenses are deductible means that in theory debt reduces the level of effective corporate tax rate. Finkenzeller and Spengel (2004) considered that the tax shield of the interest deductibility is lower for countries with low levels of statutory rates such as Lithuania and Latvia. Also for Estonia interest expenses had indirect impact on tax burden since in 2004 the tax base was formed by the distributed profit so the interest expenses had a moderate effect in this context.

Gupta and Newberry (1997), Richardson and Lanis (2007), Wu et al. (2012) obtained empirical results about a negative link between long term debt and ECTR. We constructed our second hypothesis as follows:

H2: Higher indebtedness is negatively correlated with the effective corporate tax rate.

2.2.3 The impact of the structure of assets on the ECTR

Another important 'pillar' of the academic literature regarding the effective corporate tax rates is the link between ECTR and capital/inventory intensity. Gupta and Newberry (1997), Richardson and Lanis (2007) considered that capital investments have tax benefits which should lower the level of ECTR and inventory-intensive should have higher levels of ECTR. Fernández-Rodríguez and Martínez-Arias (2014) used the emerging countries and found that the inventory intensity is positively correlated with effective tax rates. Derashid and Zhang (2003) recorded a negative link between capital intensity and effective corporate tax rate. More assets mean more debt capacity and thus, more interest expenses for tax deduction, which finally means lower ECTR. Wu et al. (2012) obtained a positive link between inventory intensity and ECTR. We set as third hypothesis (dual) the following:

H3: Negative relation between capital intensity and the ECTR; negative link between inventory intensity and the ECTR.

2.2.3 Other potential drivers of ECTR

Gupta (2007) considered that corporate income tax capture a glimpse of the political aspects from financial market. Authors such as Griffith and Klemm (2004) considered that statutory rates can be a negative influence in the 'war for investors' of tax competition between countries (emerging/developed). Devereux (2006) showed that higher statutory rates are positively correlated with higher effective corporate tax rates. Thus, we deployed a variable for statutory rate and we expect to have a positive link with ECTR.

Graham et al. (2012) considered the financial statements as the main source of risk in financial reporting. Gallemore and Labro (2015) observed that lower levels of effective corporate tax rate depend on the quality of the financial reporting. Cook et al. (2008) found a positive correlation between audit fees and ECTR, but for the companies which used "Big Four" accounting firms, the correlation reversed. Mills et al. (2013) considered that big companies have the financial resources to pay for tax specialists in order to maximize their tax savings and to reduce their ECTR. Donohoe and Knechel (2014) observed positive correlation between audit fees and tax aggressiveness which is specific to US companies. However, Baltic countries have lower statutory rates, and we expect that companies with higher audit fees have a positive correlation with ECTR because more activity from the auditors means companies' inefficiency; external auditors inhibit the managers from tax avoidance practices.

Gupta and Newberry (1997) considered that research and development expenses are deductible and act as tax shield. They obtained a mix link between R&D intensity and ECTR. Richardson and Lanis (2007)

obtained a negative link between ECTR and R&D intensity. Pilinkienė (2015) revealed that the Baltic States have R&D expenditures in low technology industries with a slowly trend. Estonia has the best R&D expenditures among the Baltic countries close to the EU average.

2. Research Methodology

3.1. Data and Variable Measurement

In order to apply our empirical models, we developed a sample which comprises public companies from the three Baltic countries: Latvia, Estonia and Lithuania. The sample is covering the period between 2000 and 2016. It comprises 40 companies: Latvia 17, Estonia 7 and Lithuania 16. We chose as starting point the year 2000 because, from our perspective, represents the end of transition for the Eastern European countries and the beginning of a new financial era. Companies with more than three years of missing data or negative pretax income/negative ECTR, were excluded from the sample. We excluded the financial companies, such as banks and insurance companies, from the sample because they have other regulations for financial reporting. Data were collected from Thomson Reuters Eikon. These filters yielded a total of 680 observations.

Table 1 comprises the variables used in the empirical analysis. We used the ECTR as proxy for the corporate tax burden. We selected different variables for profitability expressed through three proxies—return on equity (ROE), return on assets (ROA), and return on invested capital (ROIC) because each one captures the perception of company's stakeholders. Other firm characteristics included indebtedness, liquidity, and solvency.

Table 1: Definition of Variables

Acronym	Variable	Definition
Dependent variable		
ECTR	Effective corporate tax rate	Income tax (total) divided by earnings before interest and taxes (EBIT). Used by Thomson Reuters Eikon in the key ratios.
Variables on firm characteristics (Independent variables)		
Corporate profitability		
ROA	Return on assets	Net income/Total assets ROA or economic profitability measures the efficiency of capital allocation in fixed assets and net current assets. Shows the percentage of profit a firm obtains relative to its full resources.
ROE	Return on equity	Net income/Total equity ROE or financial return shows the company's performance in terms of shareholders' interests. Measure the ability to increase the dividend rate and reserves with the profit made by shareholders' money.
ROIC	Return on invested capital	EBIT(1- τ) / [total equity + total long-term debt] ROIC shows how well a company is using its invested money to generate returns.
Corporate efficiency of assets		
ASTI	Capital intensity	Property, plant, and equipment (total net) divided by total assets.
INVI	Inventory intensity	Total inventory divided by total assets.

SOLV	Equity multiplier	Total assets/Total equity An indicator of financial leverage that quantifies the overall solvency risk and inability to cover all debts with assets available to the company. It measures the percentage of company's assets owned and financed by shareholders and shows the level of debt financing necessary to maintain the firm's activities.
Corporate indebtedness		
LTDA	Ratio of long-term debt to assets	Total long-term debt/Total assets A measure of the long-term financial position of a firm that exhibits the percentage of its assets financed with long-term debt.
LEV	Ratio of debt to equity	Total debt/Total equity Financial leverage that indicates the proportion of debt and equity used by the company to finance its assets.
Corporate liquidity and solvency		
LIQC	Current liquidity	Current assets/Current liabilities (short term) A measure of short-term solvency or liquidity that exhibits the firm's capacity to pay off its short-term debt commitments.
Firm-level control variables		
SIZE	Firm size	LN(total assets)
MKC	Variation in market capitalization	Year-to-year variation in market capitalization.
GRW	Annual firm total asset growth rate	[(Total assets 2001 - Total assets 2000)/Total assets 2000] Year-on-year percentage change in total assets.
Other variables (Independent variables)		
AUDF	Audit fees	Natural logarithm applied to total audit fees paid out by companies as reported by Thomson Reuters Eikon in income statements.
ADVE	Advertising expenses	Advertising expenses to net sales
RD	Innovation	Research and development to net sales
Variables on statutory rate (Independent variables)		
STR	Statutory rate	Statutory rate as reported on taxation trends in the European Union, European Commission.

Source: Author's own work.

First of all, we used three proxies for profitability (ROA, ROE and ROIC) and we expect a negative correlation contrary to other papers from the literature (see Gupta and Newberry, 1997). We expected to find a negative correlation between debt and the ECTR due to the deductibility of interest expenses. As proxies for indebtedness we used solvency/financial leverage to ensure robustness to results. Since our study is based on financial statements, many of the variables depend on efficiency of assets. Capital intensity and inventory intensity are common variables from the academic literature. We focused our research on the opposed theories of 'political power' and 'political cost'. The first theory is linked with firm size, market capitalization and firm's annual total asset growth rate. Belz et al. (2015) consider that big companies own enough financial resources to lobby for a lower tax burden, and to achieve a reduction in the effective corporate tax rate. Financial resources mean power and with power the lack of fear for penalties arises for big companies. On the other side, political costs theory is present in the case in which a large company is targeted by authorities attempting to use taxation to help support the budget. This theory is more relevant in the context of the emerging markets and the Baltic markets are aspiring at the status 'developed market'. Political cost can be considered a barrier for the development of a stock exchange. We expected to observe both theories in our sample.

Additional to these variables we deployed audit fees as part of the corporate governance because audit is a strong element for financial quality and also for testing political power theory. Auditor's reports can reduce questionable activities conducted by the big companies in order to reduce their effective tax rate. Kern and Morris (1992) observed a direct relation between the size of a company and the difference between earnings recorded in its accounting and reported taxable earnings. We expected to find a negative link with the ECTR. Advertising expenses are very important for the development of a company and can enhance the level of political power owned by a big company. We expected to find a negative link with the ECTR. Statutory rates are directly linked with ECTR and we deployed a variable in our empirical models.

3.2. Model Specification

For the empirical model we used multivariate regressions (data panel) and we deployed as estimation method generalized least squares (cross-section weights [GLS]) regressions. Gujarati (2004) indicates GLS as a method against heteroscedasticity. In order to avoid biased results, we used fixed effects and White cross-section techniques. The general regression examines the influence on the ECTR of firm characteristics, auditing fees, statutory rates, and firm-level controls, as follows:

$$ECTR_{it} = \alpha_0 + \beta_1 \times Firm_characteristics + \beta_2 \times Other_variables + \beta_3 \times Firm_controls + \beta_3 \times STR + \varepsilon_{it}$$

where i = firms 1-40, t = financial years 2000-2016, ECTR = effective corporate tax rate (dependent variable), Firm_characteristics = variables regarding corporate efficiency, indebtedness, liquidity, and solvency, along with profitability (explanatory variables), Firm_controls = variables regarding firm size, market capitalization, and annual growth, Other_variables = audit fees paid out by companies (explanatory variables), advertising expenses, research and development intensity; α_0 = intercept, β_1, β_2, β_3 = regression coefficients, ε_{it} is the error term.

3. Empirical Results

4.1. Descriptive Statistics, Correlations, and Stationarity Checks

Estonia, Latvia, and Lithuania are in a continuous endeavor to attract foreign investors through their tax systems. For example, in Estonia there was the zero percent corporate income and the flat income tax rates[2]. Elschner and Vanborren (2009) and other authors observed that member states from the European Union had a decline of their statutory rates and implicitly on their ECTRs. Figure 1 confirms that the Baltic States reduced their statutory rates. Lithuania had the most striking evolution from 33% to 15%. Finkenzeller and Spengel (2004) said that Estonia in the period of pre-accession had a tax system with tax base not link to the corporate profits. In fact, the retained earnings were exempted from taxation and only distributed profits were exposed to corporate income tax. But our study is based on variables from the financial statements and we avoid this legal provision.

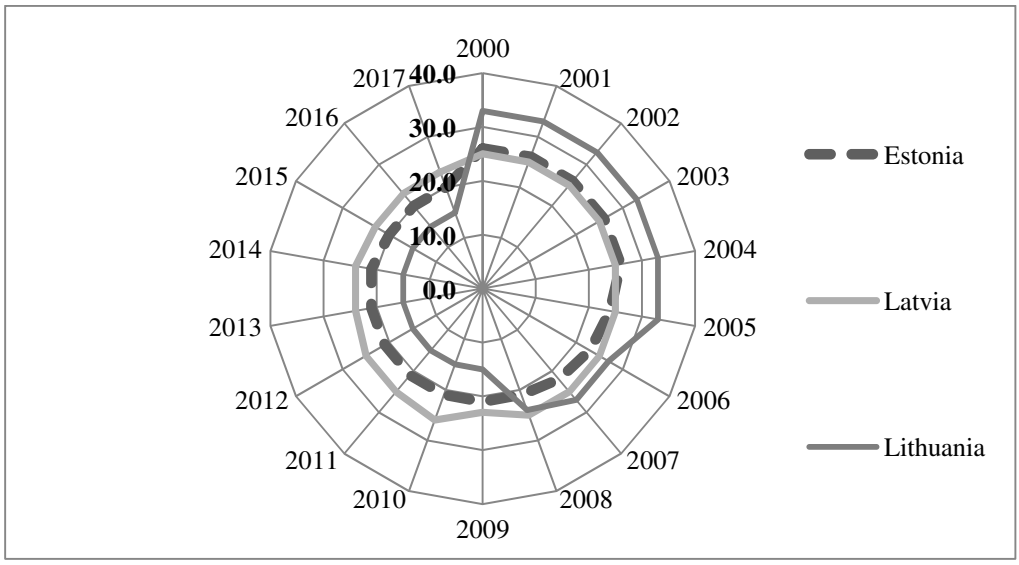

Figure 1: Statutory corporate income tax rates (including surcharges), 1995 – 2017

Source: Authors' computations. Figure 1 contains the top statutory corporate income tax rates (including surcharges) for the period 1995-2017. Data are available at: European Union, http://ec.europa.eu/taxation_customs/business/economic-analysis-taxation/data-taxation_en/.

There are some differences between the Baltic countries in term of economic development. With the lowest population (1.3 million[3]) Estonia is the most advanced. The second place is occupied by Latvia and on the last place is Lithuania with 2.9 million inhabitants (the biggest Baltic state) which try harder to attract foreign investors with lower fiscal policies. The reduction of statutory rates is connected with accession to the EU, but they can be derived from the transition process to the capitalist markets. Baltic countries have successfully implemented the international views about corporate finance, accounting standards and digitalization to obtain lower levels of effective corporate tax rates. Also, the fact that the total population combined is almost 7 million people eases the activity of the fiscal authorities and implementation of more lax tax policies. Elschner and Vanborren (2009) observed the tax differences between new member states from Eastern Europe and the older ones. They conclude that the accession fueled the gap between them as an effect of the sharp tax competition (see Davies and Voget, 2009). As it can be seen from Figure 1, after year 2004 (accession year) the statutory rates have decreased. The effective average tax rates had slightly moved over the years but are lower than the statutory rates, which means that the Baltic companies are using tax deductions and tax breaks in order to lower their ECTR. In Figure 2 there are the gaps between statutory rates and the effective average tax rates within the Baltic countries.

[3] https://ec.europa.eu/info/sites/info/files/eb024_en.pdf

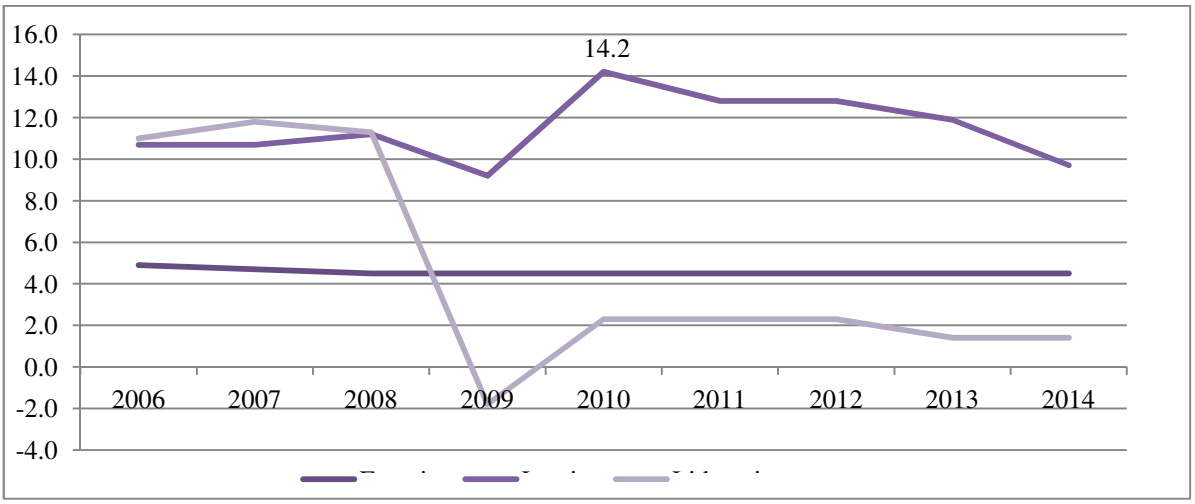

Figure 2: The gaps between (EATR) and statutory rates in Baltic countries, 2006-2016

Source: Authors' computations. Data are available at European Union, http://ec.europa.eu/taxation_customs/business/economic-analysis-taxation/data-taxation_en/.

The highest gap between statutory rate and effective average tax rates was recorded by Latvia in 2010 (14.2%) and the lowest by Lithuania in 2009 which means that EATR was higher than statutory rate. Companies from Lithuania did not cope with the shift from fiscal policies and they use fewer tax deduction. Latvia was the most affected Baltic state by the 2007 crisis and it is possible that the state allowed more tax aggressiveness for the companies to recover.

Descriptive statistics for the selected variables are presented in Table 2. It should be noted that the mean of effective corporate tax rate is 18% much smaller than US companies.

Table 2: Summary statistics (N = 680)

Source: Authors'computations. Data based on financial statements reported by Thomson Reuters Eikon.
Notes: For definitions of the variables, see Table 1.

About profitability ratios ROE 8%, ROA 5%, and ROIC 5%, which are low ratio, but expected for the emerging markets which were severely affected by the 2007 crisis, especially Latvia. On average, statutory rates are 21.13% which indicate a moderate use of tax avoidance and tax deductions.

The correlation matrix is presented in Table 3. Standard errors are increased by the effect of multicollinearity and lead to results that are statistically insignificant.

Source: Author's computations
Notes: Values highlighted with '* and italics indicate high correlation. For definitions of the variables, Please see Table 1 for definition of variables.

Profitability variables recorded high levels of correlation but we deployed them in separate models. There is high correlation between SOLV and LEV. Also, market capitalization and assets' annual growth are correlated but we decided to keep them together since they are constructed from unrelated data.

4.2. Econometric Output

Notes: Statistical significance: *, ** indicate statistical significance at the 5% and 10% significance level. The t-statistics are in parentheses. Total observations: 680. Period 2000-2016. Method: Panel EGLS

(Cross-section weights). White cross-section standard errors & covariance. For definitions of the variables, see Table 1.

For the statistical inference the coefficient of determination (R^2) is used in order to validate a model. On average, the goodness-of-fit statistic (R^2) was 37%. The low value means that only 37% of the variation of effective corporate tax rate is explained by the selected variables. In fact, there is no clear line about which variables influence the level of ECTR and there are many computation formulas for effective tax rate. We keep the formula used by Thomson Reuters because is one of the most common and spread formula from the financial analysis about ECTR. The maximum value was recorded for Eq.4 (48.8%). One possible explanation is that European States, including the Baltic ones, have lower levels of effective corporate tax rates, compared with US companies and they are less incentivized to use tax avoidance practices for reducing tax burden. This hypothesis is supported by Huizinga and Laeven (2008) who obtained empirical results about the fact that tax records is smaller in the European markets than in the United States because tax burden is less significant. Also, the quality of financial reports and the performance of the Baltic companies are at a level specific to the emerging markets and the managerial abilities of the CEOs have less impact on the ECTR.

All three proxies for profitability – ROA, ROE and ROIC – recorded a positive link with the effective corporate tax rate in all six equations. Our initial hypothesis **H1** was rejected (political power) and proved (political cost) in the same time. The results are on the same line with other papers from the literature (see Gupta and Newberry, 1997; Lee and Swenson, 2012). The logic behind this choice is related to corporate governance. We considered that they represent, in this context, the view about taxation of the most important stakeholders within a company: shareholders, managers and investors. Return on assets is considered by some authors as return of the managers; ROE is return of the managers and ROIC is return of investors. Also, they represent the financial health of the company and we expected to have a negative correlation with ECTR since a prosperous company should be able to lower its effective tax rate. Using European companies, Buijink et al. (2002) recorded negative correlation between ROA and the ECTR. ROA had the strongest coefficient (0.21) and shows the return of the managers and the positive link means that Baltic CEOs are unable or unwilling to fully use performance for reducing the ECTR. ROIC had positive link with ECTR. It is possible that lower levels of ECTR to be considered by investors questionable and to be regarded as a risky investment. Thus, companies with levels of ECTR way down above the average may not attract investors compare it with ones with higher ECTR. Efforts to increase the profitability are 'expensive' and the costs are non-deductible so more return means higher ECTR in this context. The final point is about the relation between profitability and managers. Maybe managers who are able to increase the company's profitability have more appetite for non-deductible expenses (on their own benefit or for the company). This idea is important in the context of corporate finance (the lack of protection of minority shareholders) and in the context of political power vs. political cost theories. With our empirical results, we accepted part of the hypothesis **H1** and we supported political cost theory for the Baltic companies. It could be a consequence of the fact that the Baltic States gave many deductions to the company for their struggle to become developed states and as pay back companies have to endure the political costs effect. To support even more the political cost theory, variable SIZE for firm size recorded a positive sign. Thus, we accepted half of the hypothesis **H1**. It seems that the Baltic companies are taxed more as they become bigger. Market capitalization (subject to the fact that it was statistically significant only in Eq. 6 with ROIC) recorded a positive link with effective tax rate. Companies which are successful on the capital markets and attract more investors have a lower level of ECTR, maybe as effect of the political cost theory. Because companies with high levels of market capitalization are able to attract more investors they are also able to lobby for more tax breaks. Year-to-year assets' growth recorded a negative sign which supports the political power theory (subject to the fact that it was statistically significant only in Eq. 6 with ROIC). Firm size (proxied in many ways) as driver of the effective corporate tax rate has different trends over time: as becoming bigger a company is aimed by the fiscal authorities, but after a level, when the company has enough financial resources and political

power for lobbying, it appears a reverse sense of tax-related influence – from the company to the authorities.

A positive correlation was recorded between ECTR and inventory intensity as we expected because stocks do not have tax deductions. On the other side, capital intensity recorded a negative link with effective corporate tax rate. Thus, we proved hypothesis **H3**. Intangible assets have tax deduction such as tax depreciation which lowers the level of ECTR. Stickney and McGee (1982) considered that heavily capital intensity firms and leveraged usually have lower levels of ECTR.

It is notorious that indebtedness has influence on the level of effective corporate tax rate. Variables related to debt are LTDA, LEV and SOLV which was not statistically significant. Interest expenses derived from debt are tax deductible, and is expected that ECTR for an indebted company to be lower. Variable for the financial leverage, LEV, proved this fact and recorded a negative link with the ECTR. The fact that the Baltic stock exchanges are underdeveloped, banking system remains a major source of financing. LTDA recorded a positive link with ECTR and our hypothesis **H2** was rejected. Long term debts have interest expenses but also have higher risk of bankruptcy and more control from the creditors. Thus, managers have more difficulties to search for financial resources and have more nondeductible expenses. Also, the attention of the creditors complicates the ability of the managers to use financial 'tricks' designed for obtaining a lower ECTR. Thus, for the Baltic companies and their effective corporate tax rate, indebtedness plays an important role through the fact that lowers the level of taxation, but on the long time the influence becomes opposed.

Variables for current liquidity and statutory rate were not statistically significant. This result is interesting adding the low value of R^2. It seems that for the Baltic companies, the level of ECTR is not influence in a major proportion by statutory rate established through fiscal policies, and the managers are more focused on the financial management. Nikkinen et al. (2012) studies revealed low integration between global and the Baltic stock exchanges. Thus, the Baltic countries were not incentivized to use statutory rates as a major driver of their stock exchanges and companies are more interested about profitability and financial management.

To further explore the effective corporate tax rate in the context of corporate governance, we deployed in our estimation models variables for audit fees, adverting expenses and R&D expenses. AUDF was not statistically significant and we rejected hypothesis H1. Audit fees matters for the quality of financial reports and for investors. More audit fees means that the managers are controlled and are inhibited from tax avoidance and illegal practices conducted for tax elusion. Thus, we expected that companies with higher audit fees to have higher levels of ECTR. Advertising expenses and R&D expenses were positively correlated with ECTR and we deployed these variables in our models in support of political power theory. Companies which have more advertising expenses and R&D should be more profitable and should become bigger. With size comes power. Also, some of these expenses are deductible. The positive sign indicates, again, that in the Baltic financial markets the political cost theory is present.

4.3 Supplemental Analyses

Apart the empirical analysis deployed on the Baltic countries as a sample, for further in-depth analysis we applied the estimation model for each country from the sample. Table 5 contains the drivers of ECTR for each country: Estonia, Latvia and Lithuania.

Notes: statistical significance: *, ** indicate statistical significance at the 5% and 10% significance level. T-statistics are in parentheses. Total observations = 1,836. Method: Panel EGLS (Cross-section weights). White cross-section standard errors & covariance and fixed effects. For definitions of variables, see Table 1. EE = Estonia, LV = Latvia, LT = Lithuania.

From Table5 it can be observed that the coefficient of determination (R^2) had the smallest values for Lithuania and we considered that Adj. R-sq. has values that indicate to eliminate these regressions. The negative economic performances from the pre-accession period (2000-2004) have affected the Lithuanian companies and losses affected the general level of the effective corporate tax rates, and there are no significant influence factors of ECTRs. Budrytė (2005) considered that despite the fact Lithuania has the lowest tax burden among the Baltic States there are some difficulties about collections and tax compliance. This can be the reason of the lack of statistically significance recorded for Lithuania in our models. Thus, for the country analysis we kept only Estonia and Latvia which had the highest R^2 (40.5%). Alena et al. (2017) refer in appreciative terms to the financial policies conducted by Estonia and Latvia. For Estonia, variable for current liquidity was positively correlated with effective corporate tax rate and this fact was expected since more liquidity means fewer loans and less interest expenses. Statutory rate had a positive link with ECTR in Eq.1 (with ROA) and a negative link in Eq.2 (with ROE). This result means that in Estonia, ECTR is influenced by the level of statutory rate and it is an indicator of the lack of tax avoidance practices from the managers. For example, fiscal authorities adopted a program named Controlled Foreign Companies (CFC) as a measure to reduce tax avoidance[4]. Managers focus more on the financial management than on the fiscal management, as year-to-years assets' growth shows: a negative sign on the link with ECTR. But, the positive sign of influence recorded for the market capitalization proves the political cost theory. The link between STR and ECTR is probably due to the fact that in Estonia statutory rates were constant over years and the managers could use them as a benchmark for ECTR. Deltuvaitė (2016) considered that Estonia and Lithuania are more exposed on the international risk than Latvia which is more exposed on the domestic risk drivers. Thus, public companies from Estonia are more depended and interested on the level of statutory rates because they are more exposed.

For Latvia, we recorded a negative link between capital intensity and ECTR. And a positive sign between inventory intensity and ECTR. These results are in line with the principles of tax deductions. Long term debt on total assets recorded a positive link with effective corporate tax rate which mean that on the long time debt brings non-deductible cost for the company. Again, the presence of political cost theory was proved for Latvia through the positive correlations between the effective tax rate and SIZE, GRW and adverting expenses. Big companies from Latvia are taxed more by the state and the idea of domestic risk drivers is supported by these results.

Concluding Remarks

The maturity of the Western European markets makes investors to seek for other places of investing. An interesting place from the European Union is the Baltic regions with Estonia, Latvia and Lithuania because all these former soviet countries are trying to be attractive for investors. We conducted an empirical study of the drivers of ECTR in the Baltic countries, in the context of corporate finance, for the period between 2000-2016. As results we observe that tax deductions, based on financial statements and assets composition, follow the accounting principles (e.g. heavy capital intensity companies have lower levels of effective corporate tax rates and companies with more inventory intensity have higher levels of ECTR; indebtedness with the deductibility of the interest expenses lowers the level of ECTR but on the long term the link is reversed). The positive signs obtained for profitability proxies (ROA, ROE, ROIC), proxies for size (firm size, market capitalization, assets growth) and advertising / R&D expenses supported the presence of the well-known political cost theory. It seems that for the Baltic companies their financial success is shared with the state and population. This link is expected for small countries with small population and thus, fewer contributors. Statutory rates had results that were not significant form the statistical point of view and this results means that the managers from the Baltic companies are more focused on the financial management than on the fiscal management and tax avoidance. For Estonia (models per country), we recorded a mixed link between statutory rate and effective corporate tax rate. Unfortunately, the audit fees were not statistically significant and we could not draw a conclusion about their impact on effective corporate tax rate.

There are some limitations in our articles, derived from the small number of companies included in the sample, after we applied filters of selection. Baltic stock exchanges are underdeveloped and on the future research we propose a data base with other companies from the Baltic region, in order to capture the drivers of effective corporate tax rate from these countries.

The Process of Improving Recruitment for University Studies

Petra Hollá Bachanová, University of Zilina, Žilina, Slovakia, Petra.Bachanova@fpedas.uniza.sk
Miriam Garbárová, University of Zilina, Žilina, Slovakia, Miriam.Garbarova@fpedas.uniza.sk

Abstract

Demographic development is one of the most important factors that have a consequent impact on the economy of universities across the world. In the Slovakia, it is possible to observe a drop in the total number of students in recent years. The offer of study programs of higher education institutions currently exceeds the graduates' demand of secondary schools as applicants for higher education. If a university wants to maintain its position on the market, it needs to adapt to these demographic changes. For the university, it is, therefore, necessary to ensure effective marketing communication through which it would inform potential prospective students adequately about the possibilities of studying and at the same time raised interest in the study. The Department of Communications, which is part of the University of Žilina also faces a declining trend of filing of applications for study. Therefore, focused its attention on the area of managing a continuous process of improving the recruitment of applicants for studies using new technologies and developing marketing communication using diverse forms, methods and innovative solutions. As a part of this process, it was necessary to define the criteria for selecting a college, from the point of view of potential applicants and identify the sources of information that are critical in choosing a university for the students of secondary school, and last but not least, to identify students' preferences regarding marketing communication tools. For this purpose, the survey, the results of which are presented in this paper, was conducted.

Keywords: Marketing communication, University, Student preferences, Demographic developments, Recruitment of students, Slovakia, Žilina, Department of Communications.

Introduction

In a research study by Corejova & Rostasova (2016), the importance of universities in national, regional and local systems is obvious, and the universities are aware of this impact. The higher education is nowadays for many people a way to get the necessary qualifications for employment in the labour market. Gogolova (2016) mentioned that despite the fact that the level of education increases, young people are pushed out of the labour market and are unemployed. This may be caused by the improper choice of fields of study that is affected by some factors. Many young people choose specific fields of study which interests them, respectively which they need to perform their future or current profession. However, there are also those whose decision regarding the choice of the university depends on completely different criteria. The decisive factor in this situation is that offer prevails over demand on the market of higher education institutions. Potential students, therefore, have a wide choice of study options. Each of the educational institutions must, therefore, take some care to attract potential applicants. The result of this effort is to develop marketing communication using different forms, methods and innovative solutions. Stofkova et al. (2016) mentioned that the creation of qualitative and modern tools of marketing communication is a priority for all universities to gain new students.

Overview of the number of applications filed at the Faculty of Operation and Economics of Transport and Communications (FPEDAS)

The Faculty of Operation and Economics of Transport and Communications (FPEDAS) of UNIZA currently offers study opportunities at seven departments, including the Department of Communications.

According to information from the Institute of Information and Communication Technologies of UNIZA, 1154 applications were filed to the FPEDAS in the academic year 2015/2016, representing up to 55.5 % decline since 2004/2005. The following figure demonstrates the development of the number of applications filed over the last six academic years. Based on this available data, it can be stated that the number of applications filed to the FPEDAS has been constantly decreasing since the academic year 2011/2012.

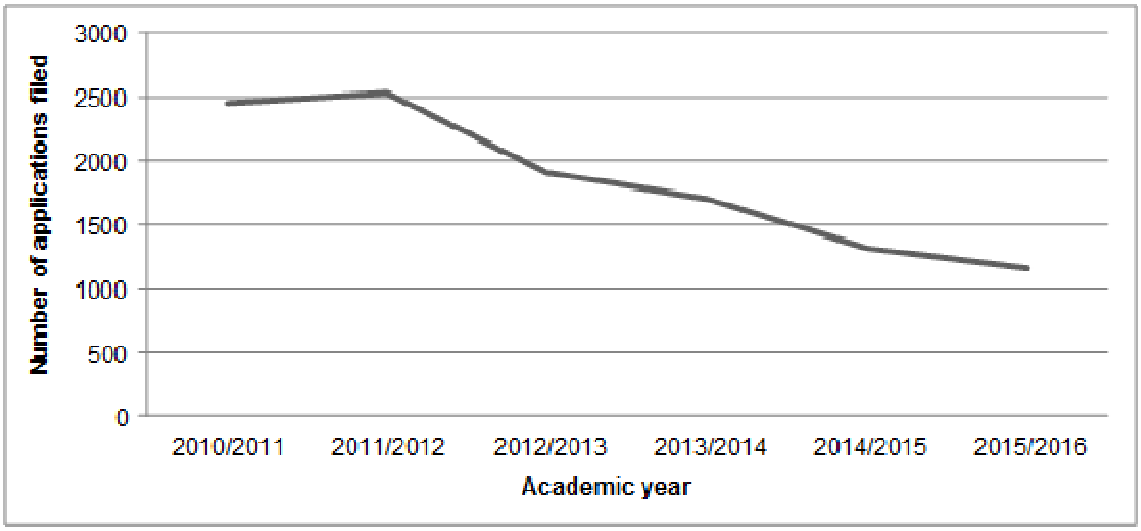

Fig. 1: the development of the number of applications filed over the last six years at FPEDAS

To solve unfavourable situation associated with the decreasing number of applicants for study it was necessary to analyse the structure of the applicants for study. Based on the analysis carried out in 2015, it was possible to further identify the structure of the candidates for study at the FPEDAS and its departments, from the point of view of the individual regions of the Slovak Republic, the districts within the Žilina Region or specific secondary schools within the Žilina Region. Available information about the structure of the applicants for study fell into the academic years from 2010/2011 to 2014/2015. The analysis showed that the highest number of applications filed at the FPEDAS came from the Žilina Region (56.00 %), followed by the Trenčín Region (17.00 %), the Banská Bystrica Region (7.00 %), the Prešov Region (6.00 %), the Košice Region 5.00 %). The number of filled applications was approximately 3 % from Trnava, Nitra and Bratislava Region.

From the point of view of the individual districts of the Žilina Region, the most filed applications were from the district Žilina (50.32 %). It was followed by the districts Ružomberok (17.00 %), Martin (9.90 %), Čadca (6.55 %), Kysucké Nové Mesto (6.08 %), Dolný Kubín (5.99 %), Tvrdošín (5.45 %), Námestovo (4.24 %), Liptovský Mikuláš (3.96 %), Bytča (2.02 %), and Turčianske Teplice (0.32 %). Based on the above data, it can be stated that the demand for study at FPEDAS is strongly concentrated in the region.

Overview of the number of applications filed at the Department of Communications

Department of Communications at the Faculty of Operation and Economics of Transport and Communications, University of Žilina is a department of higher education focused on information-

communication technologies, postal services, postal technology and electronic communications. The main aim is to educate professionals for the needs of enterprises from postal, electronic communications, financial and banking sector. Department of Communications guarantees accredited bachelor degree programs - Postal Technology and Services (PTaS) and E-Commerce and Management (EOaM) and master degree programs - Postal Engineering, E-Commerce and Management.

Based on information from the Institute of Information and Communication Technologies which manages the statistics filed to the Department of Communications, there were filed 60 applications for the PTaS study program in the academic year 2015/2016. The greatest interest in the PTaS study program was in the Žilina Region, from which came to 66.67 % of applications. From the Trenčín Region, were received 15.00 % of the applications and 8.33 % from the Prešov Region. A number of applications filed within the Bratislava, Košice and Banská Bystrica Region were smaller (from each to 3.33 %). There was no application filed from the Nitra and Trnava Region.

For the EOaM study program were filled in total 135 applications in the same academic year. Most interested in this study program were again applicants from Žilina Region (67.00 %) and Trenčín Region (15.00 %). They were followed by the Banská Bystrica Region (7.00 %), Prešov Region (4.00 %), Bratislava, Košice and Trnava Region (from each to 2.00 %) and Nitra region (only 1.00 % of applications).

Methodology

In order to manage the process of continuous improvement of recruitment of applicants for studies at the Department of Communications, it is important to propose an effective way of using marketing communication tools that would reflect the needs and preferences of potential candidates for study, in our case mainly from the Žilina region.

For this purpose, a survey was conducted to identify information the resources that applicants prefer and take into account in the decision-making process of choosing a university. The survey also looked at students' expectations from university education, at important criteria critical to the selection of a university, degree of importance of the information provided by universities from the point of view of applicants for study, as well as their perception of various forms of marketing communication.

Based on data available from the Institute of Information and Education Forecasts 13 454 students attended the 3rd and 4th year of secondary schools in Žilina region, at the time of the survey. Given that the population is less than 100 000 respondents, the sample size was determined based on the formula for a small population. Subsequently, a sample size was calculated at 374 respondents.

As a method of data collection was chosen a method of questioning. Data collection was conducted through a questionnaire consisted of 17 closed questions. Testing of the questionnaire was carried out on a sample of 10 respondents. The survey was conducted at selected secondary schools from 13. 4. 2016 to 21. 4. 2016. Students were given a questionnaire through school counsellors within the framework of teaching.

Overall, 417 were obtained completed questionnaires. The survey was attended by a total of 128 men, representing 31% of respondents and 289 women, representing 69%. Grammar school students represented a total of 191 respondents, which is 46 % of the total number of students and students of secondary vocational schools represented a total of 224 respondents (54 %).

Up to 68.9 % of the respondents were from the district of Žilina, 13.5 % of students were from the district of Martin, 11.3 % of students from the district of Kysucké Nové Mesto and 6.3 % of students from Bytča

district. These facts confirmed our assumption that the majority of the applicants come from the district of Žilina.

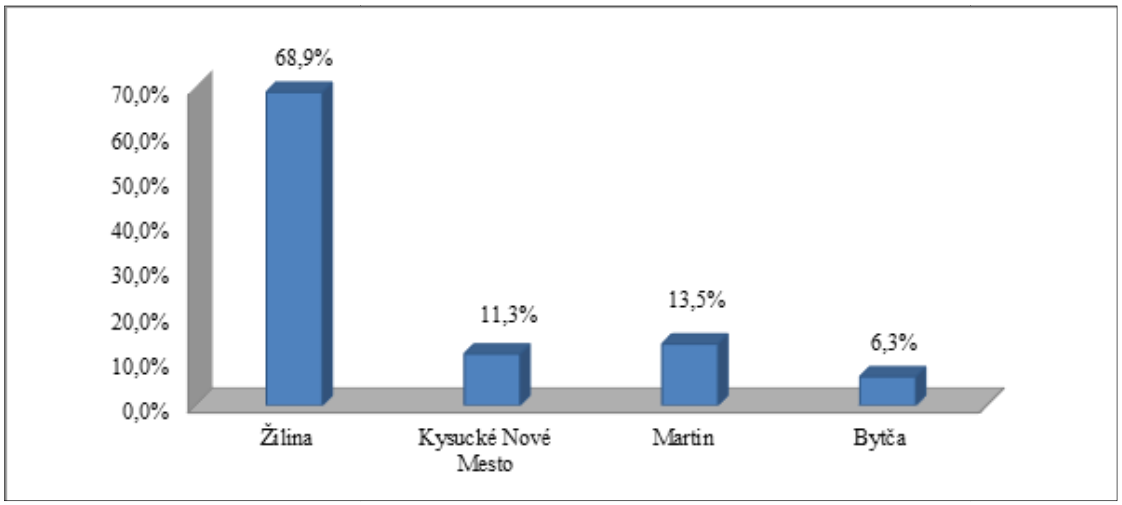

Fig. 2: The number of respondents according to individual districts of the Žilina region [%]

The survey found that half of the students (50 %) plan to study at the university after graduating from secondary school. The survey looked at the expectation of these students from the university study, and the respondents had the opportunity to select multiple options. Among the strongest motives of students for university studies belonged a greater chance of applying to the labour market (76.4 % of respondents) and acquiring a qualification in the chosen field (65.7 % of respondents). 51.3 % of students want to study at the university just to get the title. For 35.5 % of all students, a study at the university is an opportunity to gain new contacts and for the 31.3 % of them is such study a chance to extend student life.

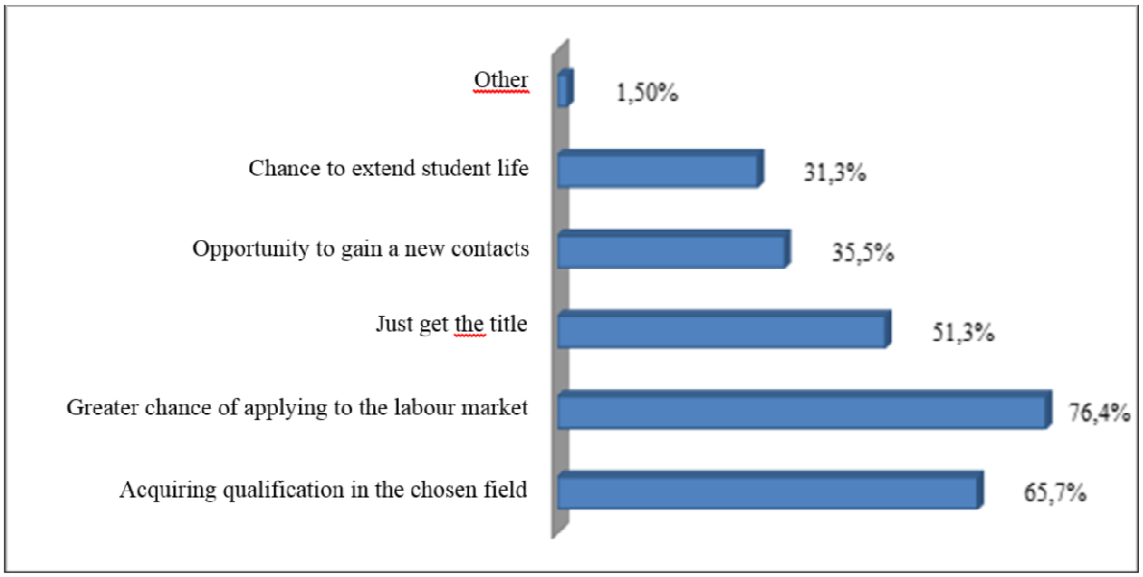

Fig. 3: The strongest motives of students for university studies [%]

The other half of students said that they did not plan to continue studying at university after leaving secondary school. The reasons for lack of interest in study at the university were varied, and the respondents had the opportunity to select multiple options.

As the most common reason, students stated that they had decided to work after leaving school (49.3 %). Following reasons such as a general lack of interest in further study (37.0 %), desire to work abroad (30.1 %) or travelling around the world (20.5 %). 17.8 % of students stated that they have not yet considered this option. 12.3 % of the students would like to take an enterprise after leaving secondary school and 8.2 % of students mentioned as the reason the unfavourable financial situation.

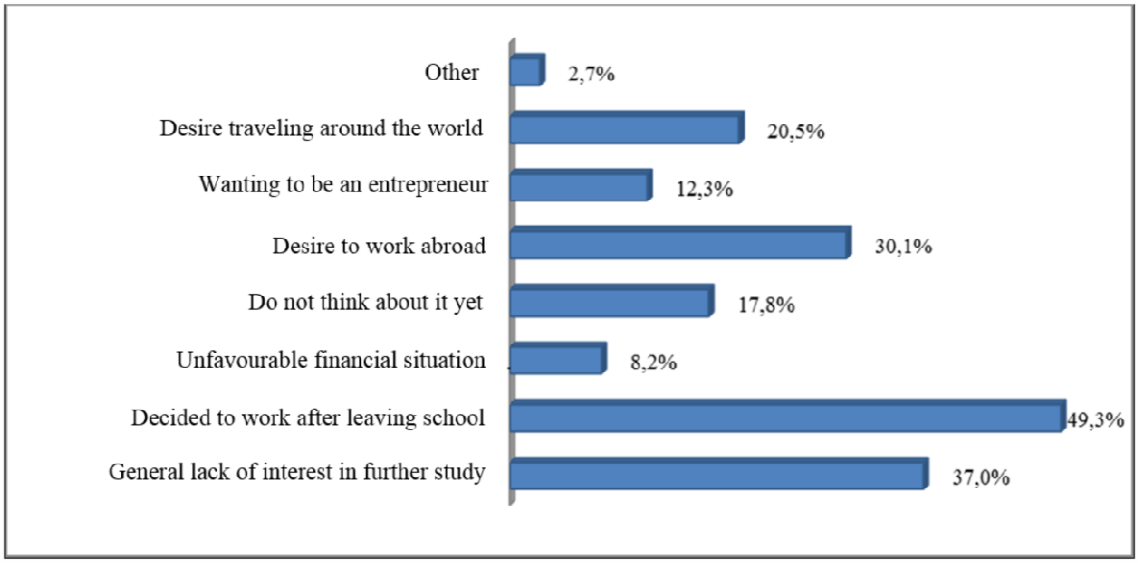

Fig. 4: The reasons for lack of interest in study at the university [%]

An important part of the survey was to determine the key criteria by which students choose a particular university. It has been found that for the choice of a particular university is most decisive especially interest in a specific field of study (for 74.9 % of students). Up to 33.4 % of students reported as a decisive factor employers' interest in university graduates. In choosing a university, students also take into account the results of various assessments and the rankings of universities (25.4 %). Many of them make decisions by recommendations from parents or friends (22.1 %). To a certain extent, their decision depends on the possibility of attending exchange study stays (17.0 %), on the offer of leisure activities of universities (7.8 %), or on the fact that they want to study, where study their friends (8.1 %). For 16.1 % of students, it is important to study at a university which is close to the place where they live. The remaining 2.4 % of respondents also stated other criteria, for example, personal interests and preferences, quality of the school, educational program, study plan, tuition or planned number of admitted applicants.

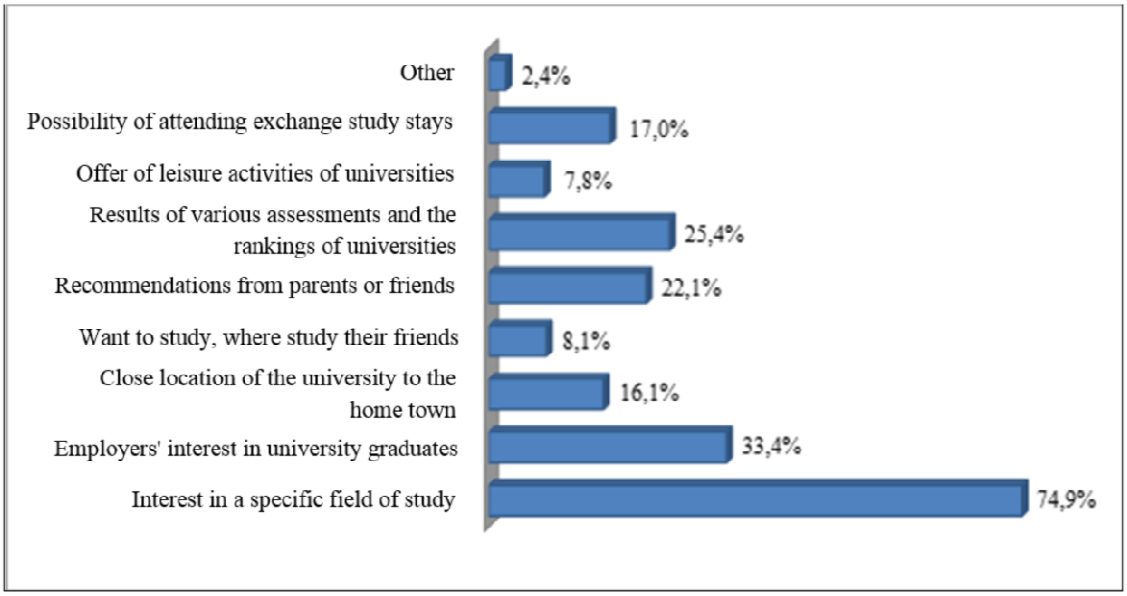

Fig. 5: The key criteria on the basis of which students choose a particular university [%]

The most frequently cited information source, from which the students obtain important information necessary to select a particular university belonged university websites (80.6 %), references from friends and acquaintances (55.5 %), the website of University portal (36.7 %) and open door day of universities (31.9 %). To a lesser extent sources such as school counsellors (18.5 %), exhibitions and fairs dedicated to education (11.3 %), social networks (10.7 %), television (10.4 %), university newspapers and magazines (8.1 %), print media (7.5 %), outdoor forms of advertising (4.8 %), radio (1.5 %), discussion forums (0.9 %) and others, were represented.

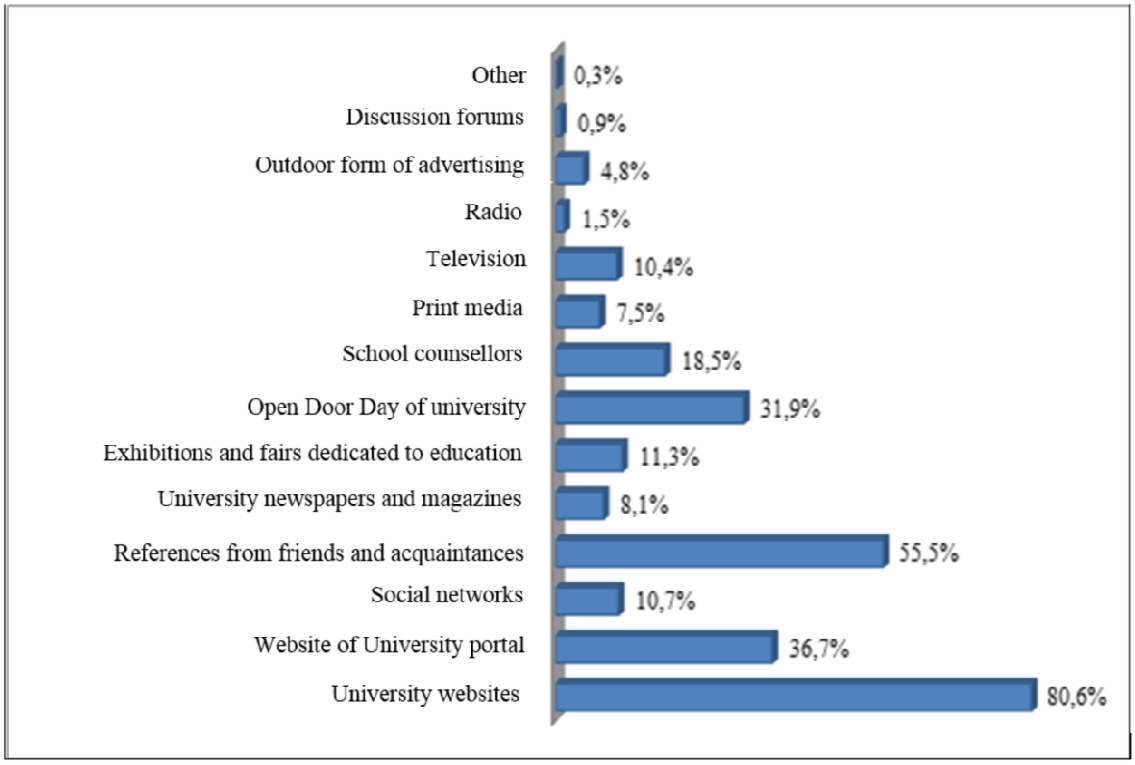

Fig. 6: The information sources for obtaining important information necessary to select a particular university [%]

The goal of the survey was also to find out which information are important for the students in the decision-making process. Students could choose from several types of information, which are regularly evaluated by the academic rank and rating agency ARRA.

The most important information in the decision-making process for choosing a university according to students are information about admission procedure (81.6 %). The following are overview of study and subjects (77.0 %), graduate employment (73.2 %), study costs (62.9 %), information about the satisfaction of students (62.0 %), graduate profile (53.2 %), universities care for students (46.4 %), successes and uniqueness of universities (44.5 %), teaching and laboratory equipment (27.2 %), foreign internship opportunities (23.9%), cultural opportunities (22.0 %), information about the teachers (18.1%), accessibility on social networks (14.0 %) and a successful graduates' club (6.4 %).

The survey showed that the respondents are most likely to be interested a combination of traditional and online communication, which was confirmed by 54.7 % of respondents. 23.1% of students prefer online marketing communications, including tools such as newsletters, online chat, internet advertising, email marketing and other online forms. On the contrary, the traditional form of communication such as promotional gifts, billboards, posters or personal contact is suitable for 22.2 % of students.

On the question “Which kind of communication can attract students in connection with the university selection?” up to 81.5 % of students answered that communication via social network Facebook. Other forms of marketing communication such as Open door day (66.0 %), meeting with alumni (62.4 %), websites of universities (61.5 %), communication with current students enriched with their advice and

study experiences (49.6 %), e-mail marketing (newsletter 49.0 %), exhibitions and fairs dedicated to education (45.7 %) and also YouTube channel (49.3 %) are also very preferred.

Conclusion

According to Achimska (2016), in the current age of globalisation, we can observe rapid development and strengthening of the international economy, especially in the EU countries. Strenitzerova & Garbarova (2016) mentioned that The impact of globalisation and labour market development very closely relate to the human resource management and personnel policy of companies. It should be emphasised that the universities significantly affect the quality of the offered labour force in the market and thus also affect the value-chain of other entities on the market.

By creating a creative marketing communication, interesting for young people, universities could attract and persuade a larger number of applicants, even those who did not think about university studies. It is important to take into account expectations of students and engagingly them present information which is important for them in the decision-making process.

In order to improve the recruitment process, it is possible to define several recommendations, based on many surveys carried out in this area as well as current technological trends that affect the needs, thinking and behaviour of potential applicants for study.

- Thinking about why university wants to recruit the students is the very important part when designing its strategy. The reason why university makes recruiting is the primary goal concerning recruitment, and also one of core missions of communication. According to Richard Levin, executive director of enrolment services and university registration at the University of Toronto in Canada, thinking about what you communicate, to whom, and how, is the key to a successful student recruitment strategy.

- Think like students**.** The messages of the communication must be clear, consistent and authentic. It is necessary to communicate what students want to hear. According to many research, highly marketable aspects are e. g. vibrant student life, history, alumni and pleasant surroundings - so those are the kind of messages which should have universities in the recruiting process to communicate. Presentation materials in a classical or virtual form should contain an accurate picture of what university is like and what it would be like to study here. When we think as students, we consider the motivations that propel them forward – things like a desire for a better job, new challenges or new skills. Knowing these motivations means that we can proactively guide students through application, enrolment, registration, graduation and, ultimately, better job outcomes by communicating the best message to them at the best time.

  According to our research, the strongest motives of students for university studies are a greater chance of applying to the labour market (76.4 %) qualifying for the chosen field of study (65.7 %) and opportunity to gain new contacts or chance to extend student life. On the other site, the key criteria on the basis of which students choose a particular university are interested in a specific field of study (74.9 %), employers´ interest in university graduates (33.4 %) and results of various assessments and the ranking of the university (25.4 %). From these facts, it is possible to formulate a marketing message that could reach potential applicants.

  The results of a survey conducted on potential students in the Zilina region, also showed that the most important information in decision-making process for choosing a university is mainly the information about admission procedure, overview of study and subjects, graduate employment, study costs as well as the information about the satisfaction of current and former students and universities care for students. These are precisely the information that the Department of communications should focus on

and mention them not only on the website but also in other forms of promotion, whether in printed brochures or events dedicated to potential applicants.

- In a research study by Madleňák & Madleňáková (2016), another important fact is that advertising, marketing and commercial activities on the Internet are the most recent trends of the last years. Internet communication is often connected with social media and especially with social networks. This phenomenon can also be seen in the sphere of education. Madleňák et al. (2015) mentioned Nevertheless that students prefer this form of communication, universities do not exploit the potential of it sufficiently still today. Prospective students are keen to engage with their university through social media channels, but students are saying that universities don't make enough use of social media in recruitment, which meant they currently didn't expect or look for information about recruitment there. Today's prospective students want to make better-informed decisions and require a greater amount of information and engagement from a university. Students want to follow, friend, tag, pin. A positive, responsive and relevant social media presence does have the potential to convert prospective students into enrolled students. Anne Whitehouse, head of marketing at Bucks New University, said: "*Social media are useful at different stages of the application process. A prospective student may not use social media for initial research, but may engage with social media to help finalise their decision."* Social networks have become a powerful tool for marketing communications, especially among the younger generation. Young people attach great importance to social network communications. Their huge potential should be used by universities to recruit new students, who are necessary or even crucial for the existence of each university. The attractiveness of social media in the recruitment process also proves the results of the survey in the Zilina region, which revealed that this form of communication attracts up to 81.5% of students in connection with the university selection.

- The survey showed that demand for education is, despite all aspects, heavily regional dependent. This is evidenced by the results of the analysis of the applications filed on university studies at FPEDAS or Department of Communications, as well as the results of the survey conducted. Based on this fact, the Department of Communications should start and direct its marketing activities primarily towards students from the Zilina region. There appears the biggest chance to get the highest number of applicants for study. This argument can be generalised as a recommendation for other universities that are trying to recruit new students. The close location of the university to the hometown of students plays an important role in the university selection process. However, it is important to note that the university should develop its recruitment activities also in other regions and, of course, also abroad, because recruiting international staff has been a crucial part of recruiting strategy as evidenced by many surveys in the world.

- Among the most important tools for online marketing is an effective and intuitive **website** which should reflect the professionalism of the institution. According to the research, the university websites are very important information sources for students to obtain information necessary to select a particular university (80.6 %). This most important source of information is followed by an electronic prospectus, references from friends and acquaintances, advertisement emails and university fairs. Websites design and the interface is proving a crucial component in how colleges and universities present themselves to prospective students. According to recent analysis "Competing Globally" (Hobsons, 2013), the homepage is a key component in the student experience and can make or break decisions about whether to attend. A university's homepage is the hub of its web presence, and in attempting to appeal to a diverse range of visitors, the challenge is staying intuitive and uncluttered, because if the visitors have to go back to homepage every time to find the content, they aren't likely to stay on the website very long. Navigation on the website is an integral component of overall site architecture which all content can flow from. The homepage must be laid out the portal to all of the content that students are looking for online. Websites often feature elements and layouts to streamline and highlight content including navigation bars, engaging visuals such as slideshows, and prominent "call to action" buttons that encourage students to action. The website experience should be strong

and inspiring for the visitor. Nowadays is important to think of responsive web design to create intuitive and easy to navigate websites that can be viewed on multiple devices and platforms. Alongside the rise of mobile technology and connected devices, colleges and universities are making greater investments in having a mobile presence. This includes not only mobile versions of websites and other content but also making a greater amount of course content mobile-friendly. According to Al-Busaidi, KA. (2006) and Stenger, T. (2008), as far as technology is concerned, it may be advisable to focus attention on search engine optimisation, web analytics, newer methods of online and technology-enhanced course delivery and CMS and CRM systems. The use of e-learning initiatives in the academic institutions has been increasing in last few years. By combining these tools, it is possible to achieve significant successes regarding the visibility of the university websites as well as to increase the chance of reaching potential students.

- Face-to-face techniques, like Open Days and fairs, are still effective methods of recruiting students, but online and e-recruitment strategies are quickly becoming the most successful ways to engage with prospective students. A recent survey found that the most effective marketing strategies for universities are nevertheless events-based and involve direct interaction with potential students. Radio, television and print media were deemed least effective, while the most effective methods of outreach were open door days and campus visit days for high school students.

Universities should integrate a range of activities including traditional media, print, and information via internet, events and social media throughout all stages of the recruitment process. The goal is to get the balance right and to be ever close to students, and responsive to their needs. With each step of enrolment cycle, such as applying, making an admissions deposit, enrolling in class there's an opportunity for communication and outreach to that student to keep them engaged. For student recruitment strategies to work, it is critical that the university not relax once a student has been admitted and enrolled. Continued proactive communication ensures that they understand the steps needed to register for future semesters or on prepare for graduation.

Abstract

The purpose of this paper is to identify the aspects that relate to performance level; including enablers and inhibitors that influence performance in the healthcare sector of the Kingdom of Saudi Arabia (KSA). Viewed through this study, the effect of culture on the performance level in this important sector can be understood and new and integrated solutions to overcome potential negative outcomes. A grounded research methodology and an action research approach that was *'issue focused'* were used to gain the perceptions of the participants from the organisational culture as an empirical data. The overall trends observed in the collected data emphasizes the important role of culture in shaping performance level. In addition, the domination of factors related to the national culture and Islamic values has appeared the greatest factor affecting leaders' decisions; it also forms their relations with subordinates as well as their commitment to the organisation. Because of the chosen research approach, the research results may lack generalisability. Therefore, researchers are encouraged to test the proposed propositions further. The paper discusses the implications of the study findings for healthcare sector managers in different levels. This paper fulfils an identified need to study how culture can influence workforce practices in healthcare organisations and to what extent can that affect the quality of services delivered to the patients.

Keywords: Healthcare sector, Saudi Arabia, culture, Islamic values

Introduction

Saudi Arabia is a country in Western Asia covering an area of 900 000 square miles. In 2015, its population was approximately 31 million people, the number of Saudi nationals being 20.7 million (66.9% of the total population) with a 1.62% annual population growth, and its foreign population was 10.24 million - 33.1% of the total population- (Saudi General Authority Statistics, 2016). The healthcare sector of Saudi Arabia is currently working intensively on comprehensive development and modernisation in order to improve performance and deliver a better service (Albejaidi, 2010). In a previous study, Walston et al. (2008) indicated that factors that affect the service of this sector; the large percent of foreign workers and the high percentage of young people of the population.

As shown in Table 1, the number of hospitals and beds in the health sectors of the KSA has gradually increased over the past five years.

In a recent study, Yusuf (2014, p. 117) stated that "The increasing population and health expenditures are forcing the government to come up with considerable changes in the healthcare system". It is estimated that by 2020 the total number of people aged 60 and above will be over 2.5 million (Yusuf, 2014). This aging of the population will increase the demand for and expenditure on healthcare.

Factors found to be influencing healthcare services have been explored in several studies. For instance, Armit et al. (2015) suggest that health and social care services must be integrated in order to meet the needs of patients, service users and communities both efficiently and effectively. Health care has to be delivered by an interdependent network of organizations and this requires leaders to work together, spanning organizational boundaries both within and between organizations, prioritising overall patient care rather than the success of their component of it (Armit et al., 2015).

This should not really be surprising to anyone, how culture plays the key role in determines the direction of the organisation performance. Culture reflects what an organization values: quality, safety, productivity, survival, power, secrecy, justice, humanity and so on (West *et al.*, 2014). Furthermore, culture can be seen as a set of shared, taken-for-granted implicit assumptions that members of an organization hold and that determines how they perceive, think about and react to things (Schein, 1996). The organizational culture reflects the values of its employees. By using these values, the members are able to make decisions when they tackle problems, address issues and seek solutions (McLaughlin et al. , 2005). According to Bass and Avolio, (1993, p. 113) "culture can affect how decisions are made with respect to such areas as recruitment, selection, and placement within the organization".

According to Mellahi (2007, p. 88), "Saudi Arabia is governed by an Islamic monarchy in which Islam makes up the civil, cultural, economic, legal, political and social fabric of the country". The role of Islam as the first tenet of Saudi culture is largely established on the basis of the Qur'an (the holy book) and the Sunna (the sayings and practices of the prophet Mohammed, peace be upon him) (Aldraehim et al., 2012).

Methodology

This study was exploratory and interpretive in nature. Hence, a grounded approach was used in order to capture the perceptions of the participants from the organisation (Glaser, Strauss and Strutzel, 1968). The interpretive paradigm and grounded theory were found to be useful for this study, in enabling the

researcher to use individuals' perceptions and meanings in order to explore, explain and describe what was going on; they enabled the researcher to construct a theory that was grounded in the data collected (Corbin and Strauss, 2014). In other words, grounded theory facilitates the understanding of social reality, and lets the data tell their story (Strauss and Corbin, 1990). An appropriate method to gather aspects controlling performance in the field study was to use some issue (Sackmann, 1991) to encourage the participants to focus their attention on a specific action. A major advantage of this method as Sakmann (1991) claims, is that it enables both the surfacing of tacit components of culture and comparisons across individuals and research settings. This method helps researchers at this stage to understand the factors that influence the organisation's culture. Identifying those specific aspects that play the key role in a field study is essential for the subsequent research process.

Table 2: Research methodology

Paradigm	**Interpretivist**		
Research Approach	**Field Study**		
Research Strategy	**Grounded Theory**		
Research Methods	**Interviews (Issue focus)**	**Observation**	**Focus Groups**
Analytic Framework	**Grounded Theory (Open Coding, Selective Coding, and Axial Coding) – Textual Analysis**		

The fieldwork for this study was to 33 interviews as shown in Figure 1. Throughout the iterative steps in data collection, theoretical sampling was followed in this study in order to determine a certain level of saturation. According to Binder and Edwards, (2010, p. 241) "The researchers kept recruiting and interviewing research participants until no new data was produced that added new insights to theory construction or no new information … about the research topic".

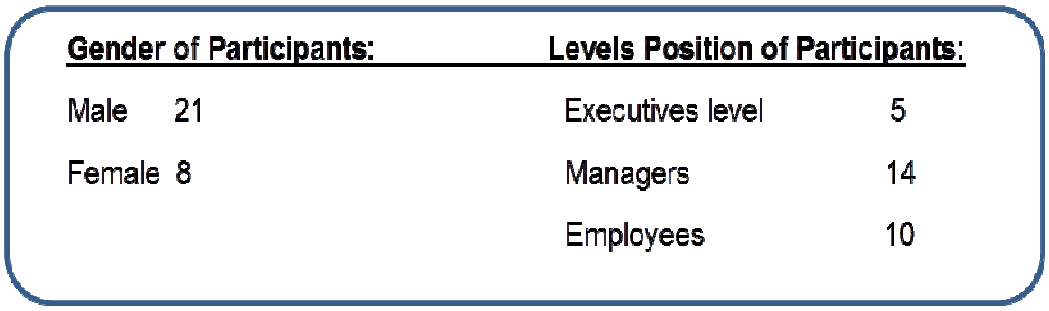

Figure 1 : participants' demographic

Face-to-face interviews took place between June and July 2015 as a first stage of data collection, lasting between 45 and 92 minutes each. Prior to data collection, the participants received an explanation of the purpose of study. All the participants approved audio taping and transcription, which produced a total of 675 minutes of speech and over 232 pages of transcripts. The interviews were conducted in Arabic, and then all the interviews were transcribed and translated into English. The major advantage of semi-structured interviews is that it allowed for a high degree of anonymity, and had a setting that encouraged participants to share their thoughts more openly.

The data management and analysis tool selected was Nvivo software. This qualitative data analysis package was used for the initial stages of coding and facilitated the coding and analytical processes. To ensure the trustworthiness of the findings and the accuracy of the coding, every response made, whether positive or negative, was considered. Data were collected over several months. Data were gathered from multiple sources at various time points during research process. Throughout the iterative steps in data collection, theoretical sampling was followed in this study in order to determine a certain level of saturation.

In the next stage of the study, Face-to-face interviews took place between December 2015 and January 2016, the participants were asked to take part in refining of the factors which emerged from the data analysed as shown in Figure 3. The data were analysed on an interview-by-interview basis. The open coding process took account of the transcript analyses line by line, word by word, and paragraph by paragraph. Cross-interview surveys then considered and compared data to identify which factors had emerged from the other interviews. In the final analysis of the findings, they were compared with those in the current literature. Constant comparisons with the literature and the collected data as well as the iterative steps of data collecting from the participants was carried out (Goulding, 2009).

The sample for the study is the health affairs of the Ministry of the National Guard in this country. The National Guard Health Affairs (NGHA) is one of the largest health organisations in the Kingdom, providing modern medical care to the employees of the National Guard and their families, as well as to Saudi nationals with tertiary health problems (Ministry of National Guard/Health Affairs, 2016). NGHA has also become well known internationally, especially with regard to the successful separation of conjoined twins; this is only one example of many high level services that have put NGHA at the heart of medicine in its own land (Geneva Health International Limited, 2016).

Results

This study provided an opportunity to advance understanding of the influences in this field study and assess how far it dominates current performance. 71 open codes had emerged in different occurrences as shown in Figure 4. The findings show that aspect ‘Islamic values’ is the most influential element in the performance of leaders and employees in an organisation, with the high frequency of 39, as shown in Figure 4. In addition, the current data highlight the fact that Islamic values affect the relationship between leaders and their subordinates and also their relationship with their organisation's environment. The second most influential factor appeared in this data was ‘fairness and equality’, with a frequency of 37.

The findings of this study pointed out the impact of ‘national culture’ on leadership performance, organisational culture and their effects in turn on employees’ job satisfaction and commitment. The frequency of this factor was 28, as shown in Figure 3. Furthermore, the study indicates that the

participants on the whole demonstrated that emotional intelligence, such as being human, honesty, initiative, cognitive skill and eagerness to develop play crucial parts as well in field study performance. Surprisingly, only a minority of participants indicated to the importance of factors such as Strategic thinking and sharing in decision making. In addition, 'Sharing in decision making' reflects the dislike of teamwork.

The main common factors among the findings were 'Combining human aspects with regulation', 'Fairness of the evaluation criteria', 'National culture difficulties', 'Openly communicating', 'Personal relationships', 'Personifying the work environment', and 'Tolerance'. The effects of these factors on performance, as shown in Figure 3, were different, scoring between 21 and 37. Other findings show how the relations between leaders and their employees can be affected negatively as a result of a decision that is taken by a leader which affects subordinates.

The study suggested that the relations between leaders and their followers need to be under the official supervision of the highest tiers of management. As number of interviewees suggested, this can provide a clear security system for both leaders and employees and protect their rights in the organisation. As one interviewee said, "Certainly, there should be something to protect and defend the employee if (sic) is right. There should be an agency to investigate the case in which an employee's evaluation is 99% and s/he does not get promoted".

One of the more noticeable findings to emerge from this study is the power of several factors which particularly affect performance in the healthcare sector of KSA; for example, help for some employees who has personal problems, Individualising employees' motivation, having moral criteria for employment, observing according to evaluation indicators, supervising the relations between managers and employees in the workplace and evaluating employees' mindset.

Number of Occurrence

Table 3 below displays the greater 22 factors that obtained from the analysis of the data and the frequency of their occurrence as well as the descriptions. These factors represent 30 per cent of the overall factors. These factors tend to be seen in the behaviours and aspects of the cognitive and interpersonal qualities of leaders. The study found that, a number of elements emerged as essential in shaping the aspects of workforce performance, such as Islamic values, fairness and equality and the national culture.

Table 3 : The emerged factors and its descriptions

Factor	Description	Frequency
1. Religious values (Islamic)	Religious values and beliefs that influence leadership thoughts, employee relationships within an organisation.	39
2. Fairness and equality	Ensuring impartial, or non-selective management of employees, but rather conforming to laid down organisational rules and policies.	37
3. National culture difficulties	Specific aspects of national culture which potentially affect performance improvement within the organization.	28
4. Tolerance	Broad-mindedness to employee mistakes, misbehaviours, and criticisms, allowing for gradual learning and improvements.	22
5. Personifying the work environment	Kind of conflicts that potentially happens between leaders and their employees as a result of discussing any mistakes which related to the workplace.	22
6. Openly communicating	Enabling direct and unrestricted exchange of messages or information between leaders and followers within an organizational structure.	22
7. Personal relations with some employees to help support their personal issues	Some employees keen on building personal relations with leaders as strategy towards easily attaining self-gains (promotions, external training, and other incentives) within the organisation.	21
8. Combined a Human aspect and Regulation	Perceived concurrent application of both social (human) and rule-based approaches could yield better employee output.	21
9. Appreciation	Acknowledging and according value to employee attributes, and (or) outputs.	21
10. Personal relationships	Building good interpersonal relationships with, and among employees is key to improving performance, and achieving a conducive working environment.	20

11. Human interpersonal relationships	Improving performance through building a good human interpersonal relationship among employees for a more friendly, and motivated workplace.	19
12. Undervaluing employees' status	Underrating and failing to appreciate the importance of employees in an organisation, likely to yield negative performance and outputs	18
13. Training	Sequence courses and activities imported into employees to build their knowledge, skills and competence for undertaking organisational roles and responsibilities.	18
14. Supervising the relationship between managers and employees in the workplace	A formal approved duty of a designated department in the organization, which will involve observing, assess, and manages the relationship between both sides to avoid relational frictions capable of affecting normal work within the work environment.	18
15. Applying Pressure	Exerting stressful requirements on employees as a second resort to solving problems, could sometimes bring about good results.	17
16. Interaction between leaders and employees	Mutual relations and interfacing between leaders and their subordinates within the organization.	17
17. Integrity	The quality of being honest, upright, and reliable. Having strong moral principles	17
18. Complaints	Complaints within organizations are inherent and critical, and should be treated with expedition in every work environment.	17
19. Capacity improvement	Employee capacity Improvement through training and education for knowledge and skills.	17
20. Solutions engagement	Being part of solution efforts to potential problems within the workplace.	16
21. Situational approach decisions	Leadership decisions depending on situation and personal dispositions.	16
22. Interpersonal skills	Leadership personal ability to relate easily and liberally, helping them manage their work while builds relationship with employees.	16

Comparison with the literature

The study findings corresponds with Bolden and Gosling (2006) who propose that leadership benefits by sets of components, such as the traits, qualities, skills, and behaviours which encourage the teamwork, development and commitment of others in an organisational environment. (Bass and Riggio, 2006) emphasises the importance of 'fairness and equality' within the successful organizations environment.

Significantly, National culture plays an important role to shape an individual's work ethic (Yousef, 2001). In a previous study, Hunt and At-Twaijri, (1996) claim that further aspects such as friendships and personal thoughts have given more attention from Saudi managers over performance and organisational objectives. Previous studies in this context confirm that the significant impact of organisational culture on worker motivation and organisational performance is widely acknowledged (Franco et al, 2002). Schein (2004) argues that culture is a perceptual structure of underlying assumptions that have been discovered, developed, or improved by a given group as the group learns to cope with its challenges of external adaptation and internal integration. Furthermore, culture has been defined to imply a set of shared, taken-for-granted implicit assumptions held by the members of an organisation, which determines the way that they perceive, think about and respond to things (Schein, 2004). This view is supported by Rees and Althakhri, (2008, p. 124) who write that the "Saudi Arabian culture is strongly affected by Islamic and tribalism systems". The concept of the Islamic work ethic (IWE) has its basis from the Quran and the sayings of Prophet Mohammed. In a previous study, D. A. Yousef, (2001) pointed out that Islamic work ethic has an strong influence on both committed to organisation and satisfied with the job. Additionally, Ali (1987), indicated in his study to the Islam as one of the most influential factors which have shaped Arab value systems.

While the data shown that only two of the participants believed the effect of 'Strategic thinking' on their performance, (Bass and Avolio, 1993) indicated to the important role of this factor and argue that "strategic thinking helps to create and build the vision of an agency's future" (p. 119). The literature also indicated certain other factors that do not appear in the field study findings, such as having public abilities and skills, matching job needs with employees' capability or talent and technical competence (Boyatzis & Boyatzis, 2008; Yukl, 2006; Hollenbeck, et al., 2006; Bass, 1990 and Riggo, 2006). Importantly, there are several factors in findings which demonstrate what affects leadership performance which are not shown to be important in the literature. These are; helping some employees to support them in personal problems, Individualising employees' motivation, Moral criteria for employment, Observation with evaluation indicators, supervising the relationship between managers and employees in the workplace and evaluating the employees' mindset.

Discussion

This study has investigated the effect of the culture influential on leadership style and practices, on job performance in Saudi's healthcare sector. The study shows that aspect 'Islamic values' is the most influential element in the performance of leaders and employees in an organisation. The results that individuals in field study investigated are highly committed to the Islamic work values are consistent with previous research (Rees and Althakhri, 2008; Yousef, 2000,2001; Ali, 1987; Mellahi, 2007). Associating the findings of this study with those other studies, Hunt and At-Twaijri (1996) indicated that the Islamic work ethic plays a fundamental role in the commitment of Saudi leaders toward their organisational tasks and with their subordinates. In a previous study, D. A. Yousef (2001) pointed out that Islamic work ethic

has an strong influence on both committed to organisation and satisfied with the job. Additionally, Ali (1987) indicated in his study to the Islam as one of the most influential factors which have shaped Arab value systems.

The findings of this study revealed that the influence of 'national culture' and organisational culture. Similarly, Yousef (2001) indicated to that the significant role of national culture to shape an individual's work ethic. Culture has been defined to imply a set of shared, taken-for-granted implicit assumptions held by the members of an organisation, which determines the way that they perceive, think about and respond to things (Schein, 1996). In addition, Hunt and At-Twaijri (1996) claim that further aspects such as friendships and personal thoughts have given more attention from Saudi managers over performance and organisational objectives. This finding is linked with Garrido-Franco *et al.*, (2002) who argued that cultural physiognomies can the influence organisational structure decision-making processes within organizations.

This study found that the domination of fairness and equality, which appears among the factors that most affect leaders' decisions; it also determines their relations with subordinates as well as their commitment to the organisation. The results in line with Bass and Avolio (1994) who indicated to the 'transformational leadership' characteristics with the application of certain values to create effective leadership is one of the deeply-held beliefs of leaders; these values include areas such as justice and integrity (Yukl, 2002). Such factors tend to be seen from the behaviours and aspects of cognitive, interpersonal qualities of leaders. The aspects all play a key role in a leader's abilities either to inhibit or enable their own performance improvement and the performance of the workforce. The participants on the whole demonstrated that emotional intelligence, such as "being human", honesty, initiative, cognitive skill and eagerness to develop play crucial parts as well.

Yukl (2002) also finds that attention should be paid to delegating authority to staff and improving communication channels between managers and staff. Furthermore, previous studies indicate to the key role of empowerment by management to enhance the employees' participation, productivity, satisfaction and commitment (Conger & Kanungo 1988; Malone, 1997; Lok & Crawford 2004). 'Appreciation' has significantly emerged from this study as an essential factor for motivating employees. This result consistent with (Yukl, 2002 and Christopher, 2013).

While the data shown that the minority of the participants believed the effect of 'Strategic thinking' on their performance, Bass and Avolio (1994) indicated to the important role of this factor and argue that "strategic thinking helps to create and build the vision of an agency's future". According to Volz-Peacock et al (2016, p. 319) "Foremost is the fact that organizations worldwide are faced with the growing challenge of increasing the capabilities of their leaders with less time and fewer financial resources"

Importantly, there are several factors in findings which demonstrate what affects performance in the field study which are not shown to be important in the literature. These are; helping some employees to support them in personal needs, individualising employees' motivation, moral criteria for employment, observation with evaluation indicators, supervising the relationship between managers and employees in the workplace and evaluating the employees' mindset. This result suggests that organisations in the healthcare sector can benefit by giving more attention to these aspects in the future. Personifying the work environment is another finding has revealed from this study, which shows how the relations between leaders and their employees can be affected negatively as a result of a decision that is taken by a leader which affects subordinates.

These results suggest that these new areas where further research would be interesting to be investigated in the future. Specifically, interesting topics for future cross cultural research. McAlearney (2006, p. 968) indicates to the important role of management in healthcare organizations, stating that "In healthcare settings, there is often little attention given to how improve management practice, increasing the likelihood that previous mistakes will be repeated". Moreover, the literature demonstrates that the current practice of planning and developing strategies in the health sector is one-sided and only from the top, justifying the view that the KSA needs to correct the direction of its health reforms (Al-Borie and Abdullah, 2013).

Conclusions and Implications

The research applies an interpretive approach to gain a deeper understanding and a clear explanation of the performance and practices in the Saudis' healthcare organizations. The findings suggest 71 factors that can inhabit and enable improvement of performance. These factors tend to be seen in the behaviours and aspects of the cognitive and interpersonal qualities. A number of elements emerged as important in shaping the development of performance, such as Islamic values, fairness and equality and the national culture.

Taken together, these results suggest that there is an association between the study findings and the literature in the vast majority of factors. However, one of the more significant findings to emerge from this study is the domination of several factors which particularly affect performance in the healthcare sector of KSA; for example, helping some employees to support them in personal needs, Individualising employees' motivation, having moral criteria for employment, observing according to evaluation indicators, supervising the relations between managers and employees in the workplace and evaluating employees' mindset. Reviewing the literature did not indicate clearly to the importance of these factors in particular in the development of performance. However, this result suggests that it would be interesting in future studies to investigate the influence of these factors on performance extensively in healthcare sector. Because of the chosen research approach, the research results may lack generalisability. Therefore, researchers are encouraged to test the proposed propositions further.

Abstract

The article is devoted to the adaptation of VaR (EaR) method for the risk evaluation of intellectual assets (digital images) portfolio. We consider this method as the case of dynamic metadata analysis. The distribution of portfolio earnings random variables in a long period is investigated giving the peculiarities of market sales mechanism of this asset class. Information on sales statistics across the assets in portfolio analyzed for the first time. The hypothesis on earnings normal distribution was approved with the aid of data time scaling. Risk metrics calculated with the historical simulation method were approved by additional evaluations with the Monte Carlo methods. The adapted methodology allows to rather accurately performing dynamic quantitative portfolio risk analysis applying different time horizons with required confidence probability.

Keywords: copyright asset, intellectual assets portfolio, risk, stochastic simulation.

Introduction

In this work we consider the intellectual assets portfolio as sufficiently extensive information resource which can be described with a few levels of metadata. Knowing these metadata allows to effectively solving some different problems, such as indexing, classification and searching as of separate assets and of their categories and groups. For this so-called descriptive and structural metadata are commonly used. Deeper metadata analysis allows us to solving more complex problems such as portfolio earnings and risk evaluation. To solve these problems it is necessary to utilize the administrative type of metadata on sales frequencies and sales earnings across the assets in portfolio. Actually these metadata belongs to special category of dynamic metadata considering the current temporal observation sequence. To perform the evaluations these metadata should be processed with the aid of certain special algorithms. In this study we adopt and apply the VaR (EaR) methodology to evaluation of "Earnings at Risk" metrics of intellectual assets portfolio.

Economic literature actually presents just a few works devoted to the portfolio analysis of intellectual assets. The first reason is explained by the lack of clear theoretical approaches to the economical analysis of that asset classes. Even the 'intellectual asset portfolio' conception not always adequately met in science media. Second reason is the deficiency of well systematized observation data. At last, the assets itself may be quite diversified, related to different industries (businesses) and regulations.

The financial engineering has collected some skills in the area of patent assets risk management. There are a lot of special financial intermediaries, who deal with the patent assets of high technology corporations. Namely for this reason the term Economics of Intellectual Property usually associated in literature with economics of patents. But the copyright assets are significantly differing, and there is very limited number of research works in this area.

First part of this article is devoted to methodological approach for the risk evaluation of copyright assets portfolio. In the second part we analyze the information on sales distribution across the digital images portfolio with renewed statistics of 2016. Third part shows the non-parametric approach for quantitative evaluation of risk metrics including stochastic simulation methods. In the fourth part we compare the evaluations made as by non-parametric and parametric methods. Summary and conclusions are in the final part.

Methodological approach

In our previous work we analyzed, at first, the peculiarities of financial models of microphotostock companies (Voronov and Ivanov, 2016). Secondly, VaR (EaR) method of financial engineering was adapted and applied for the risk analysis of digital images portfolio (Voronov, Ivanov and Darushin, 2016).

Parametric VaR (EaR) models for the risk evaluation of securities and foreign currencies usually consider normal or lognormal distribution of returns (Hull, 2011). However, there are no research works, approving this assumption for the earnings distribution in assets of our interest. Usually in those cases may be applied any non-parametric models, where the random value distribution may be found empirically. For example, the earning distribution curve may be plotted based on statistical observation data across the portfolio for the long period (historical simulation), or with the aid of stochastic simulation (Monte Carlo methods). These methods are popular and useful because the empirical data already contain all the information on random value (i.e. earning) distribution character and dynamics, and what is quite important – on correlation among assets. But the accuracy of these methods critically depends of the information sufficiency.

The VaR methodology was used in the loss risk evaluation for lending against high valuable fine art as collateral (McAndrew and Thomson, 2007). The historical simulation method was applied here for constructing the sales distribution of French Impressionists paintings brought to the biggest world auctions from 1985 to 2001. The most important conclusion authors made was that final hammer prices distribution for a long period is well similar to lognormal. From this we have got at least indirect confirmation of analogy with return distribution curves inherent to stock values and other financial assets. Also the distribution received by authors lies in positive zone (as our too) simply ‘since prices cannot be negative’. Our work also shows that due to the market mechanism peculiarities of selling assets, the earnings cannot be negative, and the right shoulder of the distribution is most interesting for quantitative estimations. As quite understandable, we began with non-parametric methods, considering that earning distribution automatically counting for mutual correlation among assets may be found only empirically (Voronov, Ivanov and Darushin, 2016).

Portfolio statistics

Initial data set for the sales of individual copyright asset was demonstrated in our previous article. Here for the first time we present sales distribution data across the portfolio at whole. Interesting, that our analysis confirmed some general features, characteristic to other intellectual asset classes (i.e. patents). Fig. 1 shows the distribution of sales numbers across the portfolio bins. In particular X-axis show that zero-bin contains assets, which had no sales at all. Next bin presents the number of assets sold from 1 to 5 times etc. In the Table 1 the same bins shown in percents.

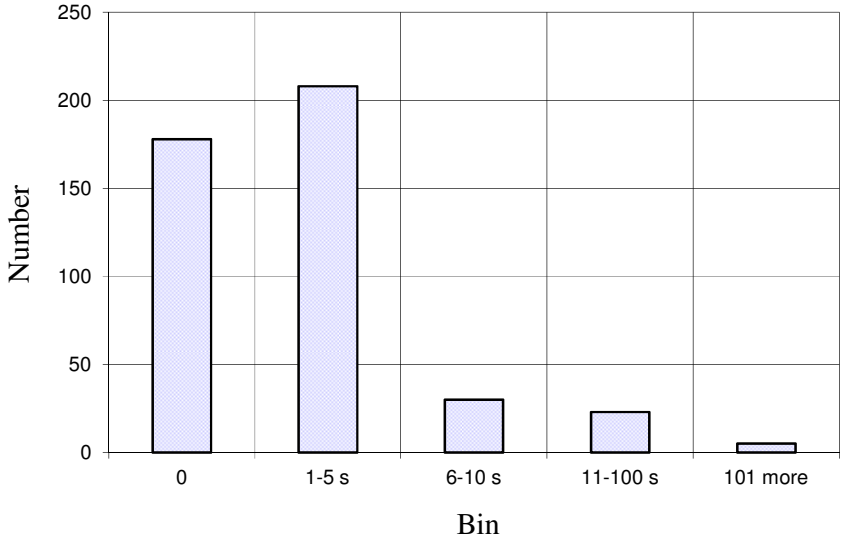

Figure 1: Distribution of sales numbers across the portfolio bins.

Table 1: Sales numbers across the portfolio bins.

№	Bins	Works number	% of total
1.	No sales	178	40,09
2.	Sold 1 - 5 times	208	46,85
3.	Sold 6 - 10 times	30	6,76
4.	Sold 11 - 100 times	23	5,18
5.	Sold 101 and more times	5	1,13
	Total:	444	100

The total distribution shows that about 40% of assets had no sales for all the portfolio exposition time (see Fig. 1 and the first bin in Table 1). During the same period about 50% of assets were sold just one time or at the best, from one to five times (see Fig. 1 and the second bin in Table 1). So, first two massive bins (summary 86,9% of total portfolio) contain assets, giving very small financial return, especially considering the prices on microphotostocks. By analogy with patent bases such assets usually called as 'ballast' (one can remember also the definitions like 'worthless patents' etc.).

The rest 12-13% images in three bins present the biggest worth as every one of them was sold tens and hundred times. However, let's note among them the worthiest, which in summary are just of 6%, but namely they brought more than 80% of total portfolio sales. Here we can remember the words of N. Myhrvold who said that just 1-3% of all patents generate a profit for their inventors (Myhrvold, 2010). More optimistic corporate and government evaluations usually not exceed 5-7%.

The last fifth bin of Table 1 is so attractive, that many microphotostocks exhibiting these works in special virtual galleries of most popular images, or so called 'records galleries'. These galleries are subject of especial interest of critics, analytics, authors-photographers and competing companies (Glückler and Panitz, 2013). They all try to understanding the reasons of every image success, revealing current trends of demand, and if possible, consider its all in their work. Quite often these images become the subject of serious artistic analysis. For this reason putting the image into the records gallery, at first, confirms authors certain creative level.

Secondly, record works performing some kind of signaling function, and may serve as sales activators as they involuntary attracting the attention of designers and other purchasers to the author's portfolio at whole. In its turn, raised attention potentially may improve the other images sales. We suppose this mechanism is quite realistic to revealing the effect of fuzzy positive correlation of this assets class in portfolio.

Some other kind of positive correlation may reveal in local groups of images united by common theme. We can connect it with the images, related, for example with great celebrations like Xmas or Easter. Designers beginning to purchase these images in advance, for a few months, considering production cycles and amounts of serial printed items (cards, calendars, package etc.). Knowing it, authors intentionally raise the numbers of images with needed themes. All this improves the sales activity inside local groups.

We already presented the sales statistics of one record work (S – image) from analyzed portfolio. By the end of 2016 its total sales increased up to 780 times, and total earnings exceeded $400. Renewed diagram on Fig. 2 gives a clear view on the sale rates for subscription and other types of sales (mostly On Demand). Corresponding rates of earnings, related to these types of sales are presented on Fig. 3.

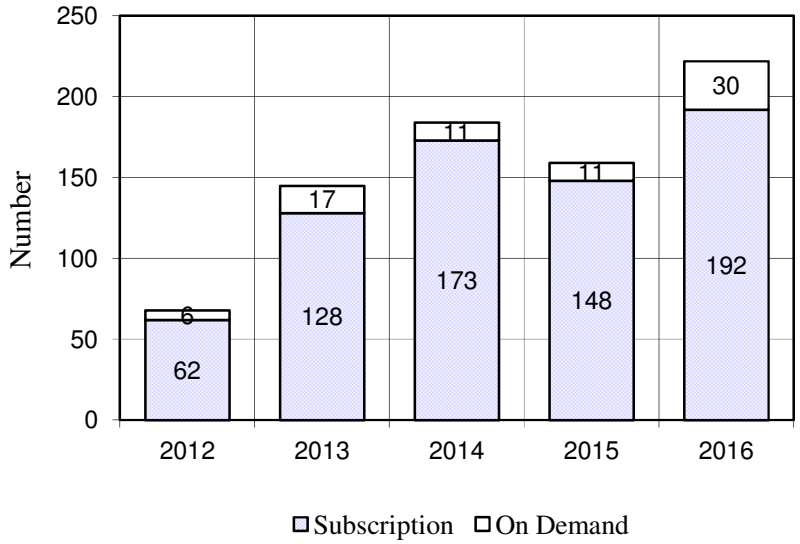

Figure 2: The number of sales of S-image in 2012-2016.

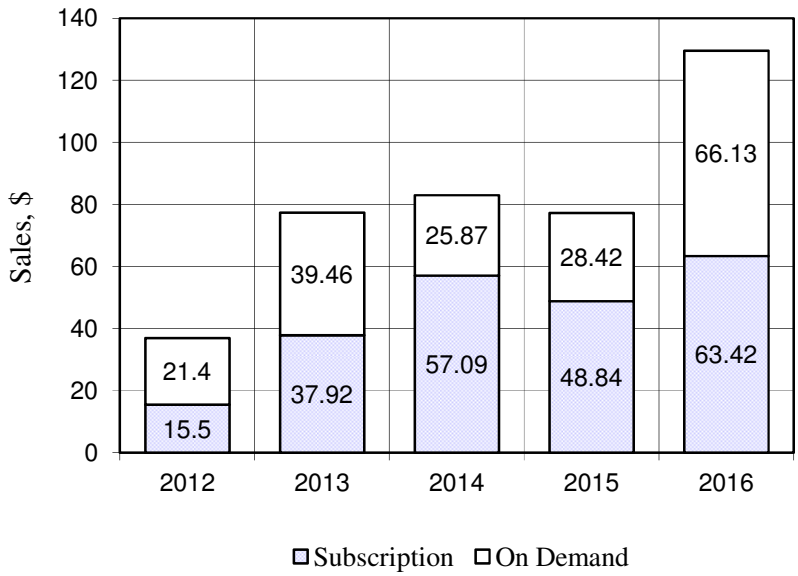

Figure 3: Sales revenue of S-image in 2012-2016.

As shown for this image, the average share On Demand in total sales is a little over 9%. On the other hand, due to higher price, sales On Demand make significant contribution to the total earnings over the same period. Their earning share for this image is about 46%, what is close to an average total value at Shutterstock (around 50%). It can be noted for this image, an average one tens share of sales On Demand yield almost half total earnings.

Non-Parametric approach

The first earnings distribution for our portfolio was received by historical simulation method. Scenario table was filled by statistical observation data with daily horizon and retrospective depth of 500 days. Initial observation data was used in rough type, i.e. without any kind of previous sorting. The first distribution histograms were visually bimodal, which is explained by different frequency and sales earnings in two categories of sales described above. The difference of these categories is well seen on Fig. 3. Rough histograms were distinctly asymmetric. Nevertheless these histograms were very useful in defining previous EaR metrics at a first approximation. It was done by the method of sorting the values of daily total earnings from all scenarios in ascending order. On the next stage the observation data was sorted in two price brackets and separate, more symmetric distribution was constructed for only subscription based daily sales.

This distribution data allowed calculating more interesting weekly forecasts. For this the observation data in sorted array was grouped so that every calendar week was presented by the single average value of sales revenue. Here is worth remember that in contrast to securities, asset trading of researched class goes on in e-commerce systems continuously 24 hours a day 7 days a week. For this reason our 500 days retrospective set is equivalent just to 72 weeks, unlike 100 weeks for securities market.

The new scenario table was constructed from the sorted data for 72 weeks, but now, every line in it reflected one corresponding calendar week. As on previous stage, scenario data was used to construct and analyze empirical sales earnings distribution renewed for weekly horizon. Different criteria testing confirmed this distribution as quite close to normal. Thus we have got a possibility, at first, to use the earnings expected values and standard deviations for the next stage – stochastic simulation by Monte Carlo method. Secondly, it allowed testing empirical evaluations in a classic parametric model and the same time – testing co called Square Root Rule (SRR) for time scaling of risk metrics.

In the first version of stochastic simulation the parameters of normal distribution of sales earnings were used to programming the random numbers generator of MS Excel tools. In fact, the random number parameter, tuned in this generator allows to programming the depth of retrospective in historical simulation. We need just consider which namely horizon to be modeled. For our weekly horizon every one scenario corresponded to one certain calendar week.

By the aid of this generator we have performed few series of ten tests with different scenario number and normal distribution preprogrammed. Then we founded percentile values for confidence probabilities of 99% and 95%, maximum and minimum random values, and other parameters to average data in each series and plotting required histograms. The distribution typical to stochastic simulation methods with sufficient scenarios amount is shown on Fig. 4. In particular, our histogram for 1000 scenarios and weekly observation horizon shows nearly quite conformity to programmed kind and parameters of normal distribution, and risk metrics found by previous method differs no more then for 2-5%.

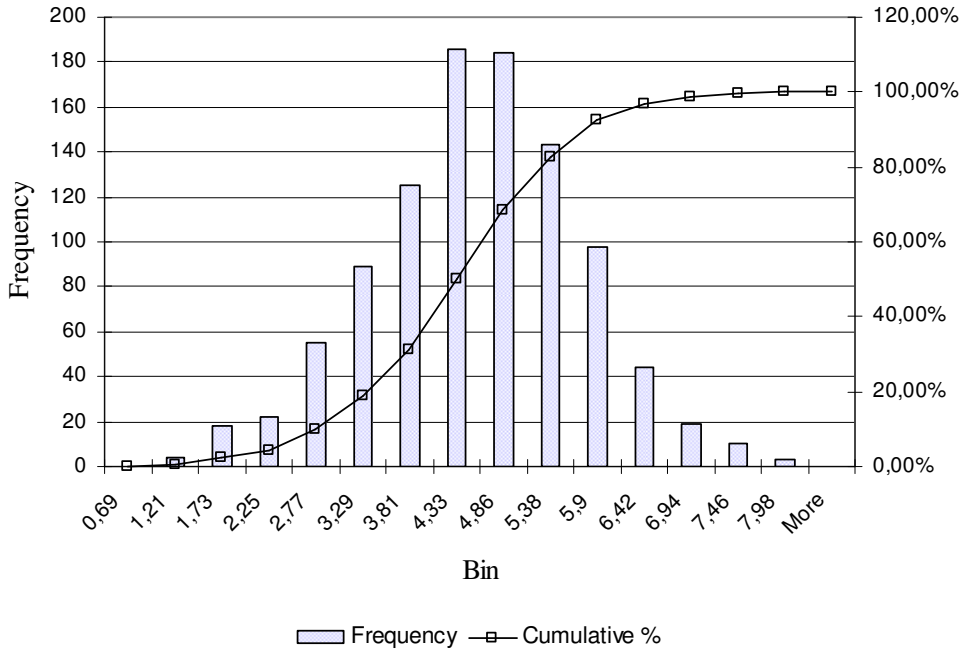

Figure 4: Stochastically simulated random earnings value distribution for 1000 scenarios and weekly horizon.

Nevertheless, as frequently noted in literature, the real market returns of financial instruments show systematic distortion from normal distribution (Hall, 2011). Actually all liquidity market empirical returns distributions show more excessive histograms with fat tails, than should be for normally distributed values especially in short periods. To consider it and modeling distribution maximally closer to empirical one, we tried next version of stochastic simulation known as Bootstrapping. In this version the standard of random number distribution is not programmed a priori, and the distribution itself is constructed based on full set of historical data. During each testing the special algorithm makes so called resampling, i.e. takes values from initial empirical distribution. The result is more accurately simulated fat tails and peak values, quite comparable with empirical distribution. For example, on Fig. 5 we show the histogram, which expected value and standard deviation equal to the same, used in classic algorithm, but strict difference is seen in tails.

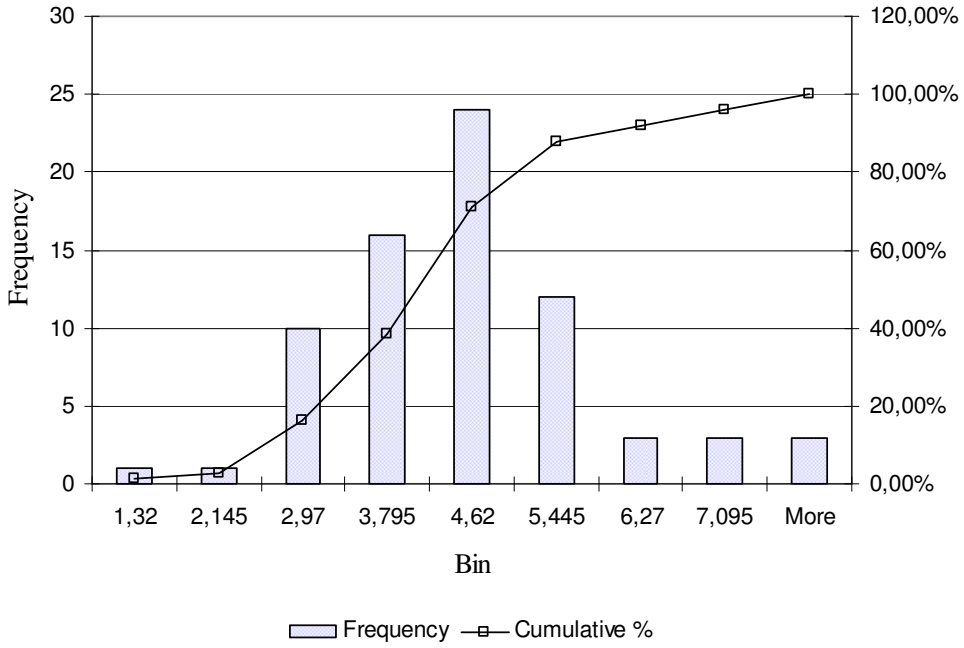

Figure 5: Random earnings value distribution stochastically simulated with resampling procedure.

Thus, more precise risk evaluations made with different non parametric models show close conformity. Worth note, it was made just after the normal distribution of earnings random numbers was approved for longer, weekly horizons.

Parametric approach

Approving the previous distribution as normal allowed us to apply parametric models for the risk evaluations as well. As the earnings expected values and standard deviation were previously received by processing our initial data, then we could compare risk evaluations made as by non-parametric and parametric methods. In this work we assumed that the standard deviation measure for our case is the same as for earnings value per portfolio and defines a certain standard root-mean-square interval of random values, which is symmetric for an expected average earnings value (Siegel, 2011). Based on received earnings expected values and standard deviation, giving the confidence probability levels of interest we received the risk metrics, differing just for 5-8% from the evaluations made by non-parametric methods.

The result was much worse when we tried to time scaling of risk evaluations by standard Square Root Rule (SRR). The first reason of this is that daily (short horizon) distribution of random earnings value is not quite normal (Voronov, Ivanov and Darushin, 2016). Secondly, this approach at whole hardly conforms the economic sense of price risk, as the risk value in SRR for the long horizons always equals the daily value multiplied by some numerical constant (Ivanov et al., 2016). Our calculation show that risk metrics made by the SRR may differ up to 30-40% of empirically received numbers.

Summaries and Conclusion

The goal of this work is to further developing methodology of intellectual assets risk evaluation. On this stage next tasks were performed. First, the background data set for the risk analysis of researched portfolio was substantially renewed. For the first time we presented the quantitative analysis of sales

distribution across the assets in portfolio. Previous assumptions on possible mechanism of correlation among these assets are discussed.

Next, initial data subjected to time scaling were used to stochastic simulation of earnings distribution. In the first version the earnings random value scenarios were produced by the random number generator based on fixed expected values, standard deviations and normal distribution function. Then the risk metrics for the corresponding confidence probabilities were found. In the second version of stochastic simulation we applied statistical bootstrapping method. The risk metrics performed in previous and present works were compared with the calculations by simple parametric model and also used to testing Square Root Rule commonly used to time scaling.

Thus, our empirical analysis approved by further evaluations confirmed that dynamic metadata processing allows to accurately forecasting 'Earnings at Risk' metrics within different time horizons and confidence probability.

Our further work will include the modeling of major aspects of intellectual assets portfolio metadata and providing a semantically defined representation of dynamic portfolio risk metrics.

Abstract

We suppose that enterprises are run by competent managers who have a clear vision, knowledge, good will, and they are able to achieve it. Competence of managers is a prerequisite for the development and efficient utilization of the funds invested in the realization of the products demanded by the market. Successful fulfilment of this goal depends on the ability of managers / owners to acquire exploit and develop all enterprise resources, including human resources. Human resource management is the reflection and outcome of managerial work. It is not enough to highlight the importance of employees, it is important to look for them, to support those who are strategic and high performing for the enterprise. It is thus essential to create an environment that motivates employees to work better and change their behavior. Verification of the above axiom will not be undertaken without conducting a survey that moves our considerations on human resource management further. The aim of the paper is to present the views of domestic and foreign experts on the importance of human resources in management processes, to recommend best practice approaches in the management of successful enterprises. Theoretical knowledge is the subject of comparison with the results of sociological inquiry in a questionnaire made in 2017 with 381 respondents responsible for personnel work in selected enterprises in Slovakia. The result of the study is the proposal of the personnel work system in enterprises.

Keywords: human resources, processes, management system, human resources management.

Introduction

The recognition of employees with their knowledge, skills, experience and work motivation as the most important source of enterprise existence and development is the basic attribute of human resource management. We consider human resource management to be an integral part of the management work of each manager (Vetráková et al. 2011) just like Kachaňáková (2001), Koubek (2007), Storey (2007), Rogers (2011), Armstrong, Taylor (2015), Wilton (2016) and others do. Human resource management is characterized by the application of a strategic approach to management, it focuses on the external factors of the work and formation of the workforce, stresses the commitment of the employees of the company, applies a complex and internally interconnected system of mutually supportive employment policy and

practice, emphasizes a strong corporate culture, performance and employee development, prefers transparent remuneration taking into account executive and competent employees. Employee relationships are based on high confidence; teamwork, management decentralization, creativity, flexibility and customer orientation are encouraged.

One of the main reasons for examining the importance of managing human resources in Slovak enterprises is to determine whether systems, established policies and procedures are designed to create and maintain a high level of employee engagement and performance. This idea is also supported by examples of best practice in human resource management (Hinkin, Tracey 2010), which are based on the assumption that there are universally applicable practices for employee work guidance to improve the performance of an enterprise. On the other hand, "best fit" approach (Šikýř, 2014) highlights the need to adapt the principles and practices of personal work to the specific situation and conditions in an enterprise. Anyway, both approaches highlight the importance of human resources in achieving business performance.

Managers' orientation towards employees as human resources points to their excellence, especially the ability to bring higher added value to their basic value. Only people can find ways to discover something new, find, create and utilize technology and other resources, increase quality or improve management. Some experts (Bach, 2005; Drucker, 2012; Prescott – Rothwell, 2012; Hitka et al., 2015 and others) support the opinion that technology can be bought and funds can be borrowed, but it's nothing valid unless there are productive employees identified with the objectives and intentions of the enterprise.

The implemented management system is effective if it creates an environment in which employees want to work, they know what to do, what the expectations are and what their rights and responsibilities are. The established system (Armstrong, 2007) is not a guarantee of employee satisfaction, if managers and employees are not aware of the reason for its initiation; no personal activities (processes, functions) and responsibility for their implementation are determined; there is a lack of procedures and standards of personnel work; employees are not informed about the possibilities of participation in achieving the objectives of the enterprise and their subsequent stabilization. The personnel work system includes all personnel activities that are associated with the employment. It means:

- identifying and selecting qualified and competent employees (job analysis, human resource planning, searching, selecting and recruiting) and releasing those who are unable to perform at the expected level and behave properly,
- providing work assignments (human resource strategy and policy, adaptation, education and development, work motivation, employee and job evaluation, HR services, PIS services, personnel controlling, human resources audit),
- retaining competent employees (career development, talent management, work performance management, remuneration and employee benefits, occupational health and safety, employment relationships, employee care, internal mobility).

In addition to system approach, the description of elements (activities) of personnel work through functions and processes can be found in the human resource management theory. According to Hittmar – Veselý (2011), this term results from the mission and the purpose of human resource management. Personnel activities, that take place on a regular basis, meet the attributes of the process because inputs (resources) are transformed into outputs in accordance with the needs of the employer and/or the employee.

We believe that it is not essential to designate elements of a human resource management system through personal activities, processes or functions. The differences in conceptual designation of human resource management elements stem from selected approaches and insights into personnel work and are related to

the scope, significance, and periodicity of the performance of the work activities. They take into account the system, process, and functional approach of exploration. It is essential that every human activity, the process, must be planned, organizationally, financially, materially and personally secured, continuously controlled to demonstrate functionality and justification. The result of investing in human resource development is to increase the competence of employees at the workplace and, above all, to increase the performance of the enterprise. If business management applies appropriate human resource management practices, it can influence work performance and thus the performance and stability of an enterprise.

Material and Methods

Personnel work has undergone significant changes after 1989 generated by the transformation of the economy and the democratization of society. During this period, a new generation of managers and other employees able to work in a market environment and multinational companies was formed. Experience in managing the market economy, new forms of work organization are used not only by multinational but also by local enterprises. Occupational management practices, traditional organizational structures are gradually changing. Employing an enterprise is no longer life-long process. The importance of human resources and their management in the enterprise is declared. Validation of the above mentioned axiom is the subject of sociological inquiry that has been conducted since 1997. We are interested in the procedures and principles of employee selection, training and development, their evaluation and motivation connected to performance. While examining this, we assume that progressive human resource management practices are applied in most of the surveyed enterprises. Sociological questionnaire survey in 2017 involved 381 businesses, 88% of which operates in the private sector and 12% in the public sector.

Table 1: Size of surveyed enterprises

Sector	Number of employees				
	< 10	10 - 49	50 - 249	> 250	total
private	85	99	80	73	337
public	2	11	24	7	44
total	87 (22.89%)	110 (28.95%)	104 (27.11%)	100 (21.05%)	381 (100%)

There is a more balanced representation of enterprises in the private sector with the predominance of small enterprises (54.6%), while in the public sector there are enterprises with a number of employees from 50 to 249, which corresponds to the structure of private and public sector enterprises. The size of enterprises according to the number of employees is characterized by the level of personnel work. It is expected that the level of personnel work is higher in large enterprises comparing to the small and medium-sized enterprises.

Personnel work in surveyed enterprises is mainly in responsibility of HR (37.1%), economic department administrators (31.3%), owners (29%) and senior managers (16.8%). Its realization, especially in small enterprises, is in the hands of line managers (5.5%) and assistants (3.42%). There is a compliance between the size of the enterprises and the professional running of human resource management. In the surveyed enterprises (73.42%), mostly apart from other work, the individual processes of personnel work are carried out by one employee (46.58 %) and two employees (26.84 %). The emphasis on personnel work is increasing in enterprises with a larger number of employees, where the workforce is divided between 5 (5.79%) and more employees (12.11%). On average, three (5,79%) to four (2,89%) employees participate in individual work activities on average, especially in medium-sized enterprises.

The questionnaire was created both in printed and electronic form and contained 24 questions related to human resource management processes. The data were obtained from human resource departments or employees responsible for personnel work in the enterprise. We have gained the views of managers and/or human resource administrators on management processes through personal meetings with the use of trained surveyors. We were also interested in the most common personnel work problems and possible proposals for change. The survey was evaluated by applying descriptive statistics using the Microsoft Excel software.

Results and Discussion

The survey conducted in 2017 revealed different findings that affect the most common problems of managers with the implementation of personnel work, compared to sociological inquiries in 1997 and 2009. According to the majority of respondents (77.16%), there is a shortage of qualified job seekers and employees who are willing and able to work. Insufficient job discipline and communication, falling reliability and accountability, dissatisfaction with remuneration, increasing employees' demands are reflected in declining employee performance and increasing fluctuations. Instead of conceptual questions of personal work, managers have to deal with everyday work problems. The order of importance of human resource management processes according to managers is as follows (in%):

Selection of employees	90.79
Recruitment and adaptation of employees	86.58
Training, development	82.63
Welfare	79.47
Performance evaluation and management	79.21
Personnel administration	78.16
Optimization and planning of employees	71.84
Work analysis	56.05
Redundancies	51.58
Creating strategies, policies and plans	49.74
Personnel controlling and auditing	41.58
Job evaluation	36.32
Talent management	17.89

We have identified responsibility for various human resource management processes, and the survey has shown that top managers and human resource managers are mainly responsible for generating strategies, policies and human resource management plans, placing the employees, performance management and evaluation. Human resource departments and people responsible for personnel work are more concerned with administrative, methodological and analytical activities in management processes. The work of human resource administrators is facilitated by a functional personal information system. From an economic point of view, there is an efficient self-service personal information system, which is used by 20.53% of respondents.

Outsourcing enables enterprises to concentrate on core business activities and the other ones can be done by external experts specialized in personnel work. Nevertheless, only 26.84 % of respondents have a positive experience with outsourcing in personnel work and 6.05% have negative experience while 67.11% have never used outsourcing services. Outsourcing is mostly used in recruiting process and in organizing thematically oriented training.

Efficiency of personnel work by personnel control is assessed by 41.58% of enterprises. Operative controlling (36.05%), in particular indicators, statistics and standards of personnel work, are the most significant.

The effectiveness of other human resource management processes depends in many respects on the professionalism of employee selection, adaptation to the work and social environment of the enterprise. The most popular way to attract job seekers in the surveyed companies is to advertise electronically (63.16%), through friends and acquaintances (59.74%), direct address (34.24%), printed advertisement (32.89%). There are 28.16% of applicants from the Labor and Social Affairs Office and 18.42% of the respondents.

An analysis of the jobseeker's file is the basis of each selection procedure. In practice, it is used by 80% of respondents. Other unstructured (47.37%) and structured interviews (43.68%), expertise testing (34.47%), competence testing (31.32%), personality testing (16.32%) and intelligence testing (8.16%) are used. The use of the diagnostic method of complex evaluation of the candidates, called assessment center, was reported in 6.32% enterprises. Managers pointed out the need to improve the techniques of staff selection and change of adaptation. They recruit employees without complicated competitions and the statutory adaptation period, if necessary to fill a position, especially during the season. The reason is to ensure the operation mainly in shops, services and production.

All the businesses under review reported experience with the job descriptions and specification of the employee requirements. What is different is the level of job descriptions, the definition of job contents, because they focus on the overview of work responsibilities (83.16%), the purpose of the work (78.95%), the responsibility (72.37%) and the demands on work performance (58.16%), less attention is paid to work tasks, the use of resources and tools at work, workplace facilities, communication and collaboration with other people, job profiles and competencies. 28.42% of enterprise with the number of jobs up to 50 report the work descriptions and other documents of personnel work, 48.68% of respondents with a structure ranging from 91 to 100. The specification of the requirements for the employees and the knowledge of the job description are essential for the execution of the personnel work.

The work success rate is a work performance characterized by the results of the work and the behavior of each individual. 25% of enterprises have introduced a system of performance evaluation and management. There is an informal assessment (43.95%) based on employee observation at work and a combined assessment (31.05%) conducted as needed. In the context of the evaluation process, we reviewed the regularity of the assessment and found that 21.58% of managers rated employees by monthly performance, which can be considered as a monthly wage, once a year (24.21%), half yearly (13, 42%), quarterly (9.21%) and irregular or not at all 31.58%. The results of the evaluation are mainly reflected in remuneration (78.68%) and education (42.11%).

Table 2 : Impact of evaluation results on human resource management processes

Processes	Sector (%)		
	Public	Private	Together
Remuneration	80.95	61.36	78.68
Training and staff development	41.07	50.00	42.11
Deployment of staff	26.79	18.18	25.79
Personal planning	19.35	22.73	19.74
Analysis of jobs	17.86	18.18	17.89
Others (employee care)	0.89	0.00	0.79

While employee assessment focuses on work performance, management focuses on what and how to achieve it. It emerges from the findings that 75% of enterprises do not notify their employees with the tasks and goals they are intended to achieve and do not create an incentive environment that promotes compliance of responsibility, behavior, competencies and capability with expected employee

performance. Evaluating and managing performance is predominant in financial terms. Employees, their performance is usually examined only if staff costs increase and labor productivity decreases. Long-term declines in the work of individuals lead to a decision to reduce the number of employees. This measure does not systematically result in the stabilization of executive employees and the long-term development of the company. A more effective measure is the internal restructuring of all processes and the adoption of measures to implement and operate the system of work with human resources.

A well-established system of personnel work reflected in all processes will increase the level of human resource management, but it does not mean that it will also solve all the problems of employers in gaining and stabilizing quality workforce. One of the tools of stabilization is to support employees in their education and development. From the survey, we found that the amount for education in 2016 increased to 42.37% of enterprises. The average amount per employee ranged from 0 to 100 € (68.95%) and from 101 to 200 € (31.05%). Classical methods prevailed in education, namely lecture (60.79%), instruction , (48.95%), model situations (27.63%), as well as coaching (31.58%), e-learning (19.21%) and role play (5.53%). 51.84% of the managers reported their support for the training. At the same time, we were interested in the managers' view of the conditions under which it is possible to characterize the talented employees who are the most valuable source of the company. According to the replies, highly valued is the employee with the long-term high performance (36.58%), the key job holder (26.05%), the employee with the potential for future growth (16.05%), the long-term stabilized (12.89%), loyal (5.79%) and an employee who knows what to do, is able, inventive and has the potential for progress (3.42%).

The survey showed that human resources management has impact on the achievement of the company's results (63.22%). With the current workforce system, 33.3% of managers are satisfied and do not think of any changes. The positive finding is that 66.7% of managers want to improve the atmosphere and workplace communication, streamline the adaptation process, expand the education and awareness of employees, change the quality of working life towards employees, look after employees more, place emphasis on increasing control workplace, reduce fluctuation and stabilize executive employees, implement examples of good practice for domestic and foreign companies, more motivate, improve the search and selection system, introduce a more efficient way to evaluate and manage work performance, develop a human resource management strategy, and introduce personnel control.

Conclusion

Despite the declared importance of human resources for gaining success and competitive advantages on the market, the personnel work in the conditions of Slovakia does not receive the declared attention. Managers and business owners focus on material, technical and financial security, and underestimate care for the acquisition, development and utilization of employees' potential. They do not realize that it is the level of personal work that distinguishes the best and most successful businesses from the others. Employees are looking for businesses that have a reputation and are financially stable. On the other hand, not every employee belongs to those who perform the expected performance. Based on foreign studies (Branham, 2009), according to work performance achieved and access to duties and work, employees are ranked in top-performing (about 10%), high-performance (20-30%), with stable average performance (40-50%) and with low power (15 - 20%). From a stabilization point of view, it is important to find a way to keep executive employees. This will be done if the processes and processes of human resource management are transparent and established. Excluding staffing exceptions, different rules, and maintaining low-performance employees are detrimental to work ethics and discipline.

Abstract

The paper aims to contribute at the debate on disruptive innovation theory by focusing on the knowledge intensive entrepreneurship as key process to address the technological development towards innovation in the market and society. Framed into a neo-schumpeterian stream of research, the paper offers a theoretical contribution at the comprehension of the disruption innovation associated to the diffusion of key enabling technologies as pervasive and knowledge intensive solutions impacting on the current structure of market and society. Furthermore, the study contributes to the debate on knowledge-intensive entrepreneurship as driver of the knowledge-economy and core process to address the knowledge advancement on technical domains into valuable innovation. The study offers an original contribution at the contextualization of disruptive innovation theory on those knowledge intensive and pervasive technologies while implications for policy makers are identifiable into the deepen comprehension of the meaning of knowledge intensive entrepreneurship as driver for the competitiveness of regions and national systems.

Keywords: Knowledge-intensive entrepreneurship, Key Enabling Technologies, Disruptive Innovation, Technology-driven Entrepreneurship.

Introduction

The disruptive innovation represents one of the most debated topic in the field of the innovation management (Schmidt and Druehl, 2008; Markides, 2006). Since its first theorization by Clayton Christensen (1997), the theory of disruptive innovation has attracted scholars and researchers aimed to comprehend the ways, the measure and the reasons at the basis of the disruptiveness caused by innovation (Schmdt and Druel, 2008). The primary definition of Christensen (1997) focused on technology as disruptive element impacting on products and processes, but it is in 2003 that definition of disruptiveness embraced the innovation in its larger definition of services, business and organizational models (Yu and Hang, 2010). The theory of disruptive innovation has so been used to explain the different forms of innovation by losing the primary focus on technology and causing a misunderstanding in its conceptualization (Markides, 2006; Danneels, 2004). The focus on the technological perspective assumes a new challengeable dimension at the light of the new knowledge-intensive technologies, also defined as Key Enabling Technologies (KETs), which are causing radical innovation in market and society. Those technologies have been identified into the Micro-nano electronics, Nanotechnology, Advanced Materials, Photonics, Industrial Biotechnologies and Advanced Manufacturing Technologies (EC, 2009). All them are characterized by cross-industries profiles of application; their pervasiveness is determining rapid innovation cycles and calls for continuous updating of competencies at both at individual and organizational level (Romano et al., 2016; Foray, et al., 2011). Their usage is nurturing a highly skilled employment demand and presents large potentialities in for the socio-economic development of society, in reason of their contribution at the solution of societal and market needs.

All this highlights the need of a deeper comprehension of the disruptive innovation theory based by KETs as well as to identifying the drivers able to sustain their full exploitation of creating sustainable innovation in market and society. In a neo-schumpeterian view, technologies are the determinants of the profile that characterizes the society. Accordingly, the knowledge intensive nature of KETs suggests the knowledge-intensive characterization of the current socio-economic context as well as its definition of entrepreneurial economy (Audretsch and and Thurik, 2001). This evidence suggests the need of new interpretative and organizational models able to manage the potentialities of KETs as well as to make possible their full exploitation towards the sustainable innovation.

Framed in the above premises, the paper intends to contribute at the debate on disruptive innovation theory by focusing on the knowledge intensive entrepreneurship as key process to address the technological development for innovation in the market and society (Malerba, 2010). Accordingly, the paper aims to shed new light on the comprehension of the disruption innovation associated to the diffusion of KETs. The comprehension of the disruptiveness associated to the KETs is in this paper strictly linked to the knowledge-intensive entrepreneurship. This is because it is the entrepreneurship to make possible the full exploitation of KETs and to address the advanced technical know-how into valuable innovation (Romano, et al., 2016; Romano, et al., 2014; Foray et al., 2011).

Accordingly, the paper is structured as follows: the first section presents the KETs as enabling factor of the configuration of the knowledge economy as entrepreneurial economy; the second section provides a synthesis of the literature on disruptive innovation aimed to comprehend how KETs can be assumed as elements for disruptive innovation; the third section presents a conceptualization of the knowledge-intensive entrepreneurship as strategic process for exploiting the potentialities of KETs and to create valuable disruptive innovation; finally in the conclusions the main features and implications for theory and practice are highlighted.

1. Key Enabling Technologies and Entrepreneurial Economy

The social and economic systems are currently interested by several structural changes due at the impact of technological knowledge. The process of advancement of knowledge in the different technological domains is experimenting an exponential growth; its intensity is increased by the ubiquity of information made available by the Information and Communication Technologies (ICTs). In accordance to the so-called “structuralist-evolutionary” model and in the frame of the neo-schumpeterian research streams, the economy can be conceived as an expression of its technologies (Arthur, 2009, 1999; Lipsey, et al., 1998; Schumpeter, 1934). This means that changes occur constantly over time as far as the technologies evolve and that the characteristics of society in a certain time will be depending by the nature of technologies of the present (Romano et al., 2013). The process of technology evolution impacts and transforms the present economic structures by causing a process of continuous destroying of the old schemas to create new socio-economic scenarios (Arthur, 2009; Schumpeter, 1934). The technologies of our days can be identified into a wide large family of knowledge-intensive and pervasive technologies. Also defined as key enabling, they have been classified by the EC (2009) into the Micro-nano electronics, Nanotechnology, Advanced Materials, Photonics, Industrial Biotechnologies and Advanced Manufacturing Technologies. KETs are the main forces behind the structural changes characterizing the current socio-economic scenario. These technologies present a knowledge intensive profile; their pervasiveness is determining rapid innovation cycles and calls for continuous updating of competencies at both at individual and organizational level, by nurturing a highly skilled employment demand (Romano, et al., 2016; EC, 2009). In an analysis performed by the European Commission, the economic impact of KETs in global market is estimated to be more than EUR 1 trillion by 2015. According the European Competitiveness Report (2013), KETs will generate a trend of growth of 10 – 20% per year. This is expected to generate new employment opportunities, to reinforce firms’ competitiveness and to achieve reindustrialisation, and to create sustainable and intelligent industries.

The knowledge intensive nature of the aforementioned enabling technologies is one of the elements at the basis of the characterization of the current socio-economic context as knowledge economy (Arthur, 2009; Romano et al., 2014, 2016). In this context, the competitiveness of individuals, organizations and regions results to be more and more depending by their knowledge assets as well as by their attitude to merge internal and external knowledge contributions (Lerro & Schiuma, 2013). In this scenario, technical knowledge related to KETs is assumable as the most strategic asset (Arthur, 2009).

Several studies have attempted to describe the main characteristics and trends of the knowledge economy, also through its comparison with the economy of the certainty and stability, typical of the last century and classified as managed economy (Romano et al. 2016; Secundo et al., 2016; Audretsch and Thurik, 2001). The managed economy has so been described as based on the intensive usage of the labor, capitals and natural resources. All these assets are limited in their stocks and not renewable; this makes the managed economy subjected to the law of decreasing returns (Romano, et al., 2014; Audretsch, et al., 2006). Knowledge is instead a renewable and appropriable resource, that grows exponentially respect to its usage. This is sufficient to comprehend that the knowledge economy is governed by the law of the increasing returns. In terms of innovation attitudes, the managed economy focused on continuity, the search for incremental innovation, trajectories of competencies and technological development oriented to the compatibility with existing firms' and industry's equilibriums. The knowledge economy is instead grounded on the radicalness of the innovation, on disruptive paths of competencies and technological development (Asheim & Coenen, 2005).

The demand and offering of products and services in the managed economy has been characterized by stability and homogeneity, and firms' competition was based on specialization. While, in the knowledge economy, turbulence and diversity are the main features of the external environment that calls for firms to promptly and continuously reconfigure (Audretsch and Thurik, 2001). The model of governance of firms in the managed economy leverage on controls and transactions, economies of scale play a strategic role, and competition was alternative to cooperation. Differently, in the knowledge economy firms' competitiveness is based on motivation, at individual and organizational level, on market exchanges and flexibility, while competition and cooperation are complementary perspectives.

In the managerial economy, public policy has an essentially constraining nature (antitrust policy, regulation and public ownership, concerns about excess profits and abuses in terms of market dominance). In the entrepreneurial economy, governmental policy aims at creating an environment suitable for supporting the success and sustainability of firms (Mazzuccato, 2015; Audretsch and Thurik, 2001. The linkages between innovation and competencies of the human capital arises so as a necessary condition for the success in the entrepreneurial economy, this because the human capital with its competencies foster innovation, by generating, new knowledge that is finalized towards radical innovation; adopting or adapting existing ideas and technologies and by this facilitating the processes of incremental innovation; reinforcing the social capital and the innovation networks; diffusing the knowledge within the organizations and enhancing a process of knowledge absorption within the components of the human resources into the organizations (Romano et al., 2014).

The elements of turbulence, continuous change, and innovation due to the diffusion of KETs, in causing the creative destruction of pre-existing equilibriums, are the distinctive features of an entrepreneurial configuration of the knowledge-economy and the driver for the creation of disruptive innovation in market and society

2. Key Enabling Technologies and Disruptive Innovation Theory

The nature and characteristics of KETs previously described highlight their relevance into the debate on disruptive innovation, as the theory made popular by Christensen (1997; 2006) to describe the process of new market development and new functionalities creation that generates a disruption with pre-existing market conditions (Yu and Hang, 2010). Since the first theorization of Christensen (1997), and in the frame of a consolidated stream of studies inspired to the Schumpeterian perspective, disruptive innovation is considered a process resulting from the technological advancement and it is the disruptive nature of technologies to create the conditions of a disruptive innovation in market and society. In the locus of their first concretization, disruptive innovations are reserved to niches markets able to value the not common and accepted performances (Yu and Hang, 2010). In 2003, Christensen and Raynor, reviewed the theory on disruptiveness by replacing the technologies with innovation with the aim to include disruptive innovation phenomena in business model, services and organizational features. Furthermore, studies on disruptive innovation theory have largely explored the process of innovation by demonstrating the relativeness of the process as depending on several variables as the timing and market of innovation (Christensen, et al., 2006; Schmidt & Druehl, 2008) or the size and profile of companies, in terms of incumbents versus startups (Ahuja & Lampert, 2001; Yu & Hang, 2010), that disruptive doesn't necessarily mean radical or destructive (Van Orden et al., 2008). The theory of disruptive innovation has so been used to explain the different forms of innovation, incremental or sustaining and radical (Schmidt & Druehl, 2008). Additionally, a disruptive innovation has been practically defined as a "simpler, more convenient and lower cost innovative solution (Innosight, 2005) According to Markides (2006) and Danneels (2004), the larger configuration of the theory and its widespread usage by academics and practitioners have caused a misunderstanding in what a disruptive innovation is, by highlighting the need of deeper studies. On this venue, Schimdt & Druel (2008) developed a conceptual framework aimed to clarify the misinterpretations arose around the topic and focused on the concept of low-end encroachment. At this purpose, they identified three scenarios that in offering a synthesis of different studies could also suggest more practical implications for managers.

In coherence with the low-end disruption of Christensen and Ryanor (2003), a first scenario occurs when the innovation doesn't open a new market but covers a limited portion of existing demand; a second scenario is instead related to the identification of a limited demand, only incrementally different from the low-end; and finally a third scenario is instead characterized by the creation of a new demand, with needs completely different from the existing low-end market. All those scenarios are coherent with the nature of KETs and mainly rely on their capacity to create new market demands, niches and large mass, as well as on positioning firms' value propositions on low-end or high-end existing or nascent demands.

The focus on the technological perspective assumes a new challengeable dimension at the light of the new knowledge-intensive technologies, also defined as KETs, that are causing radical innovation in market and society. Those technologies are characterized by cross-industries profiles of application; their pervasiveness is determining rapid innovation cycles and calls for continuous updating of competencies at both at individual and organizational level (Romano et al., 2016; Foray, et al., 2011). Their usage is nurturing a highly skilled employment demand and presents large potentialities in for the socio-economic development of society.

KETs are determining structural changes in all the components of the economic system: physical capital, human capital, organization of production facilities, labor practices, managerial and financial

organization of firms, geographical allocation of industries, industrial concentration, infrastructures, private-sectors financial institutions and financial instruments (Lipsey, et al. 1998). The level and the scale of these changes, which differ greatly from one technology to another, can produce some evolutionary effects. The main can be identified into the renewing of traditional sectors, through higher value added activities and new market niches; differentiating technologically from existing specialization into related fields; starting new economic activities, through radical technological changes and breakthrough innovations; and taking advantage of new forms of innovation, such as open and user-centric innovation, social innovation and service innovation (Romano, et al., 2016; Weber & Schaper-Rinkel, 2016; Freemann, 2009).

KETs feed into many different industrial value chains and sectors, in heterogeneous ways (Romano, et al., 2014). Their multidisciplinary profile describes trends of convergence and integration across different industries and knowledge domains. This is the reason behind their contribution of catalysis expected for strengthening and modernizing of the industrial bases, as well as for driving the development of entirely new knowledge intensive industries (Romano et al., 2016; EC, 2009).

In this view, KETs can be assumed as disruptive technologies in accordance with the primary definition of Christensen (1997) and as basis for the creation of disruptive innovation in terms of products, processes, and organizational models, as resulting by the advancement on the theory (Christensen & Raynor, 2003).

3. Knowledge-intensive Entrepreneurship: towards an exploitation of KETs into valuable disruptive innovation

Starting from the role of KETs in the characterization of the entrepreneurial economy, this section offers a throughout literature review on the knowledge-intensive entrepreneurship with the aim to demonstrate how it can be assumed as key process to exploit KETs into innovation for market and society.

Knowledge intensive entrepreneurship is a crucial process for economic growth, productivity and employment (Wennekers and Thurik, 1999) and for regional development (Venkataraman, 2004). It embraces all the activities and conditions at individual, organizational and system level to realize the shift "from idea to market", to convert a technology-based idea into a business opportunity and a successful venture capable to generate economic and social value, can also be characterized as an individual attribute (e.g. Byers et al., 2010), a capability (e.g. Hindle and Yencken, 2004), a strategy (e.g. Hitt, et al., 2001) and a system (e.g. Abetti, 1992).

Since the key role of the KETs for generating disruptive innovation, knowledge intensive entrepreneurship can be interpreted as technology entrepreneurship. This is in line with the fact that technologies reveal as really important factors for stimulating and activating the innovation process (Schumpeter, 1934). Byers et al. (2010) defined technological entrepreneurship as a style of business leadership that involves identifying high-potential, technology-intensive commercial opportunities, gathering resources such as human capital and financial capital, and managing rapid growth and significant risk using principled decision-making skills. Technology ventures exploit breakthrough advances in science and engineering to develop better products and services for customers Differently from a traditional or market-driven entrepreneurship a technology-driven one moves from the primary identification of a technology toexplore a market need toward which the technical know-how can be exploited (Gemmell at al., 2011; Scott, et al., 2007). Overcoming the temporal sequences of the actions at the basis of the two different entrepreneurial processes, the main differences emerging by comparing the two stereotypes are identifiable into their familiarity they have with technological knowledge. The first

bases the competitiveness of the entrepreneurial venture on the technical know-how by which to explore an unknown market's demand, while the second bases on the market knowledge the ground for the development of the entrepreneurial venture and later will operate to identify technological solution for satisfy the market's demand (Scott, et al. 2007).

By highlighting the importance to cope with uncovered opportunity and uncertainty and to learn from uncertain and complex technologies, knowledge-intensive entrepreneurship arises as a learning process that needs to be sustained continuously at individual, organizational and system level (Cope, 2005, Rae, 2006; Gemmell, et al., 2011; Erdélyi, 2010). At individual level, the continuous learning process allows entrepreneurs to develop and grow (Kenworthy & McMullan, 2013; Corbett, 2005). At corporate/organisational level, entrepreneurial organisations "Technology intensive" can be distinguished by non-entrepreneurial firms because they are likely to use creativity based learning as well as unlearning and experiential learning since they operate in dynamic and complex environment. Finally, at system (and network) level (Abetti, 1992), it is necessary to consider the learning dynamics and knowledge integration phases among all the inter-dependent stakeholders (individuals, entrepreneurs, companies, research centers, universities, financial operators and institutions) operating within an entrepreneurial ecosystem for influencing potentially the economy as a whole (Iansiti and Levien, 2004).

(Minniti and Bygrave, 2001). The comprehension of the main characteristics of knowledge intensive entrepreneurship suggests the need of shifting from a static perspective, i.e. a trait-based approach, to a dynamic and non-linear view, i.e. a learning-based approach (Cope, 2005, Rae, 2006; Gemmell, et al., 2011; Erdélyi, 2010; Wang and Chug, 2014). Accordingly, knowledge-intensive entrepreneurship is a permanent learning process that continuously needs to be enhanced (Cope and Watts, 2000). Learning is a strategic and central process in knowledge intensive entrepreneurship, given the growing significance of science technology innovation in new venture creation or in renewing existing companies. The literature allows to characterize different profile of Knowledge intensive entrepreneurs, that present some common elements such as the creativity and deepen knowledge of technological domains complemented by the risk taking, pro-activeness and goal attainment, around the categories of emergent young, academic, former, family entrepreneurs and intrapreneurs (Secundo, et al., 2016; Giacon, 2008). All this makes evident the strict link existing between KETs and knowledge-intensive entrepreneurship. In a cause-effect perspective, it is possible to say that one doesn't exist without the other. And that the full disruptive exploitation of the KETs into valuable innovation requires the creation of competencies and behaviors in the field of knowledge-intensive entrepreneurship.

The figure 1 offers a synthetic representation of the role assumed by the knowledge-intensive entrepreneurship in exploiting areas of entrepreneurial opportunities emerging from the convergence of KETs' potential applications and emerging needs from market and society.

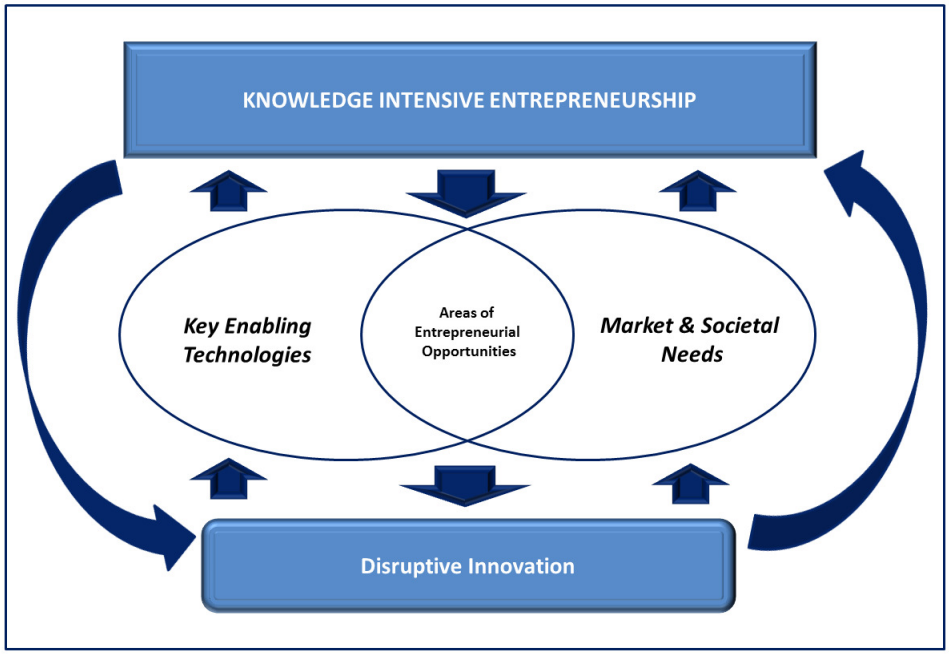

Figure 1: From Knowledge-intensive Entrepreneurship to disruptive innovation

The figure 1 represents the overlapping area between KETs and Market and societal needs that constitutes the zone where disruptive innovation opportunities can arise. Here, the needs of the society are analyzed with the lenses of KETs, to find out how it is possible to create new products, services and tools that could better satisfy new market and society needs. The Knowledge Intensive entrepreneurship process will guide the converting of a technology-based idea into a business opportunity and a successful venture capable to generate economic and social value opportunities, resulting so in the disruptive innovation.

Forms of disruptive innovation resulting from the process of knowledge intensive entrepreneurship applied to areas opportunities could be identified in:

- new products, services, processes and organizational models, in other words corporate entrepreneurship (Christensen, 2004);
- creation of new companies by individuals which industrializes/commercializes a new product, process or service or is positioning on low-end market, known as individual entrepreneurship (Ghoshal and Bartlett, 1999);
- start-up or spin-off company which valorizes the results of a given research conducted in a scientific-technological domain, capitalizes distinctive know-how and competencies, or realizes technology transfer processes and matching university-company, known as academic entrepreneurship, (Giacon, 2008).
- entrepreneurial initiative primarily devoted to the creation of social value, instead of profits and economic advantages for company's holders and investors, known as social entrepreneurship (Haugh, 2005; Martin & Osberg, 2007).

It is worth to note that the disruptive innovation generated by the knowledge-intensive entrepreneurship is a virtuous process of nurturing both the domain of KETs and market and societal needs, this is because the innovations achieved offer twofold contributions in terms of new opportunities and advancement of research in the technological domains covered by KETs as well as the creation of new market niches. This impacts positively on the creation of larger and new areas of entrepreneurial development in a continuous and positive process of socio-economic wellness.

Conclusions

With the aim to contribute at the advancement of the debate on the disruptive innovation associated to the emergence of KETs, the paper has presented a conceptualization of the knowledge-intensive entrepreneurship, as core process and attitude enabling the full exploitation of the advanced technical know-how into valuable innovation. In a neo-schumpeterian perspective, the paper referred to the current socio-economic context as knowledge economy, in reason of the knowledge-intensive nature of KETs, as well as to the entrepreneurship as primary process to concretize innovation. In reason of their inter-sectorial and knowledge intensive profile, KETs present the potentialities of changing the present configurations of market and society, by causing new industrial configurations and the enhancement of productiveness. They are expected to create new products and services, to create new industries and innovate the existing ones, by allowing to satisfy the global social and economic challenges.

As result of the virtuous combination of intellectual and entrepreneurial capital (Romano, et al., 2014), capacity of managing under uncertainty and risk-taking, and ability to identify and exploit previous unexplored opportunities (Secundo et al., 2016; Byers, et al, 2010, knowledge-intensive entrepreneurship is the process that makes concrete the exploitation of KETs into valuable innovation for market and society. The emergence of new demands of goods and services, as result of the major knowledge expressed by the market or conditioned by enhancement of the expectation of life, will cause a strong acceleration into the diffusion of knowledge-intensive entrepreneurship. Its relevance in a disruptive innovation perspective is due to the contribution. However, the full achievement of those objectives requires new conceptual and behavioral models. The nurturing of knowledge-intensive entrepreneurship, as theorized in this paper, will be necessary to allow the full exploitation of KETs and their valorization into sustainable innovation. The future moves towards scales that are more and more reduced in terms of space but faster and accelerated under a temporal perspective.

Implications for theory and policy makers. Two main kinds of implications arise. A first one can be identified for theory into the need of deepening the centrality of knowledge-intensive entrepreneurship focused on KETs in the debate on disruptive innovation, also through the empirical studies and comparative analysis referred to different industries, geographical contexts and families of technologies. Secondly, a practical implication arises for the agenda of policy makers. The study highlights the importance of investing in policies and instruments to sustain the development of knowledge-intensive entrepreneurship, unique lever for the full exploitation of the technical know-how available. However, the recent experience of European countries and regions involved into structured process of creation of new enterprises and startups suggests the primary need of creating a favorable entrepreneurial socio-economic context, in order to avoid the failure of policies focused on the entrepreneurial development (Del Vecchio & De Maggio, 2016; Mazzuccato, 2015).

Abstract

This work enters the debate on open innovation by analyzing the effects of its adoption on innovation performance, distinguishing between two different open innovation strategies - joint development and R&D outsourcing - and considering the mediating role of context-related issues. The research is performed on patents of a sample of worldwide top R&D spending companies from the technology hardware & equipment industry. Results show that open innovation adoption - in particular R&D outsourcing - positively affects innovation performance.

Keywords: Innovation performance; open innovation; R&D outsourcing; patent data.

Introduction

The open innovation (OI) paradigm (Chesbrough, 2003) has found a ready audience amongst scholars, business people and policy makers who recognize new opportunities to innovate in the access to external sources of knowledge and technology.

This work enters the debate on OI by analyzing the effects of OI adoption on innovation performance, distinguishing between two different OI strategies - joint development and R&D outsourcing - and considering the mediating role of context-related issues. Figure 1 displays the relationships under investigation.

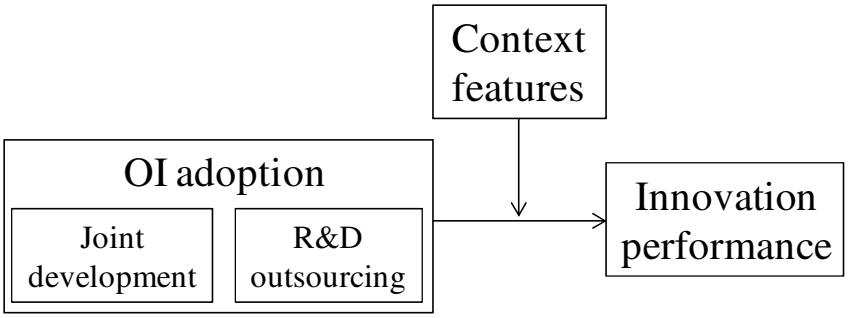

Fig. 1: Theoretical framework

In summary, the following research questions are posed:
RQ1: *How does OI adoption relate to innovation performance?*
RQ2: *Which are the differences among OI strategies in terms of effects on innovation performance?*
RQ3: *How do context features mediate the effects of OI on innovation performance?*

Methodology

Patent data are employed to assess both OI adoption and innovation performance.
The research is performed on patents of a sample of worldwide top R&D spending companies from the technology hardware & equipment industry. The sampled firms are selected from *The EU Industrial R&D Investment Scoreboard.*

PATSTAT database is used as the source of patent data and a PHP based software was developed to support data collection. For each company, the list of subsidiaries is extracted from consolidated annual reports. Thereafter, the names of both the parent company and its subsidiaries are searched in the assignee field, i.e. firms are assumed to have a patent portfolio consisting of the current granted patents of both parent companies and subsidiaries. Only claimed priorities related to already granted technologies are examined, since these are considered to be the high-value applications (Johnstone *et al.*, 2012).

The year of analysis is 2005, given the need of evaluating an *ex-post* patent quality indicator, being 2005 the latest period for which information is available in the PATSTAT 2013 version. Indeed, data from 2006 to 2013 are employed to investigate forward citations received from external parties (i.e. self-citations are excluded), which are used as a proxy of **innovation performance**. As a matter of fact, when a patent is cited within future applications, a higher technical importance can be presumed: patents that are cited are more relevant, influent and innovative than disregarded ones (Albert *et al.*, 1991; Alcácer and Gittelman, 2006; Dahlin and Behrens, 2005; Lahiri, 2010; Mazzucato and Tancioni, 2012; Miller *et al.*, 2007; Rosenkopf and Nerkar, 2001). Fleming and Sorenson (2004) argued that the number of forward citations of a patent highly correlates with its technological importance. In order to ensure consistency, the analysis is confined to citations received from patents filed at the USPTO, since the propensity to cite prior art varies among offices. As a matter of fact, when applying to the USPTO, applicants have a so-called "duty of candor" in dealing with the office, which includes a duty to disclose any knowledge of prior art to the examiner, and the same examiners tend to add other references deemed relevant (Bakker *et al.*, 2016).
The variable FWD_CIT is thus defined as the number of external forward citations received by the patent.

As to **OI adoption**, three categories of patents are defined according to the innovation strategy adopted by the focal company to obtain it:

- patents developed with the use of only internal resources, without engaging external actors;
- patents developed with the use of external partners. When the focal firm is found as the only assignee, but some inventors do not belong to it, it is reasonable to suppose that a part of the development process was outsourced to third parties;
- co-patents, jointly developed by the focal company with one or more organizations/coassignees, after a collaborative perspective.

In order to gauge such categories, different steps are followed. Before starting the analysis, any inventor disclosed in the assignee field was removed, so that only organizations were reported as assignees. After this intervention, all the patent documents disclosing the focal company in the assignee field are analyzed. If two or more assignees are uncovered in the assignee field, the patent is labeled as joint, according to many scholars (Al-Ashaab *et al.*, 2011; Kim and Song, 2007; Michelino *et al.*, 2017). Otherwise, the inventors' affiliation is detected. For each inventor, following Cammarano *et al.* (2017a; 2017b), information is detected in order to uncover whether companies absorb knowledge from external inventors by outsourcing part of the development of the focal technology. Hence, the inventors' affiliation in 2005 was detected by analyzing their *curriculum vitae* extracted from websites and platforms like Linkedin, Xing, Zoominfo, Academia, Research Gate, Google Scholar, Scopus, etc. Therefore, we assume that the existence of inventors belonging to firms different from the focal company is a proxy of R&D outsourcing services provided by their organizations to the patent owner, signaling OI adoption.

Accordingly, four dummy variables are defined: CLOSED, OUTSOURCING and JOINT_DEV - depending on the patent category registered - and OPEN, which includes patents deriving from both outsourcing and joint development.
Furthermore, the following **context features** are analyzed:

- the AGE of the focal company;
- the SIZE of the patent portfolio of the focal company, signaling its potential innovative capacity;
- the R&D intensity (RD_INT) of the focal company, i.e. the ratio of R&D expenditure on net sales, as the effort put in place for innovation.

Results

Results are obtained as to 12,090 patents applied by 82 companies in the technology hardware & equipment industry. Only 0.7% (86) of the analysed patents were jointly developed, whereas R&D outsourcing is far more widespread, with 13.7% (1.660).

Regression analyses of the innovation performance variable FWD_CIT using OI adoption and strategies as predictors are respectively shown in Table 1 and 2. For each of them five models are introduced: the first without context features, the following three by introducing one context feature at time, and the last simultaneously considering all of them.

OI adoption - in particular R&D outsourcing - positively affects innovation performance. Both firm age and the size of patent portfolio have a negative moderating effect on it, whereas R&D intensity is a positive moderator.

Economic and Legal Instruments of Labour Integration of Unemployed Persons in Slovakia

Gabriela Beresova, Comenius University, Bratislava, Slovakia, gabriela beresova@fm.uniba.sk

Daniela Novackova, Comenius University, Bratislava, Slovakia, daniela.novackova@fm.uniba.sk

Abstract

In the process of globalization and European integration the values and structure of the society is being changed at present. The rapid economic growth, the Slovak economy openness and the development of investment instruments have brought the new challenges also into the area of employment policy. Nonetheless, the active assistance of a state is needed so that the future of sustainable development and of life in dignity for every citizen would not be endangered. This article analyses the current problems of labour integration of unemployed people in Slovakia. The aim of this article is to identify legal provisions regulating the economic support of labour integration of unemployed persons. This article also mentions conditions for establishment of social enterprises of labour integration, which represent the significant subjects of social economy.

Keywords: unemployed persons, social enterprise**,** de minimis aid, legal act,

Introduction

The United Nations Organisation from its establishment accentuates inter alia also the protection of rights of citizens of its Member States. This international organisation in its International Bill of Human Rights of 10th December 1948 bound its Member States to guarantee the right of everyone to work, to free choice of employment, to just a favourable conditions of work and the protection against unemployment. Everyone who works has the right to just and favourable remuneration ensuring for himself or herself and his or her family an existence worthy of human dignity, and supplemented, if necessary, by other means of social protection. (Resolutions adopted by the General Assembly.) Several Member States have incorporated these rights to their legal systems. Besides the United Nations also the European Union adopted the Charter of Fundamental Rights of the European Union regulating the protection of social rights of citizens of its Member States. (OJ EU C 30. 3. 2010) In the Constitution of the Slovak Republic the right to work and employment for all citizens that want to work is stipulated. All Member States of the United Nations consider the policy of employment and creating the well suited legal and economic conditions as their priority, because the people are creating the profile of their personality in his or her active interaction with the real life context. It is the long life process of building and development of preconditions for the individual in order to realize himself or herself as the creative, mature and socially capable personality. (Schavel, 2016) The employment has the irreplaceable position in the life of every person. It represents the vital precondition of his or her dignified existence, it brings not only the material benefits, but also gives the feeling of self-realisation and social utility. (Buchtová, 2002). This scientific study is composed in such a way to clarify the system of legal and economic instruments that are influencing the labour integration of unemployed persons. At the same time we have focused also on the basic principle of labour relationships, which is the prohibition of discrimination. In the larger context we have clarified the subject of social economy – the social enterprise, which is the suitable instrument for the labour integration of unemployed persons.

Objectives and Methodology

The goal of scientific study is to present the current the legal framework concerning the labor integration of unemployed persons in Slovakia and economic instruments which support employment and social innovation in Slovakia. In this scientific study variety of scientific methods were applied. The main method of the study is the analysis, which was used for the analysis of the contemporary legislation related to the finance aid instruments aimed at the integration of unemployed into the work process inclusion, as well as the analysis of the selected social enterprise in Slovakia. The attention was focused on the quantification of the financial resources for creating new work position using public finance resources for this purpose.

Basic theoretical starting points

One of the biggest current social problems of the market economy in the Slovak Republic is the unemployment. The unemployment in the market economy can be characterised as the non-realised offer of labour in the labour market. It takes place in a moment, when the offer of labour force in the market is higher than the demand for it. (Hetteš, 2013) Referring to the mentioned arguments the definition of the unemployment of the International Labour Organisation have to be highlighted which defines unemloyment in a following way: *unemployment covers people who are: out of work, want a job, have actively sought work in the previous four weeks and are available to start work within the next fortnight; or out of work and have accepted a job that they are waiting to start in the next fortnight*. (ILO, 2017) It causes the serious economic problem to a state and at the same time it causes the unemployed individuals the social and health problems. (Žatkovičová, Dóci, 2012) The unemployment has economic and social consequences for the unemployed persons. Among economic consequences of unemployed can be ranked: rising costs connected with the elimination of unemployment and its of consequences, the necessity to pay the unemployment support and social allowances to unemployed persons, the losses in the tax area and in the area of social insurance which represent the burden of the state budget, the unemployment support and social allowances which reduce the revenue side of the state budget, the reduction of salaries in case of allocation to the job with lower remuneration, the loss of production and income, wasting of financial resources of the state, increasing the state budget deficit, drop in the Gross Domestic Product, loss of qualification and the costs of requalification, non-using the potential of labour force, lack of using the concrete abilities, skills and knowledge of individuals, the devaluation of the value of human capital. As the social consequences of unemployment are considered: social exclusion, increase of social tension, disruption of social reconciliation, marginalisation of groups of unemployed persons, inability to develop social, cultural and spiritual activities as the consequence of lack of financial resources, reduction of incomes, reduction of living standard of unemployed person and his or her family, material shortage and the inability of the family to ensure the everyday running of the household and to satisfy the basic life needs of the members of the family. „Pilot iniciative of the European Investment Fund – Social Impact Accelarator (SIA) started to satisfy the growing need of equity finance supporting social enterprises. It promotes social inclusion by a) providing alternative sources of employment to marginalised social groups, and b) contributing to growth." (Saxunova, 2015) „The risk situations such as loss of employment, in many cases affects in a negative way the self-evaluation of a person, reduces his self-esteem, and leads to a feeling of inferiority.“ (Treľová, 2014)

Legal and Economic Instrument of Labour Integration Unemployed Persons

One of the most pressing problems of the current global society is the labour integration of the unemployed persons. The task of the market policy is to ensure the conditions so that every inhabitant could enforce this right. States are adopting various legal instruments to this end. The Slovak Republic adopted several legal and economic instruments to support the labour integration of unemployed persons.

The problematic of the employment and labour relations are regulated in the Act No. 311/2001 coll. Labour Code. In addition to this complex legal norm the Act No. 5/2004 Coll. on the Services of Employment as amended regulates the right to access to employment. The right to access to employment is the right of every citizen who wants to work, is able to work and is searching for the job – for services aimed at assistance and support of his or her access to the labour market, as well as the continuance of the disadvantaged applicant for job in the labour market for minimum period of six following calendar months. The legislation already approved also contains economic instruments of the state making an access to the employment easier. Within the framework of employment policy the employers have to treat the employees in accordance with the principle of equal treatment that is stipulated in the Act No. 365/2004 Coll. on Equal Treatment in Some Areas and on the Protection Against Discrimination as amended. In addition to this legal norm also the Constitution of the Slovak Republic – the Constitutional Act No. 460/1992 Coll. as amended in its article 12 paragraph 2 guarantees the fundamental rights and freedoms to everyone regardless of sex, race, colour, language, belief and religion, political affiliation or other conviction, national or social origin, nationality or ethnic origin, property, descent or any other status. The Act No. 311/2001 Coll. Labour Code stipulates in its Article 6 of its fundamental principles that women and men have the right to equal treatment as regards the access to employment, remuneration and career at work, vocational training and working conditions. The Labour Code prohibits the discrimination of employees on the grounds of sex, marital status and family status, sexual orientation, race, colour of skin, language, age, unfavourable health conditions or disability, genetic properties, belief, religion, political or other conviction, activity in trade unions, national or social origin, affiliation in the nationality or ethnic group. According to article 13 of the Labour Code if the employer would infringe the principle of equal treatment the employee has the right to file the complaint on the grounds of infringement of equal treatment principle. The employer is obliged to reply to this complaint without unnecessary delay, to remedy the situation, to stop continuing such action and to remove of its consequences. The principle of equal treatment is specifically elaborated in paragraph 13 of the Labour Code, which stipulates the obligation of the employer to deal equally with all his employees. This is already a prohibition of discrimination in labour relations. (Treľová, 2015). It is obvious that in Slovakia the favourable conditions for employment are created not only for citizens of the Slovak Republic, but also for foreigners. In comparison to other Member States of the European Union there is high level of unemployment in Slovakia, however, it has decreasing tendency comparing to the previous years.

From the legal point of view the free movement of workers covers all phases of the performance of job starting with the searching for the job, its performance, the stay of worker in one member state for the purpose of searching for the new job. (Barancová, 2010) According to Morabito and Sergi „migration requires a systemic approach and qualified control“ (Morabito, Sergi, 2016) and Saxunova adds „rules of financing", as well. (Saxunová, 2016) The EU needs to establish a demand-driven labor immigration policy to ensure its future prosperity and economic growth."

The part of the legislative instruments is the Act No. 358/2015 Coll. on Adjustment of Certain Relations in state aid and de minimis aid and on amendments and supplements to certain acts. The Act on the state aid dealing with the issues of certain relations in the area of the aid *de minimis* and the latest amendments in the legislation. The state aid is provided to the selected subjects from the public resources. It is provided to the regions that are achieving results below 75 % of GDP average per capita in the EU. The regulation constitutes the terms of providing the state aid and the terms for the aid *de minimis.* Recepients of the aid *de minimis* do not have the obligation to report the aid accepted after 1 January 2016. According to the paragraph 13.1 of the Act on the state aid the provider of the state aid is obliged to report to the Central register the date on the aid provided, the data on their recipients utilizing electronic formular within 5 days after the aid is received. The unemployment directly influences the behaviour of individuals, as well as the social relations. The social consequence of unemployment of individual is the reduction of his or her living standard, social isolation, the loss of working habits, skills and professional abilities. The accompanying phenomenon of long-term unemployed persons is also their exclusion to the margin of society.

According to the statistics of the Central Office of Labour, Social Affairs and Family in December 2016 the level of recorded unemployment was 8,76 %. If we take into account the data from the year 2015, where the level of unemployment was 10,63 %, it means certain decrease. (Ministry of Labour, Social Affairs and Family of the SR, 2017) The situation in the area of long-term unemployment is being improved as well. The negative side of the employment policy is the fact that among unemployed persons there are more often persons with university education. From among graduates of 2nd degree university education the biggest proportion of unemployed graduates was in September 2016 in the area of social sciences, sciences and services I and II (32,91 % and 25,63 %) and technical sciences I (12,28 %). On the contrary, the lowest portion in the overall number of unemployed graduates were noted in the same period in the areas of sciences about art with 2,53 %, medical and pharmaceutical sciences with 3,09 %, military and security sciences with 4,41 %, agricultural and forest and veterinary sciences with 5,19 %, natural sciences with 6,77 % and technical sciences II with 7,18 %. (Ministry of Economy of the SR, 2017)

The Act on the Services of Employment enables to provide economic support from the state budget to creating the new jobs. According to article 51a of the Act on the Services of Employment in the year 2016 the financial support to create the new job was provided to 3087 young employees (until 29 years of age) in the overall amount of 12.978.320 EUR. In the interest of the development of local and regional employment on the basis of article 50j of the Act on the Services of Employment in the year 2016 were supported 2087 disabled job applicants in the overall amount of 7.803.741 EUR. The abovementioned factors suggest that in the Slovak Republic the economic instruments to support the employment are being used. (Ministry of Labour, Social Affairs and Family of the SR, 2017).

The state aid represents the economic instrument for starting the business for soleproprietors, in 2016 (§ 49) there were 8 249 299 EUR provided as the state aid to them and 1951 new jobs created. It is a part of the scheme of the aid *de minimis*, the scheme DM – 16/2014 is for supporting employment. It is complied to the aforementioned Act 358/2015 Coll. To ensure that aid is proportionate and limited to the amount necessary, the Commission Regulation (EU) No 1407/2013 of 18 December 2013 on the application of Articles 107 and 108 of the Treaty on the Functioning of the European Union to *de minimis aid* (OJ EU L 352, 24. 12. 2013) is applied. The primary legislation EU, the Article 107(1) of the Treaty on the Functioning of the European Union (TFEU) lays down the principle that State aid is prohibited. Article 107(1) TFEU has the ultimate goal of ensuring the compatibility of national policies with the EU's objective of achieving an internal market. It has therefore been pointed out that the „*Treaty requires that the application of State aid rules must never produce a result which is contrary to the Treaty rules governing free movement*." (Biondi, Farley, 2011) In certain cases, however, such aid may be compatible with the internal market on the basis of Articles 107(2) and 107(3) TFEU. To follow the interest of cohesion policy in Slovakia there is also attention paid to the social economy. The social economy is something of a contested concept, and intra-national differences in terminology and usage make it difficult to derive a consistent definition. There is however some consensus, particularly among continental European countries, that the social economy includes co-operatives, associations, mutuals and foundations. This derives from the French legalistic approach to defining the social economy, first employed in the 1970s (Monzon, Chavez, 2012). Social economy is not developed yet in Slovakia althought it contributes to the unemployment elimination and just wealth distribution.

The legal instrument in Slovakia supporting the employment is the institute of social enterprise regulated in article 50b of the Act on the Services of Employment. According to that legal regulation the social enterprise of labour integration is considered the entity that is employing employees who prior to their admission to employment were disadvantaged applicants for employment in the amount representing at minimum 30 % from the overall number of its employees. The status of social enterprise of labour integration is recognised by the Central Office of Labour, Social Affairs and Family by its decision on the basis of the written application of the legal entity or natural person, if the conditions are met.. The

activities of these social enterprises of labour integration serve to provide the job to citizens who were the disadvantaged applicants for job, are employed in the social enterprise of labour integration and are taking part in its activities in the position of its employees. The social enterprise of labour integration provides the temporary employment to them, within which they can develop their labour skills and thus it becomes the „prep" for their access to the open labour market – for the employment in the ordinary enterprise. (Social Enterprise of Labour Integration, Manual 2017) The social enterprise of labour integration represents one of the instruments of social economy which could potentially ensure the creation of new jobs inter alia for those groups of applicants who face problems in finding job in the labour market, such as long-term unemployed persons. Social economy is not developed in Slovakia, it could potentionally support creating a new working positions. The social economy employs over 11 million people in the EU, accounting for 6 % of total employment. (EU, 2009)

Briefly the social enterprise could be defined as the bridge of social inclusion. In comparison to other entities in the market the main aim of social enterprise is not to achieve profit, but in particular to pursue some social goal. In addition to its social purpose, which is the creating the new jobs for disadvantaged job applicants, the social enterprise of labour integration pursues also the economic goal, which is the ensuring the income through the sale of products or providing services. The state supports from the public resources the functioning of social enterprises of labour integration. As of 1st August 2017 there were 7 enterprises of this type registered in Slovakia in the portal of the Central Office of Labour, Social Affairs and Family of the Slovak Republic. The number of the Slovak social enteprises rapidly decreased. According to the study the social economy in the European Union assessed the share of the population involved in social entrepreneurship as 4,1 % in Belgium, 7,5 % in Finland, 3,1 % in France, 3,3 % in Italy, 5,4 % in Slovenia and 5,7 % in the United Kingdom. (EU, 2009)

Such an example in Slovakia there is the social enterprise Nezábudka, which obtained the status of the social enterprise in May 2009. It is not a profit organization. It is the business which provides the social services for seniors in the region. The organization employs 35 full-time employees (by December 2016). The enterprise received 203.520 EUR subsidy from the state, which is 36,51 % from the overal budget and the contribution from the local municipal government 50.700 EUR. (Annual Report, Nezábudka, 2016). This social enterprise generates profit in its own operations, receives gifts from sponsors etc. Emplyees are pure enthusiasts because their monthly salary is lower than 800 EUR. From the pespective of contemporary theory there are social services of general interest, which are those that respond to the needs of vulnerable citizens, and are based on the principles of solidarity and equal access. Social services of general interest: these include social security schemes covering the main risks of life and a range of other essential services provided directly to the persons that play a preventive and socially cohesive/inclusive role. (Implementing, 2006). The threshold of the social enterprise is „an enthusiastic entrepreneur not driven by profit", often with personal experience of the kind, has the needed psychological knowledge about the quality of the people with mentioned barriers, empathy for those people, who have the idea and take on potential employees without work experience or employees who are limited by their disabilities. The managers running these businesses emphasize that for the success of social enterprises the specific approach is crucial which includes a) no underestimating their workers and b) sustaining a determined marked focus. (Nízka, Saxunová, 2011)

We believe that the problematics of the social enterprise that is regulated only in the Act on the services of the employment should be regulated by the particular Act on social businesses as it is in other states such as Finland (2003), Lithuania (2004) and Italy (2005). We think that Slovak legislation should define the social business more precisely, because the social business is the subject of social economy, which main aim is not to create profit for its owners, but to achieve positive social influence. Its activity consists in service providing and the profit generated is used in social goals accomplishment.

In Slovakia also Regulation (EU) No 346/2013 of the European Parliament and of the Council of 17 April 2013 on European social entrepreneurship funds is applied. (OJ L 115, 25. 4. 2013) The regulation is compulsory for Slovakia and all business entities must fully apply it. This regulation is creating a favourable climate for social enterprises, key stakeholders in the social economy and innovation. The regulation was accepted following the Social Business Initiative (2011) and objectives set in the Europe 2020 Strategy. It constitutes the common framework of the rules related to applying the designation „EuSEF" for qualified social entrepreneurship funds. On the European Union level there has been a legal instrument approved for the social business regulation operating on the territory of the EU. Based on this regulation there is a social investment market created, partially created by investment funds targeting social undertakings that provide funding to these social undertakings.

Conclusion

Having in mind the positive development in the Slovak labour market and with respect to the mutually interconnected system of strategic support (economic and legal) of employment, there is high degree of unemployment. The inflow of foreign investors supports the regional and local employment. Providing the financial support on the basis of the Act on employment represents the effective solution for the creation of new jobs. In the concrete examples we have shown that there exist several economic and legal instruments that provide for the preconditions of labour integration of unemployed persons. Within the framework of the employment policy we think it is right that in providing the financial means from the state budget the focus should be on the effectiveness. By the introduction of legal construction of social enterprises of labour integration the Slovak labour legislation obtained the legal tool of supported labour market. They help to eliminate the unemployment and integrate people handicapped, or not qualified sufficiently or with other barriers (drug addicts, prisoners etc.). Social businesses are the stimulus of social changes. To support social business development European Union has adopted Regulation (EU) No 346/2013, which establishes uniform rules applicable to qualifying social entrepreneurship funds. A preventive approach would be favourable in terms of efficiency and effectiveness. Prevention and activation measures mainly focusing on the start of the unemployment period should be strengthened and, where necessary, complemented. (Council Recommendation 2016/C 67/01) With regard to the stipulated aim of this study it can be clearly stated that the unemployment is the special feature of economies of transition, however, it is manifested also in the developed states. The unemployment directly influences the behaviour of individuals, and also the social relations. The social consequence of unemployment of individual is the reduction of his or her standard of living, social isolation, the loss of working habits, skills and professional abilities. The accompanying feature of long-term unemployed persons is their exclusion to the margin of society. The unemployment also influences the development of economy as well as the public finances. The unemployment represents inter alia one of the significant factors of successful economic development of country or region. Every state and society are seeking to achieve the full employment. From the point of view of economic variables the generally acceptable rate of unemployment represents around 4 %.

Leveraging organizational performance and innovation Via knowledge management strategies in Turkey: Evidence from the İstanbul Stock Market

Yakup Akgül, Ass.Prof.Dr.
Alanya Alaaddin Keykubat University, Faculty of Business, Alanya, Antalya/TURKEY
yakupakgul@gmail.com

Abstract

The purpose of the present study is to examine the relationships among knowledge management strategies (codification and personalization), innovation, and organizational performance in the İstanbul Stock Market businesses. Research suggests that knowledge management strategies are essential capabilities for effective innovation and organizational performance. Through analysis of surveys collected from 203 mid-level managers, the present model under the study was empirically tested using the Partial Least Squares (PLS) method for the model assessment and analysis of the relationships among constructs. Our results show that knowledge management strategies had a statistically significant and direct positive effect on innovation and organizational performance. Most outstandingly, the results indicate that knowledge management strategies had a positive and statistically significant effect on organizational performance through the partial mediation effect of innovation. Also, findings demonstrate a different effect of KM strategies on diverse dimensions of organizational performance. Conclusions of the present study may help academicians and managers in implementing knowledge management strategies for the purpose of enhancing the innovation, effectiveness, efficiency, profitability and in improving organizational performance.

Keywords: Knowledge management strategies, Innovation, Organizational performance, BSC, Istanbul Stock Market

1. Introduction

Due to the fact that knowledge has been highlighted as a key strategic resource to create corporate value by academicians and practitioners (Abou-Zeid, 2003; Bhatt, et al., 2005; Choi and Lee, 2002; Conner and Prahalad, 1996; Drucker, 1993; King, 2001; Kogut and Zander,1992; Ndlela and du Toit, 2001; Wu and Lin, 2009; Zack, 1999), enterprises striving to develop knowledge to the maximum level in view of achieving corporate goals and competition. However, whether an enterprise can effectively utilize and develop knowledge determines the pros and cons of knowledge management capabilities (KMC) (Grant, 1996; Tanriverdi, 2005; Zack, 1999). Gold et al. (2001) further indicated that the key contributions of KMC are improved ability to innovate, improved coordination of efforts, and rapid commercialization of new products (Gold et al., 2001). Understanding a firm's KMC is essential to both providing competitive advantages and increasing firm performance (Andrew , 2005; Tanriverdi, 2005).

KM strategies have become a primary issue for many companies (Alavi and Leidner, 2001). Numerous studies have shown that Knowledge Management (KM) strategies are able to help achieve or maintain success of contemporary organizations. Indeed, the implementation of KM strategies is said to be the best way to improve organization's ability in various aspects such as innovation capacities (Brachos et al., 2007; Chang and Lee, 2008; Jiang and Li, 2009; Liao and Wu, 2010; Sáenz et al., 2009) and organizational performance (OP) indicators (Asoh et al., 2007); Bierly and Daly, 2007; Choi et al., 2008; Ho, 2011; Kim and Gong, 2009; Liao et al., 2009; Yang et al., 2009; Zack et al., 2009). KM strategies are broadly recognized that knowledge is a momentous resource for strategic organization in enhancing innovation and improving OP (Rhodes et al., 2008). Despite the increasing importance of knowledge as being a resource of strategic perspective, there is still lack of understanding the critical factors for the implementation of KM strategies (Garavelli et al., 2004; Hwang, 2003; Maier and Remus, 2003). Although there are a large number of KM strategies frameworks, organizations still face difficulty with this part due to a lack of an integrated framework of its implementation (Chong et al., 2007; Chong et al., 2009).

On other hand, a number of studies have noted that KM strategies could play a major role in increasing innovation (Darroch and McNaughton, 2002; Forcadell and Guadamillas, 2002; Rhodes et al., 2008). However, there are limited empirical studies that investigate the relationship between KM strategies and innovation (Rhodes et al., 2008). Therefore, there is an existing gap in the literature on KM strategies and its influence on innovation (Majchrzak et al., 2004; Rhodes et al., 2008). Correspondingly, several studies have indicated that KM strategies could play a major role in higher OP (Bierly and Daly, 2007; Choi et al., 2008; Chong et al., 2009; Schulz and Jobe, 2001; Shih and Chiang, 2005; Turner and Bettis, 2002). Nevertheless, there is still a lack of studies that attempt to analyze the effect of KM strategies on OP (Choi et al., 2008). In this regard, very few studies have investigated the relationship between KM strategies and the Balanced Scorecard (BSC) indicators (Chen and Mohamed, 2008; Lee and Lee, 2007; Yu and Liying, 2009). Therefore, there is also an existing gap in the literature on KM strategies and its influence on OP (Yang et al., 2009; Zack et al., 2009. That gap is consistent with Kalling's (2003) remark that "there are relatively few knowledge management texts that make an explicit connection between knowledge and performance." (Kalling, 2003).

From the gaps listed above, the issue of the relationships among successful implementation of KM strategies, innovation, and OP is still unclear, and there are very limited studies in this area. Therefore, present study contributes to the previous studies by proposed theoretical framework which explains the relationships among KM strategies, innovation, and OP from the holistic theory of knowledge and learning and knowledge-based view (RBV) perspectives. Fig. 1 shows graphically the research model and summarized the hypothesis that will be tested in the present paper.

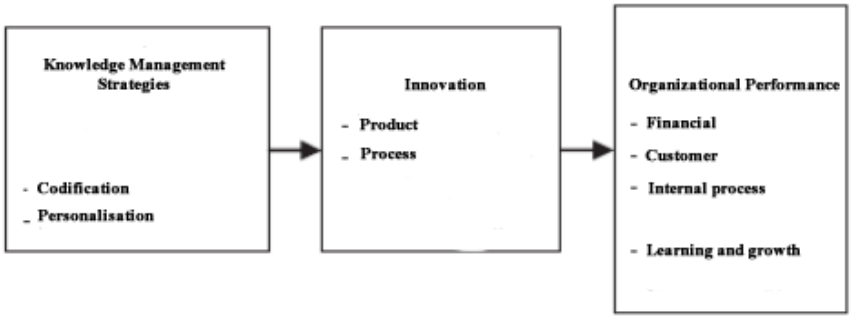

Figure 1: Theoretical framework.

The relationship between KMSs and innovation, as well as the relationship between KMSs and OP have been developed based on RBV and KBV theories. Within theoretical perspective of RBV and KBV, knowledge has become the main strategic significant source for all successful organizations and not land, labor, capital or the production of other elements. The success of organizations is argued to depend on the efficient management of internal and external knowledge sources to adapt to the change that occurs in the environment. The ability to adapt to these changes is purported to enhance innovation and superior performance (Asare, 2008; Kiessling et al., 2009; Pathirage et al., 2009). Figure 1 shows the theoretical framework of the relationships among study's variables.

As contributions to the body of knowledge, the theoretical framework of the present study is developed based on RBV and KBV theory perspectives. The proposed theoretical framework shown in Figure 1 describes the causal relationships among three variables of the KMSs, innovation, and OP. Undoubtedly, the independent variables in this framework is the KMSs (i.e. codification and personalization). Moreover, the dependent variable is and OP (i.e. financial perspective, customer perspective, internal process perspective, and learning and growth perspective). On the other hand, innovation (i.e. technological innovation, administrative innovation, radical innovation, and incremental innovation) acts as the mediating variable between the KMSs and OP.

2. Research Methodology

2.1. Data collection and sample

This is a quantitative cross-sectional study that utilized the survey questionnaire as the main instrument for the data collection. Hence, a self-completion, well-structured questionnaire was developed based on previous literature and was then distributed to a random sample where participation was completely voluntary. Sekaran (2003) stresses the importance of choosing the questionnaire language that approximates the level of understanding of the respondents. Given that the majority of the Turkish are communicating in Turkish language, questionnaire items of the study have been translated into Turkish language. The English version of the questionnaire has been translated into Turkish language by two independent translators. The Turkish version which has been translated by the first translator has been translated back to English by the second translator. The same was repeated to the second translator's version. The two versions in both languages have been compared to resolve any differences. The final version following the amendments was then used for the data collection.

The descriptive statistics of the sample showed that 53% of the respondents were male and 47% were female. Respondents aged between 25 and 35 years formed the largest age group and represented 49.26% of the sample. The majority of respondents were bachelor degree and represented 76.31%

2.2. Items Measurement

The variables of this research are measured using multi-item scales tested in previous studies. Items for KM strategies are based on (Choi and Lee, 2002; Choi and Lee, 2003). The two measures of KM strategy developed by Choi and Lee (2002) and Choi and Lee (2003) were used: codification and personalization. Codification strategy was a four-item seven-point scale measuring how their firms manage knowledge about knowledge codification, knowledge acquisition from codified forms, documentation, and knowledge sharing through codified forms. Personalization strategy was a four-item seven-point scale measuring how their firms manage knowledge about knowledge acquisition from experts and co-workers, face-to-face help by experts, informal dialogues for knowledge sharing, and knowledge acquisition by one-to-one mentoring. Innovation scale were adopted from (Singh and Smith, 2004; Prajogo and Sohol, 2003). Finally, performance measures are based on balanced scorecard outcomes (learning and growth, internal process, customer satisfaction and financial performance) were adopted from Blackmon's (2008) study and created by the researcher according to Niven's (2006) book. The major advantage of BSC is that it retains financial performance and supplements it with measures of the drivers of future potential. As knowledge management is an activity that penetrates the whole organization, and we consider BSC to be more appropriate to measure firm performance. Firm performance (FP) is measured on three dimensions: (i) financial performance encompassing marketing performance (growth, profitability, and customer satisfaction); (ii) process performance which refers to quality and efficiency; (iii) internal performance relating to individual capabilities (employees' qualifications, satisfaction and creativity). The items that measure the Conceptual model were structured on a five-point Likert-type scale that ranged from 1 (strongly disagree) to 5 (strongly agree).

3. Data Analysis and Results

PLS is a component-based approach that is widely adopted in the IS field, and has several advantages: PLS is able to deal with reflective and formative constructs, and latent constructs under non-normal conditions, it is also able to handle more minimal demands on sample size than other methods (Urbach and Ahlemann, 2010). Therefore, PLS is appropriate for the analysis of our survey samples (N=203). In the data analysis section, the first step examined the measurement model in order to check the reliability and validity of the constructs, and the second step attempted to test the relationship between the latent constructs and hypotheses. In this study, SmartPLS 2.0 M3 software

(Ringle et al., 2005) was used in order to assess both the measurement model and the structural model.

3.1. Measurement Model

In order to validate the measurement model, internal consistency reliability, and the validity of convergent validity and discriminant validity were assessed. Internal consistency reliability was examined using composite reliability (CR) values. As shown in Table 3, all of the composite reliability values were above 0.7, ranging between 0.94 and 0.98, which satisfies the commonly acceptable level, as recommended by ((Fornell and Larcker, 1981). The results showed that all CR values were reliable. Convergent validity was assessed using two criteria (Fornell and Larcker, 1981; Hair et al., 2010): (1) all factor loadings should be significant and greater than 0.5 (Wixom and & Watson, 2001), and (2) average variance extracted (AVE) from each construct should exceed the threshold value of 0.5, as this indicates that 50% or more of the variance is explained by the indicators of the latent variable (Chin, 1998a). As shown in Table 1, all factor loadings exceed 0.6, the AVE values ranged between 0.58 and 0.91, and all values were above the acceptable level of 0.5. All the factor loadings and AVEs support the convergent validity of the constructs. As such, content validity, reliability, and convergent validity of the measurement instrument are all satisfactorily met in this research. As for discriminant validity, it is actually established when the square root of the AVE from the construct is greater than the correlation shared between the construct and other constructs in the model (Chin, 1998b). The discriminant validity of the measurement instrument is confirmed in this study given that the square root of the AVE from each construct is larger than all other cross-correlations with other constructs (see Table 2).

Measurement reliability was assessed prior to data analysis. To assess the reliability of the measures, the Cronbach alpha coefficient was used. As shown in Table 1, the results showed that all the constructs had Cronbach alpha values greater than 0.7, indicating an acceptable level of measurement reliability (Nunnally, 1978). As the results of the test were satisfactory, all the items were retained for the survey.

Table 1: Measurement model results.

Construct	Range of Factor loadings	Number of Items	AVE	CR	Cronbach's alpha
Codification	0,895-0,942	4	0,838	0,954	0,935
Personalization	0,889-0,918	4	0,820	0,948	0,927
Innovativeness	0,804-0,904	14	0,740	0,975	0,973
Learning and Growth	0,802-0,915	12	0,647	0,955	0,945
Internal Process	0,608-0,909	12	0,699	0,965	0,960
Customer Satisfaction	0,790-0,869	12	0,577	0,939	0,925
Financial Performance	0,954-0,964	4	0,914	0,977	0,968

[a]Average variance extracted (AVE)=(summation of the square of the factor loadings)/{(summation of the square of the factor loadings)+(summation of the error variances)}.
[b]Composite reliability (CR)=(square of the summation of the factor loadings)/{(square of the summation of the factor loadings)+(square of the summation of the error variances)}.

Table 2: Correlation of constructs and the square root of AVEs

	COD	CS	FP	INN	INTP	LEAR	PER
COD	1,00						
CS	0,84	1,00					
FP	0,80	0,79	1,00				
INN	0,90	0,89	0,84	1,00			
INTP	0,80	0,88	0,78	0,86	1,00		
LEAR	0,85	0,86	0,83	0,92	0,87	1,00	
PER	0,86	0,82	0,75	0,90	0,82	0,86	1,00

Note: The square roots of the constructs' AVE values are shown in the diagonal line (in bold); non-diagonal elements are latent variable correlations.

3.2. Structural Model, Hypotheses Testing and Discussion

This study follows Hair et al.'s (2003) five-step approach to measure structural model; that is, (1) collinearity assessment among the constructs, (2) structural model path coefficients, (3) coefficient of determination (R2 value), (4) effect size f2, and (5) predictive relevance Q2 and blindfolding. The details of each step appear below.

The proposed hypotheses were tested using the bootstrap resampling estimation of PLS, as suggested by (Chin, 1998a). The test of the structural model consisted of path coefficients (β) and the coefficients of determination (R-square value). Path coefficients demonstrated the strength of the relationships between the dependent and independent constructs. Diamantopoulos and Siguaw (2000) classify path coefficients that are below 0.30 as (causing) moderate (effects), from 0.30 to 0.60 as strong, and above 0.60 as very strong. Table 3 shows the results of the hypothesis testing and structural relationships. R-square values indicated that the amount of variance is explained by the independent constructs. This study uses a resampling bootstrap method with 5000 along with each bootstrap sample containing the same number of observations as the original sample (i.e., 203 bootstrap cases) to generate standard errors and t-values (Chin, 1998a; Hair et al., 2013). The study assesses estimated path relationships among the latent variables in the model through the sign and magnitude of path coefficients. The findings support H1, H2, H3c, H3d, H4a, H4b and from H5a to H5d. With H1, we examined the relationship between codification KM strategy and innovation. The result showed that codification KM strategy has a significant impact on innovation (β 0.46, t-value=8.60, $p < 0.01$), which supports H1. In H2, we focused personalization KM strategy, and the findings supported H2; that is, the positive effect of personalization KM strategy on innovation was significant (β 0.50, t-value=9.55, $p < 0.01$). Yousif et al (2013) showed that knowledge management strategies had a statistically significant and direct positive effect on innovation. Yousif et al (2014) found that midlevel managers could play a critical role in insuring the successful implementation of knowledge management strategies. Regarding the relationship between codification KM strategy and organizational performance described in H3a, H3b, H3c and H3d, a positive relationship only existed between codification KM strategy and customer satisfaction (β 0.21, t-value=2.52, $p < 0.05$), financial performance (β 0.26, t-value=2.17, $p < 0.05$), which supports H3c and H3d. Regarding the relationship between personalization KM strategy and organizational performance described in H4a, H4b, H4c and H4d, a positive relationship only existed between personalization KM strategy and learning and growth (β 0.13, t-value=1.70, $p < 0.1$), internal process (β 0.19, t-value=1.70, $p < 0.1$), which supports H4a and H4b. Regarding the innovation between and organizational performance described in H5a, H5b, H5c and H5d, a positive relationship existed between innovation and learning and growth (β 0.71, t-value=7.88, $p < 0.01$), internal process (β 0.60, t-value=4.69, $p < 0.01$), customer satisfaction (β 0.65, t-value=6.60, $p < 0.01$) and financial performance (β 0.72, t-value=5.48, $p < 0.01$), which supports H5a, H5b, H5c and H5d. Duy and Tuan (2014) showed that kms seen as playing an important mediating role in innovation between strategic knowledge management and firm performance. For example, Lopez-Nicolas and Mero˜no-Cerdan (2011) showed that the two knowledge management strategies of codification and personalization are mechanisms through which companies manage to achieve greater effectiveness and performance. Yousif et al. (2011) found that core requirements of knowledge management implementation (including critical successes factors of knowledge management, knowledge management strategies and knowledge management processes) can be in place to pave the way to ensure the successful implementation of knowledge management, which is reflected in the organizational performance improvement. Yousif et al. (2013) indicated that knowledge management strategies had a positive and statistically significant effect on organizational performance through the partial mediation effect of innovation. Ordonez (2002) attempted to identify how KM strategies affect organizational performance. She applied Bierly and Chakrabarti's typology of generic KM strategies to analyze a cross-section of Spanish firms. A significant relationship between KM strategies and non-financial performance was found. Pai (2005) empirically investigated 20 Taiwanese integrated circuit (IC) design firms from 1997 to 2002, and categorized them into discoverers, discretionists, external learners, internal exploiters, and overall creationists – emphasizing both learning from external sources and exploitation from internal sources. It was found that the internal exploiters were the best performers, while the discoverers were the worst in terms of ROA and ROE. Choi and Jong (2010)

extended previous work by showing an empirical relationship between KM strategy announcements and stock prices. Authors found that investors expected future benefits to a firm's performance as a result of system- and human-oriented strategy implementation. Our results enable managers to measure the effects of KM, and help them make decisions on the issue of KM strategies and KM-related investment priorities. Liao (2011) indicated that when firms emphasize personalization strategy, the use of behavior control will enhance firm performance. In contrast, when firms emphasize codification strategy, the use of output control will make firm performance better. If personalization and codification strategy were emphasized simultaneously, firms would not use single HRM control system to better performance. Finally, it helps to explain the relationships between certain specific strategies of knowledge management and the high performance work systems, from the perspective that they contribute to firm performance (Chen and Huang, 2009; Ling, 2013; Snell, Youndt, 1995).

In addition, the R-square values of all the variables were exceeded 10%, indicating substantive explanatory power (Bock et al., 2006; Falk and Miller, 1992; Hsu and Chang, 2014). As in Table 3, The R^2 value for each endogenous latent construct (i.e. innovation, learning and growth, internal process, customer related performance and financial performance) demonstrate an acceptable prediction level in empirical research. The coefficient of determination R^2, which is the central criterion for the structural model's assessment (Klarner et al., 2013), has a high value of 0.870 for this study's key target construct; i.e. innovation. This value of R^2 which is above 25% demonstrates a highly acceptable prediction level in empirical research (Gaur and Gaur, 2006; Griffith, 1996). Indeed, the high R^2 proves the model's predictive validity (Hair et al., 2012). Codification and personalization km strategies variables together explained 87% of the variance in innovation. All three variables together explained 86% of the variance in learning and growth, 75% of the variance in internal business performance, 80% of the variance in customer-related performance and 71% of the variance in financial performance (see table 3). The literature suggests that R^2 values of 0.67, 0.33, and 0.19 are substantial, moderate, and weak, respectively (Chin, 1998). Following the rules of thumb, the values of R^2 of variables are substantial. In the end, we examined predictive relevance (Stone-Geisser Q^2) (Stone, 1974), using the blindfolding procedure in SmartPLS with an omission distance set to 8 (Chin, 1998a; Geisser, 1975). All of the cross-validated redundancy Q^2 were considerably above zero (Tenenhaus et al., 2005), which indicates that the constructs of our model possessed predictive relevance regarding the reflective endogenous latent variables (see Table 3).

This study calculates the f^2 and q^2 effect sizes. The values of effect size f^2 and q^2 of 0.02, 0.15, and 0.35 appear as small, medium, or large (Chin, 1998a), which is similar to Cohen's implementation. Changes in R-square were explored to investigate the substantive impact of each independent construct on the dependent constructs, carrying out the effect size technique by rerunning three PLS estimations, excluding in each run one of the explaining latent constructs. Understanding that a small f^2 and q^2 do not necessarily imply an unimportant effect is crucial. "If there is a likelihood of occurrence for the extreme moderating conditions and the resulting beta changes are meaningful, then it is important to take these situations into account" (Limayem et al., 2001).The results of the effect size test presented in Table 3.

Table 3: Hypotheses testing results and f2 and q2 effect size.

Hypothesis	**Path (relationship)**	**Path coefficient**	**Effect size[1] f^2**	**Effect size[2] q^2**	**Standard error**	**t-Statistic[a]**	**R^2**	**Q^2**	**Decision**

[a] t-values for two-tailed test:
* 1.65 (sig. level 10%).
** 1.96 (sig. level=5%).
*** t-value 2.58 (sig. level = 1%) (Hair et al., 2011).
Notes:***p<0.01, **p<0.05, *p<0.1
effective size: 0 – none, 0.02 – small, 0.15 - medium, 0.35 – large (Cohen, 1988).
Effect sizes calculated using the following formulas
[1]f^2= R^2included - R^2excluded / 1- R^2included (1)
[2]q^2 = Q^2included - Q^2excluded / 1- Q^2included (2)

Regarding model quality, Wetzels et al. (2009) provide a global fit (GoF) measure for PLS path modeling and derive a GoF measure with effect sizes for R^2 by substituting the minimum average AVE of 0.50. The GoF measures have been suggested as baseline values for validating the PLS model globally (the cut value of GoF_{small}=0.1, GoF_{medium}=0.25, and GoF_{large}=0.36) (Tenenhaus et al., 2005; Wetzels et al., 2009). The research model obtained a GoF value of 0.75044, which is greater than the cut-off value of 0.36 and is considered an adequate GoF. These results demonstrate this model performs well.

Table 4: Structural Model

Fit measures	Endogenous construct	Final Model
R^2	Innovation	0,870
	Customer-related perf.	0,795
	Internal business perf.	0,749
	Learning and growth	0,856
	Financial perf.	0,713
GoF		0,750
Note. GoF = √ Average Communality x Average R^2		

4. Conclusion

Our research finds and explains the importance of the KMSs in relation to enhance innovation and improve OP. Empirical evidence is provided about the consequences of codification and personalization strategies on innovation and performance, developing previous researches in the field of KM where the link has been proposed quite often, but with scarce empirical support. Now, academics and companies are aware of the implications that KM and its strategy may have. Consequently, present study contributed to the previous studies through a proposed theoretical framework, which were based on both of RBV and KBV theories. The framework explains the direct relationship between KMSs (consisting of codification and personalization) and OP (consisting of financial perspective, customer perspective, internal process perspective, and learning and growth perspective metrics) and indirect relationship between KMSs and OP through investigate the intervening role of the innovation (consisting of product and process innovations).

As revealed from the research results, the present study shows that KMSs had a statistically significant and direct positive effect on innovation and OP. Furthermore, the present study represents the empirical investigation of the role of innovation in the relationship between KMSs and OP under RBV and KBV theories' perspectives, especially in the İstanbul Stock Market. To recap, these results provide evidence of mutually beneficial for both the theoretical and practical implications of the study and will help both academics and the practitioners in the KM area.

Certainly, the present study has contributed to the KMSs field. The results of the present study have theoretical and practical contributions. As such, the current attempt has managed to fill in gaps that existed in the KMSs literature. However, the present study faced generalizability limitation. The present study was limited to the İstanbul Stock Market. In this sense, results may be extrapolated to other Turkish sectors and other countries. Therefore, the study can be replicated in different countries or sectors, as this would most likely strengthen and validate the results of hypotheses. In this case, further studies are necessary to confirm these results and incorporate the other variables that may have influenced the results. Therefore, the future is wide open for more empirical research in this area.

Differences in the Organization and Planning of Corporate Education in Medium-Sized and Large Companies in the Czech Republic

Zdeněk Caha, Mgr., MBA, PhD., Department of Management, Institute of Technology and Business, České Budějovice, Czech Republic, E-mail address: caha@mail.vstecb.cz

Michal Ruschak, Ing. Faculty of Corporate Strategy, Institute of Technology and Business, České Budějovice, Czech Republic, E-mail address: ruschak@mail.vstecb.cz

Abstract

Effective and systematic corporate education, as a part of the overall company strategy, shows to be a key aspect for the maintenance of competitiveness in the present economy of knowledge. The aim of this paper is therefore to find out by means of a questionnaire survey to what extent large and medium sized companies in the Czech Republic apply a systematic approach to education, which is among others linked to the existence of long-term and annual education plans and also to the fact that education is organized systematically by the personnel department or by a dedicated staff department focused on education. We set two hypotheses. The first one was, that at least 70 % of large companies and 50 % of medium sized companies deal with education within the personnel department or within a separate staff department focused on education, and the second one was, that at least 70 % of large companies and 50 % of medium sized companies have a long-term education plan in place and also an annual education plan. Although none of the hypotheses was confirmed, a fact has been proven, that large companies after all approach to corporate education more systematically than medium-sized ones.

Keywords: corporate education, companies, planning, Czech Republic

Introduction

The goal we set in this paper was to ascertain by means of a questionnaire survey whether more than a half of large and medium companies in the Czech Republic apply the systematic approach to education, which is among others linked to the existence of long-term and annual education plans and also to the fact that education is organized systematically by a personnel department or by a dedicated staff department focused on education. We set the two following hypotheses, which we tried to confirm by means of mathematical-statistic methods:

H1 At least 70 % of large and 50 % of medium-sized companies deal with the education within the personnel department or within a separate staff department focused on education.

H2 At least 70 % of large and 50 % of medium-sized companies have a long-term education plan in place and also an annual education plan.

Literature Review

Employees are definitely one of the most important resources of a possible competitive advantage. It is therefore important to educate and develop employees systematically and effectively (Blahuš 2011, Vaníčková and Kmecová 2014). Bencsik and Sólyom (2011) also claim that the more a company is able to maintain, develop and utilize the knowledge of its employees the more it is able to achieve business success, as knowledge becomes a resource of long-term competitiveness and an advantage from the business strategy point of view. According to Armstrong (2014) strategic education and development, like strategic HR management plays a key role in the achievement of success of an organization. Koubek (2015) presents that education of employees of an organization is most effective if it has a cyclical character, is based on the education strategy and policy in the particular organization and is in compliance with the overall strategy of the organization. The basic cycle of the systematic education of employees of an organization actually consists of the identification of the need for education for the employees of an organization, planning of education, the implementation of the education process and

an assessment of the education programme results and effectiveness. Němec (2014) claims that systematic education of employees and conceptional planning and management of their career serves for the achievement of the organization strategic goals and contributes to long-term competitiveness of a company. Barták (2011) also underlines the importance of the strategic planning of corporate education by claiming that the cost of education should represent a profitable investment, which is why education planning should be based on an analysis of the present situation, taking into account the future needs and demands for the individual work positions. According to Hroník (2017), the presence of specialists in development and education is an indication of strategic approach, particularly in medium and large companies.

According to the results of an international survey of 2010 (ČSÚ 2013) only less than a third of companies reported written education plans or similar education programmes, only less than a half reported a budget for these activities. Estimations made by the International Labour Organization (2011) show that a one-per-cent growth of the number of days spent on education leads to a productivity increase of 3 % in a company. Quality training enable people to develop their capacities and to exploit social opportunities, it improves productivity of employees and a company as a whole, it contributes to future strengthening of innovation and development, it encourages domestic as well as international investments – and therefore also creation of jobs, it reduces unemployment, leads to higher pays and reduces social inequality. Collier et al. (2011) claim on the base of their own research that companies that systematically educate their employees have 13 % higher probability that they will survive. They also say that more studies researching into the long-term impact of education or human capital on a company performance in general are necessary. Kitching and Blackburn (2002) confirm the positive impact of the strategic approach to education. Korenková (2014) is convinced that people are the factor that mostly distinguishes one company from another at present. Employees are those, who decide whether a company will be successful or not by their active and creative approach to innovation and to customers themselves. Support for education is therefore crucial for the maintenance of the competitiveness. Staff education and development should be a part of the overall company strategy and policy, and it should be a coherent and systematic process. Korenková moreover claims that particularly large companies prefer an active and systematic approach to education, while a random approach prevails in medium-sized companies and a passive approach to employee education definitely dominates in small companies. This certainly depends on the funds available to a large extent. Small companies mostly invest into innovation and improvement of technologies and they leave education on the employees themselves. Tej, Sláviková and Hrvolová, M. (2010) divide companies into three categories according to the approach to education they choose, namely companies without an education strategy, companies with a non-systemic strategy and companies with a positive systemic strategy. They hold the view that companies achieve competitive advantages through their employees. Although the effectiveness of the money invested into education is often hardly enumerable, education is an investment that certainly pays off to companies. Cagáňová et al. (2014) characterize the level of the orientation of companies active in the field of education and employee development in Slovakia and present the results of a research carried out with 340 companies in 2012. They came to a conclusion that the need for education and a complex approach to education belong to the characteristics of innovative organization. Organizations should become the so-called learning companies with the aim to achieve permanent education focused on the improvement of the performance not only on short-term, but also on long-term basis.

Methodology of the Statistical Processing

We had results from a questionnaire survey from 164 medium-sized companies (50-249 employees) and 123 large companies (250 or more employees) available for the processing. The survey was carried out among companies in the Czech Republic in the second part of 2017.

In the first phase of the assessment we prepared a table of the absolute and relative fre-quencies of the companies according to the way how they deal with the education for em-ployees. On the base of the results we prepared an interval estimation, which covers the real proportion of the companies that deal with the education within the personnel department or within a separate staff department focused on education with the confidence of 95 %. This way we ascertained in what limits the real value of this proportion may fluctuate.

In the second phase, we prepared tables of the absolute and relative frequencies of the companies in dependence on the fact whether they do or do not have a long-term education plan, on the base of the questionnaire data. As we are interested in whether a company has a long-term education plan in place, we unified the answers "yes" and "yes but it is not ad-hered to" into one answer "yes". We logically assigned "no" to the companies that had not replied to the question at all. From the frequencies obtained this way we also prepared a 95 % interval estimation, which covers the real proportion of companies with a long-term edu-cation plan.

In the third phase, we analogically copied the processing procedure for a question dealing with the annual education plan. We examined the real proportion of the companies that have an annual education plan in place.

The tables were prepared by means of MS Excel, the interval estimations by means of R statistical software.

The Results of the Statistical Processing

a) The frequency of the companies that deal with the education within the personnel department or within a separate staff department focused on education.

Table 1: Dealing with the company education – absolute numbers

Company size	Dealing with the company education			
	not systematic	at the owner/manager	staff department	total
Medium companies	22	83	59	164
Large companies	16	16	91	123

Source: authors

Table 2: Dealing with the company education – relative numbers

Company size	Dealing with the company education		
	not systematic	at the owner/manager	staff department
Medium companies	13%	51%	36%
Large companies	13%	13%	74%

Source: authors

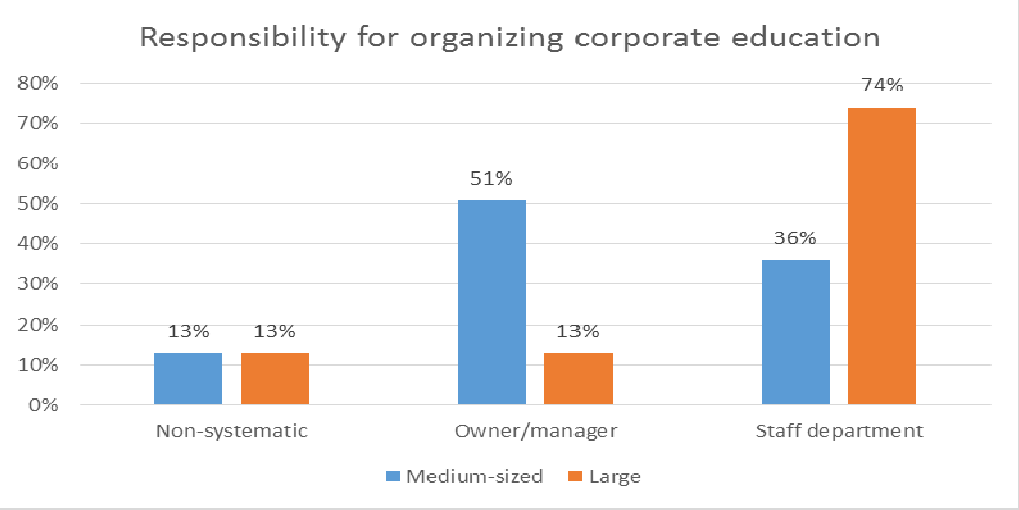

Fig. 1: Dealing with company education - absolute numbers

Source: authors

Table 3: Interval estimations for the proportion

	Interval estimation
Medium companies	(0.290; 0.436)
Large companies	(0.656; 0.809)

Source: authors

The results show that the proportion of the companies that deal with the education within the personnel department or within a separate staff department focused on education is significantly lower among medium sized companies than that among large companies. The questionnaire survey shows 36 % among the medium and 74 % among the large companies. The interval estimation then indicates that the real proportion of companies should oscillate be-tween 29 – 44% among the medium companies and between 65 – 81% among the large companies after rounding.

b) The frequency of the companies that have a long-term education plan in place

Table 4: Long-term education plan in place – absolute numbers

Company size	The company has a long-term education plan in place		
	no	yes	total
Medium companies	75	89	164
Large companies	34	89	123

Source: authors

Table 5: Long-term education plan in place – relative numbers

Company size	The company has a long-term education plan in place	
	no	yes
Medium companies	45.7%	54.3%
Large companies	27.6%	72.4%

Source: authors

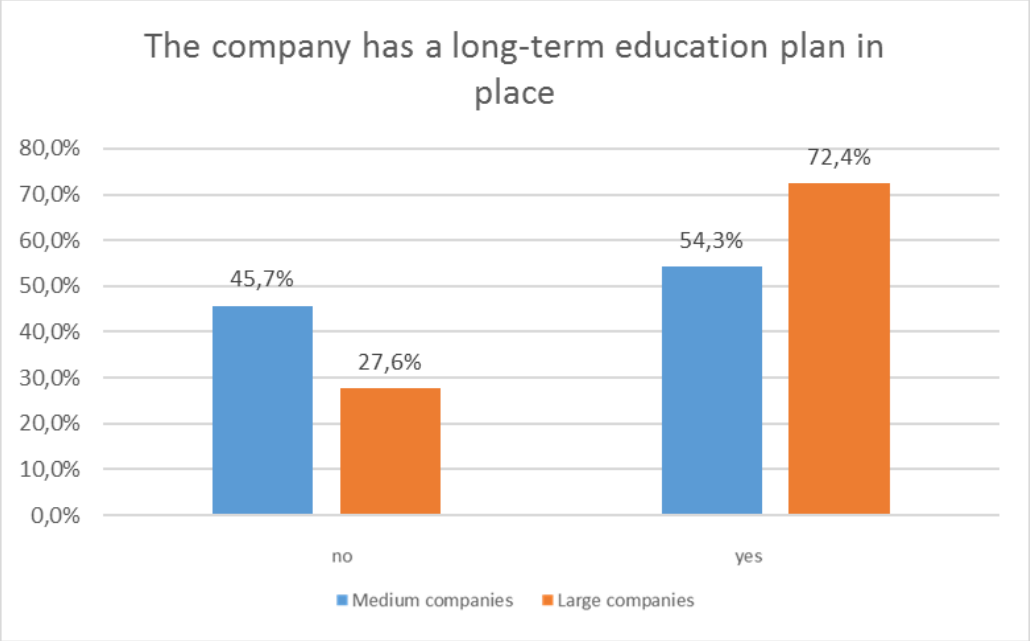

Fig. 2: Long-tern education plan in place – relative numbers

Source: authors

Table 6: Interval estimations for the proportion of long-tern education plan in place

	Interval estimation
Medium companies	(0.466; 0.617)
Large companies	(0.639; 0.795)

Source: authors

The proportion of the medium companies that have a long-term education plan in place is significantly lower. The proportions ascertained by the questionnaire are 54.3 % in the group of the medium companies and 72.4 % in the group of the large companies. If we look at the interval estimations we can see that they do not overleap at all, so the difference in the frequency of the companies that have a long-term education plan is statistically significant. The real proportion of the companies that have a long-

term education plan in place can be expected between 47 – 62 % among the medium companies and between 64 – 80 % among the large companies after rounding.

c) The frequency of the companies that have an annual education plan in place

Table 7: Annual education plan in place – absolute numbers

Company size	The company has an annual education plan in place		
	no	yes	total
Medium companies	91	73	164
Large companies	108	15	123

Source: authors

Table 8: Annual education plan in place – relative numbers

Company size	The company has an annual education plan in place	
	no	yes
Medium companies	55.5%	44.5%
Large companies	87.8%	12.2%

Source: authors

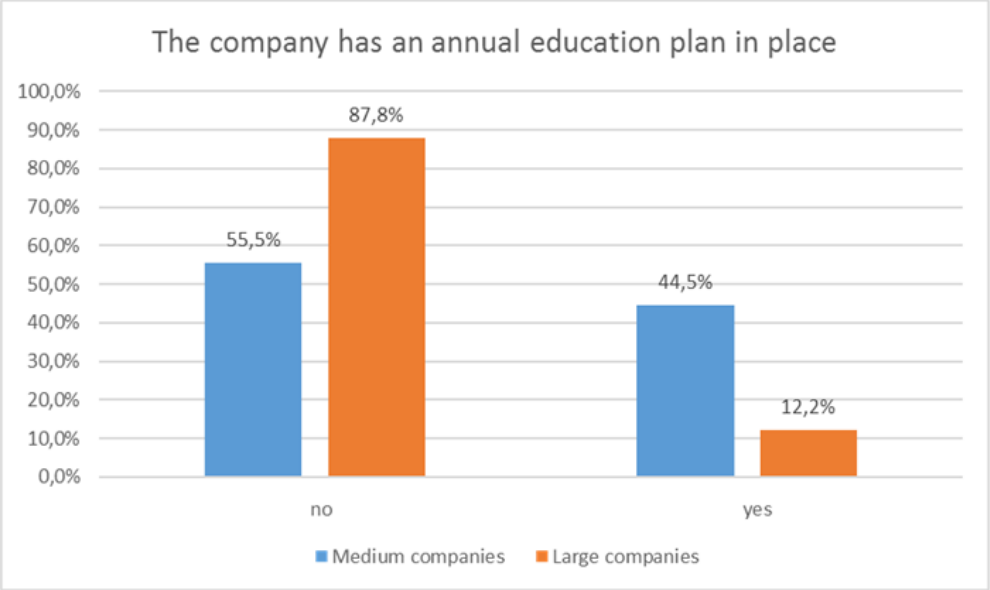

Fig. 3: Annual education plan in place – relative numbers

Source: authors

Table 9: Interval estimations for the proportion of annual education plan in place

	Interval estimation
Medium companies	(0.478; 0.629)
Large companies	(0.809; 0.925)

Source: authors

The difference between the medium and the large companies is even higher in terms of the annual education plan. The proportion of the companies with an annual education plan in place is 55.5 % among the medium companies, while the interval estimation indicates a possible position of the real proportion between 48 – 63 % after rounding. The proportion ascertained among the large companies is 87.8 %, while the interval estimation indicates a possible position of the real proportion between 81 – 93%. The two intervals do not overleap and there is the difference of 18 % between the upper and the lower limits of the interval estimation, so the real difference will probably be even higher.

Conclusion

Despite of the fact that the set hypotheses were not confirmed, the results of the research have shown a significant difference between the medium-sized and the large companies in most of the monitored aspects.

The proportion of the medium-sized companies that deal with the education within the personnel department or within a separate staff department focused on education is substantially lower (36%) than that of the large companies (74%). The interval estimation then indicates that the real proportion of companies oscillates between 29 – 44 % among the medium companies and between 65 – 81 % among the large companies.

The questionnaire survey has brought an interesting finding, that 13 % of the medium-sized companies and the same percentage of the large companies do not deal with education systematically within one department, and that among the medium-sized companies education is in the competence of the owner/head of the company in more than a half of them (51 %).

The research has also proved that systematic long-term planning of education is significantly lower among the medium sized companies than among the large companies. The proportions found out by means of the questionnaire are 54.3 % for the group of the medium-sized companies and 72.4 % for the group of the large companies. The interval estimations have shown that the difference in the frequency of the companies that have a long-term education plan in place is statistically significant. These proportions are between 47 – 62 % among the medium companies and between 64 – 80 % among the large companies.

The difference between the medium-sized and the large companies is even more remarkable in terms of the annual education plan. The proportion of the companies with an annual education plan in place ascertained by the questionnaire is 55.5 % among the medium-sized companies, the estimation indicates the real proportion between 48 – 63%. Among the large companies the proportion ascertained by the questionnaire is 87.8 %, while the interval estimation indicates the position approximately between 81 – 93%.

In general, we can conclude that a relatively high percentage of companies, particularly the medium-sized ones, still do not plan their education either on long-term or short-term basis, which shows that these companies do not approach the education for their employees systematically and do not perceive it as one of the key personnel activities, which may influence the company performance and competitiveness to a significant extent.

The Antecedents and Consequences of Consumer Engagement in Social Networking Sites

F.Zeynep Özata, Porsuk Technical School, Anadolu University, Eskişehir, Turkey, E-mail: fzozata@anadolu.edu.tr

Abubakar Lujja, Graduate School of Social Sciences, Anadolu University, Eskişehir, Turkey, E-mail: abbysa9@outlook.com

Abstract

Consumer engagement is increasingly becoming one of the important issues in the competitive business environment. Both researches and practitioners are focusing on how consumer engagement can be enhanced through different channels. The emergence of social networks has significantly caused a shift in consumer behaviors and brand relationships. With its unique features and structure, Social Networking Sites (SNS) offer an upper advantage to build consumer brand relationships and instant consumer engagement. Although researchers and practitioners are giving so much importance to consumer engagement, there is still a need to understand what influences engagement and how engagement affects consumer behavior.

Therefore, this study set out to determine the antecedents and consequences of consumer engagement in SNS. It further viewed consumer engagement as a multi-dimensional concept comprising behavioral, cognitive and emotional dimensions and as such the hypotheses were aimed at determining how each of the three dimensions of consumer engagement is affected from the customer related antecedents (involvement, satisfaction, commitment and trust) and affect the individual consequences of consumer engagement such as brand loyalty and word of mouth. Research model is designed based on the model used by Malciute (2012).

The study used a quantitative research design and developed a model that was based on the hypotheses developed for the study. It used a questionnaire survey to collect data from University students. Facebook is chosen as a case for this study. 400 questionnaires were collected and the analyses were conducted with the 387 valid questionnaire. The research data was analyzed by using SPSS and Lisrel programs. First a confirmatory factor analysis was conducted to test the measurement model and then the structural model was tested.

The results suggest that emotional, behavioral and cognitive consumer engagement dimensions were significant predictors for brand loyalty. On the other hand only the emotional and cognitive consumer engagement dimensions were significant predictors for word-of-mouth. Involvement and commitment were found to be significant predictors for all engagement dimensions. Satisfaction predicts both emotional and end cognitive dimensions of engagement, whereas trust only predicts emotional

consumer engagement. In sum, the study suggests satisfaction, involvement, commitment and trust to be possible antecedents of consumer engagement and brand loyalty and word-of-mouth to be possible consequences of consumer engagement in an online platform such as Facebook in our case.

Determinants of Capital Structure – Evidence from Karachi Stock Exchange 30-Index

Farheen Khalid, Institute of Business Management, Karachi, Pakistan. farheen.khalid@iobm.edu.pk

Bilal Ali Zafar, Applied Economics & Research Center, Karachi, Pakistan. bilalalizafar@gmail.com

Syed Aqeel Ahmed, Iqra University, Karachi, Pakistan. Syedaqeelahmed6@yahoo.com

Abstract

In this study to analyze Karachi Stock Exchange listed companies with respect to determinants of capital structure. This study is focused on KSE-30 index companies which provide the benchmark for the stock price performance over the time period. Data has been analyzed for the period 2006-2010 by using OLS regression with five variables i.e. firm size, growth rate, earning rate, debt service capacity and degree of operating leverage. For examining determinants of capital structure Pecking order theory and Trade-off theory are pertinent theories. Results show that firm size, earning rate and operating leverage have negatively significant on leverage and growth and debt service capacity have positively significant on leverage.

Keywords: Capital Structure, KSE 30 Index, Pecking Order Theory, Trade-off Theory, OLS Regressions.

1. Introduction

Financing of capital structure with refers to relationship between long term and short term with various modes such as share capital, bonds, banks, and debenture and equity capital. In other words, to attend the firm goals and to maximize its overall value, it must be to set targeted proposition by mixing equity capital and debt capital. Different thoughts of schools promulgate different theories of capital structure. Two extreme approaches, net income approach of capital structure publicize by David Durand in 1952, this approach defined the relationship between financial leverage, value of firm and cost of capital on overall basis, means a single change in the financial leverage or debts that directly effect on the firm value and total capital cost, because this have a corresponding relationship with each other, where as net operating approach contrary to net income approach means change in financial leverage will not directly effect in the value of the firm.

Traditional approach of capital structure promoted by Ezta Solomon and Fred Weston in 1963, this approach is treated as middle approach between operating approach and net income approach, according to this theory an appropriate combination of equity and debts will always lead to maximize market value the firm. This approach acknowledged that financial risk perceived by equity shareholders and expect premiums for the risks undertaken. This theory also responded that after a debt level in the structure of capital, the equity cost of capital increases.

Modigliani Miller approach 1958 (MM, 1958), widely known as Modern approach of capital structure, MM approach supported the net operating approach and go along with the fact that the cost incurred on investment (cost of capital) is self-determine of the degree of leverage and at any mix of debt-equity proportions. This approach was theoretically very sound but on the base of some assumption equal business risk among firms, similar operating environment, market without arbitrage opportunities means perfect capital market and without tax, accepted in the real world which has not been possible.

(Modigliani and Miller 1963), encompassed the capital cost of firm and its value due to the effect of tax, challenge that, with the existence of tax effect, firm value altered with the alteration of the debts utilization because of benefit of tax on bill of interest (Baral, 1996).

KSE-30 index provides the benchmark for the stock price performance over the time period which provides the knowledge to people who wants to finance in the specific firm, that how much organization applies to the purchase of full shares in Pakistan equity market. Thus, KSE-30 index gauges the various economic activities of different sectors similarly as other indicators i.e. Gross National Production (GNP), Gross Domestic Product (GDP), Consumer Price Index (CPI) etc.

The methodology of free float of index building is one of the best techniques followed globally by Standard & Poor's (S&P), Modern Index Strategy Indexes (MSCI), Financial Times Stock Exchange (FTSE), have adopted same technique to provide index building. KSE-30 Index is also applying methodology of "Free-Float Market Capitalization" because it is the better way of calculating capitalization of the market as it provides exact market movements reflections. By using Free-Float methodology, the level of index value of these 30 organizations is reflected to the base period at any point of time.

2.1 THEORETICAL BACKGROUND

In analyzing the firm capital structure four main theories must be focused which are Static Tradeoff theories, pecking order theory, Signaling Theory and Agency Theory

2.1.1 Static Tradeoff theory

Trade off theory of capital structure originally emphasizes on the relation of cost and benefit of leverage where as Modigliani and Miller in 1963 introduced the tax advantage of leverage into this theory. By using trade off theory, optimum capital structure can be determined. Firstly, component of cost of debt is considered typically bankruptcy cost of debts; which includes direct and indirect bankruptcy costs.

95% of the study gives the impression of contradiction between shareholders and managers in this area. The other gives the impression of argument share holders and debt holders. Therefore, these two theories are equally important to describe how trade-off theory is associated with agency theory.

2.1.2 Pecking order theory

This theory describe that firm proceed with the hierarchy for financing decisions in establishing capital structure. Internal financing i.e. retained earnings and the impact of depreciation is used on the first priority, before using any form of external funds, no flotation cost has been incurred by using internal funds and has not required any additional disclosure of financial information i.e. quotas and targets, sales and overhead volume, profit margin, budget etc. that could effect on of competitive advantage and more severe market discipline. Following order of financing sources preferable when a firm use external funds: leverage or debts, securities which are convertible, common and preferred stock. Motivations of the manager finance has been reflected by following order to keep hold on the firm, lower the agency costs of equity, and keep away from predictable harmful reaction of market to an declaration of issuance of new equity. (Hawawini and Viallet, 1999).

2.1.3 Signaling theory

Ross (1977) introduced Signaling theory, this theory explain, for any organization debt is assumed to be a symbol of assurance in the capital structure, organization facing problem in managing their cash flows will manage by of debt. Large size of debt is trustful for management of organization. This theory also support Pecking Order Theory concept of equity under pricing. Investor feel negative sign, managers may issue the equity on overpricing because they are mostly well up to date regarding the information of the company.

2.1.4 Agency Theory

Agency Theory is another explanation to decide on capital structure of an organization. The approach of difference in shareholders and managers is acknowledged by Jensen and Meckling (1976). The purpose of this approach is to study the behavior of manager of an organization who is just like agent of shareholders, who unnecessary increase the rate of debt of an organization and invests in doubtful projects.

This approach is similar with the approach of Myers' working (1997), in his approach gearing ratio of an organization would be low due to incomplete or unrecognized information for that graph of overall worth of the organization is also decreasing, utilization of free cash flows by managers in their own benefit whose stake is less than 100 percent in the organization.

3. Research Methodology

3.1 Data and Sample

In this study we have used time series data. The secondary source of data is the State Bank of Pakistan, listed companies of Karachi Stock Exchange 2006-2010" and "Balance Sheet Analysis of the Companies, This study has focused on the all 30 companies in Pakistan, listed in Karachi Stock Exchange-30 index.

3.4 Hypothesis

Following hypothesis has been tested in this study to analyze the relationship between the capital structure of listed companies in KSE-30 index and described variables.
H_1: There is significant relationship between the firm size and financial leverage.
H_2: There is significant relationship between the growth and financial leverage.
H_3: There is significant relationship between the earning and financial leverage.
H_4: There is significant relation between the debt service capacity and financial leverage.
H_5: There is significant relation between the operating leverage and financial leverage.

Model

Relationship between variables affecting factor, this study estimate the determinants of capital structure that is financial leverage dependent variable and size of firm, rate of growth, earning rate, debt service capacity and degree of operating leverage independent variable of companies in Pakistan, listed in KSE-30 index.

$$FL = \alpha + \beta_1 FS + \beta_2 GR + \beta_3 ER + \beta_4 DSC + \beta_5 OL + \varepsilon$$

Where
FL = Financial Leverage, FS = Firm Size, GR = Growth Rate[1], ER = Earning Rate,
DSC = Debt Service Capacity[2], OL = Degree of Operating Leverage, ε = error term

4. Empirical Results

Parameter Estimations disclose in given Table of each variable which is the major part of regression model; it shows various values like Constant (α), Coefficients (β), P-values, T-Value, F-value, value of Durbin Watson (DW), value of Adjusted R^2 and Model significance. The model is analyzed at 95% confidence interval.

Table 1 : Result Summary

Variables	**Beta**	**t-stats**	**Probability**	**VIF**
Constant	2.256	7.659	(0.0000)	-
Firm Size	-0.482*	-7.570	(0.0000)	1.096
Growth Rate	0.164*	0.028	(0.0001)	1.091
Earning Rate	-3.145*	-3.875	(0.0022)	1.198
Debt Service Capacity	0.079*	3.730	(0.0029)	1.072

Source: Author's estimation

The result achieved from the regression analysis are shown in the Table 1, the Adjusted R-Square value (0.9735) confirm that five independent variables i.e. Firm Size, Growth Rate, Earning Rate, Debt Service Capacity and Operating Leverage respond approx 97% of variation with dependent (response) variable

[1] Result extract after taking log of Growth Rate Values

[2] Result extract after taking log of Debt Service Capacity values

Financial Leverage. Value of DW (1.1059) is totally justified by Correlation LM test F-stat is (0.8629) and P-value (0.4511) that there is no serial correlation. The Coefficients (β) values demonstrating the contribution of every Predictor variable in the model, Firm Size, Earning Rate and Operating Leverage are showing Negative relation with Leverage where as Growth Rate and Debt Service Capacity are Showing Positive relation with Leverage. Level of significance is tested by P-value at 5% and overall results are significant which is witness by P-value is less then (0.05).

Table 2: Expected and Observed Relationship

Determinants	Measure	Expected Relation with Leverage		Observed Relationship
		Pecking Order Theory	Static Tradeoff Theory	
Firm Size	Log of sale	Negative	Positive	Negative
Growth Rate	$\sqrt[n]{\frac{TA_n}{TA_0}} - 1$ [3]	Positive	Negative	Positive
Earning Rate	EBIT divided by Total Assets	Negative	Positive	Negative
Debt Service Capacity	EBIT divide by Total Interest Charge	Positive	Positive	Positive
Operating Leverage	[4] $\frac{\left[\frac{(E_t - E_{t-1})}{E_{t-1}}\right]}{\left[\frac{(S_t - S_{t-1})}{S_{t-1}}\right]}$	Negative	Negative	Negative

Source: Author's estimation

The result obtained show the value of coefficients (β) for Firm Size is (-0.4829), this is the sign of negative relationship with Leverage which describe that profitable companies in KSE-30 are prefer equity financing and not interested to finance from borrowing. This result is backed by Pecking Order theory consistent with Rajan and Zingales (1995), in his views less asymmetric information related to large firms, suggested that issuance of new equity will not be under priced and thus more equity will issue by large firms and this results are contradict with Static Tradeoff approach which were supported earlier by Titman and Wessels (1988).

[3] TAn=Total assets at the end of the observed period
TAo=Total assets at the beginning of observed period
n=Number of observed period

[4] E= EBIT
S= Net sale at the end of observed period
t= Financal year (time)

Positive relationship exists between Growth Rate and Leverage, coefficient values of Growth rate is (0.1644). Growing companies in KES-30 index are using more debts instead of internal financing, in order to meet the need of huge cash flow growing companies relying on debt financing. However, this result support by broaden version of pecking order theory, as per this theory funds generated by growing firms from their internal sources may not be sufficient therefore they may prefer external financing. Similar results are obtained by Baral (2004) and Shah and Hijazi (2004).

Results of Earning Rate are showing negative relationship, a value of coefficient of Earning rate is (-3.1456). Profitable companies in KSE-30 index maintain low rate of debts. Obtained result is supported by Pecking order theory that worth full and high profitable firms first prefer equity financing funds before increasing the ratio of debt financing. Obtained outcome is backed by Titman and Wessels (1988) and Shah and Khan (2007), as describe by Frydenberg (2001b) most important source of internal financing is retained earning.

The coefficient value of Debt service capacity is (0.0797) is positively related with ratio of leverage , which statistically showing significant. This result recommend that companies are in debt as per their debt service capacity and companies have an ability to repay the debts borrowed from other sources ,this study is supported by empirical study of Baral (1996) conducted in Nepal for the enterprises of the public sector

Negative relationship exists between Degree of Operating Leverage and Financial Leverage as supported by both agency cost theory and bankruptcy cost theory, Beta values of Degree of Operating Leverage is (-0.001). Utilization of fixed cost in manufacturing process can affect capital structure of firm. The total cost in manufacturing process over the period of time with higher rate of fixed cost and higher rate of operating leverage can expend the instability in the earning of future time period. Results showing that no autocorrelation exist between the predicting variables which is justify by value of Durbin Watson (1.1059) and Correlation LM test F-stat. (0.8629) and Probability (0.4511). The diagnosis of multi-co linearity among predictors in the regression model generated by SPSS revealing that to identify existence of correlation among independent variables as Firm Size, Growth Rate, Earning Rate, Debt Service Capacity and Degree of Operating Leverage in this model. As a rule of thumb, values of variance inflation factor (VIF) justify by value of significance which is less then 10.

Conclusion

In this study we analyzed companies listed in Karachi Stock Exchange-30 index and their determinants of capital structure, time series data has been collected from published data of SBP and companies Financial Statements. Data has been analyzed by applying pooled regression model. We found that growing companies in KSE-30 Growth Rate are positively correlated with Financial Leverage which is supported by extended version of Pecking Order Theory. The suggestion in this regards is that growing companies relying on debt financing because of managing cash flows and fund generated by internal sources not sufficient for growing companies so another option would external financing. Debt Service Capacity is also showing positive relationship with leverage showing that companies have an ability to pay off the debts which they have borrowed for managing their capital structure. Thus the result backed by recognized theory presented earlier. Therefore we accept our first hypothesis.

Firm Size, Earning Rate and Degree of Operating Leverage is negatively correlated with Leverage.
Larger Firms with higher rate of profitability interested in internal financing before given preference to borrowing money. Bigger firms relying on their profit and retained earnings for investment in profitable projects so they can earn more with it and be far away from bankruptcy because relying on their internal funds. Thus the result reject the approach of Static Tradeoff Theory and support the approach of Pecking

Order Theory. Similar results obtained in studies of Titman and Wessels (1988) and Shah and Khan (2007).

Some Aspects Of System Dynamics Application In Czech Defence Strategic Management

Antonín Novotný, Ph.D., University of Defence in Brno, Czech Republic antonin.novotny@unob.cz

Dalibor Procházka, CSc. University of Defence in Brno, Czech Republic dalibor.prochazka@unob.cz

Abstract

The article deals with the topic of system dynamics application in strategic management. After several years of reducing of the Czech defence budget there is a reversal and the Czech Ministry of Defence begins to manage the increased budget. This represents a new challenge and opportunity. One of the instruments, how to reach new capabilities, is application of system dynamics. The application of systemic dynamics to the problem of military capabilities is given by the very nature of the process of building military capabilities. Some aspects of capability and equipment life cycles and human resources or personnel development are discussed. Application of system dynamics to military personnel career policy is demonstrated by means of simulation in Vensim application.

Keywords: Strategic Management; Defence Policy; Dynamic System; Vensim.

Introduction

The Czech Republic´s defence is based on the responsible approach of the Government, and the other public administration authorities, to ensure the national defence system; on the development of the requisite defence capabilities within the framework of NATO´s collective defence; an on involvement of Czech citizens in defence activities in the event of a serious threat to the state. An important aspect in proper functioning of these three pillars is to strengthen motivation and create a clear legal framework as well as real opportunities for the preparation of citizens in performing their duties as part of national defence (MoD. Defence strategy of the Czech Republic, 2017).

Establishment Of The Defence Policy And Strategy

By joining NATO in 1999 and joining the European Union in 2004, the Czech Republic joined the group of countries sharing the same values, freedom, peace and security. From this point of view, it is natural that the Czech Republic, as a member state of both these organizations, cannot be excluded from any activities and fulfilment of the commitments it has made.

In addition, it was also necessary to adapt development of the Armed Forces and their main component - the Army of the Czech Republic. The basis for this process, in addition to strategic development documents, is an adequate and predictable resource framework for defence spending, a problem faced by the Ministry of Defence for more than a decade. Meanwhile, the situation has changed. Under the agreement on the increase of the Czech Republic's defence budget, signed in September 2014, the MoD budget will gradually increase to 1.4% of GDP by 2020 (army.cz 3.9.2014). Since 2015, therefore, the opposite trend occurs and the budget of the Ministry of Defence should work with a total of CZK 460 billion by 2025 (The Long Term Perspective for Defence 2030). However, the increase in the budget should not be self-serving, but must be linked to its most efficient spending, because simple increase in defence spending does not yet ensure the development of military capabilities or their direction. The Czech Republic and its allies must be ready for predictable and prepared for unexpected situations once it comes to safeguarding of their defence and security (Procházka, Dyčka and Landovský 2016).

The framework for fulfilling the political and military ambitions of the Czech Republic represents document The Long Term Perspective for Defence 2030. It serves as a guideline for defence planning, particularly in developing five-year medium term plans. Based on an analysis of trends in the strategic environment, it outlines the basic direction for military capabilities development and provides guidance for the Concept of the Czech Armed Forces Development 2025, and other conceptual documents. The aim of Concept of the Czech Armed Forces Development 2025 is to define the frame and means of the capability development which are indispensable to fulfil tasks and commitments of the Czech Armed Forces in the horizon of 2025.

The philosophy of this document:

- is completed on the basis of Act No. 219/1999 Coll., on the Armed Forces of the Czech Republic;
- takes into consideration national security interests, principles of collective defence and prediction of the development of security environment;
- evaluates current status of capabilities and defines frame and means of the key capability development;
- provides base for strategic planning forms frame for concepts of lower grades;
- addresses a peace time structure.

The Long Term Perspective for Defence 2030 stems from the legal system and the strategic policy documents of the Czech Republic, and takes into account the principles of NATO and EU security policies and military documents.

The National Defence System is a part of the Security System of the Czech Republic as defined in the Security Strategy of the Czech Republic. The core function of the National Defence System is to prepare, manage, coordinate and support the activities of relevant authorities, forces and assets in ensuring he defence of the Czech Republic, including early identification and prediction of the development of threats and their assessment. The National Defence System is intertwined with NATO's environment. Control over the National Defence System is exercised by the President of the Czech Republic, the Parliament of the Czech Republic, the Government with its relevant working bodies, Ministries, and other central administrative authorities. The Ministry of Defence is responsible for the process of planning of national defence and coordinates the implementation of planned measures. During a state of national emergency or a state of war, special structures are formed to provide direct control over national defence. The Armed Forces serve as the principal executive element of the National Defence System, in conjunction with other state administration, regional and local government bodies as well as legal entities and individuals to the extent defined by law.

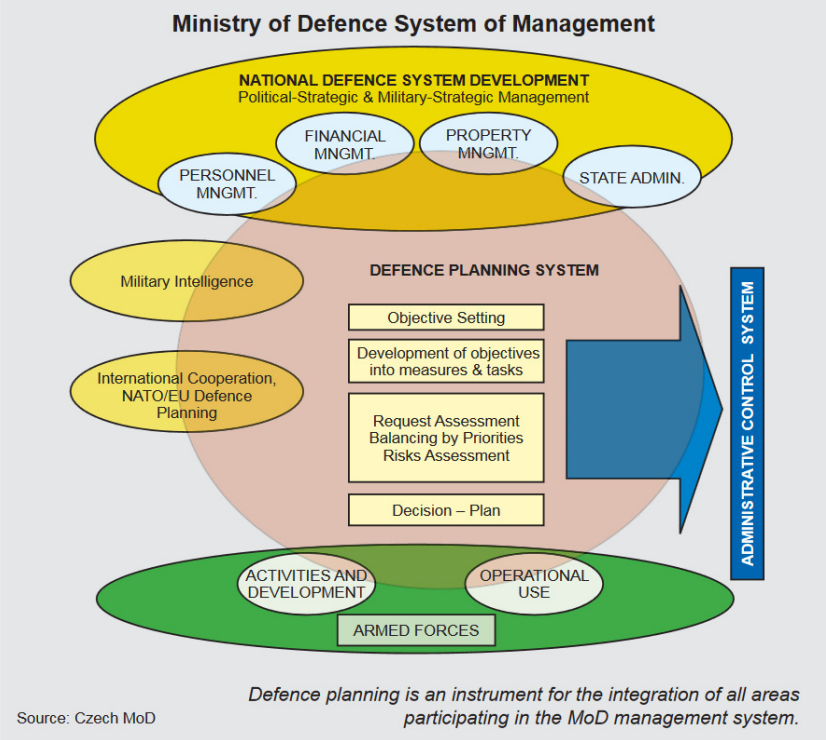

Fig. 1: Ministry of Defence System of Management

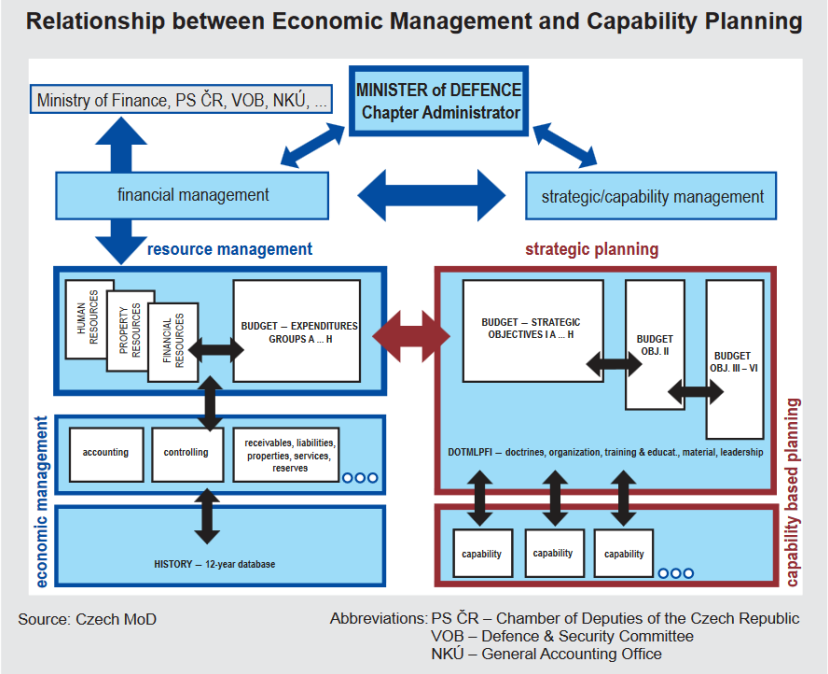
Source: White Paper on Defence. Prague 2011.

The Government of the Czech Republic and all local government bodies are responsible for safe-guarding, within their respective spheres of authority, the security of the population, the defence of the country's sovereignty and territorial integrity, and the preservation of all constituent elements of the democratic rule of law. A comprehensive and functioning security system continuously adapting to the current security situation in the Czech Republic and worldwide provides the institutional means to attain this end. The Security Strategy of the Czech Republic presents the approaches, tools and measures that safeguard the security, defence and protection of the population and of the state. Due to the nature of the present security challenges, the security policy can no longer be strictly segmented by security concerns. To effectively safeguard the Czech Republic's security, it is vital to have an institutionally as well as physically coherent and coordinated set of tools.

The Ministry of Defence has undertaken structural reform of the acquisition system, including open competition in public contract area, and asset management. This reform is based on the following principles: transparent, directed and target-oriented planning; clearly designated responsibilities of users for appropriately and factually defined needs and requirements; and professional management of the acquisition process in the system of central purchasing. This system operates under a qualified and independent technical and legal monitoring.



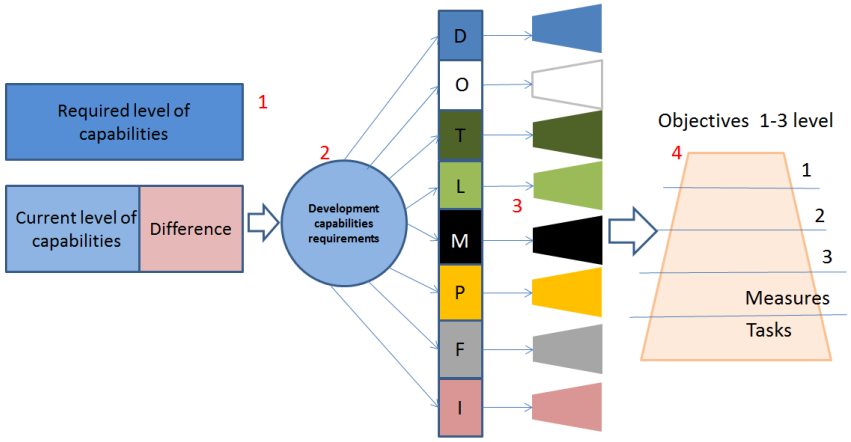


Fig. 2: Relationship between Economic Management and Capability Planning

Source: White Paper on Defence. Prague 2011.

Evaluation of a capability is important for capability planning and building processes. It provides a base for the Czech Army's capabilities building as well as for inputs to international activities. According to DOTMLPFI methodology (Doctrine, Organisation, Training, Material, Leadership, Personnel, Facility, Interoperability), during the planning processes, functional areas capabilities are considered. This facilitates comprehensive structured description of required changes of the existing state. It is obvious that the capability evaluation has a multi-criterial character, but as a simplification, we assume that the capability level can be characterized by a non-negative value.

Fig. 3: Planning by objectives

Czech National Political And Military Ambitions

The Success of the Czech national political and military Ambitions is reliant on:

- The Medium-term financial perspective of the resource framework for the defence budget and an adequate annual budget;
- A stable environment for the Czech Armed Forces personnel development;
- Support to the Czech defence industry and utilization of the research, development and innovation outcome, which in turn will help the Czech Armed Forces to achieve its required capabilities.

There are three pillars of the Czech Republic´s defence:

Pillar 1: responsible approach by the state to the defence of the Czech Republic, and NATO and EU membership commitments;

Pillar 2: Capable Armed Forces;

Pillar 3: The civil duty of national defence (MoD. Defence strategy of the Czech Republic, 2017).

To achieve military capabilities following prerequisites are necessary:

Defence Budget And Budget Outlook

The approved 2017 MoD Budget ensures essential resource framework for implementation of The Concept of the Build-up of the Armed Forces of the Czech Republic 2025 agreed and ratified by the Czech Government on 21th December 2015. This key strategic defence document outlines the scope and achievability of the identified capabilities vital to the politico-military ambitions and all the tasks and commitments of the Armed Forces up to 2025 in the context of collective defence. The implemented priorities are defined in the Minister´s Guideline for planning the MoD operation and development in 2018-2022 with specification for 2017.

The 2017 MoD Budget will cover primarily:

- non-discretionary expenditures related to personnel with the anticipated personnel number growth;
- strategic projects expenditures;
- expenditures related to the fulfilment of commitments towards NATO, represented by the adopted capability targets (CT 2013) implementation, in the area of defence planning;
- commitments resulting from the membership of the Czech Republic in international organizations;
- ACR troops deployment abroad expenditures.

MoD budgetary limit for 2017 is higher by CZK 4,751.907 million compared to the year 2016. The Mid-term outlook framework for the year 2018 is set in the amount of CZK 57,770.485 mil. and CZK 62,654.100 mil. for the year 2019 (MoD. Budget, Facts & Trends 2017).

Personnel Development

A key factor in achieving the capabilities of the armed forces is personnel, and implementation of adequate legislative measures. Recruitment, education and training of highly qualified military servicemen and civilian personnel and welfare are a priority. From the available demographical analyses, it is evident that in the next ten years the number of citizens of the ideal recruitment age, 18 to 25 years, will decrease. It is therefore important that the MoD is perceived as a responsible, reliable and attractive employer able to compete in the labour market (MoD. The Long Term Perspective for Defence 2030).

Defence Industry And Research

The Czech Republic, given its small size, has a relatively strong arms industry, with several historic defence brands, a well-developed production base, sizeable local workforce, and advanced technological expertise in a range of specialist areas. It is specially focused in the areas of aerospace, military electronics, SALW and heavy transport trucks (EDA, 2016). The Czech defence industry´s largest production centres focus on air systems and military logistic vehicles, with a range of full platforms successfully marketed for export abroad including the L-39 jet trainer, L-159 light attack aircraft, TATRA T6x6 and 8x8 military transport trucks and tactical heavy vehicles. Other key capabilities at the system, sub-system and component level include aerospace structures, radiolocation system, IT and simulation equipment, military electronic, small arms and ammunition. Czech firms are also active in maintenance, repair, upgrade and other services, including training and demilitarisation.

Czech defence firms are represented by the Defence Security Industry Association (DSIA). The association has 113 members, of which 67 per cent are involved in manufacturing and 55 per cent have R&D capability (DSIA, 2016).

The appropriate application of system dynamics methods can also contribute to assessing the effectiveness and efficiency of development of the Czech Armed Forces military capabilities.

Using Of System Dynamics In Military Capabilities Development

The application of systemic dynamics to the problem of military capabilities is given by the very nature of the process of building military capabilities, which involves both the process of accumulation of resources and their transformation in ability and potential loss of ability, for example due to wear out and obsolescence of technology or loss of personnel and so on.

System dynamics has been used in strategic management and decision making processes since mid-1950 and it was developed as a discipline by Jay W. Forrester (Forrester, 1991). The original system approach dedicated to technical systems has been applied to soft problems, allowing successful qualitative modelling and has been applied to systems with complex structure and many parameters, which

are often very difficult to formally describe (e.g. social systems). The main idea is to describe a system by its structure, information couplings and feedback loops. The primary assumption of the system dynamics paradigm is that the persistent dynamic tendencies of any complex social system arise from its internal causal structure (Papageorgiou, 2011). Models developed by system dynamics methodology do not provide forecast, but possible patterns of behaviour and it is important to interpret results of simulation in this sense. The applicability of system dynamics to defence strategic management is given by nature of decision problems. The main application areas concerning strategic problems are capability development, life cycle management and personnel management.

Capability development covers a whole bunch of sub problems and it needs to be structured to reach a specific problem solution. The capability if described by functional areas DOTLMPFI and a capability can be considered within its life cycle (Baxa, 2017). Phases of the capability life cycle, i.e. development, sustainment, reduction and termination and influencing factors are in Figure 4.

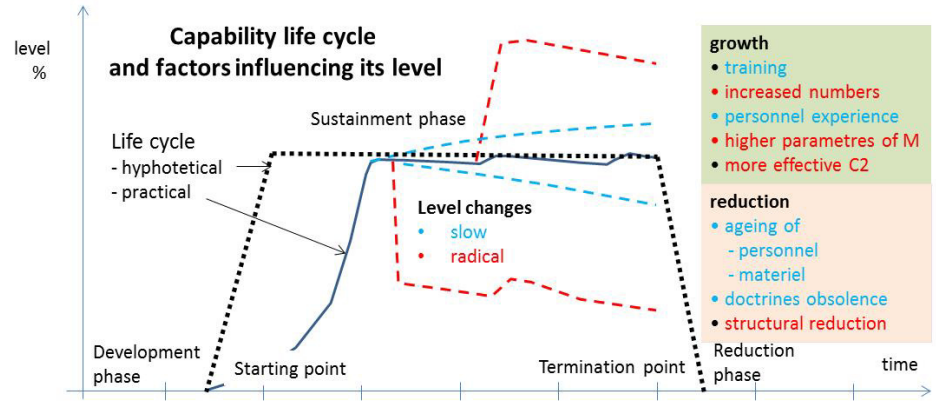

Fig. 4: Capability life cycle with influencing factors

Source: BAXA, Fabian. Translation of Capability Requirement Into Management by Objectives Environment.

A generic capability system dynamics model is in Figure 5. The model is simplified; nevertheless, the goal seeking feedback structure of the model is obvious. In accordance with Figure 3, the negative feedback is created by comparing the actual level of *Capability* with *Capability Requirement*. In case of deficiency *Resources Requirement* is generated and transformed into *Resources* that form *Resources Flow,* considering *Effectivity* of transformation resources into a capability increment.

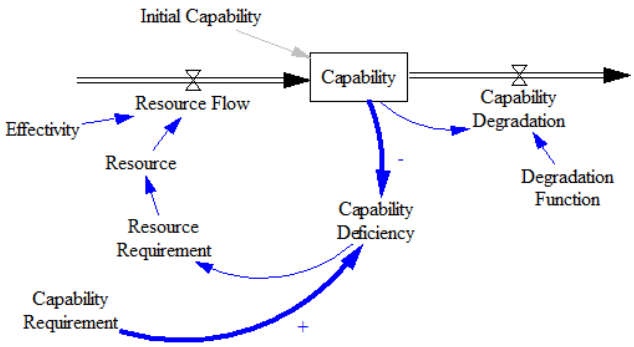

Fig. 5: A system dynamics model of a generic capability

Source: Authors

To gain concrete results, it is necessary to deal with a specific capability, model the capability using functional areas (not all need and can be modelled) and feed the model with relevant data.

Life cycle management is a problem where system dynamics has been applied, e.g. Zhi-Chao Liu (LIU, JIANG, ZHANG, 2012). Although functionality of any military system is a key requirement when a new system is procured, dealing with economical restrictions, which always present, the Life Cycle Costing is another factor which must be considered. The issue is considering not only the initial acquisition price but in-service phase cost in all supposed operation modes, which regards to the most important phase of a system life cycle, i.e. operating it.
The Life Cycle of a military system is divided into six phases: concept, development, production, utilization, support and retirement. The utilization and support phases concern operation of a system and they run parallel. The phases of Life Cycle are in depth described in *Methods and Models for Life Cycle Costing* (RTO NATO, 2007).

Dealing with the LCC analysis, the system dynamics is beneficially used in case of many factors influencing price and long-time period of life cycle. A generic system dynamics model of a helicopter LCC estimate has been developed. The utilization and support phases were further decomposed and modelled. Simulation results supported comparison of cost depending on various operation modes of helicopters (Novotný, Procházka, 2017).

Human resources or personnel development, what can be a synonym dealing with military staff, is another area where system dynamics is applied (Mehmmood, 2007). Human resources policy in the armed forces differs from the one in a private company mainly due to requirements on personnel training and education, fixed contract period and requirements on promotion. The Czech Ministry of Defence worked up a new military career concept. Application of a system dynamics to provide some what-if scenarios supporting strategic management is discussed in following paragraphs.

The military force structure is a hierarchic structure given by military ranks, number of positions for each rank and a promotion chain. The Ministry of Defence has developed new rules for military career. The law sets only boundaries, but for effective human resources management clear policies must be established in order to provide motivation and widely accepted rules. To support development of these policies, the system dynamics approach was applied.

Due to political and budget changes, the military structure has been changed relatively often. The model can support the structure change policy development and implementation to minimize financial or social impacts.

The hierarchical structure of military staff is created by a rank hierarchy. There are six categories: Men, sergeants, warrant officers, junior officers, senior officers, generals. Enrolments for men, warrant officers and officer categories are mostly new recruits, so these categories are almost independent. The paper deals with officers only, but the approach is fully applicable to other categories.
Changes of the structure were driven mostly by budget restrictions in past. Taking into account the main criterion, i.e. economy of financial resources, it was difficult to optimize the structure from the human resources point of view (individual qualities, experience, education etc.) in the same time. The military career was not clearly defined, the period of service in a concrete rank was not limited in general and a military career was driven by a contract that was usually signed from 2 to 6 years.

The new regulations introduce following rules:

- Maximal service period in one rank (promotion or retirement at the end).
- Promotion is not possible until minimal service period at the rank is accomplished.

- Necessary condition for a given rank can be an obligatory career course completion for given ranks, university bachelor or master degree and a language (STANAG 6001 SLP English) proficiency level.

There are main features and limitations above that must be reflected by the model. Thus, a rank is characterized by its attributes:
Service period – maximal time that is an entity allowed stay in a position. It differs for positions in a rank – 4 year period for commanders, 5 year period or staff officers and 7 year period for specialists. It is allowed to change position in the rank, so maximum stay in the rank is from 8 to 14 years, and then the person has to be promoted or retired from the service.

Minimal service period – minimal service time in the rank before promotion is possible.
Rank Capacity - number of entities in the rank. The number cannot be exceeded. *In practice, a soldier can be on hold for 3 or 6 months not appointed to a position in the structure, but it is an extraordinary measure.*

The simulation model created in Vensim application consists of a rank chain, where the first rank corresponds to the 2nd Lieutenant (2LT) rank and the last one to the Colonel rank. Each rank is represented by a structured accumulation, where the inflow consists of entities promoted from the lower rank (enrolment for 2LT) and the outflow consists of promoted or retired entities. The internal structure enables to differentiate number of entities within the rank by time spent in the rank, so there is no age solving within the ranks. Parallel coflows (Sterman, 2000) were created to calculate rank age characteristics. Other parameters to be analysed as language skills levels and career courses required for promotion are modelled as well. As for courses, their capacity and duration are essential; for language courses a success probability as a critical parameter for each course has been added.

Promotion is allowed only to the nearest higher rank. Ranks are (bottom-up): 2nd Lieutenant (2LT), 1st Lieutenant (1LT), Captain (CPT), Major (MAJ), Lieutenant Colonel (LTC), and Colonel (COL). Promotion chain, enrolment and retirement are simulated by corresponding flows.

Initial and planned (required) ranks ate given in the Table 1. The requirements given there were originally declared as obligatory to a given date (3 and half year). It means that e.g. a captain has to pass through Senior Officer Course (SOC) and hold STANAG 6001 SLP level 3322 certificate or better to be promoted. To be promoted in colonels, requirements are General Staff Course (GSF) and SLP level 3333. Moreover, a person who will not meet the requirement will be retired.

Those parameters of the system were used in the model and various scenarios were simulated. The most important values used for simulation are given in the Table 1. The initial values were taken from the information system and slightly variated not to deal with sensitive data. The model was set as a discrete time one with simulation step one quarter (3 months) and it was supposed that the promotion takes place every 2 quarters.

Table 1: Requirements on ranks and values for simulation

Rank	Initial Number	Required Number	Min Service Time	Course		STANAG 6001 SLP	STANAG SLP 6001 SLP Meeting – initial state		
				Required	Meeting	Required	SLP2	SLP3232	SLP3
2LT	756	985	2			2222	248	72	42
1LT	1273	1509	3			2222	466	116	109
CPT	1375	1571	3		349	2222	493	146	148
MAJ	930	1117	3	SOC	717	3322	358	101	168
LTC	709	768	3	SOC	6	3322	197	100	189
COL	286	256	2	GSC	115	3333	73	50	104

Simulations Results And Discussion

Optimistic scenario. In this scenario, we suppose enrollment according to requirement and language capable recruits accomplishing all SLP 2222, 20% of them SLP 3322 and 10% SLP 3333. Retirement is supposed only due to reaching the service time limit within a rank without possibility to be promoted. The deadline for the obligatory criteria meeting is not applied.

The **pessimistic scenario** differs from the optimistic one just with more active retirement. The actual rate of officers retired from the service was taken and applied to the model. The simulation results are given in Figures 6 – 14, where letters *a* and *b* correspond to optimistic and pessimistic scenarios respectively. The optimistic scenario presents in general a sustainable system where all ranks tend to be full at a reasonable level with some disturbances that could be possibly corrected by proper management. The problem is the time when the above declared requirement could be fulfilled. The originally declared aims in language skills are unreachable within 4 years. As for language skills, the scenarios do not differ substantially. The pessimistic scenario simulation shows potential risk. As can be seen in the Figures 6b and 7b, the ranks are not filled according to requirements. Critical ranks are 1st Lieutenant and Major. The deficiency in 1LT is given by improper ratio of positions in 2LT, 1LT and CPT ranks. Comparing Figure 15a to 15b, service time in ranks shortens in pessimistic scenario. The problem with the Major deficiency is given by limited capacity of the Senior Officer Course that blocks possible promotion of Captains, see Figure 12a and 12b. Moreover, the peak of retired Captains in Figure 15 in 14-15 year is given by reaching maximum service time without possibility to be promoted due to missing SOC. The model reflects only key features of officer career, it does not deal with military branches, different qualifications, knowledge and skill required within and across ranks, but further decomposition of the career model would bring about more restrictions on a promotion process, and thus worse results can be expected.

Conclusions

Common security cannot be identified with the absence of a military conflict, but current security is a much wider phenomenon. It covers much more aspects including purely civilian, non-military or until recently, completely outside the security perceptions. When building modern armed forces, much more emphasis is put on their interoperability, flexibility, professional performance and technical superiority. The security and defence of the state is ensured by the creation and implementation of the security policy, which is given by the internal security, economic, foreign and defence policy. The objectives of the state's political policy are to create a political mandate for the use of the armed forces and to define the tasks for their further development and construction as an integral part of the state's security system. In order to meet the political objectives, it is therefore necessary to realize the development of the armed forces, generating a corresponding military potential, consisting of the synergic effects of its conceptual (doctrine, regulations, standard operating procedures), moral (motivation, effective leadership, competent organization and development) physical components (combat power given by the quality and quantity of human and material resources). The task of the state is to define its interests and objectives in the construction of the military potential and to release the necessary resources and to create the necessary conditions for their fulfillment. The interests and goals of the state should be real (in line with the state's resources) and in relation to the construction and development of the armed forces, as well as permanent (not limited by the length of the electoral period of the elected political party). One of the instruments supporting strategic decision making processes is an application of system dynamics. Using modelling and simulations enables to test strategies prior to their implementation.

Abstract

Presented contribution deals with the problem of impacts of brownfields on prices of surrounding real estates, thus, the aim of the paper is to investigate how and why unused sites and buildings reduce prices of real estates located in the proximity of brownfields. This assumption has been surveyed and confirmed by primary research that was done in the area of three municipalities (Karvina, Orlova and Detmarovice) in the Moravian-Silesian Region (the Czech Republic). Respondents of the survey also expressed their opinions and attitudes about factors and characteristics of brownfields that are of key importance from the point of view their negative impact on the prices of real estates. Primary research has been conducted by means of the questionnaire survey in the second half of 2016 and beginning of 2017. The results from questionnaire survey are also comparing to each other with the aim to find out the differences between respondent´s answers in particular municipalities.

Keywords: Brownfields, Czech Republic, Property, Real Estate Price.

Introduction

The National Brownfield Regeneration Strategy (2008) or previously Alker (2000) define brownfield as the real estate property (land, building or ground) that is insufficiently utilized, neglected and might be also contaminated. These properties occur as remnants of industrial, agricultural, residential, military or other activities. It is obvious that nowadays when plenty of global economic, social and environmental challenges that are linked to the sustainable spatial development of cities and municipalities are being solved, the problem of regeneration and re-use of brownfields might at least partially contribute to the solution of these problems (Krzysztofik et al, 2016). One of those primary problems is to reduce the undesirable increase of extent of built-up areas on city limits to the account of the open landscape when brownfields in inner cities are being abandoned and left unused (Maly and Mulicek, 2016). Indeed, boosting support for brownfield regeneration might also contribute to more sustainable development of cities and rural municipalities from the perspective of their physical compactness, generally to increase of social responsibility for our behaviour (Tagaia, 2016) and to follow environmentally friendlier tendency to prefer utilization of existing properties over those that are being built on greenfields (De Sousa, 2003).

The aim of this contribution is to present research results on the problem of influence of brownfields on real estate prices in neighbourhoods. It can be assumed that immediate proximity of neglected, abandoned and decaying grounds causes a decrease of prices of real estates (primarily privately owned) that are located around these brownfields. Reasons behind this hypothesis lie for example in the lower level of aesthetic quality that is usually connected to abandoned or neglected brownfields. Next reason could be linked to possible contamination of these sites, their bad technical state or occurrence and concentration of socio-pathological phenomena in these buildings (like homelessness, high level of criminality etc.). Our findings are based on primary research that has been conducted in the area of three municipalities in the Moravian-Silesian (Czech Republic) in 2016 and 2017. Specifically, we worked in two cities (Karvina – population 54.4 thousand in 2017, Orlova – population 29.2 in 2017) and one rural municipality (Detmarovice – population 4.2 in 2017). All three selected municipalities are typical by the occurrence of brownfields. In the following text, the comparison of research results among individual municipalities will be conducted. Explanations and interpretations of differences will be based on results of a questionnaire survey that has been performed in the three municipalities.

1. Methodology and data

As a first step of the presented research, a detailed literature retrieval was performed to understand the problem of the regeneration of brownfields. A study of this phenomena assumes a utilisation of transdisciplinary approaches, as the usage of limited methodologies of individual disciplines might deform the meaningful perspective of the results interpretation. According to the knowledge of authors, it is not possible to perceive the multilayer problem of brownfields just from the economical, sociological or geographical point of view, it is necessary to combine these perspectives to get better results.

The phases of conducted research were performed simultaneously in two cities (Karvina, Orlova) and one rural municipality (Detmarovice) of the Moravian-Silesian Region in 2016 and 2017. The data were gathered by means of the questionnaire survey that contained 12 questions. A number of respondents that participated in the research was 347 in total (158 respondents from Karvina, 120 respondents from Orlova, 69 respondents from Detmarovice). All respondents were selected to match with socioeconomic, demographic, educational and gender structure of the population of given municipalities, all respondents were older than 18 years. The share of returned questionnaires that were distributed by trained university students on the streets of three municipalities was very high (almost 99 %). As a method for completion of questionnaires, semi-structured interviews were utilized. Such face to face communication with respondents minimized the level of refusals to participate in the survey. The aim of the questionnaire survey was to ascertain opinions and attitudes of the local population on the issue of the influence of brownfields on prices of neighbouring real estates. Factors behind were also determined to ensure why and how the occurrence of brownfields affects the value of real estates.

2. Description of the selected locations

Karvina, Orlova a Detmarovice are municipalities on the LAU 2 level that are located in the Czech Republic in the northern part of the Moravian-Silesian Region (former Karvina District – LAU 1) by borders with Poland (see Figure 1). The Statutory city of Karvina has population 54.4 (in 2017) and covers area of 57.48 km^2. Discovery of black coal in Karvina in the second half of the 20th century caused a decisive turn in the economic development of the whole region and significantly contributed to the economy of the Austria-Hungary Monarchy. The mining sector has been gradually complemented by engineering and metallurgy that constituted the backbone of the traditional economy. Karvina is also known for a spa that utilized local rich sources iodobromic ground water. Orlova is also specific by mining and heavy industry whose tradition goes back to early 18th century. Orlova (population 29.2 thousand) covers an area of 24.67 km^2 and is typical by mildly sloping terrain that was accented by visible surface effects of mining. Detmarovice (population 4.2 thousand on 13.76 km^2) are located on important railway track from Bohumin to Slovakia (Zilina) and Poland

(Katowice). On the area of Detmarovice, electrical power station with an installed capacity of 800 MW is a location that belongs to the largest in the wider region.

Brownfields that are located in the Moravian-Silesian Region are specific as for their origin. We can find a huge set of such sites that occurred as result of the decay of traditional industries and mining (Kaderabkova and Piecha, 2009, s. 72). According to the Regional Development Agency (2016), 38 brownfields were located in Karvina district. Out of them, 24 were without any contamination, 12 were mildly contaminated and 2 of them contained strong contamination soil beneath. 19 brownfields were owned by private owners, 17 were owned by public bodies, only 2 brownfields have the status of mixed ownership.

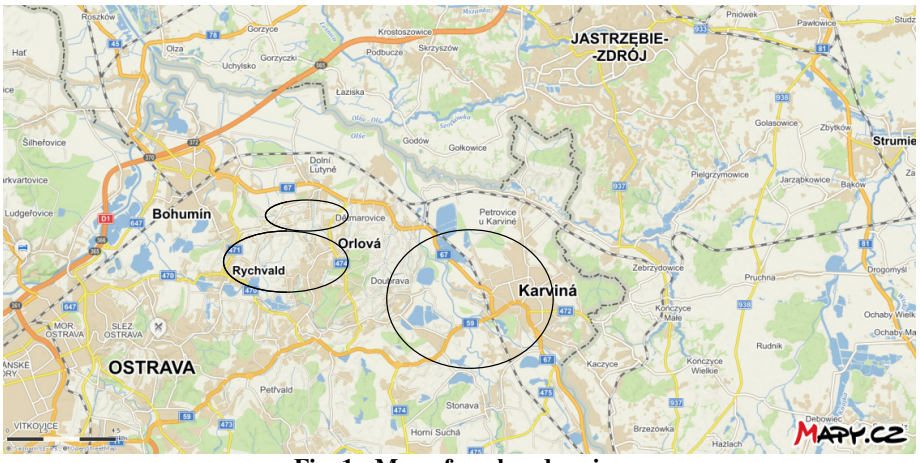

Fig. 1 : Map of analysed region

Source: 'Mapy.cz', adjusted by authors

Within three case study municipalities, eighteen brownfields were located in Karvina, eight on the area of Orlova and eleven on the area of Detmarovice. If we focused on the extent of these brownfields, the largest one could be found in Karvina (former military base and building of former industry company Kovona). Majority of brownfields in Karvina is located in close proximity to housing. Exceptional are brownfields in the eastern part of the city (five brownfields) that are connected to mining (Sovinec, former Gabriela mine, Jindrich mine, Barbora mine, area Above Barbora). Next examples of brownfields in Karvina are former panel factory, former gardening, former school, water tower, the Larisch stables, abandoned houses on the main square or former housing with name Vagonka. The total area of brownfields in Karvina is over 180 hectares.

Majority of brownfields in Orlova are linked to decay of mining that has been taking place here gradually since the middle of the 1990s. Some brownfields have already been renaturalised (technical and biological renaturalisation has been already done here), other brownfields are still waiting for such intervention. The total area of brownfields in Orlova is 5.000 hectares (former aqua park and minigolf, buildings and lands of former Lazy mine, Vaclav mine (boiler building, engine buildings, administration buildings, Doubrava mine, Zofie mine, a heap of Zofie mine, the area of Floating pit no. 2, neglected pool).

In Detmarovice, the majority of brownfields is located in the proximity to the main railway station or in the proximity of the power station (abandoned storages). Besides it, three building of former civic facilities, four abandoned buildings after industry, three neglected houses and abandoned agricultural farm. The total area is around 0.5 hectares.

3. The Influence of Brownfield's on The Real Estate Prices

During our research, it was found that living in the neighbourhoods of brownfields would be problematic for more than 70 % of respondents (see Figure 2). The Even higher rate was measured in

case of Karvina (80 %). This result and differences among individual municipalities can be explained rather as consequence of negative phenomena that are connected to the occurrence of brownfields (crime, homelessness etc.). Extreme values in case of Karvina might be interpreted a result of the stronger occurrence of previously mentioned phenomena.

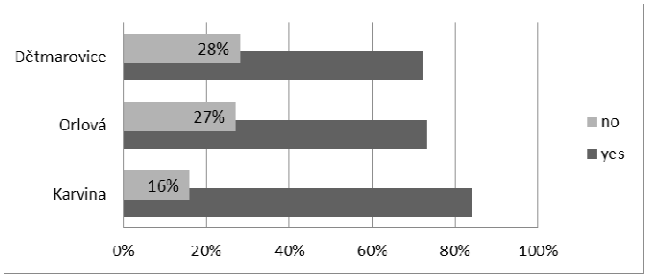

Fig. 2 : Unwillingness to live in the neighbourhoods of brownfield

Source: own survey (2017)

Dramatic differences were found in an answer to the next question in our survey. We asked respondents to identify if they live within distance of 500 meters (5 minutes walk) from the abandoned location. It was ascertained that in Detmarovice just quarter of respondents answered positively, in case of Orlova and Karvina is was much more respondents (around 80 %). This is caused by the location of brownfields in individual municipalities. In Detmarovice brownfields are more located to distant parts of the municipality, in case of Orlova and Karvina brownfields could be found directly just next to housing. It is obvious that population of Orlova and Karvina are more aware of the existence of brownfields and consequences that are connected with life in their proximity.

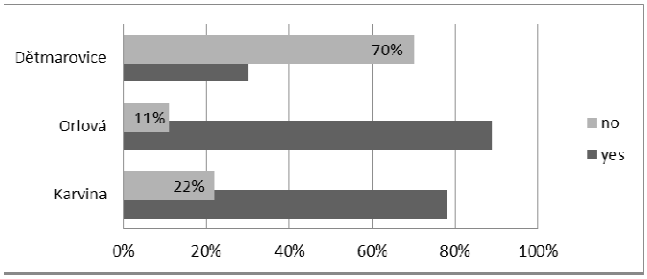

Fig. 3: Housing in the neighbourhoods of brownfield

Source: own survey (2017)

Opinions of respondents, how the real estate prices are affected by the occurrence of brownfields in their proximity, are more clearly defined in case of Karvina. In this case, 44 % of respondents stated that due to the occurrence of brownfields the real estate prices are lower than 50 % in comparison to another part of the city (without brownfields) (see Figure 4).

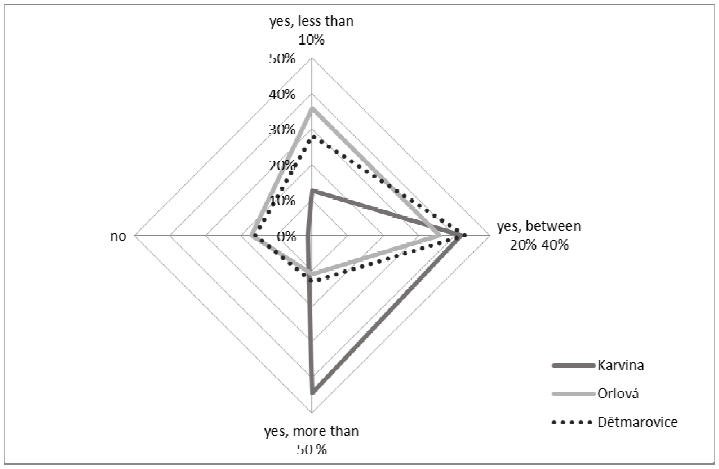

Fig. 4 : Influence of brownfields on values of neighbouring real estates

Source: own survey (2017)

If we took all three case as one whole, the most frequented answer was that brownfield decrease prices of real estates in their neighbourhoods by 20-40 %. On the other hand, almost one fifth of respondents from Detmarovice and Orlova think that there is not the explicit influence of brownfields on the real estate prices (in case of Karvina it was opinions of just 2 persons that means 1 % of respondents). Reasons behind this difference might be explained by using results presented in Figures 6 and 7 that can be interpreted as a hypothesis that population of Karvina is more clearly defined as for their relation to brownfields than the population of other two case studies. This might be caused by the dense occurrence of brownfields in Karvina and everyday experiences of the local population with life with brownfields and consequent occurrence of socially problematic phenomena.

This enquiry has rather negative replies among respondents from Karvina. Only 9 % of them were open to buy real estate in the immediate proximity of brownfield if its price was by one fifth lower than it is usual (see Figure 5). On the other hand, respondents from Orlova were not so negative in their answers and more than 40 % would be opened to buy such real estate. If samples from surveys from three municipalities are counted as a whole, more than 77 % refused possibility to buy the real estate in the proximity of brownfield if the price was by one fifth lower than it is usual for given type of real estate. Based on this finding, we can assume that value of real estates in proximity of brownfields is lower by 30 – 40 % (as perceived by respondents – see Figure 4)

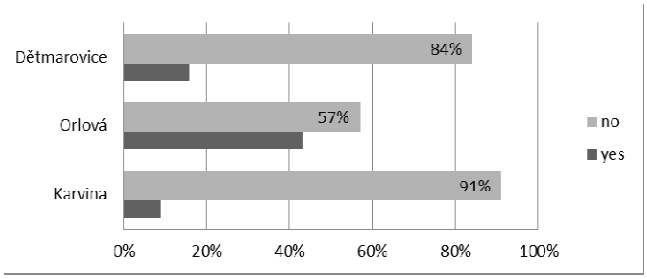

Fig. 5 : Willingness to buy real estate in immediate proximity of brownfield if price is lower by 20 %

Source: own survey (2017)

In the next step of our research, we tried to determine factors that are closely linked to the occurrence of the abandoned site (brownfield). We asked respondents to identify key factors that they find as decisive while thinking about the influence of brownfield on prices of neighbouring real estates. Respondents could select out of six answers. Shares of positive and negative answers are graphically displayed in Figure 6. Generally, it was found that that population of Karvina connects occurrence of

brownfields much more strongly to negative consequences than it is in case of the population of Orlova or Detmarovice. Our hypothesis that population of Karvina perceives brownfields differently (as also showed in case of other questions) seems to be confirmed. The only issue that was in Karvina identified differently than expected, was a case of possible contamination of soils under brownfields. We found that such concerns are more frequented by the population in Orlova.

The largest share of respondents (around 84 %) is convinced that brownfields as an abandoned site are problematic and rather dangerous which is the fact that reduce prices of neighbouring real estates. Main reasons for such argument were identified in the concentration of socially pathological phenomena in brownfields (like homelessness, higher rates of criminality, drug dealing, vandalism etc.). The second factor that was found as important (around 60 %) were environmental and health risks (occurrence contamination of soils and pollution) that might affect the health of the population that is living in the neighbourhoods. This factor might be interpreted as some kind of distrust that majority of contaminations have been removed or cleaned-up.

The population was quite unsure that these contaminants are safe and do not bear any health risks. The technical state of brownfields was identified as a third important factor (around 56 %). Respondents were expressing their fears that brownfields are dangerous as for the bad quality of their technical infrastructure, and not usually secured against the intrusion of people who should not be there. They perceive that risks connected to bad statics and neglected maintenance of individual buildings, or failures of concrete structures due to corrosion of materials are very high. Reasons why brownfields negatively influence the price of neighbouring real estates are for 43 % of respondents connected to uncertainty concerning future use of the site. They usually argued that it is not sure what will be built on a particular brownfield in future and how the site will be used. Only 34 % of respondents perceived brownfields as barriers for the further development of the city. We can say respondents were not so optimistic when thinking about the future development of their city. It seems that this distrust towards future reduces demand for housing within the city and indirectly it noticeably reduces the value of local real estates. The same share of respondents (34 %) believes that lower real estate prices of buildings in proximity to brownfields are connected to aesthetics of brownfields. These sites are usually abandoned and neglected, sometimes aesthetically unsightly with peeled façade or are ruined, covered by weed or walls are damaged by graffiti etc.

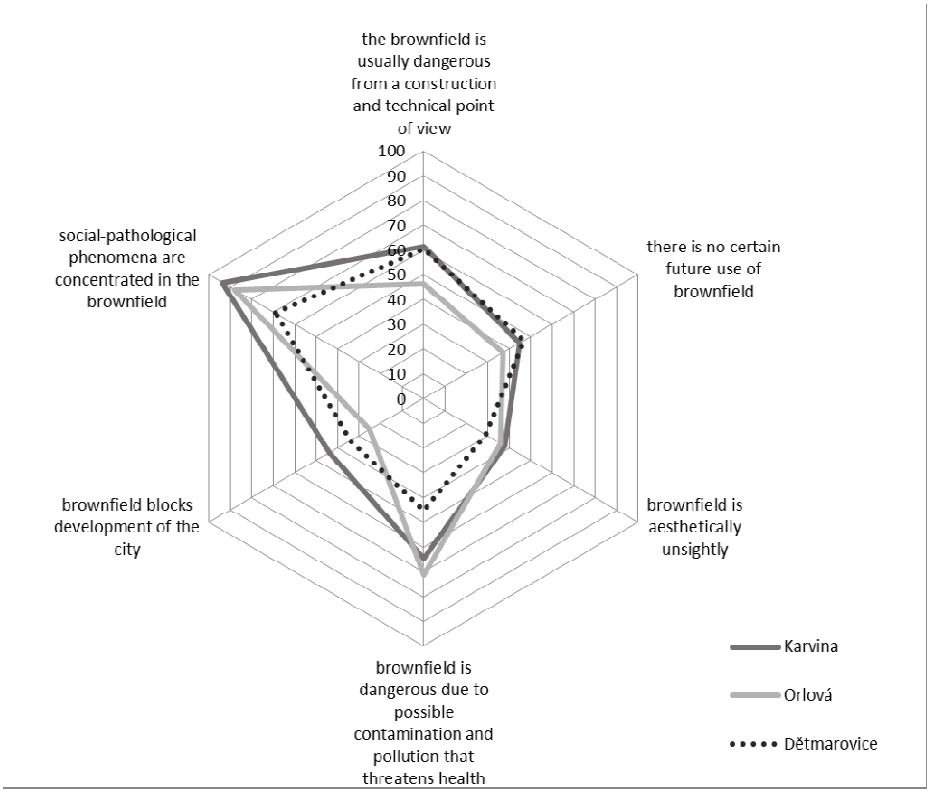

Fig. 6 : Reasons why brownfields have significant influence on the real estate prices in their neighbourhoods

Source: own survey (2017)

Respondents were asked to evaluate the possibility to buy the real estate in the proximity of brownfield. Just 17 % of them claimed that occurrence of brownfield does not influence their decision to buy real estate, 9 % of them expressed their opinion even stronger (absolutely no influence). On the other hand, as might be clearly seen in figure 7, the population of Karvina strongly refuse to buy real estates in the proximity of brownfields (64 %). This results of quite surprising due to the fact that majority of the population of Karvina lives in proximity of brownfields. These respondents argue that they would buy the real estate only of its location was in larger distance than 500 meters from brownfield. On the other hand, respondents in Orlova were not so strict and admit that they are willing to buy the real estates in closer proximity of brownfields.

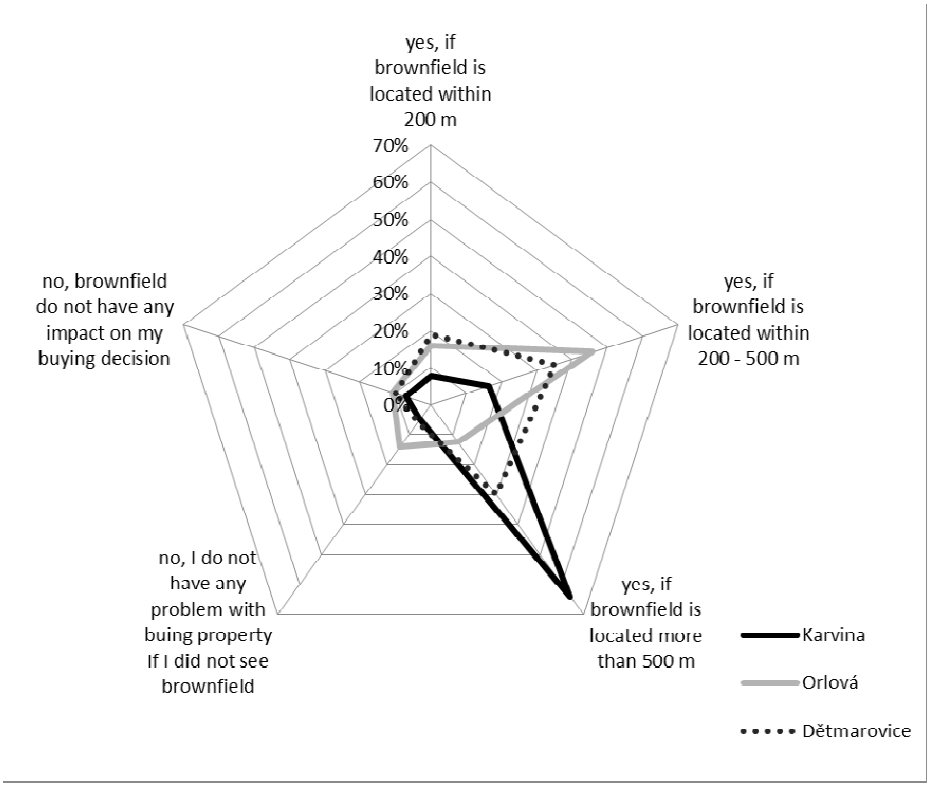

Fig. 7: Influence of brownfields on real estates buying behaviour of respondents
Source: own survey (2017)

Conclusion

The occurrence of brownfields is usually perceived as weak aspect and threat for future development of cities, towns and municipalities. On the other, they might also be considered as an opportunity for development. Nowadays, in case of cities and municipalities that are significantly affected by the decay of mining and heavy industry, where plenty of unused brownfields could be found today, these sites are usually perceived as a threat to the health of the population, they disturb urban landscape and create barriers to urban planning. These sites are usually unsightly and aesthetically do not meet requirements of the local population how the city should look like. The occurrence of brownfields in the proximity of housing reduces the quality of life of the local population. Brownfields also reduce prices of the real estates that are located in their proximity. Systematic regeneration of brownfields might significantly contribute to improvement of life in these cities and municipalities and might contribute

The aim of the contribution was to present preliminary results of a survey that was focused on the issue of perception of the impact of brownfields on prices of neighbouring real estates. By means by of the questionnaire survey that has been conducted among a population of Karvina, Orlova and Detmarovice hypothesis was confirmed that the occurrence of brownfields is perceived quite negatively (88 %) since they reduce prices of real estates. Respondents in their majority (77 %) claimed that they would not buy the real estate in the proximity of brownfield even if the price was reduced by on fifth in comparison other locations within the same city or municipality. Factors that the most significant influence such decision is a concentration of socially pathological phenomena and risks connected to possible contamination of brownfields and health risks for the local population. When results of surveys in three municipalities were compared, it was ascertained that population of Karvina perceive brownfield the most negatively than the population of Orlova or Detmarovice. The reason behind this difference in perception of brownfields might be identified in

the spatial distribution of brownfields in Karvina where these sites might be found practically everywhere (eighteen brownfield sites could be found in the area of Karvina), while on other two municipalities the location of brownfields is different (primarily on the margins of municipality). In Karvina majority of the population lives their everyday lives in close contact with brownfields and negative phenomena that are connected to brownfields (homelessness, a higher level of criminality, vandalism etc.) significantly affect their opinions about brownfields.

Abstract

This article focuses on the issue of brownfields the Czech Republic with the special attention on the town of Orlova, where eight local brownfields were studied from the point of view of their influence on values on neighbouring properties (real estates). In the framework of the primary research, a questionnaire survey was conducted among the inhabitants of the town Orlova. Thus, the aim of the questionnaire survey was to find out the views on the influence of brownfields on the perceived value of the neighbouring properties (real estates) in Orlova. The collection of information through questionnaires took place between autumn 2016 and spring 2017 and a total of 120 completed questionnaires has been gathered. Based on the questionnaire survey, the most of the population of Orlova perceives brownfields rather negatively, which naturally reduces the value of neighbouring properties. Respondents have the greatest concern about the occurrence of socially pathological phenomena, most commonly of homelessness and drug addicts. The second most frequented reason for concern was possible contamination and pollution; the third most frequently cited reason was worsened building-technical aspects of brownfields and consequent fears of the inhabitants of possible accidents. Residents do not want to live near brownfields, and for most respondents, the decisive factor in buying a property is a distance a minimum of 500 m from brownfields. Even the decline in the purchase price would not convince many respondents to buy such property.

Keywords: Brownfields, Czech Republic, Town Orlova, Property, Real Estate Price.

Introduction

The existence of brownfields is a global problem that reduces the competitiveness of municipalities (Kurtovic et al., 2015). It is also clear that the occurrence of brownfields significantly affects the sustainable development of cities, towns and municipalities where such sites are located. Regeneration of brownfields might be also considered as a contribution to sustainability a global scale (Wdding and Crawford-Brown, 2007). For the sake of designating dilapidated and unused buildings, the brownfield for the first time has been used since the 1970s. According to Zamarsky et al. (2011, p. 57) brownfields represent real estate (land, premises, building) that are underutilized, neglected or abandoned and can be dangerous and dangerous. A regeneration process is required for effective use of these sites (Doleželová, 2015, p. 6).

Brownfields that have occurred on the territory of the Czech Republic are a problem that has been discussed by both researchers and practitioners for the last 25 years. In particular, in the Czech Republic, this issue began to be tackled only around 1997 as a consequence of the delayed restructuring of the Czech economy after 1989. One reason for the creation of a large number of brownfields was the return of real estates to the original owners by means of the restitution process. The occurrence of brownfields is also the consequence of privatization processes in the early 1990s when industrial brownfields began to appear. On the other, it has to be stressed that abandoned buildings and complexes have already occurred in the past too. In modern history, we can meet them as consequence of the first industrial revolution in early 18th century (Stasakova and Kulla, 2016). In addition, great impacts on the occurrence of brownfields occurred in the early 20th century (World War I, economic crisis, World War II). A great milestone in the occurrence of abandoned complexes and buildings is the period from 1948-1989 when the former Czechoslovakia significantly focused on the development of heavy and manufacturing industry. These sectors of the economy have lost their competitiveness after the fall of the Iron Curtain and economic restructuring in the 1990s (Krzysztofik et al., 2016). According to estimation, more than ten thousand brownfields have recently appeared as a result of above-mentioned processes.

The aim of this article is to present the results of research focused on the influence of brownfields on the perceived value of surrounding properties from the perspective of the inhabitants of the town Orlova. The main prerequisite is the lowering of the value of private properties occurring in the immediate vicinity of neglected, abandoned and dilapidated buildings, complexes and other objects. The cause of the decline in the value of the private real estate that is located near brownfields can be, for example, soil contamination affecting the health of the population or poor technical condition of the buildings and a relatively high incidence of socio-pathological phenomena (Tagaia, 2016). The findings are based on the primary research that was carried out in 2016 and 2017 on the territory of the town Orlova (population 29.2 in 2017), located in the Moravian-Silesian Region in the eastern part of the Czech Republic.

1. Theoretical Background

The concept of brownfield can be from the ontological point of view interpreted as a "brown field", i.e. site that was created by humans is not now viable without external intervention (as a contrary to word greenfield). In the recent years, this term has been used in Czech terminology and it can be said that these are mainly abandoned buildings, areas or often devastated areas of various previous use that have been abandoned or underused. According to Novák (2012, p. 5), brownfields can represent large areas of industry, military barracks, surplus areas of railways and former socialist agricultural areas (agricultural farms), which are mainly located on the outskirts of municipalities.
The first brownfields originated in the mining of raw materials, which had a decisive influence on the industrial development during the industrial revolution in the second half of the 19th century. In this period also the mass creation of factories took place. In the 20th century, brownfields originate primarily as a result of structural change. In the developed countries, brownfields have been dealt with since 1970.

The Czech Republic has begun to respond to brownfields issues late. Although the massive growth of brownfields in our territory occurred in the 1990s, this issue began to be explored only in 2004, when brownfield expansion was underway. The government responded even later when the National Brownfield Regeneration Strategy was defined in 2008. In the Czech Republic, this issue is addressed by the CzechInvest government agency, which also has a number of programs to support unused areas or complexes. To map out the number of brownfields in the Czech Republic, the last mapping of abandoned buildings in cooperation with CzechInvest was carried out in 2005-2007. A total of 2,355 brownfields were located. The exact number of those objects cannot be 100% mapped and recorded. According to the Czech web portal (www.ceskovdatech.cz) approximately 10 000-12 000 brownfields are located in the Czech Republic and occupy an area of 25 000 to 35 000 hectares.

Brownfields are a problem for all municipalities as they are part of them. Some cities can deal better with the brownfield question, some worse. The emergence of brownfields and the establishment of

businesses on newly created areas must solve a number of problems. One of them is the emergence of social, economic and environmental problems in the field of brownfields and the degradation of land (greenfields) that is covered by new developments. In addition, dilapidated brownfields reduce the attractiveness of the city for investors and thus also a competitive advantage over other cities that try to regulate the number of brownfields in their territory. Another phenomenon that occurs in connection with the emergence of brownfields is the "dying of the centre of the city" (Malý and Mulíček, 2016). The non-use of brownfields can be seen as a reduction of available resources and the associated costs to the public budget. Brownfields are perceived negatively by the population and are associated with the image of the decline of the territory (Kadeřábková and Piecha, 2009, p. 2). Nowadays, most cities in the Czech Republic and abroad are confronted with brownfield problems and their reuse. Successful regeneration of brownfields is known throughout the world and it is possible to draw inspiration from them when deciding on their new use (Hollander et al., 2010). There are several ways to use abandoned and dilapidated areas and buildings. Each brownfield is specific and therefore it is necessary to choose the most suitable way of new use. Brownfields can be used, for example, for housing, commercial purposes, light industry, recreation, etc. In the Czech Republic, topic of brownfields has been covered by authors like Klusáček et al. (2011); Vojvodíková et al. (2011); Doleželová et al. (2014); Kunc and Tonev (2015); Osman et al. (2015), etc. The research focused on brownfields on the territory of the Moravian - Silesian Region may include authors such as Turečková et al., (2016); Škrabal et al. (2016); Martinat et al. (2015).

2. Methodology and Data

The basis for analysing the perception of the impact of brownfields on the value of surrounding plots was the primary and secondary sources of information. Expert publications and articles have been used to retrieve information from secondary sources. Due to the demandingness of up-to-date information, Internet resources were also used. A field survey was also carried out to collect primary information through questionnaires and a personal visit to brownfield sites in town Orlova. Survey of brownfield sites in the town of Orlova was carried out in cooperation with Orlová City Council, Environmental Department of the town hall and Cadastral Office.

In the first phase of the research, a literature search on brownfields was carried out. Based on the understanding of the topic, a questionnaire survey was carried out among the inhabitants of the town of Orlova. The aim of the questionnaire survey was to find out the views on the influence of brownfields on the perceived value of neighbouring properties from the point of view of the inhabitants of town Orlová. The collection of information through the questionnaires took place between autumn 2016 and spring 2017 and was attended by 120 respondents. The return of the questionnaires was 100% due to face-to-face communication with individual respondents.

Respondents of the survey were selected based on a residence located at a distance of no more than 500 m from the selected brownfields. Only in the case of the Orlová - Lazy brownfield, this criterion was not met due to the location of the brownfield in the periphery of Orlova with low population density. Only 13 respondents (11 %) said they did not live in close proximity to any brownfield. The remaining 107 respondents (89 %) live within 500 meters of brownfields.

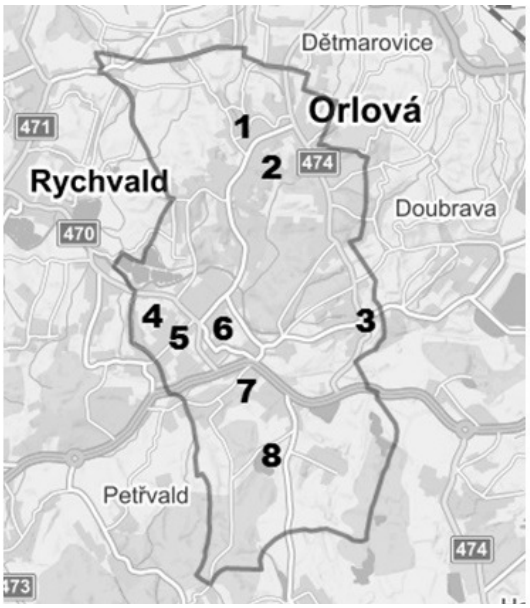
In order to analyse the influence of brownfields on the value of surrounding lands and real estates, interviewing was carried out in the form of personal meetings of the experienced interviewer with the respondents that are living near selected brownfields in the town of Orlova. In order to obtain the necessary information, a questionnaire consisted of 12 questions that were divided into two parts.

The first six questions relate to the opinions of respondents on brownfields and their impact on the value of neighbouring real estates, six further questions relate to identification data of the respondents themselves and include gender issues, age, place of residence and education. Within the questionnaire survey, women's responses (62%) over men's responses (38%) prevailed. The age structure of the respondents is the most common in the range of 26 - 45 years (51%). Most respondents are surveyed by respondents with a secondary school without a school leaving certificate, a total of 47% that is in line with the educational structure of the population of Orlova. More than half of respondents were

employed (53%) or retired (18%), while the remaining options were a small percentage of respondents. A total of 50% of respondents live in their own family house. The following table 1 shows the detailed structure of the respondents in the questionnaire survey.

While questions about respondents were closed and allowed only one answer, questions about the perception of the impact of brownfields allowed more answers or were open.

Table 1 : Structure of the respondents of questionnaire survey



Gender	Female	62 %
	Male	38 %
Age	18-25 years	13 %
	26-45 years	51 %
	46-65 years	30 %
	65 and more years	6 %
Education	Elementary school	7 %
	Secondary school with final exam	16 %
	Secondary school without final exam	47 %
	University	30 %
Social status	Students	8 %
	Employees	53 %
	Entrepreneurs	5 %
	Unemployed	8 %
	Retired persons	18 %
	Persons on maternal/parental leave	8 %
Housing	Private family house	50 %
	Rented family house	0 %
	Hostel	13 %
	Own flat	0 %
	Cooperative apartment	18 %
	Rental apartment	19 %
City part	Lazy	12,5 %
	Orlová - Town	8,3 %
	Poruba	32,5 %
	Lutyně	36,7 %
	Doubrava	10 %

3. Description of the Town Orlova

Orlova is a Silesian town located in the eastern part of the Czech Republic on the area of the Moravian-Silesian Region. The city covers an area of 24.67 km^2 and has about 29 000 inhabitants. Orlova is specific by mining and heavy industry, which has a tradition of more than 200 years. Both sectors are nowadays declining as well as population numbers of the town.

There are a large number of brownfields in the Orlova, the total number is not recorded by the town administration. Within this research, eight brownfield sites were selected and described in the town. These brownfields can be seen in the following figure 1. Most of the brownfields in the town of Orlova were created due to a reduction in coal mining.

1. Swimming pool Kaplicka
2. Aqvapark
3. Mine Doubrava
4. Areal Vaclav
5. Part of the mine Žofie
6. Areal Žofie
7. Floating pit no. 2
8. Orlová - Lazy

Fig. 1 : Brownfield´s in town Orlova

4. Perception of Influence of the Brownfields on the Value Property

In the framework of the questionnaire survey, 99 respondents (83 %) believe that brownfields negatively affect the value of surrounding properties. Furthermore, 18 % believe that abandoned buildings and complexes do not affect the price and perceived value of the surrounding properties.

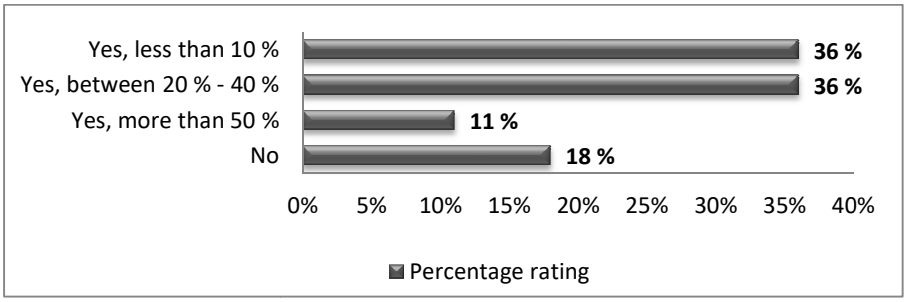

Fig. 2 : Do you generally think that "abandoned areas and areas" reduce the value of neighbouring real estate (houses, flats, land, building plots, etc.)?

Source: own survey (n=120)

The following question was focused on whether respondents would be disturbed to live near brownfields. A total of 87 respondents (73 %) would be disquiet to live near brownfields due to the occurrence of socially pathological phenomena (the occurrence of homeless and drug addicts etc.), due to the imminent danger of injuries, due to worsen aesthetics, contamination, unclear future use and concern from the loss of peaceful surroundings. The remaining 33 respondents (27 %) said they would not mind living in the neighbourhood of the abandoned brownfield.

The next question asked whether respondents would buy a property in the neighbourhood of a brownfield if the property price was lower by 20 %. A total of 68 respondents (57 %) said they would not buy the real estate. A further 52 respondents (43 %) would buy the property for the following reasons: a favourable offer, depending on the type of brownfield, for investment and future sale, to ensure a quiet living.

In addition, respondents had to classify the reasons for the negative impact of brownfields on the surrounding property in their opinion. The individual options assigned a weight of 1 to 6, where number 1 marked the most important reason and number 6 was the least important. The average value, modus, and median were calculated from the resulting values assigned to individual reasons. These values can be seen in Table 2 below.

Table 2 : Do you think that the proximity of brownfields has a bad effect on the value/cost of surrounding properties, please state the reasons why do you think so? (Rank according to importance from 1 to 6; 1 = most important ... 6 = least important)

	Average value	Mode	Median value
Construction-technical aspect (risk of injury)	3,23	3	3
Uncertain future use	3,78	5	4
Aesthetic aspect	3,84	6	4
Contamination and pollution	2,86	2	2
Limiting the development of the town	4,5	6	5
Concentration of socio-pathological phenomena	2,79	1	2,5

Source: own survey (n=120)

From the average values listed in Table 2, the reasons for the negative impact of brownfields can be classified according to their importance in this order - concentration of socio-pathological phenomena, contamination and pollution, construction and technical aspects, uncertain future use, aesthetic aspect, limitation of community development. By concentrating socially pathological phenomena, respondents most often assigned number 1 and therefore considered it the most important reason for the negative impact of brownfields on surrounding properties. As the least important reason, the respondents perceive the aesthetic aspect and limit the development of the city, which most often assigned number 6. Median determines the mean value of all responses. Modus expresses the most commonly referred value.

The following query in the questionnaire survey focused on respondents' views of how far the presence of brownfields would play a role in buying a property (see Figure 3). For 89 respondents (74 %) the presence of brownfields is a decisive factor in the purchase of real estate. A total of 31

respondents (26 %) would not mind brownfield. Specifically, 19 respondents (16 %) consider the distance from the brownfield up to 200 m, 55 respondents (46 %) consider the decisive distance between 200-500 m, 15 respondents (12 %) would consider buying the property if brownfields were located Even more than 500 meters from the property, and 18 respondents (15 %) did not mind the presence of brownfields if they did not see the site and 13 respondents (11 %) would not have the brownfield presence at all.

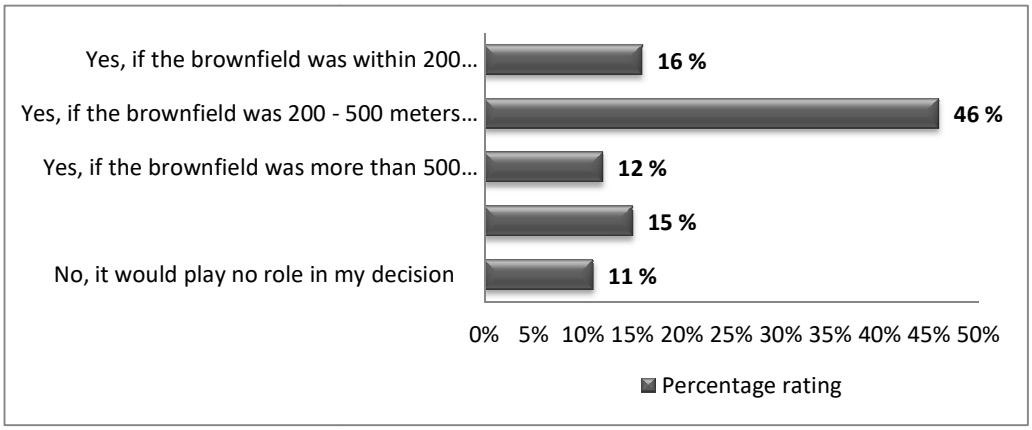

Fig. 3: If you would buy a property in Orlova, would the presence of a brownfield land play a role in your purchasing decision?

Source: own survey (n=120)

5. Conclusion

Based on the evaluation of the answers from the questionnaire survey carried out between autumn 2016 and spring 2017, it can be stated that inhabitants of town Orlova perceive the negative impact of brownfields on the value of neighbouring properties. It has to be stressed that according to opinions of respondents of the survey, local brownfields affect health condition and quality life of the local population and this problem needs to be seriously addressed. As the most important concern of local population, the occurrence of socio-pathological phenomena in neighbourhoods of brownfields were identified. Particularly, the homelessness and drug dealing was mentioned quite frequently. Another frequent reason for concern was contamination and pollution of the sites; the third most frequently cited reason was worsened building-technical aspects of brownfields and the fear of the inhabitants of possible accidents. Residents do not want to live near brownfields, and for most respondents, the decisive factor in buying a property is a distance of up to 500 m from an abandoned area. Even the decline in the purchase price would not convince many respondents to buy such property. The reasons for the negative impact of brownfields on the value of surrounding plots can be eliminated by regeneration of brownfields and ensuring their reuse. Revitalization and regeneration of brownfields are an important activity contributing to sustainable development. Abandoned spaces like brownfields have significant potential for new use. New homes, social amenities, new businesses, urban greenery, and so on can be built on their site and suitably contribute to the improvement of the quality of life of the local population.

The Complexity of Requirements Engineering Approach as a Potential Critical-Success Factor of Software Project

Igor V. Ilin, Peter the Great Saint Petersburg Polytechnic University, Saint Petersburg, Russian Federation, ivi2475@gmail.com

Anastasia I. Levina, Peter the Great Saint Petersburg Polytechnic University, Saint Petersburg, Russian Federation, alyovina@gmail.com

Aleksandr A. Lepekhin, Peter the Great Saint Petersburg Polytechnic University, Saint Petersburg, Russian Federation, lepekhinalexander@gmail.com

Abstract

Managing a software project and delivering the right product are considerably complicated and complex tasks in modern business environment. The "right" product means that it suits the needs of all stakeholders and helps the company to achieve strategic business goals. In order to visualize this "right" product and engage all the parties around it, all the requirements need to be defined and managed properly. This issue has to be addressed systematically with use of suitable requirements engineering (RE) approach. The applicability of RE approach for the particular project context is controversial and requires conceptual investigation under the prism of complexity theory. This study aims to reveal whether the applicability of RE approach for the particular project context could be potentially influential on the project outcomes. The goal of the research is to understand also whether the complexity of core problem could give a hint about the RE approach, which would be the most suitable in a particular case. The analysis of different software projects revealed the importance of approach complexity being compatible with the problem level and its influence on the project outcomes.

Keywords: requirements engineering, software project, complexity, RE approach, problem level, project success.

Introduction

The topic of requirements engineering attracts the interest of researchers in software engineering over the past decades (Schön, Thomaschewski, & Escalona, 2017). This interest could be potentially inspired by importance of overall requirements topic for the project success as well as comprehensiveness of business architectures, which dictate requirements (I. Ilin, Kalinina, Iliashenko, & Levina, 2016). The Table 1 provides the analysis of how different researches emphasize requirements as an important aspect of project success.

Table 1: The linkage between requirements and project success

Requirements and project success	Reference
"Project met all specification requirements" as Internal criteria of Success dimension	(Patanakul, Iewwongcharoen, & Milosevic, 2010)
12 requirements basics for project success with supporting information, suggestions, and recommendation	(Young, 2006)
"Functional, performance, and reliability requirements and scope are not documented" as a failure factor	(Kappelman, McKeeman, & Zhang, 2006)

"Meeting system requirements" as a measure of success	(DeLone, Espinosa, Lee, & Carmel, 2005)
Requirements as a "Product success" part	(Bannerman, 2008)
"Meeting user requirements" as a project success criteria	(Müller & Turner, 2007)
Conformance of requirements as a key aspect of quality of conformance, which is admitted as a part of project success	(Dalcher, 2009)

It can be seen from the table that requirements are constantly addressed as important issue for the software project, which makes the way of their systematic discovery, delivery and management an important part of overall software project management. It was discovered, though, that the way how Requirements Engineering could be potentially organized in order to cause maximum value for the project, is not that univocal. The same aspect of RE is found to be positively related to the successful project results or performance efficiency, but probably opposite in another. It is particularly controversial, for example, in business processes reengineering field of study (I. V. Ilin, Iliashenko, & Levina, 2016). The examples of the contradictory aspects can be user-involvement (Dvir, 2005), RE model (Cataldo, Wagstrom, Herbsleb, & Carley, 2006) and utilization of requirements engineering tools (Ji & Sedano, 2011).

This could potentially be the result of poor context addressing, when proposing the way how RE should be organized. It has already been emphasized that different methodologies could be appropriate for different projects depending on the context of the problem (Fernandez & Fernandez, 2008b). In addition, the context awareness was proposed to be a tool for project manager to act appropriately in different types of situations (Snowden & Boone, 2007).

This study seeks to understand better whether the choice of contextually-appropriate approach could be the factor, which influences the overall project success. The structure of the research is the following. Next section provides and overview of requirements engineering research area and described the approach to this research. The Results section gives an overview of empiric results and their summary. The last section compares empiric results with the existing literature and proposes the directions of further researches.

Literature Review and Research Methodology

Requirements engineering is the process of discovering, documenting and managing the requirements for a computer-based system. The goal of requirements engineering is to produce a set of system requirements which, as far as possible, is complete, consistent, relevant and reflects what the customer actually wants (Sommerville & Sawyer, 1999).

There are different ways of RE organization. The conceptual schema of requirements engineering, as seen traditionally, is represented in the Figure 1. It is also addressed in the literature as "Waterfall" model of RE (Balaji & Murugaiyan, 2012). It is seen as a sequence of steps in which the output of each stage becomes the input for the next.

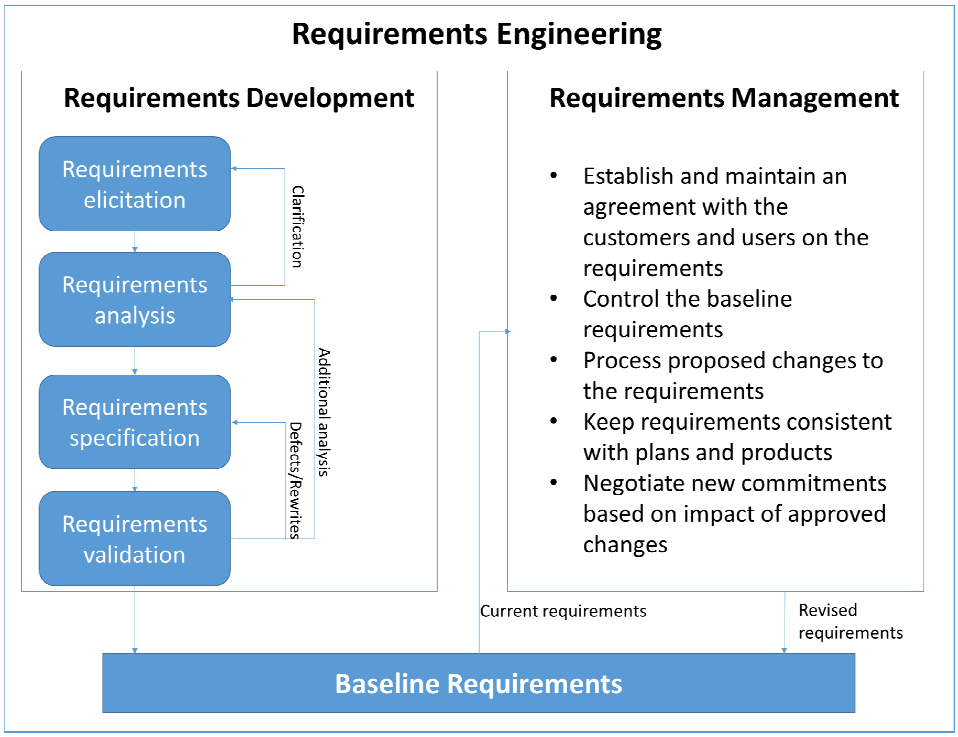

Fig. 1: Conceptual schema of traditional RE

There is another type of RE, which is "agile way" of RE. This type of RE approach is based on Agile principles, such as flexibility by cordially receiving changes (Bang, 2007). The requirements are initially defined with the customer and listed in a customer wish list format; every couple of weeks they are discussed and reprioritized, to define the scope of the next iteration (Inayat, Salim, Marczak, Daneva, & Shamshirband, 2015).

The researches argue that there is a number of advantages of Agile RE over the Traditional one: ability to cope with dynamic context of software industry (Ramesh, Cao, & Baskerville, 2010) and lower effort and schedule overruns (Molokken-Ostvold & Jorgensen, 2005). Despite that, some studies indicate that there are also weak points of this approach, such as lack of attention to architectural design issues, indicated in the research of (Falessi et al., 2010) and (Breivold, Sundmark, Wallin, & Larsson, 2010).

As long as different approaches have their own advantages and disadvantages, the issue of their mindful choice within the specific context could potentially be considerably influential on the project outcomes. The need for addressing problem's context when choosing the software project management approach has been constantly raised in the existing literature (Cheng & Atlee, 2007). There is a highly cited framework for addressing this issue – the Cynefin framework of decision-making (Snowden & Boone, 2007). The framework defines five different types of contexts, based on the nature of cause-effect relationships and the issues leaders are facing. Four of these – simple, complicated, complex, and chaotic – require leaders to diagnose situations and to act in contextually appropriate ways. The fifth – disorder – applies when it is unclear which of the other four contexts is predominant (Snowden & Boone, 2007).

The description of the problem types, proposed on Cynefin framework, is represented in the **Error! Reference source not found.**.

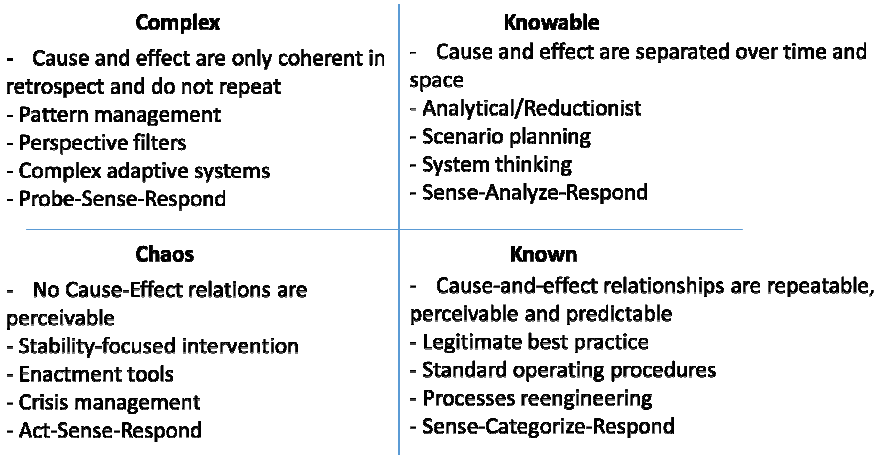

Fig. 2: Types of problems in Cynefin framework

Based on this framework, (Cockburn & Highsmith, 2001) argued that Agile development excels in exploratory problem domains - extreme, complex, high-change projects. (Fernandez & Fernandez, 2008a) proposed a mapping of different types of problems and problem-solving strategies with specific focus on software engineering field of study (Figure 3).

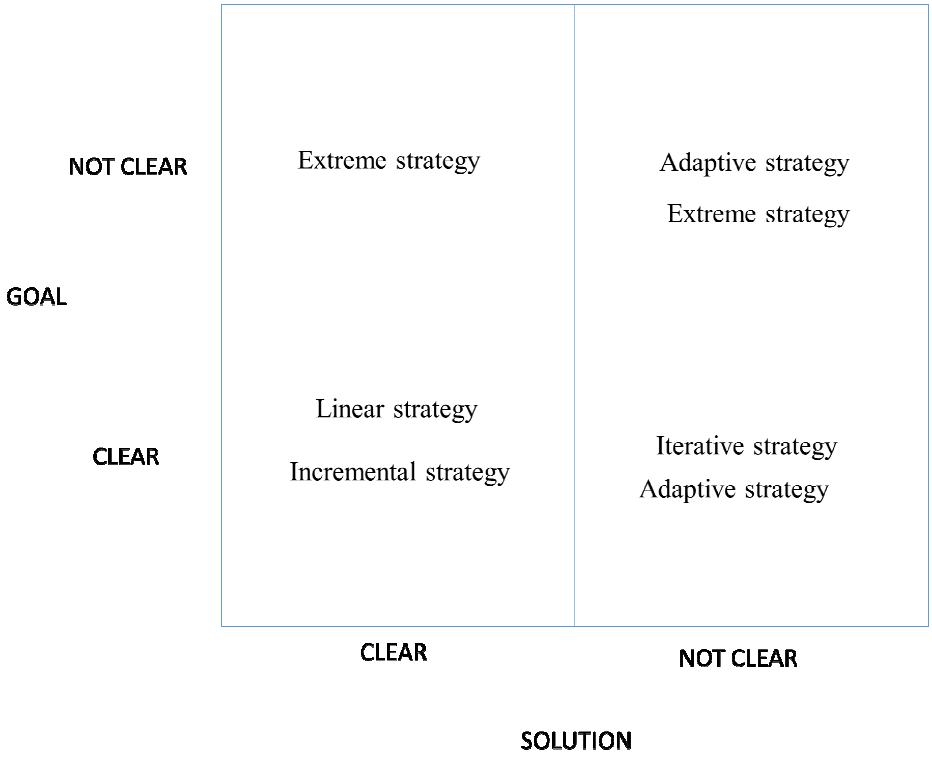

Fig. 3: The framework for solution categorization (adapted from (Fernandez & Fernandez, 2008b))

Each strategy has certain characteristics:

- Linear strategy – traditional strategy that consists of dependent, sequential phases that are executed with no feedback loops. The project solution is not released until the final phase.
- Incremental strategy – identical to a Linear strategy except that each phase of the project releases a partial solution, the business value is delivered prior to the final stage.
- Iterative strategy – a number of repeated phases that include a feedback loop after a group of phases is completed. The last phase of a group may include a partial solution if the customer desires.
- Adaptive strategy – similar to an Iterative except for that with an Adaptive strategy each iteration's feedback adjusts the next iteration so that the next solution will be grown upon.
- Extreme strategy – similar to adaptive strategy except that instead of adjusting with each iteration to coverage upon a solution, the goal of the project must also be discovered and converged upon. An Extreme strategy differs from Adaptive mainly by unclearness of the goal.

In scopes of the current research 6 project were analyzed based on the studies of (Fernandez & Fernandez, 2008b) and (Snowden & Boone, 2007). Each project was classified by the problem domain, which had become the core of the project. The requirements engineering approach, adapted in scopes of each research was also classified by 5 strategies, indicated above. Further, the mapping between the actual problem domain and adapted RE approach (problem-solving strategy) was provided in order to reveal whether the RE approach choice could potentially be influential on the project outcomes.

Results

The empiric data was gathered from 6 projects, executed by 5 companies. The table below summarizes the projects.

Table 2: Projects overview

Project ID	Problem description	RE approach	Results
C1P1	Software – Supplier Relationship Management system Customer – Large Stone production company Supplier – internal IT department Description – system development and implementation in scopes of the implementation projects portfolio dedicated to the complex change of the old software in the company. Cause and effect of implementation are separated in time – Knowable context	• Baseline solution was implemented at once on production based on the high level requirements of top-management • Further development was done based on the users' requests on a daily basis • Deployment as soon as the task is ready • Prioritization of tasks was decided in the team and tasks were tracked in the simplest tools.	Admitted to be successful
C2P1	Software – Enterprise Resource Planning Customer – Large Oil and Gas production company Supplier – internal IT department Description – system development and implementation in scopes of the implementation projects portfolio dedicated to the complex change of the old software in the company. The effect from the system implementation has been perceived over long period of time – Complex context	• Implementation is strictly regulated • Implementation consists of a number of steps, executed one by one with a set of closing documentation at the end of each stage. • Gathering all the business requirements at once in the beginning. • The changes were strictly regulated	Admitted to be close to failure
C3P1	Software – Accounting system Customer – Large Paper production company	• Rapid implementation of baseline solution • Customization based on the constant users'	Admitted to be successful

	Supplier – external team from IT company Description – implementation of the standard solution with basic functionality for certain purposes of accounting processes, the customer previously worked with the paper and Office applications without any software. Cause and effect of implementation perceivable and predictable – Known context	feedback • Continuously working with end users on a daily basis without any pending tasks	
C3P2	Software – Enterprise Resource Planning Customer – Medium Machinery production company Supplier – external team from IT company Description – customization of the existing software, which was already launched into production, but did not cover the needs of the customer. The current problem is not clearly linked to the software system, no perception of cause and effect – Chaos context	• Requirements were provided by the key stakeholder • The requirements did not change significantly • The cooperation with end users was very difficult, because they were poorly allowed to provide their own requirements • The software customization was organized by steps with periodic demonstration of result	Admitted to be total failure
C4P1	Software – Integration platform Customer – Large retail company Supplier – external team from IT company Description – development and implementation of the software in order to integrate different systems and increase their efficiency. Cause and effect of implementation are separated in time –	• It was decided to use Kanban in order to speed up • Use of physical Kanban board • Everything was done on production environment • High and intensive development. • The end product was documented afterwards.	Admitted to be successful

	Knowable context		
C6P1	Software – Website platform Customer – Large retail company Supplier – internal IT department Description – development of the software from scratch in order to use it further for expanding business. The software was aiming to be able to produce websites for the distributers in a short period of time. Cause and effect of implementation are separated in time – Knowable context	• Combination of Waterfall and Agile approaches. • The waterfall was utilized in order to get the minimum viable product based on the baseline requirements to the product. • More concrete requirements are formulated by the users after MVP delivery and executed in sprints. • RE continues after the launch into production to evolve the product.	Admitted to be successful

Each project was analyzed based on its baseline problem type. It was afterwards mapped into one of four quadrants, which represent different types of problems. The project C2P1 was admitted to have Complex type of problem based on its characteristics analysis and Cynefin framework comparing. The project C3P2 was proposed to have Chaos type of problem. Projects C4P1, C6P1 and C1P1 were admitted to have Knowable type of problem as a baseline. The project C3P1 had Known type of problem in the core. The failed projects or those, which have finished out of scopes, are indicated with orange. The projects, highlighted with blue, are admitted as successful in scopes of analyzed research.

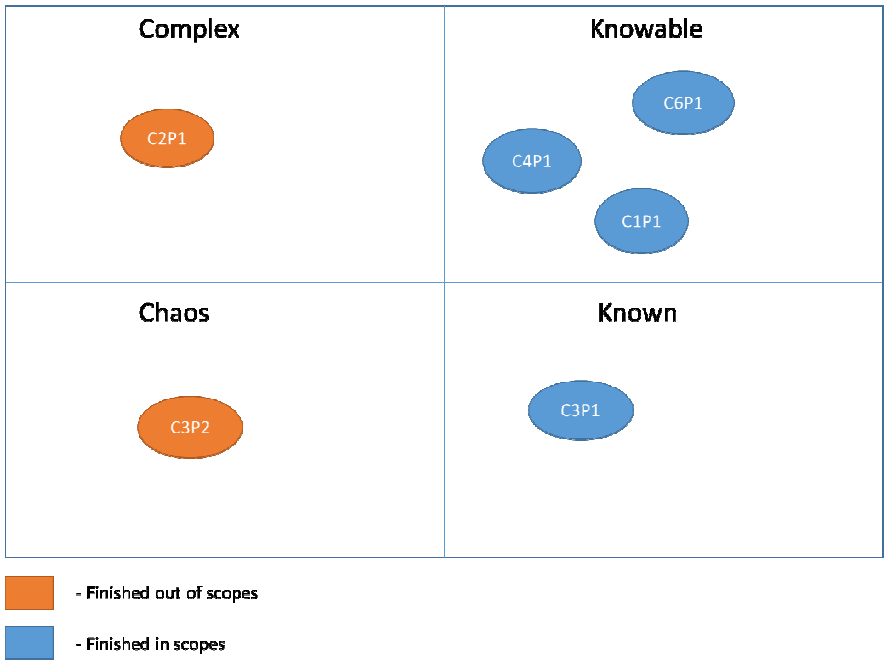

Fig. 4: The domains of projects' complexity

The next step of analysis was dedicated to the investigation of actual approach to RE, utilized by the teams within each specific project. The analysis of approaches is based on the 5 strategies, proposed by (Fernandez & Fernandez, 2008b). It was found that the characteristics of the approach, utilized in the project C2P1, are the closest to the Linear strategy. The approach of C3P2 project was admitted to be Incremental strategy. C4P1, C3P1 and C1P1 used Adaptive strategy. The project C6P1 was managed by Iterative strategy. It can be proposed that the actual approaches are not linked to the types of projects, from which they are theoretically originated. For example the Linear strategy, which was adapted within the Complex problem of the C2P1 project, is actually recommended to be suitable for the Known problem domain.

The approaches, which were utilized by the companies within each specific project, are represented with grey circles. They were mapped to those domains, in which they are theoretically admitted to be suitable, in order to demonstrate the mismatching of problem and problem-solving approach in some of the studied projects.

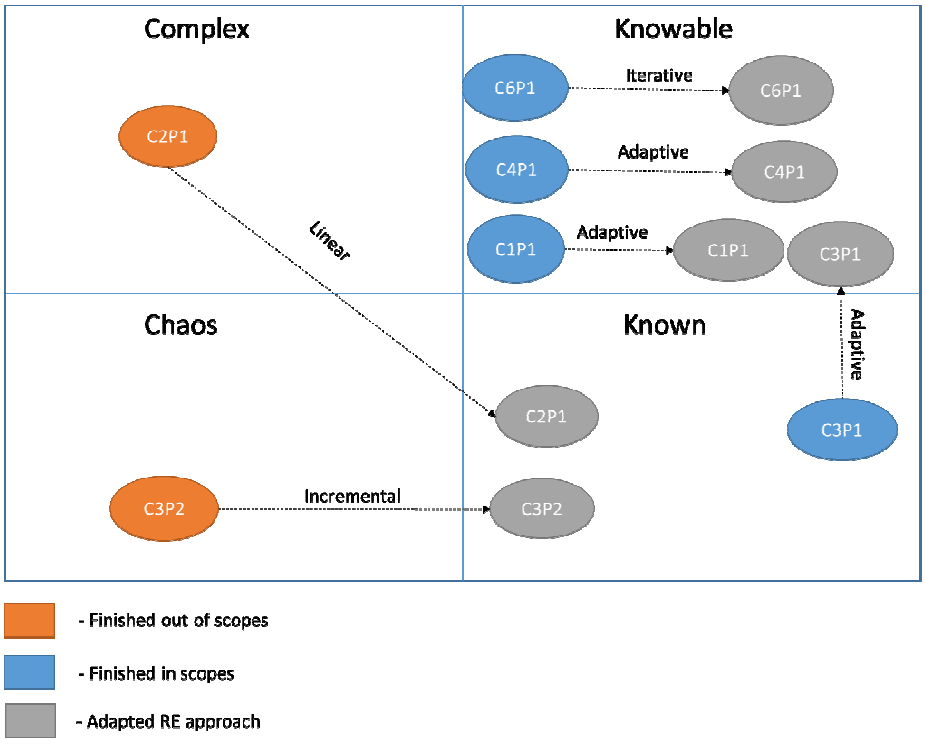

Fig. 5: Projects' RE approaches analysis

The analysis of empiric data suggests that matching of problem type and problem-solving strategy could be potentially influential on the project results. The most successful companies within the analyzed sample are likely to choose the strategy, which is compatible with the problem level, or they choose the one more complex, which still leads to the success. The projects, which have resulted in failure, have been run with use of easier RE approach, then the problem required. The results analysis propose that the software development projects are more likely to fail, if the problem-solving approach the team has chosen to use is originally intended for problems with lower levels complexity.

Conclusions and Discussions

The need for adaptation of problem-solving styles, based on problem complexity level, are highlighted in a number of researches, indicating it as a factor of sustainable development in business environment (Serrat, 2009). In addition, the question of mindful approach choice is also constantly highlighted in different studies (Glukhov, Ilin, & Levina, 2015). The research result supports the previous findings on the importance of alignment between problems and solution complexity level in order to act effectively (Wingo & Tanik, 2015). On the contrary, the described alignment of problem and solution domain was indicated only for the knowable problem type, while there is serious mismatch in complex or chaos problem domains. This could be explained by overall lack of maturity of the companies to tackle complex and chaos problems in a suitable way, which was indicated in the latest Chaos report, where the failure rate increases with growth of projects complexity (Hastie & Wojewoda, 2015). It was indicated that the more complex the project is, the bigger risk of failure.

The issue of problem underestimation could be critical for the company in terms of finishing project in agreed scopes. The Ashby's Law of Requisite Variety postulates that to obtain a desired outcome, the system must match the number of states in the input with at least an equivalent number of states in the regulatory process (Ashby, 1991). For the software engineering research it means that a solution cannot control an environment of greater complexity (Sheard & Mostashari, 2009).

The research has a number of limitations. First of all, the size of the research sample is considerably small, which reveals the need for further testing of the final theoretical propositions. The geographical location of the companies also affects the abstract level of results. All the companies are situated in one city and, possibly, some external contextual factors could have been influential. The listed limitations could be potentially overcome in the future researches.

The Quality of University Teachers as One Of the Tools of Image Building

Josef Kocourek, Tomas Bata University, Zlín, Czech Republic, kocourek@utb.cz

Romana Čočková, Tomas Bata University, Zlín, Czech Republic, cockova@utb.cz

Abstract

Branding is crucial aspect of company because it is the visual voice of the company. The brand is important for creating prestige and reputation of an university and it is difficult to influence it. The quality of teachers is an important factor of the success rate of an university and is also one of the most important decision-making attributes when choosing a university. This study deals with marketing research realized at the Faculty of Multimedia Communications of Tomas Bata University focusing of the faculty by applicants.

Keywords: brand building, image, quality of Universtiy Teachers.

Brand

There is a number of definitions for theoretical understanding of the term "brand" which set the experts apart. Many leading global brand specialists such as Aaeker, Keller, Adamson, Haig, use the brand definition that includes the relation of customer´s mind to brand. In many cases, the presence of a brand in the mind of the customer is associated with brand distinction. Differentiation is a feature that gives the brand certain individuality. "A brand is something that's settled in the head. It is a promise that connects a product or service with a consumer." (Adamson, 2011) Customer's mind and brand are closely linked, but it is necessary to add a secondary attribute to the brand. This can be a logo, because the logo is a part of the brand and with other characteristics makes a whole. From history, it can be seen that the logo and its initial use originated in distinguishing one product from the others.

Image

Image is an important psychological process that leaves an impression of a given company in minds of customers. The resulting effect in the form of a positive or negative attitude is a result of a variety of tools that shape the overall image. It consists of the individual experiences that the customer is exposed to in connection with the brand, which can also lead to a distorted image of reality. It is clear that image building is an important component of a complex brand. This is a specific and long-term path that will never be achieved by a hundred percent, because there is a certain group of customers that is changing for each subject. However, it is important to build a positive image mainly with the target group of the brand. "A positive brand image is created by marketing programs that combine strong, positive, and unique associations with the brand." (Keller, 2007) An important milestone of the image is the realization of reality. This is the only relevant image of the brand on the market. In the case of psychological processes that happen in customers' heads, there may be many distorted information that the customers evaluate on the basis of information that is currently available to them and which is available at the moment. This can often result in a situation where the customer, without any close encounter with the brand, due to negative and inaccurate information about it, creates a negative image of the brand.

Branding

The essence of branding is activities that aim to gain a desired brand position in the minds of its customers - creating positive customer attitudes towards the brand. It is one of the key and irreplaceable marketing activities that fundamentally influence product image and desirable attitudes

in the community of customers and people interested in products or services. "Branding equips the product (products and services) with brand strength. Its point is creating differences. It involves creation of mental structures and helps consumers to sort out their knowledge of products and services to facilitate their decision-making. "(Keller, Kotler, 2007) Branding of universities is a very important activity, which is currently done only by a small percentage of Czech schools. On a European scale, the situation is similar. Only a fraction of universities has a developed communication strategy, defined their own vision and mission. Those educational institutions that recognize the importance of effective communication and brand building are among the leaders in the education market. The quality of teaching, the readiness of future graduates to practice, and the scientific performance of school teachers are features that can add value to a university. It is a value that gives schools prestige, recognition, which can be one of the decisive factors for potential applicants. If a university does not function as a credible, high-quality, well-functioning enterprise, its position on the Czech market is complicated. Prestige of a university, a long-term building of a high-quality, scientific and compact entity is a guarantee of a well-established and built brand.

University Image

The brand is not only important for consumer goods but it also plays a role in creating prestige and reputation of a school. Perceived value, prestige, reputation, quality, communication and overall position of the given school within the overall system of educational institutions functioning in the Czech Republic is very important. Nowadays, at many points mentioned, the situation is very poor, and potential failure at some points may be fatal in time.

There are many risks that are important to the functioning of the university. Their disrespect may result in different forms. The situation in higher education is complicated, for many reasons. One of these is the drop in funding to education. Reputation of many universities was damaged by affairs that have been publicized in the past, and in addition to that applicability of graduates decreases each year. It is therefore a question when will universities lose meaning and many unattractive study fields will completely disappear. On the contrary, what is the way to the strengthening of study fields that are important for society, for functioning of the basic state authorities, companies and other entities that directly affect the running of the state itself. As a result of the above mentioned reasons, it is clear that universities are forced to resolve a competitive struggle for students. A strong and stable brand of a university will play an important role in decision of applicants on their further studies. Decrease in a number of applicants is a threat that can have a major impact on the existence of higher education institutions.

In the field of higher education, creating image is a very important activity that can be difficult to influence. Universities provide education to many students and the course of their studies is varied. For high-quality students who are doing well and without complications, image creation is easier because their loyalty is higher. In such cases, the school can only hardly interfere with students' opinions, but the elimination of negative information should be an important component in image building (Banyar, 2010). It is clear that image building is an important component of a complex brand.

Methodology

Within the framework of image and brand building of a university as a tool of competitiveness, a number of marketing researches was carried out at the Faculty of Multimedia Communications of Tomas Bata University (further referred to as FMC). Annually conducted research includes research focusing on perception of FMC by a target group of applicants. This research is carried out annually, and this study will involve interpretation of data from the turn of 2014/2015 with 496 respondents and the turn of 2015/2016 with 616 respondents. Respondents were interviewed as part of an Open Door Day, or during participation in an entrance examination.

Statistical Analysis

In the framework of statistical testing, the study focuses on the year-on-year comparison of the research carried out between 2014/2015 and 2015/ 2016. The quality of teachers is there a factor important not only for the overall perceived success rate of the Faculty of Multimedia Communications but also as one of the most important decision-making attributes when choosing a university.

Ordinal median or the mean value of research conducted at the turn of 2014 and 2015 shows that respondents are clear about perception of the quality of teachers. Low values of dorvar in variables confirm that students have relatively the same ideas about FMC's success and expertise. The quality factors were rated by the respondents on the Likert scale, where they evaluated from 1 - the worst to 5 - the best. In total, FMC was rated as rather successful, median shows that the reality is even closer to the value the most successful. A similar situation is with FMC's expertise. Mostly FMC was rated as rather professional. An ordinal median of 4.13 with a relatively low dispersion of values indicates that the mean value is shifted towards the "totally expert" value. The low dispersion values for the last two monitored scale variables indicates significant stability in the respondents' views, which is reflected in an estimated confidence interval, which calculates the real proportion for the total population by the inductive mathematical approach (the percentage of those who have chosen 2 or 4 respectively), but it can be estimated at 5% risk of potential error for all students, or it can be related to the relevant public).

Table 1: Values for statistical testing from research conducted at the turn of 2014 and 2015

	Educators	**Successful/unsuccessful**	**Professional/unprofessional**
Modus (the most frequent)	5	2	4
OR (ordinal median - the middle)	**4,384**	**1,774**	**4,13**
Dorvar (discrete ordinal variance = dispersion)	1,275	**0,838**	**0,972**

Table 2: Values for statistical testing from research conducted at the turn of 2015 and 2016

	Educators	**Successful/unsuccessful**	**Professional/unprofessional**
Modus (the most frequent)	**5**	**2**	**4**
OR (ordinal median - the middle)	**4,428**	1,758	4,199
Dorvar (discrete ordinal variance =	1,143	0,672	0,807

Ordinal median, or mean value from the second research conducted at the turn of 2015 and 2016 confirms the results of the research from the previous year. The median value has even shifted further

to point 5, which illustrates the highly positive opinion of respondents on teacher quality and success. Repeatedly low dorvar values in the variables confirm that the students have relatively uniform ideas about FMC's success and expertise, which are repeated every year. Even in contrast to research at the turn of 2014 and 2015, dorvar values are even lower, as evidenced and confirmed by the fact that FMC is a successful and professional school in the minds of respondents.

The most frequent occurrence of the FMC's success value was "4" for both conducted research, which meant evaluation as a rather successful. Median then proves that reality is even closer to the value of completely successful in both cases. A similar occurrence of values was also in the case of FMC's expertise. In both years the ordinal median value of the research was over 4 at relatively low variance. Even in the 2015 and 2016 research, the value approaches 4.2 which illustrates a high level of expertise perceived by respondents.

In the next part of statistical testing a statistical hypothesis was determined to confirm or reject the dependence of two variables. A zero hypothesis was determined for statistical testing: H_0: *There is no dependence between the variable "general perception of pedagogical expertise" and the variable "FMC expertise".*

The hypothesis was tested in both years and completes the coherence between the perceptions of teachers' expertise and the perception of FMC's expertise as a whole. For multidimensional statistics, we assume a symmetrical distribution of values. Deviations can be followed by chi quadratic statistics, respectively by results in a p-value if the value is less than 0.05. In this case, we can talk about a dependency relationship between variables. The test results are shown in the following tables.

Table 3: Contingency table of FMC´s expertise from research

conducted at the turn of 2014 and 2015

Professional/ unprofessional	The worst	Bad	Neutral	Good	The best	Total
Completely unprofessional		1		5	1	7
Rather unprofessional	1	1		3	12	17
Cannot judge	5	10	9	24	48	96
Rather professional	11	13	15	62	75	176
Completely professional	23	6	11	44	81	165
Total	**40**	**31**	**35**	**138**	**217**	**461**

X-squared = 28.7341, df = NA, p-value = **0.02859**

Table 4: Contingency table of FMC´s expertise from research conducted at the turn of 2015 and 2016

Professional/ unprofessional	The worst	Bad	Neutral	Good	The best	Total
Completely unprofessional	0	0	0	2	2	4
Rather unprofessional	0	1	2	3	5	11
Cannot judge	8	6	13	23	26	76
Rather professional	13	12	24	94	117	260
Completely professional	11	12	12	54	106	195
Total	**37**	**34**	**56**	**195**	**294**	**616**

X-squared = 22.267, df = NA, p-value = **0.1452**

Based on the p-value, the hypothesis H0 was rejected. It can be said that there is a relationship between the variables. For both tested hypotheses, it was confirmed that the p-value is below 0.5 indicating that there is a relationship between the variable competence of the educators and the variable expertise of FMC as a whole. The asymmetric distribution can be seen in the contingency tables attached. For both investigations, there are higher values at the bottom right in the matrix. The findings can be interpreted in such a way that students who see educators more in the direction good-to-the-best perceive FMC more as rather-completely professional and vice versa. This fact was confirmed in the second survey by the same group of respondents. Among the most important findings of the two surveys there is a fact that the public brings together the quality of the teachers with the faculty's expertise, which has a positive impact on image building of the brand. From the attached tables it is clear that only a few individuals chose "contradictory" in the sense of - the highest rating for teachers and at the same time a completely unprofessional faculty or the lowest grade for teachers and completely professional faculty.

Conclusion

The high competition of universities in the Czech Republic forces the schools themselves to think more about thinking of their potential applicants, secondary school students. It is important for universities to understand the priorities of high school students, to examine their thinking, the ways in which they choose a university, and also to analyze the brand of the university itself. Long-term research carried out at the FMC proves that the quality of teachers is high on a long-term basis. Respondents regard FMC as a quality school with quality educators. This is the main conclusion of the presented study, but it is important to perceive this fact in a wider context. The primary attribute of brand building should be to clearly define the mission of a university which would be based on the actual focus of the educational institution and which would be acceptable both for the target group - the applicants, and to the general public. The results of research at FMC are a source of strategic management that leads to the sustainability of a quality education process and the competitiveness of the university. Another important attribute is strategic goals, which should ideally be a quantifiable indicator and should mirror the set values. Brand values, their definition, work with them and effective analysis are prerequisites necessary to be aware of, to work with them and to modify them on the basis of current data. These are the long-term objectives of the research carried out at the

FMC, their ongoing analysis and adjustment will lead to a more effective FMC branding on the market. Other activities of the faculty contribute to this. In 2016, the faculty realized a large and socially significant project to present water as an exhaustible resource. The current situation around water management is not good and the work of students, teachers and their presentation at various exhibitions should serve as an education for the general public. Social issues are another way that adds to the positive perception of FMC on both the Czech and European markets.

Abstract

Femoral stems come in a variety of shapes and sizes, but all of them are assembled with the hip-bone using the same method. Current hip implants are fixed into place by hammering them down into the femoral bone, procedure which can lead to the fracture of the femoral neck. The current paper develops a new concept for a hip implant which can diminish some of these problems through its' unique shape and fixing system. The purpose of this research is to propose a design methodology for manufacturing a new hip endo-prosthesis stem using additive technologies. The numerical CAD model and simulation was undertaken in order to assess the endurance properties and performance of the new hip endo-prosthesis stem concept model. Rapid prototyping was done for functional fitting and surgical procedure validation. The technological transfer possibility was considered through cost analysis, by establishing the total EBM manufacturing costs for one part.

Keywords: additive manufacturing, custom hip implant, product design, manufacturing cost

Introduction

According to a study by Global data released in 2016 the World Health Organisation (WHO) estimates half a million total hip replacements per annum in 2030. Due to a growing number of injuries and the subsequent demand for surgeries for the required correction, the global market is expected to be worth US$9.1 bn by the end of 2024 as compared to US$6.5 bn in 2015, in conformity with the Hip Replacement Implant Market - Global Industry Analysis, Size, Share, Growth, Trends, and Forecast 2016 – 2024 Study published in 2017. The same study shows that between the forecast period of 2016 and 2024, the global market is estimated to expand at a CAGR of 3.9%. There are many disabilities involving the hip joint, as presented in a research study by Mirza et al (2010), starting from degenerative diseases such as arthritis, femoral head tumours, and femoral neck trauma when bone continuity is lost. The market is based on and will be driven by the rising prevalence of osteoarthritis and the rising aging population, as well as the increasing indications where total hip replacement is used. Current hip replacement surgeries aim to replace or, rather, strengthen the femoral neck. Currently used prostheses in day-to-day operating theatre have a longer stem that reaches all the way inside of the femoral canal, as presented by Aitchison et al (2009) and Parker et al (2010). In order to insert them into the femoral canal a wider resection of the femoral neck is needed, moreover, as McTighe et al (2015) presents in a recent study, high surgical dexterity is necessary to implant them in a position that does not lead to prosthesis dislocation. Falez et al (2015) and Rawal et al (2011) show that short stem implants have also been developed in the recent years in a variety of configurations and are used in the surgical practice due to their advantages in specific cases. Although they are better suited due the minimal invasion of the implantation area, the implants are

still assembled with the femoral neck through repeated shock delivery. To avoid all major identified complications, the paper proposes a study regarding the design for manufacture, using Electron Beam Melting (EBM) technology, of a new endo-prosthesis femoral stem concept. In a study by Cronskär et al (2013) it is mentioned that in recent years EBM technology has been shown to bring several significant advantages over conventional machining in the production of hip implants. The novelty of the design concept of the hip stem is given by its' unique shape, which allows assembly with the femoral head by screwing the stem into place, rather than hammering. The main advantage of the new endo-prosthesis stem, proposed by the authors, is that a maximum amount from the hip bone and especially from the femoral neck is kept, as shown by Moga et al (2015) in a recent patent application. Only the used volume of the femoral head is resected. The new prosthesis has an innovative fastening system, combining a non-cemented system with a cemented one. The cement does not get to fill all the bone, after screwing and initial fixation, the cement is used to further fix into place the prosthesis. On top of a cylindrical connector an intermediary part is placed to ensure contact with the rest of the prosthesis.

Methods and Materials

CAD modelling and simulation development

The numerical model, CAD renders and simulations were undertaken using SolidWorks 2016 software package. The hip endo-prosthesis stems' unique design is due to the necessity of lowering some of the complications of existing hip implants. Developed features are presented in Figure 1 and include: main stem, cylindrical fixation flange, cylindrical connector, hexagonal hole, helical fillet, main cement delivery internal channel and secondary delivery internal channels. Overall dimensions were defined for an *80 kg* male patient and were set to *40L x 40l x 63H mm*. The hip endo-prosthesis main stem is shorter than other concepts and has a helical fillet which enables an easy screwing through the hip joint. A constant pitch helix was defined with a *41 mm* height and *3.3* revolutions. Following the CAD modelling several steps are entailed in order to develop accurate simulations, namely: Define material properties; State simulation hypotheses; Identify and define stress distribution; Set mesh properties; Set initial chart characteristics; Run simulations for the implicit analysis.

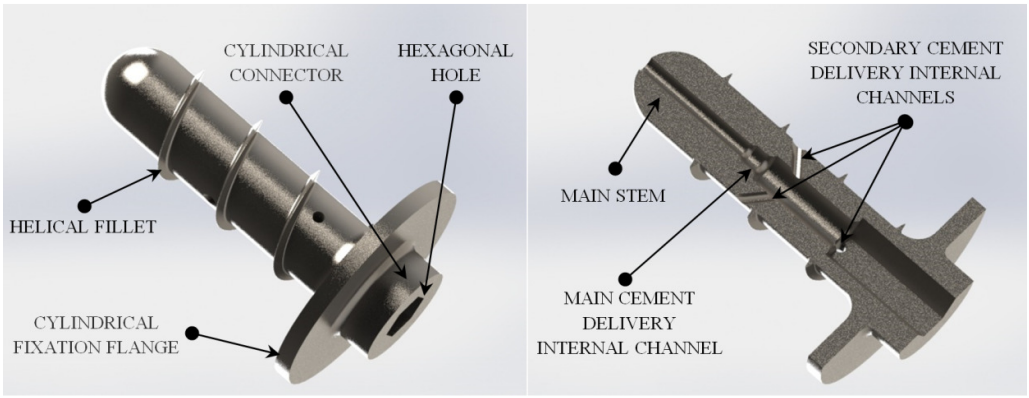

Figure 1: Main features of the hip endo-prosthesis stem

Accurate material definition is crucial to the realistic results of the simulation and thus, to the optimisation of the final endo-prosthesis stem. Electron Beam Melting (EBM) will be used to additive manufacture the hip endo-prosthesis stem on Arcam Q10 equipment from Ti–6Al–4V titanium alloy. Characteristics of the alloy are set using SolidWorks material data base, as seen in Figure 2.

Three hypotheses have been developed for the simulation of the hip endo-prosthesis stem in accordance with two states of its existence: fitting and operation. Stress load values were considered,

for all three hypotheses, in accordance with ISO 7206-4 (1989) standard for determination of endurance properties and performance of stemmed femoral components.

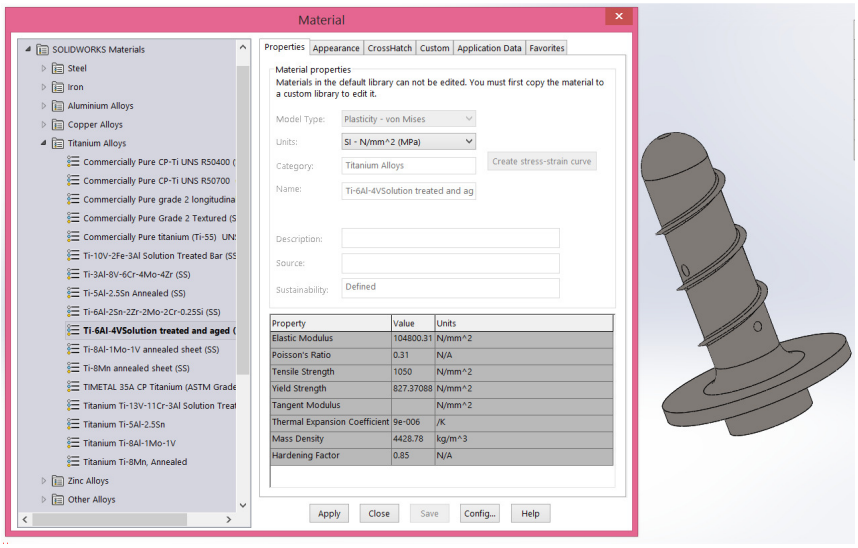

Figure 2: Ti–6Al–4V material characteristics set-up using SolidWorks material data base

The first hypothesis is defined for the fitting of the endo-prosthesis stem in the surgical theatre. The procedure is done by the orthopaedic surgeon using tools from the regular hip replacement surgical tool kit. Stresses were defined by taking into consideration the main stages of the hip replacement procedure, namely: femoral head resection; intermediary CT data control; hip prosthesis position and screw; cement insertion and hardening; final CT data control. Classic hip prosthesis are usually hammered into place, leading to bone damage such as micro fissure, chipping and even fracturing of the femoral neck. In these cases the stresses are usually present as forces delivered in shocks. In order to diminish these common complications, a different fixation technique is proposed for the studied endo-prosthesis. Using a hexagonal key the endo-prosthesis stem is screwed into place and secured with bone cement. Fixation is achieved when the cement delivered through the internal channel structure of the endo-prosthesis stem is hardened. Using this surgical technique a different stress distribution is achieved. A torque of 11 *Nm* is defined all throughout the hexagonal hole, as the product between the pressing force (F = 200 *N*) and the length of the hexagonal key (L = 55 *mm*). The second hypothesis is defined for regular usage and a force of *1550 N* is applied, in accordance with a study by Dharme and Kuthe (2016). The third hypothesis is defined for usage in case of shocks and high weight of the patient, therefore a force of *2300 N* is applied, in accordance with ISO 7206-4 (1989). Computer aided design models were built to simulate the ISO7206-4 loading, which determines the endurance properties and performance of stemmed femoral components. According to the description of ISO7206-4 (1989), the stem is fixed in cement distally and proximally is unsupported. The cement holds the distal end of the stem starting at 35 mm from the center of the femoral hex hole. In addition, the model of the stem was oriented in adduction of 10^0 and flexion of 9^0 (Figure 3). As the cement dimensions are not indicated by the standard, a cylinder of diameter *ø40 mm* and height *35 mm* was defined.

Loads and fixtures were defined for all three hypotheses and the centralised data is presented in Figure 4.

Contact sets were defined as bounded between the cement cylinder internal cavity and the body features of the hip endo-prosthesis stem on a *30 mm* distance. Meshing was undertaken using the characteristics given in Table 1. In accordance to the book by Radostina (2015), several types of studies were defined for each of the three hypotheses, as follows: Von Misses stress; URES: Resultant Displacement; UX, UY, UZ: Displacement on X, Y, Z directions; ESTRN: Equivalent Strain. All initial charts were set to show an automatic deformed shape with a superimposed

transparent model. Number formats were set to scientific and the legend had an automatically defined minimum and maximum values. No errors were found when meshing the assembly.

Rapid Prototyping

One of the most challenging geometries to manufacture was helical fillet with a peak radius of R0,1 mm, which is the key feature that gives the endo-prosthesis stem its novelty and advantages over pre-existing hip replacement devices. Due to the required precision of the study, prototyping was done on a Projet 1500 3D printer. The equipment uses Film Transfer Imaging (FTI™) technology that allows parts to be built much quicker than other methods of_rapid prototyping. A film is coated in UV curable photopolymer. This resin is then transferred from the film to the build platform and is cured by a flash of light from a DLP projector. The process is repetitive, building layer over layer until the part is entirely built. By curing each layer with a single flash of projected light, instead of tracing each layer with a laser or ejecting material in specific locations, parts can be built quickly, accurately and with fine resolution. The VisiJet® FTI-Ivory material was chosen for the final concept models, due to its specific material characteristics, which brought visible benefits. VisiJet® FTI materials created durable plastic concept models with excellent, high resolution detail that were tough enough for functional testing and snap-fit applications. The characteristics of the photopolymer composite material allowed an accurate representation of the proposed hip endo-prosthesis stem.

Table 2: Main FTI™ 3D printing stages

Stages	**Prototyping sub-stages**
1. Analysis and redesign	FTI™ technology characteristics identification
2. Prepare, orientation and position	Print job layout using PJP3P software
	Support generation using PJP3P software
3. 3D Printing	Machine preparation
	3D printing
	Component cooling
4. Post-processing	Part removal
	Ethylic alcohol part cleaning
	Part UV Curing
	Removal of support structures
	Sanding of support witness marks
	Silicone based solution spraying
	Part drying

Printing the concept model of the implant lasted for two hours and 23 minutes. The main characteristics of the print job are summarised in Table 3.

Table 3: Print job characteristics for the hip endo-prosthesis stem prototype

PRINT JOB CHARACTERISTICS		VALUES	UNITS

Functional tests and measurements were undertaken for validation purposes of the 3D printed prototype.

Cost Analysis

The global implants (hip and knee) market reached $8.6B in 2016 and had a constant annual growth rate of 6% from 2009 to 2016, according to a study by Global data released in 2016. In order to commercialize the proposed hip stem, a thorough technology transfer strategy must be put into place. Cost analysis is undertaken as a first initiative in this direction, with the goal of series production of the endo-prosthesis stem. In order to properly calculate all manufacturing costs of a custom endo-prosthesis stem the following characteristics must be set: main technology manufacturing stages; mechanical properties of the used material; unit production costs; manufacturing speed; post-processing treatment; energy consumption; workforce; salaries. The custom hip endo-prosthesis will be manufactured using the Electron Beam Melting (EBM) additive technology on the Arcam Q10 equipment. The main EBM manufacturing stages are summarized in Table 4.

Table 4: Speciffic EBM manufacturing stages of the hip endo-prosthesis

EBM Stage	**Intermediary stages**
S1. 3D Modelling	*IS 1.1.* CAD modelling
	IS 1.2. Material properties definition for Ti–6Al–4V
	IS 1.3. *.STL file compilation
S2. Prepare, orientation, positioning	*IS 2.1.* Support structure generation using a specialised software package
	IS 2.2. Print layout for one manufacturing cycle
S3. 3D printing using EBM technology	*IS 3.1.* Equipment preparation
	IS 3.2. EBM 3D printing
	IS 3.3. Printing chamber cooling
S4. Post-processing	*IS 4.1.* Part removal
	IS 4.2. Part cutting from the metal support plate
	IS 4.3. Cutting of the support metal structures
	IS 4.4. Grinding and polishing of the contact points
	IS 4.5. Preparation of the work-piece: washing and pickling
	IS 4.6. Hydroxyapatite coating
	IS 4.7. Curing and drying

The material used to manufacture the custom implant is Ti-6Al-4V titanium alloy. An extras of the material mechanical properties are shown in Table 5.

Table 5: Mechanical properties of Ti–6Al–4V

Material	*E* (GPa)	*YS* (Mpa)	σ_f (Mpa)	%EL	BF × 10^{-3}
Ti–6Al–4V	105	900	550	13	5,2

E = Young's modulus, *YS* = yield strength, σ_f = fatigue strenght, BF = biofunctionality = σ_f /*E* %EL = elongation.

With a production cost below 2€/cm^3, Arcam Q10 has a construction speed of 15cm^3/h for complex structures with a pore size up to 400µm. To estimate the production costs of the hip endo-prosthesis, it is necessary to know the volume of the CAD model. Figure 5 shows the weight and volume definition using SolidWorks Premium 2016 Design Software.

The post-processing treatment is proposed to be carried out using the immersion coating method in hydroxyapatite solution, with the chemical composition shown in *Table 6*. The hydroxyapatite based solution covers homogeneously metal surfaces with layers of thicknesses between 0.05-0.5 mm.
The first stage of manufacture will be carried out by a design engineer, and the next three stages will be carried out by a specially qualified technician. Considering that the financial remuneration of an engineer is 1.7820 €/ h, and of a technician is 1.7004 €/ h, it is necessary to define the time frame of the intermediary stages of the manufacturing process for the labour calculation. This has been done taking into account the following: the technical book of the machine, the technical sheet of the material, recommendations from the literature, the experience of the technician and the designer. Energy consumption was set according to the technical documentation available for each piece of equipment. Calculations and interpretations are given in the following chapter.

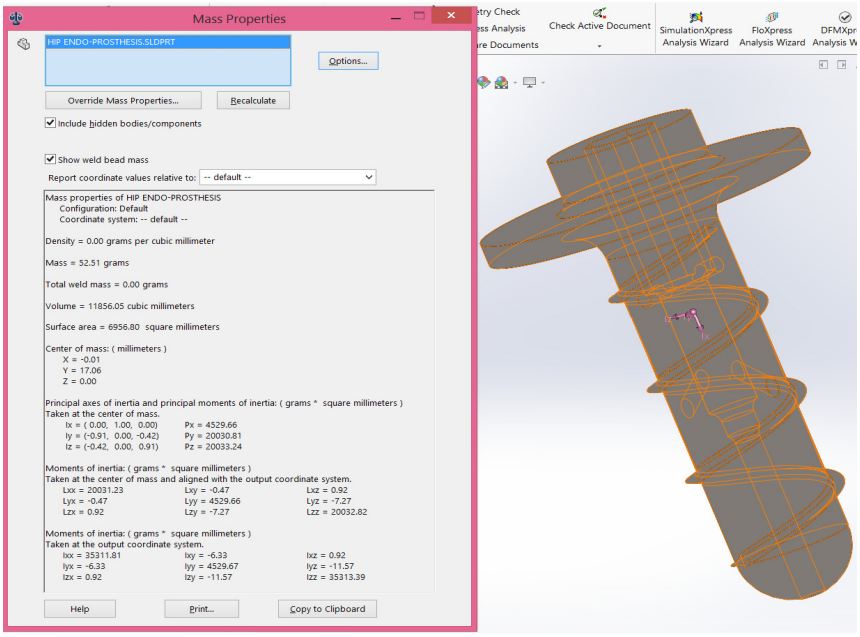

Figure 5: Hip endo-prosthesis stem mass properties using SolidWorks Premium 2016

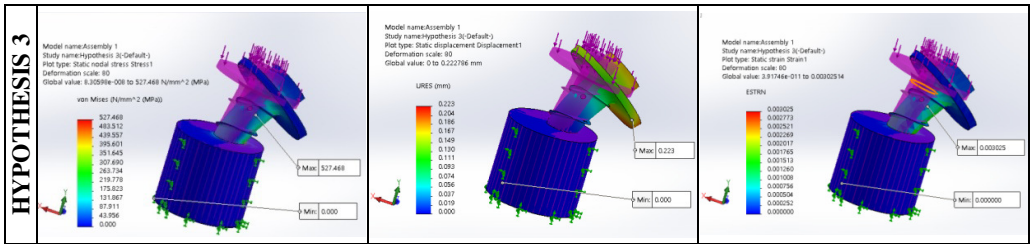
Results Interpretation



Simulation Results

Simulation results were analysed considering the following stages: Mesh compilation; Study simulation with integrated solver; First evaluation of simulation results; Optimise chart characteristics; Generation of the simulation reports; Interpretation of results; Simulation conclusions regarding the endo-prosthesis stem concept model. Mesh was compiled with the characteristics presented in Table 1 and no errors were given by the mesh solver. Several studies were undertaken for each of the three defined hypotheses, as follows: Von Misses stress; URES: Resultant Displacement; UX, UY, UZ: Displacement on X, Y, Z directions; ESTRN: Equivalent Strain. Simulations were run after mesh compilation and a first evaluation of the results led to the optimisation of chart plots characteristics. The deformation scale was adjusted from *automatic* to 80 units for all plots and the superimposed model on the deformed shape was set to translucent single color (bright pink) with a transparency factor of 0.5. Value units were changed from N/m^2 to MPa and a floating number format with three decimals was set. Simulation results are summarised in Table 7.

The von Misses Stress (Table 7) distribution obtained by FEA states weather the assembly will withstand the design load. Compilation of hypothesis 1 load distribution leads to a minimum value of $1.90871 \cdot 10^{-8}$ MPa, in mesh node 1012, and a maximum load of 424.014MPa in node no. 1567. For hypothesis 2 the minimum stress value was $5.59751 \cdot 10^{-8}$ MPa, generated in mesh node 1012, and the maximum stress was obtained in node 8266 with a value of 355.467 MPa. Results of hypothesis 3 shown a maximum von Misses stress value of $8.30598 \cdot 10^{-8}$MPa in node number 1012, and a maximum value of 527.468 MPa in mesh node 8266. Comparing the obtained values with the yield strength of the material used to manufacture the eno-prosthesis stem, it is clear that the assembly did not fail under the designed load distribution. All von Misses stress simulation results are situated below the yield point value of Ti-6Al-4V which is 827.3708 MPa.

Table 7: Simulation results for a Ti-6Al-4V stem: vonMisses, URES and ESTRN

	VON MISSES STRESS	URES: RESULTANT DISPLACEMENT	ESTRN: EQUIVALENT STRAIN
HYPOTHESIS 1			
HYPOTHESIS 2			

URES study is used to determine how the CAD model moves under the defined loads. The Resultant Displacement (Table 7) generates the magnitude of the resultant (compounded from the X, Y and Z directions) reaction force. ISO 7206-4 standard allows a ±3 mm deflection for vertical and horizontal displacements. Stress distribution in hypothesis 1 generated a resultant displacement with a minimum value of $1.0 \bullet 10^{-30}$ mm in mesh node 1 and a maximum value of 0.22545 mm in node no. 2109. Deployment of hypothesis 2 led to a resultant displacement with a minimum value of $1.0 \bullet 10^{-30}$ mm in mesh node 1 and a maximum value of 0.150139 mm in the 1783rd node. For the last hypothesis the simulation results shows a resultant displacement with a minimum value of $1.0 \bullet 10^{-30}$ mm in node 1 and a maximum value of 0.222786 mm in node 1783. As it can be observed, all displacement values are situated under the standard ±3 mm deflection limit.

In order to provide additional safety measures, further displacement studies were undertaken for all three hypotheses to evaluate the magnitude of the reaction forces on the X, Y and Z individual directions. Simulation results are summarised in Table 8 and they clearly show that the ISO 7206-4 standard deflection value is not exceeded.

The equivalent strain was used to measure the geometric response and the change in shape (deformation) due to applied forces for the three defined load scenarios. ESTRN: equivalent strain is computed as the rapport between the maximum triaxial stress and the Elastic Modulus. In order for the assembly to withstand the design load, ESTRN values (Table 7) should be less than the coefficient given by the ratio between the Yield Strength and the Elastic Modulus. As the Elastic Modulus for Ti-6Al-4V has a value of 104800.31 MPa, all simulation results values will be compared with a 0.0079 coefficient. According to hypothesis 1 the ESTRN global values range from $1.80858 \bullet 10^{-11}$ (node element 428) to 0.00309937 (node element 3105). Hypothesis 2 shows simulation results with ESTRN values from $2.64003 \bullet 10^{-11}$ (mesh node 428) to 0.00203868 (mesh node 2535). ESTRN values in hypothesis 3 are situated between 3.91746, in mesh node 428, and 0.00302514, in mesh node 2535. Comparing the results analysis with the set coefficient, it can be observed that the design load does not cause any failures in any of the three hypotheses.

Table 8: Displacements simulation results for a Ti-6Al-4V endo-prosthesis stem

	UX: Displacement (X direction)		UY: Displacement (Y direction)		UZ: Displacement (X direction)	
	Minimum value [mm]	Maximum value [mm]	Minimum value [mm]	Maximum value [mm]	Minimum value [mm]	Maximum value [mm]
HYPOTHESIS 1	-0.222	0.221	-0.051	0.051	-0.222	0.222
HYPOTHESIS 2	-0.091	0.001	-0.136	0.036	-0.001	0.082
HYPOTHESIS 3	-0.134	0.002	-0.201	0.054	-0.001	0.122

Comprehensive simulation results have shown that the hip endo-prosthesis stem assembly is compliant with standard endurance properties and performances. Considerring the abovementioned, the proposed CAD model is appropriate for first prototype manufacturing and testing.

Prototyping – FTI

Several prototyping stages need to be taken into consideration as a part of the surgical planning strategy: 1. Bone density is evaluated from the CT scan images using Mimics Research software; 2. The optimum cutting line is analysed when resecting the acetabular cup; 3. The *.STL files for the femur anatomical model are created and exported to 3-Matic Research software for further processing; 5. *.STL files are analysed for accuracy using Gaussian curvature analysis, maximum curvature analysis, wall thickness analysis and Extrema analysis; 6. An anatomical model of the patients' femur is 3D printed; 7. The hip endo-prosthesis stem prototype is 3D printed; 8. Functional tests and fittings are undertaken; 9. Surgical procedure is planned. Following these stages, a surgical procedure can be easily planned if there is the availability of locally manufacturing the endo-prosthesis. Prior to 3D prototyping fit tests were undertaken using a virtual simulation software (Figure 6).

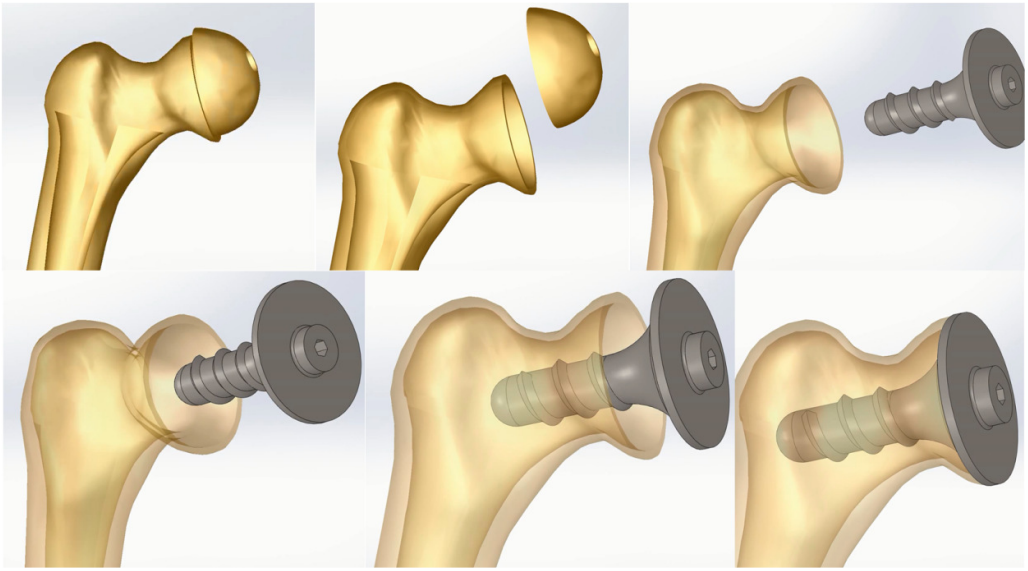


Figure 6: Simulation of surgical procedure and fit test of Hip endo-prosthesis stem with femoral neck from DICOM patient anatomical data

A CT scan of the patient was imported into Mimics Research software and DICOM data images were first processed into mask files and then into *.STL files. These were analysed and the final model presented in Figure 6 was created. Together with the CAD model of the designed hip endo-prosthesis stem, the *.STL of the femur was imported into 3-Matic Research. Fitting and surgical procedure were simulated in order to evaluate the compatibility of the CAD model with the anatomical data of the patient. As it is presented in Figure 6, a perfect fit was achieved at the interface of the cylindrical fixation flange with the femoral neck.

3D printing of the hip endo-prosthesis stem prototype was undertaken considering all criteria detailed in the previous chapter. A full 3D printing job lasted two hours and 23 minutes with intermediary times adding up to almost four hours. FTI technology implies that the part is in continuous contact with the photopolymer, thus the 3D printed prototype comes out of the machine with a viscous coating (Figure 7) which requires cleaning. The hip endo-prosthesis stem prototype was washed in an isopropyl alcohol recipient and left 10 to 15 minutes to degrease. In order to obtain the optimum mechanical characteristics, the degreased prototype was fully hardened and dried in a UV Projet curing unit (Figure 7). Due to its size, the prosthesis stem was UV cured in one cycle of 30 minutes. The UV post-processing was used to improve scratch and solvent resistance and facilitate superior bonding of the material. Other post-processing steps included: removing the support structures, sanding down the contact points of the supports, sanding any rough edges of the model and silicone spraying.

Figure 7: Stages of 3D printing the hip endo-prosthesis stem prototype using FTI™ technology: 3D printing, Component cooling, Part UV Curing, Post-processing

Surgical procedure and fit testing of the hip endo-prosthesis stem was deployed using a high quality PVC femur anatomical model (Figure 8). Assembly was done by screwing the dip endo-prosthesis into the femoral neck of the hip-bone model. As the internal structure of the model replicates a spongy bone tissue, the fitting was done fairly easy. Some of the main feedback from the fitting tests was as follows: improvement of helical fillet section shape should be considered in terms of thickness and peak radius; a smaller radius should be considered between the stem body and the cylindrical fixation flange; the cylindrical fixation flange should have a higher thickness for stability reasons; the main cement delivery internal channel must be provided with an occlusion device; secondary cement delivery internal channels should be distributed equally all throughout the length of the stem body and should have an increased number; the cylindrical connector must be elongated and tapered. The results of the surgical procedure and fit tests will be taken into consideration for further research and improvement of the hip endo-prosthesis stem concept model.

After FEA simulations, rapid prototyping and functional tests, the next step is to calculate the total manufacturing cost of the implant, as a first initiative in the technological transfer of the

Figure 8: Surgical procedure and fit test of Hip endo-prosthesis stem with HQ PVC femur anatomical model

Cost Analysis

Compiling all the input data given in chapter 2.3 of the current paper, the production costs for a custom hip endo-prosthesis stem manufactured on the Arcam Q10 equipment from Ti-6Al-4V titanium alloy are computed and summarized in Table 9.

Manufacturing costs for hip implant range from 60 € up to 300€ depending on the processes and steps necessary to produce the final device. The cost analysis undertaken by the authors showed that the proposed concept model can be manufactured in the low price range.

Table 9: Manufacturing costs for a hip endo-prosthesis stem, using EBM on Arcam Q10

Conclusion

The research paper proposed a design process of a hip endo-prosthesis stem obtained with EBM additive technology. Three main stages were used in the development of the new concept model of the hip implant: CAD modelling and simulation, rapid prototyping and fit testing, cost analysis of EBM manufacture. Result simulations for several studies were analysed in three main hypotheses, which were stated in correspondence with applicable standards. The following studies were undertaken for each of the three hypothesis: von Misses Stress; URES: Resultant Displacement; UX, UY, UZ: Displacement on X, Y, Z directions; ESTRN: Equivalent Strain. All simulation values fell within imposed limits, thus, no necessary redesign optimisation stages was needed. Rapid prototyping was done using FTI additive technology on a Projet 1500 3D machine, using VisiJet® FTI-Ivory material. Fitting and surgical procedure were simulated in order to evaluate the compatibility of the CAD model with the anatomical data of the patient. Fit testing of the hip endo-prosthesis stem with a high quality PVC femur anatomical model led to some optimisation recommendations, the most important being the modification of the secondary cement delivery internal channels structure. A step towards technological transfer was made through cost analysis of an EBM manufacture implant stem. Total production costs for one stem was 80.299 €, value which is situated in the low price range of similar medical devices.

Research results validated a new concept model for a hip endo-prosthesis stem, future research including: manufacture of the improved stem endo-prosthesis from titanium alloy, deployment of in vivo and in vitro studies and development of in vivo research protocols.

Abstract

The application of additive manufacturing technologies for the development of invasive airway devices may enhance the quality of life of tracheostomy patients. The current research is intended to reduce clinical long-term complications that appear in the frequent use of classic tracheostomy tubes in airway management. The development of a bespoke tracheostomy device aims to improve functional ability, social anxiety and overall patient satisfaction. The study was conducted in four stages: preconception, patient specific design, additive manufacturing of the new endotracheal tube prototype and testing. Using patient specific data a new concept was designed with appropriate CAD software, while implementing the findings from deploying functional analysis. Starting with a cuffed tracheostomy tube for needs analysis, three new CAD models were generated. The initial functional prototypes were developed, with the main innovations brought to the tracheal fixing system, neck plate and obturator, and were enabled by the advantages of additive manufacturing technologies. Initial tests were undertaken on an explanted pigs' trachea with the aim of identification of any surgical technique or concept shape related problems. The current research presents an integrated approach for developing a new tracheostomy device concept, fabricated using AM technologies. The advantages of AM were used to enable the design and manufacture of customised, unique features that target the reduction of late clinical complications of tracheostomy tube users.

Keywords: endotracheal tube, patient specific design, additive manufacturing, functional analysis

Introduction

Sobotta (2011) describes the tracheostomy as a surgical opening in the anterior wall of the trachea, also known as a tracheal stoma, made with the aim of facilitating ventilation. As presented by Morris and Afifi (2010) a tracheostomy can be temporary or permanent and leads, in both cases, to respiration bypassing the upper airways. Wilkinson et al (2014) shows that in the majority of cases (95.8%), the airway is managed using an endotracheal (tracheostomy) tube, immediately prior to tracheostomy. Tracheostomy tubes are available in a large variety of sizes and styles, as shown in research conducted by Morris and Afifi (2010), Wilkinson et al (2014), De Leyn et al (2007) and Fikkers et al (2013). Fisher et al (2014), De Leyn et al (2007) and NHS (2007) conclude that the main categories include cuffed or un-cuffed, single or dual cannula and continuous or fenestrated tracheostomy tubes. Morris and Afifi (2010), Wilkinson et al (2014) and Apfelbaum et al (2013) state that in order to select the best tube for a particular patient, physicians with specific training must accurately understand and set the primary goals.

The complications associated with tracheostomies and placement of a tracheostomy tube can be grouped into three main categories by their main causes: failed surgical procedures; tube misplacement; and improper postoperative stoma and tube care. Timeframe related complications can be immediate, early and late. As presented by Sobotta (2011), Wilkinson et al (2014), NHS (2007) and Muralidhar (2008) the most numerous and frequent complications occur later, after the tracheostomy procedure is conducted. Amongst these, the most significant, noted in the literature research cited above, are: cuff leak, trachea-esophageal fistula and trachea-innominate fistula, due to overinflating/ underinflating of the cuff; dislodgement of tracheostomy tube, due to poor airway management protocols; obstruction of tracheostomy tube and obstruction of permanent stoma mucus plugs or thick secretions, mostly due to humidity deficit in the airways; stoma infections, due to poor positioning or post-operative care; stomal stenosis, stomal granulation tissue, tracheomalacia, tracheal stenosis, mediastinitis, tracheocele; tracheoinnominate hemorrhage, due to improper positioning or poor choice of the tube. Research conducted by Morris and Afifi (2010), NHS (2007), Apfelbaum et al (2013) and NCEPOD (2009) shows that less frequent long-term complications may also include vertebral erosion pneumonia and sometimes, even death.

Morris and Afifi (2010), Wilkinson et al (2014), Fisher et al (2014) and De Leyn et al (2007) conclude that in some cases, current designs of tracheostomy tubes facilitate and maintain the occurrence and, sometimes, worsen the evolution of complications.

The current study presents the development of a new tracheostomy device concept proposed for the reduction of long-term clinical complications of temporary and permanent tracheostomies. Given the importance of personal anatomical features for the outcome of such surgical procedures, as presented in their research by Santos et al (2012) and Zenikos et al (2012), various authors who developed the Wohlers (2015) report consider additive manufacturing (AM) the most appropriate technology to utilise for the proposed research.

Methods

Ulrich and Eppinger (2012) claim that the design processes commence with the preconception phase. For this specific phase, the authors developed a structured procedural approach which is made up of four stages: 1. Identification of challenges in airway management by usage of an endotracheal tube; 2. Identification of specific late clinical complications and their causes, strictly related to the design of the endotracheal tube; 3. Definition of the needs that arise from prior identified causes; 4. Function definition of the endotracheal tube.

Challenges And Complications That Influence The Design Of An Endotracheal Tube

The idea behind this procedural approach was that patients with a tracheostomy encounter many challenges due to specific complications. The tracheostomy tube concept must perform all the identified functions in order to satisfy the needs generated by late complications, thus reducing airway management related challenges (Fig 1).

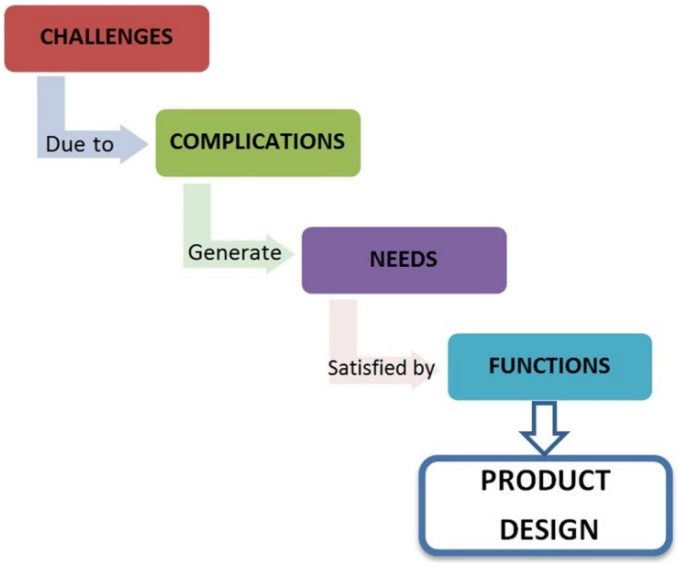

Fig. 1: Structured procedural approach for product design of TrachyLight

To validate dimensions and anatomical feature proportions of the concept, the models are developed for a real patient. Hereafter, the new tracheostomy device concept is referred to as TrachyLight (TL). Research conducted by Morris and Afifi (2010), Fisher et al (2014), De Leyn et al (2007), Fikkers et al (2013), NHS (2007), Apfelbaum et al (2013), Muralidhar (2008), NCEPOD (2009) and Engoren (2004) identify the main challenges involved in the airway management of patients with a fitted endotracheal tube in the following areas: communication; swallowing and nutrition; stoma care; tracheostomy tube management; suction; and humidification. NHS (2007) shows that in relation to tracheostomy tube design, the difficulties in communication can occur when the type and the size of the tube are not chosen properly for the anatomical specificities and condition of the patient.

Commonly, speaking valves are required to improve communication. Morris and Afifi (2010), Fikkers et al (2013) and Apfelbaum et al (2013) show in their research that speaking valves can be safely used with un-cuffed tracheostomy tubes or with a fully deflated cuff.

Swallowing difficulties can occur due to compression of the oesophagus from an inflated cuff, as presented by De Leyn et al (2007), Fikkers et al (2013), NHS (2007), Apfelbaum et al (2013) and Engoren (2004). Swallowing may also be difficult for the patient if an improper tube is used or the tube is poorly positioned or fixed. In the same time, stoma care needs to be undertaken in order to reduce the risk of infection. Stomas are a potential route for respiratory tract infection and potential site of peristomal infection. Fikkers et al (2013), NHS (2007) and Apfelbaum et al (2013) conclude that in order to avoid these risks, some tracheostomy tubes are designed with soft flanges such that a dressing between the tube and the skin is not always required. Tracheostomy tube management involves: individual assessment of the most appropriate tube; care, change and removal protocols; compliance with manufacturing recommendations for each type of tube. Research conducted by Fisher et al (2014) and NHS (2007) shows that improper usage of inner cannulae was shown to reduce the lumen of the outer tracheostomy tube, thus increasing respiratory effort. Suctioning is of great importance for patients that are unable to cough and cannot eliminate secretions in a natural way. Some complications of the current procedure involve tissue damage and hypoxia, mainly due to the shape of the tube and misuse of equipment. According to research undertaken by Morris and Afifi (2010), Fisher et al (2014), Fikkers et al (2013), Engoren (2004) and Ham (2010) the lack of proper humidification in tracheostomy patients has been also shown to cause a series of complications from thick secretions, loss of ciliary action, deterioration of pulmonary function and increased risk of infection. Moreover, heated systems can result in water vapours cooling and collecting in the tubing. The weight of different humidification systems can pull on tracheostomy masks causing increased

risk of airway obstruction when a cuffed tube is in situ. Thus, a proper design must ensure safe positioning of the tube.

The aforementioned challenges develop due to either individual or common late complications. Amongst these, the authors identify the most important as being: stoma, trachea and respiratory tract infections; haemorrhage; stoma and tracheal stenosis; thick, tenacious, crusted secretions; excessive sputum production; impaired pulmonary function; pressure sores; irritated/ damaged airway mucosa; aspiration and swallowing problems; tracheostomy tube occlusion and displacement; cuff leaks; formation of granulation tissue.

Considering the principles of needs analysis, described by Ulrich and Eppinger (2012), and the complications reported by physicians and patients, the main identified needs that require focus in terms of tracheostomy tube design are stated. Thus, the tracheostomy tube must: 1. Diminish or prevent the risk of infection; 2. Facilitate wound healing; 3. Be positioned and fixed properly; 4. Maintain correct position after fitting; 5. Be compliant with patient anatomy; 6. Provide/allow proper humidification of airway; 7. Be minimally invasive over the trachea; 7. Allow proper guidance for suction equipment. The functional expression of these needs was analysed with technical functional analysis (TFA) and translated into specific targeted functions.

A customized tracheostomy tube might reduce some of the aforementioned long-term clinical complications associated with the design of these devices. With AM technologies being more and more available to the medical industry, in terms of capabilities, materials, applications and costs, the authors consider a viable option to be research into the design and manufacture process for a new tracheostomy device.

Technical Functional Analysis (TFA)

To identify the main functions of the product, Technical Functional Analysis was undertaken, in correspondence with the stages mentioned by Ulrich and Eppinger (2012) in their research. The main function of the tracheostomy tube is to ensure and maintain an access stoma (hole) through the trachea, allowing a constant airflow and pressure throughout the breathing and deglutition process.
Function Analysis System Technique (FAST) was deployed, as a tool of TFA, in order to properly identify the main functions of the tracheostomy tube (Fig 2).
FAST was deployed to determine the four level functions of an endotracheal tube used in current surgical practice. Four levels of functions were sufficient for the current research study, but if necessary the analysis could be more detailed. Each individual function must be materialised into the final CAD concept as a particular element or shape. TFA has several other stages for cost and value evaluation of products. Further research of the endotracheal tube concept will consider such analysis by integrating all other states of existence.

Computer Aided Design of TrachyLight concept models

Given the large variety of tracheostomy tubes and their diverse applications, the redesign process was undertaken starting with a properly defined existing tube (Fig 3). The customization of the proposed concept was made according to a male patients' anatomy.

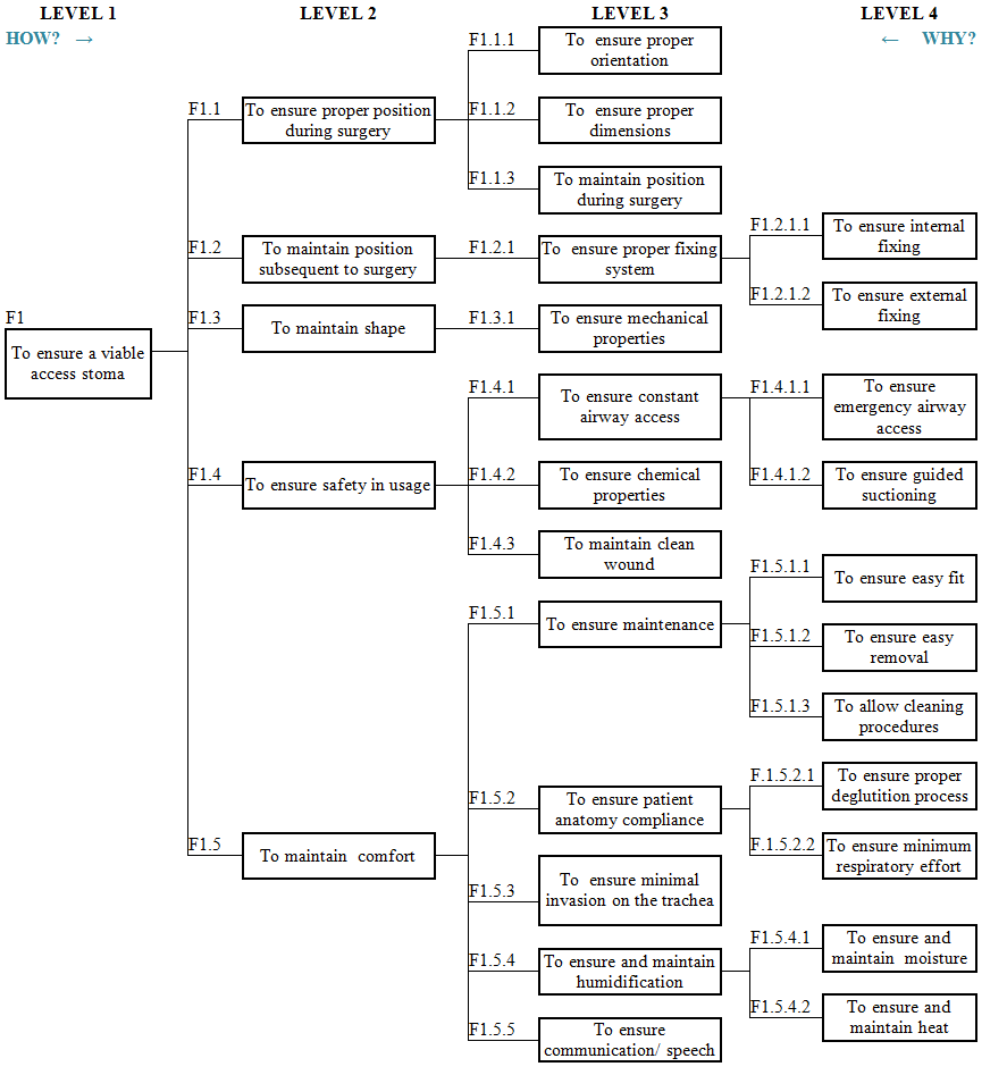

Fig. 2: FAST analysis for usage of the tracheostomy tube

The patient was selected considering that he should fit into the average of the following criteria: tracheal width, which was set according to restrictions provided by Chunder et al (2010) and Brodsky et al (1996); gender frequency tracheostomy occurrence, selected in accordance with research conducted by Wilkinson et al (2014) and Brodsky et al (1996); average demographics (age – excluding infants and children under 16, height, weight), criteria discussed in their research by Morris and Afifi (2010), Wilkinson et al (2014), De Leyn et al (2007), Fikkers et al (2013) and NHS (2007); principal diagnosis (respiratory disease), described in their research by Morris and Afifi (2010), Wilkinson et al (2014), Fikkers et al (2013) and Apfelbaum et al (2013). The average values were those mentioned in specialist literature.

A 68 year old male patient was submitted to the emergency room showing acute respiratory failure and other symptoms. An emergency Computer Tomography (CT) procedure was performed to establish the cause. It was established that the upper airway of the patient was partially obstructed due to a hypopharyngeal tumoral mass that was pushing against all surrounding tissue structures causing difficulties in breathing.

Upper airway intubation was not a viable option due to the shape and position of the tumor. The patient was respiratory stabilised using an emergency tracheostomy. He was fitted with a cuffed, single lumen tracheostomy tube with an internal diameter of 7 mm and a guiding obturator (Fig 3). Once the stoma was established, artificial ventilation was not necessary.

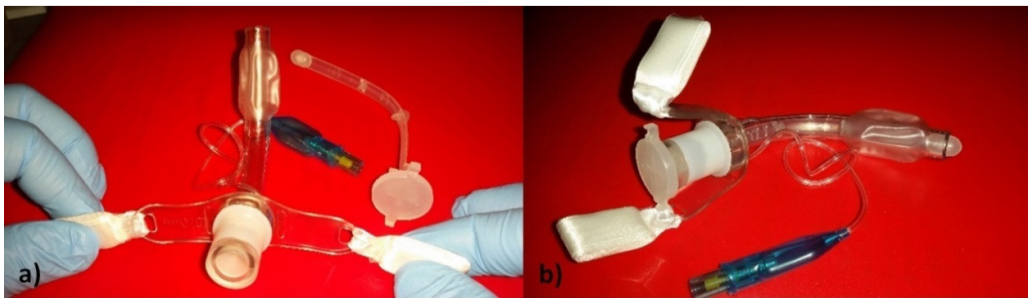

Fig. 3:Cuffed tracheostomy tube with a size of ID 7mm: a) front view; b) lateral view (Courtesy of the Emergency University Hospital of Bucharest, Emergency Room)

A cuffed tracheostomy tube was taken as a starting point for the needs analysis. The design process for the TrachyLight concepts was targeted at fulfilling the specific identified functions. Three main components, each tackling a group of functions, were designed: 1. The body of the tube, measured from the connector with the mechanical ventilators up to the trachea anterior wall; 2. The tracheal fixing system; 3. The neck plate. The obturator and adapter did not undergo any modifications.
For the design of the TrachyLight body tube**,** the following functions were taken into consideration for compliance: F1.1.1 To ensure proper orientation; F1.1.2 To ensure proper dimensions; F1.1.3 To maintain position during surgery; F1.2.1.2 To ensure external fixing; F1.3 To maintain shape; F1.4.1 To ensure constant airway access; F1.5.2 To ensure patient anatomy compliance.

In order to determine the exact dimension of a tracheostomy tube body several criteria need to be taken into consideration, apart from the anatomical dimensions of the patient. Amongst the specific criteria, some can be mentioned as follows: the position and nature of the respiratory impairment, position of the incision point, type of surgical incision and curvature of the tracheostomy tube used. According to Sobotta (2011), Morris and Afifi (2010) and Muralidhar (2008) the most common site of a tracheostomy is between the 2^{nd} and 4^{th} or 3^{rd} and 5^{th} tracheal rings. Within this area, different types of incision can be used in order to ensure the proper stoma. Airway management protocols must be used throughout the intervention and post-operative care, precisely as described by Fikkers et al (2013), NHS (2007) and Apfelbaum et al (2013). For the 68 year old male, the tomography showed that the hypopharyngeal tumoral mass was partially obstructing the larynx, thus the surgical procedure was undertaken between the 3^{rd} and 5^{th} tracheal rings. For the curvature of the tracheal tube, several design recommendations are noted from the research of Sobotta (2011) and Roe (1962) and a curvature of 60^{0} was assigned (Fig 4). As an added feature, the body of the tube can be manufactured with a length adaptor (Fig 4). The step was set at 3 mm between two consecutive cylindrical elements, creating a supplementary length of 18 mm. Accurate position of the cylindrical element ensures the orientation of the endotracheal tube during and after surgery. In connection with the neckplate it also ensures fixation and maintenance of the position during and after surgery. The internal diameter of the TrachyLight tube is 7 mm, the same as those used by surgeons in the surgical theatre. The adaptor was designed with a 15 mm external diameter, so that it connects with all general types of tubing from ventilators, humidifiers and speaking valves. Thus, the adaptor caters to the following functions: F1.5.4 To ensure and maintain humidification; F1.5.5 To ensure communication and speech.

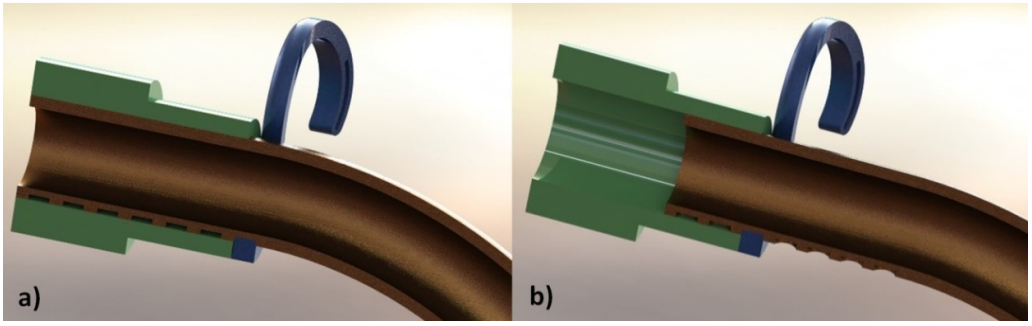

Fig. 4: Detail of the length adjustment feature (3mm step) for two different soft tissue dimensions: a) 21 mm; b) 33 mm (sagittal section view)

The TrachyLight concept was designed with a new tracheal fixing system by taking into consideration the following functions: F1.1 To ensure proper positioning during surgery; F1.2.1.1 To ensure internal fixing; F1.5.1 To ensure maintenance; F1.5.2.1 To ensure proper deglutition process; F1.5.2.2 To ensure minimum respiratory effort; F1.5.3 To ensure minimal invasion on the trachea; F1.5.4.1 To ensure and maintain moisture; F1.5.4.2 To ensure and maintain heat.

Considering the aforementioned functions, the innovative fixing system that was proposed consists of a spherical/toroidal surface (Fig 5).

Fig. 5: Main three concepts for the spherical surface tracheal fixing system: a) SFS 1 - full lateral gripping elements; b) SFS 2 - lateral gripping elements with model driven micro-perforations; c) SFS 3 - structural shaped lateral gripping elements

The dimensions of the sphere were compliant with the patient's anatomy. Studies undertaken by Chunder et al (2010) and Brodsky et al (1996) have shown that the average tracheal width for women is 17 mm (range = 13-25 mm) and for men is 22mm (range = 13-25 mm). The age range for the patients was 13 to 82 years. Situated within the average, the patients' CT shows he has a 20 mm tracheal width. For accuracy, the measurements were taken both in the sagittal and transversal plane from data series and details. Thus, three different concepts were proposed for the spherical fixing system (Fig. 6) and were presented to surgeons for feedback and validation. The first spherical fixing system (SFS 1) was designed with full spherical lateral gripping elements. The second concept of the fixing system (SFS 2) presents lateral gripping elements with model driven micro-perforations for extra grip. The third concept (SFS 3) was designed with structural shaped lateral gripping elements in order to reduce the overall weight of the concept. All three concepts were designed for a 20 mm diameter (tracheal width on both sagittal and transversal plane). In order to mimic the effects produced by a cuffed tracheostomy tube, the spherical surface fixing system can be manufactured with the upper surface of the sphere covered. Thus, a half closed sphere will totally disconnect the upper airway.

The neck plate was designed in accordance with the following functions: F1.2.1.2 To ensure external fixing; F1.3 To maintain shape; F1.4.3 To maintain clean wound; F1.5.1 To ensure maintenance; F1.5.2 To ensure patient anatomy compliance. The overall dimensions of the neck plate are 18.5 mm

by 37 mm, with a thickness of 2 mm. The arch of the part (Fig 6) follows the anatomical shape of the patients' neck and is guided by a circle of 28 mm radius. Three concepts of the neck plate were developed (Fig 6) to fulfil the functions identified previously.

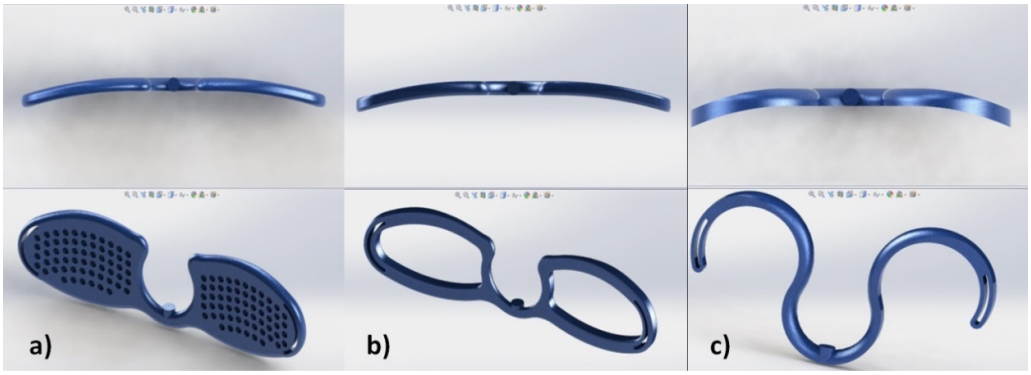

Fig. 6: Main three concepts of neck plate: a) NP 1; b) NP 2; c) NP 3

All the concepts have a common cylindrical section in the middle that fits perfectly on the outer diameter of the body tube. Also, an embossed cylinder was provided in order to orient and fix the neck plate onto the tracheostomy tube. Once in place, the shape of the neck plate indicates the orientation of the tube subsequent to surgery. It makes adjusting the TrachyLight easy and comfortable at any moment. The first concept of the neck plate (NP1) offers the most support, whilst providing skin ventilation through custom made curve driven perforations. These perforations can have any shape in a specific dimensional limit, without affecting the structural integrity of the part. Sideways NP1 is provided with appropriate slots for fixing with an ordinary neck strap. The second concept of the neck plate (NP2) is designed for medium support and has a light weight construction. Prolonged contact with skin will not cause any complications due to the wireframe structure. The shape of the third neck plate concept (NP3) ensures minimal skin contact whilst ensuring light support for patients that have a healed stoma. These patients often need to wear a tracheostomy tube for longer periods of time. The neck plate is the most adaptable component of the TrachyLight, as long as it maintains several mandatory features: the fixing and contact cylinder and the side slots.

A fully functional concept of the TrachyLight was assembled in SolidWorks, using the following components: 15mm adaptor, SFS 3 and NP 3 (Fig 7). Any combination of the designed components is possible as they are interchangeable and adaptable with standard medical devices used in care and management of tracheostomies.

Results and Discussions

Manufacturing of Trachy Light prototypes using 3SP™ technology

The TrachyLight concepts were manufactured with an industrial additive manufacturing machine from EnvisionTECH, the Ultra 3SP™. The used *.stl files had the following input parameters: deviation tolerance 0.00332345 mm; angle tolerance 0.5 degrees; output as binary; metric unit system. The print job was designed with Perfactory™ software and loaded on the machines built-in computer. Seven components were included in one build operation, as follows: three concepts of the tracheostomy tube with the different spherical surface tracheal fixing system, six parts of neck plate (two of each concept) and one 15 mm adaptor (Fig 8). The voxel size depth was set to 50 µm. The entire batch was printed in 10 hours and 35 minutes. In order to fully cure the parts, they were placed in a UV curing unit. All the parts were sprayed with a silicone based solution for a better surface finish and left 12 hours to rest. After all post-processing and secondary treatments were finished, the parts were paper dried and fitted together in order to assess assembly functionality.

The TrachyLight concept prototypes, manufactured using the 3SP technology, are presented in Fig 8. The assembly of the three neck plate concepts with the other three tube concepts was done randomly.

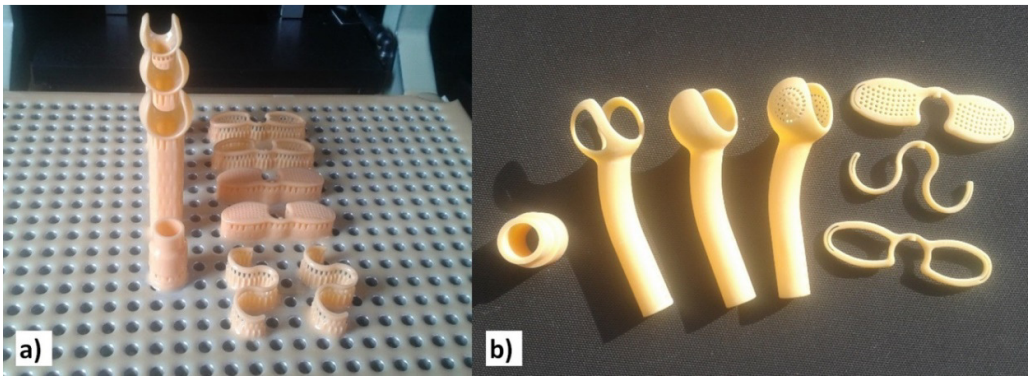

Fig. 8: TrachyLight concept prototypes manufactured with 3SP technology: a) prototypes with supports on the build platform of the machine; b) post processed prototypes

Functional Tests

Functional tests were required in order to identify any surgical technique and concept shape related problems. An emergency room suture kit was used to perform the surgical procedure (Fig 9a). The prototypes were tested on a pigs' trachea of 20 mm diameter (Fig 9b) in order to identify any functional issues. A window type incision was used to access the tracheal lumen (Fig 9c), as it is the most common method employed, presented in the research conducted by Wilkinson et al (2014). The tests were conducted by a surgeon in an appropriate medical facility. The following criteria were assessed: ease of insertion, ability to orient during the procedure, ability to maintain position subsequent to the procedure, compliance with the shape of the trachea, existence of appropriate pressure on the trachea. During the surgical procedure, it was observed that the LightTrachy tube could be inserted with ease. The concept with SFS3 was the easiest to be inserted into the trachea, due to the lateral shavings of the sphere. The surgeon concluded that if a different type of incision was used in the surgical procedure, the TrachyLight concepts could have some issues with insertion. The orientation was made instinctively, due to the shape of the spherical fixing system and the presence of the cylindrical fixing element on the lower side of the prototype. After insertion of the TrachyLight in the trachea, the shape of the fixing system made it quite easy to be snapped into position. The orientation was once again checked visually with the cylindrical elements. Position was maintained due to the shape of the spherical fixing system and the 60^0 angle of the tube body.

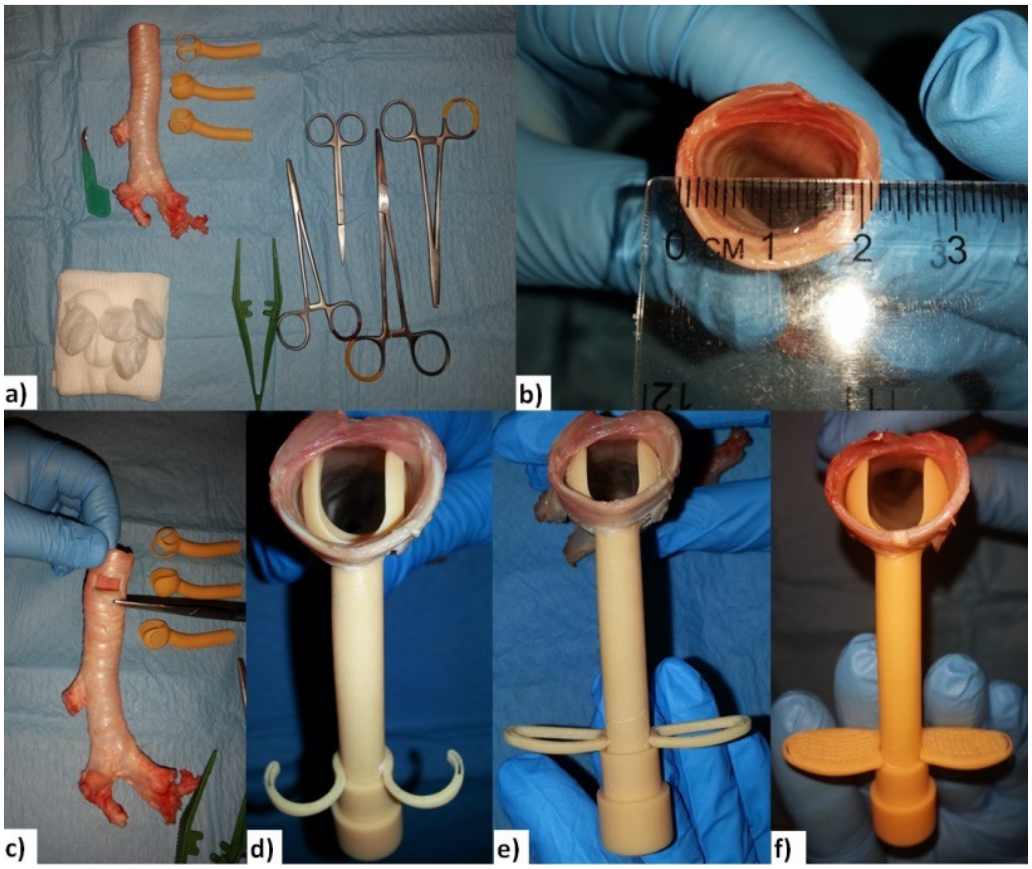

Fig 9. Functional tests on an explanted pigs' trachea: a) materials; b) 20mm trachea; c) fenestrated window; d) fit test for SFS 3 & NP3; e) fit test for SFS 2 & NP 2; f) fit test for SFS 1 & NP1

The pressure on the contact surface meant the trachea maintained a slightly tense position, with no bulges or deformations of the trachea (Fig 9 d, e, f). It was concluded that the slight tension was due to the fact that the concepts were not designed in compliance with the anatomy of this specific trachea. Out of the three concepts, SFS 3 presented minimal impact over the tracheal lumen. The most stable concepts were SFS 1 and SFS 2, both gripping securely onto the tracheal wall. Taking this into consideration, the authors will conduct future studies regarding the optimal shape of the fixing system. Concepts with a toroidal surface will be developed, as the contact surface with the trachea would be wider, thus generating more stability. It was also observed that for fitting and fixing the neck plates and the adaptor, the tube needs to be secured in place with one hand. In this particular instance, the shape of the neck plate concepts became an advantage, due to the clip-on feature.

Recommendations and Feedback

The CAD concepts generated, along with the prototypes and the results of the functional tests, were sent to a team of medical/surgical specialists for initial feedback.

Some suggestions were made for future studies, amongst which can be mentioned: 1. The wall of the trachea must always overpass the diameter of the devices' central cavity diameter; for this reason, special care must be given to the insertion, fixation and maintenance of the device in the proper position; 2. An easy removal must be ensured at all times and some concerns were stated in relation to the bulbous end if used together with a different type of incision; 3. The shape of the neck clips

could be further improved; specialists choose concept model no. 3 as a more "appealing" solution; 4. In vivo concept testing is strongly recommended after the final bio-compatible material is chosen.
The main contributions brought about by the TrachyLight can be summarised as follows: improvement of the deglutition process; limited invasion of the trachea; customised features with patient anatomy compliance; ease of orientation, fixation and overall fitting; and controlled pressure on the tracheal lumen. Depending on the final manufacturing material, the TrachyLight will be impregnated with an antibiotic solution. Due to the porous surface roughness, an inherent feature of AM technology, the antibiotic will be absorbed deeply into the material structure of the device.

After undergoing the present research, several conclusions were made: 1. For short-term users of the TrachyLight, it is better that the devices are available in several standardised dimensions of the tube and spherical fixing system. The CAD model can be parameterised with appropriate software tools and the device could be manufactured in a large scale production; 2. For long term or permanent users of the TrachyLight device, it is best that the design process should take into consideration the specific dimensions and shapes of the patients' trachea informed by CT data.

In this context, some recommendations are given for possible adaptation of the TrachyLight device for permanent tracheostomy and laryngectomy patients: the spherical fixing system is intended to be manufactured from biocompatible rubber-like material to facilitate removal by the patient themself; an easy guiding system should be designed to allow the patient to insert the TrachyLight safely and in a proper position; an ergonomic tracheostomy shield is considered for customisation. These recommendations constitute a basis for future research.

Conclusions

The current research presents an integrated approach for developing a new tracheostomy device concept, fabricated using AM technologies. The advantages of AM were used to enable the design and manufacture of customised, unique features that target the reduction of late clinical complications of tracheostomy tube users. The proposed structured approach covered the following research areas: identification of challenges and complications in airway management for tracheostomy patients; definition of specific needs; identification of targeted functions of the new tracheostomy device concept; development of CAD models for several concepts that fulfill the identified functions; manufacture of the first prototypes of the new tracheostomy device concept; deployment of functional tests on a pig's trachea; evaluation and feedback from a team of medical specialists; recommendations for usage of the new tracheostomy device concept. The research results were encouraging, thus future research will be undertaken for further development of the TrachyLight concepts.

Future research includes designing an ergonomic adaptable shield to improve speech, device and stoma protection, and physical appearance when the TrachyLight is not connected to ventilation equipment. Cleaning or sterilisation will be considered when choosing the material for manufacturing the final TrachyLight device. All the medical practitioner feedback was taken into consideration and will be given special attention when designing and testing the final prototype. In vivo tests will be conducted in a rigorously designed and managed experiment.

Agricultural land prices development in the Czech Republic and the latest legal development

Ivan Soukal, University of Hradec Kralove Faculty of Informatics and Management Department of Economics, Hradec Kralove, Czech Republic, ivan.soukal@uhk.cz

Agnieszka Tarnowska, Wroclaw University of Economics Department of Management and Food Economy, Wrocław, Poland, agnieszka.tarnowska@ue.wroc.pl

Abstract

Agricultural land is the rare resource of strategic importance and its market in the Czech Republic underwent significant development in the last decade. A continuous trend of price increase in the last decade resulted in prices that are higher 3.5 times now compared to the year 2006. However the trend was not the same over time and the year 2014 brought even higher price increase than ever before due to legal changes, non-agricultural investors and the end of the economic crisis. Tested hypothesis confirmed that there is statistically significant difference in price development before and after 2014. Legal changes concern the right of first refusal which allowed reaching more easily broader range of potential buyers. Long and medium-term non-agricultural investors were seeking the opportunity of high yield and low risk investments. However the situation may change since the share of non-agricultural investors on total purchase slowly decreases as the costs in the investments increases. Also the re-introduction of the right of first refusal will have a negative impact on the market. Similar negative effect will have CZK appreciation against EUR and USD because of higher costs for foreign investors from Germany, Austria, Netherlands and Belgium. The last significant factor is the increase of the key interest rate which may continue in the future and which increases the costs of credit used for the agricultural land purchase.

Keywords: agricultural land, price, right of first refusal, Czech Republic.

Introduction

Agricultural land is the rare resource of strategic importance for any country that cares about the food security of its citizens and it participates on GDP as a factor of production. The agricultural land market went through many changes during the last few decades. It changed from the era of "under-developed" market where less than 0.5 % (Vrbová, Němec, 2005) agricultural land fund traded per year to more than 2.3% traded per year (Ministry of Agriculture, 2015) and with a land as highly demanded investments. With the development of civilization this resource will decrease (Piwowar, Dzikuć, 2015), and its price will rise. The last ten years show that the last part of the sentence is more than precise – the land prices are 3.5 times higher than ten years ago. Such increase attracts the attention of not just investors but mainly of farmers themselves and government as well.

One of the ways how government can influence the agricultural land price development is through legal system although within the limits of EU legal system only. One of the legal means is the right of first refusal which can significantly delay or sometimes even prevent the agricultural land purchase. Unlike Poland in the Czech Republic is a lot of land in co-ownership. Co-owners had general right of first refusal to other co-ownership shares till the 31st December 2013 accordingly to the Civil code. In 2014 the Civil code Act no. 89/2012 Coll. commonly known as New Civil code (hereinafter referred to as NCC) became active and the right of first refusal was not a general principle anymore, its extended was limited. Also at the same time non-agricultural investors became dominant purchase power on the market since agricultural land offered high yield carrying only low risk. Another important feature of 2014 was that this year ended the economic crisis.

We are going to analyze the price development to find out whether the year 2014 and its two major factors were strong enough to change the price development. We are going to test a hypothesis on a sample of price before and after the change (the right of first refusal, non-agricultural investors became main buyers on the market, end of crisis). Also we will describe the latest development including recent NCC novelization. NCC implemented change concerns Act no. 460/2016, Coll. bringing re-introduction of the right of first refusal.

Methods

Data for the analysis were obtained from two sources Czech Statistical Office and Farmy.cz. The first source provides the data based on real-estate transfer tax return analysed for the whole tax payer population per year. The second source's methodology is based on monitoring market prices under a condition that both sides are well-informed and participate voluntarily in trade. We did not separate arable land from permanent grassland and so land prices per hectare are average prices per year of all agricultural land. Typical sources of these data are the land auctions. Standard inflation adjustment was performed on all land prices with a base year 2006. All prices are converted into EUR by year average exchange rates. Due to a foreign exchange market intervention of Czech National Bank are prices calculated in purchase parity power exchange rates (hereinafter referred to as PPP) as cross-parity from USD/CZK and USD/EUR rates.

Mann–Whitney test (also known as Wilcoxon–Mann–Whitney test) is a suitable method capable of testing ranked data with wider usability range than parametric tests (such as t-test). This method is widely used in social sciences for ranked data, see e.g. Bargagliotti (2009) or Aryal and Gabrielli, (2013) who employed Mann–Whitney test price development comparison under different conditions. Mann–Whitney test is a nonparametric test of the null hypothesis that it is equally likely that a randomly selected value from one sample will be less than or greater than a randomly selected value from a second sample. The both samples have to be independent of each other and the values have to be ordinal. The hypothesis tests if variable X from sample A with $n1$ observations and the variable Y from the sample B with $n2$ observations got the same distribution i.e. the distributions of both populations are equal. All observations got the rank. Let R_A bet the sum of the ranks from A sample and R_B the sum of ranks from the i sample. Test value is the U_{min} from:

$$U_A = n_1 \cdot n_2 + \frac{n_1 \cdot (n_1 + 1)}{2} - R_A \tag{1}$$

$$U_B = n_1 \cdot n_2 + \frac{n_1 \cdot (n_1 + 1)}{2} - R_B \tag{2}$$

$U\ (\alpha,n1,n2)$ is the critical value of Mann–Whitney test for selected α.
If $U_{min} > U\ (\alpha,n1,n2)$ then the hypothesis of distribution match cannot be rejected.
If $U_{min} < U\ (\alpha,n1,n2)$ then the hypothesis of distribution match can be rejected.
Hypothesis 1: the distribution of land areas trade per year is equal for years before and after the liberalization.
Linear regression described e.g. by Hebák (2005) or Bowerman and O'Connel (1997) is based on least square method. It solves the problem of finding a linear function that best fits a set of data points. Let us have a set of n pairs of observations $\{yi,xi\}$. The linear function represents the relation of value of the dependent variable Y to the values of an independent one X. This function describes in other words the relation between the data set and the prediction. With one variable and a linear function, the prediction is given by the following equation:

$$\hat{Y} = a + bX \tag{3}$$

This equation involves two parameters which specify the intercept and the slope b of the linear regression function. The least square method defines the estimate of these parameters as the values for which the sum of the squares between the dataset and the prediction (observed yi and the predicted yi) is the least one possible. The minimization problem is given by the following equation:

$$\sum_{i}^{n} \varepsilon^2 = \sum_{i}^{n} (y_i - \hat{y}_i)^2 = \sum_{i}^{n} (y_i - a - bx_i)^2 \quad (4)$$

The estimation of the parameters is obtained by derivation of (4) with respect to a and b and setting them to zero.

Results

Legal changes

Co-owners had general right of first refusal to other co-ownership shares till the 31st December 2013 accordingly to the Civil code. The only exception was a transfer to the close person. Close person is a legal construct describing a situation when two persons are so close to each other that a detriment or harm to one of them, the other would felt as detriment or harm to one's own (generally a close relative, a spouse, a registered partner, a sibling, or any other person who would reasonably be harmed by another person's detriment). The general right of first refusal was applied to both immovable and movable property. The New Civil code became active from the 1st January 2014 and general right of first refusal was not applied anymore. The regulation of selling a real estate share became liberal almost abolishing general right of first refusal although agricultural plant co-ownership had a special treatment. Agricultural plant was a new legal construct representing a set of assets created by entrepreneur and being used to perform farming. The right of first refusal was kept valid concerning agricultural plant but only for a specific case when co-owners got their share under the conditions when they could not influence their rights and obligations from the beginning. This covered mainly a situation such as if the co-ownership was based on the acquisition by previous owner's death (by the last will, by inheritance agreement). However, at the same time another exception was involved. Co-owners could not apply right of first refusal if the share transfers was a co-owner and another co-owner, his or her spouse, sibling or a direct relative. The right of first refusal was applicable also in case that a transfer was a voluntary conveyance to prevent right of first refusal evasion. Although the right of first refusal was kept valid for agricultural plant in much wider range than for other property types, extend was significantly narrower.

The situation changed due to a recent New Civil code novelization by Act no. 460/2016, Coll., namely article I. § 1124, 1125 of NCC. The amendment of the New Civil code re-introduced the general right of first refusal. As of 1st January 2018 the general right of first refusal will be applied again on all real estate. Therefore, if the co-owner transfers his or her share, the other co-owners can apply right of first refusal. An exception will be again concerning close person and so transfer to a close person cannot be blocked by the right of first refusal. Co-owners will have the right to redeem the seller's share of ownership according to the size of their shares, unless they agree otherwise. Unlike before the exception will not be applicable on the co-owner-to-co-owner transfers and so even in this case the right of first refusal has to be taken into consideration. This extends the right of first refusal into a general principle. The latest amendment of NCC treats co-ownership in almost the same way as Act no.140/2014, Coll. from Slovakia (valid from 1.6.2014). This shows continuing legal similarities in former Czechoslovakian territory.

Price development

The year 2006 was selected a base year for inflation adjusted prices per hectare. Prices were converted by EUR/CZK for both average year exchange rate and average year exchange rate in PPP. See the price development on the fig. 1 below. As mentioned earlier, a significant legal change in land market became active in January 2014. Therefore a mark divides a price development chart below into the part with the general right of first refusal (till 2013) and without (2014-2016).

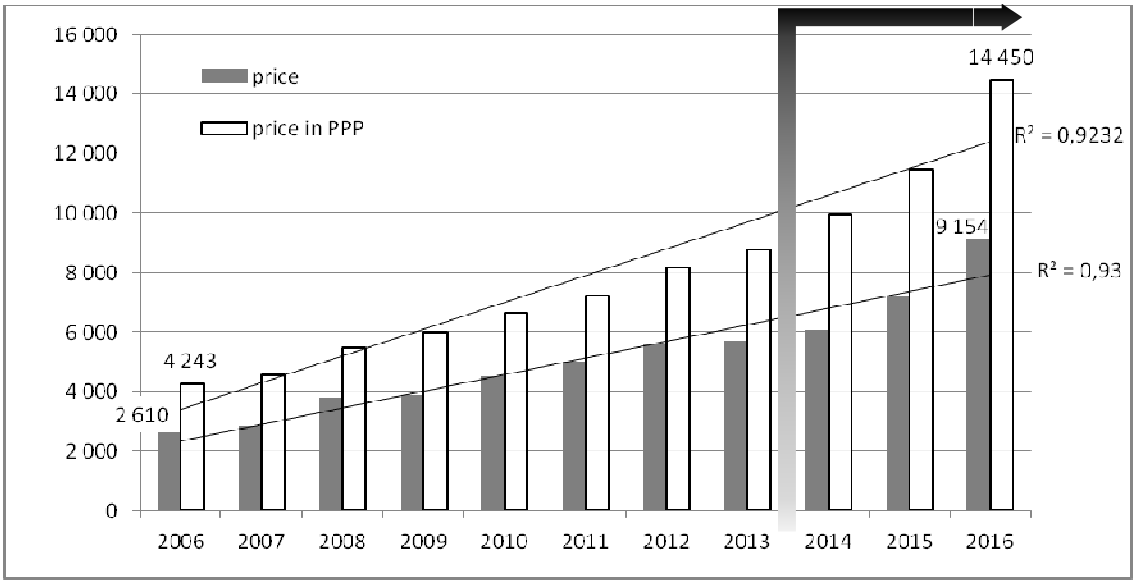

Fig. 1: Development price per hectare in EUR, own calculation based on (Farmy.cz, 2017; Czech Statistical Office, 2017; OECD, 2017; Ministry of Agriculture, 2009).

The chart shows continuous increase in land price per hectare in both expressed in EUR and in EUR in PPP. The increase is described with regression function for prices in EUR $y = 559{,}62x + 1769{,}6$ $x \in \{2006, 2007, \ldots, 2016\}$ and with regression function for prices in EUR in PPP $y = 900{,}54x + 2496{,}1$, $x \in \{2006, 2007, \ldots, 2016\}$. Both functions show very high index of determination suggesting that the slopes are good price lead in the surveyed period. The prices per hectare rose by a bit more than 350 % regarding the EUR and by a bit more than 340% from 2006 till 2016.

The hypothesis regarding the price development before the year 2014 and after was tested with the test criterion 0 below the tabled critical value for Mann–Whitney test 2 for alpha 0,05 (two-tailed). We managed to reject the hypothesis that the prices of two samples were from the same distribution.

The year 2014 brought not just a legal environment change but also an approach of agricultural investors changed and created highly competitive environment. Farmers often profited from excellent knowledge of a local situation and relatively low local demand and achieved favorable land purchase. This situation was a typical one in the previous decade. However as the land became more and more attractive to nonagricultural investors and so opportunities for local favorable land purchase became much less frequent. Agricultural buyers had to compete with investors who are capable and willing to pay the seller real market prices on a new platforms such as land market auctions seeking adequate return on investment which is safer than other means of investment. Large share of long and medium-term non-agricultural investors arose also due to an expected increase in demand of various churches. Regular compensation for the land that cannot or will not be returned to church was a part of restitution process

closure in 2013. Churches are spending money from compensation also on land acquisition. Long and medium-term non-agricultural investor does not have an advantage in excellent knowledge of a local situation and cannot use the same means of addressing thousands of land owners by mail or newsletter campaign. This is what speculative investors try and serious investor seeking long-term or at least would only discredit oneself by such campaign. Serious investors compete by better price bid and they are successful because they became almost a half of effective demand. However their share very slowly decreases during the last years, see the fig. below. All groups contain homeland as well as abroad buyers. However foreign buyers are focused almost only on greater parts of land and it is very rare that they buy parts below 5 hectares. Most of foreign investors come from Germany, Austria, Netherlands and Belgium.

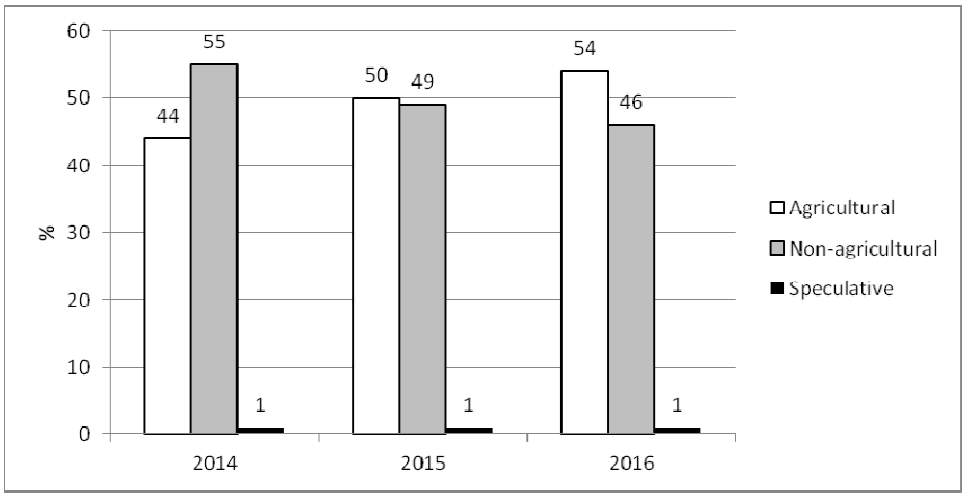

Fig. 2: Development of shares on total year agricultural land purchase, own elaboration based on (Farmy.cz, 2015; Farmy.cz, 2016; Farmy.cz, 2017).

In 2014 speculative investors (very short-term investment or direct resale) intensified considerably their campaign and a lot of landowners received a bid with disadvantageous conditions or significantly below the market price. Existing or emerging companies are trying to buy a land from owners without up-to-date land price information. However, they are not able or willing to pay the real market price in case of greater number of competitors or an auction. Although this group of investors is not generally successful its activities also contribute to market price increase because they reduce the overall supply of agricultural land on the market.

The recent market situation is that in 2016 was the most common interval of agricultural land purchase (5.549; 9.248) EUR per hectare and that is (8.759; 14.598) EUR in PPP per hectare. Year to year average land price per hectare rose by 25.5% in CZK and 26,7% in EUR due to CZK appreciation. This rate of change is the highest one for the last fifteen years. The price in the fig. 1 do not include the real estate acquisition tax of 4% from the tax base which is the higher price of the purchase or appraisal one. Generally are the prices in the last year even higher by 4% because the tax burden was in 2016 moved to buyer.

Discussion

We managed to reject the hypothesis that the prices of two samples were from the same distribution. This means that the price development before and after 2014 are not the same. Since the trend is easy to identify it is natural that ranked based non-parametric test was negative. If the trend curve is used on the time series 2006-2013 it is less steep than trend curve that would be for years 2014-2016. The difference

in slope for prices calculated in EUR is as high as more than 300%. 2014 was the year of change but we are not able to distinguish whether the factor of easier and faster agricultural land purchase or high interest of non-agricultural investors in land purchase or the end of the economic crisis was the main cause. It is likely that it is a combination of these three factors and that one strengthened the other one. In the next years 2015 and 2016 were all these factors still present increasing the price up to 9.154 EUR per hectare and 14.450 EUR per hectare in PPP.

The fig. 1 shows significant price increase trend which became even greater in the last three years. Agricultural land market prices increased by almost 65% during the last three years. The trend of price increase doubled the level of market prices over a period of only 6 years (from 2010 to 2016). This made the agricultural land one of the highest yield investment with very low risk. However the market situation can change. Continuing demands of the Agrarian Chamber of the Czech Republic and the Agricultural Committee to establish the right of the first refusal for lessees as well may succeed in the future. However it is less probable that the rest of the demand, extend the right of the first refusal for farmers from the municipality where the land is being sold and for state as well, will succeed. This would be too strict market intervention and could be seen as infringement of common EU market. However, generally any further extension of the right of the first refusal would have an impact on price. The group of non-agricultural investors would have more limited access to land purchase which would reduce competition on the demand side. At the same time, all owners would lose the opportunity to offer their land to wide range of buyers and we are not considering the time factor. Although we do not expect any further changes soon because of the parliament elections in the October 2017. It is almost impossible to approve such changes before the elections and after the elections it always takes a few months before the ministries start working properly again due to a government negotiations.

Although further legal change is highly improbable we presume the present one will be enough to slow down the price increase. Re-introduction of the right of the first refusal was known from the spring of 2016. This stimulated both the demand and supply to make a deal before the new regulation will come into force. The re-introduction creates a problem of co-owned asset liquidity increasing mainly time needed for trade. Also asset consolidation will be more demanding task because the amendment of the NCC brought the right of the first refusal even in case of transfer between two co-owners. Due to these two mentioned factors in the paragraph we except lower amount of land traded in the next year.

The next events with an impact on the market will be the monetary policy of the Czech national bank. Since both groups agricultural and non-agricultural investors contain abroad companies the exchange rate interventions or appreciation of CZK would increase their costs on land acquisition making the investments lees profitable. The CZK continues its steady value increase against EUR and USD due to both transparent and well-managed end of an asymmetric foreign exchange commitment regime and moreover due to excellent performance which Czech economy shows during the last few years. With the lowest unemployment rate in the EU and stable GDP growth we expect CZK to appreciate even more during the next year up to the EUR/CZK 25.5. Another factor which could cool down the market we see again in the monetary with increase of the interest rate. Czech national bank recently increased key interest rate 2T REPO from 0.05% to 0.25%. In case of overcoming of the inflation target another increase is possible. This would certainly lead to increase of market interest rate on credit. This would not just only decrease the number of possible buyers but mainly it could increase installments of already provided credit at the end of their fixed interest period. It is possible that some debtors would not be able to pay the installments anymore and their land would be offered on the auction. All effects mentioned in this paragraph got effect on the slowdown of observed long-term price increase.

Conclusion

The agricultural land market development showed significant and steady trend of price increase in the last decade. The price increase was as significant as 350%. Average land market price went from 2.610 to

9.154 EUR per hectare. If the calculation takes into account PPP the amount are even higher: from 4.243 to 14.450 EUR in PPP per hectare. The market changed significantly in the year 2014 and the price increase trend is steeper than before. Our hypothesis that the development before and after the year 2014 was rejected. The main factors of change in 2014 were legal aspects, demand from the side of non-agricultural investors and the end of economic crisis.

The legal aspects allowed landowners on co-ownership to sell their share to much wider range of buyers. The fact that they could reach more buyers without the obstacle in form the right of the first refusal increased the competition and resulted in price increase. The remaining factors had also price increase effect. Increased number and purchase power of non-agricultural investors (long and medium-term ones) became greater than the numbers of agricultural investors. High yield carrying only low risk was the main feature that brought the attention of investors on the agricultural land market. The end of crisis removed not just pessimistic expectations but mainly increased the agricultural business turnover and yield motivating and allowing farmers to invest in a new land acquisition. Although the price rise continued in 2015 and 2016 the share of non-agricultural investors dropped by almost 10% as the costs of land acquisition became higher decreasing an investment yield.

We do not expect strong price rise to continue on the contrary we expect certain market cool down. The factors are mainly legal and macroeconomic ones. The legal factor concerns the novelization of the NCC which re-introduces general right of the first refusal. The amendment of the NCC comes into force at the beginning of 2018. There are only very specific exceptions from right of the first refusal (transfer to close person) which means that agricultural land for purchase will reach narrower range of potential buyers or it will take more time. CZK appreciation against both EUR and USD will increase the costs of an investment for foreign investors that are part of both agricultural and non-agricultural group. Key interest rate increase will increase the costs of credit limiting the demand for agricultural land purchase.

Customer Service Standards In Authorized Dealer Stores - Blueprinting Technique

Associate Professor Katarzyna Hys, Opole University of Technology, Opole, Poland
k.hys@po.opole.pl

Abstract

Purpose – analysis of the customer service standards applied in stores of authorised dealers of passenger cars from Ford, development of the blueprinting map for the process. **Design/methodology/approach –** The process of customer service in authorised car dealer stores was studied using the mystery shopping method in 21 authorised dealer stores in the period of X-XII 2016 in Voivodship, i.e. Opolskie, Dolnośląskie, Śląskie. The obtained results were elaborated on and the results of the analysis were used to develop the blueprinting map in the scope of the customer service standard in accordance with the methodology described by L Shostack. **Findings –** The key findings concern the identification as well as cause and effect arrangement of the customer service process elements, development of the executed activities with division to service provider and customer. **Research limitations/implications –** The sample size was restricted to 21 authorised car dealers located in 3 Voivodships of southern Poland. This might limit generalizability. **Practical implications** – The study provides managers with insight on the potential opportunities and weaknesses related to customer service. **Originality/value –** Research of the customer service standards in the authorised car dealer market is a relatively new area of study. Majority of the studies on this topic concern other aspects, i.e. economic, technical, amongst others. The purpose of the article is to specify the required customer service standards to be targeted by the managers and towards which their strategies should evolve.

Keywords: blueprinting, buyer-seller relationships, customer service standards, process design service.

Introduction

In economic terms, the improvement of humankind's well-being worldwide is reflected, amongst others, in the formation and development of the services sector. An analysis of the subject structure of the Polish economy demonstrated that 76.8% of the companies registered in the REGON[1] system is comprised of companies from the services sector. Simultaneously, the contribution of the services sector in the growth of the gross value added and GDP amounts currently to 63.8% (Poland 2015 Report). It is estimated that the sector employs every other Pole of working age. It is therefore possible to state that the services sector is a key component of the Polish economy. Hence, the structure of the Polish economy draws near to the composition of OECD states, in which the average share of the services sector in the growth of the gross value added and GDP amounts to 70% (others include industry and agriculture).

Due to the above, it is justified to conduct scientific analyses in the scope of the services sector. The service activity is developing dynamically and the decision-makers expect solution proposals that will support effective decision-making in the economic sense. This paper will be focused on the issue of customer service standards based on the example of authorised passenger car dealers (Johri and Petison, 2008; Jung-Wan and Tai, 2009; Grosse, 2016).

[1] The register REGON fulfils the function of the national Register of National Economy Entities in Poland.

Literature Review

The review of literature on the paper's topic will consider, amongst other, the following aspects: term and attributes of service, customer service standards and the blueprinting method - enabling the service visualisation process.

The "product" as an economic category has a very broad meaning, however it does not always mean the same. When making the division of market offers based on the share of (in)tangible value, L. Shostack has defined "the product tangibility spectrum" (Shostack,1977). This means that the products are a combination of tangible and intangible attributes. Similarly, Ph. Kotler noticed a lack of precision in the product specification and proposed the concept of "product-service continuum". Depending on the content of (in)tangible features, the market includes the following groups of products: classic tangible good, the so-called clean product, product with associated services – it is a mixed offer, in which the most important role is played by a hybrid product, i.e. offer consisting of an equal share of (in)tangible elements, service with associated products and lesser services, classic service, the so-called clean service (Kotler and Keller, 2012).

The "continuum" and "spectrum" theories indicate the existence of a continuity between the product and service (Figure 1).

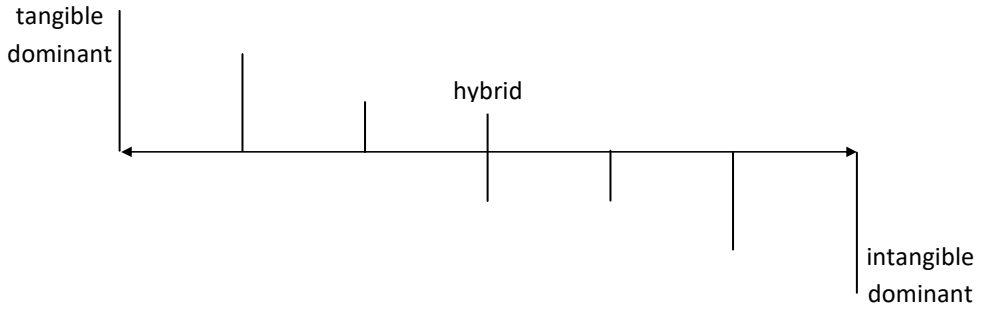

Fig. 1: The product (in)tangibility spectrum/ the product-service continuum

In practice, this means that the product-services boundaries are fluid and depend on the degree of dominance of the (in)tangible features. This paper will focus on the group of service with associated products and lesser services (Phongpetra and Johri, 2011).

In the subject literature, services are defined, amongst other, as follows: activity, benefit, activities, or actions taken by service providers for the benefit of the customers to provide them with specific benefits and/or meet their needs (Groonross, 1994; Parasuraman *et al.*, 1991; Kotler and Keller, 2012; Alam, 2013; Hys, 2016). In contrast to ready-to-use tangible products - services require special attention to their specificity. Aside from such attributes, as: heterogeneity, inseparability and instability, the primary feature of services is their intangibility.

The intangibility of services means that they cannot be seen, tasted, felt or heard prior to purchase (Hill, 1999; Bowen and Ford, 2002). The customer purchases a certain process which is a result of the service provider's knowledge, experience and competencies. On the other hand, the service provider present a ready-to-use service or measure the level of customer satisfaction prior to its provision (Parasuraman *et al.*, 1985; Oliver, 1993). When providing the service, the service provider relies only on arrangements

with the customer. The more accurate they are, the higher the level of customer satisfaction after the service is provided (and vice versa).

Heterogeneity means that the service can be perceived by service providers and customers in various ways. This dependency was defined and described in the gap model (Parasuraman *et al.*, 1985). When broadening the researchers' interpretation of services, it is possible to notice that depending on the adopted customer segmentation criteria (geographic, demographic, psychographic, or concerning their behaviours, amongst others), the expectations and perception of customers and service providers can differ. Factors, amongst others, such as: place of residence, traditions, customs, religion, level of innovation, Internet access, wealth of the given society (and other) affect the customer's knowledge and experience, hence his expectations and perception of the service. Similar dependency exists in the case of the service provider. Depending on the type of customers identified in the segmentation process, services can be provided by employees with various competencies and at the level of various service provision standards (Jung-Wan and Tai, 2009). This process features the asymmetry of information, which means the existence of differences in the level of information concerning the service in possession of both parties in the market transaction. The service provider usually has more information about the service offered by him in the market than the customer. Furthermore, the highly diversified nature of services results from the heterogeneity of particular service products. Due to its nature, the exact same service is never created twice. The emotional state and psycho-physical disposition of the service provider and customer differ at the time of service provision/consumption every time, hence the service itself is always different. This reveals the problem of lack of possibility of standardising the service provision process (Khmel'nyts'ka and Swift, 2010; Macintyre *et al.,* 2011). On the other hand, inseparability means the simultaneity of service provision and consumption - in practice, this means that the service provision process features simultaneous participation of the service provider and customer. The service product may not exist outside the process of its provision and consumption may take place during the time of its provision.

The last feature mentioned is instability, i.e. fleetingness of services. This feature evokes most controversy among researchers. They are raising the issue of lack of possibility to warehouse the services or stocking them. Despite the fact that services (in the sense of intangible values) cannot be stored, moved in space and time or stocked strictly speaking, all of these activities can be executed with the so-called service effect or outcome (Gadrey, 2000; Hys, 2016).

Knowledge concerning the term and attributes of a service is essential for making effective managerial decisions. The primary purpose of each market transaction is the effective exchange of the service for other value (usually expressed in payment units). The service provider aims at meeting the customer's expectations, and the customer seeks a service provider who is able to meet his expectations. However, in the service process, the service provider and customer make decisions taking into consideration, aside from the service costs/price, the customer service standards.

Customer service standards are defined as an organisation's ability to meet the needs and desires of its customers. When aiming at gaining the long-term loyalty of the customers, the decision-makers should design the customer service standards. These standards should especially be adapted to the changing social and cultural, technical and technological as well as economic conditions of the customer (Li *et al.,* 2001, Hoecht and Trott, 2014). The purpose of designing a service is to obtain the optimal level of customer satisfaction with the provided service. In countries in which customers become increasingly wealthy, their expectations and requirements in terms of service standards also increase (Parasuraman *et al.*, 1991). S.M. Walton summarised the market situation in the credo of his company as follows:

> There is only one boss, and whether a person shines shoes for a living or heads up the biggest corporation in the world, the boss remains the same. It is the customer! The customer is the person who pays everyone's salary and who decides whether a business is

> going to succeed or fail. In fact, the customer can fire everybody in the company from the chairman on down, and he can do it simply by spending his money somewhere else.
>
> Credo from Sam Walton the owner and CEO of Wal-Mart – an international chain of department stores and the most successful company in retailing in the world.

Due to the above, the cycle of developing the customer service standards is executed using the following activities:

1. Analysis of the needs and preferences of current and potential customers.
2. Development of the customer service standards.
3. Development and exercise of the work standards by employees in the following scope: company value, aims, operating tasks and roles, effect assessment methods, activities preventing the loss of customers.
4. Provision of services meeting the service standards.

Blueprinting is a tool intended for supporting the service designing process. Blueprinting is a tool used to record the entire service provision process in a graphic form. The visualisation of the service process according to a specific methodology allows to increase employee awareness in the scope of the executed work. A correctly designed service using a blueprinting map allows the decision-makers to identify areas that do not meet the identified customer needs. By adapting these areas to customer requirements, it is possible to significantly affect the perceived service standards. It is recommended to use blueprinting in the modelling of the service process' components (Shostack,1977; Randall, 1993).

In the other words, blueprinting is an optical process recording that presents an image of communication between the exchanging parties. Shostack's arguments were accepted by scientists and a lot of analysts demonstrated the advantages of this method. In the subject literature, the positive contribution of blueprinting is being raised for: internal marketing, service development process, parking behavior, monitoring of the customer preferences, services innovation, services efficiency, process effectiveness, business processes and first of all for management and control of already existing customer service processes. The use of blueprinting known from the literature regards to specific services such as for example: non-profit, pro-health education, industry or the hotel industry (Hys *et al.*, 2014; Li, 2014).

Research Methodology

This study is exploratory and descriptive, and uses the case study strategy (Linker, 2004; Gibbert *et al.*, 2008). For the purpose of this study, it was decided to use the case study strategy and the qualitative data concerning the strengths of this approach with respect to the study's aims (Sroka, 2012; Guillen and Garcia-Canal, 2012; Grosse, 2015; Thomé et al., 2016). The techniques guaranteeing the quality of this research, identified by Yanow and Schwartz-Shea (2015) and detailed in Table I, were carefully observed to avoid the potential threats to the inherent quality of this approach.

The study was conducted in eight stages specified in Table I and included 21 authorised Ford dealer stores in the period between X-XII 2016 in 3 Polish Voivodships, i.e. Opolskie, Dolnośląskie, Śląskie.

Table 1: Research steps

First Stage	Literature studies	Identification of the state of knowledge in the subject literature. Searching for research gaps and prerequisites for conducting studies.
Second Stage	Research design	Review of the relevant literature and its analysis embracing domestic and foreign references, and Internet sources. Specification of the aim and scope of research. Aim - answering the question: What is the customer service standard in the authorised Ford dealer stores in Poland? Scope: substantive - development of a visualisation of the customer service standard in the authorised Ford dealer store in Poland. geographic - 21 stores in the Opolskie, Dolnośląskie and Śląskie Voivodships.
Third Stage	Research strategy	Analysis of the Ford brand dealer market in Poland. Selection of entities for study execution: Opolskie (3 stores), Dolnośląskie (5 stores), Śląskie (13 stores).
Fourth Stage	Study	Study using the mystery shopping method and observation. Scenario: purchase of a new Ford Focus car.
Fifth Stage	Data collection	Recording of observation results and filling out the mystery shopping form.
Sixth Stage	Data analysis	Analysis of the obtained data and reconstructing the actions taken by the service providers and customers. Development of the blueprinting map for the customer service standards in authorised Ford dealer stores using the L. Shostack methodology.
Seventh Stage	Findings	Drawing conclusions and specification of the study's limits.
Eighth Stage	Future research/ limitations	Developing future research paths and questions.

The obtained results were elaborated on and the results of the analysis were used to develop the blueprinting map in the scope of the customer service standard. Based on the obtained study results, the visualisation of the customer service process was developed in accordance with the methodology described by L. Shostack. The blueprinting map was divided into five topical parts: physical evidence,

customer activities, frontline employee activities, backline employee activities and the support process. These parts were further divided as follows: material aspects, interactions between the customer and frontline employees, visibility – area of interaction between frontline and backline personnel, and internal interaction, showing the relations of the backline personnel and the persons executing works aimed at supporting the entire working organisation (Figure 2).

The blueprinting map was developed for the authorised car dealer following the stages provided below (Zeithaml *et al.,* 2006; Sirikrai and Tang, 2006):

- Specification of primary events and typical sequences (flowchart).
- Modelling the customer service process from the customer's point of view.
- Modelling the activities of the frontline and backline employees, as well as the material aspects.
- Establishment of direct and indirect communication connections.

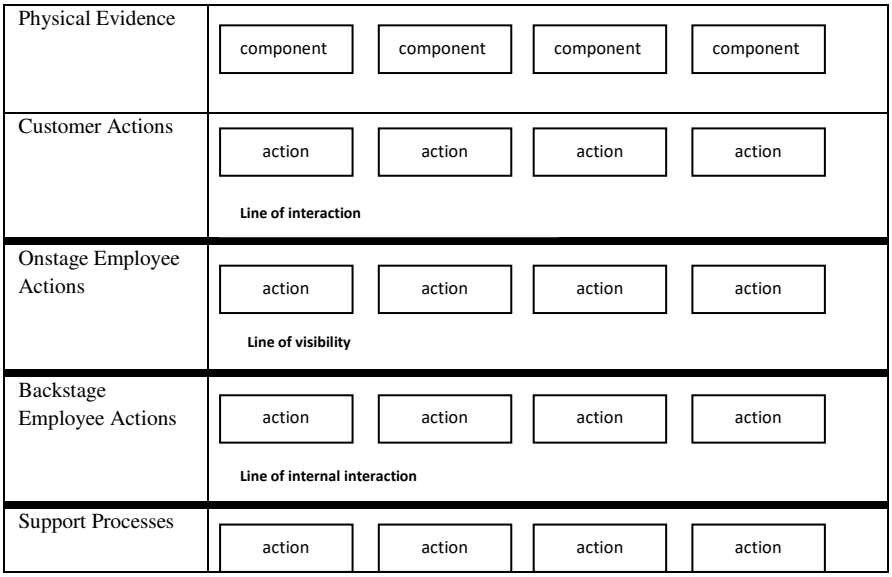

Fig. 2: The blueprinting map

Findings and Discussions

In general, according to the data analysed by the Harvard Business School, researchers demonstrated the following customer focuses: taste (1%), touch (1.5%), smell (3.5%), hearing (11%) and vision (83%) (Wen, 2015; Stolovitch and Keeps, 2002). This information is especially important for the service designing process. It puts the decision-makers' attention on the key aspects of the service, thus allowing the determination of priorities in this process. The first contact of the customer with the service provider can take place via various channels. Contact is usually established via the dealer's website, a telephone conversation or by directly visiting the store of the authorised Ford dealer.

The study conducted at the authorised Ford dealer would allow identifying the key elements for the level of physical evidence. These elements were grouped into five key topical groups. These include: online visits/telephone contact, convenience/accessibility, employees, additional customer services and interior design. Specific elements were identified as part of these groups. If the given reality is evaluated by the service provider at the degree of 83%, the designing of all aspects of "physical evidence" should be

executed with due diligence of the decision-makers. The evaluation of the appearance of the store and its employees performed by potential customers affects their latter purchase decisions. The decision-makers are aware of the above fact. Thus, services are designed in a manner that ensures that the customers' rating for the identified elements of "physical evidence" is a high as possible.

The material aspects of the service design determine only the external image of an authorised car dealer. These aspects are evaluated by customers, but the main point of car selling is the process of customer service, including direct contact with employees. The actions taken by the frontline employees of an authorised car dealer constitute a mirror image of the customer's actions. This means that the customer executes specific actions that are matched by designed reactions of employees. The activities executed by the customers and store employees were divided into three stages: first contact: service provider-customer, visit to the Ford dealer store, using other service points in the store and, additionally, the support processes for all activities in the store were determined (Table 2).

Table 2: Area of customer's and service provider's responsibility

AREA OF CUSTOMER'S RESPONSIBILITY		**AREA OF SERVICE PROVIDER'S RESPONSIBILITY**		
No.	**Activities taken by** the customer	**No.**	**Reactions of/ activities taken by** the employees	**Type of employee:** Frontline (F), Backline (B), Support (S)
STAGE 1. First contact: service provider-customer				
1	Analysis of information about the dealer and his products/services specified on the website	1	Regular updates of information on the dealer's website.	B, S
2	Contact with the service provider via an online form, telephone and other forms of communication	2	Professional management of communications with the customer.	F, B, S
STAGE 2. Visit in the Ford dealer store				
3	Personal visit of the customer in the store: greeting, initial conversation with the employee	3	Customer reception: greeting, identification of needs and preferences, creation of needs	F
4	Contact with the employee, evaluation of the customer service standards, including:	4	Contact with the customer - presentation of the offer, including:	F
4 A	Evaluation of the employee's appearance, including, amongst others, the following: outside appearance, clothing, tidiness, jewellery and other attributes	4A	Evaluation of the customer's potential via analysis and assessment of his or her appearance and obtained information, including, amongst other, the following: appearance, clothing, jewellery and other attributes	F
4 B	Evaluation of the method of having a conversation (the ability to articulate own needs, focusing on the customer, commitment)	4B	Ability to have a conversation with the customer - ability to obtain information from the customer concerning his or her needs, appealing presentation of the car, providing substantive	F

			information about the car	
4 C	Evaluation of the employee's interpersonal features, such as: communicativeness, personal culture, ability to inspire trust	4C	Building relations with the customer - invitation to the service office to have a conversation about the offer's details, presentation of information and advertisement materials, proposing a beverage	F
4 D	Review and determination of the conditions of the preliminary car purchase offer	4D	Review of the conditions and preparation of the car sale agreement	F
5	Recording of the time of next visit/car collection Manner of saying goodbye	5	Determining the time of next visit/car collection Manner of saying goodbye	F
STAGE 3. Using other service points in the store				
6	Other agreement conditions:	6	Other agreement conditions:	F, B, S
	review of the conditions of agreement with the consultants in terms of the financial/credit/lease and insurance service			
7	Using other service points available at the store:	7	Serving the customer in terms of using other service points available in the store:	F, B, S
	including, amongst other, the following: technical support, spare parts sales point, gastronomic point, company souvenir and gadgets sale point			
Support processes				
8	Updating the drafts of documents according to the headquarters' guidelines in terms of the agreement conditions and other formalities			B
9	Vehicle exhibition: maintaining the cleanliness of rooms, cars Service standards and infrastructure in other service points: technical support, spare parts, gastronomy, company gadgets sale point			B, S
10	Advertisement, operation and office materials: designing, delivery, updating			B, S
11	Feedback - introduction of changes as result of recommendations, reported demands (redefining the offer, customer service standards)			F, B

It is necessary to be aware that the preparation of a sale consists of many stages. The customer sees the finished product in its original packaging in the store. However, customer service is a multi-dimensional process and consists of many tangible and intangible elements. The results of the conducted studies and observations was elaborated on in the form of a map illustrating the customer service process in the authorised Ford dealer stores (Figure 3).

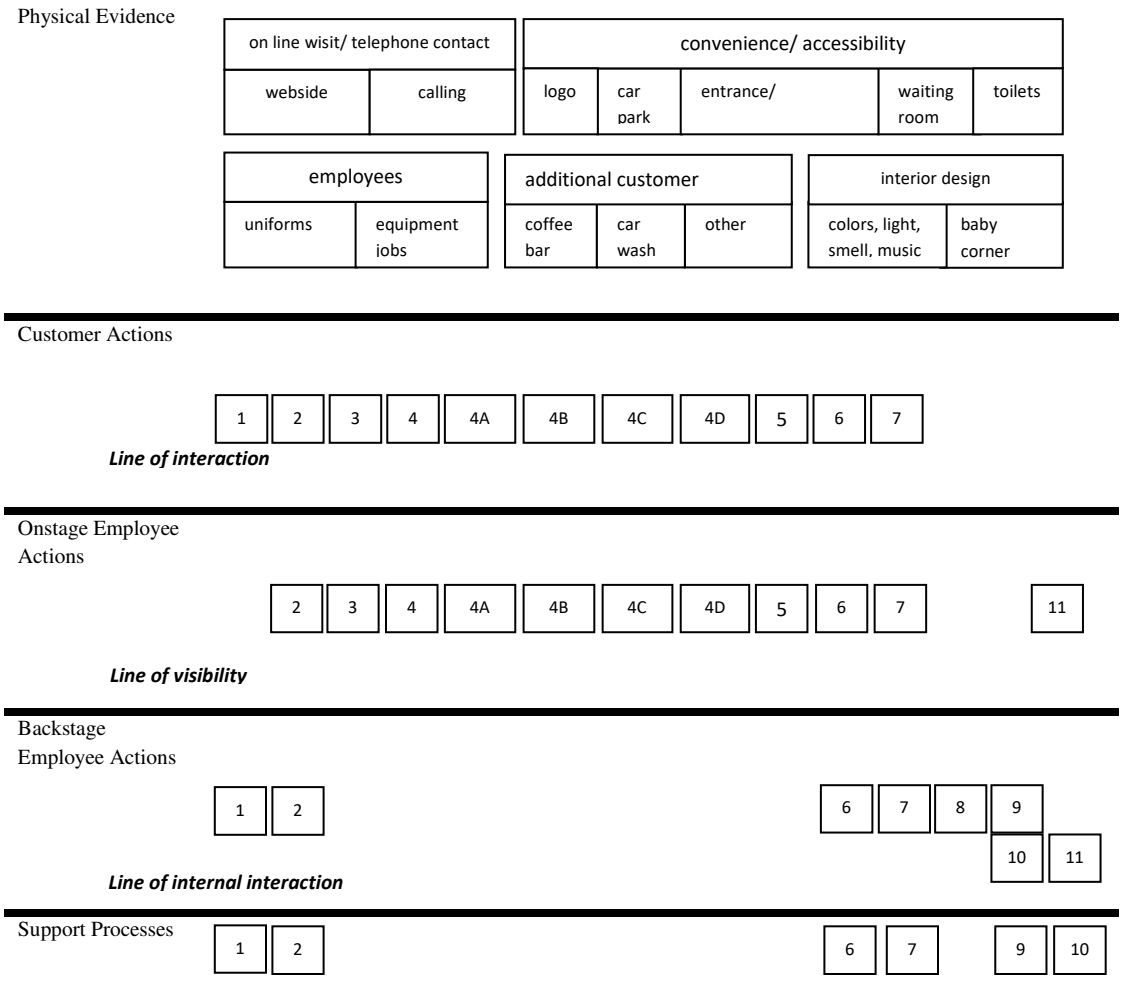

Fig. 3: Blueprint map for authorized Ford dealer stores

Its purpose is to affect the customer's decision on buying a car. All tangible and intangible properties, which constitute parts of an image, are previously arranged and organised by the managerial and support staff. The employees are properly motivated, and the effects of their work are subject to monitoring and assessment. The result of the interactions are amending and preventive activities, which are aimed at working out of the best customer service standards. Related activities are not directly visible to the customer. This is the reason they are situated beyond visibility - in practice, it means that they are not directly available to a customer. Customers use the results of work of many people without even getting to know them.

However, it would be impossible to meet the customer service standards without these activities. These required activities are executed by the backline employees at the strategic, tactical and operational level. In order to ensure the effectiveness and efficiency of the delivery, it is essential to prepare a professional sales offer. In practice, it means using all of the store's attributes to delay and/or eliminate the competition.

The customer deems the lines of interaction and visibility as most important. These lines determine the zones of service process, in which the client directly participates in and assesses the results of any management and operational activities taken at all company levels, including the material aspects, which are assessed by the results of the organisation's activity support procedures. When the customer visits the car store, he or she assesses all available elements, including the material aspects of its surroundings. The materials aspects are all attributes available for the company and used in everyday work. These elements constitutes parts of the company's organisational culture (Randall, 1993; Adkisson, 2014). The material aspects also enable creating the image of the organisation, which is important from the customer's point of view, especially in comparison to the competition. The components of an authorised car dealer surroundings include tangible and intangible aspects. These aspects constitute the customer service standards, on the one hand, and on the other hand, they are evaluated by the customer and affects his or her shopping decisions.

The visualisation of each stage and activity executed by the customers themselves or with the assistance of a customer service representative constitutes the basis for modelling the blueprinting map. The main aim of this modelling is communication, analysis and control of the executed activities (Coderre et al., 2009). All of the above elements contribute to continuous improvement. Each meeting with the customer is different due to the nature of the services. It is however possible to plan the most essential element of the service process – each subsequent service element is to be provided by employees who are expected to behave in a professional manner []. The blueprinting map visually demonstrates the sequence of events in a two-dimensional system. It is necessary to note that the activities taken by the customers are essential for the mapping, because they determine the entire mapping system. The horizontal axis presents the chronological schedule of activities taken by the costumer and employees. The vertical axis constitutes the second dimension of the analysis. This means that it categorises the activities based on their type and role in the service process. Two groups are visible here: customers - in the role of potential buyers, the employees - in the role of first contact persons, and the support of activities implemented in the entire process. The division of particular groups of stakeholders is additionally marked by the lines isolating each zone of influence. The following lines are considered: interaction, visibility and internal connections (Shostack, 1987). They correspond to the following relations respectively: customer and frontline employee, frontline employee and backline employee, as well as backline employee and other employees.

The blueprinting map illustrates one more element, i.e. the service's tangible properties (Zeithaml *et al.,* 2006). The customer evaluates the service's tangible elements during the entire service process. Despite the fact that the customer is not always aware of this evaluation, it affects his or her perception of the service. All of these components create the blueprinting map, which consists of lines and sequences of the activities of the process participants who establish interactions between each other. The conducted studies allowed answering the following research question: What is the customer service standard in the authorised Ford dealer stores in Poland? Conducting the study in 21 stores allows developing a universal blueprinting map, thereby specifying the existing customer service standards applied in the authorised Ford dealer stores.

Conclusions

Despite the dominant role of services in modern economies, and their rapid growth worldwide, the small quantity of research, number of methods and techniques addressing the unique market challenges is surprising.

Blueprinting is a useful tool which allows designing the customer service process with special consideration of the customer's point of view. The visualisation of the service process provides information concerning the purposefulness, logicality and effectiveness of the activities executed in the customer service process. The blueprinting map subject to an in-depth analysis of professionals from various departments of the given company can be the basis for developing optimal customer service solutions. The skilful use of the opinions of experts, analysis of the adaptive capabilities of the service organisation to the specified needs can substantially affect the customers' evaluation.

My hope is that by capturing what is already known about blueprinting and sharing our experiences and relevant case studies, I will be able to inspire a broader adoption of this technique and its creative extensions to further enhance its value to service managers and researchers from various fields.

Limitations and Future Research Directions

The primary limit of the study is the number of authorised Ford dealer stores in which it was conducted. There is 125 stores in Poland and the study was conducted on 21 of them. This fact simultaneously constitutes the basis for determining the direction of further research. The study should be conducted for all other stores and the obtained results should be compared to the existing ones. Such broadening of the research would allow conducting complete studies and would constitute the basis for executing further research purposes.

Abstract

The area of motivation reward and perception of employees toward the motivation effects area is unknown area yet. The motivational factors choose for research are: organizational climate, industrial relationships, leadership style, financial rewards, promotion conditions and personal needs. In this paper we presented the statistical analysis of clusters using Ward's method to identify the motivation. The correlations between motivational factors and the hierarchical cluster analysis were realized using Ward's method. The statistical instrument used were the survey to identify the factors which influence the motivational attitude and perception of staff to the motivational potential of managers. This article also present and analyzed the proximity matrix, for that reason it was calculated the optimal number of cluster grouping the 24 motivational factors that cover the motivational factors which permit to group theme into clusters. Each cluster allowed the identification of maximum and minimum motivation influence on the staff level. The proposed analysis of motivational factors according to their influence on the degree of motivation can be used in every company and served as a positive effect for improving the human resources relationship. Also the analysis can be used as a potential instrument used to develop and implement like a program to correct the motivational factors found in the clusters and identify comprising factors with minimal influence on the degree of motivation of human resources.

Keywords: cluster, factor, influence, motivation, dendogram, analysis

Introduction

There have been many theories developed by researchers surrounding the area of motivation.
Armstrong & Stephens (2005) design a typical motivation model or process and establish that is comprised of four parts or steps, these being needs, establish goals, taking action and attending goals (Figure 1).
Motivation is usually brought about by the acknowledgement of unsatisfied needs, that's why according to Armstrong (2012, p.182) there are two types of motivation.
These are intrinsic and extrinsic motivation. According to Ryan & Deci (2000, p. 57-60) intrinsic motivation can be viewed as carrying out an activity for the satisfaction that derives from doing such an activity and job done rather than the rewards offered for doing it.
While extrinsic motivation develops from the connection between carrying out an activity with the aim of attaining a distinguishable outcome.

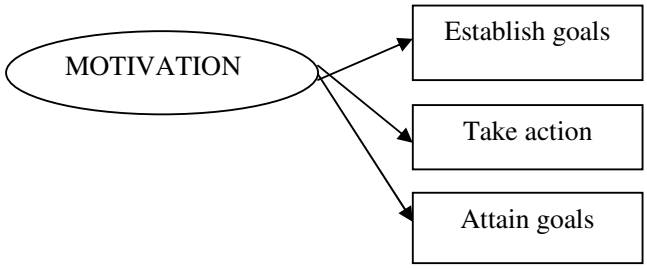

Fig.1: Motivation process

Source: Adapted after Armstrong & Stephens, 2005, p.70.

Flynn (2013) in his research about an exploratory analysis of the role of motivation within the workplace observed that in order for motivation to be effective, it is necessary for the organization to call on motivations from all five categories.

Of course, formal motivations will register the most frequent and intense usage, being established by the organization's strategy and policies and for which certain managerial and economic methods and techniques are addressed.

The motivational potential of informal motivations should not be underestimated, especially those moral and spiritual. For the latter, there is a greater sensitivity to most employees, presenting the great advantage that they have no financial cost or very little, indirectly. Regarding informal economic motivations, their use is recommended to be approached with great care, under strict observance of laws and morals of society in each country.

Appealing to codes and protocol dinners are relatively common ways practiced by companies in developed countries, obviously subordinated to clearly defined objectives and under certain conditions, according to the pre-established regulations and procedures.

The range of motivations used in modern organizations is particularly comprehensive and varied. To facilitate the perception and their usage, the general picture of motivations which can be used in companies, is structured in multiple categories and it is presented in Figure 2 (Nicolescu, 2008, p.304).

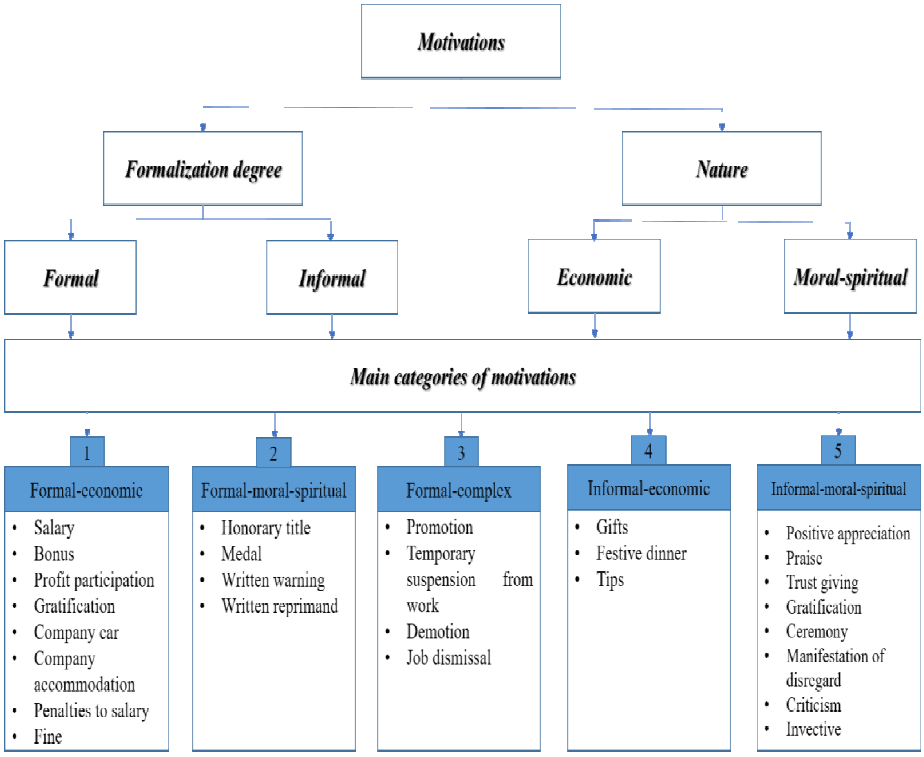

Fig. 2: Types of motivations

Source: Nicolescu, 2008, p.304

Instead, tips should be avoided as they distort the system of values, attitudes and behaviors of employees, with considerable negative impact on organizational culture, functionality and firm's performance. (Nicolescu, 2008, p.303)

Motivations design those elements, formal and informal, economic or moral-spiritual that owners and managers utilize towards employees, satisfying their specific individual and group needs in order to determine through their attitudes, efforts, decisions, actions and their behavior to contribute to the accomplishment of the activities of the organization and to the fulfillment the objectives of the organization.
According to Beardwell & Claydon (2007, p. 496) and Fully"(2013), there are three main factors that individuals may deliberate on when choosing the level of effort to put into work behavior:

1. ***Valence:*** The level that the anticipated outcome is attractive or otherwise.
2. ***Instrumentality:*** The belief that a certain level of performance will result in attaining coveted rewards.
3. ***Expectancy:*** The scale in which an individual believes that a certain level of effort will lead to a certain level of satisfactory performance, will that level of effort

Stephen Flynn (2011, p.12) created a direct link between motivations and maturity levels within the organization.

1. The first one relates to the compliance management which relies almost entirely on extrinsic motivations, money being the main motivator, capable of solving the problems of workers.
2. For the second maturity level, process management, money is still present along with the generation of goals with external influence, hygiene factors (sense of security), perception of equity (horizontally and vertically), encouraging supervision of employees.

3. Regarding the third level, this refers to the capability management, in which all the motivations presented before are also available at this level, along with the presence of clear opportunities for career that provides the possibility of achieving a social position that is valued within the organization.

Also, due to the job enlargement, the tasks are more varied and the use of Key Performance Indicators for measuring performance also enhances the employees' goals regarding their professional development. The last maturity level, strategic management, encompasses all motivations found at lower levels along with intrinsic motivations that encourage individual control and the perception of equity at horizontal, vertical and personal level.

2. Case Study

The study take in consideration the motivation of employees, staff and human relationship between employees and managers.

A total number of 100 employees from Eaton Production Company an economical agent from Maramures County was the target of our research. Another element taking in consideration was the top position of company in Maramures market because it is a successful company and a model from quality point of view.

The instrument used in research activities was the survey.

The survey was structured in 24 questions with possibility select an option using a Likert scale from 1(not agreed) to 5 (strongly agreed). Each question was created to identify the motivational factors and their impact upon the employees.

Because motivation it is a complex phenomenon we can include here many factors of influences which require attention. As literature review show, there are numerous theories develop on motivation and how employees are motivated, however for this research on the simplest way we ask employees what motivates them.

Taking in consideration Nicolescu (2008) and Flynn (2013) classification of motivation, for our study we select the following factors for employees: OC= organizational climate, IR=industrial relationships, LS= leadership style, FR=financial rewards, PC=promotion conditions and PN= personal needs (Figure 3).

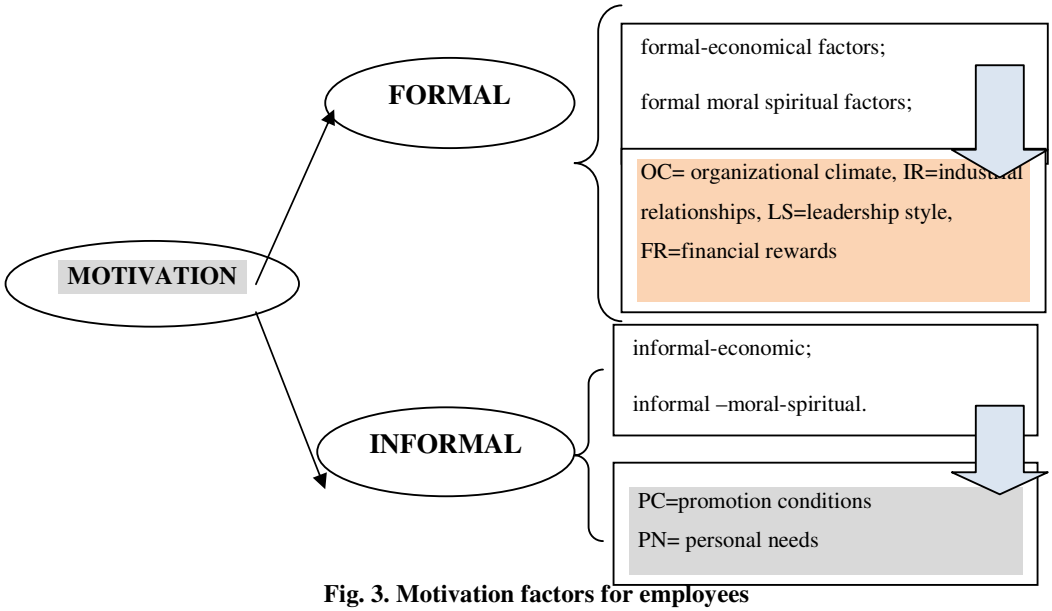

Fig. 3. Motivation factors for employees

Source: By authors

Method of Research

To be able to realize an analysis it was used the SPSS program database that includes the results of questionnaires of 100 employees for the six groups of motivational factors, formal motivation OC, IR, LS and FR and informal motivation factors PC and PN.
For statistical analysis of clusters, it was used the Ward's method in SPSS, in order to examine similarities between motivational factors, in order to group them as clusters with elements as similar as possible within the same class and as different as possible between them if these elements belong to different classes.
Subsequently, it was examined the validity of the results of the questionnaire, it was presented the proximity matrix comprising the Euclidean distances and there were identified the minimum distances with a view to grouping the motivational factors in clusters.

Results

3.1. Hierarchical cluster analysis through Ward's method

It was computed the Ward distance between clusters that comprise motivational factors, which aims to compute the cumulative intra-cluster variability.
Following, the merger of two clusters will seek to obtain the maximum homogeneity at the level of clusters identified for grouping the motivational factors.
The ranking of motivational factors based on the sum of scores given for each motivational factor from the questionnaire present that the first motivational factor ranked is PN2 (personal needs).
As we can observed the safety as a motivation factor it is the most important factor for employees in 85% percent with a score of 5 and for 13% percent with a score of 4 from maximum 5 (Figure 4).

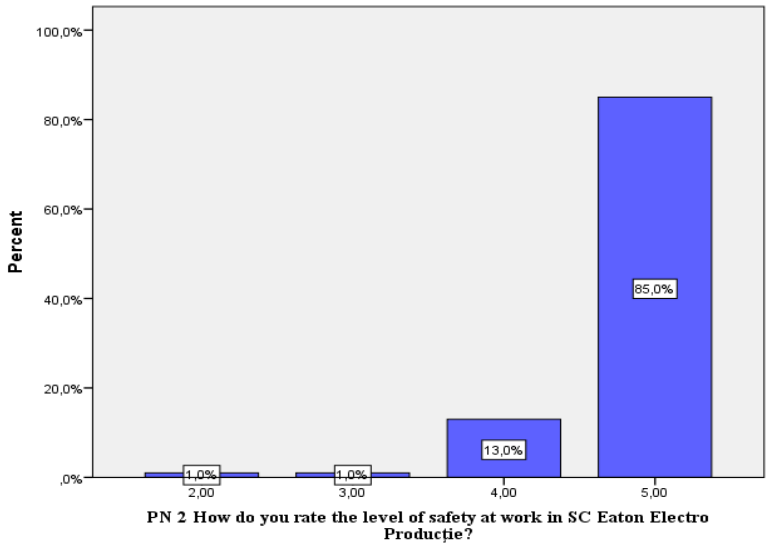

Fig. 4 : The employees perception upon safety as motivation factor

Personal needs as safety needs is the most important motivational factor, while the factor with the lowest score is OC3 (organization climate).

The Proximity Matrix, which is a symmetrical matrix that contains the Euclidian distances for all 24 motivational factors it is presented in Table 2.

Table 2: Proximity Matrix

Euclidian distance: $d = \sqrt{\sum_{i=1}^{v}(p_{1i} - p_{2i})^2}$

Regarding the number of training programs for employees are valid in a proportion of 100%. For employees with a 65% percent the training programs are score with 4 and 21 % percent from employees gives a score of 3 from maximum 5 (Figure 5).

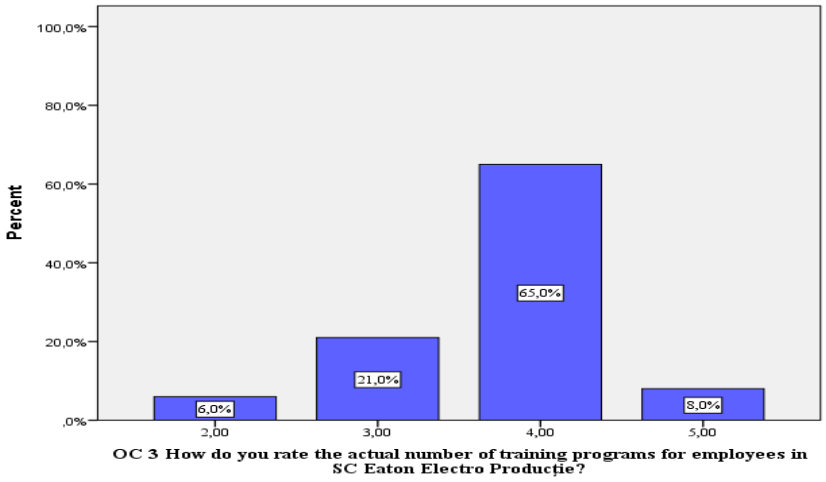

Fig. 5: The employee's perception upon training as motivation factor

Figure 6 present a 57% percent from respondents considered reward package very important with a score of 5, they consider motivation from financial point of view, different bonus for encouragement in traveling tickets or weekend treatment ticket as sign of appreciation for their work. Euclidian distance between ''How do you access the financial reward package in your company ?'' and ''How do you rate the coerciveness of the establishment of job hierarchy within your department ?'' has the greater value 4,796.

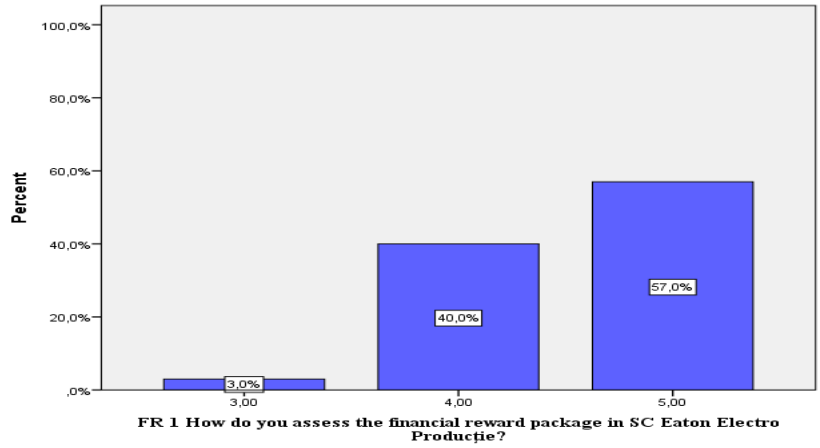

Fig. 6: The employee's perception upon reward package as motivation factor

We can observed that the minimum distance d=4,796 is found between motivation factor variable 13= FR1 (financial reward package) and PC4 (variable 20- correctness of the establishment of jobs hierarchy). Because 99% percent from employees give a score between 4 and 5 to the correctness in job hierarchy, we can consider that the department of human resources applies a good strategy (Figure 7).

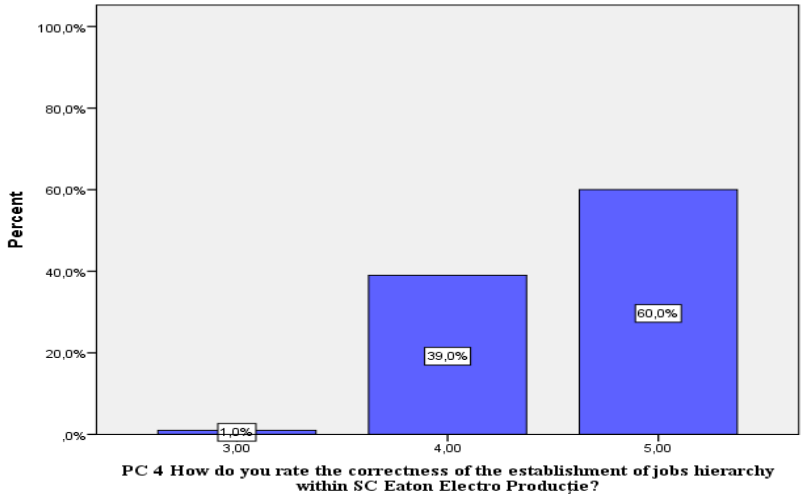

Fig.7: The employee's perception upon correctness job hierarchy as motivation factor

These variables form the closest pair and they will be the first to be joined, as it can be seen in the Dendogram (Figure 8), as well as in the Agglomeration Schedule.

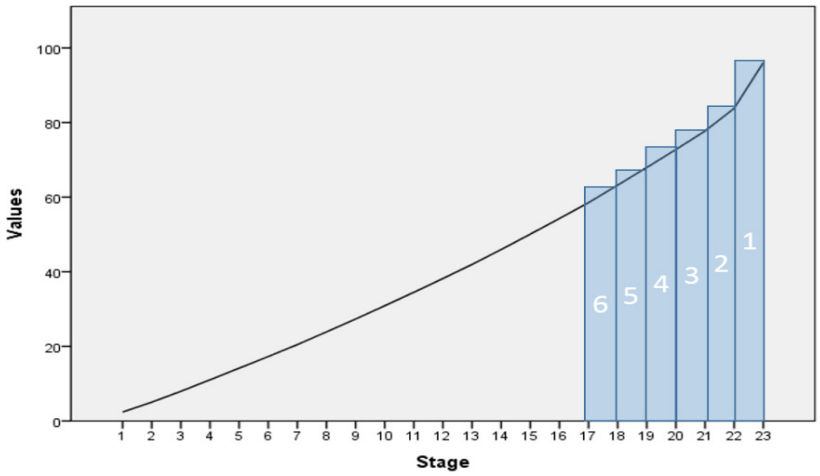

Fig. 8: The degree of change in agglomeration coefficients

In order to validate the hierarchical cluster analysis and to determine the appropriate number of clusters, we can observe the degree of change of coefficients in the agglomeration schedule.

Thus, Figure 8 indicates that cluster 1 would mean perfect heterogeneity, as it can be seen a higher change in the value of coefficients.

Two distinct clusters also represent a heterogeneous solution, but often 2 clusters may not be the ideal and meaningful solution, as it can be seen that the degree of change in coefficients is constant. Thus, due the fact that 24 motivational factors were involved, the optimal number of clusters chosen for our analysis it is 6. Table 3 presents the Agglomeration Schedule in which the coefficients represent the Ward's linkage coefficients that are calculated in respect to the cluster and not to motivational factors, this is why they differ from the distances in proximity matrix. They represent the amount of heterogeneity that we observe between the 6 clusters.

Table 3: Agglomeration Schedule

Stage	Cluster Combined		Coefficients	Stage Cluster First Appears		Next Stage
	Cluster 1	Cluster 2		Cluster 1	Cluster 2	
1	13	20	2,398	0	0	5

Source: By authors processing in SPSS

The result of the clustering analysis made is a hierarchical structure of the motivational factors grouped in 6 clusters, as it can be seen in the dendogram, from figure 9

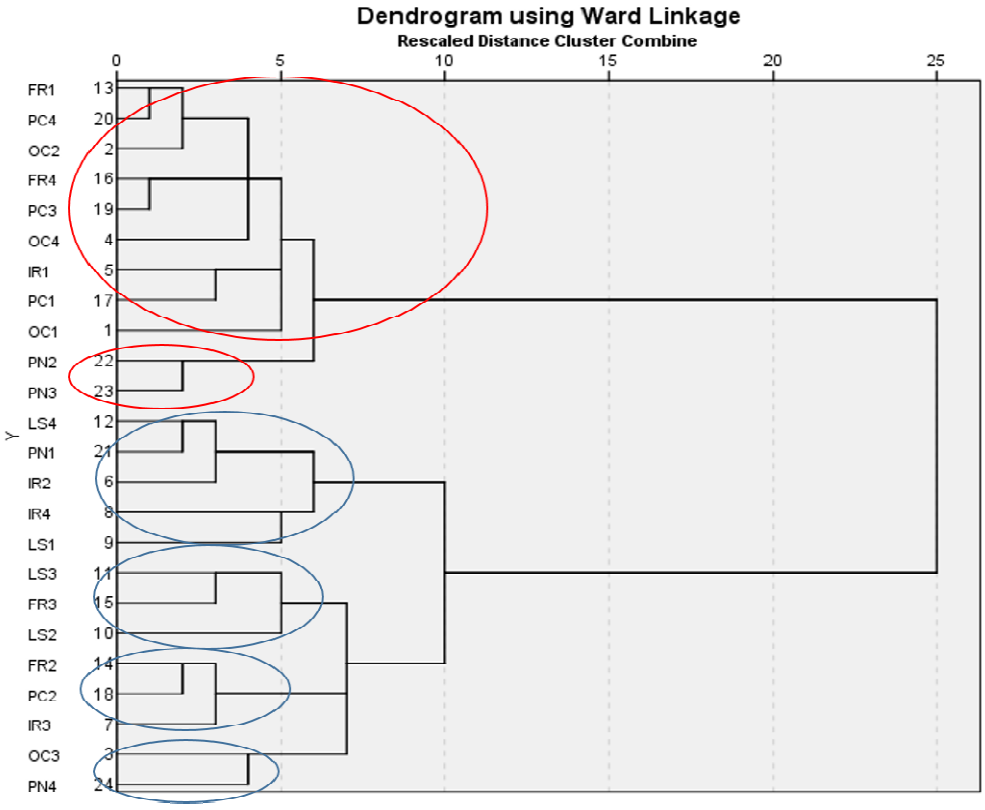

Fig. 9: The Dendogram for cluster membership

Source: By authors processing in SPSS

To sum up, clusters 1 and 6 comprise motivational factors with the highest influence on the level of staff motivation in companies. The maximum values are for personal needs PN2 and personal needs PN3, from cluster 6.
Cluster 2 includes organizational climate OC3 and personal needs PN4 motivational factors with a minimum positive influence on the degree of motivation of human resources.
Knowing the results of the analysis at the level of companies, it can be implemented as a program of motivation of human resources based on the level of influence of motivational factors, knowing clusters with maximum and minimum influence on the degree of motivation.
Many companies cannot function without commitment and cooperation of the employees to carry out the set ask and objectives of the organization.
The research explore the area surrounding the how employees were positively motivated by employee reward and the perception of these employees towards the motivating effects of reward and benefits.

3.2. A proposed Model for Motivation factors

Taking into account the information provided by the Cluster Membership and the dendogram, we can establish a model for motivation factors and obtain the clusters:

1. internal environment (organization environment);
2. individual environment;

3. management environment (employee-staff-manager);
4. social environment (reward, promotion);
5. leader style;
6. personal needs.

Cluster 1	FR1	Financial rewards	INTERNAL ENVIRONMENT
	PC4	Promotion conditions	
	OC2	Organization climate	
	FR4	Financial rewards	
	PC3	Promotion conditions	
	OC4	Organization climate	
	IR1	Industrial relationship	
	PC1	Promotion conditions	
	OC1	Organization climate	
Cluster 2	OC3	Organization climate	INDIVIDUAL ENVIRONMENT
	PN4	Personal needs	
Cluster 3	LS4	Leader style	MANAGEMNT ENVIRONMENT
	PN1	Personal needs	
	IR2	Industrial relationship	
	IR4		
	LS1	Leader style	
Cluster 4	FR2	Financial rewards	SOCIAL ENVIRONMENT
	PC2	Promotion conditions	
	IR3	Industrial relationship	
Cluster 5	LS3	Leader style	LEADER STYLE
	FR3	Financial rewards	
	LS2	Leader style	
	LS3		
Cluster 6:	PN2	Personal needs	PERSONAL NEEDS
	PN3		

Conclusions

Hierarchical cluster analysis using the Ward motivational factors allows identifying groups of motivational factors with great influence on the degree of motivation and suggest ways of improving motivation in companies.

The program can be implemented in order to correct motivational factors from the cluster with minimum influence on the degree of motivation of human resources in companies.

The hypothesis is also confirmed, such that there is a similarity between the motivational factors that determine their grouping into clusters with minimal variability depending on the results of the respondents.

Thus, the company should pay attention to the clusters with minimal influence of the staff motivation level in order to implement corrective measures to increase the number of trainings for personnel, both qualified and unqualified, as well as to improve their socio-professional integration level in the company, these being the factors with the lowest scores.

The proposed research model for the analysis of motivational factors according to their influence on the degree of motivation can be used to develop programs in order to increase the efficiency of management in companies and to identify motivational strategies in order to increase company's performance.

The case study undertaken in companies in Maramureș County, Romania, showed that elements considered motivating by employees which stimulate them in the activities carried out are: job security, salary growth, awards for performances at work, advancing to a superior position, relationships with colleagues and superiors.
A very important aspect in companies of Maramureș County is knowing and complying with the conduct rules which bring benefits at work, improving the working climate, increasing employees' morale and creating a favorable image of the company.

Institutional Structures Influence on the Technological Development of the Economic System

Sergey Bodrunov, Institute of New Industrial Development n.a. S.Y. Vitte,
Saint-Petersburg, Russia, e-mail: sergbod@mail.ru

Vladimir Plotnikov, Saint-Petersburg State University of Economics,
Saint-Petersburg, Russia, e-mail: plotnikov_2000@mail.ru

Abstract

Technological development is one of the key factors in the competitiveness of the national economy. Its achievement requires an appropriate state economic policy. The effectiveness of this policy can not be achieved without its coordination with the institutional structure. Institutions, especially informal ones, have a high degree of inertia. Therefore, if economic policy comes into conflict with them, it leads to inefficiency. At the same time, institutions can gradually change if economic reforms are carried out purposefully and systematically. Failure to meet these requirements (this is shown on the example of the experience of the 30-year transformation of the Russian economy) leads to stagnation in the economy and degradation in the social sphere. The ideological and methodological reason for the low success of reforms is the reliance on inadequate economic models. The authors distinguish two approaches to their construction. The first approach is based on the concept of universalism. The second approach is based on the consideration of national specifics. The article proves that the second approach is more effective. Countries that have chosen a second approach to reform (for example, China) have made significant progress. The governments of these countries manage to ensure long-term economic growth. Based on this approach, the authors recommend modernizing Russia's economic policy. It is suggested that the institutional features of the three subsystems allocated in it be more fully taken into account in the measures of state regulation. This is traditional-conservative; liberal-market; the new model of the mixed Russian economy. Such an approach will allow: to stimulate the development of industry, re-industrialize, accelerate technological development, reduce the technological gap with developed countries.

Keywords: institutional structure; national economic development; economic policy; economic reforms; technological level of the economy.

Introduction

In economic science, as in science generally, there is a certain opposition between the unique and universal elements. This opposition, of course, has origins in philosophy. Note that the proponents of the universalism of economic theory, represents the mainstream, triumph in education (Komlos, 2015). Standard textbooks in microeconomics and macroeconomics operate with abstract categories. These abstractions are far from the real events of economic life. However, their value is undeniable. They allow to generate economic thinking (Browne, Hoag and Boudreau, 1995; Caldwell, 1988; Enste, Haferkamp and Fetchenhauer, 2009; etc.). This standardized way of thinking, in accordance with the provisions of institutionalism, reduces transaction costs and increase economic efficiency.

Representatives of universalism in economic science say: "No Italian (Chinese, Brazilian, Russian, etc.) mathematics (physics, chemistry, etc.)". In this regard, can not be specific (national) economic theory. Economic theory, like any other science, universal in its essence. We can partly agree. Indeed, the basic methodological approaches in any science should be unified. At the same time, the use of abstract models in scientific analysis connected with the problem of adequacy in modeling. In the process of formation models, the researcher simplifies reality. The goal of this process is the selection of the most significant elements of the modeled phenomenon. This approach allows us to identify important common features not only of this phenomenon, but also a whole class of similar phenomena. Abstract economic models, when they are reflected in the mind of a person, typify reality. This leads to its monotonous understanding. As a result, collective agreed economic behavior

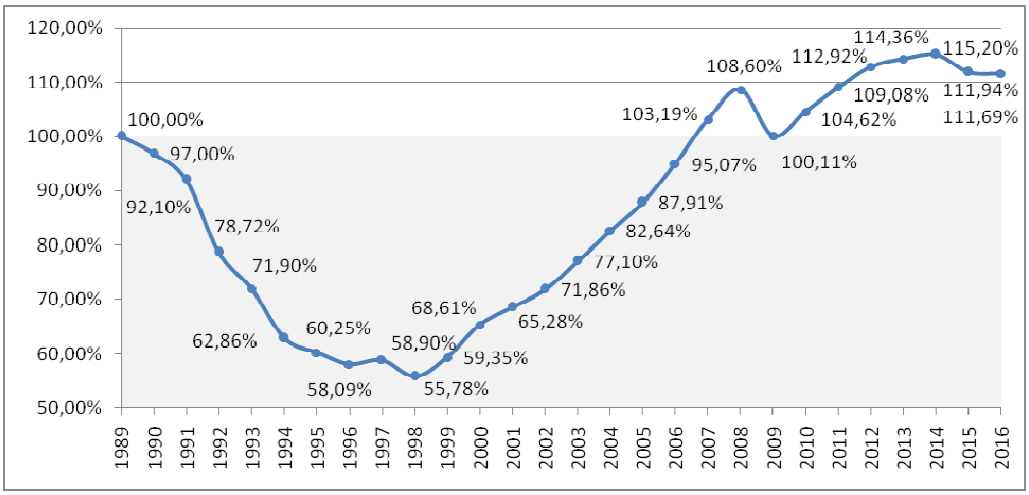
is formed. This behavior contributes to the reduction of decision-making time, reduces the uncertainty of the business environment, makes possible the conclusion of contracts based on incomplete information of the parties.

On the other hand, the presence of models does not change the economy itself. Simulation only makes it easier to understand as a complex system. In this regard, direct use of the results of modeling in economic practice is not always possible. Important features of the real economic system, the specific economic behavior of specific people in abstract models are not taken into account. Therefore, another approach to the discovery of the essence of economic phenomena and processes was widely adopted. It is based on emphasizing the national (geographical, cultural, religious, etc.) specifics of economic systems. An example of such specific economic theories is the German Historical School of Economics (for example, Grimmer-Solem, 2003, Peukert, 2001, Senn, 2005, Steiner, 2003), Eurasianism (for example, Bassin, Glebov and Laruelle, 2015, Maksimtsev, Miropolsky and Tarasevich, 2016) and other. An attempt to construct a system of specific economic theories, united by unified (few) basic principles, is essentially done within the framework of this approach.

The strength of specific approaches to the comprehension of economic phenomena and processes is, in our opinion, not in their ideological underpinnings (often pointed out by critics), but in a more practical direction. In this sense, such a specific approach is very much in line with the methodological position of the institutional direction in economic science (see, for example, Hultén, 2005). For this reason, there is no contradiction with mainstream. There is only a discussion about the priority of certain groups of institutions. Supporters of universalism note the priority of universal (global) institutions that regulate economic processes. Adherents of specificity point to a more important role of local institutions.

The last position has serious empirical study. It is sufficient to point out the negative effects in the socio-economic development of post-Soviet countries during their transition from socialism to a market economy. They were related to ineffective implantation of the institutions of the Western-European economic culture . These, contrary to the system prevailing informal norms, institutions were rejected. As a result, instead of economic growth have been major transformational recession in the economy. In addition, there was a decrease in law-abiding society, the growth of social nihilism and conflict, increasing corruption, etc. On the contrary, China, which has chosen a gradualist model of institutional development, has achieved impressive results in socio-economic development.

We hold the view that economic science should adequately reflect not only the fundamental principles, but also the specificity of a particular economic system. To achieve practical usefulness of theoretical developments it is possible only so. Taking this position into account, the article considers the influence of the institutional structure on the technological development of Russia's economic system.



Characteristics of the Russian Economic System

Russia was in a difficult historical situation. Its economy for a long period of time was in a state of transition: the collapse of the old economic system and the formation of a new one. The duration of this transition period is about 30 years. Obviously, from the viewpoint of life-cycle theory, any economic system eventually collapses, and a new one comes to replace it. But the transition period itself is characterized by incompleteness, lack of integrity, coexistence of elements of the new and old economy. The period between two mature states includes, on the one hand, the emergence of a new economic system, on the other hand, the descending development of the old system (Grinberg and Rubinshtein, 2000).

Incompleteness, lack of integrity of economic systems in transition can lead to economic decline. As Russian experience shows, in the transition period, due to institutional incompatibility (rejection of new institutions and the destruction of old institutions) institutional voids are formed. Developing process of primitivization of production, deintellectualization of labour and degradation of the social structure. There is a massive poverty, increases social inequality. Economic policy of the state carried out the formation of new economic relations in the direction not corresponding to the current material, economic and socio-cultural backgrounds. The economy responded to the uncertainty and

distortion of economic signals contraction in demand and, consequently, production, the shortening of the planning horizon when making economic decisions and the rejection of long-term investment and high risk projects.

The long-term dynamics of the Russian economy is reflected in Figure. From the Figure, we can see that immediately after the start of market reforms (1989), Russia's GDP began to fall precipitously. These reforms were accompanied by a radical breakdown of the national institutional structure. The bottom was reached in 9 years (1998). During this period, GDP fell by almost half, by 44.22%. To restore the GDP to the level of 1989 it took another 9 years. Only in 2007 the pre-crisis level was exceeded by 3.19%. This happened after 18 years of institutional transformation. The conclusion about the ineffectiveness of reforms is obvious. The efficiency was extremely low, negative. If we sum up the results of the country's development in 27 years (until 2016), it can be determined that the Russian economy has nevertheless grown. The average growth rate for this period was 0.41%. This is a very small value. At the same time deindustrialization and destruction of technological potential occurred in the country (Bodrunov, 2016).

Calculated and compiled by V. Plotnikov according to the data of World Bank (http://databank.worldbank.org/data/reports.aspx?source=world-development-indicators#).

Fig.1: Long-term dynamics of Russia's GDP (1989 - 100%).

De-industrialization and technological lagging block sustainable economic growth. Because for growth can not create an infrastructure basis in the form of modern real physical assets. The importance of industrial development is high. This conclusion is based on both historical examples and facts from the current state of the world economy. It was the transition to machine and industrial production that led the countries of Western Europe (and then the US, Japan, etc.) to the position of leadership in the world economy. Prior to this, the leaders were China and India. Industrial monopoly for a long time ensured first Britain and then the West as a whole a dominant position in the world economy and in world politics, allowing for a long time to derive direct material and financial benefits from this provision.

However, it is not just about the past. Despite all the changes in the GDP structure, the "core" of the world economic system is those countries that were the first to pass along the road of industrialization. They hold the first positions in the world not because of the service sector, but because of their technological leadership. Therefore, those states that are successfully moving towards overcoming economic backwardness (Republic of Korea, Taiwan, China, Brazil, Malaysia, etc.) have chosen industrial development as an economic revival strategy. The industrialization of the economy allowed these countries to rapidly build up their economic potential, created prerequisites for the development of high-tech industries.

Now these countries face a very difficult task: to challenge the scientific and technological monopoly of the most developed countries. But without industrialization, raising the question of the formation

of an independent national scientific and technological core of the economy would be a utopia. Studies have shown that only with the developed industry the necessary material base is provided, the necessary ground for industrial innovations is created and real demand for corresponding scientific research and development is formed. Now the countries that have chosen as a priority the pursuit of industrialization as the main driver of economic development, demonstrate impressive successes in industrial growth, raising the standard of living. They increase spending on education, training of qualified personnel, on research and development. That is, in addition to success in the economy, these countries are also developing the social sphere (Polozhentseva, 2016).

The above arguments, facts and their description show that when implementing reforms in Russia, the wrong methodology was chosen. It was based on the universalist liberal-market model. This model rejects the existence of national specifics in the economic system. It is built on a misconception about the institutional structure. Countries that have taken into account national institutional specifics in economic policy, for example, China, have achieved much greater results in socio-economic development. In this regard, it is necessary to consider the current institutional structure of the Russian economy in order to take it into account in the state economic policy.

Analysis of the Institutional Structure of the Russian Economic System

In our opinion, economic policy should not be based on the universalist concept of economic science. A more preferable paradigm is the consideration of national-state specifics in economic policy. Among the key ideas of economic policy aimed at the formation of a sustainable model of Russia's development, in our opinion, the following should be attributed:

The first, the recognition of the need for advanced development of modern material production. It should be built on the basis of technologies typical for 4 and 5 technological orders. The provision of these production facilities with research and development and highly qualified personnel should be carried out.

The second, carrying out re-industrialization with the fullest possible consideration of the civilizational specifics of Russia.

The third, the creation of an economic policy based on a thorough analysis of the real structure and contradictions of the existing economic system in Russia.

The fourth, it is necessary to take into account the fact that in transformational economies, politics and ideology have a significant impact on the implementation of economic strategies.

The structure of the economic system of Russia can be described on the basis of the allocation of its key subsystems. These subsystems reflect both the historical stages of the formation of the Russian economy and the levels of its development. The analysis was carried out by us on the basis of the separation of technological, socio-economic, legal, civilizational and socio-cultural factors. We identified three institutionally separate subsystems of the Russian economic system.

(1) *The traditional-conservative subsystem* includes:

- Traditionally important, but often conservative role types of economic activity. Here we include agrarian production and other "old" branches of material production growing from the 19th to the beginning of the 20th century; technological systems based on manual and poorly industrialized labor; machine production of products of low degree of processing, which includes the raw materials sector.
- Market relations burdened with survivals of subsistence economy, patriarchal relations and state-bureaucratic protectionism and paternalism.
- Traditional Russian civilizational invariants that gravitate towards the ideology of conservatism.

(2) *The liberal-market subsystem* includes:

- Predominantly assembly industries that are part of a network of transnational corporations; service, trade, finance, other spheres of intermediary business.
- Close to the classical, although substantially modified by Russian specificity, market-capitalist economic relations and institutions.
- Predominantly liberal-Western ideology.

(3) Elements of *the new model of the mixed Russian economy*. This model presupposes the priority development of high-tech production on the basis of socially-oriented regulated economic development. This system must be critical, overcoming the main vices of the past (deficit, bureaucracy of directive planning, equalizing distribution), use the experience of the Soviet economic system and its achievements so far (in particular, in the defense industry) and use the experience of countries such as China, Vietnam, etc. This emerging subsystem includes:

- High-tech industries, are typical of the 5th and 6th technological orders, and clusters combining manufacture, research and education (Kryzhanovskaya at al., 2016).
- Programming and selective regulation of the market economy, public-private partnerships and similar mixed forms of economy that integrate the advantages of the market and state regulation.
- The ideology of advanced development based on the critical integration of civilizational achievements of the West and traditional Russian values.

The main sector of the Russian economy should be the third, based on the joint use of market elements and the plan (hierarchy). The mixed economy of Russia should be based on the system of informal institutions inherent in the country. The failure of this circumstance led to negative consequences in the past. The available data on the structure of the economy reflect the negative trends that characterize the structural shifts in the Russian economy.

In the structure of Russia's GDP (Table 1), even during the favorable economic situation in the 2000s (see Figure), there was a reduction in the share of processing industries, and the country's food security, based on domestic agricultural production, was weakened. At the same time, the proportion of mining operations, financial activities and real estate transactions grew. The branches on which the strengthening of human potential depends, were characterized by sluggish tendencies towards recovery after the failure of the 1990s. In particular, the share of education remained at the same low level, and health care only slightly (by a percentage share) increased.

Table 1: Russia's GDP structure, %

Indicator	2002	2012	Change 2012 to 2002
GDP at market prices	100	100	-
Agriculture, hunting and forestry	5.3	3.1	-2.2
Fishery, fish farming	0.3	0.2	-0.1
Mining	5.9	9.3	3.4
Processing industries	15.2	13.0	-2.2
Electric power and other	3.2	3.0	-0.2
Building	4.7	5.5	0.8
Wholesale and retail trade; repair of motor vehicles, motorcycles, household products and personal items	20.2	16.9	-3.3
Hotels and restaurants	0.8	0.8	0
Transport and communication	9.0	7.0	-2.0
Financial activities	2.6	3.7	1.1
Real estate, lease	9.4	10.1	0.7
Public administration and military security	4.5	5.6	1.1
Education	2.6	2.6	0
Health care	3.0	3.3	0.3
Other social services	1.7	1.4	-0.3
Net taxes on products	11.5	14.5	3.0

Calculated and compiled by S. Bodrunov according to the data of the Russian Federal State Statistics Service (http://www.gks.ru).

The same tendencies are also traced in the analysis of the distribution of investment in fixed assets by types of economic activity (Table 2). The observed distribution of investments fixes the existing inefficient structure of the Russian economy, and is not aimed at improving it. Such a structure freezes the technological backwardness of the Russian national economy.

Table 2: Structure of investments in fixed assets in Russia, %

Indicator	2008	2009	2010	2011	2012
Investments in fixed assets	100.0	100.0	100.0	100.0	100.0
Agriculture, hunting and forestry	11.2	10.1	9.6	12.92	11.6
Mining	0.2	0.4	0.2	0.58	0.5
Processing industries	27.7	21.5	13.4	23.23	28.8
Production and distribution of electricity, gas and water	10.3	8.4	11.0	12.09	17.1
Building	1.5	0.7	1.0	1.09	0.6
Wholesale and retail trade; repair of motor vehicles, motorcycles, household products and personal items	1.4	5.5	1.8	3.47	1.8
Hotels and restaurants	0.4	0.3	0.3	0.69	0.6
Transport and communication	14.8	13.7	24.2	18.14	14.1
Financial activities	1.5	1.5	1.9	1.53	1.8
Real estate, lease	8.6	9.9	19.9	10.01	9.4

Directions of Economic System Development Taking into Account its Institutional Structure

We believe that the main attention should be paid to the development of the third of the subsystems we have identified. It is capable of providing technological leadership, sustainable economic growth, improving the quality of life and stability of the socio-political system. This does not mean that Russia's prospects should be exclusively connected with the development of the third of the subsystems that we have identified. Substantial corrections are needed in all blocks of the Russian economy.

(1) *The traditional-conservative subsystem*. Here, it is necessary to reduce production costs in the agrarian and fuel and raw materials sectors, sharply increase innovation activity - in order to provide the necessary infrastructure base for the other two subsystems. An important role is played by factors of economic security (ensuring food independence, high importance of revenues from fuel and raw materials exports for the long term). In addition, it is desirable to combine the impulses of development with the stabilizing role of patriarchal and conservative traditions.

(2) *The liberal-market subsystem*. This subsystem requires the restoration of mass production (naturally, in the industries demanded by the market), the overall growth of small and medium-sized businesses, ensuring the availability of credit, financial, insurance and other services for business, debugging competitive institutions and institutions for protecting property rights, using the spirit of personal initiative positively.

(3) Elements of *the new model of the mixed Russian economy*. We propose a priority development of high-tech production on the basis of socially-oriented regulated economic development. As we have already noted, the Russian economy is characterized so far only by the elements of the third subsystem. However, it is based on the mobilization of intellectual and social capital of the nation, should ensure the implementation of positive functions of the first two subsystems through the formation of a constructive, innovative, focused institutional environment. An effective policy of re-industrialization is possible only in such an institutional environment.

The existing experience of development in this direction requires studying both positive and negative experience of joint participation of business and state structures. Analysis of this experience allows us to conclude that the implementation of the tasks of the development of the third subsystem is

possible, but it will require a significant change in the system of economic relations, institutions, economic policies and cultural and ideological stereotypes.

At the level of the technological foundations of the economy, the positive historical heritage of Russia is the tradition of developing, first of all, the basic branches of material production. These industries used raw materials and other natural sources of the country for the progress of machine building, aircraft building, nuclear energy, space and related industries, as well as other high-tech spheres of the economy. Especially typical for Russia is the priority development of the economic foundations of the country's defense power and the corresponding high-tech industries. It is this tradition, in our opinion, that can and should be extended to the future. To this end, Russia has a potential for development that has been preserved to this day, a certain revival of which began in recent years.

This trend fully meets the defining civilizational codes of Russia, which presuppose the priority of the whole, the powers in relation to private interests, but with the active use of private initiatives of entrepreneurs in case they meet the tasks of the country's revival. We do not undertake to assert that this should be the trajectory of the development of the empire, but we insist that the economic system should ensure the development of such material production that will ensure the country's complete economic, technological, military and other security.

We believe it significant that the development of high-tech industry involves the revival of the system of industrial integration that was destroyed over the years of reform, with science and education. This should be implemented at a new level and in fundamentally new economic forms that use the potential not only of the state, but also of the market and private property, which should have some independence, being oriented not only to solving the problems of production development, but also to solving the fundamental problems of development technologies and human qualities, solving social and environmental problems.

Conclusion

Economic transformation in Russia proved to be ineffective due to mistakes in the formation of institutions. These mistakes are due to the excessive enthusiasm of the reform leaders in the universalist paradigm of economic theory. Experience has shown that it is necessary to take into account nationally specific institutions. Their failure leads not only to the economic decline, but also to technological backwardness, the destruction of the moral foundations of society. These errors must be taken into account in the new model of economic policy. In the perspective directions of Russia's development, changes in the systemic quality must occur. These include the development and implementation of long-term programs and medium-term indicative plans, as well as the implementation of an active industrial policy.

These changes will not impede the expansion of the market initiative (this possibility is indicated by the adherents of the universalist economic paradigm), but will also contribute to it, providing state support for the most modern and advanced national productions and hindering parasitic mediation and excessive expansion of transnational capital into the Russian economy. The latter preserves the technological backwardness of Russian industry and reduces the level of the country's security against external political and economic challenges.

An important tool for linking the plan and the market into a single system can and should be private-state partnership (PPP). PPP is based on a stable system of institutions that guarantee private business opportunities for long-term investment in R&D and technological re-equipment of production. The taxation and crediting of the real sector, especially the high-tech sector, should be built accordingly. They are called upon to ensure the stimulation of the development of these industries and their innovative potential. Finally, the government should provide a moderate level of social differentiation (Galbraith, 2011). Variations in personal incomes should depend mainly on the real contribution of individuals to the development of the economy.

The formation of a new vision of development presupposes reliance on a more complete account of the country's institutional specifics. This should be taken into account in the strategy for creating a new model of the economic system and technological development. This is due to the implementation

of economic policy, which should be combined with social, educational, scientific and cultural policies.

Technological Development as a Factor of Ensuring the National Security

Sergey Bodrunov, Institute of New Industrial Development n.a. S.Y. Vitte, Saint-Petersburg, Russia, sergbod@mail.ru

Vladimir Plotnikov, Saint-Petersburg State University of Economics, Saint-Petersburg, Russia, plotnikov_2000@mail.ru

Yulia Vertakova, South-West State University, Kursk, Russia, vertakova7@ya.ru

Abstract

The high technological level of the economy is one of the conditions for the effectiveness of economic growth. This level in the article is proposed to be considered from two sides. On the one hand, it ensures the sustainability of economic development. On the other hand, it creates prerequisites for technological and, in general, economic security of the country. Due to the crisis development (since 2008), the authors suggest to consider the second direction as a priority. Technological development is seen as a factor in ensuring national economic security. A promising economic model is built on the ability to generate innovations, develop and introduce new technologies into production. These abilities must be realized within the country. This avoids its dependence on external actors. In support of this idea, the authors have established a correlation between national competitiveness, the level of socio-economic development of the country and its technological level. A technological innovation requires the formation of a national innovation-technological ecosystem. This ecosystem covers the real sector of the economy, as well as the social sphere (education, culture, health, etc.). To form such an ecosystem, national re-industrialization is necessary. Reindustrialization requires measures for its resource, methodological and ideological support. The article substantiates the composition of such measures (the use of national financial reserves, the expansion of the practice of program management, the legal provision of re-industrialization, ensuring the availability of credit resources for the modernization of the fixed capital of industrial enterprises, etc.) and the positive consequences of their implementation.

Keywords: national economic security; technological backwardness; technological development; state regulation of the economy; economic policy; industrial policy; re-industrialization.

Introduction

In our opinion, from the standpoint of a systems approach, management tasks in the economy can be divided into two large groups. The first group is connected with economic development. The second group is concerned with ensuring security, i.e. with ensuring the existence of a managed system. The priorities and interrelationship of these tasks in different periods of time can be different.

Since 2008, the world economy and the system of international relations have entered a period of turbulence. The observed facts of this are: crisis phenomena in the economies of large countries, the growth of interstate contradictions in the economy and politics (a bright example of this is the BrExit), an increase in the level of protectionism in international economic relations, the expansion of international economic sanctions regimes, etc. It is possible, therefore, to assert that the level of economic security of individual countries and territories, and of the world economy as a whole, is declining. As a result, it is difficult to solve the tasks of social and economic development.

When solving the tasks of ensuring economic security, it is necessary to take into account not only the current threats to the normal functioning of the economic system (in particular, the government's anti-crisis policy is directed at this), but also the long-term risks associated with its dynamics. One of the main vectors of development today is the formation of an innovative model of the economy. Technological breakthroughs can devalue already existing competitive advantages. These

breakthroughs can also fundamentally change the situation in the sphere of ensuring economic security. For this reason, technological development should be seen as a factor in ensuring the country's economic security.

The Short Literature Review

The technological development is traditionally considered by economists as a key driver of economic growth. In particular, Nobel laureate Robert Emerson Lucas (1988) believed that one of the main models of economic growth is a model emphasizing the physical capital accumulation and technological change. Chief Economist and Senior Vice President of the World Bank Paul Romer (1990) believes that economic growth is driven by technological change. Robert Hall and Charles Jones (1999) in the article "Why do some countries produce so much more output per worker than others?" say that the reason for this is the differences in physical capital and educational attainment. The authors point to the key role of technological development in ensuring high labor productivity. This is a factor of economic growth and high efficiency of resource use. Similar opinions are also heard by other specialists (Brandaõ Santana et al., 2015; Frishammar et al., 2015; Miller et al., 2017; Shrivastava et al., 2016; Teletov et al., 2017; Vertakova and Plotnikov, 2016; and other). At the same time, the influence of technological development on ensuring economic security in the literature is considered poorly.

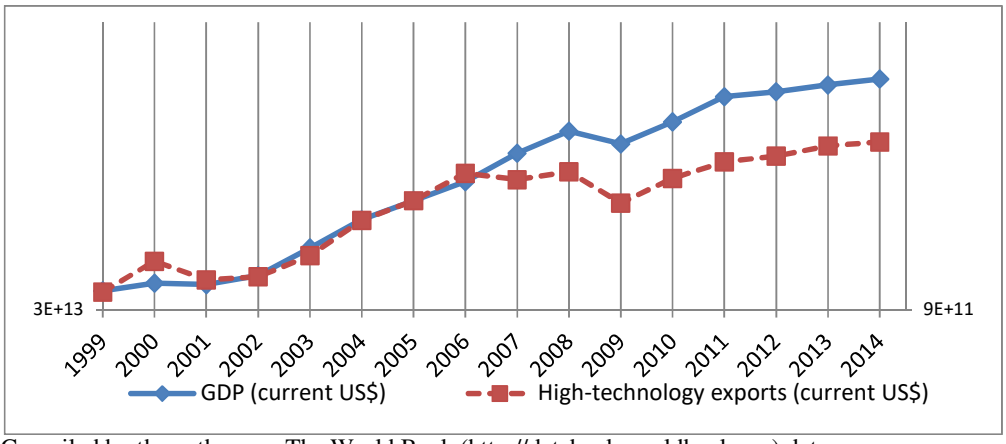
The scientific community recognizes the urgent issue of economic security. A number of authors (Barry, 2007, Gasparatos and Gadda, 2009, Hacker et al., 2014, Jizhong and Guoyu, 1992, Zhang, and Zhang, 2004; and other) analyze this phenomenon in detail, both in general and in relation to specific countries, regions, sectors and types of security (food, social, technological, etc.). We note the great importance attached to ensuring economic security by the governments of the world's leading countries. The weakening of the economic security of the partner country, on the contrary, is viewed in foreign policy as a way of exerting international pressure on its government. Suffice it to mention in this regard the international economic sanctions imposed by the United Nations against North Korea, Iran and other countries. As well as unilateral economic sanctions, which are regularly resorted to by governments of developed countries to achieve their own political and economic goals. Economic sanctions are introduced to weaken national economic security and block economic development (Halberstam and Stein, 2009; Marinov, 2005; Shin, Choi and Luo, 2016; and other).

The Impact of Technological Development on Competitiveness

A promising model of the economy is called innovation, information, knowledge-based, post-industrial, etc. The crucial point is that this economic model is built on the ability to generate innovations, develop and introduce new technologies into production. A country with such a property becomes a source of technology for other countries. As a result, they fall into technological dependence. This allows the country - the technology leader - to influence the economic and political decisions in the country - the technological donor.

There is a significant correlation between the levels of socio-economic and innovative development of countries. Table 1 shows the indicators of GDP per capita, PPP (current international $) and Rank in the Global Innovation Index of the countries leading in these indicators in the world. In the Table 1, countries are ordered according to the GDP per capita indicator. The richest countries in the world include innovative leaders and oil exporting countries. At the same time, high positions of innovative countries are provided not by natural conditions, but by knowledgeable and intellectually intensive resources created in the country. That is, their competitive advantage is more stable.

These countries have sustained revenues from technology trade and exports of innovative industrial products. At the same time, this trade itself is an indicator of the "health" of the world economy. This is evident from a comparison of indicators of the dynamics of world GDP and world high-tech exports (Figure 1). World figures of High-technology exports (current US $) and GDP (current US $) from 1999 to 2006 grew at a similar pace. But in 2006, two years before the crisis, the innovative and technological development of the world economy began to slow down. This was reflected in the change in the dynamics of the two indicators considered. After the fall in 2009, the growth of both indicators resumed. At the same time, the growth rates of the High-technology exports indicator



(current US $) have become outstripping. In our opinion, this testifies to the restoration of the economy, in terms of its technological structure.

The importance of the technological factor is not reduced to the cost accounting of its direct contribution to economic growth. The qualitative component of this contribution is also important. It is determined by the creation of prerequisites for future development. "Innovation is making innovations." New technologies change social reality. They form a new foundation for the industry. The lack of national development technologies and their inaccessibility (economic or physical) for acquisition on the world market can preserve the country's socioeconomic backwardness.

Table 1: Leading countries of economic and innovative development

Country Name	GDP per capita, PPP (current international $), 2016	Global Innovation Index 2017 rankings
Qatar	127523	
Luxembourg	105888

Fig. 1: Dynamics of changes in indicators of High-technology exports (current US $) and GDP (current US $), logarithmic scale.

We give an example from the field of microelectronics. In June 2017, Forbes magazine reported that IBM has created a process for manufacturing electronic chips with a topology of 5 nm. This twice exceeds the most advanced for today development (10 nm). It is implemented by Qualcomm in the processor Snapdragon 835, which is installed in the smartphone Samsung Galaxy S8. According to expert estimates, the characteristics of the new chip will allow a 2-4-fold increase in the battery life of smartphones and other mobile devices. This development was carried out in cooperation by IBM, Samsung and GlobalFoundries. According to the plans of the developers, the production of new chips can be launched from 2020.

At the same time, the modern minimal topological size for mass production of commercial products is 14 nm (from 2014-2015). For comparison, in Russia the minimum mastered technology is 65 nm. Such chips are made by Micron company. It also develops a chip with a topology of 45 nm. At the same time, the government decided to set up the production of chips using 28 nm technology. This will require financing in the amount of more than $ 1 billion (only for the construction of the plant). In May 2015, the Russian company Baikal Electronics released a prototype of the processor using 28 nm technology. The processor is developed in Russia, but is produced at the TSMC plant in Taiwan. And this development is not entirely Russian. Baikal Electronics licensed a number of blocks from the British company Imagination Technologies.

This example is convincing. Developed by one country, even economically developed enough (according to the World Bank, in terms of GDP, taking into account the PPP, Russia is ranked 6th in the world in 2016, accounting for 2.83%), modern technology in the field of microelectronics is very difficult. And while blocking access to foreign technology, this can not be done. And it's not just about financial costs, but about time. In the development of microelectronics, Russia, like many other countries in the world, is in the "catch-up" position. Overcome the existing lag is theoretically possible, but during this time, the leading countries will also increase the initial gap. As a result, technological dependence is formed on foreign supplies, which weakens the national competitiveness. This import dependence is a threat to national economic security.

Measures to Reduce the Technological Gap and Increase the Level of Economic Security (on the Example of Russia)

The term "technological boundary" is used in the construction of innovative technological forecasts. It assesses the level of advanced technologies that have a decisive influence on the main parameters of the economic system. According to the calculations of the Higher School of Economics (Russia), while maintaining the current pace of technological development, the country will reach the current technological frontier of advanced countries by 2050. During this time these countries will make a further breakthrough. As a result, most likely, the existing gap will not decrease, but will increase. It can be concluded that an attempt to reduce the technological gap in all areas is ineffective. It is necessary to use a selective approach.

We should choose certain priorities in technological development. In the future, on their achievement, most of the available resources should be concentrated. This step is fulfilled in Russia. The Decree of the President of the Russian Federation of 07.07.2011 # 899 "On the approval of priority directions for the development of science and technology in the Russian Federation and the list of critical technologies of the Russian Federation" was adopted and entered into force. The list of 8 priority directions for the development of science and technology, as well as 27 critical technologies has been officially announced. Efforts of state (and with state participation) scientific, innovative and production organizations are focused on their development. Private business is involved in the implementation of these priorities through the system of indicative planning and state programming.

Experience shows that development only in priority areas is not enough. A technological innovation requires the formation of an innovation-technological ecosystem. This ecosystem covers most branches of the economy, as well as the social sphere (education, culture, health, etc.). The latter circumstance ensures the formation of innovative human capital. To form such an ecosystem, national re-industrialization is necessary, as one of the authors has repeatedly pointed out earlier in his speeches and scientific developments (Bodrunov, 2016). Thus, today it is necessary to

reindustrialize the economy on a new technological basis, focused on advancing technological development.

Now the next technological revolution is beginning in the world. Today's technological leaders will be the economic leaders in the future world. There is a transition of advanced countries from 5 to 6 technological order. Russia is in 4 with elements of the 5 technological order. Therefore, the country has risks in the sphere of economic and national security. These risks are critical. In this regard, it is necessary to stimulate international innovation-technological and production cooperation, support cross-border technology transfer. This requires the creation of special institutional conditions, as well as the adjustment of state economic policy.

As a model, the experience of state support of automobile production in Russia can be used here. The government provided the world's automakers with a special legal regime for working in Russia - the "industrial assembly regime". It was established by the Decree of the Government of the Russian Federation of March 29, 2005, # 166 "On Amending the Customs Tariff of the Russian Federation with respect to Automotive Components Imported for Industrial Assembly". As a result, the Volkswagen Group, Renault-Nissan, Ford, Toyota and others opened their enterprises in Russia. Following the production of finished products (cars), in order to reduce the tax burden and achieve competitive prices, the localization of the production of auto components began in the country. As a result, for example, the overall level of localization of Nissan cars produced in Russia is 64%. We can talk about reducing import technological dependence in this area. Following the production of the final products, modern automobile clusters were created in a number of regions of the country (St. Petersburg, Leningrad, Kaluga, Kaliningrad regions). They include a significant number of supporting industries, the infrastructure of training, service, sales, R&D, etc.

The task of searching for a new model of economic growth and, perhaps more broadly, the new economic doctrine is facing the economic community and political authorities. For a long time, the country was pursuing an economic policy that nominally had the right strategic goals for creating a modern social market economy that provides a modernization strategy for development. However, the tools that were chosen to achieve it (a combination of the ideology of "market fundamentalism" and the practice of "manual" government) caused the stagnation of the economy. The implementation of the liberal-monetary model of economic development led to a decline in production, a decrease in the stability of the economy, an increase in the level of dependence of the economy on foreign capital, technology, products, consumer goods. The economic security of the country was weakened.

A major problem that has a negative impact on the state of the economy and, in particular, on the development of industry, is the outflow of capital from Russia. This problem was exacerbated in 2014. According to the Central Bank of Russia, the outflow amounted to $ 151.5 billion, which is almost 2.5 times more than in 2013 - $ 61 billion. This exerted additional pressure on both the national currency and on the dynamics of financial markets. Together with anti-Russian sanctions, this has reduced the sources of "long money" for Russian companies. And along with this, the country has accumulated excessive international reserves (Table 2). These reserves continue to grow.

Table 2: International Reserves of the Russian Federation, $ million

Date	Total	Including foreign exchange reserves	Including		
			Foreign currency	Special Drawing Rights	Reserve position in the IMF
September 01, 2017	423 978	350 478	340 669	6 824	2 985
September 01, 2016	395 198	330 488	320 610	6 725	3 154

Source: Central Bank of the Russian Federation (http://www.cbr.ru/hd_base/?PrtId=mrrf_m).

The minimum sufficient amount of national reserve assets is established (in accordance with world practice). It should correspond to the value of imports of goods and services for 3 months. In Russia,

this indicator is much higher (Table 3). Over the past 10 years, the country is in the top 10 in terms of volume and sufficiency of international reserves in the world.

Such volumes of reserving resources in conditions when the national industry, including its high-tech sector, do not have enough funds for development, are groundless. The authors believe that the amount of resources "frozen" in reserves can be significantly reduced. This will not lead to macroeconomic instability or other negative consequences. How large are the reserves that can be used to stimulate technological development? Let's consider this issue in more detail.

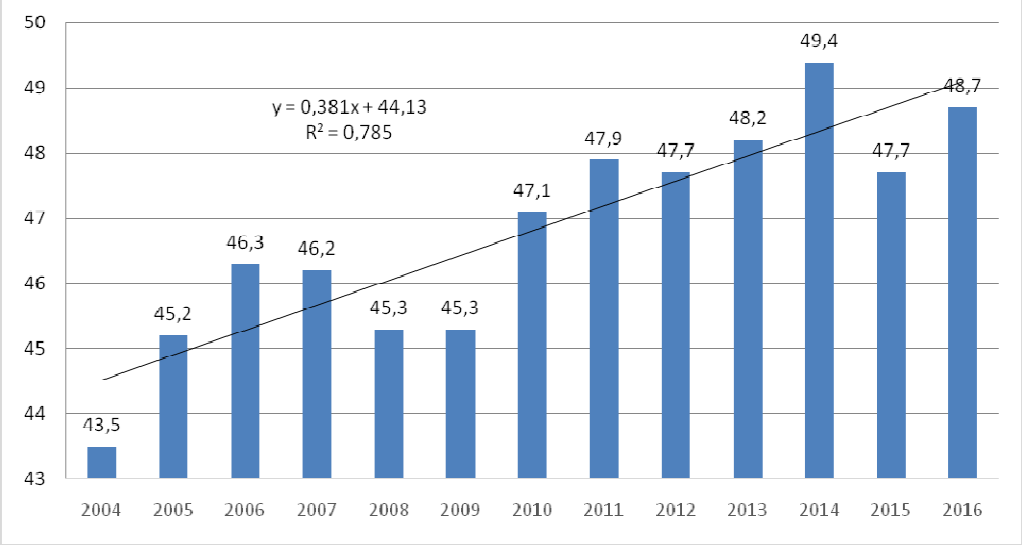
Table 3: Assessment of the sufficiency of international reserves of Russia

Date	Level of sufficiency of reserves, months of import (optimal - 3)	The world's position on the sufficiency of reserves	The world's position on the volume of reserves
January 01, 2011	18	2	4
January 01, 2012	14	4	4
January 01, 2014	13	9	5
January 01, 2015	11	11	7
January 01, 2016	16	8	7

Compiled by the authors on Central Bank of the Russian Federation (http://cbr.ru/statistics/print.aspx?file=credit_statistics/res_import.htm) data.

Decree of the Government of the Russian Federation of April 15, 2014 # 328 "On the approval of the state program of the Russian Federation "Industry Development and Enhancing its Competitiveness" for 2013-2020 provides for the amount of funding from the federal budget is 1059 billion rubles. At the current exchange rate (on September 01, 2017 - 58,5454 RUR / USD) this is about $18 billion. This is only 4.27% of the gold and foreign exchange reserves accumulated on the relevant date (see Table 2), which are planned to be spent for 8 years. In terms of a year - about 0.5%. This is an insignificant amount. It is at the level of natural fluctuations in the volume of reserves (over the past year they increased by 7.28%).

We believe that it is necessary to more actively attract reserves for financing re-industrialization programs, modernization of industry, its innovative and technological development, etc. For this, an appropriate political decision is needed. The main trend of the new economic policy is reindustrialization based on the priority development of high technologies. To solve this task, we must concentrate available resources. One declaration is not enough. Without resource support, reindustrialization is impossible. It is not so much the restoration of Soviet industry that is required (although in some cases these steps are necessary), but a qualitative update of the technological basis of production. The solution of this task should be concentrated available resources: not only financial, but also managerial, intellectual and human.



The task of creating a qualitatively new technological base for the industry should be solved on the basis of the wide use of technologies of the 5th and 6th technological orders, informatization, miniaturization, individualization and network organization of production, wide use of the creative potential of workers (Kharlamov et al., 2015, Polozhentseva, 2016; and other), etc. One can not speak of the current re-industrialization, in the "classical" sense, as the industrialization of the economy of a retrospective period. The goal of reindustrialization as an economic policy, which is a set of concrete measures, should be the restoration of the role and place of industry in the country's economy as part of its structural adjustment as a basic component, and the priority development of the real sector of the economy on the basis of a new, advanced technological order.

One of the consequences of deindustrialization in Russia is the diminishing effectiveness of Russia's integration into the world division of labor. Deindustrialization processes have occurred over the past decades in the economies of the United States, United Kingdom and other developed countries. But they developed differently. Industrial production was transferred to developing countries. At the same

time, technology development, R&D units, management and financing centers remained in developed countries. This made it possible for their companies to extract a greater specific income per unit of invested resources. In global value chains, developed countries have high-yielding links.

In Russia the situation is reversed. National companies tend to participate only in the initial stages of global value chains. This not only generates import dependence on a number of basic products and technological dependence on developed countries, but also reduces the level of economic security. One of the goals of re-industrialization is to occupy a fundamentally different niche in the world division of labor than the one that now belongs to Russia. We must avoid specialization in the production and supply to the international markets of low-grade products: natural gas, oil, ferrous and non-ferrous metals, potash fertilizers, etc. But not by building up the high-tech exports already in existence (it is mainly connected with armament and military equipment), but by entering new markets with new products (information and communication technologies, transport systems, including the Arctic, nuclear energy, materials production with given properties, etc.).

In the future world, those economies that will be able to take the leading positions in the sphere of development and application of high technologies will be competitive and ensure the quality of human capital that can realize them. Technological modernization of production is the main factor in ensuring the solution of this problem. But in order to achieve technological leadership, it is necessary to update production capacities, modernize the fixed capital of enterprises. This is confirmed by data on the degree of depreciation of fixed assets of Russian enterprises (Figure 2). This indicator stably exceeds 40% and has a stable growth trend with a linear trend. It is obvious that it is impossible to produce innovative products on physically and morally obsolete equipment.

Compiled by the authors according to the Federal State Statistics Service (http://gks.ru).

Fig. 2: Dynamics of depreciation of fixed assets of Russian enterprises, %.

Is the solution to the task of updating the equipment of the industry on a national scale realistic? The authors believe that yes. Under the current management system, when business in Russia is predominantly private, it is necessary to solve this problem by developing partnerships between the state and business. The state should not only pursue a strategic goal-setting (an example is the implementation of the state program of the Russian Federation "Development of Industry and Enhancing Its Competitiveness"), but also to establish a system of indicators of technological development coordinated with the interests of private business and create institutional conditions (administrative support, interest rate subsidies on credits, tax incentives, etc.) for the technological re-equipment of industry. Forms of state support are described in the Federal Law "On Science and State Science and Technology Policy" of 23.08.1996 # 127-FZ. But, unfortunately, they are not being used actively enough.

In the Concept of Long-Term Social and Economic Development of Russia for the Period to 2020, the strategic goal is to make Russia one of the global leaders in the world economy. An innovative model of economic growth presupposes the ability not only to produce new knowledge embodied in new technologies, but also to effectively introduce the latter into production using appropriate types of new technology. Only an innovation that has passed from a full life cycle - from the germination of an idea to diffusion, complete "dissolution" in economic practice, turning into a traditional routine technology - can give impetus to development. This requires a developed industrial base. It is not accidental that in the innovative economy countries with developed industrial potential are leading, first of all - with modern machine building and instrument making. These industries are the nucleus of national innovation systems: on the one hand, they themselves form a steady demand for technological innovation, and on the other hand they promote their practical development in production processes and in the social sphere.

At the same time, the phase of production of final consumer and investment demand using new technologies and technical means can be carried out outside the national territories (production outsourcing). But the owners of technological knowledge and integrators of the production of the corresponding types of new technology, and consequently, the recipients of innovative rent, remain, and increasingly become, companies - innovative leaders. In the future economy, new conditions are proposed for the development and maintenance of competitiveness, based on advancing technological growth. Only such growth can ensure national economic security. Not only the scale of industrial potential, but also its innovativeness, ability to technological renewal play a primary role in maintaining the competitiveness and development of both a particular business and the national economy as a whole.

The essence of the modernization of the Russian economy is the renewal of its industry on a qualitatively new technological basis, in the transition from technological to meta-technological leadership. When implementing such a modernization strategy, it is advisable to take into account that the policy of stimulating the innovation-technological leap must be implemented through the re-industrialization of the economy in the context of the need to solve import substitution problems. Starting with a phased, "layer-by-layer", deepening from simple to complex import substitution, continued with the appropriate restructuring of exports, Russia can deploy the country's re-industrialization. This should form the basis of industrial policy.

Conclusion

The level of technological development in the perspective model of the economy is not only a factor of competitiveness, but also as a factor in ensuring national economic security. Providing technological leadership, in this regard, is becoming one of the key tasks of state policy. International competition is exacerbated in this sphere. Without the active support of business, the state can not achieve technological leadership. In particular, this is true for catching countries, for example, Russia. To stimulate economic growth, increase the quality of life of the population and ensure national economic security should be integrated. This can be done by accelerating technological development. The state economic policy should be concentrated on the solution of these problems.

Fostering Community Engagement through Crowd sourcing: Case Studies from the Czech Republic

Barbora Haltofová, Tomas Baa University in Zlín, Faculty of Management and Economics, Zlín,

Czech Republic, haltofova@utb.cz

Abstract

Crowdsourcing in urban governments is defined as the use of new technologies in order to take advantage of citizen knowledge to find solutions to municipal problems. Driven by the constant technological advances and ubiquitous Internet connection, the crowdsourcing platforms are proving to be valuable tools for triggering and engaging the public towards active participation and the collection of citizen knowledge through crowdsourcing has become commonplace. In this article we present the emerging role of crowdsourcing in public administration and systematically review existing crowdsourcing initiatives deployed in the Czech Republic. We first introduce the overall challenge of information collection in public projects. Then, we identify two crowdsourcing usage types: crowdsourcing for participatory budgeting and crowdsourcing for environmental data collection, and illustrate with examples of case studies from the Czech Republic that crowdsourcing leads to deeper civic engagement.

Keywords: Civic Engagement, Crowdsourcing, Participatory Budgeting, Environmental Data Collection.

Introduction

Citizen´s engagement is considered as one of the important dimensions for the development of smart city (Boukhris, Ayachi, Elouedi, Mellouli et Amor, 2016), which is a new city model resulting from the rapid development of new technologies and innovation processes. According to Gooch et al. (Gooch, Wolff, Kortuem, et Brown, 2015), smart cities must focus on people rather than on technologies, or better, as stated by Desouza and Bhagwatwar (2014), to use the potential of technologies to foster citizens´ engagement by deploying of technology-enabled participatory platforms for civic engagement.

In this context, the notion of wisdom of the crowds (Surowiecki et Silverman, 2007) has gained the importance. Crowdsourcing enable public officials to work outside the traditional structures (Dirks et Keeling, 2009) and engage citizens in innovative ways such that local issues are resolved without causing much strain in their resources (Desouza et Bhagwatwar, 2014).

Here we present different crowdsourcing initiatives deployed in the Czech Republic, focusing on participatory initiatives organized in Czech cities, such as participatory budgeting and environmental data mapping through crowdsourcing. In this article, we explore the role of participatory budgeting and volunteered geographic information in encouraging citizens to contribute to important local issues through crowdsourcing.

Crowdsourcing to Foster Community Engagement

Crowdsourcing is a term coined by Howe 2006) referring to the process of outsourcing a task to the crowd – an unknown group of individuals, non-experts or experts, acting as volunteers. Despite this

concept has primarily been developed in the field of business, it can be used as a particular form of citizen participation in the public policy process (Brabham, 2008) (Brabham, 2009).

Citizen e-participation in urban governance is defined by Silva (2014) as the ubiquitous use of information and communication technologies to support citizen involvement in the urban policy process, in its different stages, without limits of time and space, through processes of information, consultation or active participation, being crowdsourcing in urban governance a specific mode of active e-participation. As stated by many scholars (Macintosh, 2004), (Fung, 2006), (Albrecht et al, 2008), the value of e-participation is closely linked to the level of citizen engagement.

The move from off-line and paper-based urban governance to a mode based largely on digital and online environments requires new working methods and new tools (Silva, 2014) such as innovative Web 2.0 applications (Casey et Li, 2012), user generate content applications, citizen consultation platforms, central portals for petitions, social computing platforms, geo-visualization and geo-location technologies (Anttiroiko, 2012), and mobile applications (Sundstrom, 2012). Although these tools are now opening new channels and possibilities for communication between citizens and government, offering new possibilities for data collection, information and consultation in urban governance, many scholars (Moody, 2007), (Sieber, 2008) agree that they should not be seen as a replacement of conventional modes of citizen participation in urban governance, but should be seen rather as a complement to traditional participatory methods and tools.

Although in most cases e-participation is part of a wider participatory process that also includes non-virtual and off-line activities, the tendency seems to be for public officers to use little by little the new e-participation tools as they allow simpler, inexpensive, less time-consuming and more effective way of interaction with citizens, and thus foster citizen engagement in urban governance (Silva, 2014).

In the remainder of this paper we outline how different crowdsourcing tools are used to foster community engagement in the Czech Republic. This is presented using case studies.

Crowd sourcing for Participatory Budgeting

Participatory budgeting (PB) is a form of active civic engagement that enables citizens to participate in budgetary decision-making processes. It serves as an instrument by means of which citizens are capable of deciding on the projects in which the public money will be invested (Boukhris et al, 2016), and thus directly influence the allocation of public financial resources. As PB empower citizens by providing them with the mechanism to express their preferences and opinions, it contributes to civic engagement (He, 2011). This is confirmed by Garcia et al (2011) who states that as people feel their suggestions and demands are heard by the government, their actual desire to participate will increase.

Simultaneously, many scholars agree that PB has the potential to change the relationship between local government and citizens in favor of the latter. In the context of PB, citizens have greater feelings of access to a local government, and better understanding of the complexities of spending public funds. This leads to more positive view of government officials, and bolsters the legitimacy of local government (Swaner, 2017). Citizens not only become familiar with public finances´ operations, but also exercise control over local authorities which helps bridge the distance between them (Soltysiak et Suraj, 2016). PB is viewed as an instrument for introducing local democratization as well (He, 2011). According to Brun-Martos and Lapsley (2017), the idea of PB has the potential to enhance both democratic accountability and effective city management through transparency. It allows the enhancement of social inclusion, and thus the development of civil society (Soltysiak et Suraj, 2016).

Participatory budgeting in Czech communities is still in its infancy. However, there are some city leaders who decided to modernize the established practice and provide citizens with greater transparency by inviting them to the budgetary activities. One such as city where PB is operating is Prague-Zbraslav. The case study will be presented within the next chapter.

Crowd sourcing for Environmental Data Collection

Researches (González, Gilmer, Foley, Sweeney et Fry, 2008), (Bugs, Granell, Fonts, Huerta et Painho, 2010) show that crowdsourcing can be used as a support in environmental data collection. Recent advances in Geographic Information Systems (GIS) as well as in Web 2.0 technologies provide new ways of creating and sharing of georeferenced user-generated contents which may complement traditional spatial data sources. The availability of Global Navigation Satellite Systems (GNSS) and sensors in smartphones, as well as geo-browsers or location-based social networks enable to produce the novel type of geographic information, commonly referred to as a Volunteered Geographic Information (VGI) (Goodchild, 2007). This novel source of information collected by way of crowdsourcing is becoming especially important where authoritative geographic information is lacking, therefore institutions use it as a mechanism to build local capacity to support collaboration, supplement traditional data sources, and inform decision-making (Fast et Rinner, 2014).

As a result of the use of VGI, sophisticated Web and smartphone mapping applications are created. Through these apps emphasizing the role of citizens as volunteer sensors (Goodchild, 2007), citizens can report various types of non-emergency civic issues helping the local authorities to find out and map problems in their surroundings.

Usually, when citizens tap into an illegal waste dump or any other civic issue they want to complain their municipality about, they have two options. They either go personally to the city hall, or they visit the municipality´s website where they look for the contact information of the officer responsible for an issue. As it may be confusing and time-consuming procedure, they are not motivated and usually forget about their claim. This way of traditional reporting leads to a decrease of the interaction between authorities and citizens willing to report the issues. Therefore, a faster and easier way is needed (Alikhani, 2011). The web/smartphone application through which citizens report civic issues simply by choosing the category for the issue, pointing the position on the map, and optionally add a photo with some details about the issue, is the solution which leads to the greater civic participation. As stated by Bugs et al (2010), these geo-crowdsourcing apps not only strengthen social interactions between the citizens and their municipalities, but also improve the public participation.

The GIS-based crowdsourcing mobile applications taking advantage of geographical information provided by the crowd deployed in the Czech Republic can be divided into two groups according to their provider: those which are provided by the third, usually commercial party, and used by multitude of municipalities (e.g. apps Dej tip, Lepší místo, ZmapujTo, etc.); and those which are created by city IT specialists, and used exclusively in one municipality. One such as app is Plznito developed and deployed in Pilsen which will be presented within in next chapter.

Case Studies

In this chapter, two case studies will be presented. One dealing with the participatory budgeting practice in city district Prague-Zbraslav, second dealing with the use of mobile application for reporting civic issues in Pilsen city.

Participatory Budgeting in Prague-Zbraslav

City district Prague-Zbraslav joined the pilot project called the "Participatory Budgeting – an Innovative Tool for City Hall Dialogue with Citizens" in 2015. The initiative was successful. Therefore, one year later the city representatives decided to build on the experience of the pilot year, set more courageous goals, and allocate 1% of the municipal budget (1 million CZK) to projects designed by community members. As the city representatives wanted to make it easier for participants to share ideas about the projects, enable community feedback, ensure safe registration, and give the opportunity to vote online, they have used the D21 digital voting system.

The city hall at first launched the information campaign through the Internet, local newspaper and outdoor promotional areas. The aim of the campaign which culminated on September at a public meeting was to explain what is expected and how to proceed with the process of drafting and submitting proposals. By the end of October, citizens could submit their ideas either electronically, or in a paper form to the registry office of the City Hall. In total, 19 proposals were submitted, each being analyzed with respect to their feasibility and expensiveness. The public discussion, during which all feasible proposals were presented to the public, was next. Finally, the public vote through the voting application was realized. The application was accessed through the web, where all the proposals were described in detail. The voters were able to vote during February for any proposal, each having four positive and two negative votes. Citizens without Internet access were able to vote physically with the help of the public officers at the City Hall. Voting results were published at the web, further via other media, and send by e-mail to those who leave their e-mail address in the voting application. Immediately after announcing the winning projects, the City Hall started in cooperation with the designers, to prepare the realization itself (Agora-CE, 2017).

In total, 1 556 citizens were involved in the vote, and they have chosen 5 from 13 originally submitted proposals (see Table 1 – The Submitted Projects). Concerning the voters, only one quarter declared that they live and work/study in Prague-Zbraslav, while 47, 8% of voters live in Prague-Zbraslav but work/study elsewhere. The most represented age group were citizens aged from 31 to 40 years (31, 9%), followed by 41 – 50 (21, 5 %) and 21 – 30 (17, 4%) years old. The number of female voters (56%) predominated.

Tab. 1: The Submitted Projects

	Votes in total	*Positive votes*	*Negative votes*	*Costs (CZK)**
Outdoor workout course	**684**	**709 (46%)**	**25 (2%)**	**250 000**
Fixing community road	**470**	**557 (36%)**	**87 (6%)**	**248 000**
Outdoor table tennis tables	**419**	**473 (30%)**	**54 (3%)**	**186 000**

The most successful project was the construction of the outdoor workout course, which received 684 positive and 25 negative votes. The statistics shows that while 46% of citizens voted for the winning project, only 2% declared against this project. The second winning project was fixing of about 350 meters long damaged community road. This project received 470 positive (represented by 36 % of voting citizens), and 87 (represented by 6% voting citizens) negative votes. Third most successful project was construction of two outdoor table tennis tables decided by vote of almost one third (419) of voting citizens (D21, 2017).

The total costs of realized projects was 984 000 CZK. The city representatives, who earmark 1 million CZK for the participatory budgeting initiative, were satisfied with the results. As stated by Filip Gaspar, the Deputy Mayor of Zbraslav: "Not only record number of projects was submitted, but twice as many people joined the poll than last year." (Joachymstál, 2017) Moreover, as the number of citizens involved into the project doubled comparing to the previous year; the city representatives state that the participative budgeting initiative has been a great success.

Civic Issue Monitoring Application Plznito

The city of Pilsen, in its endeavor to simplify communication between the citizens and the municipality officers, has developed a web and a mobile application which enables citizens to communicate actively with the office through the website or by means of their smartphones (MPMP, 2015). The Plznito is an e-participation application online and mobile platform, available for iOS, Android and Windows operating systems, which improves the communication between municipality officers and inhabitants of Pilsen

allowing them to report almost any kind of non-emergency issues in their neighborhood. With Plznito, citizens can report defects and damage to urban property, such as overfull litter bins, damaged benches or non-functioning public lighting lamps, in easy way by couple of clicks.

With Plznito, Pilsners have several possibilities how to inform their city officials about civic issues. They can either use the web portal, or download a free mobile application to their smartphones directly form the web page www.plznito.cz, or via Google Play, Apple Store or Microsoft Store.

Once having installed the application, a citizen only needs to select the exact location on the map (the smartphone pinpoints the position thanks to its GPS location), select the category (car wreck; road sign; pavement; sewer system; benches and banisters; waste and waste dump; sandpit, playground and playing field, roads and cycle tracks; public green; street lighting and public transport stop), and take a photo of the issue being reported. Then, the report is sent to the official responsible for the resolution of the problem. Citizens not having the smartphone can alternatively use the web and report via an online interactive form which can be opened in a computer with a common web browser.

Each report is verified by an administrator and sent to the official assigned to the issue. He/she processes the report directly in its administration interface, by changing the status of the reported issues to inform the users, and leaving the comments with feedback on state of the problem handling (MVČR, 2017). In case he/she needs more information about the issue, he/she can ask the citizen once filled his/her e-mail address. At the same time, the report appears on the interactive map with detailed information. The Pilsners can therefore track the processing of their reports. Moreover, all citizens can easily look into the interactive map and see what is happening in their municipality.

The Plznito was launched in April 2015. Since, more than 3 000 reports have been submitted, from which 2 604 have been successfully resolved. As stated by city representative, the city had noticed the increased public participation since the deployment of the app (Smetanová, 2016).

Conclusion

This paper´s assumption is that crowdsourcing help to develop alternative ways for public participation, encourage open communication between citizens and decision makers, and thus foster civic engagement. The goal of this article was to outline how some of the Czech municipalities, namely Prague-Zbraslav and Pilsen, interact with their citizens by way of crowdsourcing. We explored the potential role of crowdsourcing technologies, namely voting and mapping websites and mobile apps, in encouraging citizens to contribute to important local issues such as participatory budgeting and mapping non-emergency civic issues by providing an effective computational support to participatory collective decision-making.

The results of first case study show that participatory budgeting not only open new channels of communication among residents and local officials but also forge a collective communal identity among those who participate. What is more, it has been shown that the participatory budgeting can be more creative than normal urban bureaucratic process.

In addition, it has been indicated that geo-crowdsourcing could help citizens as well as public officials to spatially visualize and understand where the problems are located allowing these two groups to communicate more effectively. Moreover, it has been recognized that geo-crowdsourcing is able to provide significant benefits in public participation and enhance opportunities to not only to involve the public but also to identify spatial data about the potential problems that either had not been considered, or had been hard to identify in a tradition way.

The outcome of this article, based on two case studies from The Czech Republic, suggested that crowdsourcing could facilitate participative processes and has the potential to significantly contribute to the openness and accountability of decision making. The results obtained from both case studies show that the crowdsourcing initiatives have been able to foster civic engagement and provide useful input data not only to public officers, but also to citizens themselves.

Abstract

The purpose of presented research is to confirm the hypothesis that the reduction or elimination of internal innovation environment barriers in the economic system and, as a consequence, the stable innovative growth of the Russian economy can be achieved by increasing the value-added of businesses. The current paper examines the link between value-added created by regional industries (Gross Regional Product) and innovative activity of organizations in the region (different indicators). Most importantly, the study finds that most of these innovation indicators are considerably linked with regional economic growth. It has been determined that increase of value added share in the total revenue structure is motivating factor for owners and employees of enterprises to innovate. Hence, in the context of Russian regions the relationship between value-added and innovative activity of organizations is statistically confirmed. Allegedly, management of innovation system should be aimed at formation of efficient institutions for innovation development, identifying main directions of development, and promotion of interaction among all stakeholders. The main contribution of this research is the understanding that there is simultaneous relationship between regional innovation effectiveness and value added created by organizations. The policy implication of this study is that countries should recognize the key internal motives for innovations' reproduction in the economic system.

Keywords: innovation system, value added, innovation system development, management concept

Introduction

The economic balance of the world's economy power has also been changing during recent decade. The Russian economy is exhausted; growth rates are falling. Russia is attempting to speed-up economic growth. The escalation of geopolitical tension, objectively determined by structural changes that accompany the occurring shift of techno-economic paradigm, is strengthening by the low efficiency of the Russian economic system. Along with competent political decisions, there is an urgent need for a new economic policy. This innovative scenario of economic development is recognized to be the only possible one by the most number of leading researchers. The geopolitical crisis and the policy of sanctions pressure towards Russia have opened many implicit problems that exacerbated by the fall in oil prices, as well as the suddenly unfolding policy of import substitution and economy modernization. It is noteworthy that the reverse side of the current crisis can be the generation of a powerful momentum for the mobilization of hidden reserves for development and realization of potential possibilities of the national innovation system. The last year has shown that to solve the problems of innovation system management, the existing approaches, tools and mechanisms, which are not considering features of the current crisis and behavior of the leading factors of the economic system, are insufficient. We have to state that the antimonopoly regulation and competition have exhausted themselves, there are new challenges that require fundamentally different methodological approach to the analysis and scientific comprehension of principles and innovative system management tools at the macro, meso and micro levels. In order to

overcome these problems and take into consideration the current economic, political, environmental, social and technological frameworks there is a need for a development model, that takes into account all those mentioned above perspectives and considers the adoption of long term view for achieving innovation system effectiveness. In Russia, as well as in other similar macro-economic systems, government intervention is required in economy and innovation processes as a generator of incentives for innovation, which neither the market nor the current poorly developed institutional environment are able to insure. It is necessary to realize that the implementation of the innovation system model, which has successfully established itself within the framework of other socio-economic systems, leads to unpredictable results, because the existing institutional environment is not ready to accept and adapt the implemented principles and mechanisms of management. In Russian economic conditions the overcoming «path dependence» can be achieved, in our view, by taking into account the key patterns and principles of innovative economic growth and development. A number of leading scholars have assumed that path dependence is one of the fundamental features of the economic system (Walker, 2001; Margolis, Anon, 2016). Building on these studies as well as the frameworks of innovation system concept, described by C. Freeman, B.-A. Lundvall and R.R. Nelson, we propose the necessity of the coherence and correlation of socioeconomic and innovation state policy. We draw on the thesis that innovative activity should be integrated, inherently presented in the economic mechanism of all economic entities, it also should be carried out without any barriers. Hence, the principal point is to reveal the key internal motives for the reproduction of innovation in the economic system and effective governance of which will facilitate their dissemination and self-development of innovative systems as a whole. It has to be admitted that the antimonopoly regulation and competition, which worked effectively in an industrial economy, have exhausted itself. There are new challenges that require completely different management approaches. According to O.G. Golichenko (2011) "In the economy, where most of the institutions have long been obsolete, it is impossible to create a modern national system". For developed countries, the positive effects of innovations on the economy take place when economic agents effectively operate on the market and the owners of the enterprises have high propensity to reinvest its profits productively, that leads to the active private sector development. This leads to the investment attractiveness in the short term and provides the basis of the expanded reproduction in the economic system. One of generally recognized indicators that assess the effectiveness of innovation, as it is known, is the innovative activity of the enterprises. It is obvious that in the economic sector of our country has developed a practice when the innovative activity of the enterprises has been extremely low (Table 1).

Table 1: Innovative activity of the enterprises (the proportion of organizations implementing technological, organizational and marketing innovations in the reporting year, in the total number of organizations surveyed)

Industries	The proportion of organizations implementing technological, organizational and marketing innovations in the reporting year, in the total number of organizations surveyed (percentage)				
	2012	2013	2014	2015	2016
Altogether	10,3	10,1	9,9	9,3	8,4
Extracting industries	8,2	7,6	7,5	6,9	7,4
Processing industries	13,4	13,3	13,6	13,3	13,3
Production and distribution of electrical energy, gas and water	5,6	5,3	5,1	4,9	4,8
Communications	13,3	14,2	12,2	13,3	12,2
Activity connected with the use of computer facilities and information technologies	13,3	14,2	12,2	13,3	12,2
Research and development	13,3	14,2	12,2	13,3	12,2
Providing other services	13,3	14,2	12,2	13,3	12,2

Compiled by the authors according to the data of Russian Federal State Statistics Service. URL: http://www.gks.ru/

Thereby, the innovative activity of the enterprises in Russia has been at a low level in recent years. Meanwhile, according to the level of this index, the Russian economy is noticeably inferior to not only leading developed countries (Germany – 70%; Canada – 65%; Belgium - 60%; Ireland, Denmark and Finland – 55–57%), but to the most of Central-Eastern European Countries, where the figure is in the range of 20–40%. In addition, Russia lags significantly behind in terms of the export of high-tech products on international market. Russia's share in this market is only a quarter percent (Gohberg, 2011). It is necessary to identify the underlying reasons for these negative economic consequences, in order to use them in the management practices. The copying of forms, methods and innovation management models, had been successfully implemented in most of foreign countries and had a great impact through the contribution in innovation development, did not work in Russia. These attempts have been undertaken for a long time and, obviously, have not led to the expected results that is statistically confirmed.

Literature Review

In this paper, we specifically look into the linkage between innovation and economic growth in the selected Russian regions. Awareness of the significance of innovation in economic development is correlated with the growing interest in this issue within the academic community. In parallel, awareness of the phenomena of innovation and accumulation of empirical data in this area are increasingly growing. Innovations even more often are described as a process endowed with special properties, the combination of which determines the need for the simulation an approach going beyond the classic "mainstream", that is, beyond the paradigm that recognizes the existence of a superrational representative agent. There is a need for conducting the analysis of research questions directly and indirectly related to the problem of innovation system development. The relevance of the innovation was recognized already in the 18th century. A. Smith in his famous work “An Inquiry into the Nature and Causes of the Wealth of Nations”, mentioned about the new generation of specialists who would increase productivity through knowledge. J. Schumpeter highlighted that innovation is a huge force of the economic activity (2008). A brief analysis of innovation is made by Jon Sundbo (2003). He presented the development of the innovation theories, various approaches to the concept starting from the papers which treat this subject based on the definition of Schumpeter, in a classical way, to the modern studies published after 1970 when the innovation started to be considered a priority theme. Moreover, approaches from the narrowest to the broadest definition can be found. Abernathy and Utterback distinguished the radical innovation and incremental innovation in 1978. L.D. McLean’s paper presents a review of the existing literature, the major contributions on organizational culture and creativity and innovation, supports and impediments to organizational innovation (2005). Long years, the neoclassical economical approach has been criticized for its failure to include institutions into their theories and models (Nelson, 1993). Partially, as a response to this challenge, scholars invented the National Innovation System concept. Notoriously, the innovation system conceptual framework appeared in the late 1980s and came from researchers like C. Freeman, B.-A. Lundvall and R.R. Nelson. According to this framework innovation system is consist of such sectors as government, university, industry and their environment. It focuses on the relationships between all sectors as the reason that explain the performance of innovation system. This approach offered a new rationale to explain the technological gaps and competitiveness, that led to numerous debates among the scholars. According to R.R. Nelson, national innovation system can be defined as «a set of institutions whose interactions determine the innovative performance of national firms» (Nelson, 1993). The concept of innovation systems focuses on the complex web of relationships and interactions among the various actors in the processes of knowledge creation, distribution and utilization. This approach allows us to analyze the most important issue of "innovative activity" to capture the phenomena more comprehensively, with a focus not only on result - innovations, but also on the processes leading to them, and the diversity of actors involved in the creation of these innovations. Innovation systems approach is based on the knowledge and conceptualization of thesis that an innovation process is non-linear process and it involves different actors with their own interests, engaged in coevolutionary processes. The academic literature is quite extensive on issues concerning determining the most suitable scale to sustain innovation system (local, regional, national, international levels etc.). We should to state, scientists more and more often have been perceived the region as a locus of innovation. Regional innovation system

(RIS) is a concept assumed that interactive relations between the RIS organizations are regarded to be of central importance (Cooke, 2001, Asheim and Gertler, 2005). An institutional approach to the problem of innovation effectiveness has played a significant role in understanding the mechanism of innovation, focusing on the adoption and adaptation of new ideas and practices, showing that in the process of diffusing innovation, the interaction between people takes a leading role. The institutional approach has largely been developed within the framework of economic and juridical disciplines and has revealed objective patterns in the functioning of society, as well as in the nature and content of the existing social order. Russian scientist, economist and sociologist V. V. Radaev (2002) implies that, from the viewpoint of modern institutionalism, institutions are considered not as a rigid frame, but as a flexible supporting structure which changes under the influence of practice and has typical ways of acting Institutions simultaneously regulate human interaction and are governed by them. More accurately, according to Menard and Shirley (2008), "Institutions are written and unwritten rules, norms and constraints that humans devise to reduce uncertainty and control their environment. These include written rules and agreements that govern contractual relations and corporate governance, constitutions, laws, rules that govern politics, government, finance, and society more broadly, and unwritten codes of conduct, norms of behavior and beliefs. One more significant question is what are the main incentives to innovate under the current socio-economic conditions? In this sense, it will be important to consider the link between Gross Domestic Product (GDP) and innovation effectiveness. It is assumed that innovation helps in the economic growth by enhancing it. Nekabashi et al. (2013) have highlighted that the institutional quality affects the innovation standard. Authors have also mentioned in their study that the stimulation of innovation with institutional quality enhancement often leads to higher growth. Galindo and Picazo, (2013) worked on studying economic growth, innovation and entrepreneurship. Authors have assumed that innovation plays a central role in the economic growth process and the entrepreneur is the vehicle to introduce the new technologies to improve the firms' activity and to obtain higher profits. Other studies published in the last decade by Rosenberg (2004); Castellacci (2005); Fagerberg (2004, 2006), Cameron (2010) have also found that the innovation is the engine of the growth, an important element of the development achievements. R. M. Goodwin (2008) developed a tri-dimensional model to study the interaction between the business cycles and economic growth. P. Romer worked in the field of the theory of growth and innovation. G.M. Grossman (1991) contributed to the growth theory by indication the role of the innovation in the growth: he revealed the resources which provide the long term economic growth. In the last period, the number of studies that explain and introduce the role of innovation in socioeconomic transformation of developing countries has been growing increasingly. They proposed that the innovation activities in developed and developing countries must be treated in a different manner. Despite the rising interest of scientific community with regard to the problem of innovation development effectiveness, the issue is still unsolved concerning what reasons determine that implementation of innovation system model, which successfully established itself in the management practice of some countries, leads to negative results within the framework of certain socioeconomic systems.

Hypothesis and Methodology

Smith argues (1995), that an innovation performance of an economy depends not so much on how institutions perform, but on how they interact with each other. Precisely, the key problem is an ability to utilize knowledge, that is abundant. In our previous work we found out, that innovation system lacks a very important element of the knowledge assimilation. Thereby we concluded, the subsystem of mechanisms of knowledge assimilation must be presented in the innovation system. It will allow to realize the innovative potential of the domestic companies through the formation of the primary ideas - the driving force in the development of innovative systems, indicating the need for new innovations in the company. Hence, for effective exploring fundamental knowledge in the country and in the world we need to create an effective system of its assimilation within entities (Vasin and Gamidullaeva, 2015). Thereby, the main question within this study is what are the main incentives for introduction of knowledge assimilation mechanisms into the companies' management systems? The essence of innovation manifested in growing instability in the existing enterprise communications and relations, and as a consequence in the growth of overall costs at intermediate stages of the innovation process. Hence, it

resulting in low innovation activity of economic entities, that can be explained by relatively high rate of innovation costs, which for the most part made up of transaction costs (mainly due to the need of the collaboration and networking) rather than of transformational (related with the transformation, a change of inputs). This occurs because an innovative product is transferred to a new system of B2B (business-to-business), and its realization is usually carried out in the B2C sector (business-to-consumer). This, in its turn, makes it impossible to use only governing approaches to innovation system management. The lack of mutual awareness between economic agents in Russia causes high risks of doing business, as a result, for instance, – an inadequate high cost of bank loans. Accordingly, in the absence of access to "long term" money, companies are forced to narrow the scope of investment activity, which subsequently almost completely reduces motivation to create and implement innovation, being reflected in the country's economic development. Monopolization is likely to have a similarly negative impact on innovation development. It leads to the fact that at this level of competition among Russian enterprises, the straightening of innovative activity is useless for owners of businesses and carried out in most cases under the condition that it is necessary step towards the publicly funded. As a result, we can observe a growing disparity between the cost of the state on innovation development and the level of innovation activity of Russian enterprises. We should to state, that the level of budgetary expenditure on research and development in the Russia is quite high and is ahead of countries such as USA, Japan, Israel and China. At the same time, the percentage of organizations carrying out technological innovation, has been steadily decreasing. The Russian practice of shaping innovation infrastructure where the majority of budgetary resources are mobilized, is developed de facto following the logic of industrialization, primarily for replication of industrial and infrastructure projects. Basically, in our view, a clear understanding that without the creation motives for the innovative development of economic agents, the innovation process is likely to continue to be mainly a rare phenomenon in the Russian economic system, giving way to a reduction in competitiveness and economic slowdown. We absolutely agree with the point of view of scientist L.I. Abalkin (2002), who formulated the essential precondition for the progress in science and technology. He argued that scientific and technological progress and the associated high culture of production and labor will be of great benefit and in demand if this would yield the revenue exceeding potential cost savings on salaries expenses. It logically follows therefore that the overall growth of incomes of workers, which constitute a substantial share of the enterprise's costs, is inevitable when the enterprise is engaged in innovation activity. In fact, the practice proves that the enterprise involvement in innovation activity does not always have a positive impact on the business in terms of enhancing economic efficiency. All of the above determines the following conclusion: the owner of the company will be motivated to innovation, provided that the effectiveness of such innovative projects will exceed the loss of the benefits of saving money on the qualifications and quality of labor resources. This, in turn, confirms the following thesis that without the creation of motivations and drivers for the market players to innovative development, the innovation supply would not match with the innovation demand and innovative development remain a rare phenomenon. Thus, the fundamental question is to determine the key internal stimulus for the reproduction of innovation in the economic system. Their management would in fact enhance the diffusion and dissemination of innovations. We argue that as the main element, that it is reasonable to optimize in the process of macroeconomic policy should be considered value added and its structure. Along with the significance of tax policy, competition, etc., it should be noted that low pay levels and added value created, provide the inability of mass diffusion and application of innovation within certain economic system. To increase added value we need to use not only the innovation potential of the enterprises, but also of institutional factors, which are seen in the current economic conditions of Russia more effective than others, in particular the demand factors. In order to stimulate enterprises to be actively involved in the innovation process, there is a need in institutional support of the process in terms of the creation of appropriate institutions at the micro level. In this process, the government' efforts could affect only indirectly. The initiative must come from the owners and managers of enterprises which want to maintain its competitive advantage and to remain competitive in the innovation economy. In our opinion, the development and improvement of institutions at the meso and macro levels of the innovation system will likely to have a positive impact in the form of the institutionalization of innovation at the micro level of economic system. The study hypothesis is the following: the reduction or elimination of internal innovation environment barriers in terms of the

existing economic system and stable innovative growth of the Russian economy can be reached by achieving the growth of value-added of businesses and, as a consequence, innovative development of certain regions and the country as a whole. GDP is the market value of goods and services produced within a country. It is known that GDP comprise of different sectors composition such as agriculture, manufacturing and services. Each country has a different percentage of agriculture, manufacturing and service % in the GDP. Some countries have largest share of services and other have manufacturing or industry among sectors for GDP. This together gives an indication of the economic health of a country. GDP has a great impact on the citizens of the country. Almost, all sectors of business get benefits because of good economic growth. Standard of living can be raised with the economic development of a country. For determining a level of country's innovation performance there are some generally accepted indicators. In the first instance should be mentioned the Global Innovation Index (GII). This is an indicator that ranks countries for having environment for innovation and the output of innovation. GII is a formal model which responded to innovation challenges and applied to the worldwide context. Moreover, it is provided as a very useful tool to help business leaders and policymakers to identify challenges, to improve competitiveness and innovation. Several studies assess the innovativeness of countries. Both INSEAD and the Innovation Capacity Index use a comprehensive methodology to measure and rank the innovativeness of approximately 130 countries. Both use a combination of around 60 variables that cover both enablers and output of the innovative power of countries. INSEAD's Global Innovation Index is the most comprehensive of the two as it, in addition to technological innovation, also includes business and social innovation. The Global Innovation Index (GII) by INSEAD Business School is based on innovation input and innovation output each calculated from different pillars. Its input index covers institutions, human capacity, ICT uptake and infrastructure as well as market and business sophistication. The output index measures scientific and creative outputs and social well-being. Furthermore, each pillar is divided into sub-pillars and each sub-pillar is composed of individual indicators. Both studies largely use hard data instead of surveys that are subject to perceptions. Data is drawn from sources like the World Bank, the United Nations and the International Monetary Fund. The Global Competitive Index (GCI) by the World Economic Forum is determined by a weighted average of 12 pillars: institutional environment, infrastructure, macroeconomic environment, health and primary education, higher education, goods market efficiency, labor market efficiency, financial market development, technological readiness, business sophistication, innovation. At the same time, it should be underlined that we are primarily interested in in innovation system at the meso-level (regional innovation system) in close connection with the innovation system of enterprises. Definitely, that the regional innovation system (RIS) operates and develops within a single state and is open to international cooperation. However, in our study we try to focus directly on the regional context of the innovative development and management. It is obvious that the disparities in the development level of different regions will always exist. All differences in socio-economic situation of the regions, especially in such a large and diverse countries as Russia, in parallel with the development of market economy will only get worse. According to international ratings of innovative activity and the competitiveness their level in the Russian Federation is extremely low (Table. 2).

Table 2: International ratings of innovative activity and competitiveness of some countries by the method of INSEAD and GCI WEF *

Countries	Global Innovation Index INSEAD, 2015		The Global Competitiveness Index WEF 2015-2016

Compiled by the authors

In this paper the relationship between Gross Regional Product and innovation activity of enterprises is examined. The research hypothesis was tested with correlation analysis between the three international indexes using Pearson correlation coefficient. According to the Constitution, Russian Federation consist of 85 Subjects of the Federation. To assess the level of innovation activity of the Russian Federation subjects we considered it appropriate to draw upon ratings of innovative development of regions, which were calculated by Higher School of Economics (NRU HSE) in the period from 2008 till 2015 as well as official statistical indicators in the same period. Russian regions vary greatly in the level of innovation activity. Lagging regions consist mainly of national territories, especially the republics of the North Caucasus, while the innovation-active regions are located in Central Russia. This may be due to the proximity to the sales markets, the multinational composition of the population living in these regions, which provides a variety of ideas and approaches to solving the problems of life. Innovation activity at the regional level is characterized by extremely high volatility.

Results

We started by testing the normality of the samples through Kolmogorov-Smirnov Test. In case the data follows a normal distribution, it means that we can use Pearson correlation coefficient and in case this does not occur, we should use correlation coefficient Spearman Rho. Both these correlation coefficients evaluate the intensity of the relationship between ordinal variables and indicate the strength of linear association between independent and dependent variable. The correlation coefficient may be positive, if dependent variable tends to increase when independent variable increases, and negative - in the opposite case.

Kolmogorov-Smirnov Test was used and the significance levels are all greater than 0,05. It shows that all distributions are normal so we can use Pearson correlation coefficient to test our hypothesis.
The results of Pearson correlation test are presented in Table.

The Table 3 shows the correlation between the regional GRP level and individual indicators that characterize the innovative activity of organizations (the average values of these indicators):
1) Volume of innovative products, works and services (*Volume*);
2) Level of costs of enterprises in the region for technological innovation (*TechInn*);
3) Share of organizations implementing technological innovations in the reporting year, in the total number of surveyed organization (*ShareOrg*);
4) Ratings of innovative development of regions (*InnIndex*);
5) Innovative activity of organizations (*InnAct*).

Table 3: Pearson correlation coefficient between GRP and individual indicators of regional innovation activity

Correlations								
		GRPpercap	Volume	InnAct	InnIndex	ShareOrg	GRP	TechInn
GRPpercap	Pearson Correlation	1	,314	,176	,289	,137	**,876****	**,591****
Volume	Pearson Correlation	,314	1	,616**	,058	,055	,231	,145
InnAct	Pearson Correlation	,176	,058	1	,647**	,994**	,305	,281
InnIndex	Pearson Correlation	,289	,616**	,647**	1	,665**	**,397****	,346
ShareOrg	Pearson Correlation	,137	,055	,994**	,665**	1	**,362****	,302
GRP	Pearson Correlation	,876**	,231	,305	**,397****	**,362****	1	**,872****
TechInn	Pearson Correlation	**,591****	,145	,281	,346	,302	**,872****	1

**. Correlation is significant at the 0,01 level (2-tailed).

Therefore, the strongest association (high correlation) is between GRP and Level of costs of enterprises in the region for technological innovation (0,872), and also there is a noticeable association with the Ratings of innovative development of regions (0,397) and the share of organizations implementing technological innovations in the reporting year, in the total number of surveyed organization (0?362). Therefore, in the context of Russian regions the relationship between value-added and innovative activity of businesses is statistically confirmed.

Identifying Key Barriers to Innovative Development in Russia

Considering value added as the main goal of optimization, should refer to its structure, which in general consist of profits and wages intended to be distributed among managers and salaried workers, who are the source of its creation at the enterprise. Therefore, the maximization of value added requires increasing profits and salaries. Growth in profits from innovation, in turn, may be provided by a decrease in the level of transaction costs related with innovation activity. And therefore, increasing labor income - by increasing the share of value added, created by the intellectual capital, through its motivation for innovation. It is clear from the above considerations that the main barriers in the internal environment of innovation are the high transaction costs, related with innovation activity, and the low staff motivation to innovate. It should be clarified that under the minimization of transaction costs, we understand not reduce them down towards zero, but the optimization in the normal range, as they are objectively necessary for the functioning of economic systems. Stable innovative growth of the Russian economy can be reached by achieving the optimal level of transaction costs, which is a prerequisite for innovation development within individual regions and the country as a whole. In the frameworks of transactional approach, innovative activity of economic entities is considered as a set of transactions carried out with the aim of achieving a temporary competitive advantage. We agree with most of the critics of neo-institutionalism, as well as institutionalism as a whole, that the main problem of this theory is the vagueness of the terms and definitions. Indeed, there is currently no universally accepted definition of transaction costs, despite the fact that the representatives of these theories actively employ such terms in its conclusions and recommendations for policy makers. As a consequence, we encounter problem of evaluation, because you can not properly assess what has no unambiguous definition. According to A. Shastitko (1997) the growth of transaction costs is compatible "with increased efficiency and economic growth." The reduction of transaction costs at the macro level theoretically will provide increased demand for transaction services, and as a consequence, the growth of total transaction costs at the meso level, determined by an increase in the complexity of the economic system by improving co-operation processes, division of labor and of responsibilities between the various actors etc. According to a synergistic approach increasing the

economic complexity presuppose the increase in diversity of types of collaborations, occurring cyclically, being a "necessary condition for sustainable economic development" (Saviotty, 2001). At the same time in parallel with the increase in complexity of the system increases the difficulty of reconciling the operation of its individual elements, and, as a consequence, it results in increasing the value of the transaction costs. We can conclude, therefore, that the increase in transaction costs in the economic system is a reflection of the complexity of the processes of economic cooperation between business entities and economic agents. It is assumed that the institutions would not reduce the overall transaction costs, but only unit costs on separate operations. Thus, transaction costs – this is an objective indicator of the economic system.

Discussion and conclusion

We consider that the management of innovation development should be embedded in the management system, in a way that the control mechanisms would be coherent with mechanisms and patterns of self-organization and self-management. All participants of the innovation process must be able to interact without obstruction, build up experience in the implementation of joint innovation projects. Therefore, management of innovation system should be aimed at developing and implementing a strategy providing the formation of structure-attractors, attracting innovative trajectories of development, identifying the main directions of development, and promotion of interaction between all stakeholders. As attractors, we consider an innovative environment institutions, which have the greatest potential to reduce transaction costs related with innovation activity and optimization of the volume and value-added structure, generated by economic agents.

Based on the analysis it was found that the dual nature of innovation, which is manifested in the growth of instability and uncertainty in the existing communications and relationships for innovative enterprises, and as a consequence, increase the transaction costs of activities at the intermediate stages of innovation process, results in a low level of innovation activity of economic agents in the Russian economic conditions. It has been determined that increase the share of value added in the total revenue structure will be able to motivate the owners and employees of enterprises for innovation. Such increase is achievable on condition of promoting collaborative processes, encouraging active participation of key actors in the innovation system, the accumulation of experience in the implementation of joint projects. All these processes occur, as a rule, simultaneously with the growth of trust among the population (both interpersonal trust as well as trust to government agencies). Consequently, a priority task of the state is to create a favorable institutional environment for the development of these processes by creating mechanisms to reduce transaction costs of innovation. It is important to realize that in the innovation systems management should be used their ability to self-organization and self-development. Further, the key point is identifying structure-attractors. They could include certain institutions of innovative environment that have the greatest potential to reduce transaction costs of economic agents and optimize the value added created by them, which, presumably, should attract innovative trajectories of the region's development. The results are in line with previous studies. In the work of J. Bichler established and illustrated the relationship of 120 countries between an innovation index and their GDP per capita. The link between the innovation index and the GDP per capita is strongly correlated with a Pearson correlation coefficient of 0.80. Countries which innovation capacity is growing at the same pace as GDP may be characterized by well-balanced development and they move along the regression line in their economic development. Countries above the regression line are able to generate a higher GDP per capita than can be explained by their innovation capacity. This is basically due to natural resources and favorable geographic position. For example, many oil-exploiting countries like United Arab Emirates or Qatar are experienced such a development (Bichler, 2012).

Theoretical and practical contribution

The main contribution of this research is the understanding to be aware of the simultaneous relationship between regional innovation effectiveness and value added of economic entities. Despite limitations of the study, it contributes towards the critical question of revealing the main incentive of economic entities to innovate. Our findings can be crucial both for policy and managerial practices, as they suggest that innovation policies, strategies and practices should pay great attention to the growth value added of businesses. Our results will allow to identify the key internal motives for the reproduction of innovation in the economic system. Due to the effective governance of these motives it is expected to provide their dissemination and self-development of the innovation system as a whole, as well as to ensure predictability of the management decision-making and selection mechanisms for the implementation of management actions, which are especially significant in conditions of current geopolitical situation, sanctions policy and occurring shift of techno-economic paradigm. Expectedly, this research may help to further work on these field with the purpose of gathering future knowledge on the innovation system effectiveness.

Limitations and suggestions for future work

In our view, we might propose the following hypothesis as a subject for future research: there is a two-way relationship between the level of transaction costs, value-added and innovative activity that has qualitatively and quantitatively determined optimal boundaries beyond which there is a decrease in the efficiency of the economic system. Stable innovative growth of the Russian economy can be reached by achieving the optimal level of transaction costs, which is a prerequisite for innovation development within individual regions and the country as a whole. Additionally, there is some controversy concerning the reliability of the indexes used in this research.

Acknowledgment

The research results were obtained while working on order of the Ministry of Education and Science of the Russian Federation.

Characterization, Classification and Assessment of Non-Energy Benefits of Energy Efficiency Measures

Michael C. Krutwig, Bucharest University of Economics Studies, Romania, michael@krutwig.com

Kejo D. Starosta, Bucharest University of Economics Studies, Romania

Abstract

Non-energy benefits (NEBs) have become an overwhelmingly important factor in the calculation of energy efficiency measures (EEMs). Often the share of these benefits even outweighs the calculated energy savings. Nevertheless, these NEBs rarely find their way into practical application in the performance of energy audits and operational energy management. The consideration of NEBs can be regarded as a quality factor in energy management. With the emergence of mandatory energy audits for large companies in the European Union, the issue of quality is taking on a new dimension. Is punishment avoidance the right motivator for good energy management? The dissemination of energy efficiency is the goal of every audit program. The dissemination of knowledge about NEBs can be a great help here.This paper contributes to a better understanding of NEBs by presenting the development of a characterization scheme and thus supports an improved evaluation. In addition, it presents a concept for an extensible classification for NEBs with the intention of facilitating the transfer of research into practice. The classification provides an initial framework for implementation in the form of an online NEB database. By suggesting an extensible mapping matrix, we use the relation between NEBs and EEMs as a supporting tool for the determination and assessment of consumer NEB within an energy audit. With this, the discovery and calculation of NEBs can be systematized in the energy audit. In addition, the introduction of the concept of non-measures related energy investments (NREI) can open a new door for further research activities in the field of EEM calculation.

Keywords: energy efficiency, non-energy benefits, co-benefits, energy audits, non-measures related energy investments

Introduction

The Directive 2012/27/UE of the European Parliament (EED) (Parliament, 2012) has given a new face to the character of energy audits. Energy audits have been supported by a wide variety of regional, national and international programs for decades, but participation has always been voluntary. The EED has lifted *mandatory* energy audits out of the cradle, which have been incorporated into national legislation by the member states and which obliges all non-manufacturers to carry out an energy audit at least every four years. A comprehensive overview of all national implementations of this audit obligation is provided (Commission, 2012). One common feature of all national laws on mandatory energy audits is the voluntary decision to implement energy efficiency measures. To this day, no one can be forced to make an investment. Rather, the efficiency measures that have been detected and calculated are intended to arouse companies' interest in investments.

In addition to the previous motivations, such as energy cost savings, environmental protection, or productivity advantages, the penalty avoidance has now become a new motivation for companies. In Germany, this obligation is enshrined in the *Energiedienstleistungsgesetz* (EDL-G) (Bundestag, 2010), whereby the (BAFA, 2017) prescribes supplementary regulations, including, for example, the procedures according to which the efficiency measures (EEM) must be calculated. The classical static and dynamic methods of investment calculation (Blesl & Kessler, 2013) and life cycle cost (LCC) models (Greene & Shaw, nd) are specified for the economic calculation (BAFA, 2017). Mostly chosen is the net present value or the payback period of an investment.

The biggest problem is the lack of quality in mandatory audits. The requirements for the efficiency calculation are not able to prescribe rules for the inclusion of non-energy benefits (NEBs), the financial and non-financial advantages of energy efficiency measures beyond energy cost savings. To achieve the highest possible adoption rate, these NEBs should always be included even though it's practically impossible to formulate concrete rules. The calculation of the NEBs is very specific; often, numerous assumptions have to be made. More knowledge of NEBs will help us to find solutions to this quality problem. According to a survey about an audit program (Harris, Anderson, & Shafron, 2000), the rate of adopters from all recommendations is around 80% for the more than 1000 companies. An average of six EEMs is proposed per audit, five of which are implemented. Although this is a very positive example, one can without a doubt assume a rather low adoption rate for mandatory audits.

The concept of the advantages of EEM, which are beyond energy conservation, has many names in the literature. The following variations were found during this work (each with one exemplary source): "non-energy benefit" (NEB) (Mills & Rosenfeld, 1996), "productivity benefit" (Worrell, Laitner, Ruth, & Finman, 2003), "ancillary benefit" (Jakob, 2006), "non-energy impacts" (Skumatz & Gardner, 2005), "co-benefits" (several energy and non-energy related papers e.g. (Mayrhofer & Gupta, 2016), "synergy effects" (Kasprowicz & Schulz, 2015), and "multiple benefits" (Ryan & Campbell, 2012). (Rasmussen, 2014) brings clarity to these concepts. We follow her suggestion for the use of "non-energy benefits" (NEB), as this appears to be the most appropriate term.

(Skumatz & Gardner, 2005) provide many uses of NEBs such as cost analysis, measuring barriers to adoption of programs, program design, program targeting and marketing for programs. As a result, the NEB factor should be a decisive adoption criterion for EEM. (Boyd & Pang, 2000) analyzed ‘best practice’-companies and indicated a correlation between productivity and energy efficiency. This reveals that those EEMs that influence productivity have a particularly high NEB.

Numerous studies and research works show how drastically the computation of energy efficiency option (EEO) improves by including NEBs in the calculation. (Worrell et al., 2003) showed in an evaluation of 52 case studies that in 63% of cases, NEB had an equal or even higher portion of savings than the energy benefits (EB). The average energy payback was reduced from 4.2 to 1.9 years when the NEB was included. According to an evaluation of interviews on an energy efficiency program in (Dennis Pearson, 2002) NEB's share of the savings is 40%. The average NEB per EEM was 1.03 (in a range from 0.33 to 3). This study names the industries office, hotels, manufacturing, warehouses and potentially medical business as the sectors with the highest NEB content. (Pye & McKane, 2000) expound that EEM and environmental friendliness increase shareholder value. They show how to generate persuasive arguments through profit analysis. (Kluczek & Olszewski, 2017) highlight the importance of NEBs and give many examples, but NEBs are not mentioned in the presented tools and calculation examples.

Despite these advantages, NEBs are still not included in the programs. (Freed & Felder, 2017) provide insight into the barriers to the consideration of NEBs in policy and programs. While energy power indicators (Patterson, 1996) (EnPIs) are required to measure the savings effect in retrospect (BAFA, 2017), NEBs are still ignored in calculating those effects prior to the investment. Key figures are an important indicator, but neither (16247-1:2012, 2012) nor (BAFA, 2017) establish binding guidelines for specific EnPIs in the context of mandatory audits. Additionally, energy intensity should not necessarily be used to measure efficiency (Proskuryakova & Kovalev, 2015).

Why is an efficiency measure not being carried out even if the calculation of the measure has proven its economic advantage? This so-called "energy paradox" is well explained in (Shama 1983) using a framework for the diffusion of innovation. The paradoxical behavior is because of the energy analysis, which does not include a critically relevant behavioral perspective of the decision-maker in the analysis of energy and efficiency measures. The discrepancy between actual and potential energy efficiency can be described using five types of "optimality" (Jaffe & Stavins, 1994): the “economist’s economic potential,” the “technologist’s economic potential,” the “hypothetical potential,” the “narrow social optimum”, and the “true social optimum.” One of the largest barrier for energy

efficiency is the low priority of energy issues (Thollander, Danestig, & Rohdin, 2007), so the promotion of NEBs can contribute to faster dissemination and a greater adoption rate for this type of company.

1. Methodology

This work aims to improve EEM's cost and thereby support the dissemination of energy efficiency. For this purpose, a comprehensive literature search on non-energy benefits was carried out as well as a partial search for the calculation of EEM. By analyzing the character of NEBs and their calculation, a discussion arose about a NEB counterpart called NREI, which is presented here as a new concept.

From the viewpoint of benchmarking, the schematization of EEM supports cross-audit evaluation (Andersson, Arfwidsson, Bergstrand, & Thollander, 2017); but owning to the impossibility of generalizing NEBs, these can never be taken into account. There exists nothing such as "non-energy performance indicators (Non-EnPIs)" that would be suitable for benchmarking. At least, a characterization of NEBs can support these types of evaluation.

The presented scheme for the characterization of NEBs results from numerous use cases mentioned in the literature. According to the idea of (Fleiter, Hirzel, & Worrell, 2012) an attempt is being made to characterize the NEBs in the form of a morphological box (Zwicky & Wilson, 1967) in order to be able to provide a better structure for further research. Additional non-referenced samples were provided by an evaluation of more than 4,500 EEMs from the database of an online tool for the preparation of energy audits, which were created in the period 07/2015 to 09/2017 and stored in a structured manner. As this database does not contain any information specifically on NEBs, the analysis was supplemented with telephone interviews on about 50 energy audits with questions specific to the NEB.

A structured and schematic investigation of NEBs is also important in order to include them in generalized models for EEM planning. The connection between factory planning and energy management (Müller, Poller, Hopf, & Krones, 2013) and in particular the schematization of EEM (Krones & Müller, 2014) for this exemplary field of application shows the potential for further research work. As a result of this methodology, the user receives a set of suitable EEMs.

(Krones & Müller, 2014) have recognized that a theoretical characterization is not sufficient; in practice, methods are needed to provide the solutions. During our analysis of existing classifications of NEB, the question of their usefulness arose. It became clear that different classifications with exemplary NEBs were not intended or suitable for extension. Therefore, we have developed a classification concept that can provide the basis for a comprehensive NEB database. The huge challenge of non-existent calculation standards for NEBs is addressed by the presentation of an extensible matrix in which the relationship between EEM and NEB is illustrated and used in order to identify the potential for NEBs. The online tool mentioned above was helpful to determine and supply a set of commonly working EEM categories. This classification including a methodology of use not only serves the purpose of research about the gradual limitation of the calculation problem. It also helps to with finding and calculating NEBs in practice.

2. A scheme to characterize NEBs

In (Fleiter et al., 2012) a scheme in the form of a morphological box (Zwicky & Wilson, 1967) was developed for the characterization of EEM, in which the NEBs appear as a characteristic with the attributes "negative", "none", "small" and "large". We continue this approach in the same methodology for the characterization of NEB. In our development, however, the adoption rate is

irrelevant. NEBs are about their detection and their ability to calculate, not about their adoption. The characteristics of this scheme derive from thorough literature research on NEBs. The chosen characteristics must affect at least one of the three properties: identifying, classifiability and the ability to calculate. Distinctness is not a selection criterion, the selected characteristics can overlap.

A breakdown into the beneficiaries "utility system benefits", "participants benefits" and "societal benefits" can be found in the layer cake model of (Lazar & Colburn, 2013), also earlier used in (Skumatz & Dickerson, 1997) and others. The cake takes into account six sub-categories under each main category, which are too specific for a generalized characterization and which do not cover the main category completely. Our schema uses “consumer” as a synonym for “participant” which is mainly used in papers related to programs. In our scheme, we’ve added a “main” to exclude multiple choices.

The social level characteristic follows the typology of (Ryan & Campbell, 2012) and distinguishes between the individual, sectoral, national and international level, where a higher level always includes the lower levels. According to (Rasmussen, 2014), it should be noted that at the international level the term NEB is to be replaced by co-benefit or ancillary benefit.

NEBs can also be classified as monetary and non-monetary benefits, the former influencing a direct investment decision. The saving of raw materials is an apparent monetary NEB. The non-monetary benefits usually flow into an investment decision when generating strategic justifications. (Small, 2006) illustrates this behavior using the example of investment decisions in AMT (advanced manufacturing technologies). The evaluation of energy efficiency projects in (Cooremans, 2011) yields competitive advantage as the dominant motivation for the adoption of measures. Other examples of strategic objectives include risk minimization, improving comfort and better reputation. (Cooremans, 2012) reveals that the strategic character of energy efficiency measurements is a significant factor for adoption. Non-monetary incentives can also be used to achieve reductions in peak demand, as (Ankit, 2016) shows in modeling the effect of non-cash incentives using utility functions. The environment is also a significant motivation: only 9% of companies taking part in the audit program survey disagreed to the question about the 'importance of environmental considerations' in the investment decision progress (Harris et al., 2000). Better working conditions are another instance of non-monetary NEB (Thollander & Ottosson, 2008).

The outcome delay differs between direct and indirect outcomes from energy efficiency. Often, improvements in health, working conditions or production improvements are also made directly with the implementation of a measure. On the other hand, it is the indirect effects that make NEB so difficult to calculate. These occur with a delay, in the worst case even after the evaluation of the measure has been completed. Lower energy prices, owing to lower peak loads, lower maintenance costs and improvements in energy security, are examples of indirect outcomes.

The next two characterizations and attributes are taken from (N Martin, 2000) who divides the benefits into three areas: productivity benefit, product quality benefits and other benefits. In our scheme, the class "other" from the original source has been omitted.

A striking characteristic of a NEB is its correlation with energy saving: Higher energy saving = higher NEB? For some NEBs, the utility value is a fixed value in an EEM cost estimate, regardless of the size of the calculated savings. The next characteristic measures the value of the NEB in comparison to energy saving. Numerous studies have reported that NEBs have exceeded the actual energy benefit. The attributes smaller, equal and greater are roughly classified in this respect and are an indicator of the attractiveness of a NEB. This can be answered with a simple yes (it correlates) or no.

For the key measurement method, (Skumatz, 2014) offers three basic techniques for assessing NEBs: engineering or model-based estimates (M1), incremental incidence (M2) or specialized comparative (M3). M1 covers all input-out-models, economic and climate change models; M2 uses marginal

estimations including factors and can combine measurements and factors from literature; and M3 is based on statistical methods and surveys. If none is applicable, a “N/A” helps out.

In most cases, assumptions have to be made when calculating NEBs in order to quantify the benefit. Only rarely can a NEB be measured without a presumed factor (attributes "None"). The number of these assumptions is an indicator of the complexity and the resulting precision of the calculation.

NEB-Characteristics	Attributes			
Main Beneficiaries	Consumer	Utility System	Societal	
Societal Level	Individual	Sectoral	National	International
Monetary effect	Monetary	Non-monetary		
Outcome delay	Direct	Indirect		
Productivity benefit	None	Compelling	Significant	
Product Quality Benefits	None	Compelling	Significant	
Relative to energy saving	Yes	No		
Compared to energy benefit	Smaller	Equal	Greater	
Key Measurement Methods	Estimates	Incremental incidence	Specialized comparative	N/A
Assumptions to calculate	None	One	More	Unknown

Figure 1: Characterization scheme for non-energy benefits (Source: authors)

3. A classification concept for consumer NEBs

Numerous, always incomplete classifications of NEBs appear in the literature. These are mostly based on evaluations of funding programs for a specific target group such as households (Skumatz & Dickerson, 1998). The approach is justifiable, as it is practically impossible to take full account of all NEBs. An incomplete list of literature with NEB classifications is (Fleiter et al., 2012; Lazar & Colburn, 2013; Lung, McKane, Leach, & Marsh, 2005; Mills & Rosenfeld, 1996; Pye & McKane, 2000; Ryan & Campbell, 2012; Skumatz & Dickerson, 1997, 1998; Skumatz & Gardner, 2005; Skumatz, 2014; Worrell et al., 2003). Discussions of classifications can be found in (Trianni, Cagno, & Donatis, 2014) and (Rasmussen, 2014).

But what is the usefulness of these classifications, beyond the scientific evaluation? We claim that the main benefit of classification has to be an easier identifying of NEBs when considering energy efficiency measures. Therefore, we do not only want to offer another incomplete classification, but rather a classification concept consisting of a relationship matrix between EEM and a proposed methodology for the implementation of this matrix in order to maintain the desired utility value. We restrict ourselves to the main category of consumer benefits, because their calculation is the most difficult (Skumatz & Gardner, 2005) and skip NEBs for utility system and societal.

When considering an energy efficiency measure, the user should be given a set of as many as possible NEBs matching the selected measure, each of them supplemented by remarks on the calculation of these NEBs complemented by their characteristics. This requires a growing knowledge base and contribution from many sides. If further EEMs and NEBs are evaluated, these findings must be

incorporated into the matrix. We propose to make this system available in the form of an online database to a wide range of users and scientists.

The calculation of the NEBs can only be schematized on a relatively abstract level, for example using the key measure methods (Skumatz, 2014). The calculation is too specific for individual NEBs, as the example of the increased availability of the machine as a NEB of an EEM (Kasprowicz & Schulz, 2015) shows. (Jakob, 2006) demonstrates another example of countless use cases of how fast the NEB calculation gets a high complexity in specific areas. It remains the realization that it will be necessary for each NEB to have one or more concrete references to the calculation.

Table 1: Matrix scheme for NEB classification

(Source: Authors)

(Mills & Rosenfeld, 1996) show a first approach for an EEM-NEB mapping, which contains specific use-cases in both dimensions and probably might become too complex in an extendable system. The approach of (Trianni et al., 2014) envisages individual EEMs as an open extendable set for a framework, but the NEBs are not clearly delineated here. Our approach reduces the EEM itself to a fixed and manageable set of EEM classes and stretches the extensibility to individual NEBs. As there

is no uniform standard for EEM classification, we adopt the scheme of the online-tool *energiesparbericht.de* consisting of 15 categories (+ "other") for consumption areas and measures, as this has evolved through practical evolution and has proven itself in more than 4,500 measures: building envelope, combined heat and power, heating system, pumps, lighting, ventilation and air conditioning (VAC), refrigeration systems, compressed air systems, drives and electric motors, information and communication technology, renewable energies, production. The selection of the six NEB categories (waste, emissions, operation and maintenance (O&M), production, working environment and others) were taken from (Worrell et al., 2003). These serve for a better overview within the matrix, the arrangement of the NEB within these categories is arbitrary.

Table 1 shows the matrix concept. The EEM categories and the NEB categories are fixed and the entries of the individual NEBs can be expanded line by line. The star symbol documents the relationship between NEB and EEM and contains a text entry, consisting of notes and references to calculation methods. Every time a NEB has been detected and examined for an EEM, it can be entered into the database. This entry extends the matrix either by one line or, if the NEB exists, it extends the entry by another star or a further note on the calculation. A suggestion for supplementation is to add the characteristics of each NEB as suggested in the previous section. In (Cagno & Trianni, 2012) various energy efficiency opportunities are ranked in top lists according to various criteria such as industry, company size or payback period. This ranking idea is included in our concept: the more incidents are recorded for a NEB, the more references the matching star contains.

The proposed classification concept is intended as a template for implementation as an online database similar to the existing databases of implemented EEM[1]. If an EEM is considered by a user, the online service can provide all associated known NEBs including calculation scheme and characteristics to support a more precise calculation. It is possible that a finer subdivision of the EEM headings may be necessary in the future.

Let's pick (Mikulcic, Klemeš, Vujanovic, Urbaniec, & Duic, 2016) as example project in the context of the cement industry to validate the concept. This paper's focus on the reduced emission of greenhouse gas is not a consumer NEB and therefore not intended to be included in our scheme. But a closer look reveals an EEM by using replacement of cement in concrete or mortar with alternative materials. This measure also brings up a consumer NEB that we can add to our matrix: We now place a new line in the section "production" with a specific NEB "cement replacement in concrete or mortar with recycled materials" and place a matching star in the column of "renewable energy". In this "star dataset", we note the paper as a reference for further calculation instructions.

4. Non-measures related energy investments (NREI)

The following question drives us to introduce the concept of non-measures related energy investments (NREI): What is contradictory to a NEB? Two obvious answers could be the energy benefit (EB) or the negative NEB. However, NEBs are not the opposite of EBs. Both are rather a decisive - but not completely - disjoint class of benefits. For example, reduced maintenance costs for a machine can be included in the amortization of the measure, provided that they can be quantified exactly. NEBs are often characterized by the factor "unexpected" or "incalculable." This incalculability results from the unclear possibility of assigning benefit shares to a specific EEM. For instance, the improvement of working conditions owing to the implementation of a more modern air conditioning system can hardly be quantified in figures. Moreover, one NEB can be a long-term result of several EEM. The benefit of an individual EEM often remains unclear in case of doubt; the precise calculable measures remain in place. Also the negative NEBs (Skumatz & Gardner, 2005) cannot be the opposite, because depending on the estimation of unknown calculation magnitudes, the

[1] One example is the Database of the Industrial Assessment Centers (IAC), see https://iac.university

NEB calculations can assume a positive or negative value. In the quest for the opposite, we have to change the page from output (benefit) to input (investment).

Similar to NEBs we find such incalculable influencing factors on the calculation of EEM, which are often not taken into account in the investment calculation, as they cannot be (accurately) mapped to the measure. Non-measures related energy investments (NREIs) denote investment costs in energy efficiency, which cannot be clearly assigned to an individual energy efficiency measure. These costs are because of the general energy strategy. Although NREIs are not directly involved in the calculation of individual measures, they should at least be considered pro rata in investment decisions. Examples of NREI are:

- Energy audits costs (internal and external)
- External consulting
- Training of employees
- Costs for management systems (ISO 50001), including software for monitoring and controlling
- Costs for metering Equipment

These cost factors are often not taken into account in EEM cost because their costs were incurred already at the time of the cost estimate. They are therefore not part of the investment decision. However, these costs should be taken into account in the evaluation of individual EEMs, because a separate evaluation of these NREIs does not make sense because of the lack of a benefit factor.

(Fresner, Morea, Krenn, Uson, & Tomasi, 2017) evaluated energy audits of 280 European companies. With 499 energy efficiency options, the number of measures per audit results in 1.78. According to the SME program *Energieberatung Mittelstand (EBM)* (Ausfuhrkontrolle (BAFA), 2017) the number of measures per company is 2.5 (Harris et al., 2000) and even reports on five implemented measures per audit in an Australian program. According to this factor, the total audit costs must be included in each measure on a pro-rata basis: (Mai et al., 2014) have figured out that the initial consultations in EBM cost about €1,600 and detailed consultations €7,760 on average. For consulting and training, an average daily rate of €800 can be calculated. The introduction of a management system compliant with ISO 50001 until certification is usually beyond €10,000. The problem here is that investment decisions for measures are often made in isolation, so it is not always known when calculating the first measure how large the NREI share for a measure will be.

5. Conclusions

The presented characterization scheme is a result of the literature review, combined with the analysis of numerous use cases from an EEM database. It is intended to support the structured analysis of NEB and this initial approach has certainly not yet reached its full maturity. The concept of the non-measures related energy investments (NREI) completes the discussion of EEM calculation and is also intended to provide impulses for further research work.

The presented concept for the classification of NEBs using an extensible matrix focuses on the user value. The concept offers a template for implementation as an online database. It is designed to provide auditors and energy managers a compass through the NEB jungle when using the future intended tool. NEBs will be identified easier and EEM can be calculated more accurately. Program developers can include such an instrument in the design of their programs to achieve a maximum adoption rate, which promotes dissemination of energy efficiency. This concept must undoubtedly be refined and a finer subdivision of the EEM headings may be necessary in the future. Semantic methods can also be helpful in the generalization of similar and synonymous NEBs in order to avoid multiple inputs for the same NEB. We recommend the implementation of such a matrix as a publicly accessible online tool, as a broad participation in the completion is required. A structured recording

of as many existing and future applications as possible leads to a continuous improvement of this tool.

The presented work is of particular relevance for mandatory audits. In contrast to voluntary audits, in which the project is restricted and staffed by experts, mandatory audits must cover the entire energy balance of a company. The auditor has to be a universal expert for all business areas and processes, so he can hardly calculate all possible EEMs in detail or know their NEBs. (Sardianou, 2008) and (Duflou et al., 2012) consider the lack of knowledge about energy efficiency opportunities and NEB as a strong barrier to efficiency.

Acknowledgments

The authors are grateful to Prof. Dr. Bernhard Kölmel at the Pforzheim University and to Prof. Dr. Marieta Olaru and Prof. Dr. Dr. Adrian Dumitru Tanţău, both from the Bucharest University of Economic Studies, for their helpful support.

Svetlana S. Gutman, associate professor, Peter the Great St. Petersburg Polytechnic University, St. Petersburg, Russia, svelanka@mail.ru

Abstract

The scientific feasibility study of innovative mechanism for education system arrangement and its human resource management is approved. The focus an online learning resource developed based on practical application of the Triple Helix concept adjusted to Russian environment is made. Successive stages of formation of academic broker system are shown.

Keywords: human resource management, human resource development, innovation, mechanism, concept, Russia, education system.

Introduction

Changes in the Russian economy directly affect the sphere of education. Education reforms (introduction of autonomous management of educational institutions (Federal law of the Government of the Russian Federation, November 03, 2006), passage of the Law on Education (Federal law of the Government of the Russian Federation, December 29, 2012), transition to test system for performance measurement and two-cycle system of higher education etc.) aim to increase responsibility of educational institutions and specific specialists, to promote wider application of IT technologies in educational institutions, to adopt continuing education principles for the economic sector etc. Despite reforms in the social sphere, there is currently no unified system (at federal, regional and municipal levels) of education management, forming the background of human potential system in macrolevel, and education performance is measured separately at each level (preschools, primary schools, intermediate schools, secondary schools and universities). In this regard the purpose of this study is to suggest a justification of the necessity of the formation of human resource development mechanism through the system of academic brokering.

Recent Research and Publications Analysis

A significant number of researches have been published on the subject of human resources development. The majority of works which study this aspect of human resource management Bril et al (2017), Chapman et al (2016), Chukreeva (2015), Jacobs (2017), Kalra (2004), McLean (2013), Hedayati Mehdiabadi and Li (2016), Rodionov et al (2016), Zaitseva (2009), Zaychenko et al (2016), Zolotareva (2016) share the view that human resources are the source of sustained competitive advantage and that the high-performance work system created by certain human resource development (HRD) and human resource management (HRM) practices leads to greater firm performance.

In the work performed by K. McDonald and L. Hite (2015) a strategic framework that demonstrates the role of career development within the human resource function is offered, the key topics of HRD from the perspective of the individual and from the economic perspective are viewed.

Detailed analysis of global and national aspects of HRM and HRD is provided in Borisova (2012), Budhvar et al (2017), Dyrin (2008), Garavan et al (2016), Kalinina and Vasilieva (2016), Mizintseva et al (2016), Viatkina and Zakharova (2016), Zelenova (2010).

The problems devoted to the connection of HRD and education system are considered in works by Russian and foreign economists such as Averin (2017), Guzakova (2006), Homma et al (2014), Kadiresan (2015), Podyraev et al (2016), Salleh and Sulaiman (2015), Sotnikova et al (2014), Tasdiyanto (2017), Volkova (2016), Glukhov et al (2014), Ilin et al (2016) and others. The work performed by M. Akdere and T. Egan (2013) describes the relationships between higher education and community partnerships and what strategies the field of HRD may offer to advance such collaborative efforts. The role of school education system is analyzed by E.A. Nazarova and S.S. Ushakova (2012), A. Seezink and R. Poell (2011), O.V. Rogach (2009) and others.

The new approach to HRD through e-learning education is described in works by M.V. Dzhigan (2015), I. Ilin et al (2017), H. Nawotny et al (2003), A.N. Sergeev (2009), E.S. Spiro et al (2013) O.I. Tarasova (2013), and others. The paper by M. Gharibpoor et al (2013) presents a comparison between e-learning and traditional training methods; both are used by small and medium-sized enterprises. In such case efficiency measured using data envelopment analysis and eventually came to the conclusion that e-learning is more efficient than traditional education.

Problem Formulation

Education system is one of the key elements required to create scientific and innovative environment as it is the main source of human resources for the economy and as innovative breakthrough in the technical and social spheres depends on the quality of education in the country. Achievements of modern information and communication technologies should be taken into account when establishing a new education system and education management structure. Such technologies allow reduction of transaction costs for information search and conclusion of an informal contract between students or their representatives and an educational institution and other parties concerned. Development of the innovation system is not possible without education reforms, at the same time development of the education system is not possible without introduction of innovations in education.

Such innovations in education may be of the following types:

- Process innovations which affect education process structuring, education management at various levels etc.;
- Product innovations which provide for the use of modern technologies in education;
- Radical innovations which directly affect and significantly alters the way education services are provided;
- Incremental innovations which do not affect the essence of educational services at various levels but rather improve the quality of such services;
- Micro-innovations which are implemented in respect of a certain educational institution and a certain process in an educational institution.

Problem Solution

Modern education system is a consolidation of competing interests, which makes it impossible to come to a consensual decision. Mediators may be engaged in order to arrange a productive dialogue between the participants of the system that cannot come to a consensus (mediators draft scenarios of education process depending on selected conditions which form cross-level paths for students: school – college – university – postgraduate education – professional training).

In order to improve the economy, the social sphere, state administration, science and education it is necessary for the education system to be aimed at training well-educated specialists who can make rational and effective decisions and who in terms of their competence meet the requirements set for graduates of prestigious universities in leading countries. At the same time it is important to trace return on capital investments in education made under existing government projects and programmes

(Federal Targeted Programme for Education Development for 2016-2020, State Programme of the Russian Federation for Education Development for 2013-2020, Development Strategy 5-100-2020 etc.), as well as to determine capital capacity and return on capital in respect of education.

Certain problems related to the lack of proper regulation in the social sphere may be resolved by providing open access to information. One of the options which make it possible to resolve some of the described problems is the use of innovative mechanisms for human resource development in a company, a region or the economy taken as a whole, for example, the concept of education mediation (academic brokering, unified electronic learning platform). By human resources the authors mean an aggregate of competences, skills and knowledge of employees of a company and an aggregate of human resources of the companies which are incorporated in a region's or a country's human resources. An innovative mechanism aims to improve efficiency and transparency of interaction between government, private business, public organisations, as well as educational and scientific institutions.

An academic broker is a self-developing organisation which is characteristic of the post-industrial world (network economy, Web 4.0. and Web 5.0.) the main purpose of which is to produce, transfer and apply knowledge; to connect researchers (theoreticians) to those who practically apply knowledge. Such resource should be a unified (but not the only) source of reliable information in the Internet. A term "knowledge broker" is also used in foreign publications. A knowledge broker, in its turn, is described in scientific literature as an organisation which provides remote education services and manages education system elements. By an academic broker the authors, in their turn, mean an information system for management of education at various levels. An academic (knowledge) broker may become a basis for a unified electronic learning platform.

Academic brokering is tightly connected with the Triple Helix concept. The Triple Helix elements in Russia differ from the traditional model introduced by Henry Etzkowitz (Etzkowitz, 2008) and commercial element here is not as high as in western countries (Table 1 and Figure 1).

Table 1: The main parties concerned, their roles in the traditional Triple Helix and in the thesis (prepared by the authors)

Traditional Triple Helix	Triple Helix in Russia
Government	
- Sets rules; - Manages society; - Provides resources required for promotion of R&D and innovation activities at the universities	- Sets requirements to education (establishes standards, federal and regional components of educational programmes etc.); - Develops programmes and arranges events related to education and healthcare; - Provides resources required for promotion of R&D and innovation activities at the universities
Educational institutions	
- Practically apply knowledge; - Use research findings in new disciplines	- Arrange training programmes for healthcare specialists; - Responsible for education process
Business	Employers
- Establishes subdivisions at scientific parks of research universities; - Engages students in research	- Implement social functions of the government and satisfy the needs of population in healthcare services; - Rationally distribute available resources; - Participate in scientific activities

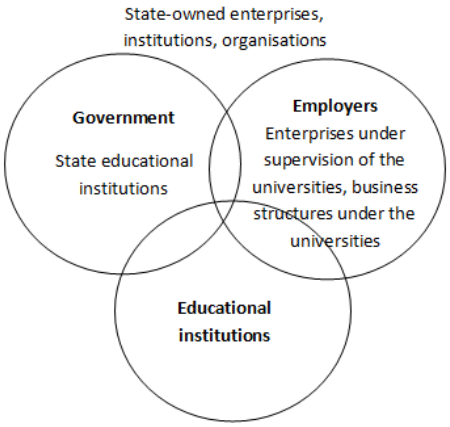

Fig. 1: Application of the Triple Helix concept in Russian environment

(Prepared by the authors)

An academic broker may be of use in the sphere of professional training and human resource development in the national economy industries due to the gap between expectations and reality of interaction between participants. Secondary school graduates and students who enter the universities do not always have a clear understanding of educational programmes they select, key competences, knowledge and skills they will obtain or positions which they will hold after graduation. At the admission stage selection of an educational institution is not always well-thought-out. Employers, in their turn, are willing to obtain well-trained specialists who can adjust to the work environment with minimum transformation and transaction costs and are not willing to pay attention to the adaptation process.

An online learning resource may be developed using several directions:

1) As consolidation of best practices in educational institutions and practical application of achievements;
2) As establishment of an "over-level" for educational institutions which has additional characteristics and allows their application to improve education at municipal, regional and federal levels.

The government sets out goals and priorities but not always determines measures to be taken to achieve them. Only in 2013 the government of the Russian Federation passed a Resolution on Approval of the Rules for Setting Reference Figures for Educational Institutions to Enrol Students for Professions, Qualifications and Directions of State-Accredited Education Programmes of Professional and Higher Education Funded by the Federal Budget (Decree of the Government of the Russian Federation, April 17, 2013; Decree of the Government of the Russian Federation, April 08, 2015). For the first time a regulation incorporates the position of experts in respect of enrolment in the universities based on potential demand for various specialists in medium-term and long-term perspectives. Furthermore, the Agency for Strategic Initiatives has prepared an atlas of emerging jobs which includes over 180 new jobs (including state-private partnership specialist for the social sector and government authority communication platform moderator) and about 50 endangered jobs which will become obsolete (www.atlas100.ru).

As Russia is integrating in international organisations (for example, EEU, transition to two-cycle education system similar to the Bologna process etc.), application of information learning resource may ensure transparent alignment of our system to the education systems of other countries, establishment of open boundaries in the education system and easier benchmarking process for national and regional innovation systems.

The project provides for development of an information resource similar to a social network with elements of organisation, coordination and control functions, i.e. with options of formal and informal communication, exchange of experience and resolution of relevant issues.

The academic broker has two main elements, namely education (formal) and communication (informal) elements. The formal element is meant to solve the issue of inefficient official channels used to distribute information and division of responsibilities between the student and the teacher which has developed lately. In accordance with the concept of the entrepreneurial university, professors are viewed as innovative scientists and education is reduced to training during practical scientific and business activities. Education should be incorporated into innovation activities and develop entrepreneurial skills. At the same time, any economy needs not only entrepreneurs (managers and directors), but also executors who are ready to accomplish assigned tasks. Development of the innovation system may fail to reach its goal but rather liquidate existing advantages of the Russian education system.

The communication element (platform) should include discussion of professional topics, issues indirectly related to education and education as such, for example, generation of ratings and rankings. The communication element is also meant to create online scientific communities of researchers from various parts of the Russian Federation and other countries.

General analysis of the rate of interest shown by the Triple Helix participants is based on cumulative rates of interest of the Triple Helix participants in the unified information resource, which makes it possible to ensure coordination and continuity of education and practice, to implement continuing education process, to automate designing of individual educational paths which include individual personal and educational growth opportunities at various stages.

Identification of the rate of interest of each Triple Helix participant in the resource is based on the results of the opinion poll with breakdown by groups taking as an example the sphere of healthcare personnel training (Figure 2).

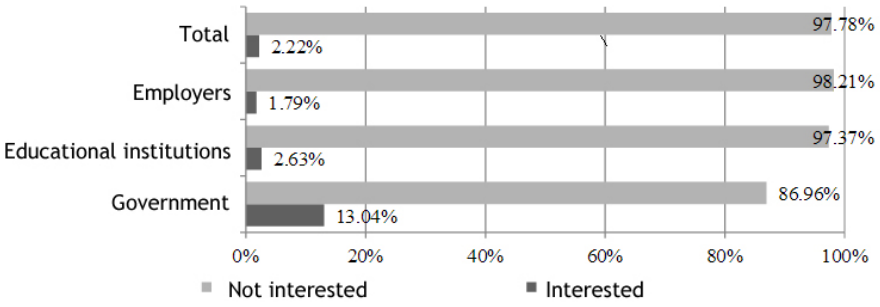

Fig. 2: Assessment of the rate of potential users' interest in the resource

(Prepared by the authors)

As reflected in the assessment results, government bodies are more interested in such resource (or "government" if we use the term of the Triple Helix theory) – 13.04%. It is necessary to take into account the way the results were obtained: government bodies show more interest as they are legally obliged to reply to all requests. On the whole, the pollsters show little interest in such resource (2.3%). At the same time each group has its potential growth engine.

It should be noted that all segments are not active users of information resources or common programmes (e.g. email). Therefore, our analysis has an indirect but rather important result which shows that government bodies, educational institutions and employers rarely use internet communication, which shows low involvement of information and communication technologies in their activities.

Scientists actively discuss the need to develop information learning systems, however, the research results show that there are not many signs favouring active development of such resource.
Such resource may resolve several issues:

1. To provide the basis for monitoring of problems faced by different students;
2. To apply information distribution models for prompt solution of problems;
3. To arrange more flexible information exchange system (diagrams, rules of answering to requests received by various educational institutions).

Currently part of information at the universities which is sometimes rather big is distributed informally and does not correspond to the facts. A unified resource should make it possible to obtain answers, more promptly resolve arising problems and search for similar situations. The time needed to obtain answers may vary and certain questions may already become irrelevant.

Using the Internet as an environment for development of the learning platform will have the following advantages (Sergeev, 2009, Glukhov et al, 2015):

- Purposefulness, motivation and efficiency of individual and common activities;
- Collaborative setting of goals, involvement in goal setting process;
- Enhanced tendencies of isolation and consolidation of community members as a condition for establishment of individual and collective subjectivity;
- High intensity of online communication, possibility and demand for direct interaction between participants;
- Cooperation, support, open development of own resources available for other participants of an online community;
- Various forms of group activity;
- Competition between participants of an online community, self-improvement;
- Development of internal rules of conduct specific to a certain online community.

Internet technologies may be actively applied in the education sector by using existing social networks or developing new networks. Comparison of these options is given below (Table 2).

Table 2: Advantages and disadvantages of an academic broker as an innovative mechanism for human resource development by using existing social networks or developing new networks (prepared by the authors)

	Existing networks	**New network**
Advantages	1. Users already exist 2. Certain (not all) ideas may be implemented 3. Experience in development and user acquisition 4. No need to fight competition 5. No costs	1. All ideas may be implemented 2. Experimental integrity 3. Territorial project (St. Petersburg)
Disadvantages	1. Not possible to start from scratch 2. Need to accept the rules used by existing platforms 3. Difficult (or impossible) to separate St. Petersburg as a territorial unit for the pilot project	1. Need to fight competition, to develop new means to acquire users 2. Possible territorial limitation for the pilot project

Comparative characteristics of two directions of active using the Internet technologies have shown the possibility of selecting both the first and the second options. Regardless of existing disadvantages of two considered variants they both have good prospects for development.

Such projects already exist in various forms:

- Social networks (general or specialised),
- Continuing medical learning platforms,
- Electronic resources for advanced training etc.

One of the problems of modern education is low motivation of students who do not view education as a process of acquiring knowledge but rather a formal obtaining of a university degree. The system of seminars and lectures is becoming outdated as it does not meet modern requirements of professional education oriented to audiovisual representation, especially using information and communication technologies. Innovative education projects to a large extent support visualisation of education.

The novelty of the education in Russia regardless of the branch of economics is the necessity to train specialists who can work both with state-of-the-art technologies and equipment and with obsolete outdated technologies and equipment, which means that they need not only to know what measures to take and in which order, but also to know how to determine at which stage problems arise and how to solve them. Furthermore, theoretical background should be at the highest level and at each level of education students should learn how to apply obtained knowledge and assume responsibility for their decisions.

The scheme of the academic broker development in St. Petersburg provides for measures to be taken at each project stage (Figure 3).

<table>
<tr><th colspan="2">Project concept development</th><th>Development of a selected model</th></tr>
<tr><th>Development of a prototype based on existing social networks</th><th>Development of a new platform</th><th>Functional enhancement, search for business opportunities</th></tr>
<tr><td>Creation of a group in a social network</td><td>Creation of a new platform if interested persons are identified at the first stage</td><td>Functional enhancement (addition of functions, attraction (guest access) of students and researchers, specialists)</td></tr>
<tr><td>Identification of interested parties at the universities and scientific institutions, possibility of their participation and coordination of work</td><td>Arrangement of work separately for the platform and for the group (duplication of information and possible functions). The platform will have more functions</td><td rowspan="2">Appointment of the project coordinator to transfer management functions. When the goal to improve efficiency of interaction between the universities and students is achieved, it is necessary to achieve a goal of education efficiency improvement. It is preferable to transfer the project to scientific or non-government organisations in order to ensure its non-commercial and autonomous nature</td></tr>
<tr><td>Determination of the group structure depending on possibilities and interested persons</td><td>Selection of a more efficient instrument between existing social networks and a separate platform</td></tr>
</table>

Fig. 3: Components of the academic broker development scenario with breakdown by stages (prepared by the authors)

The main steps to be taken to introduce the academic broker are currently as follows:

1. Identification of interested parties in government bodies as potential employers such as educational institutions, municipal (public) and business organisations in current economic and

geopolitical environment are ready to follow guidelines but not ready to show initiative. Government plays the lead role in education development. It is the government that sets the rules in the sphere of education in Russia.

2. Identification of interested parties among employers and educational institutions. It is necessary to determine key competences through open discussion with employers and educational institutions with their further inclusion in the federal state educational standard of next generation. Such changes were made for certain qualifications in 2014. It is necessary to provide this information to students and other parties concerned in order for them to have an understanding of knowledge, competences and skills to be obtained as a result of education and opportunities for self-education.

3. Application of career guidance mechanisms to improve the rate of interest of the secondary school graduates, possibility to identify their strengths, abilities and interests, development of individual education paths depending on preferences.

Conclusion

The academic broker differs from existing Internet resources which offer various education services as it creates a unified universal information resource (virtual learning platform) which combines interests of the Triple Helix participants as a basis for an online community and continuing education in modern Russia. It is meant to supplement traditional education, to provide wider opportunities for education in terms of selection of subjects and institutions, as well as to promote communication on up-to-date topics. Under current conditions when communication via the Internet is starting to prevail, information, communication and computer technologies should form an integral part of the education process, as well as supplement but not replace traditional education. The unified electronic learning platform for various levels of education should become a mechanism for implementation of continuing education concept and ensure human resource development as a component of Russian human capital.

Abstract

This article deals with the issue of the influence of brownfields on the price and value of the given properties in the municipality of Detmarovice. These municipalities are located in the Moravian-Silesian region. There are 180 abandoned complexes and facilities in the mentioned region. There are 11 brownfields in the village that were previously used primarily for industrial activities. The purpose of this article is to determine whether brownfields affect the price or value of real estate in Detmarovice in some way. In the framework of this article, marketing research was developed, where a structured questionnaire was created. Respondents were asked to comment on their views, factors, and characteristics of brownfields that are of key importance in terms of their negative impact on property prices. Marketing research ran from autumn 2016 to spring 2017. The research focused on the views of respondents and their more detailed segmentation. According to the findings, most of the populations did not want to live in the vicinity of the brownfield. In addition, the addressed residents did not buy property that is located near the abandoned real estate. Subsequently, it was found that among the most serious reasons why brownfields reduce value or price is the occurrence of pathological phenomena and dangerous from the point of view of the construction-technical conditions.

Keywords: Brownfields, Dětmarovice, marketing research, respondents, real estate,

Introduction

The definition of brownfields varies between countries. According to Novosak and Bednar (2011), a country with a relatively low population density and thus sufficient open areas for new uses place emphasis on site contamination as key aspect in the definition of brownfields (like USA, Denmark, Sweden, Norway). On the contrary, countries with a relatively high population density highlight the development aspect of the concept of brownfields in their definitions (like the Great Britain, the Netherlands). At the beginning of the 21st century, the term brownfield came also into Czech terminology. There are three ministries in the Czech Republic (Ministry of Industry and Trade, Ministry for Regional Development and Ministry of the Environment) whose competencies are at least somehow linked to regeneration of brownfields. In the Czech Republic, the issue of brownfields has become a major concern in early 2000s. According to the National Brownfield Regeneration Strategy (2008), 2 355 abandoned buildings and sites were located in the Czech Republic. However,

this number is only indicative. Experts estimate the occurrence of 10 000 - 12 000 brownfields that occupy an area of 25 000 to 35 000 hectares. The definition of brownfeilds according to the Ministries of Industry and trade and the CzechInvest Agency can represent real estate that is under-utilized, neglected and eventually contaminated. These objects and places are mainly created as industrial, agricultural, residential, military or other activities.

The origins of brownfields on the territory of the Czech Republic can be dated to the 19th century, which was significantly affected by the first industrial revolution. The reasons for the abandonment of industrial sites might be found during the First and the Second World War and the great economic crisis (1929). In recent years the occurrence of brownfields has been caused by the return of property to the original owners when the socialist era ended (1945-1989). Owners either ceased to be interested in the property or did not have sufficient funds to repair buildings and other objects. Nowadays there are plenty of abandoned buildings, whole occurrence is mainly cause by competition forces. Reason behind this process is the fact that smaller business units do not survive pressure of competitors and therefore become abandoned. It is also a drop of industrial production when the premises are not used after the previous production ends. Last but not least, it is the creation of brownfields after former public amenities.

The issue of brownfields is nowadays very important. Abandoned buildings and sites create threat for local population that lives nearby. The occurrence of brownfields can also significantly affect the development of the city or community. An important solution is brownfield regeneration and reuse. There are several brownfield regeneration strategies in the Czech Republic on the regional level. The most interesting strategies have been developed for regions that the most affected by the occurerence of brownfields (the Liberec Region, the Ústecký Region and the Moravian-Silesian Region). These strategies should help these regions to regenerate abandoned buildings and sites and to help business units to reuse these objects, thereby reducing employment and improving living standards in the affected areas.

The purpose of this article is to determine whether brownfields affect the price or value of real estate in Detmarovice in some way. It is expected that the value of properties near abandoned buildings and sites will be somehow reduced or affected by dilapidated buildings. From a subjective point of view, it can be assumed that residents will not want to live in these buildings because they pose a danger both from the construction and technical condition and from soil contamination, which can affect the health of the population.

The assumed structure of this article is as follows: After an introductory part short theoretical framing of study follows, which describes brownfield issues according to experts who deal with the issue. The theoretical part is followed by part Methodology and data, where marketing research was carried out, when a structured questionnaire was created and gathered among inhabitants of Detmarovice. The third chapter focuses on the location of brownfields in the given village. Most abandoned buildings are located near residential or family homes. The next chapter deals with the evaluation of the questionnaire survey, where the most important questions from the structured questionnaire were selected. Finally, the most important findings from this article and the analysis are evaluated.

1. Theoretical background

The term brownfield appears for the first time in the 1970s in the USA. Later on, this concept is widely discussed in Great Britain and even later in continental Europe. Under the notion of brownfield, as noted in the introduction, each country presents something quite different. In the Czech Republic, this term means mainly abandoned buildings, areas or often devastated industrial areas that have lost their original use. This is particularly visible in the large industrial-mining conurbations (Krzysztofik et al 2016). Brownfields can be a large area of military barracks, unused areas of railways or areas former socialist agriculture (former cooperative) that are located mainly on the outskirts of villages (Novák, 2012). Gradually, the range of brownfields began to expand in relation to buildings that were formerly used for agricultural production or transport infrastructure or abandoned military areas (Syms 1999; Litt, Burke 2002; Dixon 2006; Thornton et al 2007; Wedding,

Crawford-Brown 2007). Due to this broad territorial coverage social exclusion has many aspects that differentiate between countries of East Central Europe. Particularly employment, housing and education are those dimensions in which risks associated with social exclusion are higher in countries with more disadvantaged socioeconomic conditions (e.g. Albania, Bulgaria, Kosovo, Serbia) than in those states which have more favourable position (Czech Republic, Slovakia, Slovenia) (Tagai, 2016).

An important step in eliminating brownfields is their regeneration or reclamation and reuse. The potential for brownfield redevelopment is in many cases reduced by the location of brownfields in inner cities (Doetsch, Rüpke, 1998). Such a location tends to be connected with a limited space for firm expensed and with complicated transport accessibility (e.g. Koll-Schretzenmayr, 2006). This situation reduces the redevelopment potential of brownfields because transport infrastructure is an important location factor in the decision-making process of developers (Holl, 2004). Moreover, it is noteworthy that city centres and suburban areas are regarded as morphogenetic zones with the most evident changes in the functional-spatial structure of post-socialist cities (Sýkora, 2003). Thus, the potential of brownfield redevelopment in inner cities is further affected.

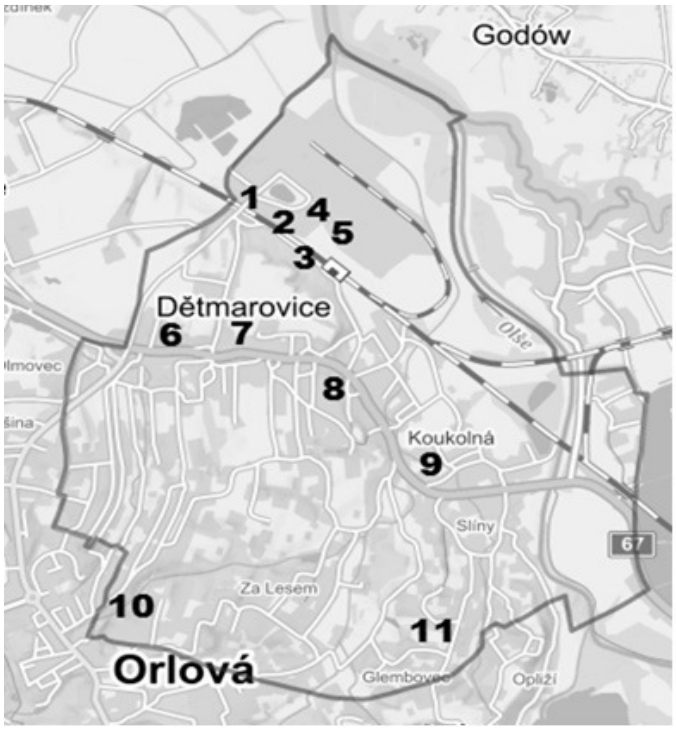
In the Czech Republic, brownfields deal with scientific disciplines and scientists such as Vojvodíková et al. 2011; Klusáček et al. 2011; Chrysochoou et al., 2009; Doleželová et al., 2014; Martinát et al., 2015). The above-mentioned researchers deal with the collection of data on abandoned obsoletes and sites, the creation of databases and the prioritization or classification of brownfields. The concepts that are related to the given issue are urbanization, which is the expression of the percentage of inhabitants living in the city on the total population of the territory (Harmáček, 2016). An important term is also suburbanization, where the term can be interpreted as moving people, commercial and other entities from the nucleus to their periphery (Kuráž and Mansfeldová, 2011). Nowadays, the phenomenon of moving to the outskirts and building new neighbourhoods and new industrial zones is becoming a phenomenon in the Czech Republic. In the centres of smaller towns (Karvina) and the big ones (Olomouc), there are abandoned buildings and former industrial sites. The brownfield issue in Karvina was dealt with in a case study (Turečková et al., 2016)

It is important to take brownfields not as a threat but as an opportunity. Cities should rather grow to be compact and not cover the open fields on the city margins. Each particular urban system involves a specific arrangement of territorial interdependencies reflecting, among many other factors, political strategies articulated in the form of planning doctrines and policies. Spatial planning can be therefore regarded as an important 'platform' translating essentially political concepts of territorial cohesion into the worlds of everyday urban activities (Malý and Mulíček, 2016).

2. Methodology And Data

The survey was conducted from autumn 2016 to spring 2017. The questionnaire was distributed to residents of the village Detmarovice (population 4.2 thousand, located in the Moravian-Silesian Region), and further was placed on the social network and the internet to cover balance of all social groups for our survey. The total amount of respondent was reached 69. Respondents were selected to be older than 18 years and live or work in Detmarovice (large power plant in Detmarovice is decisive employer in the municipality). The return of questionnaires was 100 % that was caused by targeting querying of individual respondent. The aim of the questionnaire survey was to ascertain the views of population of the village Detmarovice on the impact of brownfield on the real estates that occur in the vicinity of brownfields and how the existence of brownfield sites is affecting the surrounding real estates.

The questionnaire survey consisted of twelve questions that were divided into two parts. The first section dealt with the respondents' views on the issue of brownfields. Key question was if brownfields that are located in the vicinity of another real estate, affect the prices of real estates. The second part of the questions was focused on more detailed segmentation of the surveyed population. The questionnaire survey was answered by 61 % men and 39 % women. Within the age, the structure is greater than residents aged 26-45 years (48 %). At the occupation of the respondents, the most



dominate residents who are employed, where in the context of the relative frequency was 59 %. Another question related to the highest achievable education polled the residents. The majority of respondents reported that the high school with school-leaving exam (45 %). The following question in the framework of the questionnaire survey was the focused type of housing surveyed residents. Most respondents said that they live in their own family house. It was about 81 % of the respondents. The last question in the second part of the research was focused, in what part of the village Detmarovice lives. Here, respondents indicated that live outside the centre of the village, where it was about 57 % of the polled population. The table below shows the detailed segmentation of the respondents in the questionnaire survey.

Table 1 : Structure of the respondents of questionnaire survey
Source: own survey (n=69)

Gender	Female	61 %
	Male	39 %
Age	18-25 years	22 %
	26-45 years	48 %
	46-65 years	24 %
	65 and more years	6 %
Education	Elementary school	7 %
	Secondary school with final exam	23 %
	Secondary school without final exam	45 %
	University	25 %
Social status	Students	13 %
	Employees	59 %
	Entrepreneurs	10 %
	Unemployed	2 %
	Retired persons	10 %
	Persons on maternal/parental leave	6 %
Housing	Private family house	81 %
	Rented family house	9 %
	Hostel	2 %
	Own flat	1 %
	Cooperative apartment	4 %
	Rental apartment	3 %
City part	Around the municipal office	20 %
	Near to the railway station	14 %
	Koukalna	9 %
	Elsewhere	57 %

3. Brownfields in Detmarovice

On the territory of the municipality of Detmarovice 11 brownfields is located. The figure 1 below shows their location. Most abandoned buildings are located near the train station in the premises of the power plant Detmarovice. Most of the brownfield sites have been used in the past for industrial use. The following most numerous group of their use is ex-amenities and housing. As for potential environmental burden it can be said that in four brownfield sites the possibility contamination is very limited. In case of six brownfield sites we can say that they occur near residential areas. It is obviousthat, that certain way can affect the prices of surrounding real estates.

4. The influence of brownfields on the prices of surrounding properties

Based on a questionnaire survey that was carried out it can be said that majority of respondents indicated that brownfields generally reduce the value or price of the property (84 % respondents). Only minimal response appeared to statement that the abandoned objects and facilities do not affect the price and value of real estate. The Figure 2 shows the results on a given question.

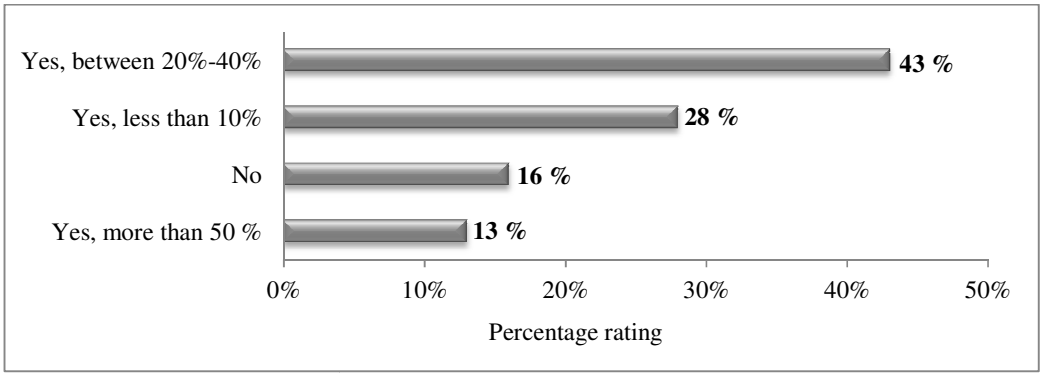

Fig. 2: Do you generally think that "abandoned areas and areas" reduce the value of neighbouring real estate (houses, flats, land, building plots, etc.)?
Source: own survey (n=69)

The following question was focused on question whether the inhabitants perceived problems while living in the proximity to brownfield. In a higher relative value (72%), housing was not in the vicinity of the abandoned area or building. The remaining 28% did not mind living in the vicinity of the brownfield. Another question was aimed to find out if the people are living within approximately 500 meters of a brownfield. As a result, 70% of respondents do not live in an abandoned building or area. The remaining 30% are within 500 meters of the brownfield. The question that asked "Would you buy a real estate in close proximity to the "brownfield area" if its price was about 20% lower than the usual price?", Respondents in a relative number of 84 % said they did not.

The following Figure 3 shows the results for questions why respondents think that brownfields are reducing the value or price of real estate. These questions asked respondents to assign values from one to six, where value one was considered the least important, and value six was very important. Average values were constructed as follows: Within each question, the number of respondents ranged from one to three and four to six. The mean value of the question was also drawn.

The biggest reason why brownfields reduce the value of real estate is the occurrence of dubious existence, or drug addicts and homeless people. Relative frequency is 69 % of the addressed population. The second most serious problem is that abandoned buildings are dangerous from their construction and technical condition. This option had a relative frequency of 60 %. The next option was that we do not know the future use of the brownfield. This is 47 % of the people addressed. The remaining questions were below 50 %, so they were not considered as a serious problem. To other residents, other options did not come as a problem when brownfields can affect the value of the surrounding property.

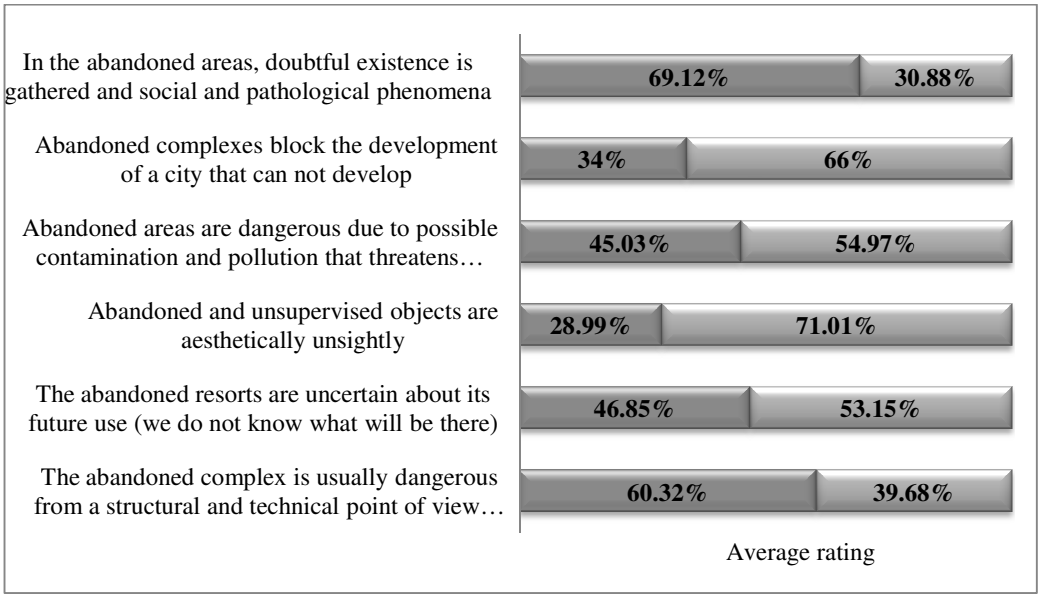

Fig. 3: Evaluate questions about the reasons why brownfields reduce the value or price of real estate.

Source: own survey (n=69)

Next question of the survey was focused on whether respondents would buy a property within a certain distance from the brownfield. The largest share of respondents would potentially buy real estate if it was 200-500 meters away from the brownfield. This is a relative frequency of 35 % of the populations addressed. Furthermore, 30 % of the population would consider a potential purchase if the distance from the abandoned building and the premises are more than 500 meters. Subsequently, the third option of buying a property within 200 meters of brownfields was reported by 19 % of respondents. The last two options were a small percentage.

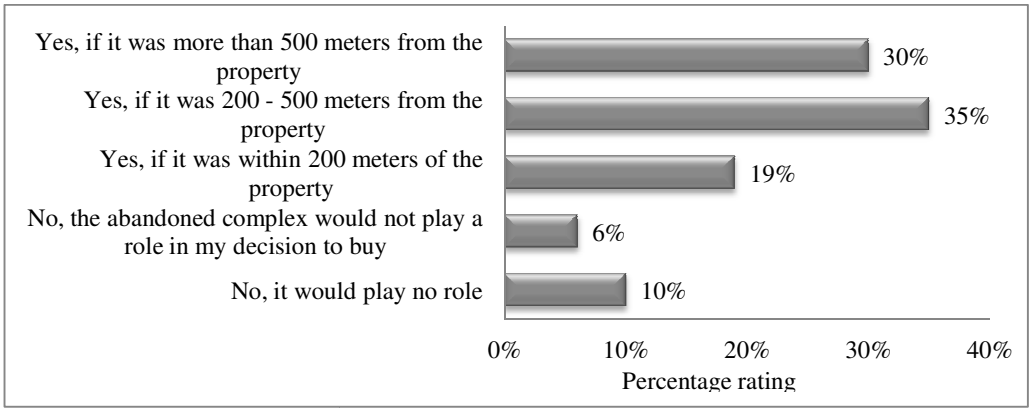

Fig. 4: If you buy real estate in Karvina, would the brownfield presence play a role in your purchasing decision?

5. Conclusion

Brownfields are a very current topic today. Abandoned buildings and sites are a weak point and a threat to the cities and municipalities where they occur because they reduce the development possibilities of the regions, especially they burden the public budgets. On the other hand, it can be added that properly exploited brownfields, which have a certain potential, can contribute to the development of the regions and increase not only economic and living standard, but also might help environment.

The aim of this contribution was to interpret the results of the survey that was focused on brownfield issues and to study their impact on the value or price of surrounding properties. In the framework of the primary research, a structured questionnaire was produced that was distributed to the inhabitants of the village of Detmarovice. The result is that brownfields have an impact on the value and price of properties that occur near abandoned objects and real estate. The results show that 84 % of the respondents believe that brownfields reduce the value of surrounding properties. Among the most serious reasons that affect the price of the neighbouring real estate is the occurrence of socially pathological phenomena. This is thought by 69 % of respondents. The next reason is that brownfields are dangerous from a construction and technological points of view. According to the relative frequency, 60 % of the respondents are concerned.

According to the survey, it has been confirmed that brownfields are threatening the price of real estate in Detmarovice. Residents do not want to live in abandoned buildings and areas because they are dangerous, can cause health problems and in some way affect the living standards of the community.

Abstract

Nowadays, to maintain a competitive business, a company has to adjust to the pace of globalization and rapidly changing market needs. Companies, involved in software development projects, are more commonly working with territorially distributed and international teams and remote customers. It happens that in order to maintain effective and rapid work on such projects, cloud are used. But despite these positive aspects of cloud-based tools, some companies and project teams more prefer physical tools instead of cloud. Such contradiction raises the need for reasoning what are the cases for cloud tools usage in software development projects in order to diagnose whether the tool would be useful in the specific case or activity. The goal of this work is to understand better how companies use cloud technologies to support their software development projects. Moreover, based on gathered data, the framework of companies' behaviour was proposed. The results obtained in this work can be used by companies in order to understand their behavioural type, assess their readiness to the cloud adoption and pick up a set of cloud-based tools for conducting their software development projects.

Keywords: cloud computing, cloud services, cloud-based tools, software development projects, project management.

Introduction

Nowadays science, society and business are rapidly changing and becoming more global. IT companies are a prime example of such globalization. Increasingly, software development is becoming international and territorially distributed, outsourcing specialists from all over the world start working on projects (Glukhov et al., 2015). It means that additional tools are needed to maintain high pace and quality of development (Eckstein, 2013).

There is large amount of software development tools, which could potentially support different essential project activities (for instance, business process modelling (Ilin et al., 2017). This could be due to the assumption of some researchers that tools utilization can be considered as an important factor for the team efficiency. But as long as the business globalization gains momentum, the stand-alone software becomes potentially more and more inutile, because of strong need in distribution of data through Internet (Bompani et al., 2000).

The history of the term "cloud" has long routs into the past of technologies and the first ideas emerged in the air in early 1960s with further rapid and aimed development in alignment with society growing needs (Jadeja and Modi, 2012). Cloud computing is a type of internet-based computing, that provides shared computer processing resources and data between devices on demand (Buyya et al., 2010). In other words,

it is technology, in which a computer infrastructure can be seen as a "cloud". It makes possible for businesses and individuals to use applications from anywhere on demand (Glukhov et al., 2016).

In some studies it was indicated that the use of cloud could potentially affect the efficiency of project activities: documentation storage, communications, planning, budgeting, remote and parallel work (Rozman et al., 2017). It was even proposed that there is possibility of cost reduction as a result of utilization of "pay as you go" model and scalability of cloud-based services (Hashmi et al., 2011). It was also argued that geographic issues, linguistic and cultural challenges could be potentially overcome by cloud due to its ability to be customized and easy accessed.

Despite the identified strengths of using cloud-based tools to support software development, some software development teams still use stand-alone or physical tools (Azizyan et al., 2011). This research seeks for better understanding of cloud-based tools usage are used and factors around it. The structure of the research is the following. The second section of current paper addresses the analysis of previous literature and description of chosen research process and methodology. The third section contains the gathered data analysis and results of conducted research. In the last section the conclusions and discussions are presented.

Literature Review and Research Methodology

Cloud computing is defined as a technology of distributed data processing in which computer resources, capacities and services are provided to external users on demand over the Internet (Foster et al., 2008).

Reuven Cohen, the expert on ICT, defines cloud computing as "Internet centric software", where the possibility of distributing processes through the Internet will make the software development more global and perspective (Geelan, 2008). In the same research Praising Gaw, argues that cloud is the "concept of using the Internet to allow people to access technology-enabled services". Finally, Jeff Kaplan proposed that the concept of cloud computing can be defined as "broad array of web-based services".

Current cloud "State of art" is represented in the Figure 1, in which the ranking of cloud vendors is amazed based on the Gartner's Magic Quadrant 2014 for Cloud Services. The cloud services' providers can be distinguished into four groups:

- "Leaders" – the companies, which are well established and promising (Amazon, Microsoft);
- "Visionaries" represents the vendors, which have huge perspectives in the future, but do not yet execute well (AT&T).
- "Niche Players" vendors are focused on a small segment and do not out-innovate others (IBM, Rackspace, HP);
- "Challengers" describe the companies, which do not catch the market direction, even if they execute well (Google).

Fig. 1: Gartner's Magic Quadrant 2014 for Cloud Services

These vendors provide users with a wide range of cloud solutions. In order to provide reader with existing solutions of these vendors, the overview of the most popular services of Amazon, Microsoft and Google is presented below:

- Amazon Simple Storage Service (Amazon S3) is an online web service offered by Amazon Web Services, providing the ability to store and retrieve any amount of data, at any time from anywhere in the network, the so-called file hosting ("Amazon Simple Storage Service (S3)," 2017). In case, presented by (Nasuni, 10.14), the experiment on a massive amount of data (12 TB) transmission from one cloud service to another was organised. Three huge vendors were participating: Amazon S3, Windows Azure and Rackspace. According to the results, researchers admitted that the best rate of data recording was for Amazon S3, the transfer of data from two other services took only 4-5 hours, while the data transfer to Rackspace took a little less than a week, and in Windows Azure - 40 hours.

- Microsoft Office 365 is a set of services, which allows users to access to various programs and services based on the Microsoft Office platform, business-class email, functionality for communication and document management ("Office 365," 2017). It was reflected by (Rahimi et al., 2014) that Office 365 is a SaaS model of cloud computing, which provides customers to direct access to services and application.

- Google Drive is a cloud-based data warehouse, which allows users to store their data on servers in the cloud and share them with other users on the Internet ("Google Drive," 2017). In the study of mobile cloud storage (Huang et al., 2013) admitted that Google Drive offers to users convenient software for devices based on different platforms, with different interfaces and with different operational systems.
