The Nature of Modern Money: Base Concepts and Genesis of Theories

Igor Lyukevich, Graduate School of Public Administration and Financial Management, Peter the Great Saint-Petersburg Polytechnic University, Saint-Petersburg, Russia, lyukevich_in@spbstu.ru

Olga S. Nadezhina, Graduate School of Public Administration and Financial Management, Peter the Great Saint-Petersburg Polytechnic University, Saint-Petersburg, Russia, nadezhina_os@spbstu.ru

Abstract

This paper explores some of the major categories of monetary theories and theories of money. It defines the essence, the origin, and, to a large extent, the nature of money, classifies monetary theories, substantiates some concepts of classical quantity, cash balance, liquidity preference, pure monetary theories. It introduces the notions of monetary chartalism, monetary commoditizatonalism and monetary constitutionalism into the scientific use. It proves fiat essence of modern money. It applies praxiological approach to money research. Debatableness of money itself is shown.

Keywords: money, monetary theories, praxiological approach

Introduction

The universe sets a problem of searching for a matter that should prove, on the one hand, that economy is the only base for humanity, and, on the other hand, to ensure order and eliminate chaos in economic exchanges of society. Such a foundation, saving the human race, is money, one of the most important institution. Money is still not fully comprehensible. Furthermore, it is, perhaps, unknowable at all. In economic research such metaphorical representations of money as "fat", "blood" or "language" of economy are known. Money is also identified with "water", "time", "evil", "happiness" or other substances. Possibly, the characteristic of money as energy phenomenon of human actions is true (Lyukevich, 2011).

Money is a way of thinking. The ability to comprehend money in its historical evolution is related to our ability to reinstate conceptual horizons and discourses which have encompassed, defined and described money again and again. Hence, it is impossible to distinguish monetary history from the history of thought. (Nenovsky, 2009).

Quantitative aspects of the impact of money demand and supply on the economy, though debatable, are adequate. The problem of money research is mostly connected not only with disquisition of new quantitative, but also that of qualitative regularities. Qualitative characteristics of money are even more mysterious. Despite various and versatile research, in essence, the origin and nature of money does not seem to be a common notion, the same as differentiations and explanations of these concepts. In addition, various characteristics of modern monetary system as symbol, notal, representative, fiduciary, fiat, etc. are there.

Literature Review

There are a lot of works concerning quantity monetary theories, as well as monetarism and Keynesianism. The following ones should be noted among the papers of the Russian researchers: search for the causes of inflation in the debate of the XVIII - XIX centuries between currency and banking schools (Moiseev, 2014); works devoted to inflation targeting (Glazev, 2015), transmission mechanism of monetary policy (Ershov, 2016).

Economists speak about the shortcomings of the modern monetary system (Rodionov et al, 2014). All of them are connected, from our point of view, to one factor – today national banks do not have at their disposal any effective tools or techniques for direct effects on economic growth. (Naumenkova S., Mischenko V., 2015).

Researchers emphasize transcendence of money, calling it "the highest form of abstraction" (Abramova, 2013), "anthropo-cosmological substance" (Bazulin, 2008), "special information resource" (Krolivetskaja, 2013), "energy phenomenon" (Lyukevich, 2011).

There are some papers, close to the subject of the present research, which are devoted to modern chartalism (Dubjansky, 2015), K. Marx's monetary theory (Tronev, 2007), search for the essence of money (Gogohija, 2012), research of communication between the concepts of the origin of money and judgment of problems of the modern banking system (Portnoy, 2015). Qualitative characteristics of money have practical importance, for example, in constructing world rankings (Rodionov etc , 2015), formation of tax scale (Kalinina, 2016), assessing not only economic, but also social efficiency investments (Kudryavtseva, 2015).

Problem Statement

Changes in the economic structure lead to changes in the theory of money and economic theory in general. The aims of our survey are to search for qualitative regularities in the monetary system. It appears that correct understanding of the nature of money can argue theoretical conclusions about stability of the monetary system, or, on the contrary, be the basis for judgments about the problem of the current monetary standard, imbalances between social and economic relations, impossibility of one or another currency to be the basis of the international financial order or to carry out money functions in full.

Methodology

This study uses systematic approach to the analysis of monetary theories, as well as praxiology and phenomenology as a concept of money phenomena learning. A unity of the historical and logical method, methods of comparison, scientific modeling, classification and grouping techniques are applied.

Base Concepts: Theories of Money and Monetary Theories

When exploring the money, scientists from ancient to our days are trying to answer the question: how, with the development of culture, metals and paper in the form of coins and banknotes have become willingly accepted in exchange for goods; why the forms and standard of currency change; what determines the value of money; what the reasons for and patterns of changes in the purchasing power of money are and so on.

Some researchers believe that the essence of money can only be determined through religious and cultural cognition. People will never be able to know what money is. Their knowledge about money is not broader than the knowledge of God: namely, that God is in the spiritual world. Money is not endless, but uncertain and generates an astounding complex of all kinds of psychological reactions, as well as material ones. (Skidelsky, 1992). Secondly, many scholars believe that money is primarily a social rather than economic product. And thirdly, most economists consider the nature and essence of money through the need to find an equivalent for material exchange and obtain essential benefits.

So we can see a system of views about the essence, origin and nature of money, calling them the *theory of money*. Analysis of this system suggests a possibility of three directions for the above-mentioned views, which are correspondingly named "transcendental", "socioeconomic" and "economic" theory of money.

On the other hand, in order to understand the economic mechanisms, scientists are trying to formulate a view about the influence of money on the economy.
There is a unique economic idea that the price level is directly proportional to the quantity of money, and the purchasing power of money is inversely proportional to the quantity of money. This concept was formulated in the XVI century (Bodin, 1568). The mathematical ratio between the money supply and prices was formulated by Newcomb (Newcomb, 1885) and developed by Fisher (Fisher, 1911). There is direct proportion between money supply and money demand if the velocity of circulating money (V) and the total quantity of purchased goods (total number of transaction in economy over the period in question) (Q) are constant, the average selling price (p) will be influenced directly by increase or decrease in the money in circulation (M). Changes in the money supply (M) cause changes in prices (p) - the total circulation of money in the sense of money expended is equal to the total money in circulation multiplied by its velocity of circulation or turnover: $MV = \Sigma pQ$ – "equation of exchange".

Wherein, there is a quite different view that the key element of money circulation is not the price of things in terms of money, but the price of money in terms of things, or, in other words, exchange value of a unit of money. Therefore, the price level is secondary in relation to the demand for legal tender money, which depends on the choice of the society to keep resources in the form of legal tender-coins, bank notes and bank demand deposits. Based on these trends, the equation of exchange is as follows: $P = kR / M$. In this formula P is the real price of money as the quantity of goods that a unit of legal tender can purchase, instead of p in the equation of exchange above there is nominal price of money as the quantity of legal tender that a unit of goods can purchase ($P = 1/p$); k is the proportion of real resources that the community holds as titles to legal tender; it is the inverse of the velocity of circulation ($k \sim 1/V$). R is total resources, enjoyed by the community (other than banks). M- the number of units of legal tender. In terms of Fisher's equation this approach could be expressed as $M = kpY$. Where Y –Gross national income in real price; p - price index; pY - nominal gross national income; k - the factor to make the ratio of the money supply and national income identity; it is part of the national income which people want to keep in the form of cash. Thus, the demand for money is directly proportional to the nominal income. (Pigou, 1917. P.53)
A popular enough "paradox of thrift": the more one saves for a rainy day, the faster it comes. It bases on liquidity preference views. Monetary liquidity, in common, the same as legal tender is assets in the form of cash or near-cash (coins, bank notes, current bank account). Liquidity preference, the same as the demand for money, refers to the preference for holding on to savings as money (i.a. in liquid form) rather than investing them. People will need money to satisfy the transaction motive and precautionary motive regardless of the level of interest. So, there is only one, namely speculative, motive to change the demand for money. Liquidity preference (i.e. demand for money) will be high if interest rates are low and people expect them to rise and hold money to satisfy the speculative motive for the future, and vice versa.

Then Keynes (Keynes, 1936) notes that economic development implies active investment by means of households' lending money through buying bonds. Rise in investment is followed by increase in the money supply. But with the increase in the money supply the cost of money (interest rate) reduces. Lower interest rates diminish the speculative motive and increase liquidity preference and the demand for money. Thus, you can get into a "liquidity trap", when an increase in the money supply does not result in more investment to ease economic depression. The cost of money (interest rate) decreases and people hold cash and wait for better investment opportunities.

Finally, there seems to be a view which switches the monetary analyses from a long-term to a short-term focus: the primary determinant of the state of macroeconomic aggregate demand - whether there will be unemployment, whether there will be inflation - is money, M1 or M2, and more specifically, perhaps, its various rates of change (Samuelson, 1969). The conclusion that an increase in the money supply leads to a similar increase in inflation and short-term fluctuations in real GDP are directly connected with the supply of money, was first made in

papers by Warburton (Warburton, 1945-1953). Later Friedman and Schwartz argued that money is not an asset which is held for its own sake. It is a "temporary abode of purchasing power" waiting to be spent on other types of financial or physical asset. (Friedman and Schwartz, 1970) Sooner or later an increase in the supply of money would find its way onto the goods and cause price to rise. The demand for money is a function of the yield on money and the yield on other forms of holding wealth.

Thus, we select four basic systems of views about the influence of money on economic processes, which we call "classical quantity monetary theory", "cash balance monetary theory", "liquidity preference monetary theory" and "pure monetary theory".

In quantity theory the most important is that money is the velocity of circulation; in cash balance it is that it is kept hold of. That is, the first one is focused on how prices depend on the money supply and the second one on what the demand for money is, what people and businesses will want to have to maintain the purchasing power. Pure monetarists believe that the price of money (interest rates) are the result of interaction between the money supply and demand for money. Keynesians do not believe in the impotance of money. A change in the money supply may lead to lower interest rates but does not necessarily affect the level of national income or result in increase in the general level of prices. Whereas monetarists argue that changes in the money supply will lead directly and quickly to changes in the national income, Keynes argued that an increase in the money supply would merely result in lower interest rates, with no immediate effect on the national income. We will illustrate the differences between Keynesianism and Monetarism in conclusion, the figure 1 are below.

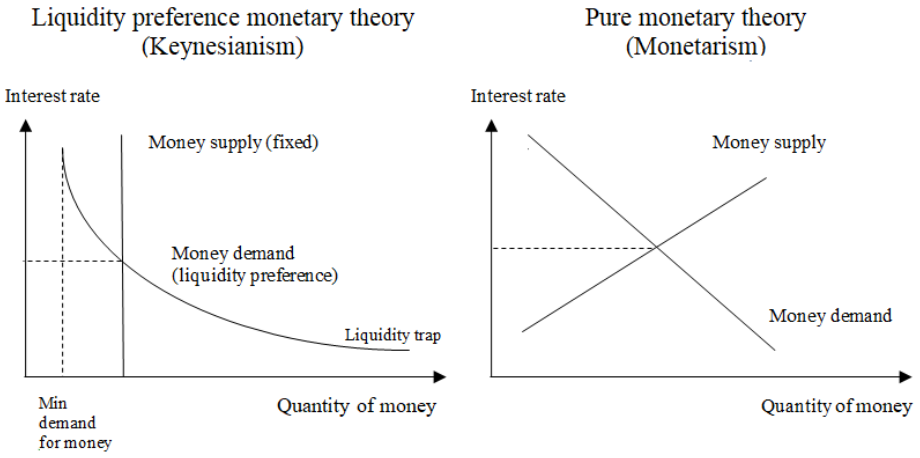

Fig. I – Cost of money (interest rate) in Keynesianism and Monetarism – summary

Nature of Money

Now let us regard the system views on the nature of money and introduce the genesis of these theories. So we need to distinguish between the categories of *the essence, origin and nature* of money.

It seems that the essence of money is in its own value. The understanding of the essence of money gives an answer to the question about the role of money in society, culture, economy, civilization in general.

Let us call emergence and being of money in society as their origin. The origin of money is not quite known: it does not disappear and does not come to an end. The life of money reminds the existence of time, but time with a various standard.

The nature of money, in our view, - an underlying cause of capability of one or another matter to carry out monetary functions at a historical moment - is the changing form of money. The nature of money is, possibly, connected with economics, but, more probably, with social relationships, with human spiritual, physiological and psychological activities. The nature of money is similar to that of language, information. But it is "secured" rather than simple information, and any matter can act as security if only the habit and practice of its use confirm its moneyness.

The analysis of concepts from Ancient Greece to the present day allows saying that all the views of the nature of money are anyway about to understand the reason: why is money value? Why are economic participants ready to exchange their goods for small slices of metal, cut paper or bank promises (information) for possible payments? It seems that explanations of it are finally reduced to one of three concepts.

On the one hand, many researchers consider that the nature of money is statutable. That is, the value of money is stated by that who establishes it. In turn, it is caused by multiple factors including subjective views, economic difficulties, wars, etc.

Another opinion which many scientists stick to is that the nature of money is in the general value of one kind of the good for all people. This value is not statutable, but is defined by supply and demand of the most significant goods. The value of these goods depends on circumstances, but indirectly, through free market relations.

And, at last, the third concept: the nature of money is social. Emergence of money is the same organic process as emergence of language, law, customs. It is not the result of an agreement, contract, special idea, value of goods, but the result of satisfaction of individual interests. Acting on the assumption of economic reasonability, economic actors change one goods for others, not valuable on their own, but possessing the greatest ability to be exchanged for other goods. The value of money is only in the functions which it carries.

Thus, the concepts of Monetary Chartalism, Monetary Commoditizatonalism and Monetary Constitutionalism were introduced into scientific use.

Chartalism (from lat. charta - a sheet of paper, here means a symbol or ticket) is a construct according to which money has a status and symbolical nature. The state (in early doctrines - people) chooses some symbol and legislatively allocates its face value. This matter is not valuable as such, and acts as a means of exchange, unit of account, standard of deferred payment. But the main function of this monetary substance is to store value, i.e. accumulate wealth and divide society into estates. It is necessary, jn as much as public relations dealing with exchange are supported by fairness, which means proportionality, but not equality as society relies on the principle that everyone is awarded in proportion to their activity If proportion is not observed, exchange is impossible, and social relations are impossible too.
This concept seems to have begun as early as in works by antique thinkers. In this case, the analysis of primary sources suggests that the term *charta* in reference to monetary circulation was first used by Knapp, who called money “chartale zahlungsmittel” (Knapp, 1905. P.21). Subsequently, Keynes characterized modern monetary circulation as the “age of chartalist”. (Keynes, 1930. P.4).

In the 18th century a concept was formulated, which causes a commodity and evolutionary nature of money we call commoditizationalism (from eng. commodity). According to amonetary commoditizationalism, money is the matter which nobody will refuse to take in exchange for others because of its own value, usefulness of its consumer properties. The nature of money is based on exchange of market surplus of products (unlike the antique thinkers’ view who found the nature of money in exchanging for satisfaction of one’s own needs). The process of commoditization is a loss of exclusiveness, uniqueness by goods (for

example, at the expense of a brand) and their transformation into goods of mass demand. A popular similar term commodification bears some negative sense. It is used to characterize the process during which an increasing number of various goods, services, human activity, initially not intended for sale, acquire cost and are bought and sold in the market. One can speak about commodification of science, culture, education, family values, etc. It is possible to argue with Marxists, but they consider what exactly was called commodification, but not commoditization by K.Marx as «Fetischcharakter der Ware». (Marx, 1972. S.47).

The third frame of reference is monetary constitutionalism (from fr. constitutionnalisme). That is the way we call a group of beliefs which explain the organic (democratic) nature of money - similar to emergence of language, customs of law, etc. The nature of money is in its functions. In sociology constitutionalism is a concept about formation of personality genetic and biological factors. Also constitutionalism is understood as ideals of social democracy in a wide sense. In the monetary theory, the word constitutionalism, can be used to refer to the views according to which money is a product of human action. In the concept of those individuals without any enforcement, special agreement, state regulation but only on the basis of economic foresight for economic purposes goods with a lower ability for exchange are exchanged for the goods though not valuable as such but with a higher ability for exchange. The constitutional concept of the nature of money is the most modern. Its ideas were formulated in the 19th century by Menger. Now it is the official views of the origin, nature and essence of money in the western economic school.

Modern Money: Different Opinions

Modern money is nothing more than faith obligations of the national bank to accept something (even not material) as a means of payment issued by it. Belief in the value of these substances is based on practice and habit of using them in economic exchanges. The state also uses in payment only what is issued by its National bank. So the essence of modern money is that they are property (asset) just because of this obligation (liability) of the National Bank. Thus, the present monetary system can really be described as a fiat one («let it be money») - which would never occur according to what they believed in the 19th century; at the beginning of the 20th century it was called temporal, inferior, degenerate money, but in the middle of 20th century, it appeared as permanent.

Why is modern money fiat? Let us try to answer this question, tracing the genesis of monetary theories.

According to the chartable concept, ancient thinkers believed that people, as participants of economic exchange, introduced silver or gold as a currency symbol in the role of medium of exchange. (Платон), (Аристотель). Scholars of the Middle Ages timidly objected to the role of the State in regulating monetary circulation in part of the replacement specie of specie money for notal money.

Later economists still believed in the real value of currency, but spoke about the need to support its value by the State. (Locke, 1689), (Barbon, 1690). Physiocrats had already noticed that money did not have a real but symbolic value. (Quesnay, 1766). Knapp justified the crucial role of the State, not people in money circulation, and pointed to the right of the State to determine the status and value of the currency symbol. (Knapp, 1905). Keynes finally formulated an attitude to money only as a unit of account, having certain properties, which should have the matter so that it could be used as currency (Keynes, 1930).

Once people agreed to make payments by weighing metal. Soon coins appeared that contained a certain amount of metal money. After some time, for easy transportation coins were left in the custody of moneychangers, and replaced with their note or description of differed payment - thus money of account appeared. Coinage becomes the State prerogative. The State reduces the weight of the specie, money became Representative, Token (Notal, para-typic). Then the

State renounces the use of metal in monetary circulation. Payment is made by piece-of-paper. Money has become a symbol: first Managed, and then Fiat.
Supporters of the commoditizational concept disagree with the ancient and medieval thinkers. Smith argues that the nature of money is not about people finding a tool to facilitate exchange or about surplus of labor products. (Smith, 1776). Say said that the State could not set the value for money: because goods are exchanged for money, to the extent that the value of money also determined by demand on the part of goods and by supply them on the part of the holders of money. (Say, 1803). Ricardo believed that the State could not set the value for money also because it did not have a monopoly on the creation of money, because of the need to meet the demand for banks. (Ricardo, 1817). Marx develops Smith's idea that with the advent of banknotes the true value of goods was not money, but work. (Marx, 1959). In view of the fact that money was not a commodity, but just a promise to deliver goods, Hicks called money the most perfect type of security. (Hicks, 1939). Friedman, using the terminology of the 19th century, called modern money not a "promise to deliver the goods" (Fiduciary), but Fiat - in general not provided with anything, except for discretion of the monetary (Friedman, 1960).

In the early stages a product appeared valuable for everybody in the community, therefore it was easily exchanged for any other products. The amount of this particular product was easily to value with another because everyone wanted them – a product was commoditized. This is commodity money. Metals won the competition among other commoditized goods. To facilitate the exchange, the State had to put a mark on these special goods, so coins appeared. Commodity money has an indigenous disadvantage: to multiply the amount of cash money real resources are to be used. Therefore, to comply with its monetary obligations the State "cheats" - reduces the weight of the coin, then replaces the coin with a promise to deliver the precious metal (bills, devises, bank liabilities). There are public securities - fiduciary money. At the end of the 20th century the authorities ceased to connect monetary security with the obligation to deliver the goods (coins), so money became Fiat.

In our view, the most truly the nature of money can be explained by monetary constitutionalism. Menger, Mises, and Hayek build a theory about effective operation of free individuals as the basis of society. Menger formulates an idea that economic expediency (influenced by practices and habits) stimulates people to exchange their goods for others with a greater potential for exchange, and despite immediate consumption they do not need them. (Menger, 1871). Mises stresses that this process is only possible on the basis of people's free behavior. (Mises, 1949). Hayek proves that what we call "money" is only the most liquid medium of exchange at this time and in this place. To explain this phenomenon it would do more good if the word "money" would describe the property which various objects have to a various, yet changing degree, for example "moneyness" and «near-moneyness». (Hayek, 1976). According to the constitutional monetary concept, something which is commonly called money is certain objects, emerged under the practices and habits in the form of the most liquid asset which has no other value, but function as generally accepted medium in exchanges. In a broader sense, money is the continuum of these objects at all times and in all territories.

Initially, producers trade their goods for the units with utility value (for example, wine for bread), then for the units that do not meet its needs, but are notable for a great potential for exchange (it could be cattle, salt, furs or stones). The economic interest of this trade is based on personal preference, without coercion, only on the basis of practices and habits. This free people's behavior turns one of the medium of exchange substance to which we used to call "money:. When the economy becomes more complex and rich, they begin to use precious metals as an intermediary in exchange. The most popular medium of exchange (the so-called "money") starts to acquire other functions. With the development of turnover, according to the needs of society, the most liquid exchange tool at this stage, in this time, in this place (in the form of pieces of metal, sheets of paper, disembodied information or otherwise) gets authorized by the State so that all payments can only be made by using this substance.

Conclusion and direction for further investigation

There are different views of money – monetary theories and theories of money.
Monetary theories explain the influence money on the economy. Classical quantity monetary theory considers the primary function of money as a means of exchange, cash balance monetary theory as a unit of account, liquidity preference monetary theory as a store of value, and pure monetary theory as a standard for deferred payment (Table 1).

Table 1: Concepts of money impact to economy (monetary theories)

Theories	Classical quantity	Cash balance	Liquidity preference	Pure monetary
Beginning and founders	16th cen, (Bodin, Newcomb, later – Fisher)	Beg.20th cen. (Pigou)	Mid 20th cen. (Keynes)	Enid 20th cen (Warburton, Friedman)
Primary determinant	Quantity of money	Exchange value of a unit of money	Money demand	Money supply
Key feature of money circulation	Price level is directly proportional to the quantity of money	Price level is secondary in relation to the demand for money	"Paradox of thrift": the more money is saved for a rainy day, the faster it will come	Change in money supply will lead directly and quickly to changes in national income

Each theory of money differently systematizes and generalizes the monetary factors - its beginning, evolution, the role of the State and others (Table 2).

Table 2: Beliefs about the nature of money (theories of money)

Views	Chartalism	Commoditizatonalism	Constitutionalism
Beginning	Antiquity	17th cen.	19th cen.
Nature of money	Division of society into estates for justice	Consumer value the goods	Free human behavior
Origin of money	Activities of the State	Economic exchanges	Social interaction
Role of State	No State - no money	Prevents illegal (incl. counterfeit) currency	Authorizes **the appearance and** form of **currency selected by society**
Significant contribution	Barbon, Locke, Quesnay, Knapp, Keynes	Smith, Say, Ricardo, Marx, Hicks, Friedman	Menger, Mises, Hayek

The genesis of monetary theories, described above, can be used for modelling and forecast of the international monetary system. It should be ubstantiated whether crypto-environment (cryptocurrency) will be the framework for future money or whether the transformation of the modern monetary system will follow some other suit.

Cultural Sector Personnel Management (Based on the Example of Music Department of Perm Children and Youth Art Center (Russia))

Anatoly M. Redko, Head of Music Department of Perm Children and Youth Art Center, Perm, Russia, redko.anatoly@mail.ru

Abstract

The article is concerned with the issues of managing the groups of creative people. The objective of the article is to review a personnel management system based on the example of Music Department of Perm Children and Youth Art Center (Russia). The most difficult key process in the management of any organization is human resource management. Effective personnel administration is a correctly and accurately built system using human resources in the organization. Provided the organization has an optimum number of qualified employees, such a system makes it possible for the organization to achieve set goals within the shortest possible time period and at minimum expense. The issues of personnel administration improvement under the conditions of increasing requirements to the quality of public administration seem to be especially critical; thus, the given aspect has determined the timeliness of the research topic. Based on the results of the music department personnel analysis on such criteria as education, qualification, and teaching experience, a project of activities targeted at the development of personnel management has been worked out and its efficiency has been evaluated. The main advantage of the cultural sector personnel management system proposed by the author of the article includes thoroughly developed recommendations for the personnel department with regard to recruiting candidates, as well as a performance reward system for the music department employees.

Keywords: supplementary educational institution for children and youth; management; personnel; music; culture; educational system; performance reward; motivation.

Introduction

A personnel management system is vital for any company, even if there are only a few employees involved in the work process. Personnel management is the domain of senior personnel, executives and HR specialists and is targeted at the increase in work efficiency and productivity of the organization due to the increase in efficiency of its employees by means of psychological, legal and economical methods. Cultural sector personnel management is quite specific because people working in this sphere are talented and gifted and require a special attitude on the part of their superiors and administrative staff. Thus, the urgent nature of this research work proves to be of global importance, for there is a great many of talented people all over the world. As a rule, they tend to be drawn together forming creative teams which have their own management system, where managers are well aware of artistic people's peculiarities and, as a rule, are creative themselves. Perm Children and Youth Art Center (PCYAC) is a municipal interdisciplinary supplementary educational institution for children. It implements educational activities and bears signs of a complicated multilevel system. Annually more than six thousand children come to the Art Center to study technology, tourism, regional history, physical training, sport, art, science, sociology and pedagogy. In regards to the education sector a multilevel system determines the methodology of program field formation, form and technology of educational activities' content implementation, as well as form and content of various types of educational programs integration. As of

January 1, 2016, a hundred and forty children's clubs and associations had been functioning successfully at the premises of the Art Center welcoming 6,771 children from all the areas of the city of Perm. The classes were held on a budgetary and non-budgetary basis. As of January 1, 2016, 5,550 students had been provided budgetary services within the scope of a municipal order. Disabled children have a right to receive two educational services. 1,078 children attend the Art Center on a fee paid basis, 554 of them are preschoolers. Due to the availability of technically-equipped classrooms and a concert hall fitted with up-to-date sound and light systems, the largest number of children attend art clubs and associations (57%), such as choir, theater and choreography classes. A maximum number of students per class in every club testifies to the quality of educational services which meet the requirements of the service consumers represented by club members and their parents. As a result of the personnel management analysis carried out at the Art Center, a number of problems have been determined. They can be classified into several categories: adjustment process of new employees, personnel training, succession pool formation and individual growth programs implementation. The main problems in the area of new employees' adjustment include a high rate of staff turnover, a small share of young professionals, and an undeveloped system of discipleship. Managers from many other countries beside ours face problems of this sort. Such problems have to be solved, and the search for proper solutions has stirred a global interest. In this context the given article presented to the world scientific community involves new concepts and practical significance. As for the matter of personnel training, the main problem lies in the lack of adequate professional training: only a small share of the employees have obtained a professional education. When it comes to the issue of a succession pool formation and implementation of individual growth programs, the main problem lies in the fact that if given an opportunity the most promising personnel leave the organization. Thus, it can be concluded that the personnel management system does not clearly assign functional duties and the process of personnel recruitment is too intense. The personnel training and development system, as well as the system of work motivation require a lot of improvement. These conclusions are based on the analytical and statistical data on Perm Children and Youth Art Center obtained during the years 2013 – 2015. The practical significance of the research involves the implementation of the developed project activities as an effective means of improvement of personnel management system. The results of the research can be used in any similar organization independently of the country of origin. Practical experience which has been obtained as a result of statistical research, questionnaire surveys and implemented methods of personnel management in the city of Perm have led to the students' excellent results and, therefore, may serve as a valuable contribution to the world science. This research was carried out at the Music Department of Perm Children and Youth Art Center with the consent of its authorities and every individual teacher involved in surveys and questionnaires. No grants or financial support was offered to the participants. The research was carried out at the author's account.

Methods

In order to carry out the research the following general scientific methods were used: analysis and synthesis, methods of comparative statistical and economical analysis, comparison and matching, content analysis. Sports and art clubs and associations are in the maximum demand among the younger generation. Out of the total number of club members 40% of boys attend sport and technical study clubs. Training and education activities at the Art Center are conducted through 174 supplementary education programs with the timeline equal to 1 to 10 years and 1 professional development program (fencing).

Literature Review

A lot of research works in the world science have been focused on personnel management. Thus, exhaustive solutions have been found in order to achieve and implement core principles of leadership and personnel management in the context of organizational ethical culture development (Information Resources Management Association USA, 2016). Differences of opinions of employers and employees are elaborately illustrated in the book "Public Personnel Administration. Situations and Strategies" (Klingner et al, 2009). Traditional models of human resources management from the point of view of such factors as service supply, purposeful nature of the communicative model, a type of feedback, value orientation, the role of the personnel, the role of a human resource manager, perception of the human resource management profession and the focus on education for personnel management are thoroughly described in the books by Stephen E. Condrey (2010), Zehra Alakos Burma (2014) and N. Nayab (2011), as well as by Russian Scientists A.K. Aykazyan, S.V. Andreyev (2014), I.A. Gerchikova (2014), and A.P. Yegorshin (2014). Problems of music education and other educational programs have been considered and researched by many modern scientists. Thus, for example, P. Miktsa, M. Rider and D. Biggz conducted a survey among orchestra directors. As a result, it was confirmed that management personnel strive for measuring up to high professional standards, motivate perseverance and patience of the personnel. Besides, professional recommendations for the students who aspire to become music teachers have been worked out (Miksza et al, 2010). According to the classification proposed by M.I. Magura, the following programs have been determined: adapted programs, modified programs (Magura, 2015:85) and authorial programs. As a result of Carlos A. Abril and Julie K. Bannerman it was determined that teachers perceive micro level factors (school) to have a substantial impact on their programs. Teachers' actions are mostly focused on a micro level, although some teachers consider meso-level (school district) engagement to be vital for maintaining and improving music programs in a given school (Abril and Bannerman, 2015). A comparative study of music programs in traditional and charter schools systems carried out by Jamie Kelly and Steven M. Demorest (2016) showed a high level of test results and a high level of attendance, which gives us a solid foundation for developing our own testing system. Pedagogical principles of children's supplementary education system development have been studied by V.A. Gorsky and A.Y. Zhurkina (2014). The research work by O.E. Lebedeva (2015), L.V. Yershova (2014) and L.N. Buylova (2014) is also focused on the problems of children's supplementary education. The fact that music education profession requires the best and brightest students with a great potential was studied by Linda C. Thornton (2015). Young people and children's motivation to choose musical-pedagogical education as their future career is described in the research work by Michelle L. Henry (2015). The research of vacancy market, its analysis and music teachers' preferences carried out by Nicole R. Robinson, pointed to the administrative support in the matters of employment (Robinson, 2012). Comparative analysis of personnel management in several countries was conducted by Fang Lee Cook, Debby C. Saint, Joe Vong (2014) Ecrem Tatoglu, Ellison J. Glaster, Mehmet Demirbag (2016). Our research is concerned with a special field of work, a specific sphere which requires managing creative, talented employees. A similar problem was studied in the research conducted by Maria Christine Meyers and Marianna Van Woerkom (2014). The study of the problem and strategic opportunities in the area of global management is touched upon in the research carried out by David G. Collins (2014). New perspectives in human resource management under the conditions of globalization considering a so-called "brain-drain" problem were studied in the research by Rosalia L. Tang (2016). L.E. Yershova notes that all the activities of a supplementary educational institution are carried out in a competitive educational environment of the city of Perm and are influenced by the growth of the market of private services and depend on per capita financing of the municipal order – permanent changes in the system of personalized electronic accounting of educational services (Yershova, 2014:27). Innovation-related risks are always inevitable. According to the provision of Perm city administration from 09.11.2010, #758 and provision from 17.12.2015, #1076, every child has a right to receive one free service. When a service has been received, it has to be confirmed in the personalized accounting system by means of

an electronic card check-out. Supplementary education is necessary in order to support and develop gifted children. The more we encourage and teach talented children today, the more successful the society of a particular country and of the whole world will become. Intelligent, educated children of the future will be able to use art in order to stop tragic bloodsheds, because every creative, artistic person desires to perfect their personal qualities. Such growing talents will create beauty inside themselves and in the surrounding world. In order to bring up such a unique generation it is vital to have an appropriate teaching staff which will function under the conditions of equal financial support.

Results

An analysis of the music department personnel was carried out by the author of the research. Human resources were analyzed according to such characteristics as education, qualification and work experience. As a result of the analysis some changes of the teaching staff have been detected. A number of young specialists has increased by 5 teachers, a number of the first rank and top-rank specialists has decreased. On the whole it can be said that the Art Center is not fully staffed – a factual number of staff members is 4 % (8 teachers) less than planned. A lack of teaching personnel has been detected in all personnel categories.

According to the research work conducted by a Russian Scientist E.V. Maslov, the personnel is represented both by in-service-teachers and by secondary job employees. (Maslov, 2015:26). In our case the largest part of the personnel has higher pedagogical education, there are several teachers with a post-graduate degree. It should be noted that during the period of this research the number of employees of supplementary education with higher pedagogical education has decreased by 21. The number of secondary job teachers has increased by 4 specialists. When taken on staff teachers are aware of their duties and requirements related to their professional and personal qualities. When considering a matter of promotion, not only the teacher's professional experience, superiors' opinion and achieved results are taken into account, but the teacher's self-assessment in the area of potential professional growth, as well. The author of the article analyzed the effectiveness of the educational process, expressed in the students' participation in various contests and festivals. The ratio of winners and runners-up of contests and festivals to the total number of students demonstrates the service consumers' degree of satisfaction and their ability to apply obtained knowledge and creative skills practically. When studying the ratio of the students' participation in festivals, contests and competitions to the total number of prize-winners (Table 1) it can be observed that their number decreased by 8% between the years 2014 – 2015.

Table 1: Statistics of performance ensembles' participation in contests, festivals and competitions

Level of festivals and contests	Academic year 2014-2015, number of times	Academic year 2015-2016, number of times	Rate of increase/decrease, %
Municipal	172	140	81
Republican	120	101	84
Regional	26	23	88
All-Russian	34	54	159
International	16	10	63
Total number	368	328	89

The number of prize-winners increased by 24% compared to the results of the last year. Thus, the ratio coefficient of the total number of students to the number of prize-winners of different contests and festivals in 2015 was 13/100, i.e. there are 13 laureates, runners-up and diploma winners to a hundred students of the Art Center. Thus, compared to the year 2014 the performance indicator and the level of evaluation and self-evaluation of the students have increased, which testifies to a highly-qualified and proficient education offered by the staff at Perm Children's Art Center. Such showings are possible only when the teachers' staff is well-qualified. Nevertheless, considering the personnel problems mentioned above it seems necessary to implement innovations into the management process. The goal of this research is to work up strategies of improvement and development of the personnel management system at the Art Center. In order to reach the set goals the following objectives have been defined:

1. To perform an analysis of the current personnel management system at Perm Children and Youth Art Center.

2. To give ground to the necessity of improving the current personnel management system.

3. To work up strategies of improving the current personnel management system.

4. To assess the effectiveness of suggested strategies.

The Object of Research: a Municipal institution for supplementary education "Perm Children and Youth Art Center". The subject of research: a system of personnel management. The novelty of this research lies in the development of practical recommendations for chief HR officers on hiring and retention of highly qualified staff, which may prevent an organization from employee attrition caused by strong competition in the job market. Culture sector personnel is especially subject to such changes. Our methods may be used by music departments both in state and private institutions of supplementary education worldwide. The analysis of statistic data indicates that most teachers in the field of supplementary education are middle-aged. The largest share of teachers belong to a senior group (43.86%), the share of young specialists is quite small. It is necessary to attract young professionals in order to start the process of a natural company renewal. The teachers whose work experience equals to 10-20 years make up 32% of the total number of teaching staff. The number of teachers whose work experience exceeds 20% comes to 33%. It should be noted that in the year 2015 the number of young specialists whose work experience was less than 5 years came up to 9%; along with the group of teachers whose work experience was 5 to 10 years, they made up 35% of the total number of the teaching staff. Thus, a gradual staff changeover at the Art Center is taking place. The length of teaching experience makes it possible to determine that the personnel is highly proficient, but a tendency for the aging of the teaching staff can be clearly observed. The structure of personnel formation fully conforms to the legislative acts, all the specialists have appropriate education which allows them to participate in educational activities; most of the teachers have higher pedagogical education (65%). The analysis of staff rotation indicated an abnormally high level of personnel turnover in 2015 (10%), even though in 2013 a significant staff renewal had taken place. Such natural staff rotation has an adverse effect on the quality of education, which can be confirmed by the decrease of quality indicators. Even though the older teachers retired and were replaced by their younger colleagues, it did not produce the desired effect – the students' performance rating decreased; some of the young specialists who had come on staff in 2014 left after having worked for only one year, which led to a 10% increase of the turnover coefficient. A social survey was conducted among the teachers of the music department in order to determine the typology of work motivation and to indicate the staff's value orientation, forces of motivation and the direction of further improvement of the personnel management system. Using a questionnaire the type, the force and the direction of the teachers' motivation were determined. After the survey, the staff was divided into four groups based on similar views and opinions. As a result of the survey, the teachers demonstrated a high level of motivation. Based on the conducted

analysis the author of the research carried out a comparative analysis of the answers on the left and on the right sides of the questionnaire ranked by the level of importance for employees and a graph built on its basis (Figure 1).

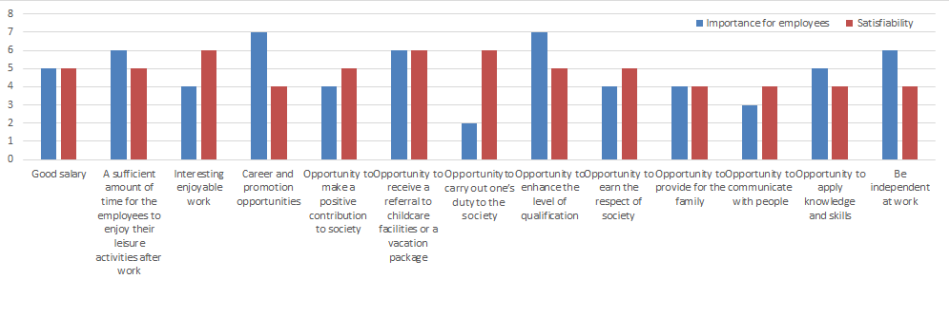

Fig 1. Determination of work aspects related to work motivation

All the collected data and image 4 showed a high level of the teachers' motivation. It was confirmed that the teachers have an advanced level of intelligence and regularly participate in creative events which allows them to unlock their pedagogical potential and achieve excellent professional results. Perm Children and Youth Art Center demonstrates both hygiene motivation factors (rewards and benefits) and motives (advanced vocational training and promotion perspectives). The main attention of the Art Center's administration is focused on hygiene motivation factors; in other words, the implemented bureaucratic value system implies traditional approaches to work stimulation. The human resource analysis makes it possible to conclude that on the whole, the teaching staff is rather qualified and efficient both age and ability-wise. The teaching staff is not stable, a gradual renewal of the personnel is taking place due to the lack of clear personnel management policy which does not give young professionals a chance to gain a stable position in the organization. As a result of the analysis of the current personnel management system, it can be concluded that professional competence of the personnel that has an ability to analyze, and design their professional activities and chooses the most effective and optimal ways to organize the academic process should be regarded as the main means of organizational quality changes. The analysis of the personnel management system of Perm Children and Youth Art Center indicated a need for the improvement of the personnel management system, which allowed to solve problems of personnel requirements, recruitment criteria development and selection of optimal means and methods. The supplementary children's educational institution does not possess its own regulations for personnel selection and recruitment. As for the numerical composition of the personnel, it can be noted that in spite of being quite low the Center's personnel turnover coefficient has increased compared to the previous time period. It brings us to a conclusion that the current level of the personnel turnover gives cause for concern. As for the organizational level, it must be mentioned that on the average a number of employees is compliant with a standard function span. In order to justify the need for the improvement of the personnel management system, a questionnaire was designed and distributed among the teaching staff. The music department was selected for the survey. The results of a general satisfaction questionnaire conducted at the music department showed a low satisfaction rate related to the size of salary and moral incentives. A survey was also carried out in order to evaluate the teachers' inner motivation. As a result, a low level of motivation was observed among the personnel of the given department. Thus, a current system of stimulation, officially defined as a system of labor and pay organization, can be considered satisfactory but requires some improvements. The author of this research has defined the measures that have to be taken in order to improve the personnel management system. The main problem area has been pointed out: personnel turnover, especially among young professionals. At the same time, the analysis of personnel motivation according to the results of the questionnaire has demonstrated a high strength of motivation among the teachers - most of them have an achievable motivation. The teachers are scrupulous about their job and do it efficiently. They

like performing difficult and interesting tasks which allow them to reveal their abilities and skills. At the same time, the analysis demonstrated an insufficient clarity and comprehensibility for some employees of the personnel development system. It is noteworthy that this area showed the most significant deviations as for the opportunity to fulfill one's potential within the organization and its importance for some particular employees. A program for Perm Children and Youth Art Center personnel stimulation has been elaborated with the consideration of the current crisis situation in the country and in the world (Figure 2).

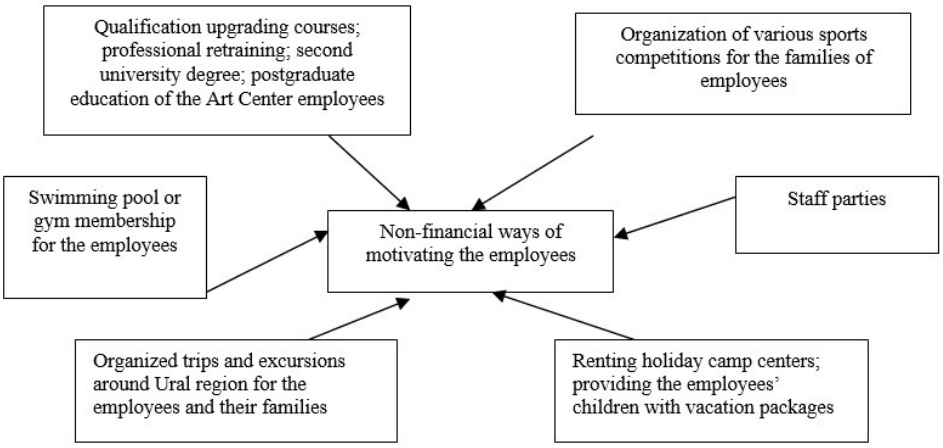

Fig 2. Non-financial ways of motivating the employees

As a result, it has been determined that the main share of expenses falls to the personnel's professional training. The recruitment procedure includes a number of relatively independent blocks set in a sequence; each block has a goal, a task, an action plan, tools and methods and a responsible party. The hiring process is handled through the interaction of the personnel department, the psychologist, the chief HR officer and other executives interested in having particular vacancies filled. Various globally recognized methods are applied: the WAIS test in order to determine the level of intellectual development and Lusher and Szondi tests for emotional and neuropsychic resilience evaluation. HR specialists are responsible for general supervision over the observance of recruiting, selection and hiring procedures.

Discussions

The main blocks (stages) of the employee recruitment process include the evaluation of recruitment needs; developing a set of requirements for a job candidate; announcing a competition to fill the vacancy; looking for candidates; hiring. The main techniques used at Perm Children and Youth Art Center in order to increase the efficiency of personnel recruitment and selection include the following:

1. A position requisition form.

A standard position requisition form has been developed and ought to be filled out by department managers once every quarter or half-yearly, and in the case of a position with a high turnover rate – monthly. A position description has been developed, as well. Internal candidates are considered according to the same procedure as the external ones with only one exception: one can gather more information about an internal candidate's abilities and skills. Sometimes it is useful to ask candidates to fill in an application form, where they should describe their qualifications and experience, explain why they are interested in this particular position, and why they regard themselves as a suitable candidate. It gives them an opportunity to introduce themselves and helps HR officers to obtain information about a candidate in a

standard form. This form also helps to understand the motivation and, if necessary, find out the candidate's ability to commit their thoughts to paper.

2. The development of an application form for candidates which may help HR officers to discover some well-kept facts that a candidate wants to keep private. These might include facts from the candidate's biography and professional experience, or it can help to obtain important information about the candidate's professional suitability for a vacant position and his or her personality traits.

3. The development of the text which can be used during a job interview in order to select a suitable candidate.

A job interview for the candidates that desire to take a teaching position comes down to several basic questions and appropriate replies. All the key elements and specific features of the requirements applied to candidates had been taken into consideration before a standard job interview form for every single position was developed. Time expenditures for every selection method have been considered and it has been determined that on the average every candidate takes approximately 7 to 20 minutes; only the length of the interview and the time spent on test evaluation are included into the time expenditure calculations because an HR specialist can fulfill other functional duties while the candidate is filling out an application form. After the interview has been completed and tests have been evaluated, a decision concerning the candidate's suitability, the start of a probation period and professional adjustment should be made. As a result of the analysis of the current personnel selection system and the new system developed according to professional recommendations, it has been decided that the use of the system offered by the author of this research would be more efficient. Being of preventive nature this system will be used for recruiting and selecting candidates. A personnel planning system will be introduced. A prognosis for personnel requirements will be made and a search for candidates will be initiated reasonably in advance.

4. The development and implementation of a standard vacancy request form for all departments. When recruiting candidates it is necessary to implement a competitive selection practice and to attract external sources. It is equally important to develop a candidate application form for a job vacancy post, to make up a plan of an interview with a candidate, carry out an economic assessment of expenditures for a job interview and develop a standard text for a job interview (which has already been done). Development of a hiring plan will make it possible to regulate and standardize the whole process, will make the process simpler, will decrease time expenditures on the personnel selection procedure and will determine the responsible party. The procedure of personnel adjustment is supposed to make the adaptation of new specialists to the pedagogical process of the institution smoother. As a rule, newcomers face a number of difficulties caused by the lack of information about the work process, location, and colleagues' peculiarities. The practice of inviting a professional psychologist on staff of an educational institution is widely used abroad, which is confirmed in the works by R.T. Marle and T.A. Schmidt (2015), and in our country according to the research works by L.V. Ivanovskaya (2014), V.D. Patrushev, I.A. Kolmakin (2014), and B.M. Smirnov. A psychologist staffing position is necessary for the music department in our case, as well. The introduction of a mentoring or discipleship system, when mentors receive a monetary reward for helping newcomers adjust, may defuse conflicts and improve psychological climate among the staff. The project measures consist of the development of the following documents: personnel adjustment program, mentoring regulations, a duty description for the psychologist responsible for personnel development organization, selection and hiring personnel, and newcomers' adjustment. The program of new specialists' adjustment consists of two basic parts: general and individual and is designed to cover the whole probation period. Every newcomer who does not have a proper work experience (or no work experience at all) should have a designated mentor who plans, accompanies and evaluates the work of the new employee during his or her probation period. The mentor evaluates the work and passes the report to the head of the department. We have developed a

post adjustment form. During the process of career management, it is necessary to consider the fact that employees' interests and needs change as they proceed from one step of the career ladder to another, as well as the qualification requirements that they have to meet. Therefore, it is necessary for the Art Center to implement differentiated career management systems at the initial, intermediary and final stages of the professional growth. Thus, a suggested adjustment program for new specialists consists of two main parts – general and individual. A duty description for the HR specialist responsible for personnel adjustment has been developed. One of the key directions of the personnel management policy at the Art Center is providing a sufficient amount of the personnel reserve for taking managerial positions at different levels. The evaluation of the economic efficiency of the project has been carried out. As a result, it has been determined that complicating the selection process, using a preliminary telephone interview may allow HR specialists to eliminate some candidates at the initial stage and decrease time expenditures of HR specialists by approximately 40 – 25 minutes. Using an effective and well thought-out form of a "vacancy advertisement" and a more "targeted" advertisement positioning might narrow down the number of candidates by 10%. The quality of targeting the audience by means of advertisement will increase by 50%. The analysis of vacancy advertisement placement has indicated that using proper means of advertising and changing the sources of advertisement placing might help the organization save up to 50% of its advertisement budget. In order to evaluate economic damage related to the personnel turnover and conditioned by a lack of motivation, appropriate calculations have been made. Implemented initiatives will significantly reduce the rate of personnel turnover. The administration of the Art Center paid close attention to the employees and their creative approach to work and has made a decision that the personnel's creativity has to be rewarded, which is especially important in the sphere of supplementary education.

Conclusions

Personnel is a strategic factor which determines the future of any organization. Qualified employees distinguished by a high level of motivation represent the main source of competitive advantages of the organization. Recently a number of problems related to personnel management in organizations has been on rise. The system of personnel management has to be tightly connected with the principles of organization management restructuring. The following problems are peculiar to Perm Child and Youth Art Center: absence of incentive for the employees' career development, low level of motivation and, as a consequence, an insufficient inflow of qualified specialists, a high level of personnel turnover, and a decrease of service quality. As a result of the survey, statistical data processing, questionnaires, observations and economic calculations conducted by the author, a need for improvement of the current management system in the culture sector institution was substantiated, which made it possible to work out new measures of improvement. As a result, the efficiency of the institution has been assessed and the following recommendations which can be applied worldwide have been developed. In our opinion, when teachers are hired to take a position at a supplementary educational institution it is very important to pay extra attention not only to the assessment of their professionalism but to find out their reason for choosing this job, seriousness of candidates' intentions to work in the culture and art sector; find out what position the candidates would like to take. If the candidate does not have a clear picture of his or her future job or career aspirations, it indicates an insufficient qualification of the candidate. From the author's point of view, only the best professionals should be able to work in the educational sphere. They should have a lot of opportunities for professional and personal development. Their level of motivation should be considered, as well. All these measures will increase the level of provided educational services. In order to manage personnel at a supplementary educational institution, one should: understand the peculiarities of the current HR system; determine and periodically follow the personnel's motivation concerning their career. In order to increase the effectiveness of operations, to comply with the inner motivations of the personnel, to form an internal personnel reserve the following measures have been proposed: implementation of a new personnel motivation system which considers the motivational profile of the employees; implementation of an adjustment program for new specialists, which will allow newcomers to blend into the team and create positive

social and psychological atmosphere among the staff; implementation of the personnel reserve restructuring program, which will make it possible to not only effectively plan the employees' career development, but will also increase the efficiency of management in general; implementation of a clear hiring and selection program will allow HR specialists to use the funds allocated for the work of the personnel department. This may lead to an opportunity to fill vacant positions on a competitive basis with the best professionals in the field; the teacher who is hired after a competition will be valued by the chief of the department who has been directly involved in the selection procedure. Besides, it will boost the confidence of the teachers who were hired by the organization after a competition.

Corporate Management of the Value of Business Units: Discrepancies and Ways to Overcome Them

Oksana V. Askanova, Doctor of Economic Sciences, Associate Professor, Head of the Finance and Credit Department, Rubtsovsk Industrial Institute, Rubtsovsk, Russia, oaskanova@bk.ru

Aleksandr V. Karpenko, Candidate of Economic Sciences, Associate Professor, Finance and Credit Department, Rubtsovsk Industrial Institute, Rubtsovsk, Russia, mr.aleksandr.viktorovich@inbox.ru

This study has been conducted with financial support from the Rubtsovsk Industrial Institute (as a branch) of the federal state budgetary educational institution of higher education I.I. Polzunov Altai State Technical University (Grant No. 1522 of December 19, 2016).

Abstract

Object: Ensuring the successful operation of a conglomerate corporation and attaining the efficiency of its activity requires not just the development and implementation of a general corporate strategy but also the efficient management of the company's business portfolio and adequate distribution of resources across its major business areas and divisions – with a view to developing existing and cultivating new competitive advantages for it. A key precondition for the proper interaction between the corporate and business levels is the ability to properly assess the prospects for growth in the value of particular businesses based on the corporation's "parent abilities" matching the needs of business units that make it up. ***Methods:*** This study is grounded in the fundamental tenets of the parenting advantage concept, which describes the process of managerial interactions, as well as the tenets of the systemic-resource and target models for efficiency. ***Results:*** Based on an analysis of the specificity of the interaction between the corporate centre and the business unit, the authors have identified the key discrepancies between them in the context of managing the value of the company and business. The study points up the equivocal role of the corporate centre in implementing the strategy for growth in the value of business units. It provides a rationale for the need to differentiate business units and proposes a conceptual approach to managing the value of business units based on strategic fit across resources, knowledge, competences, business process elements, and the role of the strategic apex in ensuring growth in their value. ***Conclusions:*** The research reported in this paper is expected to open up wider vistas of opportunity for further research related to the corporate management of the business units portfolio and make a considerable contribution to understanding corporate strategy.

Keywords: corporate management; strategic management; business portfolio; business unit; synergism

Introduction

Coordinating and integrating the key competences and business processes become possible thanks to the theory and methodology of strategic management as the fundamental basis of managing the development and the companies' growth under conditions of turbulence in the environment. In a climate of continual changes in the scale and boundaries of activity, it is worth ensuring that the company is highly adaptable with respect to various dynamic external and internal factors (Adizes, 2014; Ansoff, 1979). The promptness of reacting to changes in the conditions ought to be ensured within the framework of a corporate strategy adopted, while it also pays to make timely reactive or proactive changes to the strategy. The latter is needed in corporate management not just when there are cardinal changes taking place in the macro-environment, the 'business – state – society' system, but also when there are significant innovative solutions generated within the company – in its business units.

A company's business units may differ in a great deal of characteristics (the product turned out, technical-technological parameters, key competences, stages in the lifecycle of a business unit and the market it operates in, etc.). However, the key criteria for making managerial decisions in the

corporate management of business units' portfolio are the prospects for the creation of a unit's added value and its effect on the value (capitalization) of the company as a whole. To carry this objective into effect, the corporate centre ought to possess relevant competences, skills, and resources, which should align with the key factors for the success of its business units. In other words, the strategic apex (Mintzberg, 1983) ought to create such conditions for the actualization of business units' potential and capabilities, which will ensure boosts in the efficiency of their activity and help maximize their value.

A strategic approach, predicated on transforming the business unit's intra-corporate strategic fit into a whole new competitive advantage, which cannot be attained by each and every business unit under conditions of independent operation, was a genuine breakthrough in strategic theory in the early 1990s. Over the last 20 years, there has been conducted plenty of research into the integrative interaction between entities within corporate associations which has facilitated further enriching the theory and enhancing the practice of strategic management. It has laid down the conceptual, methodological, and procedural foundations of this type of management and provided the basis for the company's configuring and coordinating its multi-field activity. Yet, at the same time, there remain a whole array of key issues related to strategic theory that need to be given a clear-cut form and resolved once and for all. In particular, the theory of root competences has never been employed for the purposes of developing an intrinsically sustainable typology of discrepancies arising out of the 'strategic apex – business unit' interrelationship. Most of the existing research is focused on the causes of conflicts acting as a concentrated expression of a particular discrepancy: the inhomogeneity of organizational culture (Merchant et al, 2012; Roth and Nigh, 1992), the diversity of stakeholder interests amid a lack of resources (Zietsma and Winn, 2008), institutional context (Kostova et al, 2008), etc. This being said, the methodological basis for that research is, normally, a narrowly directed approach – from the perspective of psychology, sociology, economics, and the theory of organizational conflicts.

In addition, the basis for the authors' conduct of this study has been the insufficient insight into the issue of managing eventual business units, which, based on the parameters of their economic status and strategic compatibility, constitute a maximum risk area for the corporate centre. Due to this circumstance, the subject to further theoretical substantiation is the issue of assessing the potential for growth in the value of these business units, as well as the analysis of the efficiency of alternative strategic solutions in the process of putting together a corporate strategy.

Thus, this paper is intended to help fill the gaps and ensure the further development of the corporate management theory and provide a rationale for the interaction of the strategic apex with business units in the process of putting together business strategies based on managing their value. The paper identifies the major discrepancies between the company's strategic apex and business units and provides a rationale for taking a conceptual approach to managing the value of business units based on the principles of harmonization of interests and strategic fit across resources, competences, and parameters representing the activity of the above entities, as well as the principles of synergy and portfolio management. To note, certain tenets brought forward and substantiated as part of this study have been taken on board and used in the activity of certain large integrated establishments – more specifically:

- the authors have gained an insight into the mechanism underlying the management of the value of the TAREKS company group (the city of Novosibirsk) within the system of corporate management and determined the major discrepancies between the interests of the head centre and the management of the subsidiary companies;

- the authors' model for the interaction of the corporate centre with business units, which is designed to ensure strategic fit among the above entities in terms of resources, knowledge, and skills, has been employed for the purposes of cultivating an organizational-economic relationship between AO Rubtsovsk Machine-Building Plant (the Rubtsovsk branch of AO NPK Uralvagonzavod) and the managing company.

Materials and Methods

The theoretical basis for the programme for the interrelationship between the corporate centre and its business units is the concept of "parenting advantage", developed in the 1990s by M. Goold, A. Campbell, and M. Alexander (Goold et al, 1994) based on M. Porter's (1985) competitive advantage theory and A. Chandler's (1962) theoretical speculations on the role played by the corporate centre. According to the original concept, the strategic apex ought to ensure the maximization of the value of business units that form part of its portfolio or the redistribution of corporate assets through their merger or sale to a more preferential owner. The role of the strategic centre consists in not just ensuring growth in the value of business units but also offering guarantees for this value to be a lot higher than the costs associated with its upkeep, while the positive synergy of their interaction is the greatest of all possible boons. Otherwise, the corporate strategy will be inefficient and may ruin the value.

To put together an integral picture of existing scholarly knowledge on the activity of the corporate centre and its actual participation in creating the group's value, the authors employed an integrated approach to search for relevant literature. First, in their search for scholarly papers published in top academic and practice-oriented journals, the authors drew upon Scopus, the world's largest universal abstract database, as well as the Russian Science Citation Index, which currently contains over 9 million publications by Russian authors. Second, of considerable interest to the authors were publications reflecting the domestic and foreign experience of managing integrated corporate establishments. The authors' theoretical analysis of the literature helped identify some of the fundamental tenets and prevalent focus areas related to the development of economic thought with respect to the issue under exploration, identify some of the common features and some of the differences in the nature, character, and specificity of the interrelationship between the corporate centre and business units, identify the latest trends in constructing corporation's divisional structure, and more.

The authors' development of a conceptual approach to managing the value of business units is grounded in the experience of Russia's largest integrated corporate establishment AO NPK Uralvagonzavod, which comprises around 40 industrial enterprises, research-and-development institutes, and design bureaus across Russia and Europe and is engaged in the design and manufacture of automotive and agricultural machinery, road construction machinery, railroad cars, as well as products for the military-industrial complex.

The elements of the authors' conceptual approach incorporate the tenets of the systemic-resource and target theories of management. More specifically, the use of the systemic-resource model (Yuchtman and Seashore, 1967) helped the authors assess, in the context of the objective of ensuring the efficiency of the operation of the company and its business units, the congruence of the required strategic resources of the business unit and those of the corporate centre (the key criterion being the optimum use of favorable opportunities and relevant resources available in the environment). The use of the target model (Holl, 2001) under conditions when the hierarchy's different levels work within different timeframes ensures a proper interlinkage between strategic, tactical, and operational objectives across the company's hierarchical levels, cooptation (the process of absorption of new elements into the corporate centre, the company's policy-determining establishment, as a means of preventing its instability), as well as a coalition of business units with a view to creating sustainable competitive advantage. Thus, the target model helped determine the degree of coordination of multiple and discrepant objectives and limitations at the corporate and business levels factoring in the interests of external interested parties.

Literature Review

There has been plenty of empirical research into strategic and corporate management attesting to the substantial role and significance of the corporate centre in managing a conglomerate corporation. More specifically, a study by D. Collis and C. Montgomery (1998) suggests that the corporate centre acts as an intermediary in the internal and external environment wherein the corporation operates and

plays a decisive role in creating its value – thus, justifying economically its own existence. In the view of R. Adner, C. Helfat, and E. Bowman (Adner and Helfat, 2003; Bowman and Helfat, 2001), the strategic apex, may, by facilitating boosts in the efficiency of strategic decisions made, ensure greater gains in the added value for its business units as a component of the organizational system than their activity can under the conditions of progressing factorization.

It is worth pointing up several key focus areas in terms of exploring the functions of the strategic apex as the organizational-economic centre of management and its role in the overall system of managing the organization.

The first focus area develops the original concept proposed by M. Goold et al. and focuses on certain corporate functions and objectives, including corporate planning, investment analysis, risk management, organizational design, etc. (Campbell et al, 2012; Goold et al, 1998). Without question, this research facilitates our better understanding of the nature, mechanisms, and resulting role of the corporate centre in creating value – however, its narrow focus on certain aspects of the corporation's activity is resulting in somewhat fragmentary knowledge in the area.

The second area of focus is research into the role and functions of the corporate centre, which it performs outside the internal market (Bartlett and Ghoshal, 1989; Mudambi et al, 2014; Nell and Ambos, 2013). It offers empirical testimony to the fact that active corporate centres facilitate the realization of synergetic advantage from multinational coordination, which surpasses behavioural costs associated with interference with the business of subsidiary companies. However, in the authors' view, a dominant role in this research is played by the potential and limitations of international divisions and their significance in the value creation chain. That being said, what is being ignored is the prospects of the actual corporate centres, which, in effectuating the objective of achieving gains in added value, get to face significant difficulties – their subsidiary companies being geographically distanced and scattered and all kinds of cultural (e.g., the characteristics of interaction with the management team and colleagues, an attitude toward resolving non-standard objectives, an attitude toward failure), regulatory (e.g., difficulties associated with formalizing the document flow system; mismatches regarding the requirements for accounting policy), and other discrepancies.

There is another area of scholarly search that has been in wide use in research into the potential and resources of the corporate centre and has found reflection in the development of the concept of resource-oriented strategic management of an organization. The focus here is on the structure of the corporation's resources, which are distributed unevenly among the businesses that make it up (Grant, 1991; Peteraf, 1993; Wernefelt, 1984), and the specific potential and competences of the strategic apex as a source of added value expected to ensure their best use (Evans and Schulman, 1992; Prahalad and Hamel, 1990). Summarizing the findings of research in this area may lead to the conclusion that there is a certain degree of differentiation in viewpoints voiced by various authors at the terminological and conceptual levels, as well as an insufficient degree of development of applied methodological solutions.

Overall, it may be stated that the ideas of the Western founders of scientific management have given a powerful impetus to the process of making and development of the theory of management all across the globe. The theory of a firm's behaviour, which is closely linked with the practice of the operation of conglomerate corporations, has helped develop a virtually flawless strategy for the interaction of the corporate centre with its business units. A detailed insight has been gained into issues related to managing the business portfolio and making investment-related decisions on the purchase/sale of particular businesses, the types of the organizational structuring of the corporate centre, etc. Yet, at the same time, there still remain a number of key issues which require further thorough investigating, including the characteristics of interaction between participants in corporate relations in transitive economies, the organization of the system of intra-group cooperation between business units making up the corporate portfolio, etc.

The issues related to the theory and practice of strategic management and ensuring gains in value have been examined in works by Russian scholars as well – as applied to Russian reality. However,

considering the fact that on the whole the domestic system of corporate management is still not perfect and is continually undergoing reform. A major portion of this research is devoted to reconceiving the role of the corporate centre and its functions in Russian holdings (Zietsma and Winn, 2008; Ponomarenko and Korotky, 2015; Sokolov, 2014; Chitipahovyan, 2012; Shtefan and Lutchenko, 2013), the characteristics of the cross-functional interaction between business units (Nakonechnikova, 2014; Tarasova, 2014; Tsevelev, 2016), issues related to managing the value of integrated establishments within the system of corporate management (Burenina and Yakushina, 2012; Karpenko and Askanova, 2015; Orehov, 2014; Reshetko and Sokolov, 2014; Jurkovska and Agafonov, 2015), etc.

Worthy of separate mention are a series of research studies devoted to focus areas for the development of Russian divisions of international corporations and their engagement in the system of intra-corporate social relationships (Gurkov, 2015, 2016). The authors of these studies are pointing out a high degree of dependence of Russian businesses on support from their foreign head centre, as well as the dualistic nature of the processes of cooperation between the "sister divisions" located in different countries.

No less interesting, in the authors' view, is research (Kochugueva, 2012) devoted to assessing the activity of natural monopolies within the Russian economy. An analysis of the strategic status of the portfolio of the business units of one of the world's largest network companies indicates that a total lack of competition may significantly detract from the ability of corporate centres to develop their root competences, which may lead to the inefficient distribution of resources and greater expenditure on the upkeep of non-core businesses.

Summarizing what has been said above, it may be concluded that, on the whole, the development of management thought in Russia is proceeding along the path of domesticating the Western theory of management and adapting it to Russian reality. Right now, there is just a limited number of publications attesting clearly to the practical orientation of the concept of parenting advantage and notions of the root competences of conglomerate corporations. Research having a limited empirical base and scholarly works being excessively theoretized makes it hard to get a detailed picture of and assess the combined effect from the interaction of all participants in the corporate system. It pays to convert separate, scrappy theoretical findings into a finished theory of corporate management, which should help not just identify and explain corporate processes taking place in the country but also make it possible to forecast them.

Based on the aforesaid, the object of this study is to develop a conceptual approach to managing value as applied to eventual business units with a potential for generating additional value for other business units and producing a synergetic effect via strategic fit across resources, competences, and business process elements. This objective was attained through resolving the following objectives:

- exploring the forms of interaction between the strategic apex and the business unit, discrepancies between them, as well as ways to harmonize their interests aimed at ensuring the maximization of market value and a synergetic effect;

- summarizing the types of business units depending on the degree of strategic fit across their resources, competences, and business process elements and identifying the ones that are most attractive for the corporate centre from the perspective of the objectives set;

- providing a rationale for the use of a conceptual approach to managing the value of the eventual business unit.

Results and Discussion

The strategic potential of business units varies: some are capable of influencing the outcomes of operation thanks to a high degree of centralization of management (note that these outcomes will be better than those they would exhibit if the units were independent), while for other business units the

key function of the corporate centre is facilitating the exchange of knowledge, competences, and technology, which would not occur among autonomous units.

At the stage of the divisional establishment growing and developing, what becomes a crucial issue is increased bureaucracy and escalating discrepancies between the strategic apex and the business unit, caused by poor control and coordination. These discrepancies are grounded in the issue of harmonizing the interests of the above entities. This antagonism shows itself especially acutely in the goal-setting process, as objectives and limitations for each business unit are normally determined without factoring in the interests of a particular business unit. As a consequence, the activity of the business unit aimed at achieving its own goals may run afoul of the interests of the entire company.

Based on the authors' analysis and summary of the outcomes of research conducted by a number of scholars specializing in the area of corporate management (Johnson et al, 2014; Gurkov, 2008), as well as by reference to the real practice of corporate management in the TAREKS company group, the authors identified some of the key discrepancies in the 'strategic apex – business unit' interrelationship known to have a negative impact on value management processes, such as:

- *structural* discrepancies – the blurring of the boundaries of areas of responsibility between the corporate centre and business units. A branched hierarchical company structure will not let the corporate centre efficiently control the situation in its business units, which leads to greater timeframes for making and coordinating decisions and, consequently, to slower reacting to changes in the needs of the market on the part of the company;

- *organizational* discrepancies – the strategic apex of a multi-field company determines the key factors of success and competitive advantage mainly within the political and social areas, whereas the key factors for the success and competitive advantage of each business unit and their sustainability belong to the competence of the executive team of business units; to note, it oftentimes is virtually impossible to integrate them at the corporate level;

- *personal-psychological* discrepancies – managers at business units view the company's strategic apex as a means of realizing their claims for success and career growth, ignoring their chief role – creating value at the level of the business unit. This leads to the need for the corporate centre to tighten up control over their activity and requires developing relevant stimulating mechanisms (including negative motivation) that would urge senior management to act in the interests of the entire company;

- *regulatory* discrepancies – in a climate of non-related diversification in the process of interaction between the corporate centre and business units, there is a need to factor in the specific characteristics of the operation of each of these units. This kind of differentiation has a negative effect on the processes of implementing uniform corporate standards. Furthermore, it is worth understanding that each business unit is unique in its own way and has its own system of regulations, which enable taking account of not just the specificity of the business unit's activity and the strategy for its development but also the objectives which the corporate centre effectuates in implementing the system of corporate standards;

- *cultural* discrepancies – corporate culture and the subcultures of business units influence each other and there may arise certain discrepancies between them, which may be reflected in the differences in value systems (declines in costs or increases in and differentiation of output), ethical norms (the openness degree of business units), the types of management (mechanistic or organic), interpersonal relations, etc.

As we can see, the role of the corporate centre in effectuating the strategy for growth in the value of business units is multi-faceted: the strategic apex directly participates in creating the value of business units through managing interrelationships with entities operating in the external environment, ensuring the diffusion of knowledge and competences, optimization of the use of strategic resources by several business units, etc. However, limitations imposed on business units in

terms of decision-making by the corporate strategy, their inability to participate efficiently in managing and enhancing business-processes, etc., may facilitate ruining the value of business units and encourage their aspiration for isolation and even total autonomy (business units rely more on market mechanisms for self-regulation than on administrative forms of management).

There can be both absolute and relative assessments of the match between the competences of the corporate centre and business units under its management (Goold et al, 1998). In the first case, the strategic apex ought to ensure growth in the value of business units, while business units ought to demonstrate a return on the investment. In the second case, the strategic apex compares, based on the principles of benchmarking, its activity with that of other corporate centres, which also shows in a mediated fashion in the competition between the business units. In addition, the strategic apex assesses:

- the type of competitive advantage which it will ensure the business units;
- the extent of its negative impact on the business units;
- the advisability of retaining the right of ownership in respect of the entire portfolio of business units or sale of business units to a corporate centre under whose management they will create greater value.

It is worth noting here that the complexity and multi-facetedness of the issue of intra-corporate interaction, the eclecticism of economic and administrative mechanisms underpinning management provide a rationale for the need to coordinate the interests of the organization as a whole with internal management processes taking place at the various levels of managing the corporation. It is how neatly and competently the distribution of powers and responsibilities between the head centre and the management team of business units is constructed along the entire hierarchical chain of management and the degree to which one is able to achieve coherence between multiple and discrepant objectives and limitations at the corporate and business levels that the adequacy of managing the value of subjects of corporate relations will largely depend on. Otherwise, as evidence from practice indicates, there is no avoiding a conflict of interests within the corporation (Homayoun and Homayoun, 2015; Berezinets et al, 2014; Kuruzov, 2014). In addition, in a climate of quick technological changes and political and social-economic instability, issues related to putting together and practically implementing corporate and business-strategies appear to be indissolubly bound up with those related to interrelationships between various groups of stakeholders (Bonnafous-Boucher and Rendtorff, 2016; Magill et al, 2015; Pletnyov, 2014).

Thus, the above makes it possible to bring forward a set of key principles on which the interaction of strategic apex with its business units may be expected to be built:

- *the company's integrity for external interested parties* – stakeholders ought to have a clear idea of the boundaries of the company's activity and its vision of common objectives. Otherwise, investors may develop a misunderstanding as to the advisability of certain types of business and ways for the corporate centre to create value for its business units, which may immediately reflect on the price of the company's shares;
- *the participation of the strategic apex in managing business units based on strategic fit across top competences* – the corporate centre's primary objective is to ensure that the value of the business unit as a component of the organizational system is greater than its value in a climate of progressing factorization. That being said, the corporate centre can make use of its competences, skills, and power to interfere, to some degree or another, with the work of business units and administer control over their activity;
- *the degree of interest by the senior management of the business unit in the strategic apex* – managers at business units ought to be motivated to work with the corporate centre, failing which

they may start looking on it as a source of additional expenditure, which may have a negative impact on the overall efficiency of the company's activity;

- *boosts in the strategic potential of a business unit based on the potential of other business units*, which is reflected in declines in costs, entry to new sales markets, development of new types of products, etc.;

- *rotation of managerial personnel within the company and boosts in management potential* – moving business unit executives consistently along the horizontal makes it possible for them to gain the necessary knowledge and skills and cultivate exceptional competence;

- *synergy,* which is created in integrating the various types of resources, which ensure the development of existing and cultivation of new competitive advantages (entry to new markets; implementation of large projects).

Based on the above, the authors suggest construing *managing the value of a business unit in the system of corporate management* as a set of goals, objectives, principles, functions, means, methods, and instruments that can ensure boosts in the value of a business unit and gains in added value via synergetic interaction with other business units through the strategic apex, which acts concurrently as both the administrator of the unit's portfolio and its owner.

The strategic apex provides business units with centralized services and resources (investment-related and infrastructural), which ensure economies of scale, intermediary services (the interaction of business units with the external community), and "movable management potential" (rotating top managers between different business units), with unique key competences being cultivated along the way, which may ensure high rates of growth for business units.

By focusing on ensuring well-balanced growth and development for business units (e.g., in alignment with the BCG matrix), the strategic apex supports their strategic initiatives aligned with the corporate strategy. Nonetheless, during the process of developing its potential, key competences, and interrelationships with stakeholders, etc., the level of strategic fit between the company (the corporate centre) and the business unit (in terms of resources, knowledge, competences, business process elements, and the management system) diminishes. In this regard, it is worth pointing up the following types of business units:

- *leading* business units, which form the company's strategic core. In relation to these, the corporate centre has a wide range of strategic capabilities and competences, which form the basis of the corporate strategy and make it possible to boost value without any negative consequences for the actual business units;

- *autonomous* business units, which are self-sufficient units whose efficient operation outside the company (as independent organizations) will not change, despite the fact that the corporate centre possesses the necessary competences in the area of managing them;

- *encumbering* – business units incapable of making a substantial contribution to the cause of achieving corporate objectives, since their strategic resources, competences, and processes do not match the corporate strategy; the corporate centre, in turn, does not possess the resources and competences needed for boosting their value. It pays for the strategic apex to resort to the strategy of restructuring the corporate portfolio with respect to these business units and keeping them out;

- *eventual* – business units that are of value to the strategic apex thanks to their potential for producing strategic fit between the potential of the business unit itself and the resources, competences, and other characteristics of the corporate centre and top business units. Having said that, there is likelihood that the efforts of the strategic apex aimed at transforming eventual business units into "leading" ones and ensuring gains in the company's value through a synergetic effect will not result in desired outcomes; what is more, decisions made by the strategic apex may lead in this

case to some of the value getting ruined. Consequently, the corporate centre's top competences ought to be in line with the corporate portfolio and market potential specific for each, including eventual, business unit.

There are various interaction mechanisms (including financial-economic ones) known to ensure growth in the company's value (e.g., in terms of managing non-core assets) that have been developed in the theory and practice of corporate management with respect to the first three types of business units. The specificity of managing eventual business units and their value has been discussed in the literature in quite a scrappy manner (Johnson et al, 2014; Gurkov, 2008), which may require developing a proper organizational-methodological instrumentarium for assessing and managing the value of eventual business units. Its basis ought to be grounded in a mechanism for harmonizing the interests of subjects of corporate relations, which could be implemented based on the integration of the systemic-resource and target models for efficiency.

The author's conceptual approach to managing the value of business units in the system of corporate management is illustrated in Figure 1.

Under the approach, the strategic apex assesses the match across key factors for the success of each business unit, its business processes and competitive landscape on the one hand, and the strategic resources, strategic influence groups, top competences, and other parameters for the activity of the corporate centre on the other. What is more, the business unit itself must be interested in the strategic apex as a source of additional competitive advantage. Here, one should expect a match between the business unit being interested in help on the part of the corporate centre and the latter's strategic capacity to provide it. As a consequence of this strategic fit, there can be created the necessary and sufficient conditions for the sustainable development and growth of the company, its competitive positions getting bolstered, and gains in the value of business units and the company as a whole.

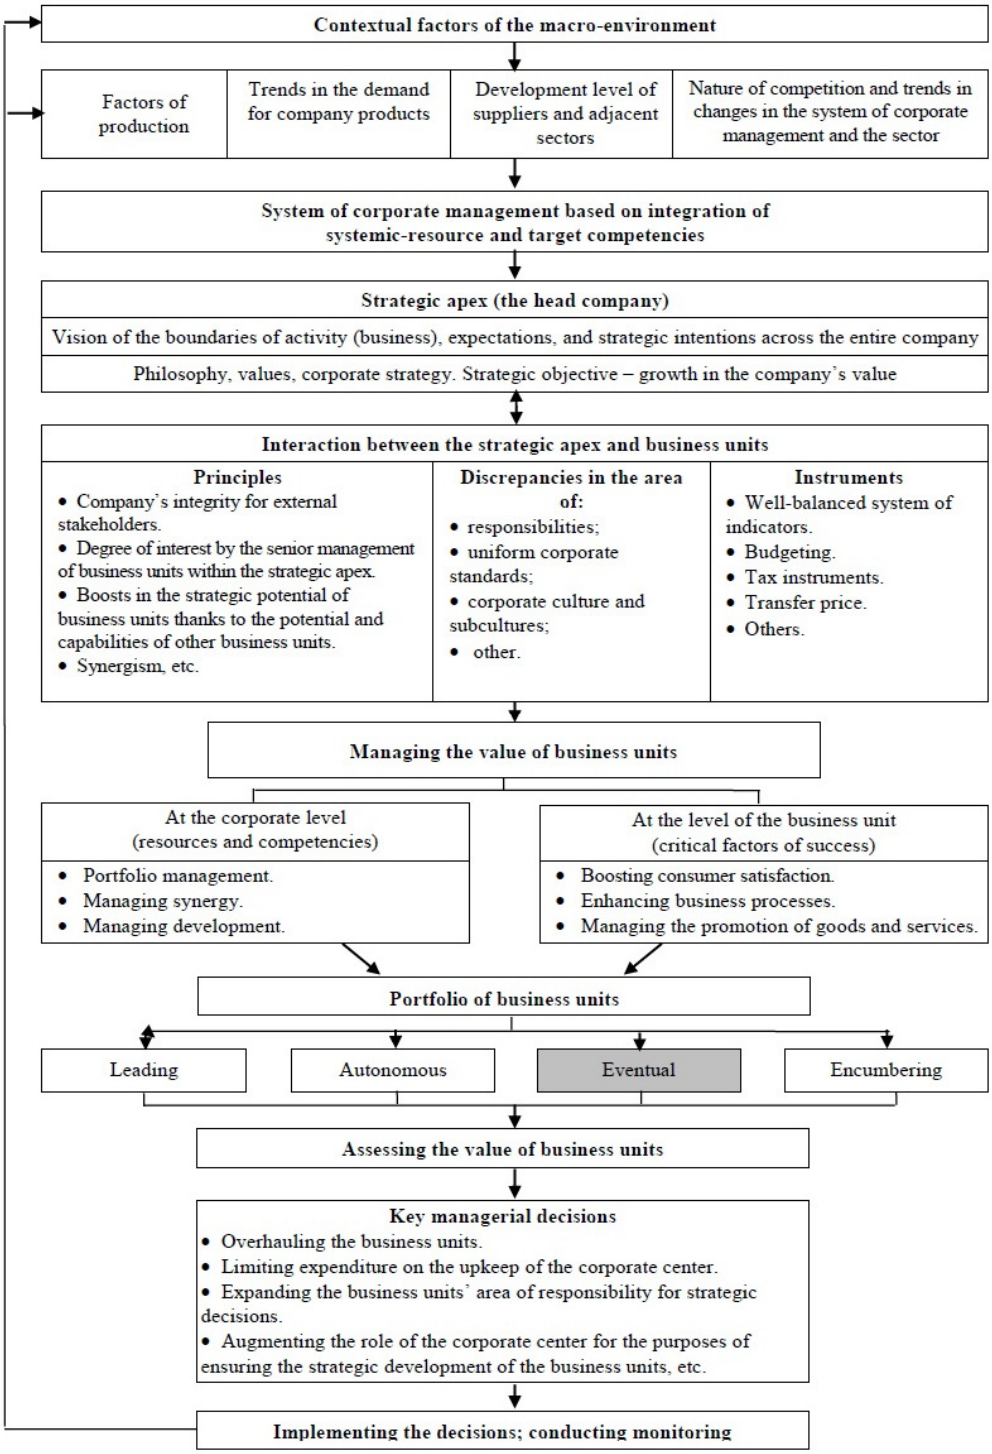

Fig 1. A conceptual approach to managing the value of business units within the system of corporate management

The approach proposed by the authors was tested on a number of Russian corporate units. More specifically, an assessment of the existing businesses of the machine-building holding Uralvagonzavod on the parameters of their economic status and strategic compatibility with the key competences of the head centre (cutting-edge production technology, design of products with the needs of individual clients in mind, and the inter-organizational level of integration of product components) helped the authors single out the Rubtsovsk branch of AO NPK Uralvagonzavod as an eventual business unit. This business division is largely autonomous financially in terms of both its current turnover and long-term prospects – a significant portion of its production volume is associated with defence procurement contracts on the manufacture and maintenance of military equipment, as well as contracts on modernizing custom machinery designed and manufactured in Russia. At the same time, there are a number of issues preventing ensuring strategic compatibility in full measure, like:

1) a time lag between the development and assimilation of cutting-edge production technologies in the head company and their implementation in this particular business division, which is due to the elements of the corporate system being largely scattered and distanced territorially;

2) an incomplete match between the technological and scientific potential of the corporate centre and the eventual business unit under examination, which does not always permit ensuring the fulfilment of the head company's objectives on the design of products with the needs of individual clients in mind;

3) the impossibility of meeting in full measure all the needs of the business unit under examination for parts to execute special orders through the inter-organizational integration of product components.

The eventual business unit in terms of income approach was valuated. It was done in order to determine the head centre's potential strategy against eventual business unit taking into account different combinations of factors.

The valuation was based on:

- Economic Value Added (EVA) model;
- Edwards-Bell-Ohlson (EBO) model.

The Rubtsovsk branch of AO NPK Uralvagonzavod total assessed value under current market volatility conditions exceeded net asset value by 7.8%. Such index is acceptable in terms of current conditions. This particular business generates significant funds flow that ensures its high worthiness.

Due to high management effectiveness and growing financial autonomy of the branch the authors suggested the reasonable change strategy. The strategy included expansion of eventual business unit liability in terms of policy decisions. That means liability transfer to business level and, as a result, the use of inhouse references for competitive tactics development. Monitoring of changes mentioned above implementation demonstrated company's market value increase. Market value was calculated by the use of different valuation models (Table 1).

Table 1: Eventual business unit valuation (total result), in thousands of USD

Information dynamics parameter	Under current conditions	In terms of eventual business unit liability of policy decisions expansion	Deviation %
Company's valuation by EVA model including useful life of Goodwill	68,965	76,068	+10.3
Company's valuation by EBO modified model	47,074	50,887	+8.1
Company's total valuation including adjustment factors	58,020	63,478	+9.4

High level of management decentralization against successful business units provides market value increase by 9.4%. This conclusion is supported by empirical data of other corporate entities. A nice example of a company with a high degree of management decentralization in relation to successful business units is AutoVAZ. In particular, these units have the right to bring in external orders, the ability to make independent decisions regarding the use of their extra-plan profit, etc. The managing company is only responsible for overall financial and tax planning (Smykov, 2003).

Conclusion

Within the framework of the theories of corporate management and strategic management in a climate of turbulence in the external environment and constant changes in the scale and boundaries of a company's activity, particular significance is getting attached to the coordination and integration of key competences and business processes within the company's various lines of activity. That being said, priority significance is getting assigned to the strategic management of the company's business units, while the key criterion for decision-making in the area of managing the portfolio of business units is the indicator of value. The strategic apex ought to have an idea of key factors for the success of its business units and make use of relevant knowledge, skills, and competences at the corporate level so as to be able to add value to each business in its portfolio.

Overall, the study has helped achieve the following significant results:

1. The authors have fine-tuned the concept of 'managing the value of business units within the system of corporate management', which they have done through integrating the company's systemic-resource and target concepts, identifying specific contextual factors of the macro-environment, and determining the major discrepancies between the company's strategic apex and business units.

2. The authors have identified several types of business units, differing in the degree of strategic fit across their resources, competences, and business process elements, as well as the role of the corporate centre in ensuring growth in their value. It has been substantiated that eventual business units are the most attractive for the corporate centre in terms of strategic fit. This, however, requires that the strategic apex develop its top competences, resources, and characteristics.

3. The authors have developed and tested a conceptual approach to managing the value of business units, which is predicated on the principles of harmonization of interests, strategic fit across resources, competences, and parameters representing the activity of the above entities, as well as the principles of synergy and portfolio management.

The authors associate the prospects for further research with extending the focus to multinational corporations with eventual business units across Russia. There is a need to elaborate on the issue of the possible extent of strategic relationships between the corporate centre and similar business divisions of the international corporation and the intensity of financial flows between them. In the authors' view, this topic is worthy of separate, independent research. In addition, future research into the area may significantly expand the ken of the scientific community, if the focus is centred on

enhancing mechanisms underlying corporate interaction factoring in the interrelationship with other crucial aspects of strategic management – the exchange of knowledge and information, getting access to production technology, tapping into new sales channels, etc. A combination of quantitative and qualitative research methods will facilitate enriching scholarly knowledge and secure a considerable contribution to the development of corporate strategy theory.

Scientific Research Management Developed via 2016 ERA Fellowship and Horizon 2020 ENHANCE Project

Suzana Carmen Cismas PhD, The University of Agronomic Sciences and Veterinary Medicine, The Faculty of Management and Economics Engineering in Agriculture and Rural Development, Bucharest, Romania, suzanacismas@yahoo.com

Abstract

Universities increasingly resemble companies in their competition for learners and resources. To facilitate students and knowledge circulation for mutual benefits of educational systems, science managers spot opportunities and assist in capitalising them. The job profile of the newly-emerged position of science manager in EU academic environments requires advanced skills in identifying and facilitating access to funding and research opportunities. Science managers should not only cater for prestigious researchers with confirmed results, but also for doctoral candidates of visible potential and aptitudes, capable to confirm the investment in perspective. The teaching focus shifts towards modern research and project work, thus enabling the enhancement of dedicated facilities. Science managers closely cooperate with technology consultants, so as to implement all acquired results; in order to do it, proficiently consistent background in international organization is needed, as well as extensive partnering experience with industry networks and SMEs.

Keywords: scientific research management, 2016 ERA Fellowship, H2020 ENHANCE Project

Introduction

Scientific Research Management Fitting H2020 Proposal Evaluations

In accordance with the job profile of the science manager in EU research and academia, which requires advanced skills in identifying and facilitating access to funding & research opportunities, close cooperations with international organisations/associations multiply success odds. Research bases may target topics like safety and security research, advanced computing, resource & energy efficiency, autonomous systems with ambient assisted living, applied science institutes, centres for entrepreneurship, innovation and SMEs management.

Science managers hold a central position in matching resources with opportunities, valuable and available researchers with the key infrastructure they need, funding with adequate projects, ideas with implementation solutions, all meant to comply with the excellence & ethics criteria in H2020 Proposal Evaluations.

Horizon 2020 is an EU R&I Program with more emphasis on innovation and cross-cutting issues. Independent experts play a key role, hence specific measures for granting confidentiality and for avoiding conflicts of interest. In practice, the evaluation procedure follows these steps: individual evaluation, including evaluation criteria and proposal scoring; reaching consensus; panel review and ranking, including proposals with identical total scores.

Calls/Proposals are challenge-based and open to innovative approaches. Calls are less prescriptive as they do not outline the expected solutions to the problem, nor the approach to be taken to solve it. Additionally, topics descriptions allow large scope for applicants to give innovative solutions of their own choice. Greater emphasis is on impact, via expected impact statements: applicants are asked to explain

how work will generate the described impacts and, during the assessment, the evaluator is required to estimate this potential contribution. Critical focus is on innovation: H2020 supports all stages in the research & innovation chain including activities closer to the market and non-technological, social innovation. Proposals may bring together different disciplines, sectors and actors to tackle specific challenges (scientists, industry, SMEs, society partners, stakeholders, and, last but not least, end-users).

Science managers should see that the proposals they assemble and manage obtain marks of 4 or 5, to stand chances in the competition, complying with the following EU interpretation of the scores, seen in http://docplayer.net/23811214-Training-workshop-on-proposal-writing-introduction.html:

- 0 The proposal fails to meet the criterion or cannot be assessed due to missing/incomplete info.
- 1 Poor. The criterion is inadequately addressed, or there are serious inherent weaknesses.
- 2 Fair. The proposal broadly addresses the criterion, but there are significant weaknesses.
- 3 Good. The proposal addresses the criterion well, but a number of shortcomings are present.
- 4 Very Good. It addresses the criterion very well but few shortcomings are present.
- 5 Excellent. It successfully addresses all relevant aspects and any shortcomings are minor.

There is a balanced approach to research and innovation, not limited to developing new products and services on basis of scientific & technological breakthroughs. The use of existing technologies is incorporated in novel applications and constant upgrades/updates, with activities close to market that emphasise the widest possible use of know-how generated by supported activities all trough the commercial exploitation. The spotlight is on activities operating close to the end-users and the market, e.g. demonstration, piloting or proof-of-concept, that include support to social innovation, and support to demand side approaches (standardisation, innovation procurement, user-centred measures) to accelerate the deployment and diffusion of innovative products/services on markets.

Cross-cutting issues are integrated in the work program fusing social sciences, humanities, gender dimensions, strategic approaches to international cooperation, responsible research and innovation including science education, open access to science publications, ethics, standardisation climate change and sustainable development.

2016 ERA Fellowship Training on Scientific Research Management

ERA Fellowship is a German Federal Government Grant for science managers in EU-13 member states. The objective is improving national research systems and their inter-cooperation through providing state of the art training and enhancing networking actions among partner countries. It is awarded by competition and the author's application was filed by IAMO to Leibniz Association as collateral action of H2020 Project ENHANCE, grant agreement 691681, cf. Acknowledgement. The activities in the program target managing scientific research so as to gain fast and wide visibility and to improve the infrastructure of science management capacities in post-communist academic and research organizations. The program is designed for science managers (middle administrative management) from research organisations, research funding organisations or higher education institutions in EU13 area and German counter-parts as host organisations interested in sharing knowledge, and in establishing or expanding networks. In the German science institution the EU13 fellow gets practical experience in science management at expert levels.

As the application stipulated, (www.era-fellowships.de retrieved March 14, 2017, also containing ERA Fellowship Application Materials by IAMO Professor Thomas Herzfeld PhD), ERA Fellow-ship objectives for the IAMO stay aimed at training and using the fellow, author of this article reporting on the project actions, 'as a multiplier in supporting professionalisation of scientific management in the Faculty of Management, Economics Engineering in Agriculture and Rural Development, University of Agronomic Sciences and Veterinary Medicine Bucharest'. She shared viewpoints with colleagues 'on

topics like third-party funding acquisition, administration of third-party funds, public relations, graduate school organisation and scientific events management. She also got the opportunity to learn about the structures and functioning of the German scientific sector while meeting staff members of International Office of Martin-Luther-University Halle-Wittenberg, Leopoldina – Nationale Akademie der Wissenschaften and Nationale Kontaktstelle Lebenswissenschaften. Besides gaining personal practical insights the stay enabled the fellow to broaden her international network with respect to IAMO as well as with respect to other fellows during the campus weeks'. With the support of a reflection report she was able to identify possible innovations for her home institute. The mentor was ENHANCE Project Team Leader Professor Thomas Herzfeld PhD, and all IAMO colleagues working closely with the fellow assisted and provided feedback and reflection so as to reach the best training results. To them all I am indebted and truly grateful as this has proved an extremely effective learning chance.

Overview of the Evaluation Process Presented in 2016 ERA Fellowship

The impact of grant preparation on evaluation is decisive. The time from proposal submission to grant evaluation and signature is set to maximum 8 months. Each proposal is assessed on its merits without grant negotiation phases. Science managers also prevent shortcomings in project drafting that might generate a lower score for the relevant criterion assessment. Evaluators explain short-comings, but do not make recommendations i.e. do not suggest additional partners, additional work packages, or cutting resources. Proposals with significant weaknesses that prevent the project from achieving its objectives or with resources being seriously overestimated never receive above-threshold scores. Any proposal with scores above thresholds and where there is sufficient budget will be selected and successful applicants are invited to address shortcomings.

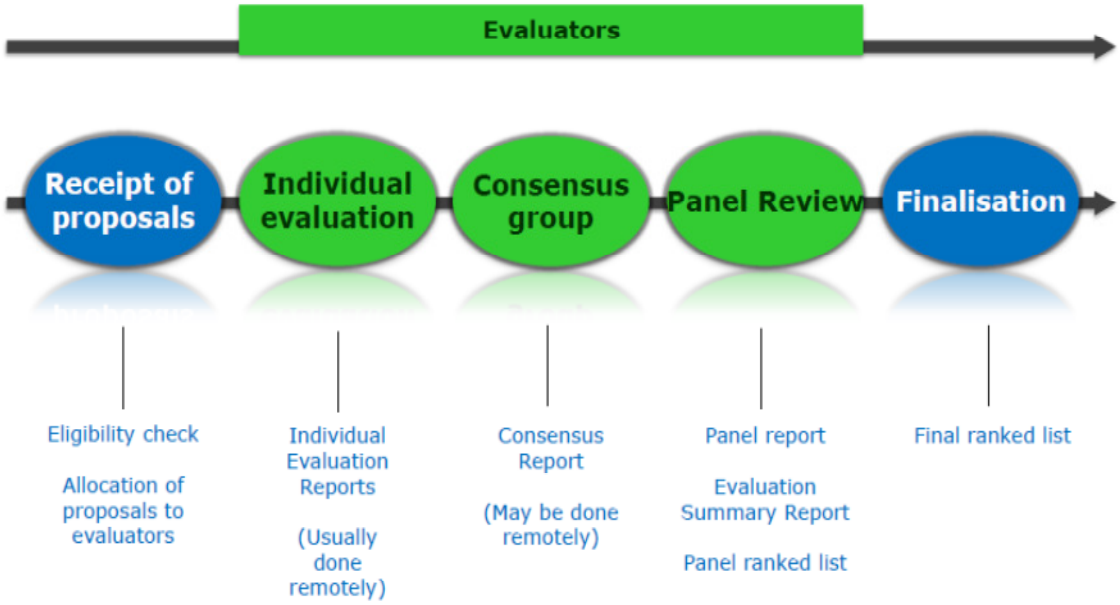

Fig.1. Overview of the evaluation process in EU H2020 Projects, cf. 2016 ERA Fellowship course https://www.slideshare.net/empresaenxarxa/aspectes-clau-sobre-el-mecanisme-davaluaci-de-projectes

The role of independent experts is to evaluate proposals submitted in response to a given call, and they are responsible for carrying out proposals assessments without delegating the work to another person. Reports are closed in the electronic system within a given deadline, as part of the experts' contractual obligations. As significant funding decisions are made on basis of such assessments, experts must report any form of misconduct (e.g. plagiarism, double funding) to EC/Agency staff.

The principles for project assessment are (according with http://docplayer.net/15164429-H2020-rules-for-participation-new-instruments-evaluation-criteria.html):

- Independence (experts assess in a personal capacity, not representing their employer or country)
- Impartiality (proposals are treated equally and evaluated impartially on their merits, irrespective of their origin or the identity of the applicants)
- Objectivity (each proposal is evaluated as submitted: meaning on its own merit, not its potential if certain changes were to be made)
- Accuracy (assessment exclusively on the official evaluation criteria and the call or topic the proposal addresses; nothing else)
- Consistency (the same standard of judgment applied to all proposals).

Confidentiality is kept. Experts must not discuss evaluation matters (proposal content, assessment results, fellow experts' opinions) with anyone, be they other experts or staff in the Commission or Agencies, colleagues or students not directly involved in the proposal grading. The sole exception concerns fellow experts evaluating the same proposal in a consensus group/panel review. Experts must not contact consortium partners, sub-contractors or any third parties.
Experts never disclose names of fellow experts. No link can be made between an expert and a certain proposal since the Commission publishes the experts' names annually, as a group. Paper or electronic documents confidentiality must be maintained at all times and wherever the evaluation work occurs (on-site or remotely).

Pertinent Evaluation Criteria

There are three evaluation criteria for full proposals: excellence (relevant to the description of the call or topic), impact (quality and efficiency of the implementation), and implementation (work plan effectiveness, including the extent to which resources assigned in work packages are in line with objectives and deliverables). The criteria are adapted to each action type as specified in WP.

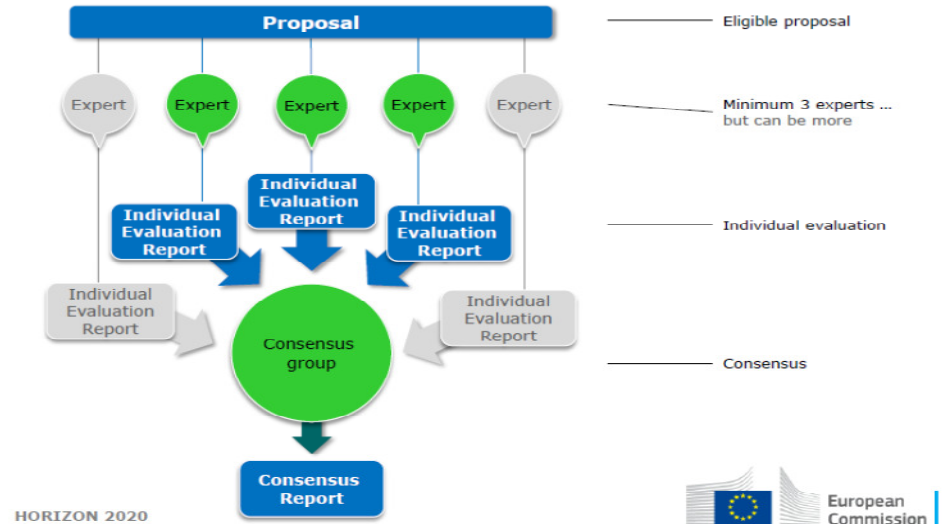

Fig. 2. Diagram of assessment steps in EU H2020 Projects, cf. the European Commission
http://docplayer.net/47255378-Horizon-2020-proposal-evaluation-standard-briefing.html

Admissibility, eligibility checks & additional requirements should be readily accessible; proposal completeness and the presence of all required forms are verified, as well as the inclusion of a plan for results exploitation and dissemination. Eligibility is checked by the Commission/Agency, who focus on the minimum number of partners, as set out in the call conditions, and on other criteria that may apply on a call-by-call basis as delineated in the call conditions.

Excellence is the first criterion hereby analysed. It reveals the extent to which the proposed work corresponds to the topic description in the work programme: clarity and pertinence of objectives; concept soundness and credibility of proposed methodology; the proposal being beyond the state of the art, and demonstrating innovation potential (e.g. ground-breaking objectives, novel concepts and approaches, new products, services or business and organisational models); appropriate consideration of interdisciplinary approaches and, where relevant, use of stakeholder knowledge.

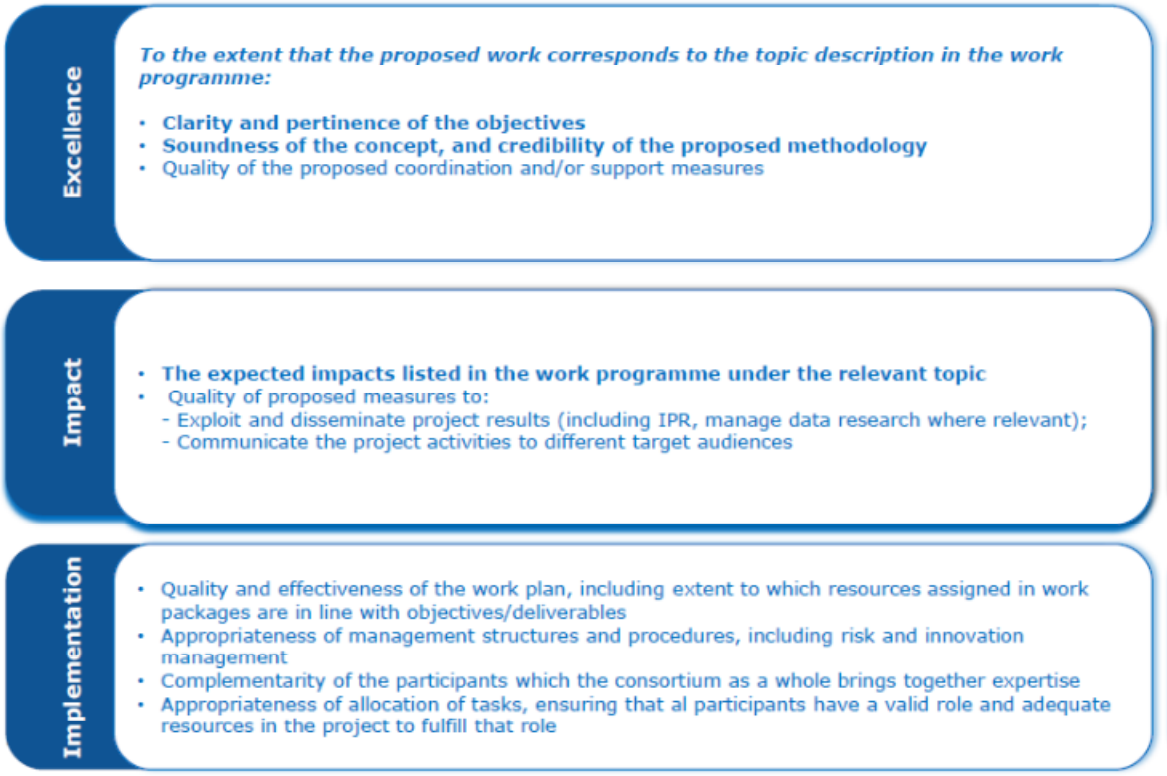

Fig. 3. The excellence criterion within the framework of evaluation criteria in EU H2020 Projects

cf http://docplayer.net/11573603-Sesar-2020-exploratory-research-info-day-proposals-submission-evaluation-programme-management-requirements.html

Impact shows the expected consequences listed in the work program under a certain relevant topic. It includes any substantial outcomes not mentioned in the WP that would enhance the innovation capacity, create new market opportunities, strengthen competitiveness and growth of companies, address issues related to climate change/environment and bring further relevant benefits to society.
The quality of proposed measures to communicate project activities to various target audiences and to exploit &disseminate project results including data research management is highly relevant.

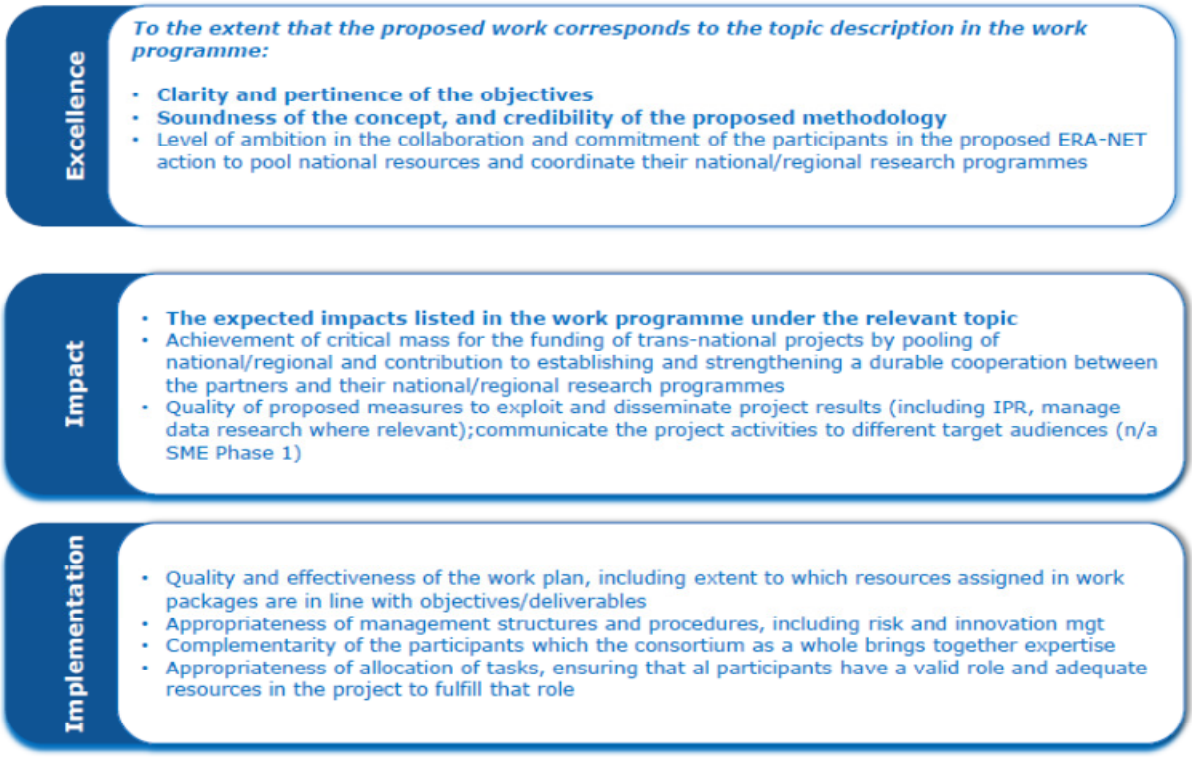

Fig. 4: The impact criterion within the framework of evaluation criteria in EU H2020 Projects
cf. http://docplayer.net/14960201-Guide-for-applicants.html

Implementation focuses on quality & effectiveness in the work plan, including the extent to which resources assigned in work packages are in line with objectives and deliverables. It deals with the appropriateness of management structures and procedures, including the management of risk and innovation. Complementarity of the participants' expertise which the consortium as a whole brings together is a factor of interest. Last but not least, appropriateness of tasks allocation ensuring that all participants have a valid role and resources in the project to fulfil that given role is assessed.

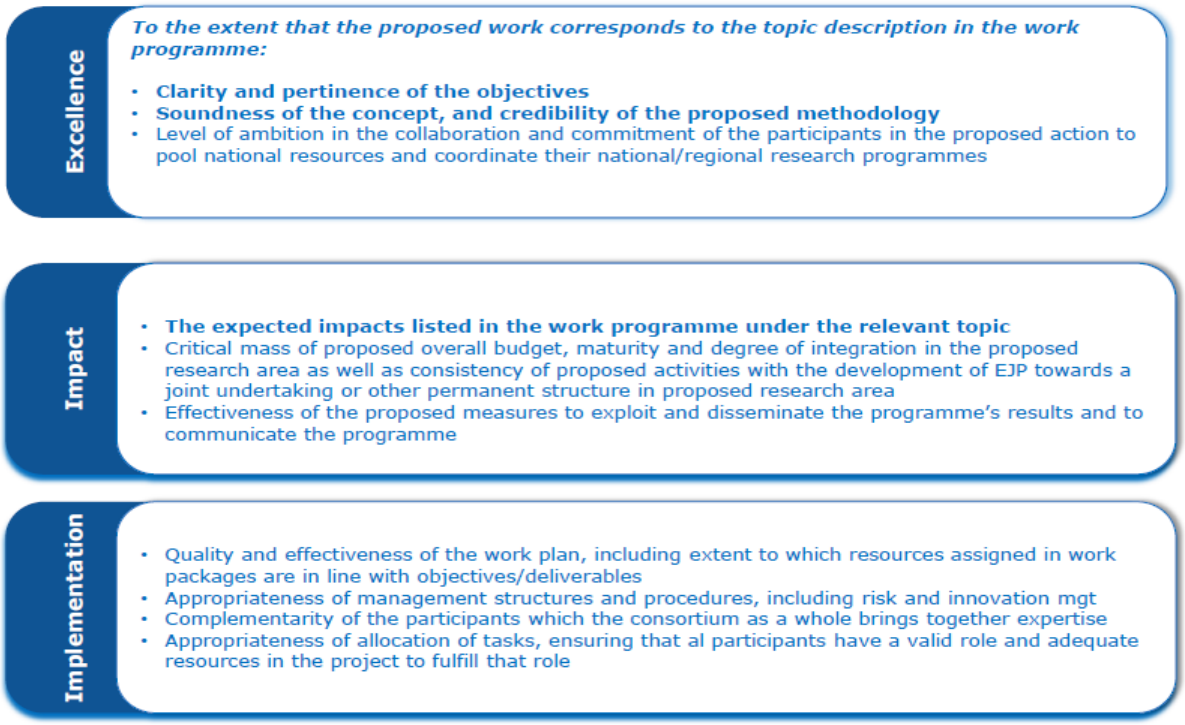

Fig. 5: The implementation criterion in the framework of evaluation criteria in EU H2020 Projects

cf. http://docplayer.net/23946515-Participant-portal-and-practicalities-from-idea-to-bbi-project.html

The operational capacity is assessed as part of the individual evaluation where the expert expresses views on whether each applicant possesses the necessary basic operational capacity to carry out their proposed activities based on the information provided. At the consensus group, experts consider whether applicants lack basic operational capacity. Proposal scoring is assigning marks of between 0 and 5 to each criterion based on expert's comments; the whole range of scores must be used with steps of 0.5; scores must pass thresholds if a proposal is to be considered for funding. Thresholds apply to individual criteria. The default threshold is 3 and the default overall threshold is 10 (unless specified otherwise in the WP). For Innovation actions and the SME instrument, the criterion Impact is given a weight of 1.5 to determine the ranking.

Individual evaluation concerns the substance: some proposals might be handicapped by language difficulties, others deceptively well written, so read the proposal&evaluate it against the evaluation criteria and check to what degree the proposal is relevant to the call or topic. If a proposal does not significantly contribute to the expected impacts as specified in the WP for the call/topic, the expert reflects it in a lower score. If cross-cutting issues are explicitly mentioned in the scope of the call and not properly addressed (or their non-relevance justified), it will reflect in a low score for the relevant criterion. A successful proposal is expected to address them, or convincingly explain why they are not relevant in a particular case. Proposals addressing cross-cutting issues which are not explicitly mentioned in the scope of the call or topic can also be evaluated positively.

Achieving consensus usually involves a discussion on basis of the individual evaluations. For full proposals, it is most effective if experts do not immediately converse it on the average score. For first stage proposals, the average is a starting point. The aim is to find agreement on comments and scores, and

agreement on comments should precede scores. Outlying opinions need to be explored as they may be just as valid as others, so experts need to be open-minded.

Consensus is moderated by Commission/Agency staff (or by an expert in certain cases), as they are neutral and manage the evaluation, protect confidentiality and ensure fairness, alongside with objectivity and accuracy, with all voices heard and points discussed, not to mention the fact that a moderator helps the group keep to time and reach consensus.

The consensus report is drafted by the rapporteur who, in some cases, may not take part in the discussion. The document provides clear proposal assessment based on its merit, with justification and clear feedback on its weaknesses & strengths, with explanations of shortcomings, but without making recommendations. In a consensus-targeting debate certain approaches are ineffective and they should be avoided: comments not related to the criterion in question; comments too long, or too short and inappropriate language; categorical statements that have not been properly verified; scores that do not match the comments; marking down a proposal for the same critical aspect under two different criteria. Applicants will read these comments and, on this basis, they can challenge the evaluation through the evaluation review procedures.

The panel review consists of experts from the consensus groups and/or new experts. It ensures the consistency of comments and scores given at the consensus stage and resolves any cases where a minority view is recorded. The panel review endorses final scores&comments for each proposal and any new ones, if necessary, must be clearly justified before being noted. Then it recommends a list in priority order, prioritises proposals with identical total scores, and may hold hearings at which applicants are invited to present their proposal. The panel orders them according to their score for Excellence and then the score for Impact.

If there are ties, the panel takes into account the following factors: first, the absolute EU budget allocated to SMEs, second, the gender balance of personnel doing research and innovation activities; if there are still ties, the panel agrees further factors to consider, e.g. synergies between projects or contributions to the objectives H2020. The same method is then applied to proposals that address topics that are already covered by more highly-ranked proposals.

Observers appointed by the Commission/Agency may attend any meetings or monitor remote evaluation, to ensure high quality assessment; they check overall process functioning and advise, in their report, on the conduct & fairness of the evaluation sessions (1st stage or 2-stage processes) and, if necessary, suggest possible improvement. They do not assess proposals, so do not express any opinion on their quality but they may raise questions and full support should be given to them.

The ethics review is important as only proposals complying with the ethical principles&legislation may receive funding. For proposals above threshold and considered for funding, ethics screening and, if necessary, ethics assessment is performed by independent ethics experts/qualified internal staff in parallel with the scientific evaluation or soon afterwards. Proposals involving the use of human embryonic stems cells automatically undergo an ethics assessment. For those proposals in which one or more ethical issues have been identified, the experts will assess whether the ethics issues are adequately addressed. The ethics experts produce an ethics report and give an opinion on the proposal, granting ethics clearance, recommending the inclusion of ethics requirements in the grant agreement, or recommending a further Ethics Assessment and/or an Ethics Check/Audit.

Types of Actions

The Research and Innovation Action primarily consists of activities to establish new knowledge and/or explore feasibility of new or improved technology, product, process, service or solution. It may include

basic and applied research, technology development and integration, testing and validation on small-scale prototypes in laboratory or simulated environment. Projects may contain closely connected but limited demonstration or pilot activities to show technical feasibility in a near to operational environment.

The Innovation Action consists of activities that produce plans&arrangements or designs for new, altered or improved products, processes or services. It could include prototyping, demonstrating, testing, piloting, large-scale product validation and market replication, as it aims to validate the technical & economic viability in a (near) operational environment or support the first application on the market of an innovation that has already been demonstrated but not yet deployed on the market due to market failures/barriers to uptake. Such projects include limited research activities.

SME Instrument phase 1 deals with feasibility studies verifying the technological/practical as well as economic viability of innovation idea/concept with considerable novelty to the industry sector in which it is presented (new products, processes, design, services and technologies or new market applications of existing technologies). Activities target risk assessment, user involvement, market study, intellectual property management, innovation strategy development, partner search, concept feasibility to establish a solid high-potential innovation project aligned to enterprise strategy and having a European dimension. Bottlenecks in increasing enterprise profitability by innovation shall be detected and analysed during phase 1 and addressed during phase 2 to increase the return in investment in innovation activities.

SME Instrument phase 2 envisages innovation projects that address a specific challenge and demonstrate high potential in terms of company competitiveness and growth underpinned by a strategic business plan. All activities focus on innovation such as demonstration, prototyping, piloting, scaling-up, miniaturisation, design, and market replication, aiming to bring an innovative idea (product, process, service) to industrial readiness and maturity for market introduction; it may also include some research. Under exceptional circumstances, duly justified by the character of an area, a topic may provide for actions where the research component is strongly present, as an alternative to the innovation actions above. SMEs can subcontract work and knowledge that is essential for their innovation project in the spirit of the innovation voucher concept. Proposals should be based on a strategic business plan developed through phase 1.

Coordination & Support Actions consist in accompanying measures: standardisation, awareness-raising and communication, dissemination, networking, coordination or support services, policy dialogues , mutual learning exercises and studies, including design studies for new infrastructure; they may also include complementary activities of strategic planning, networking and coordination between programmes in different countries

ERA-NET Co-fund supports public-public partnerships, including joint programming initiatives between member states, establish networking structures, design, implement and coordinate joint activities as well as EU topping-up of trans-national call for proposals. The main activity is the implementation of the co-funded joint call for proposals that leads to the funding of transnational research and/or innovation projects. In addition, consortia may implement other joint activities e.g. joint calls without EU co-funding. Depending on the research area and the underlying national programmes and their governing principles, they target governmental research organisations. The co-funded call will be based on contributions from their institutional funding and the beneficiaries carry out the transnational projects resulting from their call fully or partially themselves.

Pre-Commercial Procurement Actions encourage public procurement of research, development and validation of new solutions that can bring significant quality and efficiency improvements in areas of public interest, while opening market opportunities for industry and researchers. It gives EU co-funding for groups of procurers to undertake together one joint PCP procurement, so that there is one joint call for tender, one joint evaluation of offers, and a lead procurer awarding the R&D service contracts on behalf

of the group. Cross-border PCP cooperation must address issues of common EU interest where interoperability & coherence of solutions across borders is required.

Public Procurement of Innovative Solutions Actions enable groups of procurers to share the risks of acting as early adopters of innovative solutions in opening market opportunities for industry. Each action targets a concrete need shared by all participants and requires the innovative solution deployment to a significant extent similar across countries hence proposed to be procured jointly. It means that the innovative solutions got by all in the group must have the same core functionality and performance characteristics, but may have additional 'local' functionality due to differences in the local context of each individual procurer.

Conclusions

Wide-ranging decisions at EU level envisaging institutions and organizations influence creativity in scientific research. At team level, creative accomplishments occur in small groups, in contexts with sufficient access to complementary technical skills, under stable research sponsorship terms, with timely obtained resources and outsourced skills, in the framework of facilitating leadership. A potential institutional threat to creative science is the increase in competitive research funding at the expense of flexible institutional sponsorship. Implications may become dramatic for research management and for national research policies.

Creative scientific outcomes followed by fast implementation for enhanced societal change, as H2020 outlines, are influential in shaping new, cutting-edge research environments. EU research policymakers need to know more about the factors contributing to scientific progress in step with the substantial changes seen in the last decades in the conditions of conducting research. Public research funding is now increasingly allocated via competitive processes rather than long-term institutional block grants; enhanced research collaboration is encouraged in a variety of measures including organized research centres, networks, excellence centres, and inter-disciplinary teams, to address the diverse challenges we currently face (complexity, convergence, knowledge exchange, scale, scope, and internationalization in contemporary science). Research performance assessment systems are implemented as a supplement to peer review.

In the context of heightened competitive pressures to foster science-driven business development and the rise of new global locations for research, policymakers in developed economies hope that adjustments to research organizations and broadened institutional environments for science will promote efficiency as well as scientific excellence and creativity. Research groups conduct work according to team features like size, members' careers and levels, organizational variables and environment where they operate with typical leadership, funding structures, competitive pressures.

H2020 facilitates organizational and institutional influences on scientific creativity including work group factors, like research group size or communication patterns, and organizational issues such as sponsorship or inter-disciplinary variety. Research management and research policies enhance creative knowledge environments.

The scientific community is aware of the fact that novel ideas of value need validation in time and by other scientists. Creative processes, including the selection of problems, methods, partners and knowledge sources, are key areas of inquiry. Innate individual traits spur creative processes which are facilitated by opportunity structures in collaboration networks that enable the generation and diffusion of new ideas. Networking favours people placed at the intersection of heterogeneous social groups with increased likelihood of drawing upon multiple knowledge sources, leading to the generation of new concepts; hence managers who occupy brokerage positions are more often than others the source of good ideas. Cohesive collaborative networks provide the benefits of trust, shared risk taking, and easy

mobilization in facilitating information and knowledge transfer. Therefore individuals with cohesive social ties are more likely to be involved in innovations. The network structure itself has to be suitable for diffusing ideas and this is what H2020 Projects strive to achieve: network structures that enhance novelty generation, also able to increase propagation.

Considerations of research environments add further elements of organizational and institutional nature to the examination of scientific creativity. Research environments influence opportunities for collaboration and multi-disciplinary approaches, which in turn affect processes of knowledge discovery. Organizational and institutional issues stimulate creative research situations: autonomy for researchers, adequate facilities and funding, development of complementary disciplines and fields, staff selection, management structures, and leadership. Obstacles include: insufficient basic funding, limited time for research, bureaucratic management, narrow range of subject expertise, and excessive evaluation and accountability pressures. Research productivity is correlated with the high frequency of intra-organizational communication, across disciplinary and thematic lines, with strategies for integrating scientific diversity with rigorous standards of scientific excellence.

Further strategies for intellectual integration within the limits of an organization are mobility of researchers and inter-department teamwork. Problems in productive research climates stem from human resources, instrumentation and funding. Effective dialogues with other groups that have complementary knowledge and expertise lead to accomplishing more numerous creative events. Effective group leaders bridge seemingly unrelated knowledge areas, carefully select new group members for their merits and attributes, have the flexibility to address new problems or ideas that arise, and help post-docs with good ideas to attract funds so they can become self-sustaining. Team Leaders prove good intuition about the right measure of risk to take on with their new idea, and provide a protected area under which group members conduct their research. The variables at the organizational and institutional level must be understood as interrelated contributing influences rather than as independent, cumulative factors.

Acknowledgment

This article is a dissemination report on development steps and outcomes of two projects: H 2020 Project ENHANCE, grant agreement no. 691681, and 2016 ERA Fellowship, whose overall aims it reflects and accomplishes. For H2020 Project ENHANCE deep appreciation goes to Project Team Leader Professor Gina Fintineru PhD, USAMV Research Vice-Rector. For 2016 ERA Fellowship the mentor was IAMO Project Team Leader Professor Thomas Herzfeld PhD, a role model for academic competence and performance.

Abstract

Waqf in the education sector is no stranger because its implementation has been implemented starting from establishment of traditional educational religious-oriented such as *Sekolah Agama Rakyat* (SAR), *Sekolah Agama Negeri* (SAN) and madrasah or *Sekolah Pondok.* However, implementation of these waqf at the higher education institution level is still new. There are only few of university that have been running these waqf activities currently include Universiti Putra Malaysia (UPM), Universiti Sains Islam Malaysia (USIM), Universiti Teknology Mara (UiTM), Universiti Kebangsaan Malaysia (UKM), Universiti Teknikal Malaysia Melaka (UTeM) and Universiti Islam Antarabangsa (UIAM). This study will used mixed method include qualitative and quantitative to get the detail information. This study purposed to find out more detail about the waqf activities at Malaysian public university.

Keywords: Waqf, Public Universities, Endowment, Funding, Education Waqf

1. Introduction

Waqf in the education sector has started from the establishment of traditional education institutions based on Islamic religion school such as Sekolah Agama Rakyat (SAR), the School of Religious Affairs (SAN), madrasah and cottages (Asmak, 2009; Mustaffa & Muda, 2014). In addition,

Muslims are encouraged to give the land for development of Muslim community through the education and to help other Muslim in need. The types of waqf for education is usually in a form of asset such as land, houses, buildings, books, mosques and other that give fully benefit for the purpose of studying (Hisham Sabri, 2007; Mustaffa & Muda, 2014). According to Mohd Jelani (1998) and Mustaffa and Muda (2014), the beginning of waqf activities for education is started in Johor Bahru where the request of waqf is to meet the requirements of religious schools integrated.

The passage of time shows the development of waqf activities in education no longer focused on religious education but growing to the general education sector (Utusan Malaysia, 2012). The development of waqf activities in education sector already consist of the higher education in public and private institutions. An example of successful in implementation of waqf in education is Al-Azhar University where it can cover university expenses using the waqf funds. Another example is Pondok Modern Darussalam Gontor (PMDSG) in Indonesia and Al-Fateh University in Turkey (Raja Ramli & Abd Hamid, 2014). All these universities use the waqf fund in finance their education sector. According to Ali and Wahid (2014), the research about waqf is less explored in the context of higher education institutions. The waqf focused studied in the field of religious institutions including in the school level (Mujani et al., 2014). Here, this research difference with other research because it further explores more to the current scenario of waqf implementation at Malaysian higher education institutions nowadays; that least discussed in the previous research.

2. Literature Review

In Malaysia, Waqf started from traditional endowments, including land, buildings, schools, mosques and consists of fixed assets. However, the development of the endowment has grown along with the development of the country in which the changes in waqf activities that are more focused on cash waqf are more effectively (Alhabshi & Abdul Razak, 2012).The difficulties to get property caused an innovation of waqf from the property to cash. Cash waqf is refer to the endowment based on money or certificate that usually be used in the finance to do charitable and welfare such as investment (Aziz et al., 2013; Ismail et al., 2014; Johari & Haji Alias, 2013; Nurrachmi, 2012). According to Ismail et al. (2014), the concept of cash waqf is the collection cash money and can be converted to a permanent property that can be used for welfare and also community.

In education institution in Malaysia, there are five public university that has been implemented the waqf activities and the others universities that committed to the future application of this waqf. Among them is the University Putra Malaysia (UPM), which was established a “Dana Wakaf Ilmu”, Universiti Kebangsaan Malaysia (UKM) has establish the UKM Endowment fund, Universiti Teknologi Malaysia (UTM) set up the UTM Endowment fund, Universiti Sains Islam Malaysia (USIM) with Al-Abrar USIM Waqf Fund, and Universiti Islam Antarabangsa Malaysia (UIAM) with IIUM Endowment Fund (Noor Inayah, 2014; Najibah Mustafa, 2014; Siti Zakiah, 2014; MoE, 2015). However, there are two university that are committed and already implement the waqf activities that are University Teknology Mara (UiTM) and University Teknikal Malaysia Melaka (UTeM).

Wakaf Ilmu UPM involve in the cash waqf where the cash received than will be allocated to Dana Wakaf Ilmu UPM fund. The objective of “Wakaf Ilmu UPM” department is to be an organizer for the sadakah and development of knowledge through the contribution and waqf activities, encourage the community to do the charity, and play a role as a facilitators in the practice of charity include the waqf. Besides that, the university can raise fund through the contribution of waqf and gift for university facilities. Furthermore, at Universiti Kebangsaan Malaysia (UKM) and Universiti Teknologi Malaysia (UTM) waqf activities have been managed under its owned Endowment Fund. University Technical Malaysia Melaka (UTeM) has compiled a strategic plan in mobilizing

university generating income activities through the establishment of an endowment fund to raise funds based on the donations from corporate, alumni, staff and the public. The function of this fund is as alternative to UTeM citizens and alumni also the general public in contributing a sum of money or financial aid to cover the various activities or programs which could give benefit for all based on the concept of charity. UiTM is the first university in Malaysia to be allowed to carry out the collection and distribution of zakat, and only collection for charity and waqf. This operation was conducted by the Center for Zakat, Sadaqah and Waqf (PZWS), the Academy of Contemporary Islamic Studies (ACIS).

However, based on the previous scholars, these studies faced the same problem in order to further explore in depth about the waqf model and it concept in higher education institutions. There are some challenges or issues that need highlight in this research based on the waqf implementation. The first is the term of management system. The management of waqf is important factors that influence the waqf implementation. However, the lack of management the waqf fund generated inefficiently (Ali & Wahid, 2014). Second is in financial terms. The weak in financial system caused the waqf property or cash waqf not develop and rise (Azha et al., 2013). The strong fund helps the institutions to do a lot of research and also promotion for fundraising campaign. Third is in the term of specialist unit (Azha et al., 2013). Not have any specialist unit for waqf can caused the week in planning the sources, manage the fund, and make decision to generate income. Fourth is in the term of marketing. Marketing is help to spread information about waqf in community. Lack in marketing activities affects the number of contributors involved in activities (Ali & Wahid, 2014). Fifth challenge is in the term understanding and knowledge of society. The knowledge of community about waqf in education is low and mostly not really understands the concept of waqf for education (Mustaffa & Muda, 2014)

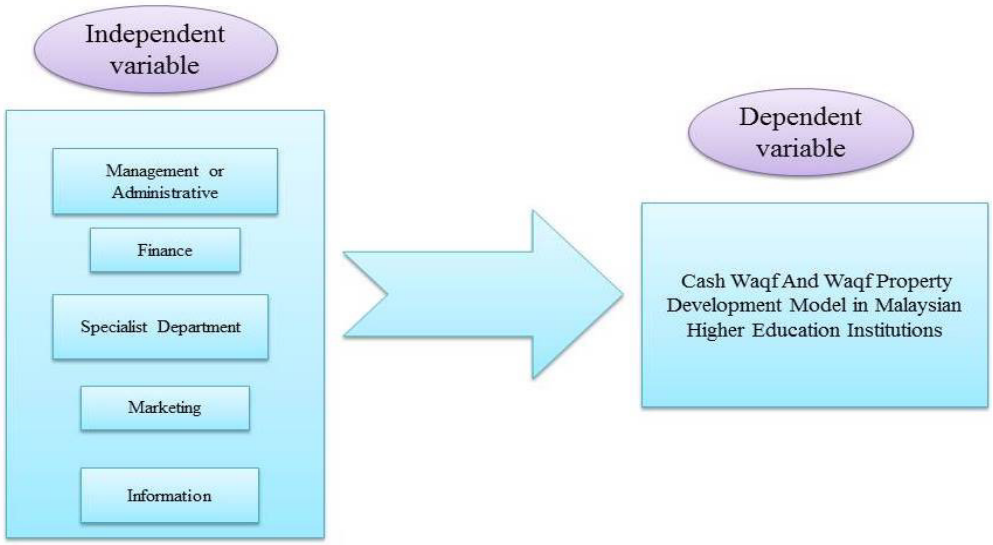

Figure 1: Conceptual Framework of Study

According to Ahmad Zaki (2006) there are five factors that influence the waqf activities will became the independent variables. The independent variables that be analyse are: (1) Management and administrative, (2) finance, (3) specialist in department, (4) marketing and (5) information. These factors will lead the Cash waqf and Waqf Propety development model in Malaysian Higher Education Institutions (HEIs). These Cash waqf and Waqf Propety Development Model in Malaysian Higher Education Institutions (HEIs) became the variables in this research.

3. Methodology

This research will be using mixed method approaches which are qualitative and quantitative method. In the qualitative method, information is gained from semi-structured interview among the respondents. This approach supposed to give a detail understanding about the topic. While, in the quantitative method, information are gained from the questionnaire survey given to the targeted respondents which are from the public universities that are new to the waqf implementation. These approaches help in understanding and collecting information or problem that happen before its implementation of waqf.

4. Results

The implementation of waqf in Malaysian Public University can be described as the beginning or first stage in the waqf activity where the university still focused on searching the information about the waqf implementation from the other country that already successful. However, it has some barriers in the waqf implementation caused difficulty to implement it in all the public universities. The waqf development still tied with the basic concept where the community thought that the waqf is only for mosque, the site for primary school and secondary school and cemetery. In addition, the contributions from outside education sector such as corporate and private company still not have any response. If had, they just want something such as reward, a good name and others that can give benefit them.

The management systems for the waqf activities in higher education institutions are still not strong where institutions are still looking for a waqf system that is suitable to be implemented in higher education institutions. They also still combined with the bursary department to collect, find the sources and distribution of waqf fund. They still not move by themselves yet for this the waqf activity. The financial are important in ensuring the success and failure in this waqf activity. Strong financial helps the higher education institutions to do a lot of research and also promotion on the waqf implementation for fundraising campaign. In addition, the waqf activities should focus on activities itself in terms of the sources of waqf fund, fund accumulation and distribution of the fund. In the sources of fund, communities still not involved in waqf activities in contribute the fund under the term of waqf fund. While, students and university management is a major of receiver for waqf fund in higher education institutions.

The organisational structure plays an important role in conducting waqf activities productively to ensure it can be developed. Moreover, a special body should be set up to manage the waqf fund and control all waqf activities. However, the lack of staff is not a major problem but most of the universities lack the skilled staff and had to search for information from foreign countries. The purposed of marketing is help to spread of information for waqf activities in community. Marketing activities can help to expand the collection of waqf funds from community, universities staff and corporate company. The promotion activities also play a role to improve the collection of waqf funds other than to providing information to the public. However, the promotion in all the universities is still low and focused only internal staff. It will influence the amount of wakaf fund obtained by each university.

The understanding and knowledge of society towards the waqf implementation in higher education slightly increase. They start understand the benefit of this waqf activities for university and also student. Many efforts are suggested to increase the understanding of the community to be more active to get involved in these waqf activities. Each university that has been implemented waqf have different modus operandi or waqf activity proses but still follow the real concept of waqf. Most public universities have started the waqf activities with implemented cash waqf and just a few of universities beginning with the waqf property. Most of the universities get their fund from the universitiy alumni, staff, community, corporate company and other contributor. Then the fund will manage by the unit waqf in each of university and the bursary will collect all existing waqf fund. The staff and university management a major recipient of waqf fund other than the local community in need.

5. Conclusions

The implementation of Waqf in education sector becomes very important nowadays because it help the universities to cover the additional coast while reducing reliance on government funding. The history has shown that the practice of waqf in education institutions has grown over the years among Muslims in Malaysia where it has been started since the arrival of Islam in the Malay world but regarded as a positive tradition that should be expanded (Yaacob, 2013). In addition, the waqf implementation in Malaysian Higher Education Institution gives the good impact in term of funding where the universities no need reliance to the government fund. However, there are some factors that should be considered by institutions before implement the waqf because the concept is still new in higher education institution.

Abstract

Innovations affect our actions by improving or facilitating processes for both the business world and the daily life. While the biggest recent technical innovations include smartphones, 3D-printing and cloud computing, also non-existent innovations – innovations that are announced but not yet released - are under discussion and in the process of development. Autonomous vehicles for example that can operate in every possible circumstance are not yet developed, prototypes with limitations are however already being tested and marketed. This development phase is characterized by mass media communication that allows for the process of opinion formation on the customer side. The continuous information stream with stressing the advantages of such innovations shall consequently lead to acceptance on the customer side.

Technology acceptance models and theories in the literature aim at explaining the variables in the process of acceptance forming on the customer side for existing innovations (e.g. information systems). These models and theories cannot be transferred to non-existent innovations to the full extent, but are applicable with minor adjustments according to the carried out comparative analysis and the combination with models from the field of marketing.

The results of this paper can be used by researchers aiming at developing modified acceptance models as well as companies trying to evaluate acceptance of innovations in the development process.

Keywords: Technology acceptance, innovations, comparative analysis, non-existent innovations

Introduction

The last centuries were characterized by different streams of disruptive innovations, influencing not only the economy, but also the daily life of the people. Starting with the industrial revolution in the 18th century and coming to the 4th industrial revolution (or digital transformation), all disruptive innovations are characterized by a breathtaking or new improvement which disturbs an existing environment or even destroys and reshapes it (Marquardt et al. 2017). While the influence of the innovation depends on its level of impact, the impact of an innovation also relies on the acceptance of the people. Steve Jobs once phrased the innovation cycle in the following way "you've got to start with the customer experience and work backwards to the technology" (Forbes 2013).

The significance and impact of innovations on the one hand and the acceptance of new technologies on the other hand demonstrate the correlation on both the customer and the market (provider) side. The correlation of the innovation development phase and the customer acceptance forming process can occur in two different ways according to the authors:

1. Consumer requirements push the market to create an idea for improvement. While the development process of an innovation can take longer, acceptance towards the final product is already established on the customer side regardless of the outstanding realization. The customer acceptance then further pushes the development phase and leads to the creation of an innovation. The ultimate stage for the success of an innovation is the acceptance towards the new product. This process usually occurs with high-impact innovations with a long development phase (e.g. internet).
2. The second option starts with the innovation itself that then leads to acceptance on the customer side in case of success. This shortened innovation acceptance process usually applies to innovations that are created without broad and long-term public notice on the development. This shortened process is supported by a quotation of Steve Jobs "A lot of times, people don't know what they want until you show it to them" and holds true for the publication of the first iPhone (Forbes 2011).

The following illustration demonstrates the correlation of the market and the customer regarding innovation development and acceptance.

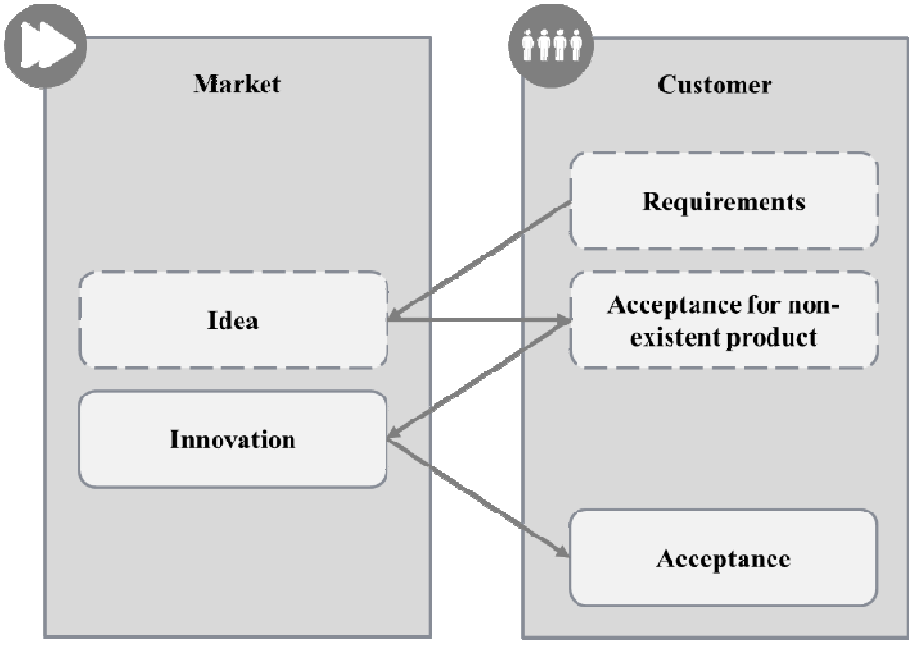

Figure 1: Correlation of market and customer (own figure)

While the acceptance forming process for existing technologies has been scientifically analyzed numerous times in the literature, the forming process and measurement of new and non-existent innovations and technology is mostly unexplored. The importance of acceptance towards non-existent products or technologies is however huge, as major developments are based on the continuous input from customers for the creation of a final product.

The following paper is a comparative study of technology acceptance models that is used for explaining the acceptance forming process for existing innovations. In a second step, the strengths of these models are compiled with additional insights for the application to new innovations. The results set the basis for future modification of technology acceptance models.

Technology and technology acceptance

Technology has been defined in various ways throughout the last centuries, as its meaning has evolved over the course and according to the changes technology has brought to the people. Technology in today's meaning is predominantly characterized by Gibert (2004):

- Increase of productivity
- Essential in various fields for further development (e.g. business, health care, education)
- Positive change for the daily life

The use of technology eventually leads to technology acceptance that is described as a psychological process starting with interest and leading to the daily use of an innovation (Kollmann, 1998; Jockisch, 2010). Technology acceptance describes a construct of evaluation and affect (Fishbein and Ajzen 1975) that is influenced by the subject, the object and the context (Lucke 1995).

As technology acceptance requires a regular use of the innovation or the intended use as well as a positive attitude towards it, technology acceptance describes a prerequisite for a successful innovation. Per above definitions of technology and innovations, a new technology describes an innovation, as long as the resulting improvement is considered as breathtaking and environment-changing. Due to the similarity of the definitions, both terms technology and innovations are to the greatest possible extent mutually used in this paper. It is recalled that acceptance describes a phenomenon of social science (psychology), but is strongly related to the fields of marketing and thereby to economic sciences.

Technology acceptance theories and models

Technology acceptance theories and models are used for the analysis of acceptance and the consideration of various influencing factors. While many different technology acceptance models have been established in the history, the following research focuses on the fundamental and mostly used technology acceptance models. Although many of the selected models reach back as far as 1975, they are still in use and form the basis for recently modified and further developed models and theories. The following presented models and theories all aim at predicting the phenomenon of establishing acceptance, but follow nonetheless a different approach. Models and theories that are presented and further elaborated include:

- Theory of reasoned action (TRA) by Fishbein and Ajzen, 1975
- Theory of planned behavior (TPB) by Fishbein and Ajzen, 1975
- Technology acceptance model (TAM) by Davis, 1989
- Technology acceptance model 2 (TAM 2) by Davis and Venkatesh, 1996
- Technology acceptance model 3 (TAM 3) by Davis and Bala, 2008
- Technology acceptance model by Degenhardt, 1986
- Technology acceptance model by Schlag, 1997
- Technology acceptance model by Kollmann, 1998
- Unified Theory of Acceptance and Use of Technology (UTAUT) by Venkatesh et al., 2003
- Unified Theory of Acceptance and Use of Technology 2 (UTAUT 2) Venkatesh et al., 2012)

The "Theory of reasoned action" (TRA) by Fishbein and Ajzen (1975) is one of the first established models and displays both influence and trigger factors of a particular behavior. A revised and extended version of the TRA was generated shortly after the publication in 1975 and is described as the "Theory of planned behavior" (TPB). This model is characterized by the inclusion of three main influencing factors: attitude, subjective norm and perceived behavioral control (Fishbein and Ajzen 1975).

In 1989 the so-called "Technology acceptance model" was established by Davis (1989), based on the TPB. In Davis' model, the user himself plays a predominant role as the factors of perceived usefulness and the perceived ease of use are incorporated. A further extension of the TAM has been suggested by Davis along with Venkatesh in 1996 and is known as TAM 2. TAM 2, in contrast to TAM, additionally considers external influences on the perceived usefulness and the perceived ease of use. TAM 3, developed by Venkatesh and Bala (2008), further breaks down the influencing factors on the perceived ease of use: confidence, perception of external control, system anxiety, playful use of the system, perceived enjoyment and usability.

Along on the time scale with the TAM, Degenhardt proposed a model in 1986 that was originally set up for explaining the acceptance of the utility of screen texts. Nonetheless, the general idea of the model can be applied to other innovations alike, as Degenhardt (1986) limits acceptance to three main elements: system configuration (form, function and utility of the innovation), task characteristics (importance and frequency in use) and user characteristics (skills or motivation).

A rather infamous, but specific heuristic model was developed by Schlag (1997) to measure acceptance of the implementation of road charges in urban areas. In addition to influencing factors (problem awareness, objective, responsibility attribution, subjective knowledge, perceived effectiveness, perceived fairness, social norm, income) the correlation of mobility and acceptance is incorporated in the model.
A very complex model that considers acceptance as a dynamic process with different stages was set up in 1998 by Kollmann and includes peripheral influences on a macroeconomic, socio-cultural, technological and political-legal level. Kollmann's model was created for explaining the acceptance forming process of innovative goods and systems.

A recent and famous technology acceptance model, called "Unified Theory of Acceptance and Use of Technology" (UTAUT) by Venkatesh et al. (2003), combines the strengths of various previous models, including TAM, TRA and TPB, and is based on four latent variables: performance expectancy, effort expectancy, social influence and facilitating conditions. A moderating effect of gender, age, experience and voluntariness of use was incorporated as well for the application on information technology. In a further extension of the model in 2012 (UTAUT 2) the variables hedonic motivation, price value, and habit were added to the previous model (Venkatesh et al. 2012).

The literature research has not revealed significant developments in the field of technology acceptance in the recent years. Instead, the models by Venkatesh et al. as well as Davis have been applied to current business cases.

Comparison of Technology Acceptance Theories And Models

Three key elements can be derived from the explored models or theories and include (Geldmacher et al. 2017):

- external influencing factors, e.g. macro-economic influences
- individual influencing factors, e.g. subjective knowledge, and
- stages of use (e.g. trial).

For a more detailed analysis, the elements of each model or theory are allocated to one of the three above mentioned elements. This allocation allows for a more detailed comparison to the latest UTAUT 2 model that aims at combining existing models. Similar wording of model components of different models is aggregated (cf. table 1).

Table 1: Allocation of variables to elaborated acceptance models and theories (own table)

		TRA	TPB	TAM	TAM 2	TAM 3	Degenhardt	Schlag	Kollmann
External influencing factors	Voluntariness				●	●			
	Image				●	●			
	Output quality				●				
	Usability					●			
	Objective				●	●		●	●
	System configuration						●		
	Political-legal influences								●
	Macro-economic influences								●
	Social-cultural influences							●	●
	Technological influences								●
Individual influencing factors	Attitude	●	●						
	Subjective Norm	●	●		●	●			
	Confidence					●			
	Job relevance				●	●			
	System anxiety					●			
	Perceived effectiveness						●	●	
	Perceived enjoyment					●			
	Perceived usefulness			●	●	●	●		●
	Perceived ease of use			●	●	●			●
	Perception of external control					●			
	Perceived behavioral control		●						
	Perceived fairness							●	
	Income							●	

	Individual/user characteristics						●		
	Subjective knowledge							●	
	Responsibility attribution							●	
Stages of process	Problem awareness							●	
	Interest								●
	Trial								●
	Experience				●	●			
	Behavioral intention	●	●	●	●	●			
	Use/behavior	●	●	●	●	●	●		●

While TRA, TPB and TAM do not include external influencing factors, all other explored models include both external and individual influencing factors. Especially the individual influencing factors are of high importance in the explored models. Most models and theories distinguish different stages of use, however the model by Kollmann incorporates most process stages of the explored models and is comparable to a famous marketing model by Lewis: AIDA model (Lewis 1903). The importance of incorporating the different stages from attention to interest, desire and action into technology acceptance models has been highlighted by Geldmacher et al (2017).

Comparing the different components (variables and influencing factors) of each model and its origin, the UTAUT model clearly is a combination of existing models with below explained origins, illustrated in figure 2 (Venkatesh et al. 2003):

- Performance expectancy: perceived usefulness (TAM, TAM 2, TAM 3)
- Effort expectancy: perceived ease of use (TAM, TAM 2, TAM 3)
- Social influence: subjective norm (TPB)
- Facilitating conditions (playful use of the system, system anxiety, perceived enjoyment, perception of external control (TAM 3)
- Experience (TAM 3)
- Voluntariness of use (TAM 3)

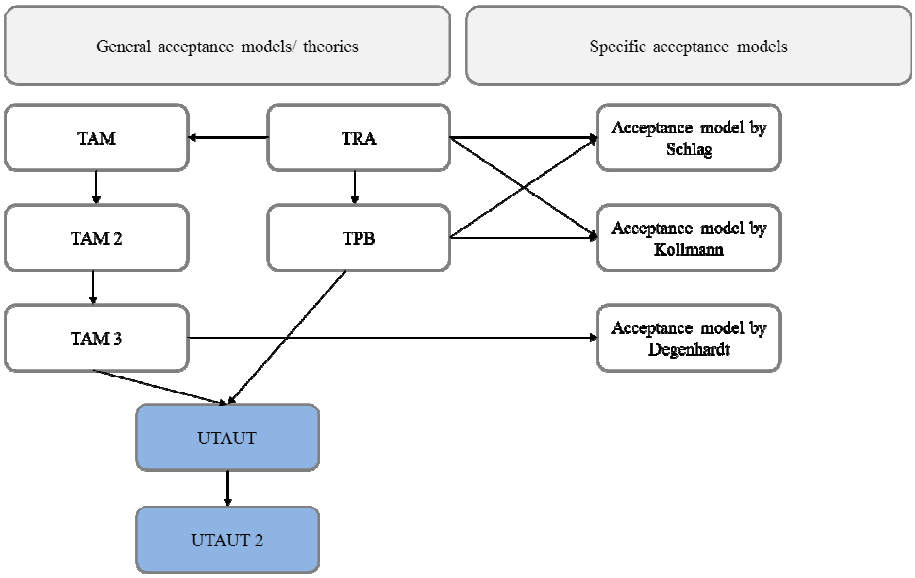

Figure 2: Relation of elaborated acceptance models and theories (own figure)

Derived from the above analyzed models, two types of theories can be distinguished, based on internal and external influencing factors: generally applicable acceptance models and theme-specific acceptance models.

While the presented models all refer to existing innovations that are analyzed and measured in regard to the level of acceptance, new innovation that are not yet released are not considered in the first place with these models (e.g. experience is expected). Nevertheless, the hypothesis is made that most of the models are still applicable to a certain extent for non-existent innovations with minor adaptions that are further outlined below. However, it is expected that UTAUT is the most applicable model for non-existent innovations. This hypothesis is further verified below.

The Application of Technology Acceptance Models To Non-Existent Innovations

Before the explored models are evaluated based on their content and methodology, the degree to which these models are applicable to non-existent innovations has to be explored. Research on the acceptance of innovations is an essential step in the product development cycle, as resistance to the product or service offered can be easily detected and adjusted accordingly to fit the customer requirements, even before the production and selling process starts (Arnold & Klee 2016).

For the purpose of model and theory evaluation, the different variables and components in the respective models and theories are investigated regarding their transfer for non-existing innovations. The variables of UTAUT are incorporated in this examination. While some variables and components of the models are fully transferable to non-existing innovations, others require an adjustment or different interpretation than to the original meaning (cf. table 2).

Table 2: Transferability of different technology acceptance models and theories (own table)

	Full transferability to non-existing innovations	Part-transferability to non-existing innovations	No transferability given	Required adjustment/ interpretation/ comment
Voluntariness	●			Assumption
Image		●		Only partly applicable, e.g. companies with a good image develop new innovations (e.g. Tesla)
Output quality		●		Only partly predictable from a customer perspective
Usability		●		Predictable to a certain extent before the release of a new innovation.
Objective	●			
System configuration		●		System configuration can only be assumed by customers
Political-legal influences	●			
Macro-economic influences	●			
Social-cultural influences	●			
Technological influences	●			
Price value		●		The price value can only be partly evaluated in advance.
Attitude		●		Attitude is formed with the development process of the innovation, based on the released information
Subjective Norm		●		Subjective norm as social pressure is only to a certain extent predictable.
Confidence		●		Confidence towards a non-existent innovation can be only party-predicted when compared to similar innovations or systems.
Job relevance	●			
System anxiety		●		Expected anxiety
Perceived effectiveness		●		Expected effectiveness from customer perspective
Perceived enjoyment		●		Expected enjoyment from customer perspective

Perceived usefulness		●		Expected usefulness from customer perspective
Perceived ease of use		●		Expected ease of use from customer perspective
Perception of external control			●	Not assessable before release of innovation
Perceived behavioral control			●	Not assessable before release of innovation
Perceived fairness	●			Assumption
Income	●			Influence on prospective potential use of innovation
Individual/user characteristics	●			
Subjective knowledge	●			Information and knowledge increase the level of acceptance (Geldmacher et al. 2017)
Responsibility attribution			●	Not assessable before release of innovation
Problem awareness	●			Cf. AIDA-model (attention)
Interest	●			Cf. AIDA-model (interest)
Trial	●			
Experience		●		Partly applicable, e.g. testing of self-driving vehicles in designated areas
Behavioral intention	●			
Use/behavior			●	Not applicable, but replaceable with "acceptance" as this term does not presume the use/behavior/affect
Gender	●			
Age	●			
Hedonic motivation	●			
Habit			●	Habit is not predictable with non-existent innovations as habits cannot develop before release.

For further evaluation of the presented models in regard to the application for non-existent innovations, three requirements were formulated that relate to both the content (C) and the methodology (M):

- C1 Acceptance modeling: extent of describing the complex process of acceptance building including the influencing factors

- C2 Transferability: the model is applicable or transferable to both existing and non-existing innovations, based on the transferability matrix above (cf. table 2)
- M Evaluation: the model allows a more detailed measurement of correlation for the acceptance forming process (e.g. structural equation modeling)

The above outlined models are evaluated by the authors with respect to the proposed requirements. The score is based on a five-point scale with high numbers implying a good evaluation. The three defined requirements (C1, C2 and M) are all equally evaluated and added to compose a sum (with 15 points being the maximum possible number). It shall be noted that the following scoring is based on a subjective evaluation that is recommended to be further examined by e.g. expert interviews:

Table 3: Evaluation of acceptance models

	C1	**C2**	**M**	**Sum**
TRA	1	3	1	5
TPB	2	3	2	7
TAM	2	3	2	7
TAM 2	3	3	3	9
TAM 3	3	4	3	10
Degenhardt	2	2	3	7
Schlag	3	3	3	9
Kollmann	4	3	4	11
UTAUT	4	4	4	12
UTAUT 2	**5**	**4**	**5**	**14**

The high evaluation of UTAUT and UTAUT 2 were expected and are explainable through the fact that this theory can be described as a compilation of the other models and the fact that they are more complex and include variables for internal and external influencing factors as well as different stages of use.

Although many of the explored models were created for theme-specific purposes, the general idea of the models is mostly transferable to all existing innovations. The transferability to non-existing innovations is however limited for some of the explore models and theories, as many of the variables require full knowledge or even trial of the innovation.

Based on this evaluation, a modification of UTAUT or UTAUT 2 is recommended to further explore the acceptance of non-existent innovations. A modification of these models shall consider various following aspects according to the authors. Customer statistics for example reveal relevant purchase decisions and user requirements for a comparable product or service (Geldmacher et al. 2017) that can be aggregated to a variable that influences the acceptance process. In addition to statistics, also models from the field of marketing, including the AIDA model in combination with the diffusion theory by Rogers (1962), shall be considered when modifying acceptance models and theories.

Conclusions

The acceptance of innovations is measurable with technology acceptance models and theories. Only non-existent innovations that raise awareness through a long development process are legible for acceptance measuring with existent models and theories. These models and theories however require minor adjustments in case of application to innovations.

The authors suggest the modification of existing models and theories, in particular based on UTAUT, per above outlined factors to allow for an application and verification for non-existent innovations. Model verifications can be conducted by operationalization of the respective variables and evaluation of correlations through structural equation modeling. In addition, it is recommended to verify the author's subjective evaluation on the elaborated models and theories by qualitative research (e.g. expert interviews).

Selection and Justification of Priorities of Innovative Development of an Industrial Region

Lidiya A. Galkina, South Ural State University, Chelyabinsk, Russia, baevia@susu.ru

Abstract

The relevance of the problem is related to the need to resolve the contradictions between increasing investment in formation of innovation infrastructure and the results achieved. The low level of competitiveness of a larger share of domestic products does not allow them to compete not only on external, but often in the domestic market. The aim of the research is to develop approaches to selection of priorities for innovative development from the point of view of the regional economy, a special emphasis is placed on the fact that for sustainable regional development it is necessary to "complicate" the economy and increase the level of its diversification. The paper employed the statistical methods of research, optimization methods, and production functions. Results: there had been developed the models, according to which the priorities of innovative development in the Chelyabinsk region were calculated. Key conclusions: for the successful development of innovation in industrial regions, it is necessary to create a regional register of industrial technologies, when choosing priorities for innovative development, it is reasonable to proceed from the criterion of economic complexity of the region.

Keywords: innovation development, import substitution, priorities, complexity of the economy, investments, network economy.

Introduction

Possible ways to stimulate innovation in the Russian economy began to be actively developed in the early eighties, even before the collapse of the Soviet Union. Even then it became obvious that the current mechanisms for "introducing" the results of research and development are not effective, the innovative activity of enterprises is low, the competitiveness of products is insufficient, the average age of production equipment is constantly increasing, and the technologies used are rapidly becoming obsolete.
Since then, a number of state concepts for regulating and stimulating innovation have been adopted, the national innovation system has been announced, a number of mechanisms for public financing of innovation have been created, including the creation of a highly developed innovation infrastructure, and state and regional innovative development programs are periodically adopted. However, at present one has to state a low level of almost all indicators of the innovation activity of the Russian economy.

The level of innovation activity of large and medium-sized industrial production organizations, calculated as the share of organizations that carry out technological innovation, varies little. The dynamics of this indicator, for example, in the Chelyabinsk region is as follows: 9.8% in 2012, 7.6% in 2014 and then growth to 11.5% in 2016 (Federal, 2016).

During the period from 2005 to 2012, the innovative development programs showed low efficiency, the planned targets were achieved less than a third of the planned indicators. In addition, most of the indicators were even lower than those foreseen by the inertial scenario, and some showed clearly negative dynamics (Kilina, 2013).

There is a clear contradiction between the attention of the authorities and state investments in the innovation sphere and the results of innovation activities achieved (Rodrik, 2005)

Production function of the regional economy

The identification of priorities for economic development in general and innovation, in particular, is an important research task. The impact of public investment on regional growth and convergence has been analyzed by different authors and from different perspectives (De la Fuente, 2008; Garrido, 2007; De La Fuente, 2008; Lichtenberg, 1995). Criteria for choosing priorities can be different even in theory, moreover they differ in practice. As an approbation of a new approach to the selection of development priorities, we used the apparatus of production functions and the index of the complexity of the economy. According to the statistical reporting for 2000-2015, the production function for a large industrial area was calculated in the work. As a result, the following expression was obtained

$$\hat{Y} = 56.302K^{1.252056}L^{-1.135628}, \quad (1)$$

where $\hat{Y}$ - gross regional product, billion rubles;

K - cost of fixed production assets, million rubles;
L - number of economically active population, thousand people.

The resulting production function indicates the narrowing of the regional labor market, a lack of supply and demand in this market. This is confirmed by the data in Table 1. As it can be seen, the region has a low proportion of employees working in organizations and employed on a regular basis. If in 2011 of 1.882 million people of the labor resources, 1,123.1 million people worked in organizations, that is, less than 62.8%, in 2015 it was already 61.7%. In total, in the sphere that produces products or services at market prices, only slightly more than 1 million people were employed in 2015, of which more than 30 thousand people (3%) - workers in agriculture, hunting and fishing, who are characterized, as a rule, by part-time employment. Where are the remaining 39.3% of people of working age employed? Approximately half of them are engaged in entrepreneurial activities without the formation of a legal entity and in the production of products for their own needs, that is, in personal subsidiary plots and/or in the criminal-shadow sector. This situation substantially distorts the structural proportions and the assessment of the influence of capital and labor factors on the gross regional product. However, calculations are based on the official statistics.

Table 1: dynamics of the number of economically active population of the Chelyabinsk region, thousand people *

z	2011	2012	2013	2014	2015
Number of economically active population	1882,3	1879,3	1876,6	1859,9	1856,9
Number of employees in the economy	1758	1759,1	1763,3	1743,8	1727,5
Number of the unemployed	31,7	28,2	26,1	27,5	34,6
Number of employees in organizations	1123,1	1119,5	1121,9	1121,7	1088,5
Share of employees in organizations in the number of employed people,%	62,8	62,6	62,6	63,3	61,7

* According to the data of Chelyabinskstat (Federal, 2016) and the authors' calculations

Analyzing the received function, it can be stated that, despite the increasing output of production, there are significant disparities in the region between production factors. The elasticity of the gross regional

product of the Chelyabinsk region is higher in capital than in labor. Consequently, with the existing capital-labor ratio and technical equipment in various industries, the economy of the region is labor-surplus. The increase in the value of fixed assets by 1% leads to an increase in output by 1.252%. At the same time, an increase in the number of employed by 1% entails a decrease in output by 1.136%. Consequently, to increase the volume of gross regional product, on the one hand, there is a significant increase in the funds-for-production of enterprises, and on the other, intensive creation of high-productivity jobs. As it can be seen from the table, almost no new jobs are created or there are more retiring places than newly created ones. At the same time, the low unemployment in the region is indicative not so much of a favorable situation in the labor market as of low productivity of workers. All are employed, but the effectiveness of this activity is low. Moreover, most of the employed are performing simple jobs that do not require special knowledge, employees are trained to cope with routine tasks and do not demonstrate demand for complex jobs. Those who are able to perform difficult work, but do not have it, either leave the region or the country. The replacement of skilled labor by routine one leads to the replacement of complex tasks with simpler ones. In the corporate sector, there is a slow degradation, which is intended to be solved financially. The worst thing is that this happens in high-tech industries. It is necessary to reverse this trend and achieve a more adequate balance between the array of regional jobs and the array of proposed qualifications. Only in this case the labor market of the Chelyabinsk region will pass from the primitive to the complex, that is, the developing one. Only in this case the proportions between the elasticity coefficients of the production function of the region will change. This, of course, will lead to an increase in the efficiency of the regional economy and the growth of its impact. However, it is not possible to solve such a problem without increasing the innovative activity of enterprises. It should be noted that the analyzed area has a fairly serious but not enough realized innovative potential that can be used in this approach.

Problems of Innovative Development of Industrial Regions

The analyzed area is a region with a predominance of medium-technology high-level productions. However, the small number of successful innovative enterprises of the new economy and, most importantly, the slow pace of their creation, are a significant challenge for the development of the region and predetermine the probability of its transition from a group of high-tech industrial regions to the periphery of the Russian economy.

The new economy is characterized by relationships built on direct equitable relationships between enterprises, a small need for formal organizational structures, a high decision-making speed, as well as a maximally dispersed, flexible and innovation-dependent production. At the same time, the main issue in the networked economy is not "how to do the job best?", but "what kind of work is more correct?". In the modern conditions, it is much more important to understand what work to do next than to continue to intensively carry out the former one. When problems are solved, time and effort are invested in existing weaknesses, and when searching for opportunities, investing in development.

From this point of view, an important problem constraining the development of innovations in the field is the excessive vertical integration of large businesses. At the enterprises of the region in the engineering industry and in the defense industry, the competitive market of components within the framework of large vertically integrated companies (VINC) is not sufficiently developed. Moreover, the management companies of the most industry-based VINCs are located outside the region and make decisions that are optimal from the point of view of the company as a whole, but these decisions are far from optimal from the point of view of regional enterprises or from the point of view of the development of the region as a whole. Within the framework of vertically integrated holdings, competencies are collected for the organization of full cycle production, which leads to an almost complete absence of subcontracting. The experience of the development of the world's largest companies, for example Bombardier, which produces medium-haul aircraft, demonstrates the opposite trends: large companies concentrate only key

functions, for example conceptual design, and the remaining production stages are outsourced. In Canada, only tail empennage and general assembly are made, wings are made in Japan, fuselage in Ireland, engines in the USA. At the same time Bombardier concludes a contract for the whole batch of aircraft, and its partners in other countries, with this contract they go to banks, take loans, organize production and supply their parts. Increasing competition among suppliers encourages them to continually improve their products and continuously seek and implement innovations. Our machine-building plants, as a rule, take for everything, the level of specialization of production is extremely low, the output volumes of production do not adapt to mass production, not to mention the mass production, which significantly increases the cost of production and lowers the competitiveness of products. The machine-building plants of the region are forced to buy stainless steel in China, despite the fact that the Mechel metallurgical plant is located in the region. The problem with most enterprises is that they can produce everything, but they cannot do it massively. But in order to produce a competitive product, it is necessary to be included in the world cooperation (Knobel, 2016). However, it is clear that this cannot be done quickly, all countries are already there, but Russia is not. At the same time, taking into account the proportions and the scale of the domestic market, and the market of all Russian exports (household consumption is 54% of GDP, and the entire Russian export is 18% of GDP), in our opinion, it is necessary to orient ourselves, first of all, to the domestic market . In addition, the experience of most countries also shows that the development of new technologies and their scaling is faster and more efficient in the domestic market (Knobel, 2016).

Criterion of Economic Complexity

Harvard professor Ricardo Hausmann and his colleague from the Massachusetts Institute of Technology, Caesar Hidalgo, proposed an approach to the characterization of national economies, based on the fact that the key factors reflecting the degree of intensive development of the economy are its complexity and diversification. The central concept of this paradigm is that the economy naturally develops around existing technologies and existing competencies, gradually joining the close positions of the multidimensional space of industries with their own values of the economic product complexity index (PCI) (Hausmann, 2004; Hausmann, 2011; Product, 2015).

We tried to apply this approach to the regional economy. The practical application of the approach is realized by calculating two interrelated indices - the ECI index (economic complexity index) and PCI (product complexity index). The application of the PCI index allows combining different products into groups, ranking the existing technologies in terms of complexity and development of regional register of production technologies. On the basis of such a register, it is possible to create a regional network of industrial cooperation and subcontracting. Naturally, such a register should be open for including other regions. This will not only increase the number of products with high added value, but also get a "network effect." In physics and chemistry there are so-called "second-order reactions". They are understood as such processes in which the speed of the process depends not on the number of participants, but on the number of interactions between them, and the result of such a process is proportional not to the number of participants, but to the square of this number. At the same time, it is clear that the result, proportional to "en-square", is a collective phenomenon, and in the economy it can be achieved only thanks to the efforts of human capital. Therefore, for innovative development of the region, there is not enough interaction between business entities, and in the current level of informatization it is not such a difficult task. It is difficult to organize the process. At present, purely administrative methods of influence have little effect on the innovation process. The main impact is on the market. However, the state retains the functions of coordination, regulation and stimulation of the innovation process. For the implementation of industrial policy, a limited set of tools is available to local authorities, some of which create incentives, while others impose restrictions. The creation of a regional register of production technologies and stimulation of promising forms of production cooperation in individual sectors and in the economy of the region, as a whole, refers to stimulating tools. The limiting tools, in this case, include

reducing the use of government support measures that distort normal market proportions, and ultimately hampering the creation and development of innovative production chains. In business, in this case, two multipliers will work: on the one hand, the sales multiplier, which is formed using common distribution channels, and on the other hand, the multiplier of production, which will arise due to intraregional initiation of demand for production resources, taking into account the need for development of industry and interindustry production in the territory of the Region. All these actions should lead to an increase in the economic complexity index of the regional economy (ECI), and this will already serve as the basis for intensive innovation development, growth of the gross regional product and sustainable regional development [14].

Principles of choosing criteria for innovative development

The work is based on the following methodological principles for the formation of innovation activity priorities:

1. The principle of accounting for the diversity of economic competences in the region. This principle presupposes that a map of the existing competencies is drawn up using the competence cards of enterprises located on the territory of the region. On the basis of such a scheme, those competencies are singled out whose development will lead to the complication of the region's economy and the manufacture of products with higher added value. This will allow, firstly, to find those activities that are provided with the existing competencies, and secondly, are in demand, at least, by the national and regional markets.

2. The principle of complementing by related competences. Each type of product, allotted at the previous stage, has certain connections with other industries and sectors. Therefore, it is necessary on the basis of the regional register of production technologies, to identify key points for the development of cooperative ties, and to build a network of cooperative enterprises. On the one hand, this will allow increasing regional diversification of production, and on the other hand, it will allow building long production chains of added value.

3. The principle of ranking the allocated competences from the point of view of resource and financial provision. Ranking is the tool by which it is possible to prioritize in order of importance, significance and need for implementation. Considering the restrictions existing in each period of time for all types of resources, it is necessary to rank the types of products identified in the previous stages of production according to the most important criteria at that time (preferably on the criteria of sustainable development of the region).

Methods for solving the problem

As part of the study, a methodology was proposed to identify the optimal structure of investment in innovative projects related to different industries, according to the criterion of achieving the maximum complexity of the economic system in which these projects are implemented. The problem is solved with a limited investment budget.

At the first stage, an assessment was made of the extent to which each ruble spent to invest innovative projects in a particular industry increases the ECI.

At the second stage, the optimization task was solved. The target function was the indicator of the complexity of the region's economy

$$M = D_1 \cdot PCI_1 + D_2 \cdot PCI_2 + \cdots + D_N \cdot PCI_N,$$
$$M \to max; \quad (2)$$

where *M* - indicator of the complexity of the economy (the desired utility maximization function);
D_1 – share of the product (project) in the total output;
PCI_1 – level of complexity of the *i*-th product from the table of specific technologies (2014) [7].

As a constraint, the budget constraints of the system were taken:

$$V = D_1 \cdot C_1 + D_2 \cdot C_2 + \cdots + D_N \cdot C_N; \quad (3)$$

$$\begin{cases} 0 \le D_1 \le M_{ARCTEA,1} \\ 0 \le D_2 \le M_{ARCTEA,2} \\ \cdots \\ 0 \le D_N \le M_{ARCTEA,N} \end{cases} \quad (4)$$

where *V* - projected investment budget where V - projected investment budget;

C_1 – investment costs for increasing the share of innovative products 1 or project N in GRP or in the volume of output by 1%, provided that the increase occurred from 0. The indicators $C_1 \ldots C_N$, are calculated according to a certain methodology, and ultimately, have been adjusted by the method of expert assessments, depending on the availability and capabilities of related technologies in the region; *MARCTEA, N* – maximum amount of investments of the industry N in the corresponding commodity item of the All-Russian Classifier of Types of Economic Activities (ARCTEA).

The constraint system (4) allows to obtain non-negative values of the parameter D when solving the optimization problem, and not to go beyond the maximum possibilities of the regional budget.

As a result of solving this optimization problem, we obtained a maximized function, as well as the indicators D1…DN, which provide an opportunity to draw up an approximate plan of innovative projects in the region.

At the third stage, calculating the coefficients C1…CN was made by establishing a correlation between the changes in the volume of production of innovative products from investments in the fixed assets.

This algorithm was calculated based on the data of Chelyabinskstat and the Customs Service of the Chelyabinsk Region. When analyzing the statistical data, a correlation of the presented indices with a lag of 2 years was established. (5) Thus, the calculation of the coefficient C for the analyzed period is performed as follows:

$$C_t = \frac{INV_t}{V_{(t+1,t+2)}}, \quad (5)$$

where C_t – required coefficient of the *t* period;

INV_t – investment for the reporting *t* period, in million rubles investment for the reporting t period, in million rubles;

$V_{(t+1,\ t=2)}$ – change in the volume of production for the *t*+1 and *t*+2 period, that is:

$$V_{(t+1,\ t=2)} = V_{t+2} - V_{t+1} \quad (6)$$

The nominal value of the coefficient C is calculated as the arithmetic mean as a result of processing the statistical data of investments and production volumes by branches of the economy of the Chelyabinsk region from 2009 to 2015 (Hausmann, 2011):

$$C = \frac{C_t + C_{t+1} + \cdots + C_{t+N}}{N} \quad (7)$$

As a result of processing the results of statistical data, according to formulas 5-7, the values of investment cost coefficients were obtained, three positions of which, for example, are presented in Table 2.

Table 2: values of output elasticity coefficients

ARCTEA code	Decoding of the ARCTEA code	C
C	Extraction of minerals	1,258
D	Manufacturing	0,406
DA	Manufacture of food products, including drinks and tobacco	0,1694

To obtain the final values, these coefficients were corrected with the help of the kH coefficient, reflecting the current level of development of the specialization of the enterprises of the Chelyabinsk region in the production of the corresponding types of products. The values of the kH coefficients were set in accordance with the scale obtained by the expert method. The value of the coefficient varies discretely in steps of 0.1 in the range from -0.5 to +0.5. The economic meaning of these coefficients reflects one or another level of specialization of production in the region.

As a result of the solution of the optimization task, 70 non-negative values of D1...DN were obtained, that is, priority industries and the commodity nomenclature of innovation activity were identified, and the corresponding C*D values reflect the amount of investments for the production of this product. Table 3 shows the first 3 positions of the results obtained.

Table 3: the first 3 results of solving the optimization problem with the given constraints values of output elasticity coefficients

Description of commodity position	PCI	D*C, million rubles	D, million rubles
1. Instruments and apparatus for physical or chemical analysis	2,110	4413	4456
2. Internal combustion piston engines with compression ignition (diesel engines or semi-diesel engines)	1,546	4130,23	4093,9
3. Lathe machines (including multi-purpose lathes), metal cutting	1,629	4041	4054,73

In the course of analyzing the results obtained, it was concluded that the main positions of the investment budget for the development of innovative products, proposed on the basis of the solution of the optimization task, are based in the field of machinery and equipment (DK). Thus, for the analyzed area, the branches corresponding to the ARCTEA positions "production of machines and equipment" have a developed potential. Therefore, when investing in this area, one can expect an increase in the index of the

region's economic complexity, and in the future, stable dynamics of improving the structure of the gross regional product.

Conclusion

Thus, it can be argued that in order to resolve the contradiction between the growth of public investment in the formation of an innovation infrastructure and the results achieved, it is necessary to change approaches to the selection of priorities for the innovative development of industrial enterprises. It is expedient to provide business with systematized and structured information on the basis of the regional register of production technologies. This will significantly increase the number of interactions of the regional business entities on the basis of regional initiation of demand and the regional economy of production includes the sales and production multipliers. All this should lead to an increase in the economic complexity of the region, improving the structure of the gross regional product and the sustainable development of the regional economy.

Contemporary Approaches to Advancement of the Banking Sector – Virtual Credit Organizations

Alexey V. Bataev, Associate professor of Peter the Great St. Petersburg Polytechnic University, St. Petersburg, Russian Federation, bat_a68@mail.ru

Abstract

The development of information and communication technologies has reformatted all spheres of the economy. The fast introduction of computer networks, the Internet progress promoted to the creation of a new kind of economy – information one. Credit organizations after telecommunications companies are on the second place on the information technology usage. The presented article touches upon virtual credit organizations - the contemporary model of organization in banking sector. Classification of virtual banking institutions, in a form of the organization of financial institution is represented. In the paper, the interaction models offered by virtual credit organizations for customers are investigated. The estimation of its advantages and disadvantages in comparison with traditional financial institutions is given. Economic data of virtual credit organizations implementation are analyzed. On its basis, the perspectives for advancement and adoption of virtual credit organizations in crisis in the Russian Federation and in the world are studied.

Keywords: full-fledged global economic crisis, banking sector, virtual credit organizations.

Introduction

The development of world economy happens in difficult conditions. However, from the banking sector, the crisis spread to the industrial sectors of economy and grew into a full-fledged global economic crisis that caused a prolonged recession. At the same time, the current global economic crisis is L-shaped, characterized by a protracted economic recovery and it is hard to predict the exit time from the crisis for sustainable economic development.

In today's environment, when the growth rate of world GDP tends to decrease: it consisted 3,2% in 2014, 3% in 2015, 2,9% in 2016, all sectors of economy have to look for new forms of existence in crisis conditions, defined by a decline in manufacturing department, a decrease in funding and an increase in unemployment. (The free trade crisis; The IMF downgraded the outlook for the global economy due to Brexit; The IMF worsened the forecast of the fall of the Russian economy in 2016; The World Bank reduces the forecast for world economic growth to 2.4 percent in 2016; The world economy faces a new global crisis) The banking sector, which one of the first has got into influence of the global economic crisis, is no exception. Many financial institutions went bankrupt; others had to reduce its branch network and staff. Meanwhile, the measures of financial state support that having been provided to banks in many countries are virtually phased out now, and therefore financial institutions have to seek innovative ways of development in these conditions in order to ensure lower costs for running business.

In such circumstances, more widespread adoption of information and communication technologies for significantly cost cutting can come for aid to the financial sector. In particular, the wider introduction of virtual financial institutions, allows ensuring full interaction of customers with the bank in a virtual environment.

The main sources that reveal the theoretical and methodological aspects of the development of virtual financial institutions are the works of Russian and foreign authors: Alehin, Davidow, Mowshowitz and many others.

In these studies, the prospects for introduction and development of virtual banks are examined. The main forms of interplay with clients are analyzed. The models of the organization of virtual credit

organizations existing for today are explored. The estimation of financial justification for the implementation of these financial institutions is given.

Meantime, this area is completely new and dynamically developing, and therefore many aspects are not considered sufficiently deep or did not have time to get due assessment, despite a large number of studies. (Klochkov, Klochkova, Antipova, Kiyatkina, Vasilieva, Knyazkina, 2016; Kočović, Antić, Jovović, 2011; Ma, 2011; Sivakumar, Krishnaswami, 2011)

Key research findings

In the middle of the last century with development of information technology the foundation of a new type of the economy, which received the name of information was laid.

The next step in the development of the information economy was the introduction of global computer networks that contribute to the creation of a single digital space.

Virtual corporation

Other types of industrial cooperation has developed from the emergence of the World Wide Web. The conception "virtual corporation" were made known by Davidow and Malone in their book "Virtual Corporation", written in 1992. (Davidow and Malone, 1992)

A virtual enterprise is the most advanced and effective form of organization of an enterprise from a number of "mentally possible", the best from the point of view of the available technical and economic conditions. Thus, a virtual corporation can be defined as a dynamic open business system representing a combination of temporarily unified on the principles of cooperation within single information (virtual) space of technological resources of autonomous economic agents capable on the basis of their coordination and operational distribution to make the final product or service.

The main feature of a virtual enterprise is shown available sets of alternative ways of creation of the final product with a possibility of operational management of resources of all independent agents (enterprises) on the basis of modern information technology. The making of a virtual corporation enables enterprises to significantly increase the number of orders and improve the use of production potential, while minimizing the duration of the cycle "demand-production-sales". This is achieved through essential growth in efficiency at response to market changes (changes in the timing and volumes of supplies, price fluctuations, etc.), the optimal allocation of resources, coordination, and shortening the duration of pre- and post-production stages of the product life cycle. (Alasas, Ishkildina, Zvonov, Antipov, Ushanova, Demidenko, 2017; Bataev, 2015)

The virtual bank definition similarly emerged with conception of the virtual enterprise. The creation of the first fully virtual bank was preceded by the introduction of remote customer service systems. In particular, Internet banking (On-line banking, e-banking) - the provision of banking services through electronic channels of information transmission, including the Internet, has become widespread in the world. At the present time Internet banking is an integral part of any banking institution. On-line banking opened new opportunities for the bank's clients: to obtain information on the status of their account and to make certain transactions; now it became possible without visiting the office. And sms-messages help to quickly track every action on the account. Bank customers are less using off-line services and visit bank offices only when absolutely necessary.

In such circumstances, the idea of creating a credit organization, which has only website and registered office is shown up: clients will be able to obtain banking services, monitor their bank accounts and get help online if needed. Everybody wins: a bank saves on creation and development of a regional network, and clients receive faster and more convenient service.

Net-only bank (virtual bank) – a bank that operates exclusively through the Internet, not having actual representative offices, with the exception of the legal address.

Virtual Bank entirely works in the world wide web. There are two categories of such a system: passive and active. The first involves all data on the current account, and the active one enables to remotely manipulate finances.

The occurrence of the first virtual credit organizations

In 1995, the prime virtual bank - "Security 1st Network Bank" started its activity in the U.S.A. Over the first 18 months of its existence, the average capital gains of "Security 1st Network Bank" was 20% per month, assets reached $ 40 million, and the number of client accounts - 10 thousand. At present, it has the lead place among virtual credit organizations in the world. (Bataev, 2015; Burgess and McGrath, 2010; Chorafas and Steinmann, 1995; Mowshowitz, 1994)

In the Western Europe, the prime virtual credit organization began operations in 1996. It was Advance Bank, a subsidiary structure of the Dresden Banking Group.

One of the first virtual banks in Germany was Consors-Bank. From the beginning of the work it specialized only in securities trading and gave preference to such distribution channel of services as the Internet. In addition, such banks as BankDirect (founded in 1999), CoinpuBank (1998), E-bank (1999) and some other can be examples of virtual banks. Corporation "Sony" established its own virtual bank in 2002, trying to oppose itself to traditional banks. The popularity of the new virtual financial enterprise was beyond comparison. Only for the first hour the page was visited by 13 570 people, 340 of them started their own account at the bank and during the first month of the Internet bank opened 21 thousand accounts. (Burgess and McGrath, 2010; Stewart, 2008)

Currently some reasons take place not to allow a wide distribution of the virtual credit institutions. Primarily, classical credit organizations are actively promoting Internet banking, which performs almost the majority of functions provided by banks. In addition, clients have psychological reasons not to believe financial organizations without physical offices.

Nevertheless, it should be noted that in the global financial crisis, such a form, the provision of financial services, as a virtual bank, has every chance of development. Primarily, this is due to a significant decrease in costs for the maintenance of the bank's branch network, which takes a large share of the costs of any financial institution.

Classification of virtual credit organizations by type of its formations

Today there exists a few sorts of banks that fit the conception of a virtual bank with some allowances. In the first place, it can be called typical virtual financial institutions as defined previously: banks that completely carry out its activities via the World Wide Web, with no offices and representations. In the modern world such banks is several hundred, its development is not widely adopted enough yet (Figure 1). (Demirer, 2016; Farah, 2011; Gloukhov, Ilin, Koposov, Levina, 2014; Klochkov, Gazizulina, Ostapenko, Eskina, Vlasova, 2016) There exists simple instance of such financial institutions - "Security 1st Network Bank", which has established in the end of 1995 in Pineville, Kentucky.

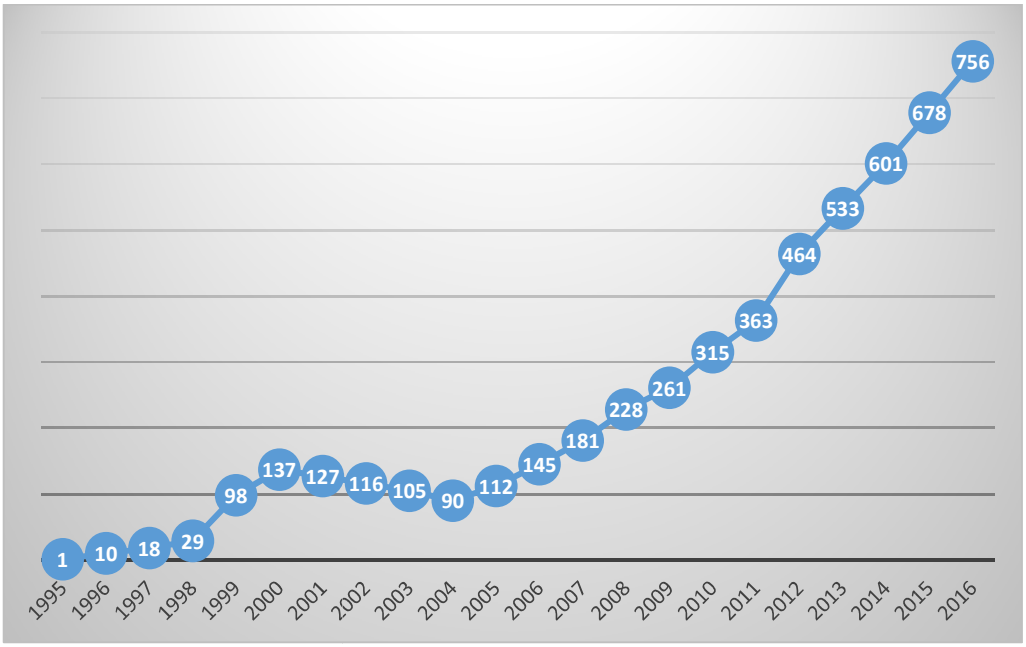

Fig 1: Changing in quantity of typical virtual financial institutions in the globe (units)

Source: compiled by the author

Secondly, it can be told virtual credit organizations formed by traditional banking institutions. Its fundamental difference lies in the fact that, having all the attributes of a virtual credit organization, they are not an independent banking institution. Clients of such banks can obtain all the necessary information in the real office of the credit institution that created the virtual bank. In Russia "Instabank" whose partner bank is the Military Industrial Bank is an instance of virtual banks.

In 2016, according to various estimates, there were 6890 virtual credit organizations of all forms of creation around the world (Figure 2).

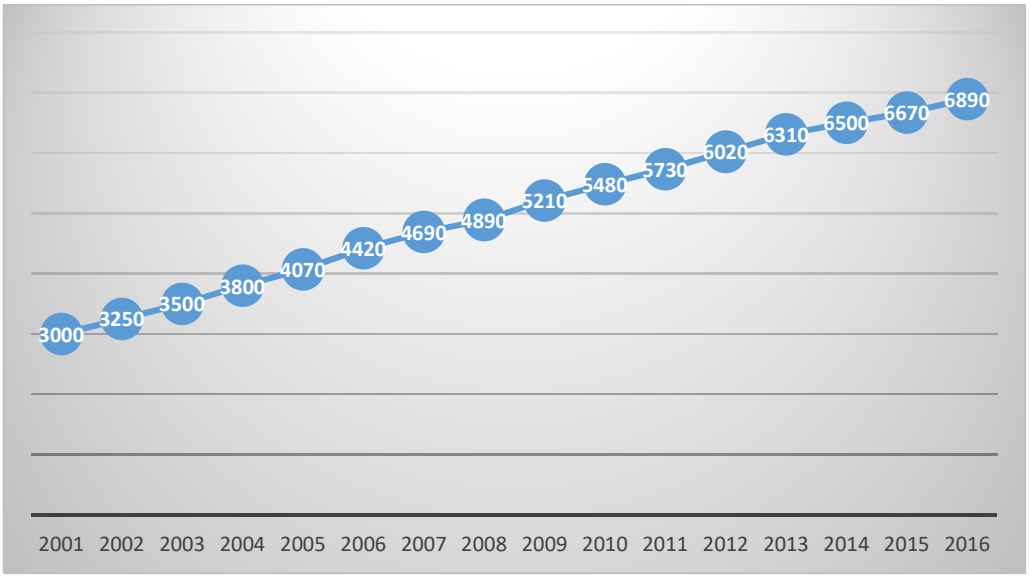

Fig 2: Changing in quantity of all virtual credit organizations in the globe (units)
Source: compiled by the author

Appraisal of the dynamics of the advancement of American virtual credit organizations

At present, the largest number of virtual financial institutions are in the United States, which are founders in this area. Now more than two hundred virtual banks carries out its activity in the U.S.A. (Figure 3) (Glukhov, Balashova, 2015; Klochkov, Odinokov, Klochkova, Ostapenko, Volgina, 2016; Li, Vierheilig, Helms, Bayrak, Vogel-Heuser, Shea, 2011; Virtual Bank: real money).

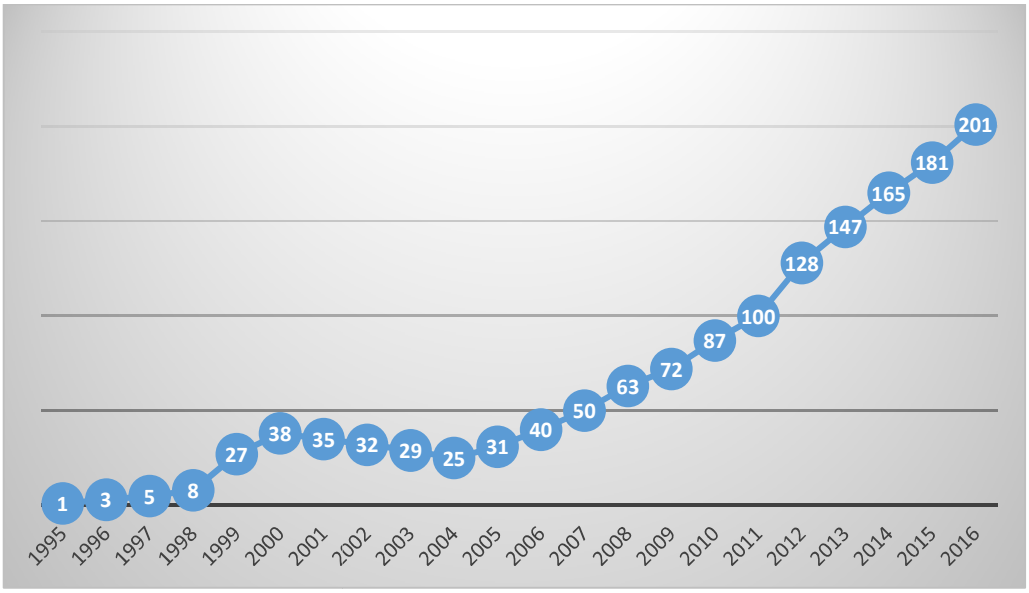

Fig 3. Changing in the number of virtual credit organizations in the United States (units)
Source: compiled by the author

In the United States, virtual financial institutions were progressing from 1996 to 2000: nearly 40 such banks was established at that time. Opposite in 2002-2005 there observed a decrease in the number of virtual banks with the advancement of Internet banking systems. However, since 2006 a steady rise of quantity of the virtual banks with average annual gain in 20% is watched.

Quite a large financial results were shown by American banks from 2004 to 2016: its profit grew by more than eight times (Figure 4). (Klochkov, Klochkova, Volgina, Dementiev, 2016; Virtual Bank: real money).

Ways of interplay of clients with virtual credit organizations

The role of network banks began to increase in the period of the global economic crisis. Due to an increase of a role of network banks, various models of interplay of clients with virtual financial organizations were offered.

There exists different models of interplay of clients with virtual banks, depending on their segment. (Alehin, 2013; Goo, Kishore, Rao, Nam, 2009; Klochkov, Gazizulina, Golovin, 2016) Consider the standard model in Table 1.

Table 1: Forms of interplay between clients and network banks by sections

Section	Mass	Upper Mass	Privileged
Videoconsulting	Call Center workers	A worker of the specialized line in call center (CC)	Personal account manager
Help Services	Maintenance service inquiries	Maintenance service inquiries	Maintenance service inquiries
Dissatisfactions and pretensions	Solvable online complaints and claims	Solvable online complaints and claims	Solvable online complaints and claims
Sales	On-line registration of applications for banking products (credit and debit cards, loans, mortgages)	On-line registration of applications for banking products (credit and debit cards, loans, mortgages) On-line advisory on financial management	On-line registration of applications for banking products (credit and debit cards, loans, mortgages) On-line performing complicate operations without visiting the bank Online advisory on financial management and complicated products Online service: concierge service, competent parties
Contact point	Smartphone, tablet, BIG PAD, Automatic Teller Machine, call from a site	Smartphone, tablet, BIG PAD, Automatic Teller Machine, call from a site	Smartphone, tablet, BIG PAD, Automatic Teller Machine, call from a site, Bank on TV

Source: Alehin, 2013

The principal benefits of these models for banks are:
- the favorable circumstances to supply services of superior quality from any access point to the bank;
- shortening queues;
- achieving the highest effectiveness of costs: personnel management, hiring of skilled employees, lease of premises and so on.
- expenditure cutting for traffic payment;
- providing mobility (terminals can be moved, it is possible to definite a maximum suitable locations of sales outlets);
- rising up customer loyalty;
- promoting increase in a number of clients and growth of sales;
- forming the Bank's image – innovative, cares about improving the quality of service

From the client side:
- 24-hour assistance and counseling is available anywhere in the world;
- provides effective planning of working time: no necessity to stand in lines to search for the right people, to dial, many times to fill out documents, etc;
- network banks' presence in molls, at the enterprises, on transport, etc;

- the ability to apply to an advisory service of bank experts;
- files a complaint without having to visit the office;
- enables to study bank documents.

Estimation of the possibilities of introducing virtual credit institutions in the Russian banking sector
The Russia's financial system has fairly big prospects to move virtual banks forward. The Russian banking sector on that are imposed Western sanctions have to find new ways of development under the global economic crisis. Lowering expenditures is the important aim for the Russian Federation's banks. In this regard, the Russian Federation's banking institutions raises the need for transition to virtual banks.

The advancement of virtual banks has been happening last five years in Russia. The first network bank appeared in the Russian banking system in the end of 2010. This bank was Tinkoff Credit Systems (TCS). Currently there exists more than 30 virtual credit organizations in Russia (Figure 5). (Klochkov, Gazizulina, Golovin, 2016).

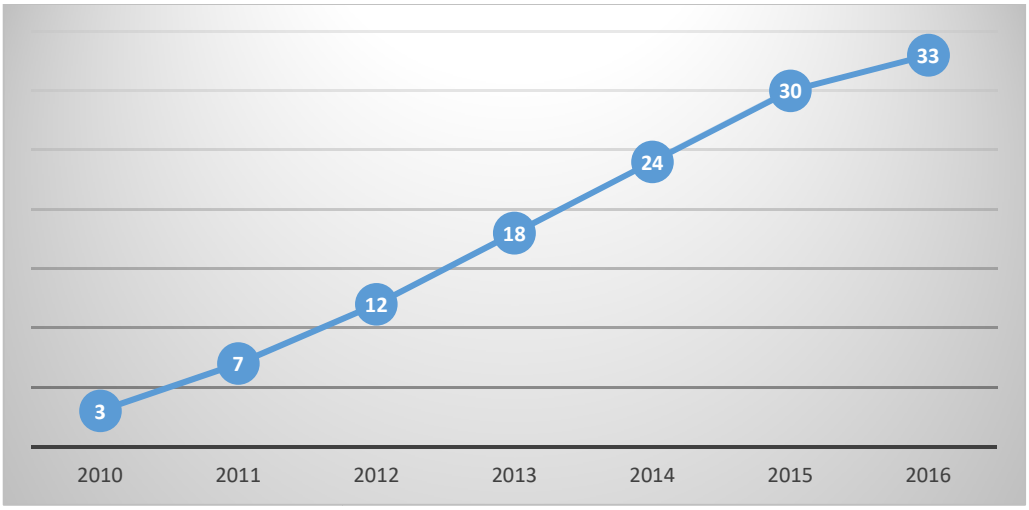

Fig 5: The amount of the Russian network banks (units)
Source: compiled by the author

The average annual growth of Russian network banks is 56 percent (Figure 6), which is much higher than the world growth rate of typical virtual banks (12.9 percent), and the pace of growth of all virtual credit organizations that make up 5.7 percent per year (Figure 7). Such advancing rate of gain is caused by the establishment of the market of Russian network financial institutions, for which even opening of one virtual credit organization considerably rises dynamics of growth. Presently 3 typical network banks 2T Bank, Bank24.ru and TCS carry out activities in Russia. All other network banks operate under the jurisdiction of traditional financial institutions. (Russian network banks)

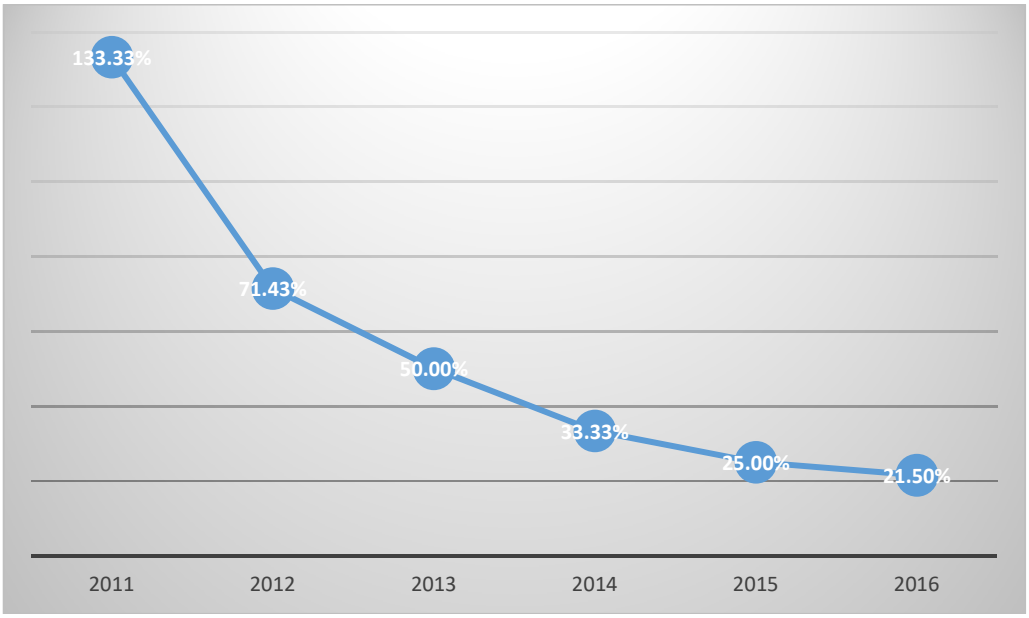

Fig 6: Growth rate of the quantity of the Russian Federation's virtual banks, percent
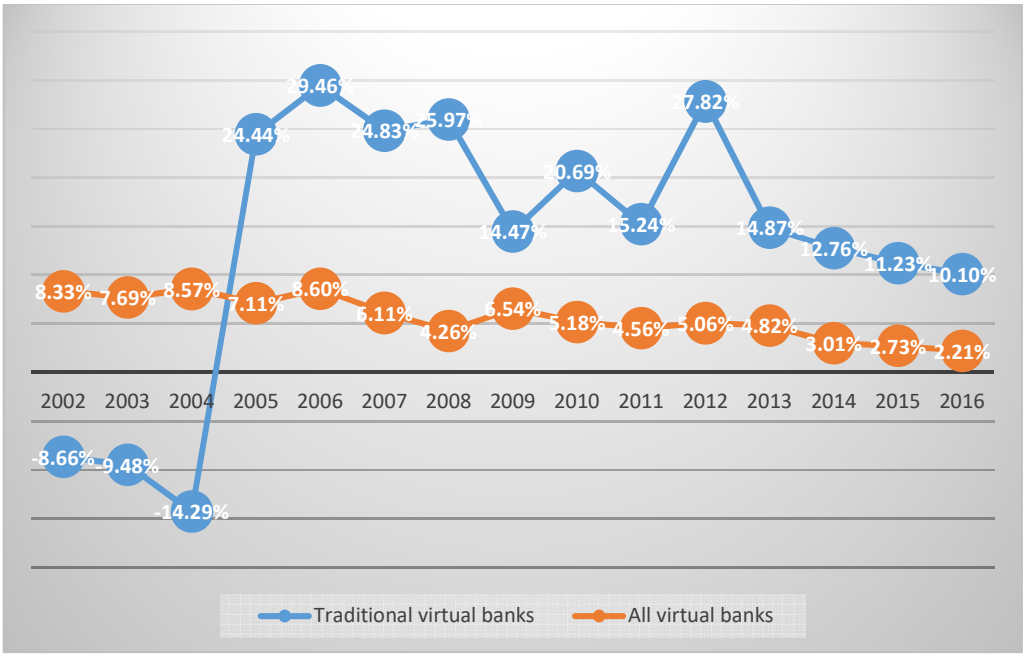
Source: compiled by the author



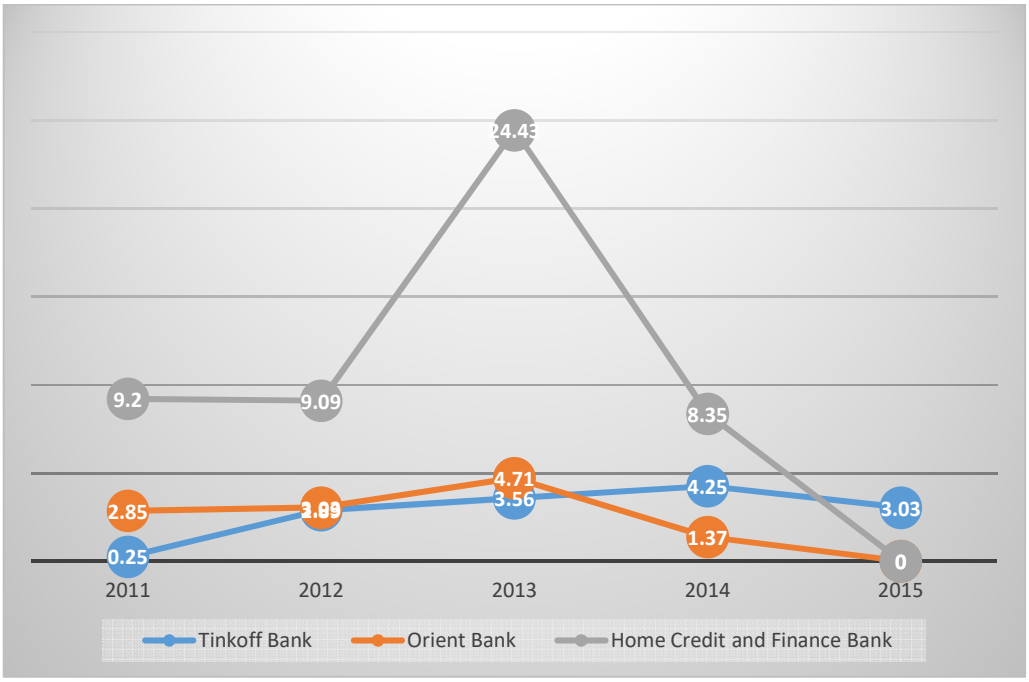


Fig 7: Rate of gain of the quantity of typical network banks and network banking organizations in the globe, percent
Source: compiled by the author

The most promising network bank in Russia has become TCS, which for 6 years of its development reached essential financial outcomes. It takes 62nd place in the Bank's ranking by benefits, 47th on

the loan book, 52nd on the household deposits. TCS occupies 2.7% of the total Russian market in terms of retail deposits, while loans - 1.7%.

When comparing the network bank TCS with traditional financial institutions in the segment of consumer lending, it can be noted that it has achieved substantial profits in crisis conditions and the regime of Western sanctions (Figure 8). (Information of financial institutions)

Source: compiled by the author

Fig 8: The income of financial institutions carrying out its activities in lending to individuals, billion rubles

TCS gained 3.03 billion rubles in 2015, profit of other banks constituted zero. Accordingly, we can say that the traditional financial institutions could not show sufficient flexibility to overcome the crisis.

Conclusions

The following findings can be drawn from the study:

- Over the past decade, the number of network credit organizations in the world has gone up more than 6 times;
- Classical banks establish its virtual financial institutions with great force that enable to significantly extend the horizons of providing banking services;
- The amount of typical network banks rose 4.2 times during the last ten years, indicating the demand for this financial institution in crisis conditions;
- The quantity of all credit organizations in the globe went up more than 2.15 times over the past fifteen years;
- The growing role of network credit organizations in the banking sphere leads to the necessity of developing various models of interaction with customers of virtual banks, especially providing an individual approach to each client;
- The possibility of cutting financial costs enables the network bank model to remain operational in crisis economic environments. Thanks to its flexibility, impressive financial

performance can be attained. For example, the TCS network bank made a profit of 3.03 billion rubles, when competitors from the same banking segment had not come out on positive figures.

Questions of Safety of Mobile Banking In Russian Financial Institutions

Alexey V. Bataev, Associate professor of Peter the Great St. Petersburg Polytechnic University, St. Petersburg, Russian Federation, bat_a68@mail.ru

Abstract

The development and realization of information technology contributed to the formation of a new type of economy – informational one. New channels of interaction between clients and organizations were caused the introduction and expansion of information and communication technologies; such as Internet banking and mobile banking have appeared in the bank sphere. The development of appropriate hardware and software in the field of mobile communications has led to a sharp increase in clients in the sphere of mobile banking. This paper discusses the basic tendencies of advancement of remote banking in the Russian Federation's financial institutions. The assessment of criteria on the basis of which mobile banking applications are programed is carried out, the hierarchy of criteria to which mobile applications have to satisfy is created. The analysis of the existing mobile banking applications in the Russian financial institutions is conducted. The most common operating systems for mobile applications are considered. The research results of volumes of thievery through mobile banking applications are given. The main forms of hacking of mobile banking applications are considered. Based on the carried-out analysis, a conclusion was drawn about the necessity of revision the concept of designing mobile banking applications in the direction of providing greater security.

Keywords: information technology management, credit organizations, mobile banking, the amount of stolen funds, safety

Introduction

The twenty-first century was marked by the rapid growth of information and communication technologies, which have firmly entered in all spheres of economy. Development of computer networks and the Internet promoted the emergence of new forms of interplay between various subjects of economic interaction.

Banking institutes are one of the most active consumers of information technology, taking the second place on investments in this sphere after the telecommunication companies.

The use of information and communication technologies in the banking sector resulted in the creation of innovative channels for interaction between clients and financial organizations: Internet banking and mobile banking.

The development of mobile banking has greatly expanded the possibilities of remote banking services for customers, allowing secure an access from virtually anywhere in the world.

In recent years, the development of hardware and software in the field of mobile communication has made possible to move from mobile banking applications, which have the ability to view the balance of accounts, to full-fledged banking applications that support enough wide range of banking operations through mobile banking.

Despite the widespread adoption of mobile banking services and expanding the range of banking operations, the developers of modern mobile banking applications primarily pay attention to the convenience of the interface for customers, to increase in high-speed performance and less to safety, which causes the growth in the amount of stolen money from customers who use mobile applications.

(Bataev, 2015; Dewan S.M., Low G., Land L., Dewan A.M., 2009; Shaikh A. A., Hanafizadeh P. and Karjaluoto H., 2017)

The main sources that reveal the theoretical and methodological aspects of the development of mobile banking are the works of foreign and Russian authors: Barnes, Dewan, Donner and many others.

In these studies the prospects for the introduction and development of mobile banking are examined, the main forms of interaction with customers are analyzed. The architecture of mobile banking systems existing today is viewed and investigated. An evaluation of financial justification for implementation of mobile banking applications is made. (Bataev, 2015; Klochkov, Gazizulina, 2016; Klochkov, Klochkova, Antipova, Kiyatkina, Vasilieva, Knyazkina 2016)

At the same time, this direction is completely new and dynamically developing and therefore many aspects are not considered rather deeply or have not managed to receive a due assessment, despite a large number of researches.

The Research Objective and Methodology

The research objective is mobile applications used in the banking sector. A comprehensive study of the perspectives for the implementation and development of mobile banking applications is conducted. The analysis of existing on the market mobile banking applications on the parameters: operating systems, the convenience of the interface, speed and security is carried out. According to the conducted research, priority directions in the development of mobile applications for financial institutions are offered.

Key Research Findings

The advancement of information technology, which began in the second half of the 20th century, resulted in the creation of a new kind of economy – informational one. In the 21st century the computer networks growth enabled users to carry out any operation, without leaving home.

The information and communication technologies has introduced in all sectors of economy, particularly, the implementation of computer technology is quickly occurring in the banking sector. Credit organizations after IT companies take the second place on realization of information technology.

In recent years, owing to the advancement of computer technology in the world and Russia new forms of remote customer service using mobile banking applications have begun to develop, such form of servicing received the name – Mobile Banking.

Mobile banking is management of the bank account by means of the tablet computer (iPad, HTC Flyer, Samsung Galaxy Tab and so on), the smartphone or cell phones. Generally, for this purpose it is necessary to load a special application on the mobile devices.

According to estimates of various experts, the number mobile banking users constituted more than 25 million people in Russia in 2015, and in concordance with prognosis the number of users can exceed 89 million people by the year 2020 (Figure 1). (Bataev, 2015; Nikolova, Kuporov, Rodionov, 2015; Klochkov, Odinokov, Klochkova, Ostapenko, Volgina, 2016)

According to estimates of J'son & Partners Consulting, turnover of payments with usage of mobile banking totaled 15, 2 billion rubles in 2014, and it rose by 30% and reached 19, 8 billion rubles in 2015. The volume of payments through mobile banking is expected to be more than 41 billion rubles by 2018, while the average annual growth rate from 2016 to 2018 is 28% (Figure 2). (Klochkov, Klochkova, Volgina, Dementiev, 2016; Nikolova, Rodionov, Afanasyeva, 2017; Shaikh, Hanafizadeh and Karjaluoto, 2017)

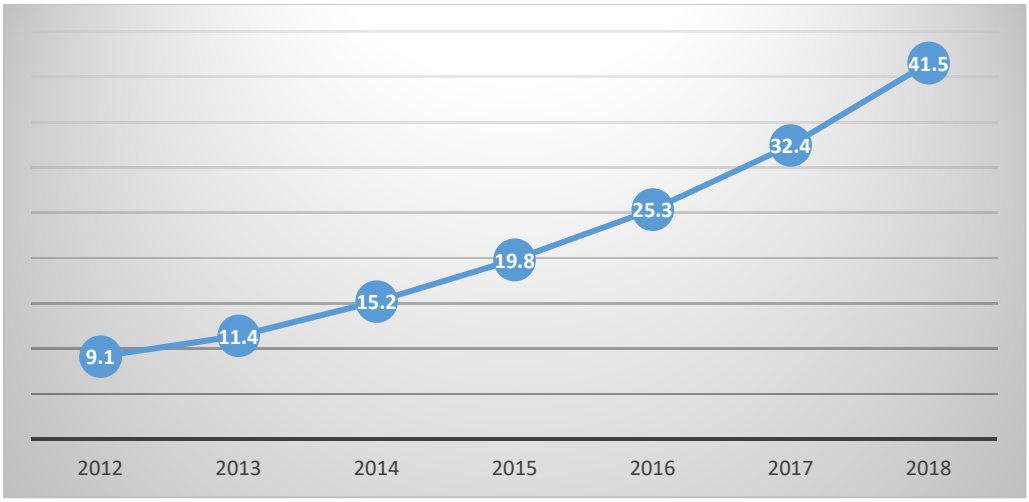

Fig 2: Changing of the volume of payments through mobile banking, billion rubles

Today more than 54% of Russian banks offer mobile banking services. A large share of customers using mobile banking applications has PJSC «Sberbank» - 48%. It is told about the huge client base and considerable financial investments in advanced information products. PJSC Svyaznoy bank occupies the next place - 37% of all client base, the share of other banks together accounts for about 15% (Figure 3). The share of customers using mobile banking applications hesitates from 10% to

20% for most Russian financial institutions. (Gloukhov, Ilin, Koposov, Levina, 2014; Klochkov, Gazizulina, Golovin, 2016)

The analytical agency J'son & Partners Consulting carried out the comparative analysis of mobile banking applications of thirty financial institutions having the most developed mobile banking. The study according to forty parameters, such as: functionality, interaction experience, the design and evaluation of applications stores and others was conducted (Table 1). (Bataev, 2015; Klochkov, Gazizulina, Ostapenko, Eskina, Vlasova, 2016; Nikolova, Rodionov, Bahauovna, 2016)

Table 1: The highest rank of mobile banking applications

№	Application	Credit Organization	Rating, %
1	Tinkoff	Tinkoff Bank	92%
2	Roketbank	Roketbank	87%
3	Instabank	Instabank	85%
4	Online Sberbank	Sberbank	74%
5	BSPB Mobile	Bank «Saint-Petersburg»	74%
6	Home Credit	Home Credit Bank	73%
7	MTS Bank	MTS Bank	72%
8	MInB	Moscow Industrial Bank	71%
9	UBRaD Mobile banking	Ural Bank for Reconstruction and Development	70%
10	Qbank	Svyaznoy Bank	67%
11	Layf-Mobile	Layf (Probusinessbank)	66%
12	Otkritie Bank	FC Otkritie	66%
13	Alpha-Bank5	Alpha-Bank	64%
14	PSB-Mobile	Promsvyazbank	63%
15	ROSBANK Online	ROSBANK	62%
16	OTPdirekt	OTP Bank	61%
17	R-Mobile	Raiffeisenbank	59%
18	MCB Mobile	Credit Bank of Moscow	56%

19	Mobile bank VTB24	VTB24	53%
20	Mobile.UniCredit	UniCredit Bank	51%
21	Avangard Bank	Avangard	50%
22	Mobile bank URALSIB	Uralsib	49%
23	SKB-Bank	SKB-Bank	47%
24	Mobile bank Russian Standart	Russian Standart	43%
25	Vozrozhdenie Bank	Vozrozhdenie Bank	43%
26	Telecard	Gazprombank Group	36%
27	Handybank	Renaissance Credit (HandyBank)	36%
28	Citibank RU	Citibank	34%
29	Orient Mobile	Orient Bank	26%
30	Mobile bank Russian Agricultural Bank	Russian Agricultural Bank	25%

As we can see in Table 1, just mobile application Sberbank entered the top five applications, while mobile banking system from Svyaznoy Bank takes only the 10th place.

The range of operations for clients using mobile banking application is wide enough, but the operations of accounts overview are on the first place (Figure 4). (Barnes and Corbitt, 2003; Dewan, Low, Land, Dewan, 2009; Donner and Tellez, 2008; Klochkov, Its, Vasilieva, 2016)

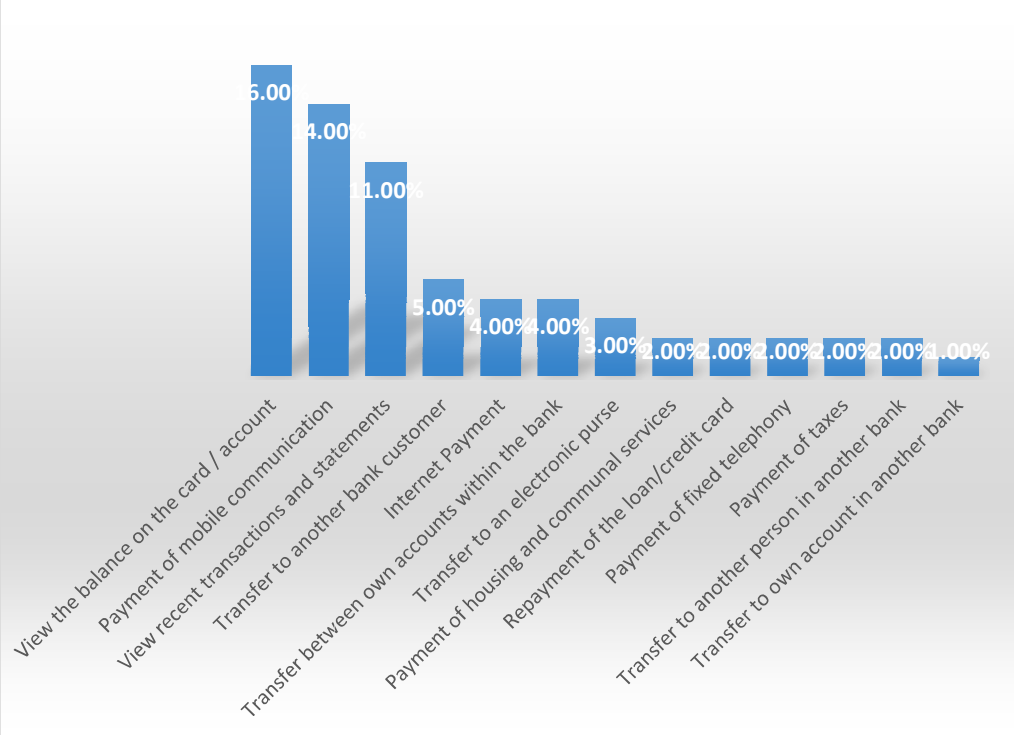

Fig. 4: Allocation of operations employing mobile banking, percent

Android and iPhone apps, which seize 25% of the market, hold the leading position to implement mobile banking in the Russian banking institutions (Figure 5). (Chen and Wu, 2011; Cristea, Zugravu, Moga, Cristea, Maftei, Oprea, 2011; Klochkov, Klochkova, Vasilieva, 2016)

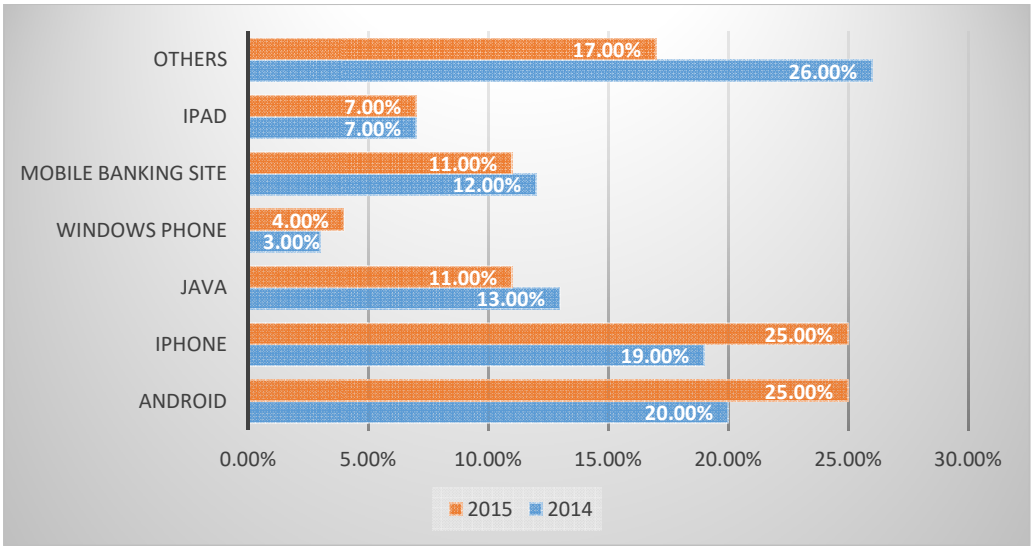

Fig 5: High-priority software applications for the implementation of mobile banking

Source: compiled by the author

The next main directions is possible to define for mobile gadgets: primarily – an ease to use application, secondly - the speed, and on the third place - safety of the used applications under designing of banking applications.

None of the applications you use does not give 100% protection of data from electronic thievery. The range of vulnerability makes from 14% to 25% depending on the used software application. Recently more attention begins to be paid to security issues and according to experts' estimates; it can come out on top on the importance. (Bataev, 2015; Dass, Muttukrishnan, 2011; De Mello Benzi, De Sousa Júnior, Bidan, Mé, 2008; Siriram, 2011)

Kinds of mobile banking brittleness

Today the attacks through mobile banking divided into three types. (Dass, Muttukrishnan, 2011; Yang, 2009; Zhou, 2012)

Physical access to the client's gadgets

A criminal can get admission to the file system having a physically access to the client's gadgets. If the application stores the identification data or other sensitive data in clear text, or data "flow away" in the clear, it is easy for an attacker to obtain this information and steal money.

Threat when a person is between the server and the gadget

This attack is directly to communication link: during the classical attack, data between the device of the client and the server are intercepted. For this purpose, one has to be in the same network with the victim, for example in public Wi-Fi network, or use a fake wireless access points. Brittleness in a mobile application, incorrect work with enciphering of transmitted data or total absence of data

enciphering is necessary for the attack's realization. As a consequence, the cybercriminal can obtain and replace the transmitted data that leads to thievery of money from the customer account in the end.

Download a malicious program to the client's gadget in various ways

An attacker can lift their privileges in the system after the installation of malicious applications on the gadget and get remote access with full access rights. It resulted in an entire compromise of the gadget: a criminal is able to steal sensitive data of mobile banking user or substitute data of payment transactions. (Dass, Muttukrishnan, 2011; Laukkanen, 2016)

There exists own ways of protection for every kind of attacks. Thus, for protection against directly physical access to the gadget it is necessary to use cryptographic opportunities of the gadget, encrypt data and if it is needed remotely reset data, and exercise constant control of security of the application that will help to reveal possible brittleness.

Threat when a person is between the server and the gadget requires proper realization of the work with the SSL cryptographic protocol that provides secure data transfer. It is also recommended confide only SSL-certificate of the bank in a mobile application in case of connection to the server.

To protect against malicious applications it is necessary to update permanently the software on the gadget, to use security software and that is important to increase user awareness of information security issues.

Therefore, the security of mobile banking application is a whole range of measures, beginning with the architecture of the application, development, taking all possible brittleness into consideration, and also continuous control of its work and regular updating and modification. (Liu, Min, Ji, 2009; Ravendran, MacColl, Docherty, 2011; Saeed, 2011).

In spite of the constant improvement in both hardware and software components of mobile banking, the volume of theft through mobile banking applications only increase.

For 2014, owners of mobile banking have been attacked by cybercriminals 942 thousand times (Figure 6). If we consider that about 15 thousand rubles is stolen on average for one time through the mobile application, the damage amounted more than 14, 13 billion rubles a year (Figure 7). (Nikolova, Kuporov, Rodionov, 2015)

In 2015, according to different forecasts, the volume of electronic thievery through mobile banking exceeded 21 billion rubles (Figure 7). The changing of electronic thievery was 1.5 times less in comparison with the period 2013/2014 year. It is a good tendency, caused by coming out to the first place to aspect of the security of mobile banking applications.

Conclusions

In the final, the next findings are drawn:

- the advancement of mobile banking in Russia goes rapidly, the quantity of clients using mobile banking applications is supposed to exceed 89 million people by 2020, and the amount of payments using mobile banking would exceed 41 billion rubles by 2018;

- today the convenience of application takes the first place, the speed is on the second one and the safety of mobile banking - only on the third one under designing of mobile banking applications;
- the volume of the stolen means through mobile banking applications increased by 6,72 times from 2012 to 2015 and amounted to 21,36 billion rubles;

- the volume of thievery through the channels of mobile banking was more than 21,36 billion rubles in 2015, the conducted research in the field of stolen funds shows that designers of mobile banking applications have to put the safety on the first place in the near future.

Abstract

Purpose: The goal is to study the activities for managing the quality of logistics processes in the context of universal responsibility for quality, taking into account the content of logistics processes and the components of the logistics system of an enterprise, as well as the principles, functions and methods of implementing the activities for quality management of logistics processes.
Design/methodology/approach: In compliance with the concept of processual approach, which determines the need for managing the chains of interrelated processes, the paper formulates the main provisions for quality management of logistics processes and specifies the concept of logistics process quality, the provision of which permits the creation and maintenance of conditions for organization of industrial processes. **Findings:** The need for developing the methods and tools of functioning determines the formation of the mechanism of logistics process quality management as a component of the quality management system, including: 1) the procedures and processes of monitoring the conditions of the industrial environment, diagnostics of current parameters of logistic processes and preventing the causes of deviations; 2) the identification of reciprocal responsibility for the quality of logistics and industrial processes between all workers of an enterprise. **Originality/value:** The developed algorithm of the quality management of logistics processes makes it possible to streamline the implementation of logistic activities by setting a clear sequence of management actions in consideration of production stages, which implies the need for constant enhancement of logistics processes and improvement of their quality.

Keywords*:* quality of processes, quality management of logistics processes, principles of quality management, methodology of the TQM system, functions of quality management of logistics processes

1. Introduction

The currently implemented system of quality management is characterized by continuous development and improvement of processes, in consideration of rationality of design and techno-logical solutions, the components of industrial capacity of enterprises.

Therefore, the identification of relationships within the industrial system and between the processes must be carried out without time loss, which allows for timely detection and elimination of possible deviations in timelines of implementing the production processes, interrelated with those of logistics. Any recurring deviation may be interpreted as a malfunction in the management system, which leads to deterioration in the quality of all processes [2, 4].

The purpose of the present theoretical study is to disclose the essence of managing the quality of logistics processes, with account of methodology of the TQM system. The subject of the study includes the principles, functions, processes and conditions of implementing the activities for managing logistics processes.

2. Theory

In accordance with recommendations of the contemporary international organization of quality management, the basic principle of the system is the process approach, the application of which stipulates the necessity for categorization of processes into three groups, namely, primary, supporting and management processes [6, 12].

The processes of logistics, focused at creating conditions for the flow of primary processes, must be regarded as supporting ones. In accordance with the concept of the process approach, all processes, occurring at an enterprise are interlinked in inputs and outputs, therefore, the quality of industrial (primary) processes directly depends on the quality of logistic (procurement) processes.

The given assumption makes it necessary to clarify the essence and content of the quality of logistics processes and quality management. In a narrow sense, the quality of logistics processes must be viewed as an aggregate indicator, characterizing the degree of correspondence between the logistics process parameters and those of industrial processes, which impacts their regularity and proportionality. In a broad sense, the quality of logistics processes characterizes the ability of the process to timely provide the industrial processes with necessary resources and ensure their quality during storage and allocation to different stages of product lifecycle [10, 11]. Consequently, the quality of logistics processes may be viewed as conditions for implementing industrial processes at an enterprise. In this case, the activities related to quality management of logistics processes are a subsystem of the process quality management system at an enterprise [5].

In our opinion, the quality management of a logistics process should be viewed as a set of organizational and technological procedures, directed at creation and maintenance of conditions for implementing the production processes, in consideration of the parameters of production environment (both internal and external), which, in their turn, determine the quality of production processes.

The main procedures for managing the quality of logistics processes are: the identification of processes, the testing of current parameters and continuous monitoring of causes of logistics process deviations, affecting the stability and regularity of industrial processes [3, 7].

The process quality management in a logistic system must be implemented, taking the following principles into account:

- the identification of the subsystem of logistics process quality assurance in the management system;
- the application of the process approach to formation of logistics process chains;
- ensuring the quality of the final result of each process in relationship with the requirements for the quality of the outcome of the logistics process chain, and in accordance with the requirements for the quality of serviced industrial processes;
- the continuous monitoring of industrial conditions, focused at timely introduction of relevant changes in logistics processes, and continuous improvement in current parameters of certain processes and the overall quality of logistics process chains;
- ensuring the sustainability and stability of logistics processes, as well as the reliability of logistics process chains;
- the formation of the infrastructure for implementing the logistics activities with account of the requirements for the quality of interrelated logistics processes;
- ensuring the involvement of all stakeholders of logistics processes and the coordination of their actions by cross-functional (integrated) management of logistics process chains;
- managing the quality of logistics processes and the attainment of the goal of logistics activity, on condition of minimizing the costs and resources used.

3. Quality Management of Logistics Processes

The research undertaken made it possible to disclose the content of the activities related to quality management of logistics processes (table 1).

Table 1: The Content Of Quality Management Of Logistics Processes

Components of the logistic system	Content of logistics processes	Content of quality management of logistics processes
Customer servicing	Classification of customers; standartization of work and the analysis of requirements for the quality of supplies; setting standards of service and warranty maintenance of customers;	The development of the customer servicing system, the analysis of requirements for the quality of service and warranty maintenance, the identification of customers' responsibility for quality, setting the criteria of the customer servicing quality
Procurement logistics	The formalization of procedures for procurement and supply management, the evaluation and selection of suppliers, the analysis of delivery contract implementation.	The standartization of work with suppliers, the elaboration of the mechanism for managing the procurement quality, setting the criteria of supply quality assessment, identification of responsibility for the quality of supply.
Warehousing logistics	Setting the requirements for conditions of product storage, the formalization of business processes in a warehouse, the formation of the order size and packaging, the forecasting in stock management.	The development of the stockpiling management system, the analysis of implementing the requirements for stockpiling conditions; the monitoring and evaluation of input and output quality, the claim work with suppliers.
Transport logistics	The elaboration of the procedure of distributing semi-finished and finished products; the creation of the system of transport process management; the optimization of transport plan implementation	The standartization of transport operations, the identification of responsibility for the quality of cargo during transportation, encouraging the responsibility of transport workers for preservation of cargo quality, improving the quality of transport means.
Industrial logistics	The elaboration of the procedure of submitting the application from the planning department, the coordination of sales, production and procurement plans, the development of the technology for recycling and sales of production waste	The analysis of sales, production and procurement plans, process losses and product quality, the monitoring of the causes of process deviations and quality flaws; the standartization of procedures for managing the logistics processes and the identification of responsibility for the quality
Distribution logistics	The establishment of relationships with sellers, software sup-	The identification of responsibility for the quality of fin-

	port of marketing process organization, the analysis of product demand, the selection of channels for product distribution, drafting schedules of product shipment	ished product supply, the analysis of customer's satisfaction with the quality of supply, the development of the system of staff motivation, the analysis of risks for customer groups, associated with quality flaws
Overall management	The development of the system for managing the logistics processes, the formation of the integral information system, the development of key professional competencies for logistics service workers, the organization of cross-cutting coordination of logistics departments, the development of the system of staff motivation	The identification of responsibility for the quality of processes and plotting the matrix of responsibility for logistics service workers, the SWOT-analysis of factors ensuring the quality of logistics processes, the standartization of workflow, the elaboration of the mechanism of process quality management in the logistics system of an enterprise.

In view of the above-mentioned provisions, the algorithm of managing the quality of logistics processes includes the following steps:

1 Setting the requirements for the quality of logistics processes, the identification of evaluation criteria and drafting the quality assurance programme.

2 The identification of the initial information on current parameters of logistics process quality, taking account of the requirements for the quality of industrial processes.

3 The continuous monitoring and statistical analysis of logistics processes and conditions of the production environment with the purpose of timely detection of causes of logistics process deviations.

4 The development of corrective and preventive measures for eliminating the identified causes of deviations in logistics processes and reducing the risk of loss in the event of their reappearance.

5 The establishment of continuous communication between the agents of logistics process chains to organize the team activity focused at quality improvement.

The proposed approach to quality management assumes the necessity for constant improvement of logistics processes on the basis of monitoring the conditions of the production environment, testing current parameters of logistics processes, preventing the causes of deviations (instead of quality control), and identifying the mutual responsibility for the quality of logistics and industrial processes, shared by all enterprise workers.

4. The mechanism of managing the quality of logistics processes

The table 2 presents the results of investigating the possibility of applying the modern principles of the TQM system for disclosing the content of functions of logistics process quality management.

Table 2: The content of functions of logistics process quality management in the context of TQM methodology

Name of the principle	Content of principles [3]	Functions of logistics process quality management
1 Client (customer, buyer) orientation (focusing)	Quality management is focused at implementation of customer requirements and the desire to surpass their expectations.	The development of logistics processes, associated with customers' assessment of supply quality with the purpose of timely identification of the possibility of satisfying customer requirements.
2 Leadership (responsibility of management)	Leaders at all organizational levels ensure the unity of goal and the trends of organization activities, creating conditions for interaction of employees to achieve the goals of an organization in terms of quality	Setting the goals of logistics activity and the analysis of their attainment by managers must be carried out on the regular basis. The plans for product (service) quality are part of the enterprise development strategy assurance
3 The interaction between all employees of an enterprise	It is extremely important for an enterprise that all employees must be competent, empowered and involved in creating wealth.	The employees must possess the knowledge of teamwork methods, which ensures the synergistic effect in selecting and implementing the solutions for improving the logistics processes
4 Process approach	The consistent and predictable results are achieved in a more effective and efficient way, when the activity is perceived and managed as interrelated processes, functioning as a coherent system	The creation of process chains makes it possible to identify the interaction between the production and logistics processes, which determines the control over the use of each type of resource and reduces the production costs
5 Improvement	The improvement is necessary for preserving and maintaining the level of process quality, as well as for timely reaction to changes in internal and external conditions of process implementation.	The improvement of logistics processes must be carried out with the involvement of administration, responsible for providing all resources, necessary for attaining the goals set
6 Relationship management	To achieve sustainable success, enterprises manage their relationships with relevant stakeholders, such are suppliers.	The management of relationships with suppliers determines the bilateral relations and permits to optimize their impact upon the results of logistics activities.
7 Evidence-based decision-making	The decisions, based upon data analysis and assessment are more likely to produce the desirable results.	The analysis of proposals, aimed at improvement of quality, productivity and cost reduction, must be carried out by united teams including the industrial and logistic service workers

8 The establishment of mutually beneficial relationships between stake-holders	The establishment of documented procedures, compulsory for a supplier at all stages of relationship with a customer	Determines the necessity for establishment and permanent analysis of feedback from suppliers and consumers of communication, which promotes the enhancement of logistics process quality

Let us consider the content of the main functions of logistics process quality management in the context of the overall quality management system. The key function is the support of activities, aimed at reducing risks of quality flaws when identifying the logistics process deviations, and the achievement of sustainable success through the development of corporate culture and social responsibility of an enterprise. The implementation of this function contributes to the progress of risk-oriented thinking in elaboration and implementation of management decisions [8].

The next function is to standardize the activity of logistics process quality management through the development and ensuring the functioning of the relevant mechanism, governing the procedures, methods and processes of logistics quality management. This function provides the implementation of the principle of systematic approach to quality management.

Equally important functions are the establishment and maintenance of mutually beneficial relations in an informal group (quality assurance team), as well as overall management, regarded as a structured process of establishing the interaction between the board and the staff, involved in logistics activities of an enterprise. The implementation of functions mentioned is in line with the content of the principle of personnel involvement in process quality management.

The following functions of logistics process quality management is the promotion of innovations and staff motivation, ensuring the continuous innovative development of methods and processes, as well as supporting personnel initiatives to improve the logistics processes. The implementation of these functions corresponds to the principle of continuous improvement of process quality.

The general function of logistics process quality management is delineation of powers, duties and responsibilities of the staff for the quality of logistics processes, taking into consideration the competence approach to management, which is in line with the content of the principle of management leadership, inherent in the TQM system.

The implementation of the above-mentioned functions is an important condition for effective functioning of the mechanism of logistics process quality management, complying with the system-wide principle of universal responsibility for quality [10].

The scheme below presents the structure of the mechanism for managing the quality of processes, implemented in the logistics system of an enterprise.

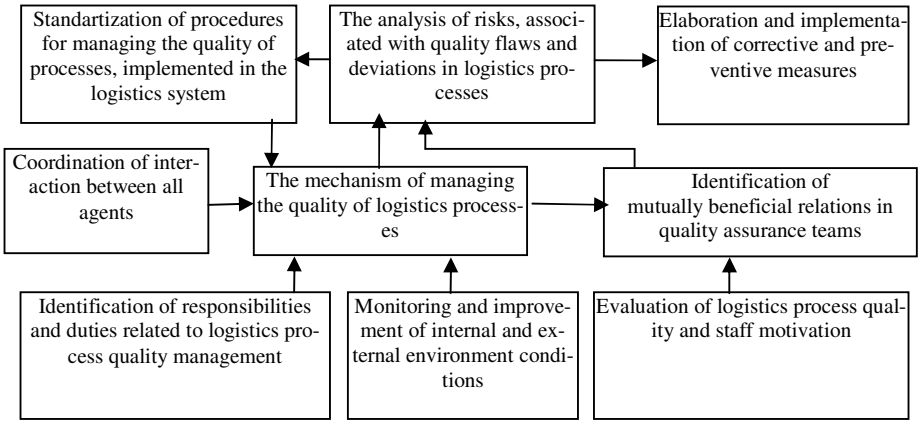

Fig. 1: The Functional Structure of the Mechanism of Logistics Process Quality Management

5. Conclusion

The development and maintenance of the proposed mechanism of logistics process quality management contributes to the solution of the following tasks, implemented as part of logistics activities of an enterprise:

- raising the degree of customer satisfaction with the quality of products and services;
- improving the competitiveness of an enterprise;
- increasing the productivity and labour efficiency;
- ensuring the economic sustainability of an enterprise, and the rational use of all types of resources;
- improving the quality of management decisions;
- implementing the latest achievements in engineering and technology;

It must be noted, that the quality of logistics processes is determined by such factors, as staff, equipment, materials, methods and components of the internal and external environment of an enterprise.

The conducted research has made it possible to reveal the basic components of activities related to logistics process quality management. One of the main components of such activities is the staff, involved in the logistics activity of an enterprise. The second component, ensuring high quality of logistics processes, is related to technical support of logistics processes, i.e. the appropriate equipment, devices and tools.

The important component of logistics process quality management is the effective use of management tools, including the principles and methods of management, the style of administration and the implementation of effective management solutions for improving the technology of logistics processes.

The next, equally important component is associated with creating the required moral climate, based on mutual interest and responsibility of each worker and the logistic service team of an enterprise as a whole.

Finally, the systematic component of activities, related to quality management, is the process approach, which is an effective tool for managing the quality of logistics processes, including the following procedures:

- identification, verification and validation;
- internal audit;

- the management of current records on the quality of processes, including the assessment and analysis of audit results;
- corrective and preventive measures;
- the solutions, aimed at improving the quality of logistics processes;
- continuous training of the personnel and identification of competences in the area of logistics process quality management.

Thus, the conducted investigation allows us to conclude that the quality of logistics processes and the content of functions, related to logistics process quality management in the con-text of main provisions of the TQM system, complies with the content of activities focused at industrial process quality management. This conclusion determines the necessity for restructuring the overall logistic activity, the coordinated work of all structural departments of the logistic service, and optimal identification of responsibility for quality shared between workers of logistics and industrial departments of an enterprise

Development of an Integrated Framework for Successful Adoption and Implementation of Mobile Collaboration Technology in Indonesian Healthcare

Faisal Syafar, Computing and Information Systems Research Centre, Universitas Negeri Makassar, Makassar, Indonesia, email: faisal.syafar@unm.ac.id

Halimah Husain, Department of Chemistry, Faculty of Mathematical and Sciences, Universitas Negeri Makassar, Makassar, Indonesia, email: halimah.husain@unm.ac.id

Abstract

Mobile collaboration healthcare system is one of the most widely accepted choices to support medical routine in healthcare organisations. These organisations are well known as having a high degree of communication, coordination and collaborative works, mobility and data and information access from many devices or tools. Although the benefits associated with mobile collaboration technology have been recognised as offering great potential in the healthcare sector, its successful adoption and implementation rate is low and many hospitals did not achieve intended goals in Indonesia. This study, therefore aims to develop a mobile collaborative healthcare implementation success framework by adapting the DeLone and McLean's IS success model to identify both critical success factors and success measures. In order to meet the study objectives, this study will employs a quantitative approach to identify the influence of various information quality, service quality, system quality and mobile collaborative healthcare implementation-related variables on Indonesian healthcare institutions' performance impacts.

Keywords: Integrated framework, Mobile collaboration, Healthcare

Introduction

Physicians and nurses are highly mobile in their daily hospital routine, moving frequently between wards, outpatient clinics, diagnostic and therapeutic departments, conference rooms and operating theatres. Their manifold information and communication needs at any number of locations and at all times of day and night are difficult to satisfy. Costly clinical workstations, which require additional allotment of valuable space, though often used, are not always accessible (Ammenwerth et.al, 1999).

Mobile technology is enabling an organization to work collaboratively or separately on a global basis while maintaining its collaborative information sharing capabilities. It has led to significant innovations in the healthcare organization, which can improve services to patients (Siau, 2003). Mobile collaboration has progressively become a significant concern in computer supported collaborative work (CSCW). Some researchers have been conducted by (Syafar et al. 2013a, 2015); (Herskovic et al. (2009), Hislop (2008), and Milrad and Spikol (2007) in efforts to recognize the implications of mobile work and mobile collaboration on collaborative applications design. Researches on application areas of mobile collaboration such as healthcare (Tentori and Favela, 2008), (Zeng, 2016) and many more have also been studied. Mobile collaborative healthcare is helping professionals provide patients with a higher standard of care-to move healthcare back into the community, reducing the pressure on hospitals and medical centers while reducing the costs of delivering services.

According to Ammenwerth (2000), mobile work in healthcare can cover several of tasks as follows:

- Routine use, everyday activities for healthcare professionals, for example: obtaining regular updates for patients.

- Mobile communications, the possibility to reach the healthcare worker anytime and anywhere.
- Mobile information access, possibility to access patient's medical record from healthcare's mobile devices.
- Mobile documentation, such as the possibility to avoid double documentation and ability to update/access through mobile devices.
- Nurses and general practitioner's assessment, outpatient care nurses and general practitioners need to use mobile communication in order to provide all relevant patient and medical information on the move.

It is indeed that the roles of mobile healthcare are significantly important. Zeng (2016) implied that an enterprise information system including mobile healthcare is an array of information technologies that will affect data, workflow, and the people in an organization. Professionals with different roles need to work as a group in order to successfully implement the systems. Jakab (2016) report, eHealth involves a broad group of activities that use electronic means to deliver health-relatedinformation, resources and services: it is the use of information and communication technologies (ICT) for health. eHealth foundation actions build an enabling environment for the use of ICT for health. However the literature series remain very limited (Fichers et al., 2003). According to Guerrero et al. (2004) and Sconavvacca et al,. (2006); a review of the literature in relation to mobile work in general has been under-researched, and research in mobile collaborative work in particular has been under-researching (Syafar and Gao, 2013a). Moreover, some research show that nearly 83.33% of companies from Indonesia (Dantes and Hasibaun, 2011), 50%-75% of US firms (Hawari and Heeks, 2010), approximately 90% China firms failed in ERP Implementations in healthcare. In addition mobile collaboration technologies adoption and use in healthcare sectors have not been popular yet in Indonesia.

Therefore the objectives of the research are:

- Investigating and Identifying the critical success factors (CSFs) for adopting and implementation of mobile collaborative in healthcare organisations
- Measuring the performance impacts of mobile collaborative in healthcare organisations
- Examining the relationship between CSFs for adoption and implementation mobile collaborative and their performance impacts.
- Developing an integrated framework for successful adoption and implementation of mobile collaborative in healthcare institutions.

This study aims to contribute into the body of knowledge on mobile collaborative, such as:

- Providing integrated understanding of the mobile collaborative adoption and implementation process by investigating and identifying the CSFs.
- Providing knowledge transfer to mobile collaborative tools vendor. The research finding will bring better understand the need of potential mobile collaborative system to the vendors.
- Formulating an integrated model for successful adoption of mobile collaborative that will contribute as a guideline of decision making process for healthcare stakeholders and other relevant organisations in adopting and implementing mobile collaborative projects.

In developing theoretical and research model, we get inspiration from Delone and Mclean (1992) with their IS success model (six dimensions of IS success, such as System quality, information quality, service quality, use (adoption), user satisfaction (collaborator satisfaction, net benefit (performance impacts). By adapting Delone and Mclean's (1992) model for IS factors, we create a theoretical model that presents a consolidated view of the literature in the area of mobile collaborative healthcare.

The rest of the paper is structured as follows: First, we present literature review, followed by proposed framework and research methodology, and the last section outlines a conclusion.

Literature Review

Mobile Collaboration Technology (MCT)

A mobile user or mobile worker is often regarded as a person performing tasks anywhere and anytime, using mobile computing devices with wireless communication capabilities. Typically they require functionalities for data synchronization and on-demand collaboration with other people (Syafar & Gao, 2013b, Messeguer et al., 2008).
Mobile workers in this research are Physicians and nurses who have to work within and or out of hospitals, move around locally or remotely. Their tasks must be performed on the site within a specific timeframe or they have to work at different locations with a carried "portable office" with limited resources. They often work based on an irregular schedule with narrow time windows for action. They have to cope with great uncertainty and interference. Moreover, they are not possible to ensure the availability of communication media when they decide to collaborate.

Mobile healthcare: adoption and implementation problems

The emerging growth of mobile technology has the potential to greatly improve sharing information and communicate with each other in healthcare routine. According to Standing and Standing (2008) the adoption of mobile technology in the healthcare sector has some problems as follows:

Need for integration of systems. Healthcare information systems are too large, complex systems and not well integrated. This means that the application of mobile in relation to data access and integration are not easily realised because the core applications of the system are not fully integrated.

Centralised systems. Healthcare administration and management has been developed along centralised lines with larger hospitals being developed to improve economies of scale. These systems have been supported by centralised IT systems. However, this type of architecture does not reflect the distributed nature of work or patient needs.

Security and privacy issues. The use of mobile technology in the healthcare sector generates anxieties related to security and privacy. As mobile healthcare professionals often store confidential patient data the loss of such a device or unauthorised access to it can be highly problematic (Fitch and Adams, 2006).

Factors Influencing MCT in Healthcare Adoption and Implementation

Information Quality

The quality of information related to successful healthcare management, according to Lehmann et al., (2008) more relevant to the dimensions of accuracy, output timeliness, consistent, complete and relevant information and selected mobile devices. Information quality refers to the quality of outputs the information system produces (DeLone and McLean, 1992), which can be in the form of reports or online screens.

System Quality

Mobile collaboration systems have particular features that are positively impact to the adoption and implementation in healthcare organisations and these are explained as follows:

- *Portability.* The physical characteristics of mobile devices that enable users to employ them more easily. Such features also allow users to collaborate with others anytime and anywhere (Syafar & Gao, 2013b, Syafar et al., 2014a, Syafar et al., 2015; Sarker et al., 2010).
- *Reachability.* With such technology, a person can be in touch and reached by other people at any time (Syafar & Gao, 2013b, Syafar et al., 2014b, Syafar et al., 2015; Sarker et al., 2003; Junglas, 2003).

- *Localization.* The ability of MCT to track the geographical position of a mobile user (Sarker et al., 2003; Junglas, 2003).
- *Identification.* The ability of a device to confirm a user's identity (Syafar & Gao, 2013b, Syafar et al., 2014a, Syafar et al., 2015; Sarker et al., 2003; Junglas, 2003).
- *Accessibility.* The extent to which an individual is able to get access to a mobile network at a given time and geographical location (Syafar & Gao, 2013b, Syafar et al., 2014a, Syafar et al., 2015; Sarker et al., 2003; Junglas, 2003).

System quality represents the quality of the information system processing itself, which includes software and data components, and it is a measure of the extent to which the system is technically sound.

Service Quality

According to Chatterjee et al. (2009), in the healthcare industry system reliability and system support use will positively affect within the healthcare context. *System reliability*: The extent to which the system can be depended upon to complete a task without problems and breakdowns. *System support*: The extent to which there is commercial software and hardware support available for the mobile device. Quality is a product which is achieved through services to attain customer satisfaction and managerially it can be defined as an excellence achieved in providing a service (Besterfield, 2006). Service quality has gained importance as it is a source for distinguishing between services and provides competitive advantage. The construct service quality has been defined as the degree of discrepancy between customers' normative expectations for service and their perceptions of service performance.

Performance Impact

Organizational performance impact is accumulated end results of all the organization's work processes and activities. The extent to which there is a reduction in the delay of healthcare service provided to patients, increase in the accuracy and efficiency of healthcare service, reduction in errors in medical records, improved security of medical records, increase in the ability to continuously monitor critical patients, etc (Chatterjee et al., 2009).

Campbel, Sarker and Valacich (2006) assume that the above capabilities of MCTs are very much required by high expertise mobile workers (e.q. in healthcare organisations). In line with the systems quality regarding MCTs, Kent (2016) and Syafar et al., (2014b) claims that with MCTs' capabilities make it possible for mobile tools to be employed by mobile workers. It has a positive business impact in that employees are supported to be more productive and more responsive to customers' requirements and collaboration in their organization.

Proposed Framework

In order to develop the mobile collaboration healthcare framework, we adapt the D&M IS success Model as presented in Figure 1. In order to develop the framework, the research questions need to be answered. The major question is: How can mobile collaboration technologies assist healthcare organization for successful adoption and implementation?

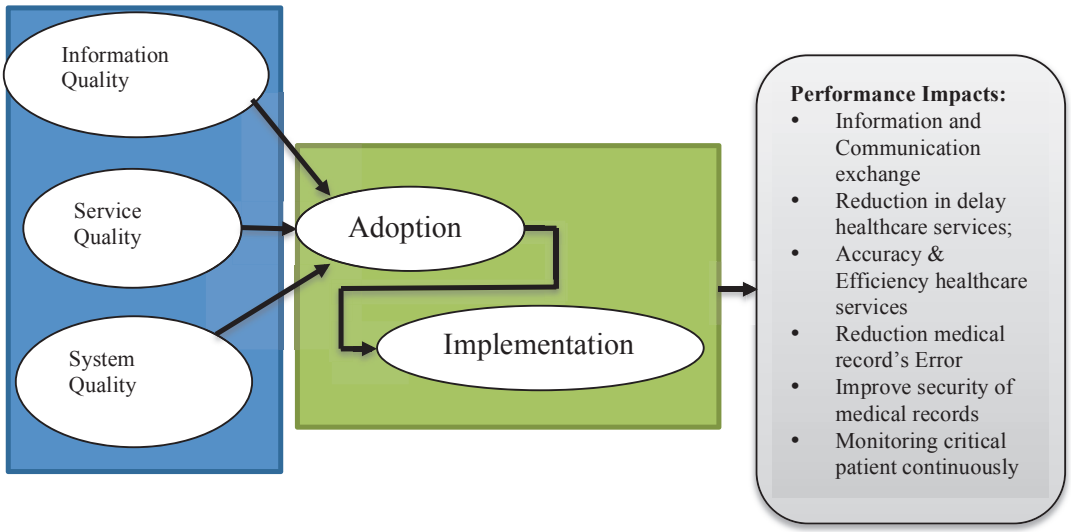

Fig 1. Proposed Research Model (adapted from DeLone and McLean IS success model (1992)

Research Methodology

The study will employ a quantitative approach to identify the influence of various information quality, service quality, system quality and mobile collaborative healthcare implementation-related variables on performance impacts.

Structural Equation Model (SEM) software program will be used to confirm the various hypotheses relationship or testing the relationship between multiple latent and measured variables.

The data will be collected through questionnaires. The respondents will be Indonesian healthcare organisations which have successfully adopted mobile collaborative systems.
Target respondent groups will be:

- Senior IS manager (who involving in the adopting process)
- Healthcare workers (physicians, nurses)

Data analysis will be conducted within two steps: assessing the measurement model, and then the structural model for adequacy of data representation. The measurement model will be tested for validity and reliability properties. Construct validity will be assessed by convergent and discriminant validity, using confirmatory factor analysis (CFA).

The proposed research model presented in Figure 1 will be tested with the related hypotheses, drawn from theoretical background of this paper. Hypotheses will be proposed for each variables relationship. These hypotheses will be drowned from theoretical synthesis from some relevant references.

Conclusion

It is expected that the research finding will build an integrated framework that meet all requirements for successful adoption and implementation. In addition, it can enhance healthcare planning and implementation as well as continuously improved, and automatically adapts to the new and changing mobile technologies. By implementing mobile collaborative healthcare routine, mobile information and communication systems will have the potential to increase quality of patient care in the long run such as: greatly improve communication, facilitate information access, decrease in the delay of

healthcare service provided to patients, increase in the accuracy and efficiency of healthcare service, reduction in errors in medical records, improved security of medical records, increase in the ability to continuously monitor critical patients in Indonesian healthcare institutions.

Abstract

The participation of the leading management (Top-line-and Second-Line Managers) in the business development of a parent company or a group company is a popular way to incentivise the managers. In private equity transactions, managers fairly regularly get the opportunity to purchase shares in order to (indirectly) participate in the future business developments of the target company. These co-investment programmes, in which managers participate, are currently challenged by the tax authorities. In co-investment structures, there is a tussle between the tax authorities and the participating managers — often in times of disposal of the co-investment — over whether reimbursements out of the co-investment programme to the managers represent wage or capital income/capital gain. The type of income is a crucial factor for all managers resident in Germany and especially abroad. The tax risks of these co-investment models have to be borne by the managers. A careful implementation of the management participation programme is necessary in order to structure these co-investments as a capital investment for the managers. That leads to low taxation for German residents or possibly even no taxation for non-German residents. The article wants to highlight the current developments in this context and to carve out solutions for management participation programmes for international managers in Germany.

Keywords: Private Equity Transaction, Co-Investment Programme, Management Participation, Capital Investment

1. Introduction

In response to global and domestic competition, Cooke (1994) pointed out more than twenty years ago, that (here: American) companies try to improve their business performance through a more effective use of their available work forces with the implementation of employee participation programmes. For this reason, it is a popular practice among shareholders and investors to appropriately involve executive employees in target corporate success (Poenicke and Buenning 2014). These days, there is, in the private equity context, hardly any transaction without the participation of the management in a purchased target company (Hohaus and Inhester, 2003). Furthermore, family-equity investments, i.e. the participation of family offices in successful companies, also regularly use such instruments (Schulte, 2016).

The reasons for the implementation of management participation programmes in typical Leveraged-Buy-Out Transactions are diverse, but boil down to a sustained increase in corporate value. The managers participate in the chances and risks of the current business activities as an incentive for better work performance. For these reasons, managers often get the chance to purchase shares of amounts equal to one or two gross annual salaries.

The legal form of the management participation or co-investment programmes can be very diverse, e.g. stock options, preferred shares, rights embodied in a participation certificate, indirect participations etc.

Such (indirect) participation in the target companies needs to be efficiently designed for both parties. For this reason, in medium-sized or large buy outs, the management participation would typically be bundled into a separate investment vehicle (see Section 3). By way of an equity contribution to the investment vehicle, the managers receive shares in the investment vehicle, representing an indirect participation in the target company. The investment through a vehicle also facilitates the administration, when many managers from several countries are to participate in the target company. In this article, such programmes will be reviewed with regard to their prominent position in practice (Thiele, 2017).

In the context of the purchase of the participation in an investment vehicle, all parties enter into a co-investor and shareholders' agreement with respect to their holding of shares in the target company. In such agreements, the terms and conditions are codified, especially with respect to exit clauses, leaver schemes, drag-along-right, tag-along-right, anti-dilution-protection, and other aspects like admission of further co-investors.

The terms and conditions of these agreements especially are regularly scrutinized by the tax authorities. Most frequently, the central question in this context is whether a co-investment/equity participation of a manager in the target company (directly or indirectly) represents an *additional* source of income apart from the person's employment relationship in the target organization. And, in case of an exit, whether the capital gains out of the disposal of the shares held by managers in an investment vehicle, represents capital income at the level of the manager. In some cases, the tax authorities consider capital gains to be wages because of a close connection between employment in the target and capital investment. The huge tax impacts of these re-qualifications of capital gain in work income will be shown in Section 4.

2. Review of Scientific Journals, Views of Fiscal Authorities, and Federal Fiscal Court Decisions

Within the usual tax audits done by the fiscal authorities, management participation programmes have been focused on for many years (Poenicke and Buenning, 2014). In management participation programmes, the main tussle between the fiscal authorities and the managers results in a fiscal treatment of these programmes and the revenues earned from them (e.g. profit distributions, capital gains).

It is necessary for all parties to differentiate between the employment contract of the manager and the special right resulting in the capital participation of the managers (indirectly) in the target company, where they also happen to be employed. Such an agreement is generally accepted by the German Federal Fiscal Court as a separate privity of contract, which is independent of the employment contract (BFH, 2005; BFH, 2006; BFH, 2008; BFH, 2009; BFH, 2014; BFH, 2016a, BFH, 2016b). For this reason, the capital contribution needs to be concluded in an independent agreement next to the employment contract (BFH, 2016b).

Questions and uncertainties arise in cases where the employment contract and capital participation are closely connected. That might be in cases where the benefits of profiting from a separate capital contribution are induced by the employment relationship as a kind of remuneration for work (BFH, 2009). It is a kind of sweet equity contribution, which means a manager receives capital contribution in the target company freely or at a cheap rate, overlapping the special right, resulting in a capital participation through the employment contract (von Braunschweig, 1998; Hohaus and Inhester, 2003; Poenicke and Buenning, 2014). So, such an agreement would totally qualify as wage, which would include (i) the non-cash benefit arising from the reduced or free purchase price of capital contribution, (ii) revenues from this participation, and (iii) the capital gain at the time of disposal of the participation represents wage according to German Income Tax Act (ITA 2009). In contrast, no

action under the German tax law would be evoked, if the target company or the investor would grant a loan to the managers in order to enable them to finance the capital participation in the target (BFH, 2010). In this case, it would be necessary to determine the loan conditions in accordance with the arm's length principle (Hohaus and Inhester, 2003).

Another big issue in the management participation programmes, which has been challenged for many years in the tax audits, is the leaver scheme in the co-investment programmes. In practice, the management participation programmes differentiate between managers who leave the company as "Good-Leavers", "Bad-Leavers" and, where appropriate, as "Bad-Bad-Leavers". As a general rule (Koch-Schulte, 2015), the leaver-types can be characterized as follows: (i) a Good-Leaver is manager who is unable to work anymore or dies or the employment contract is terminated by the target company, (ii) a Bad-Leaver is a manager who terminated the programme or the employment contract, or becomes insolvent, and (iii) a Bad-Bad-Leaver is a manager who breaches the manager's duty and/or is dismissed for that (an important) reason.

With regard to such leaver schemes, the tax authorities argue in favour of an overlapping of the employment contract and the separate capital participation through the management participation programmes (Koch-Schulte 2015, FG Cologne 2015). This is based on a very special decision of the fiscal court in which a bad-leaver arrangement in a co-investment programme led to an overlapping of the parallel contracts of employment and capital participation (BFH 2013). Basically, other underlying aspects of these decisions must be taken into account. However, the tax authorities have come to consider this decision to be universally valid. This leads, in practice, to the conclusion that the tax authorities assumed an overlapping of the employment and the capital investment solely based on a bad-leaver scheme in a management participation programme (Roedding, 2017).

In this context, another senate of the German Federal Fiscal Court has contradicted the authorities' interpretation by a decision published in 2017 (BFH, 2016b). According to the Federal Fiscal Court, there is, on the one hand, no overlapping of the employment contract in cases where the management participation programme is solely offered to a closed group of employees. On the other hand, leaver schemes, as described at the level of the management participation programme, are a consequence of these programmes, independent of the employment contract (BFH, 2010; BFH, 2016b).

Consequently, a leaver scheme on its own is not harmful from the tax point of view. The management programme must be considered with an overall view, if there is a close connection between the employment contract and the capital investment of a manager. Moreover, it is important, that managers drawn to participation bear the chances and risks involved in capital investment. Comparable to a capital investment, the sale and purchase price of the managers' co-investment should be at fair value. Tauser (2017) criticises this norm set by the fiscal court.

Furthermore, according to the current decision, typical vesting-clauses, which represent sales restrictions on co-investment participation by a manager, are acceptable as well. Such clauses are generally not contrary to the beneficial ownership of the managers in the interests in the co-investment vehicle (Tauser, 2017).

Hence, such programmes need not be completely compliant with the arm's length principle (Poenicke and Buenning 2014). However, a careful implementation of the co-investment programme is necessary in order to avoid tax risks (see Section 4).

3. Typical Structure of Management Participation Programmes

Financial investors, who invest in (here: German) target companies, typically have a multi-level acquisition structure (Bussian et. al., 2016). Such an acquisition structures can be simplified to look like the following structure, which will be especially helpful in understanding the next chart.

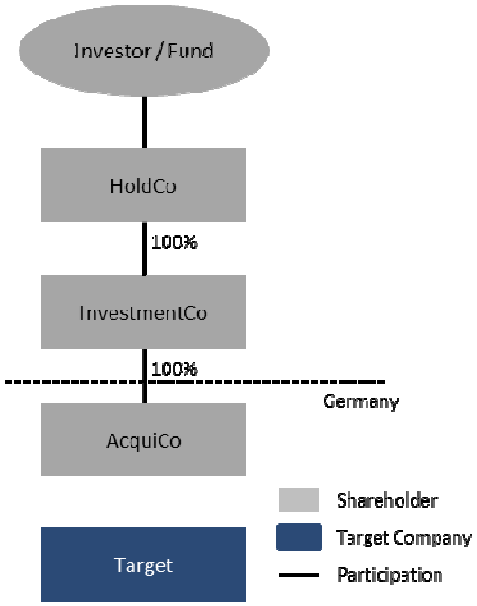

Fig. 1: Acquisition Structure of a Financial Investor with a future German Target Company (prior to signing the sale and purchase contract)

The participation by co-investors is typically bundled via a tax-transparent German (limited) partnership. The managers can participate in these investment vehicles, which are often organized in a BGB company ('Gesellschaft buergerlichen Rechts'), a partnership organized under the German Civil Code, or in a limited partnership with a limited liability company as a general partner ('GmbH & Co. KG'—descriptions of company types that follow 'Co-Invest Partnerships'). Later, a legal form is given under the current practice. Furthermore, it will ensure that these vehicles will not qualify as commercial units, according to the German Trade Tax Act. This can be met by engaging a limited partner, who is entitled to be a managing limited partner of a Co-Invest Partnership (ITA, 2009).

These co-investments aim at indirect equity participation by co-investors in the target company employing top-line and second-line managers. These managers, who are also co-investors, will become limited partners in the Co-Invest Partnership. The managers generally acquire (indirectly) 5–15% of the share capital in the target (Roedding, 2017). The structure can be simplified and illustrated as follows:

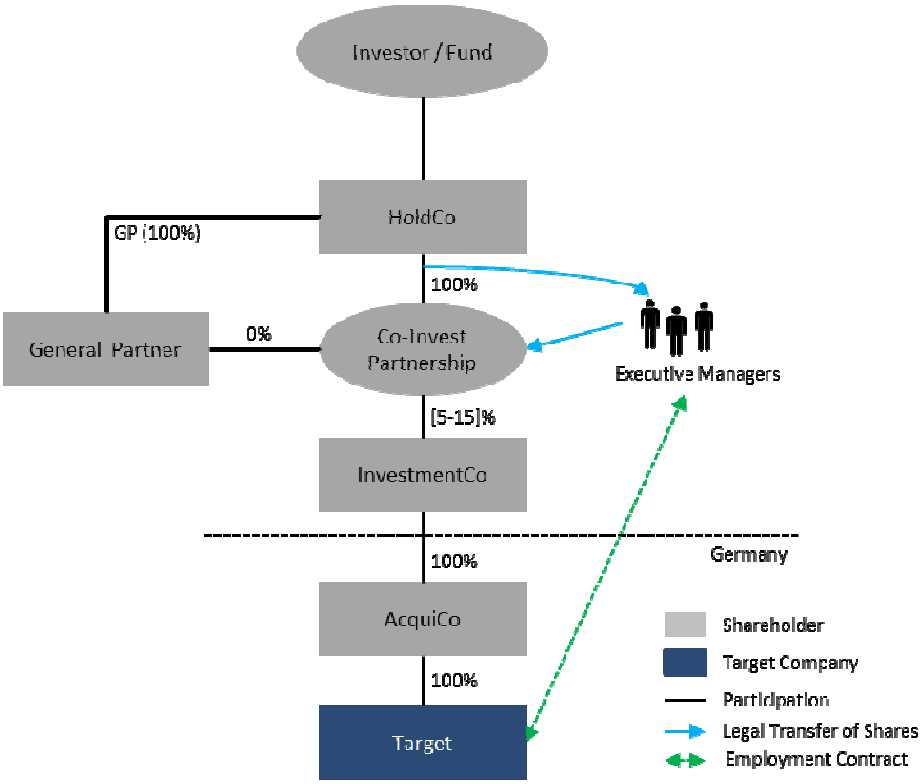

Fig. 2: Typical Structure of Management Participation in a Co-Investment Vehicle (post signing the sale and purchase contract)

In this case, HoldCo has established the co-investment structure. Thus, HoldCo sells limited partnership interests in Co-Invest Partnership to the selected managers in consideration of cash. After the payment of the purchase prices, the managers will indirectly hold shares in the InvestmentCo.

Along with the signing of the sale and purchase agreement between a separate acquisition vehicle ('AcquiCo') and the seller, the HoldCo, InvestmentCo, the Co-Invest Partnership, enters into a co-investors' and shareholders' agreement with respect to their holding of shares in InvestmentCo. Such an agreement regulates the rights and obligations of all parties and helps to avoid future conflicts, for example, over the direction of business activities.

Such a structure links the executive managers in two respects to Target, which is also the primary interest of the investor. On the one hand, the managers enter into capital participation by way of contributing their own money to the investment vehicle, and, on the other, such equity participation leverages the managers' participation in a partially credit-financed purchase by AcquiCo (Table. 1). For these reasons, the managers are incentivized to develop the business of Target in order to increase the refund value of their capital in the case of an exit by the investor.

Regarding the restrictions of the German Holding Companies Act (UBGG, 1998), the acquisition of Target in private equity transactions can be financed maximum with 3 portions (shareholder) loan and 1 portion equity (Bussian et. al., 2016). Such a finance structure leads to fact that managers will only bear (here) 2.5% of the total equity, while holding 10% of share capital in InvestmentCo and indirectly in Target (Eilers et al., 2016).

Tab. 1: Incentive System by Debt-Financed Purchase—Consolidated Sources and Uses

Equity Funding by Investor					Debt and Equity Funding by Investor			
Sources	*mEUR*	Uses	*mEUR*		Sources	*mEUR*	Uses	*mEUR*
Purchase Price Target	95	Investor Equity	90		Purchase Price Target	95	Investor Equity	25
							Shareholder Loan	72.5
Transaction Cost	5	Managers Equity	**10**		Transaction Cost	5	Managers Equity	**2.5**
Total	*100*	*Total*	*100*		*Total*	*100*	*Total*	*100*

The table illustrates that managers indirectly participating with 10% of the shares in Target, need only to contribute one quarter to reach this ownership in case of debt-financing by the investor (see also Table 2).

4. Tax Considerations and Calculations

Based on the review, a careful structuring is required of the co-investment, especially the leaver scheme. The tax risks arising from an inappropriate structure has to be borne solely by the managers with regard to the transparent structure.

Tax risks can arise at three stages within the holding period—first, at the time of acquiring the interest in the investment vehicle; second, during the holding period; and, third, at the time of the disposal of the shares in the partnership. These three periods shall be considered from a German international tax perspective.

Preamble

Co-investors who are tax-resident in Germany are subject to unlimited German tax liability with their worldwide income, e.g. dividend income, interest income from loans, and capital gains. Investors who are tax-resident in Germany can be subjected to limited German tax liability with income earned in Germany such as capital income, depending on the type of financial instrument and other conditions.

(a) Tax considerations during the purchase of indirect interest in the Co-Invest Partnership

The sale and the transfer of limited partnership interests in the partnership by HoldCo to the managers should be tax neutral provided the transaction is based on fair market value. In case of a sweet equity contribution, taxation would arise at the level of a manager. According to the German comprehension, the sweet equity contribution would qualify as wage in the amount of the difference between the purchase price and the fair market value of these interests. The tax rate of wages can rise to 45% plus a solidarity surcharge.

In case of managers living abroad, the German target can be made liable to pay wage taxes as an indemnitor. The tax authorities qualify such wages as “wage by third parties”, based on Sec. 38 of the Income Tax Act (ITA, 2009). In tax audits, expenses towards the implementation of the co-investment structure (e.g. notary services, tax, and legal advice regarding statutes and the shareholder’s agreements, inter alia) are qualified as “wage by third parties” by the tax authorities. This currently causes considerable frictions in practice.

As a result, it is not necessary to check a double taxation treaty in this case. The target probably would have repayment claims.

(b) Tax considerations in the holding period of the interests in the Co-Invest Partnership

In this scenario, the managers can profit from their investment by way of dividend distribution along the shareholding chain. In this period, it is not common to partially realise capital gains from the disposal of shares because of vesting clauses. Bad leavers, too, touch their capital contribution only after the total sale of the shares.

Depending on the legal design of the programme, dividend distribution to the managers could also qualify as wages. This can have bad impacts on the manager, as it will be shown in the tax calculations at the time of exit.

(c) Tax considerations at the time of disposal of the interests in the Co-Invest Partnership

The most relevant taxable event is the sale of Target shares. Based on the typical drag-along-right in the agreement, managers are also obliged to sell their interests in case the investor wishes to realize the investment by way of an exit.

There are two levels at which the capital gain can be realized in case of a resale of the target.

The capital gains can be realized at the level of InvestmentCo, which is typically not resident in Germany. That means, from a German tax perspective, these capital gains upon disposal of at least 1% of the shares in AcquiCo would be subject to a limited German tax liability, according to the German Income Tax Act (ITA, 2009). However, Germany would not be entitled to tax such capital gains pursuant to Article 13, para. 5, of the OECD Model Tax Convention (OECD, 2014).

If, in contrast, AcquiCo sold all shares Target, 5% of any capital gain would be subject to German CIT and TT, resulting in an effective tax rate of approximately 1.5%. In addition, the capital gain would have to be distributed as dividend to its shareholders, inviting the German withholding tax.

Against this background, InvestmentCo should sell shares in AcquiCo in order to mitigate the exit tax burden because there is typically a participation exemption regime in the state of domicile of InvestmentCo that should be applicable at the level of InvestmentCo.

Capital gains from the disposal of shares in InvestmentCo realized by investors resident in Germany for tax purposes are:

- Subject to the final flat tax at a rate of 26.375%, if the investor holds its shares among its private assets and has a participation quota of less than 1%;
- Subject to the so-called part-income taxation regime, 40% of the capital gain is tax exempt, and the remainder is subject to progressive rates of up to 47.48%, if the investor has a participation quota of 1% or more;
- 95% tax exemption for CIT and TT purposes, if the investor is a German corporation.

According to the national law, this tax burden has also to be borne by non-German resident investors. If there is a double taxation treaty, comparable to the OECD Model Tax Convention (OECD, 2014), between Germany and the country of the manager's residence, Germany will not have the right to tax these capital gains.

In that case, these capital gains will be treated as wage, where Article 15, para. 1 and 2, of the OECD Model Tax Convention (OECD, 2014) can be relevant. Non-German resident managers employed by Target and stationed periodically at its headquarters would be subject to German taxation only to the extent Target has borne the wages. That means the capital gains realized by non-resident managers would be subject to limited taxation according to a German international tax convention. As a consequence, these capital gains will be taxed as wages with the proportional tax rates up to 47.48% (taxable income in the amount of EUR 256,000).

The following table will illustrate the tax impacts for managers, whose capital gains qualify to be (i) capital gain and (ii) as wage. In this example, Target is sold at a multiple of three and the manager, who is not resident in Germany, holds participation to the extent of 10% of the interests in the Co-Invest Partnership.

Tab. 2: Profit Determination and Taxation Depending on Qualification of Income from Co-Investment Programme

	mEUR	**mEUR**
Sales Proceeds of Target	300	300
Book Value at Level of InvestmentCo	./. 100	./. 100
Transaction Cost	5	5
Capital Gain at Level of InvestmentCo	195	195
Repayment of Shareholder Loan	0	72.5
Profit Distribution (and Capital Repayment)	*195*	*122.5*
Investor	175.5	110.3
Co-Investors (90%)	17.5	11
Co-Investor (10%)	**2**	**1.2**
German Tax Burden (Capital Gains)	0	0
German Tax Burden (Wage)	0.95	0.57
Capital Repayment	*1*	*0.25*
Total Net Return (incl. capital contribution)	***3 vs. 2.05***	***1.45 vs. 0.88***

Within this realistic scenario, a manager, who has participated with 10% in a managing participation programme, will have a total net return to the amount of EUR 3 million (scenario: equity funding by investor) and EUR 1.45 million (scenario: debt and equity funding by investor) in case the capital gain is qualified as a capital income. Germany would not tax this capital gain in case the investor is resident in a contracting state. In contrast, if the co-investment programme is closely linked to employment relationship of the relevant manager, the total net return of these investments amounts to EUR 2.05 million (scenario: equity funding by investor) respectively EUR 0.88 million(scenario: debt and equity funding by investor) . Thus, the capital gain is considered as wage from the German tax perspective. That would reduce the capital return compared to the initial investments about almost 100% (scenario: equity funding by investor) and 160% (scenario: debt and equity funding by investor).

Incidentally, this example also shows the leverage effect in case of a partially debt-financed purchase of Target (see also Tab. 1).

5. Conclusions

Co-Investment Programmes are a common vehicle in transactions to keep relevant managers on board. As part of their incentive, these managers can profit from a separate capital contribution to the investment vehicle, where they indirectly participate in the company's business success. In case of a debt-finance purchase of Target company, the managers can extraordinarily profit by participating in such a programme.

According to the current decision of the Federal Fiscal Court (BFH, 2016b), leaver schedules can be agreed without endanger tax treatment of a programme. It is to be hoped that the fiscal authorities will accept that decision and apply that principle beyond the individual case of the decision. Nonetheless, the fiscal authorities have—especially in tax audits—a critical view on such programmes (Roedding, 2017). Leaver schedules are an important aspect of such programmes for the designing of fair conditions. From the economic perspective of an investor, a bad leaver should not profit from corporate development in the same way as a good leaver does. So, co-investment programmes are basically no tax-driven considerations of the investor (Thiele, 2017).

In case of fiscal treatment of the management participation programme, the consolidated overview of the individual agreed conditions in the programme is significant. For this reason, co-investment programmes need to be implemented very carefully with regard to the strict attitude of the tax authorities. It should be ensured that the following fundamentals will be met in management participation programmes:

First, the management participation programme must be a special contract next to the employment contract. Moreover, it is necessary that the co-investment is purchased at a fair value by all managers who participate. In addition, the managers should also bear all risks and chances resulting from that investment. That means they will have to hold the beneficial ownership of the interests by way of voting and profit participation rights. In case the Target is hit by economic difficulties, managers must implement restructuring measures compared to shareholders.

In contrast, besides leaver schemes, it is also not directly harmful from a German tax perspective, if only a special group of managers are able to participate in such a programme and there are restrictions on the disposal of the interests through the managers.

In case of implementing co-investment programmes without considering tax restrictions, the employment contract can overlap the co-investment capital investment. Consequently, all distributions to the managers (e.g. dividends, capital gains) will be considered as wages. Managers, irrespective of whether they are German or non-German-residents, will be subject to (un) limited tax liability in Germany. In case of double taxation treaties, German authorities would carry out their right to taxation based on Article 15 of the OECD Model Tax Convention (OECD, 2014). If there is no double taxation treaty between Germany and the state of manager's residence, Germany would execute its right to taxation based on the national income tax law (ITA, 2009). Therefore, in case of a requalification of capital gain to wage, a manager would bear a German tax burden of up to 47.48% compared to a tax burden of 0%. On behalf of the relevant managers, the investors should carefully implement a co-investment structure with target assets based on the tax restrictions.

Economic Discomfort Trend – Where Do The European Union Countries Stand?

Assoc.prof. Ph.D. Iustina Alina Boitan, Faculty of Finance and Banking, the Bucharest University of Economic Studies, Bucharest, Romania, iustinaboitan@yahoo.com

Assoc.prof. Ph.D. Ionela Costică, Faculty of Finance and Banking, the Bucharest University of Economic Studies, Bucharest, Romania, ionela.costica@fin.ase.ro

Abstract

The economic discomfort felt by households is a matter of great interest for policy makers and economic agents. Increasingly more misery indices and economic sentiment indicators are considered reliable measures of the economic satisfaction. The paper has several qualitative and empirical objectives, namely: *i)* a comprehensive review and comparison between the existing misery indices; *ii)* the assessment of the degree of economic discomfort felt by European Union households during 2001-2016 by relying on a comprehensive range of misery indices and sentiment indicators; *iii)* performing an exploratory statistical analysis, called Cluster Analysis, to identify the presence of similar economic discomfort patterns, from both a temporal and regional perspective. Direct results consist in gathering into homogeneous, meaningful groups the most resembling countries, and respectively time periods from the viewpoint of several objective and subjective indices that reveal the public perception on contemporary economic developments. The clustering solution obtained indicates that some countries are synchronized in terms of macroeconomic fundamentals that lie at the origin of the computed misery indices. Indirectly, the results of the cluster analysis depict the current state of economic convergence in the region.

Keywords: misery indices, economic convergence, correlation, cluster analysis.
JEL codes: C40, G01, O52

1. Introduction

European Union (EU) member states' economies are still confronted with major distortions and imbalances in terms of the volatility of currency exchange, unemployment, inflation rate, the share of public debt in GDP, the fiscal deficit, the current account deficit, the different pace of GDP growth contraction, changes in direct and indirect tax rates etc. All these dimensions of the macroeconomic framework are reflected in people's expectations relative to their standard of living.

Finding an appropriate measure of the consumer's satisfaction regarding macroeconomic performance is a matter of great importance for policy makers and economic agents as people base their decisions also on subjective expectations regarding the future evolution of the economy.

Traditionally, to assess the macroeconomic performance of a country, researchers rely on fundamental variables as GDP growth, government deficit, current account deficit, unemployment rate or inflation rate. Nevertheless, economic literature outlines the incomplete nature of this type of analyses. Cherchye (1998) stresses the need to create synthetic measures, in order to gather several macroeconomic indicators in one variable, able to preserve the informational content of the initial dataset and to allow the hierarchy of countries. Rothschild (1999) remarks the predilection of assessing the success or failure of certain macroeconomic policies in relation to the real GDP growth rate. Navarro et al. (2014) agree that, although GDP is a basic variable in many research studies, it is not the unique tool for assessing the economic

development of a country. It has to be complemented by several other intangible variables, such as human development, country image, employment conditions, environment, innovation or public sector efficiency. A noteworthy contribution to the debates related to finding appropriate and comprehensive measures of economic development is provided in the report written by Stiglitz et al. (2009). Their purpose is to identify reliable alternative indicators for measuring a country's economic performance and social progress, in addition to broadly used standard indicators such as GDP, unemployment rate, inflation. Moreover, they state that GDP might be wrongly used as a measure of societal wellbeing.

A complementary way to assess the macroeconomic performance of a country is to resort on public perception. Over time, economic literature has developed a number of alternatives represented by the construction of several composite indices, whose central focus is the determination of the level of discomfort (known as Misery Indices) or the degree of satisfaction felt by the population and the private sector (known as sentiment indicators). In this respect, the United Nations Economic Commission for Europe (2014) provides a classification of the indicators that explain a country's macroeconomic performance in three typologies, namely leading, composite and sentiment indicators. After an in-depth review of main indicators developed over time by different countries around the world, the conclusion is that analytical and empirical research on issues related to misery indices is extremely limited in the existing literature.

The aim of our paper is to bring together, in a comprehensive and topical approach, the entire typology of Misery indices developed over the years, as proxy indicators of an economy's performance. It is a singular analytical and empirical initiative in the existing literature, meant to unify all the Misery indices' meanings. Based on the original formulas proposed by economists, financial institutions or rating agencies for calculating the indices, we compute their values in order to obtain a dynamic picture of their evolution over time and to identify whether there is a concentration of the state of economic discomfort in some EU countries.

The novelty of our research is given by several features: a) the analysis of a broad range of Misery indices; b) the large time frame considered, covering the years 2001-2016; c) the high frequency of data, consisting in quarterly data series; d) the methodology employed, represented by an exploratory technique, to depict whether there is a concentration of the economic discomfort felt by households in EU member countries and how this pattern of resemblance has evolved over a time period of sixteen years; e) the granular, country level analysis for each EU member state, to provide a comprehensive and individualized snapshot of the changes in the degree of economic discomfort over the time period considered. The results of this empirical approach might be of great interest for policy makers at national and European level, as they can get a picture on the effectiveness of funding facilities (provided to several EU countries after the onset of the financial crisis) in alleviating national vulnerabilities.

The paper has been structured as follows: section 2 depicts the different alternative public perception indices launched until present. We propose delineation between two categories of indices: a) official indicators developed by prestigious institutions based on surveys conducted among households and economic agents; b) indices that gather different dimensions of the macroeconomic performance of a country, developed by professionals and known as Misery Indices. Section 3 illustrates the state of art in this research field. The fourth section employs the cluster analysis method to identify similarities in the Misery Indices levels, and hence the presence of concentration, from two perspectives: a) a temporal one, which accounts for the magnitude of the economic state of discomfort felt in the EU; b) a regional perspective, to account for the state of economic discomfort perceived in each of the 28 EU member states, at key moments in time. The last section concludes.

2. Typology of Economic Discomfort Indicators

In practice, the composite indicators for quantifying the public perception on a country's macroeconomic prospects are classified into two main categories:

a) *Sentiment indices* - official indicators built by prestigious institutions based on surveys conducted among households and economic agents. An increase in the indicators' value provides a positive signal, by depicting respondents' confidence in a favorable economic and financial climate.

The concept of economic sentiment was attributed mostly intuitive meanings, being a variable difficult to accurately observe and quantify. Keynes was among the first economists who noticed the correlation between the business cycle fluctuations and economic perception changes. In his work *The General Theory of Employment, Interest and Money*, Keynes defines the psychological expectation as anticipation on a long-term horizon, on which individual decisions are founded. Therefore, the evolutions of the economic discomfort or the state of mistrust represent a signal concerning the future path of the economy. When the degree of trust in economic prospects staggers, the first adjustment economic agents make is reducing expenses and moving from holding or investing in risky assets to more liquid ones. Hiring and investment in machinery and buildings freeze, production falls and unemployment rises. As economic agents become more aware of the economic downturn and the negative dynamics of unemployment, even if not directly affected they will worsen their own economic expectations, thereby prolonging the state of economic downturn.

Among the most representative indicators included in this category are the Consumer Sentiment Index, calculated and published monthly by the Michigan Survey Research Center, the ZEW Economic Sentiment computed by the Centre of European Economic Research in Germany and the Economic Sentiment Indicator, calculated by the Directorate-General for Economic and Financial Affairs (DG ECFIN) within the European Commission.

These indicators are known for their ability to provide additional information to official statistics, being used in economic analyses, monitoring and short-term forecasts, but also in quantitative or qualitative analyses made by financial institutions, research centers or academia. According to the United Nations Economic Commission for Europe (2014, p.4), the economic sentiment indicators are able to provide valuable information, which might be a useful source for developing macroeconomic policies. It is argued that sentiment indicators try to estimate future macroeconomic behavior, by taking into account different impact factors, such as unemployment, inflation, macroeconomic conditions or politics.

Drozdowicz-Biec (2012) states that there are three economic fundamentals which influence most the consumer confidence levels, namely: the inflation rate, employment and income. Consequently, the values attributed to various consumer confidence indicators, measured through surveys, might vary widely as a result of people's perception and sensitivity to changes in economic fundamentals' level.

b) *Misery Indices* - gather the different dimensions of a country's macroeconomic performance, being developed by economists, rating agencies or financial institutions.

This second category has seen an evolution over time regarding the variables included in the index base. Nevertheless, the signal provided by the level of the index maintained its substance: a high level indicates a high degree of discomfort/dissatisfaction. A common feature of all the indices to be presented below is the computation methodology: they all involve the mere summation or deduction of certain equally weighted macroeconomic variables. The variables included in the formulas are meant to depict the presence of potential imbalances and weaknesses of the national economy in terms of price stability, employment, share of fiscal or current account deficit in GDP and real GDP growth rate. It should be mentioned that these variables are closely monitored by European institutions in order to assess the process of economic convergence in the region. Therefore, indirectly the misery indices signal the amplification or mitigation of disparities between EU countries, in terms of fulfillment of economic convergence criteria.

Economic literature recognizes the contribution of the economist Arthur Okun in the development, in the '70s, of the first dissatisfaction index known as the original Misery Index. It is determined by simply

adding the inflation rate and unemployment rate. It is assumed that both a higher rate of unemployment and inflation increase the economic and social costs of a country.

Relying on the basic Okun's index, Calmfors and Driffill proposed the interpretation of a country's macroeconomic performance by adding the unemployment rate to the current account deficit as a percentage of GDP (called the Calmfors-Driffill index) while Barro (1999) amended Okun's index by including in its structure two additional variables, namely the real GDP growth rate and long-term interest rates, represented by 30-year government bond yield (the Barro Misery Index).

In 2008, Carsten Hoegh, director at Credit Suisse, suggested expanding the Okun's Misery Index formula by adding a new component, so as to capture the evolution in the value of real assets held by households, namely the annual change of house prices. This variable enters the formula with negative sign, because it was considered that a decrease in homes value contributes to increasing economic discomfort. The new index had been called Enhanced Misery Index.

In parallel, we found evidences of three similar attempts. Hufbauer et al. (2008) have proposed, too, the inclusion of the housing price variable into the basic formula of Okun's index and named it the Augmented Misery Index, while Dye and Sutherland (2009) called it the Household Economic Stress Index (HESI). In 2011 the Center for Economic Development and Business Research has begun to compute a Misery Index for three geographic areas (USA, Kansas and Wichita), based on the same three variables: consumer price index, unemployment rate and housing price index.

Moody's (2009) adapted the Okun's original formula for calculating the Misery Index to the economic context characterized by excessive deficits. As a measure of the challenges some countries will face over the next ten years, it has been proposed the New Misery Index, which includes unemployment rate and public fiscal balance.

3. Literature Review

In the following we have summarized the findings of other papers that have previously contributed to this strand of the economic literature.

Starting from the four variables that compose the Barro Misery Index, namely the long-term interest rate, the unemployment rate, inflation rate and growth rate, Welsch (2007) tries to reconsider the relationship between macroeconomics and subjective well-being, by including them as additional variables in life satisfaction regressions. Using annual data for 12 EU countries, covering the period 1992-2002, he finds that unemployment, inflation and the growth rate hold the highest influence in a macroeconomic life satisfaction regression.

Lechman (2009) tests the ability of two Misery Indices (Okun's and Barro's) to be used as a tool for measuring a country's degree of poverty. The empirical results indicate that Misery Indices are not a reliable measure of poverty, but their changes over time and across different countries definitely reflect changes in society`s economic performance. Consequently, they are most suited for being used as proxies of economic and social welfare.

Another empirical approach has been proposed by Iqbal and Nawaz (2010) who investigate the effect of fiscal decentralization on macroeconomic stability by using Okun's Misery Index as a proxy for the state of macroeconomic stability. The findings indicate fiscal decentralization has a significant positive impact on macroeconomic stability.

Gaddo (2011) performs a comparative analysis of two Misery Indices (namely the Okun and Barro's indices) across 10 countries during 1970-2010 to investigate if there is a link between their evolution and international trends or type of government, measured by the political party in power.

The paper of Nordin and Said (2011) points that the macroeconomic performance of a country has to be periodically monitored, and indicates the use of Okun index for this purpose.

Grabia (2012) analyzes the various measures of the economic system's efficiency, both widely accepted such as the GDP per capita and subjective indicators such as the Okun Misery Index, the rationale being that the level of poverty might be a determinant of an economy's efficiency.

The study developed by Marvasti et al. (2014) found that an increase of Okun's index more than its threshold value is associated with a high income inequality. In a comprehensive study covering over 35 years Grant (2014) reveals that American households' macroeconomic perception has a multifaceted nature, being based mostly on genuine, individual perceptions of economic conditions, not media reports of economic statistics.

4. Regional and Temporal Distribution of the State of Economic Distress

Before proceeding to the computation of Misery indices, the time series of the macroeconomic variables had been seasonally adjusted because we want to capture those characteristics that seasonal movements tend to hide, especially changes in the direction of the series. Also, as a proxy for the EU households' economic sentiment we opt for the Economic Sentiment Indicator as it acts as a barometer of an economy's soundness and welfare. As the paper focuses on households' perception, we keep only one component of the ESI, namely the consumer confidence indicator, which measures the level of optimism that households have about the economy, in terms of current economic and financial situation, savings intention and expected developments regarding: consumer price indexes, general economic situation and major purchases of durable goods.

The time horizon covers the time frame 2001 to 2016. We rely on quarterly data collected from Eurostat so as to have a balanced sample of observations, not to lose valuable information and have an as accurate as possible picture on indices changes over time.

To test the ability of various Misery Indices of being a relevant, adequate and comprehensive measure of the state of economic discomfort, we computed the correlation matrix between each Misery index and the official EU indicator published by the European Commission, namely the consumer confidence indicator (CCI). A high statistical significance of the correlation coefficients between New Misery Index and respectively between Barro Index and the other indices suggests that these indices are likely to measure a similar dimension of the economic discomfort and hence, their simultaneous use in further empirical analyses might be redundant. The low levels of correlation recorded by the Okun and the Calmfors-Driffill Index indicate that they depict the state of economic discomfort by looking at different macroeconomic dimensions, and hence they will be further used in the cluster analyses, complementary with the Consumer Confidence Indicator, to give a more comprehensive picture of the level of distress dynamics.

In the following we performed a cluster analysis to identify similarities in the indices levels, and hence the presence of economic discomfort's concentration, from two perspectives:

a) *a temporal one*, which accounts for the magnitude of the economic state of discomfort felt in the entire EU, by using quarterly data series covering the period 2001-2016;

b) *a regional, spatial perspective*, to account for the granular state of economic discomfort perceived in each of the 28 EU member states, at key moments of time: 2007 - the year preceding the financial crisis; 2008 - the crisis onset; 2009 and 2010 – the years immediately after the crisis and the years 2011, 2012, 2013, 2014 and 2015 for depicting a more recent dynamics.

In our study, cluster analysis is used as a tool for data reduction, with the purpose of diminishing the large set of observations into a few, meaningful groups sharing common characteristics. The technique of clustering is an exploratory analysis, which reveals how the different time periods or countries cluster into groups, relying on the values recorded by the two indices mentioned above.

The group membership is established by identifying a set of homogenous time periods (in our case quarters), respectively countries. Entities that belong to the same group are characterized by the highest degree of similitude (in statistical terms minimum within-group variation) and maximum between-group variation. It is not a typical statistical procedure, as it doesn't aim at validating a pre-established research hypothesis but at discovering the intrinsic structure within the considered variables and aggregating the information on temporal or regional data (Yasodha and Ponmuthuramalingam, 2012).

We have applied the agglomerative hierarchical cluster analysis method, which starts by placing each entity in its own cluster, followed by successive mergers of resembling clusters until the obtaining of a single, large and heterogeneous cluster. The basic steps for performing a cluster analysis have been summarized below.

The first step is to measure the resemblance or similarity between the intrinsic characteristics of the indices considered. We employ the Squared Euclidean distance as it is best suited for continuous variables and it is able to accurately identify the outliers in the sample considered, by putting greater emphasis on entities depicting highly varying features. A high value of the Squared Euclidean coefficient indicates a low resemblance. Put in other words, it highlights the presence of pronounced discrepancies between the entities analyzed and hence greater heterogeneity across the time period or countries considered. On the other hand, the lower its value, the more resembling the entities included in a given cluster.

Secondly, one has to define a clustering algorithm, in the form of a linkage rule to determine when two clusters are enough similar to be linked together into a bigger group. We employed Ward's method, which uses the sum of squares for each entity in a cluster to find the grouping with the least sum of squares. Ward's minimum variance algorithm computes the sum-of-squares variance for each cluster and will merge only those two clusters that show the smallest increase in the value of the sum-of-squares variance (Liao, 2005).

The third step, comprising the final output of cluster analysis can be synthesized in the form of the hierarchical tree or dendrogram, which is the starting point for identifying the time frames or countries that show similar patterns of the economic discomfort. It helps indicating sudden, large jumps in the level of similarity as more dissimilar time frames or countries are merged.

The results of the first Cluster analysis, developed on a temporal perspective, revealed the presence of three clusters. The first cluster gathers most time periods, its specificity lying in that the quarters considered depict values around the mean for both Misery indices. The second cluster groups those quarters characterized by the lowest values of the two Misery indices or by values below their mean. Most part of the 2001 and 2002, the years 2006 and 2007 and the recent time period during 1st quarter of 2014 – 2nd quarter of 2016 correspond to the lowest levels of the economic discomfort measured for households in European Union countries. Overall, these are good signs for people's wellbeing, as the macroeconomic environment is improving. Looking at fundamentals we observe a persistent decline in inflation rate, relatively high unemployment rate (around 8%) and a current account deficit, as a share in GDP, of about 1.2%.

The third cluster gathers the time periods (years 2008, 2009, 2012 and the first 2 quarters of 2013) that recorded the highest values, well above the mean, of the two indices. Hence, these particular quarters that lastly join the group are characterized by distinctive patterns of misery relative to the other quarters in the sample, mostly driven by a high and persistent unemployment rate.

The output of the second Cluster analysis, based on a regional perspective to count for country-specific fluctuations of the discomfort indicators, provides valuable insights as we are able to detect how the financial crisis has accentuated the disparities between the EU member states.

The main two conclusions are:

1) there is a constant pattern of ressemblance between several countries, and consequently they persistently join into the same cluster for each and every year considered. It is the case of: Belgium, France and Italy; Greece and Spain in 7 out of 9 years considered; Austria, Denmark, Germany, Luxembourg, Netherlands and Sweden; Romania and Hungary in 8 out of 9 years. We might also argue that these countries depict a similar stage of economic convergence, at least in terms of inflation rate, unemployment rate and current account as a share in GDP.

2) related to clusters' number and composition, the years 2009 and 2015 witnessed the highest heterogeneity between countries, which have been clustered in four groups. Prior to 2009, the two Misery indices provided mixed signals of economic discomfort. For a given country, one of them point a low level of distress, in terms of inflation rate and unemployment while the other show a current account deficit, or viceversa. After 2009 and onwards, the two Misery indices evolved in the same direction. Starting with 2010, the clusters composition became highly unbalanced, the first cluster gathering most EU countries. In 2012 and 2013 it has appeared a cluster comprising two outlier countries, namely Greece and Spain, suggesting that they depict particular features, unressemblant to the ones of the majority of EU countries. By analysing the values recorded by the two Misery indices for the countries included in the first cluster, for each of the years 2010-2015, we noticed they always fluctuated around or slightly exceeded their average. Consequently, these countries record moderate levels of the economic discomfort. The clusters comprising Greece and Spain always faced the highest values for both economic discomfort indices. The remaining cluster constantly gathers the countries recording the lowest levels of both Misery indices.

To sum up, in 2007 and 2008 the analysis delineates between three main groups consisting roughly of: i) the core euro area members around Germany; ii) Western European countries and iii) Eastern European countries. During and after the financial crisis onset, only the core euro area group around Germany remained stable, being included in the same group composition, whereas the composition of the other two groups rearranged significantly into a crisis group and the group of less affected EU-members.

6. Conclusions

The paper aimed at assessing the degree of economic discomfort felt by EU consumers, as indicated by various forms of Misery indices and household confidence measures. The empirical findings summarized above have to be connected with the various ranges of monetary, fiscal policy measures or structural reforms adopted by these countries or at European level, in order to gain an insight on whether they have been efficient for improving the economic prospects and people's perception of wellbeing, which translates in a country's shift from one cluster to another. Several European and international bodies have stepped in and provided complementary financing tools and facilities, namely the European Central Bank provided liquidity support under various conventional and unconventional monetary operations, the European Commission has diversified its range of financial instruments meant to provide loans, equity and guarantees to end users, while the IMF has designed several financing facilities and instruments for addressing a country's balance of payments needs. Thus, this multifaceted array of financing tools has had the purpose of addressing the financial and economic challenges that have put pressure on people's standard of living. Specifically, they have been meant to alleviating the quality of financial sector and private sector's impaired balance sheets, to address the market failures and defreeze lending, investment and growth, and to lower the public debt deficits.

Therefore, by reconciling the spatial clustering of EU countries during the nine years considered with the policy measures adopted by EC and IMF, several reasons for the persistent positioning of Greece as an outlier country emerge. Greece was the first euro area country that requested financing from the IMF, in 2010. In addition, it is the EU country that has obtained the largest financing from European Commission's financial assistance mechanisms and this safety net is still active.

The results have shown that the global financial crisis indeed marked a turning point in the degree of economic discomfort felt by European population. In 2012 and 2013 two countries (Spain and Greece) clearly detached themselves from the other EU members, as their macroeconomic imbalances increased, becoming highly non-resembling with the majority, while for the end-2015 data Greece appears to be the only country depicting high values of economic discomfort.

The Synergy Mirage in Russian Industry: The Study of the Effectiveness of the Biggest M&A With Acquired Goodwill

Abstract

In this article we present the results of the study of the financial statements of the participants of the biggest M&A in the Russian industry. The aim of the research is to determine the declared reasons of the buyer to pay the price which exceeds the fair cost of the purchased company and to evaluate the degree of validity of buyer's decisions about such overpayment. The main hypothesis of the study is that usually goodwill in the Russian industry is recognized because of the buyer's expectations of the synergy effect from business combinations, which most likely will not be achieved later. For the analysis we have chosen financial statements of the acquiring companies that have made the biggest M&A deals in the Russian industry in 2008-2013. The selection condition is the recognition of the goodwill in their financial statement after the deal. In the next step we analyzed the financial statements for the 2009-2015 in order to reveal the occurrence of the goodwill impairment. For the companies that have not recognized the devaluation of the goodwill we have calculated indicators of assets payback for the end of each year and compared them with the identical indicators before the M&A. This allowed us to evaluate the changes in the effectiveness of the combined business. Results of the study confirmed the hypothesis that the most frequent reason of the acquired goodwill is the synergy effect which is expected by the M&A participants. However, the results of the yearly tests for the goodwill impairment and the analysis of the merged company assets payback show that such expectations are mostly unfounded. Practical implication of the study is the revealing of the low efficiency of the methods which are used to predict the M&A results. Every year it leads to the millions of losses from the goodwill impairment and decline in the merged company efficiency. This situation creates a threat to the development of the Russian industry. We have concluded that in order to decrease this threat a new synergy effect evaluation methodology is needed. Such methodology will take into consideration the probabilistic nature of the synergy effect. The novelty of the paper is the subject of the research: obtaining of the synergy effect in the M&A deals in the Russian industry. Goodwill here is considered an indicator of the deal efficiency.

Keywords: mergers and acquisitions, Russian industry, synergy, goodwill, impairment.

Introduction

Mergers and acquisitions (M&A) is one of the most popular strategies for business development. Strategies connected with expansion of an existing business by an established business are usually viewed as less risky as opposed to creation of a new business. At the same time, M. Bradley, A. Desai and E.H. Kim have confirmed that only 7% of M&A deals lead to an increase of value of a merged business (Bradley et al., 1988). A more recent research of M.A. Hitt, J.S. Harrison and R. Ireland showed similar results: most M&A don't produce any additional value, or produce it in very small amounts (Hitt et al, 2001). J.W. Hunt has decided that almost half of all the M&A does not generate synergetic effects (Hunt, 1990). M.L. Sirower has proved that 70% of M&A brings fewer profits, than a premium, paid for an acquired business (Sirower, 1997). A. Agrawal and J. Jaffe have stated that within the first years after conducting the M&A the income of the merged business gets lower or stays the same (Agrawal & Jaffe, 2000). Despite the unfavourable statistics, while conducting the M&A, the buyer often pays for acquired

business the price that exceeds the fair value of its net assets. The central issue of this research is to determine the justification of such overpayment, which is recognized as goodwill in financial reporting of Russian manufacturing enterprises.

In the 2000s the obligatory annual goodwill impairment test was implemented in International Financial Reporting Standards. Starting from that point researchers have got the opportunity to study the justification of goodwill in M&A on the basis of the information containing the volume of recognized goodwill impairment. An economic nature of goodwill must reflect expectations of buyers concerning the possible synergetic effects, that can be implemented as a result of M&A procedure and would lead to an increase in profits of business and capability of the acquired company to generate an excess profit. However, in practice goodwill can sometimes be acknowledged due to some mistakes in fair value measurement of assets of an acquired company, tender overpricing and other "waste" components (Johnson & Petrone. 1998).

Theoretically speaking, only the entrepreneur knows his or her own state of affairs best, and so, acknowledging the goodwill impairment losses can be a signal that says the following:

1) potential synergies haven't been implemented;
2) acquired company has stopped making excess profits;
3) goodwill consist wholly or partially of "waste" components.

In practice multiple researches showed the high degree of subjectiveness in goodwill evaluation while conducting the impairment test (Generalova et al., 2016). This fact doesn't allow to fully trust the financial reporting in this question. Sometimes there is a high possibility that the goodwill has been impaired, but the losses from its impairment were not acknowledged.

Such researches have never been conducted in Russia despite the more than 25 year experience of market relations. The key branch of the Russian economy is an industrial sector, that's why the subjects of this research are groups of companies in partnership with Russian industrial enterprises. Authors have formed and tested the hypothesis of the research: acquiring of the synergetic benefits for manufacturing industry in Russia is the main declared reason for buying a company at price, exceeding the fair value of its assets (such exceed is often considered to be a significant one). This being said there is a high possibility that potential synergetic effect would not be achieved, and more than that, effectiveness of buyer's resources exploitation would be lowered.

Data and Methodology

We have continued the research of A.E. Ivanov and used his selection of companies (Ivanov, 2016). He summarized the results of annual overviews of mergers and acquisitions of the "Mergers and acquisitions in Russia" project of KPMG group, "Mergermarket" analytical agency, "Mergers and acquisitions" journal and AK&M news agency. The results showed the biggest M&A deals in 2008-2013, where Russian industrial enterprises were either buyers or sellers. Then the deals, where the buyer was a non-public corporation, were excluded from the list due to the fact that financial reporting of such companies is not publicly available and therefore is not subjected to a mandatory audit. This fact doesn't guarantee its credibility. In order to provide the compatibility of financial reporting data of industrial groups and consistency of the following deductions, deals where buyers were groups that don't disclose their financial reporting in IFRS (or US GAAP), were cast out. As the result of the following analysis of financial reports of the members of the deals that remained in the research, the acquisitions, where the goodwill wasn't acknowledged, were also crossed out. The readings of the reports were re-counted in USD millions at the official conversion rate of Russian Central Bank at the date of the deal conclusion. If the exact date of the deal conclusion was unknown, then the recalculation was made by the end of the month in which the deal was closed. If the month of deal closure was also unknown, then the recalculation was conducted by the end of the report year. Hence, the selection was formed and it now

includes 60 largest M&A with involvement of Russian industrial companies (10 deals for each year) that ended with the recognition of goodwill in financial reporting of the buyer.

We have used the improved methodology, originally developed by A. E. Ivanov (Ivanov, 2016). Unlike the original research project, we've studied the financial reports of the selected industrial groups over the two years that followed the year of performing the M&A. The choice of the two-year period is due to the fact that the greatest risk of goodwill impairment arises in the first two years after the implementation of M&A (Ramanna & Watts, 2012, Ivanov, 2015). We've defined the exact volumes of dealings, the amount of goodwill, acknowledged in financial reports, and justification of its appearance. Then we have analyzed the stated financial reports over two years that followed the year of performing the M&A, in order to unravel the facts of writing-off the acquired goodwill as the result of impairment. If the group wouldn't agree to disclose the information on goodwill impairment, acknowledged in a certain deal, we then would analyze the goodwill fluctuations according to the reporting segments. If the information on segments was not disclosed in financial reports, we would analyze the fluctuations of goodwill in its entirety. If there were no signs of goodwill impairment in the segments or in the whole group, then we would make a conclusion that the goodwill was preserved in the original amount. If some of these patterns could be detected, then we would stop tracing the following fluctuations of goodwill because of the impossibility to ascertain which goodwill exactly was impaired. To preserve the compatibility of the data we've recalculated the goodwill balance-sheet value, acknowledged in roubles or in other national currency, into the USD at the official conversion rate, determined by the Bank of Russia at the end of the corresponding year. Therefore, we've specified the M&A, ended in acknowledging of the goodwill impairment two years after the deal closure.

We have calculated and compared the ROA indices over the year that preceded the year of M&A, and over the year in which the impairment losses were registered for companies which have registered the goodwill impairment. We've increased the financial result of the company by the impairment sum in order to rule out the influence of the recognized goodwill impairment losses on ROA index. Comparing the above mentioned indices allowed us to detect the connection between the decrease of ROA and impairment losses acknowledgement. Then we've calculated the ROA of buyers, who haven't acknowledged the goodwill impairment in financial reports in the year, preceding the conduction of M&A and in the first two years that followed the year of M&A conduction. The ROA index characterizes the effectiveness of group assets' effectiveness. In the works of (Li & Sloan, 2009, Jordan et al., 2011) the strong positive correspondence between the decrease of ROA and goodwill impairment losses acknowledgement was proved. Therefore, the decrease of ROA is an important indicator of the fact that potential synergetic effect was, possibly, not achieved, despite the goodwill impairment losses were not acknowledged.

Results and Discussion

Analysis of the reports of financial groups that made it to the selection allowed us to prove the part of the hypothesis that explained the motives for buying a company at a price, exceeding the fair value of its assets. In financial reports of some buyers there were no justification of goodwill (it is a characteristic feature of reports made in 2008-2009, later reports of Russian industrial groups disclose more information). Sometimes the financial reports of buyers would explain certain motives. The most frequent one: in 33% of cases the recognition of goodwill was explained by the expectation of synergetic effects appearance from interaction with the acquired company. A range of buyers described the synergetic effects in a more specific way: it's the increase in sales of the group due to entering the new markets, the use of intellectual capital to increase the labor productivity in a merged business, the cost savings while implementing the economy of scale etc. In practice, the only motive that wasn't connected with synergy, was the pay for assuming control over the acquired company – such motive was declared in 7% of cases, but it always neighbored with the expected synergy. From there, we've stated that the expected synergy

for Russian industrial sector is the main declared motive for acquiring a company at a price, exceeding the fair cost of its assets.

The part of hypothesis about the relevance of goodwill amount in the cost of acquired companies has also been proven. The average relation of the amount of acknowledged goodwill to the refurbishment for the acquired company amounted to 44%. The similar results (40-50%) were shown in the previous research of T. Laamanen (Laamanen, 2007).

Table 1 provides the data, concerning M&A that ended in recognition of goodwill impairment in financial reports of the buyer.

Table 1: the data on the deals ended in recognition of goodwill impairment in the first 2 years after conducting the M&A deal

Factor	The year of the deal						Total
	2008	2009	2010	2011	2012	2013	
The amount of deals ander analysis	10	10	10	10	10	10	60
The amount of deals that ended in recognition of goodwill impairment	7	1	1	5	3	0	17
The amount of deals that ended in recognition of goodwill impairment, and in the ROA index decreasing in respect to ROA of the year, preceding the M&A year	7	1	0	5	3	0	16
The average reduction value of ROA in the year of recognition of goodwill impairment in respect to the ROA of the year, preceding the M&A year	91%	32%	-	149 %	76%	-	103%

Source: financial reportings, authors' calculations

The main reason for goodwill impairment that was stated in financial reportings of the analysed groups became the reducing of the prognosed cashflow rate of the acquired company. The ROA of the year, in which the impairment losses were recognized, have decreased in relation to the year that preceded the year of conducting the M&A in 94% of cases and this fact proves the conclusions of the previous research material on the strong positive correlation between the decrease in ROA and goodwill impairment (Li & Sloan, 2009, Jordan et al., 2011).

Table 2 gives the data on M&A which didn't end in goodwill impairment recognition during the first two years after the closure of the deal.

Table 2: The Data On M&A, Which Didn't End In Goodwill Impairment Recognition, During The First Two Years After The M&A Conduction

Factors	The year of the deal						Total
	2008	2009	2010	2011	2012	2013	
The amount of deals under analysis	10	10	10	10	10	10	60
The amount of deals in which the acquired company either was sold within the stated period, or it was impossible to identify whether the goodwill lost value.	1	3	2	1	1	5	13
The amount of deals in which in the first 2	2	6	7	4	6	5	30

years after the M&A, the impairment of goodwill wasn't recognized							
The amount of deals in which the goodwill impairment wasn't recognized in the first 2 years after the M&A, and the average ROA index kept decreasing in the first 2 years after conducting the M&A in relation to the ROA of the year that preceded the M&A year	2	1	3	4	6	3	19
The average value of the decrease of the average ROA in the first 2 years after conducting the M&A in relation to the ROA of the year that preceded the M&A year	29%	117%	74%	34%	76%	54%	61%

Source: financial reporting, authors' calculations

We have stated that 36% of the largest M&A with involvement of the Russian industrial enterprises in which the goodwill was recognized have ended with its impairment within the first 2 years after the closure of the deal. This leads to the acknowledgement of the aggregate loss over 4,5 billion USD. What is more, in 40% of cases the average ROA was lowered significantly within the first two years after conducting the M&A as opposed to the ROA of the year that preceded the year of M&A. It is impossible to derive that such decrease is directly connected with the M&A, however, these results justify the more close and detailed study of the segmental reporting of the stated groups and also the individual accounts of the acquired companies. Unfortunately, financial accounts under IFRS in Russia are made not by all industrial groups and enterprises, and the rules for preparation of Russian financial statements differ significantly from IFRS requirements. This complicates the conduction of the massive research projects, involving econometric modelling of the correlation between the acknowledged goodwill in M&A, its share in assets of the group, and the decrease of ROA index after the closure of the deal that ended with the goodwill impairment. The following continuation of our research of the whole market of M&A can be made possible by the expansion of the selection with groups that belong to other fields.

Conclusion

The results of the conducted research proved our hypothesis: the expected synergy in M&A with the participation of Russian companies will most likely be a mirage. We think that the evaluation of the target company shouldn't be based on the assumption that the synergy will definitely be achieved, but rather it should make allowance for its achievement. Insufficient judgement while preparing for an M&A deal leads to an increase in entrepreneurial risk rate. However, methods of assessment of the target companies utilized in practice in Russia are usually based on the evaluation of its discounted cash flows after the merging due to the lack of sufficient data necessary for applying the market-based approach. Such evaluation is characterized by a high degree of subjectiveness and, as the research showed, it often leads to overestimating the deal price. Therefore, we came to a conclusion that the effectiveness of implementation of M&A as an entrepreneurial strategy in Russian industrial sector suffers from the insufficient level of development of synergetic effects evaluation tools.

Abstract

The relevance of the quality of institutions evaluation increased after the recognition a slogan – "important institutions" by a scientific community. The article is based on the review of scientific publications carried out a classification of existing approaches to the assessment of institutions. Exclusive conceptual approaches (social, entropy, dysfunctional, costly, effective, and pragmatic) and approaches implemented at the empirical level (comparative, legal, regulatory, and behavioral) were dedicated. A new key drawback of the popular method for institutional assessment – method ratings – was found. Modern methodological problems of assessing the quality of institutions regardless of the level of study were defined in this article. According to these problems the most popular are abstraction from the internal structure of the institutional system and the complementarity of its elements and concentration of estimates at the output of the system. For correcting actions of this key disadvantage the concept of the institutional option described on the example of small enterprises of the Russian industry was proposed. In conclusion part, practical importance of the concept in the assessment of the quality of institutions at all levels of study was presented.

Keywords: mergers and acquisitions, Russian industry, synergy, goodwill, impairment.

Introduction

Institutionalists argue that any institutional environment forms a certain level of transaction costs, the structure of which determines the forms and mechanisms of doing business. However, the low quality of the institutional environment, and therefore an excessive burden of transaction costs sharply affect the interests of small enterprises (SME). This is due not only to the specifics of these forms of entrepreneurship, but also to the high volatility of the macroeconomic conditions in recent years.

In Russia the industrial enterprises are in the worst situation from all industries. Excessive burden of transaction costs on these businesses impose costs of formation of demand for products, search of the investor, the excess tax burden under the standard tax system. The survival of small producers in conditions of chronic scarcity of resources and low quality of institutions leads to the formation of such informal institutions as “salaries in envelopes", “encashment", "one-day firms", "kickbacks" and so forth. In such circumstances a number of methodological issues adequate assessments of the quality of institutions for SME are revealed.

In this article, firstly, the role of institutional factors, depending on the volatility of macroeconomic conditions for the development of SME was assessed. Further, systematization of accumulated knowledge in the field of quality assessment of institutions, both in Russian and world scientific literature was proposed. Main drawbacks of the existing approaches and methods of evaluation were presented, after that the author's concept of the institutional option was proposed as a contribution to the solution of methodological problems of assessing the quality of institutions on the example of small enterprises of the industry. In conclusion the possible applications of the concept of institutional option were shown.

The importance of institution quality for development of SME in Russia

We assessed the significance of institutional environment for development of SME in Russia, using the following source limitations.

1. As indicators of SME development two types of indicators were selected: absolute indicators: number of small enterprises in Russia, number of small enterprises in industry; and relative indicators: number of small firms per 10 000 population (density, MP), the number of small enterprises per 10 000 population (density, WFP).

2. The time period of analysis is divided into two: 2003-2007 and 2008-2014. This is necessary to ensure the comparability of SME development indicators before and after 2008, in which criteria for attributing to SME entities in Russia was expanded. In addition, in 2008 the first wave of the global financial crisis took place, therefore, these two periods can be designated as pre-crisis and post-crisis.

3. As is customary, key international ratings were used to assess the quality of institutions: "Perception of corruption", "Government Effectiveness", "Business", "Quality of legislation", subscript in the rating of "Global competitiveness" – the "Quality of institutions", within the ranking of "Economic freedom" – "Fiscal freedom" and "Property Rights".

As shown (Table 1), during the pre-crisis period the SME developed in the context of stable growth of oil prices and GDP prices against to the low quality of institutions.

Table 1: dynamics of indicators in the pre-crisis period

Indicators	2003	2004	2005	2006	2007
The business place, place	–	–	79	96	106
Property rights, scores	30	30	30	30	30
Fiscal freedom, scores	90,6	91,6	91,5	90,8	79,5
Perception of corruption index	2,7	2,8	2,4	2,5	2,3
Quality of institutions, scores	–	–	3,0	3,1	3,3
Government effectiveness, rank	40	44	38	40	43
Quality of legislation, rank	48	50	50	39	42
Economic Sentiment Indicator (Index HSE)	101,2	101,8	101,6	107,9	115
The index of business confidence in the industry	1,25	0,25	-1,5	0,25	1,25
The price of oil, $ per barrel	28,9	33,3	54,4	65,4	72,7
GDP growth rate, %	107,3	107,2	106,4	108,2	108,5
Number of MP, thousand units	882	891	979	1032	1137
Number of WFP, thousand units	119,0	128,1	126,5	131,6	138,0
Density of MP, units per 10 000 population	60,8	61,7	68,1	72,1	79,6
Density of WFP, units per 10 000 population	8,2	8,9	8,8	9,2	9,7

Source: compiled by the authors on open data of Rosstat, the HSE, the World Bank, World Economic Forum, Transparency International, The Heritage Foundation.

This means that the presence of relatively stable and effective demand in terms of economic growth leveled the lack of qualitative institutions for entrepreneurship.

In the post-crisis period extensive development of the SME continued background of weak post-crisis economic recovery (Table 2).

Table 2: Dynamics of Indicators In The Post-Crisis Period

Indicators	2008	2009	2010	2011	2012	2013	2014
The business place, place	118	120	124	120	112	92	62
Property rights, scores	30	25	25	25	25	25	25
Fiscal freedom, scores	79,2	78,9	82,3	82,7	82,5	86,9	85,6
Perception of corruption index	2,1	2,2	2,1	2,4	2,8	2,8	2,7
Quality of institutions, scores	3,2	3,2	3,1	3,1	3,3	3,5	3,5
Government effectiveness, rank	45	43	40	41	41	43	51
Quality of legislation, rank	39	39	40	39	39	38	37
Economic Sentiment Indicator (Index HSE)	105,7	81,3	101,5	104,5	105,6	100,1	97,9
The index of business confidence in the industry	–2,5	–13	–3,5	–0,25	–0,25	–1	–4,75
The price of oil, $ per barrel	97,7	61,9	79,6	111,0	121,4	108,8	98,9
GDP growth rate, %	105,2	92,2	104,5	104,3	103,4	101,3	100,6
Number of MP, thousand units	1347,7	1575	1644	1836	2003	2063	2352
Number of WFP, thousand units	156,6	180,1	181,3	188,9	211,4	215,9	224,1
Density of MP, units per 10 000 population	94,4	110,4	115,1	128,5	140,1	144,0	163,7
Density of WFP, units per 10 000 population	11,0	12,6	12,7	13,2	14,8	15,1	15,6

Source: compiled by the authors on open data of Rosstat, the HSE, the World Bank, World Economic Forum, Transparency International, The Heritage Foundation, The Wall Street Journal.

It can be seen that the average annual rate of growth significantly accelerated from 6% to 11% for the whole economy and from 3.8% to 7% for the MP industry. We believe that this was facilitated by several types of institutional changes, namely:

1) a significant reduction of transaction costs of opening a new enterprise, which is reflected in the improvement of Russia's positions in the rating "doing business";
2) a slight decrease in the total tax burden at the macro-level;
3) a change of the criteria for small businesses, which expanded this sector.

Thus, the importance of the institutional factor increases during periods of stagnation and recession of economy. During the same periods, entrepreneurs are most sensitive to the quality of the institutional environment.

Modern Approaches to the Assessment of Institutions

Due to the existing variety of methods and the parameters for assessing the quality of institutions authors attempted the systematization of the accumulated experience in assessing of institutions, based on a set of initial constraints.

1. For the selection of scientific papers, we used the concept of "evaluation of institutions/institutional environment", "quality assessment of institutions/ institutional environment", "evaluating the effectiveness of institutions/ institutional environment".

2. The concept of "efficient institutions" and "institutional quality" we considered as synonyms. In a modern institutional economics, both these terms are mentioned when talking about the results of institutional functions.

3. The whole range of possible approaches to the assessment of the institutional environment regardless of the level of research and carrier was considered.

4. We divided the approaches to evaluation into two types - implemented in practice and developed exclusively conceptually. In determining the names of approaches, we focused on the essence of the approach in the author's presentation.

Among the exclusively conceptual, from our point of view, we can distinguish the following approaches:
- Social (Authors: V.V. Volchik and I.V. Berezhnoy [2007]),
- Entropy (Authors: S.A. Dyatlov [2015], E.V. Balatsky [2007]),
- Dysfunctional (Authors: O.S. Sukharev [2013], V. M. Polterovich [1999]),
- Cost method (Authors: E.V. Popov, A.Y. Veretennikova, M.V. Vlasov [2011]),
- Effective (Author: E.V. Balatsky [2007]).

Approaches implemented at the empirical level include:

- Comparative / competitive (Authors: Rodric D. Subramanian A., Trebbi F. [Rodric, 2004], A. Baranov, E. Malkov, L. Polishchuk, M. Rohlin, G. Syunyaev [Baranov, 2015], V. Polterovich and V. Popov [Polterovich, 2006], Kunčič A. [2014], LiPuma, J.A., S.L. Newbert, J.P. Doh [LiPuma, 2013], T.P. Loginova, I.N. Polushkina [Loginova, 2012], E.A. Panfilova [2013], K.I. Nikitina [2013], J.A. Alonso, C. Garcimartín [Alonso, 2009], A.V. Gorshkov, E.S. Silova [Gorshkov, 2006]).
- Legal (Authors: S.G. Kirdina, I. Kirilyuk, A. Rubinstein, I. Tolmacheva [Kirdina, 2010], La Porta R., Lopez-de-Silanes F., Shleifer A., Vishny R. [La Porta, 1997; 1998], Buchanan J. [2014]),
- Standard (Authors: Voigt S. [2013], L. Feld and S. Voigt [Feld, 2003]),
- Behavioral (Authors: T.V. Morozova, G.B. Kozyreva [2015]).

As it can be seen, the most commonly used is a comparative approach, based on the rating and index methods. Today generally accepted metrics of quality of institutions are such well-known international indexes, like the Worldwide Governance Indicator Doing business, The Global Competitiveness Index, Index of Economic Freedom, Corruption Perception Index Rule of Law Index, Investment Climate Index and institutional index project BEEPS.

However, criticism of the rating evaluation in the scientific literature circulated not less than the method itself. Disadvantages of the ranking method were described by Knack St., [2006]; Thomas M., [2010]; Kurtz, M., A. Schrank [2007], Kurtz M., A. Schrank [2007], P. Bardhan [2002].

The concept of institutional matrices, which is developing today in the Russian institutional school, complements this criticism with a new observation: the vast majority of international ratings assess the

institutional changes in the economies of different countries in terms of their compliance with the market development paradigm. In the context of the theory of institutional matrices it is, in fact, tantamount to the evaluation of the level of development of institutions specifically to national economy compared to countries-carriers of the Y-matrix. But, according to research by S.G. Kirdina [Kirdina, 2016] many countries are carriers of the X-matrix. In addition to Russia they are China, North Korea, Nepal, Republic of Korea, Japan, Brazil, Egypt, Cuba, Laos, Mexico, Myanmar, Peru, India etc. Is this existing standard Y-matrices applicable to the institutional systems of these countries? If the answer is yes, so to what extent and if the answer is negative, what should be the standard of quality of institutions for the X-matrix? These questions do not even appear in the world scientific community.

In general, there are a number of key methodological problems of assessing the quality of institutions regardless of the level of research:

1. The deficit of the concepts brought to empirical testing with respect to a specific carrier of the institutional environment.
2. The absence of an universal method of evaluation.
3. The market paradigm of assessment, incorporated in the most popular method of ratings, does not allow to fully trust the obtained results.
4. Abstracting from the internal structure of the institutional system and the complementarity of its elements.
5. The concentration of evaluations at the "output" as a result of the "work" of institutions.

The Concept of an Institutional Option

In the process of scientific research of decision-making processes by an individual / group of decision-makers it is possible to precede from institute – specific tasks which it can solve, a kind of "specialization" of the Institute; and from task – search the institutional technologies through which it can be solved. In the first case, there is a problem option of the institute, in the second case - an institutional option for solving the problem.

However, the institute is only one of the possible solutions of tasks facing the firm/individual. Along with the institute, there is also the opposite technology – non-institutional behavior. Consequently, the solutions of the problems have institutional and non-institutional nature. In the case of institutional option we are talking only about the first type.

Institutional option is the set of alternative options of institutional solving the problem, which are available to economic agents and used to coordinate their actions. We offer the term bunch of institutions – a set of interrelated formal and informal institutions used by economic agents for solving a particular problem, achieving a particular goal. In other words, institutional option describes a choice made by economic agent from the set of options for institutional linkages.

Theoretically, the number of possible bunches tends to infinity, but in reality, due to the cognitive limitations of the person, as well as the asymmetry of information, the individual / decision maker is not able to consider all possible institutional connections (like all possible solutions to the problem). This means that the institutional option at the individual / decision-maker level is always limited to a small number of options. So, a management of the company, when developing a strategy, business plan or justification of other management decisions, chooses, as a rule, 3 scenarios of events.

The term “bunch of institutions” allows the researcher due to the limitations of structure and disorder of the institutional environment to "work" not with a single element or a whole set of institutions at once, but with the part of the institutional system, which can be conditionally classified as a relatively independent object of study.

Let us formulate the basic properties of the institutional option as a separate category.

1. Hierarchy – institutional option may be selected at several levels of study – of an individual (employee) level, individual firm level and at the macro level as a whole. At the level of the whole society institutional option will be a combination of all the types of institutional solutions to the problem used by the actors.

2. Breadth of the option (differentiation) – number of bunches. As already noted, at the level of individual actors institutional option has got a limited number of institutional bunches, at the macro level the number is unlimited, while the number of possible combinations of institutions tends to infinity. The wider institutional option is, the higher the differentiation of behaviors (solutions for problems) becomes. According to the ideas of V.M. Polterovich, one of the fundamental principles of institutional reforms is "maintaining the diversity of institutional forms. The richer "institutional life" is, the more opportunities to exit from institutional traps appear" [1999]. G. Haken, in the framework of synergetics claimed that in case of conflict situations when one decision fundamentally excludes the other, the only solution is to increase differentiation [Haken, 1988]. However, we believe that in relation to the latitude of the option measure is very important, since an increase in the latitude of option reduces the predictability of the behavior of actors, increasing the entropy and the probability of transition of the whole economic system into chaos.

3. Coordinating property – institutional option implements the choice of actors within the institutional technologies of the solution. The starting point is the availability of some problems of development in individual / individual firm. Awareness of the problem allows formulating the problem for next solving. It is human nature firstly to appeal to existing patterns of behavior – social experience as it saves resources and time required for decision-making. After reviewing a set of institutional solutions "proposed" by legal system and current business practice – institutional option, the individual/group decision maker selects and implements it. The choice in favor of a particular bunches of institution is influenced by many factors, among which motives of decision-making, asymmetry of information and cognitive limitations of decision makers can be highlighted as the main. If, a necessary institutional solution is not found because of different reasons (ignorance, the lack of templates, the motives and incentives), the individual / group decision-makers are forced to use non-institutional solution based on their own intuition and experience.

4. Relevance (sufficiency) of an option is determined by the actual behavior of the actors, whether they choose those bunches that are represented in it, and with what frequency. In our opinion, the relevance of institutional linkage can be recognized when it is used by more than 0.5% of actors (more than 5 cases out of 1000). If there are an increasing number of the most popular bunches with the specified limit in the total number of ligaments, the higher the demand for the option will be. Accordingly, the previous property and the adequacy of the option are not interdependent. The option may be differentiated (a wide variety) but it is not required (most of bunches are not used by the actors) and vice versa.

5. Semantics of option is the semantic content of its elements. Evaluating the quality of an option, it is impossible to abstract from the semantics of institutions, since it allows characterizing the institutional mapping in the option as a destructive or constructive. An important thing is the perspective from the position of whose interests we evaluate the option. For example, the destructive bunches are viewed from the point of view of the authorities; the institutions of the shadow economy for entrepreneurs can be quite rational choice, allowing to reduce transaction costs. In addition, semantics helps to determine the coherence of institutions – options for their combination among themselves and, consequently, affect the breadth of the institutional option.

6. Institutional option as well as many institutional changes, depend on technological progress. Such influence extends to all stages of the life cycle as individual institutions and institutional option in

general. In modern science, the relationship has not been properly studied yet. In our opinion, this effect is easy to find out on the example of information transfer technologies. The development of Internet technology leads to the fact that open access has an extensive knowledge base, data sets, ready analytical solutions and algorithms. Nowadays there are various forums for specialists, Internet community, social networking, online consultation of experts, the database of normative and technical documents, database of reviews of various type, etc. on the Internet. All this increases the availability of collective experience in solving a variety of problems. As a result, the speed of information dissemination increases, which generally reduces the level of transaction costs of acquiring knowledge and data. So, the development of Internet technology leads to the fact that new institutions arise and propagate much faster than before. Thus, the individual can address to his collective (social) experience – the institutional solution of the problem - at any time with little transaction costs to solve his specific task. In this case, the influence of the Internet on the breadth of the institutional option of the individual / firm is obvious, compared with the situation of the absence of such technologies (search through books, the press and acquaintances).

These speculative arguments about the institutional properties of the option let us assume that it is the main mechanism of self-organization of institutional systems.

We will describe the institutional option on the example of one of the main problems of the development of the small industrial enterprises according to surveys – a high level of the tax burden. The figure 1 shows the logical scheme of institutional option in a macro-level for this case. As shown, the social experience (the country's legal system and informal institutions, the business community) is the original base of the institutions, which small companies use to generate various institutional bunches. At the level of each individual small firm institutional option is determined by the group decision maker or owner themselves. It is obvious that institutional option will contain significantly fewer valid, from the perspective of the decision maker, bunches of institution, than institutional option on macro levels, where the entire set of potential bunches is presented.

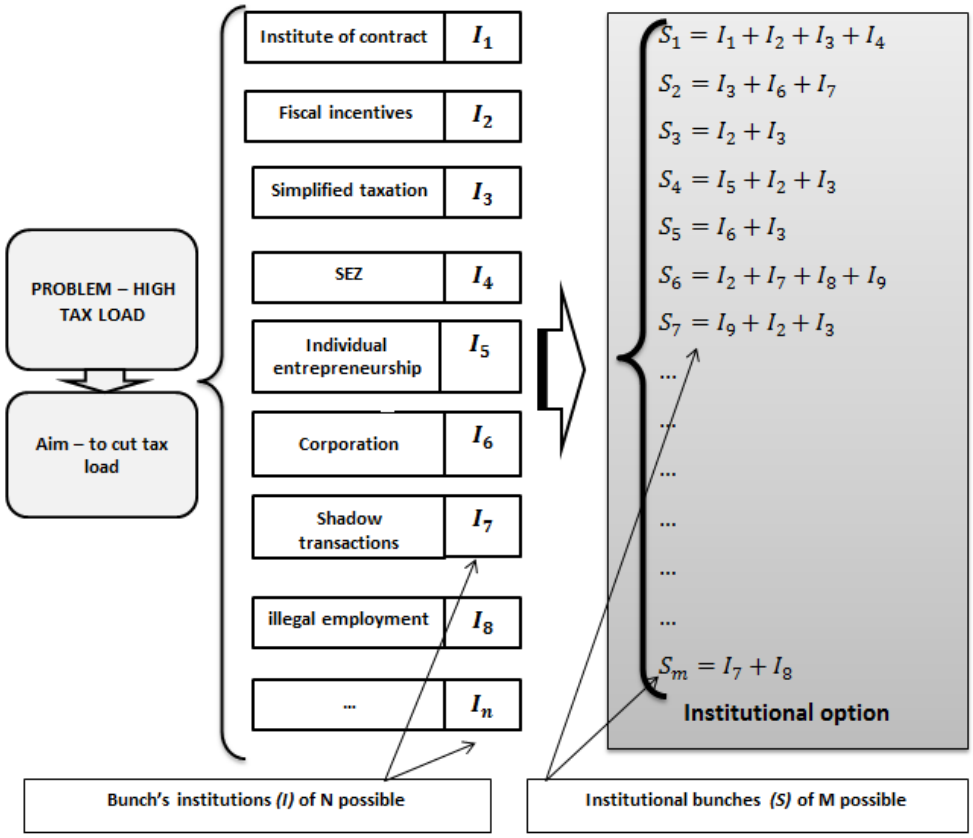

Fig.1: The logical scheme of institutional option for the problem field MPP-high taxes (macro-level).

Based on the practice of existing methods of tax optimization for small enterprises, we selected the following institutions as the initial elements of ligament fillers:

1) Formal – Simplified Tax System; benefits provided by general tax regime, including tax accounting rules, using which a taxpayer can reduce the tax base; taxation for residents of special economic zones, including offshore ones; the institution of the contract, in particular, the lease of real estate; institute of the individual entrepreneur, for which since 2017 "tax holidays" are available; institute of the economic society, including both options for creating new firms, "friendly", subsidiaries and affiliates, one-day firms, and business reorganization in order to optimize taxation (separation, allocation);

2) Informal institutions – shadow turnover and shadow employment.

Small industrial enterprises form bunches, combining in different variants the listed institutions (on the graph this is reflected through the addition of the institutes- elements I), and thereby solve the problem of excessive tax burden each within their own targets.

Conclusion

In conclusion, the concept of institutional option is useful for evaluating the quality of institutions, including small industrial enterprises. The main advantage of an institutional option is that it is empirically studied with respect to specific problems of enterprise development.

The category of institutional option can be applied to the extent of its practical suitability, being aware of the instrumental and conditional nature inherent in all scientific concepts. In particular, the empirical value of the proposed approach is expressed in the fact that it allows:

a) assess the degree of differentiation of institutional support for specific problem fields actor;

b) identify institutional ligament competitors, existing as institutional support for the solution of a particular problem of a small firm;

c) improve the quality of analysis of institutions at any level of study: macro, meso, micro, mini;

d) take into account the structural complexity, complementarity and semantic content of institutions in the quantitative assessment of the quality of institutions;

e) identify the mechanism of action of such institutional environment phenomena as the stability of individual institutions and ligaments in time, including the phenomenon of "institutional traps", the neglect of institutions, the immutability of institutional matrices;

f) usage of a "problematic" paradigm in the formation of an option allows a quantitative assessment of the quality of the institutional environment in dynamics, since binding to a particular "problem field" of the environment enables to compare options in terms of semantics and latitude in time.

Abstract

The emergence of massive amount of data in clinical and healthcare fields leads to the need to implement a Big Data Analytics platform in medical area, due to the advantages of scalability and efficiency of these proven architectures and platforms in the processing and management of large datasets. Big Data Analytics is the process of analyzing huge amounts of data from different sources of data and different formats, like electronic health records, prescriptions, medical imaging or genomic data in order to deliver useful information used to take decisions in real time. Software tools and applications for predictive analytics or data mining enable those implied in healthcare industry to improve the quality of clinical services or an early diagnosis of diseases. Big Data Analytics can generate revenues by providing insights for third parties, such as payers (patients, health insurance companies), or pharmaceutical. In the paper we will present issues and how we intend to solve them with an open source platform for clinical Big Data processing. The objective is to facilitate development of more efficient clinical and healthcare applications and improve accuracy of predictions.

Keywords: Clinical data, EHR, Big Data Analytics, architecture

1 Introduction

Continuously generating massive amounts of large data in fields such as financial, IoT, transportation, healthcare, marketing, agriculture and retail, has prompted the emergence of technologies dedicated to the acquisition, storage, management and analysis of Big Data. In recent years, Bahga and Madisetti (2016) reported that an explosion of clinical data has been observed and both data collection from distributed health information systems and clinical data processing and analysis have become critical problems.

We can speak of a healthcare ecosystem as Bahga and Madisetti (2016) mentioned, consisting of patients, payers (government, health insurance companies, employers), suppliers (doctors, medical institutions), pharmaceutical companies and other medical service companies and medical devices companies. Clinical patient information is aggregated with ecosystem information (laboratory results, diagnostics, treatments, demographics) and is found in EHR (Electronic Health Record) systems.

Data generated in real time, as in Balladini et al (2015), by medical equipment from patient-connected sensors for measuring physiological parameters (heart rate, respiration rate, body temperature, blood oxygen saturation, blood pressure), established diagnostics, laboratory tests, data generated by evaluation equipment of patients continuously, the data collected from the critical patient monitoring systems (vital signs), reported by Poucke et al (2015), are considered clinical data. Clinical data along with physicians, written prescriptions, pharmacy, insurance, social media posts,

blogs, web pages, publications about health form Big Data in healthcare. Because daily, millions of records can be collected just of the ECK parameter (1000 samples per second) for a single patient, as in Balladini et al (2015) and the clinical data comes from different sources, has different formats and is generated with different speeds, we may consider that we are experiencing a Big Data problem in healthcare.

Thanks to digitization, Big Data Analytics has grown in the healthcare sector, which promises benefits both for the patients in the healthcare institutions and the quality of clinical services, as well as for the stakeholders to reduce the cost and to a rapid improvement of quality in healthcare reported by Poucke et al (2015), Raghupathi and Raghupathi (2014). Analytics refers to processes, technologies, frameworks, and algorithms as Bahga and Madisetti (2016) mentioned, that extract fruitful information from rough data. There are four types of analytics - descriptive analytics, diagnostic analytics, predictive analytics and prescriptive analytics. Descriptive analytics wishes to answer the question, "What happened?" and refers to analyzing past data in an easy-to-read form. Diagnostic Analytics wishes to answer the question "Why has it happened?" and refers to analyzing past data to diagnose the reasons some events happened. Predictive Analytics refers to predicting the occurrence of an event, the probable outcome of an event, or predicting future values using prediction patterns, and wishes to answer the question, "What can happen? ". Prescriptive Analytics uses multiple prediction models to predict different outcomes and the best mode of action for each result. It wants to answer the question, "What can we do to accomplish this?", as reported by Bahga and Madisetti (2016).

The objective of this research is to present an architecture for a clinical big data platform that offers the capabilities to acquire, store, analyze, and visualize real-time clinical data in order to make the best medical decisions regarding the health of patients. The remaining of the paper is organized as follows: Section 2 briefly describes the potential and benefits of the Big Data clinical analysis, Section 3 reviews the challenges and requirements for a Big Data Analytics platform, Section 4 shows the architecture of the platform and emphasizes its features, Section 5 formulates conclusions about the reported results and shows further research work aiming to demonstrate the benefits of the implemented platform by several significant use cases.

2 Big Data Promise and Potential for Clinical Data Analysis

The features offered by Big Data Analytics, as referred to in Wang et al (2016), such as analytical capability for patterns of care, unstructured data analytical capability, decision support capability, predictive capability and traceability that can be used in the information technology infrastructure, operational, organizational, managerial and strategic domains, can save lives by improving healthcare services, reducing patient care costs based on previously unidentified models, and improving the organization's financial performance with descriptive analytics and mining/predictive analytics techniques used in medical documents and unstructured clinical data analysis. By processing large volumes of data, of different formats, with different data generation types (batch, streaming), can be identified new markets of interest for hospitals.

Costly healthcare services or laboratory tests and unnecessary treatments can be identified through unstructured data analytical processing, as mentioned in Wang et al (2016).

The benefits of Big Data Analytics are reflected at IT infrastructure level by sharing resources and thus avoiding additional IT costs. Operational benefits are obtained by improving the quality and precision of medical decisions, efficiently processing a large number of health records, reducing patient's travel time, reducing diagnostic time, and reducing the length of hospitalization. Managerial benefits are obtained from the allocation and control of resources, operations monitoring and, improving strategic business decisions. Strategic benefits are obtained from strategic activities on long-term decision-making, as described by Wang et al (2016).

Decision support capability highlights the ability to generate daily reports on health care, which helps in setting actions and decisions at the management level.

For predictive capability, complex statistical tools are used to develop models and estimates of what will be done in the future. Reports, alerts, hospital performance indicators, and interactive views are harnessed, resulting in improved medical risk, identifying best clinical practice, understanding future healthcare trends based on knowledge of patient habits.

Traceability is the ability to track output data from all IT components of the system within a healthcare facility, so hospitals can improve the rate of use of medication, reducing patient flow delays, as reported by Wang et al (2016).

The potential of Big Data Analytics is also reflected in the epidemiological surveillance, patient-based decision-making, adverse drug prediction as described by Bahga and Madisetti (2016), non-invasive and continuous monitoring of physiological parameters according with Simpao et al (2015), decreasing the risk of illness as in Simpao et al (2015), monitoring of elderly, people with dementia or with Parkinson's disease as in Simpao et al (2015) with the help of wearable devices, detection of abuse or errors following the analysis of complaints from health insurances (detecting claim anomalies) as mentioned in Bahga and Madisetti (2016), Raghupathi and Raghupathi (2014), Balladini et al (2015).

Real-time health monitoring can lead to the discovery of new vital sign patterns that help detect early clinical pathologies and plan early treatments or stop the progress of a condition, reducing mortality and the cost of caring for patients as reported by Wang et al (2016).

The potential of Big Data in Healthcare has led to the collection of data from the EHR into national data sets as in Simpao et al (2015), the development of national projects for Health Data (http://www.ahrq.gov), (http://www.hscic.gov.uk) and the creation of anesthesiology-specific databases such as the Multicenter Perioperative Outcomes Group (MPOG) conform with Kheterpal et al (2013), the National Anesthesia Clinical Outcomes Registry (NACOR) as in Dutton R.P. (2014), the Society for Ambulatory Anesthesia Database And the Pediatric Regional Anesthesia Network in accordance with Kheterpal (2014), Simpao et al (2015). Improved clinical outcomes have been observed in intensive care units for children, where appropriate decisions are made for each patient in real time as referred to by Simpao et al (2015).

The term Visual Analytics (VA) as in Zamfir et al (2016) describes a new multidisciplinary field that combines different areas of research, including: data mining, data management, data fusion, cognitive science and statistics among others as mentioned in Simpao et al (2015).

In biology and medicine, computerized tomography and ultrasound imaging for 3-D digital reconstruction and visualization produce gigabytes of medical data according with Zamfir et al (2016).

Likewise, the use of VA tools for anesthesia and the installation of AIMS (Anesthesia Information Management Systems) as reported by Simpao et al (2015) will become a real source of Big Data, especially as it aims to combine electronic anesthesia records with hospital data and ambulatory surgery centers with EHR data. Increasing efficiency in patient care, optimizing resource allocation and utilization, improving decision-making at both clinical and organizational levels are pursued when using VA tools and complex analysis methods. Anesthesia is another area in which Big Data collection and the results Big Data Analytics can support predictive risk assessment and resource use as mentioned in Simpao et al (2015). VA techniques are used in clinical operations in pediatric hospitals for exploring clinical data in accordance with Simpao et al (2015). The field of bioinformatics uses Visual Analytics techniques to analyze large amounts of biological data. Researchers in this field are experiencing unprecedented increased of data volumes, such as in the

human genome project, with 3 billion base pairs per individual as observed by Zamfir et al (2016), Simpao et al (2015).

Visual Analytics (VA) tools mitigate the deficiencies of data analysis tools that do not provide cognitive activities and work with large, complex and heterogeneous datasets. It also combines interactive visual representations with advanced analysis techniques to synthesize, analyze, and facilitate visual-analytical reasoning with other data-engaging activities as described by Ola and Sedig (2014).

3 Challenges and Requirements

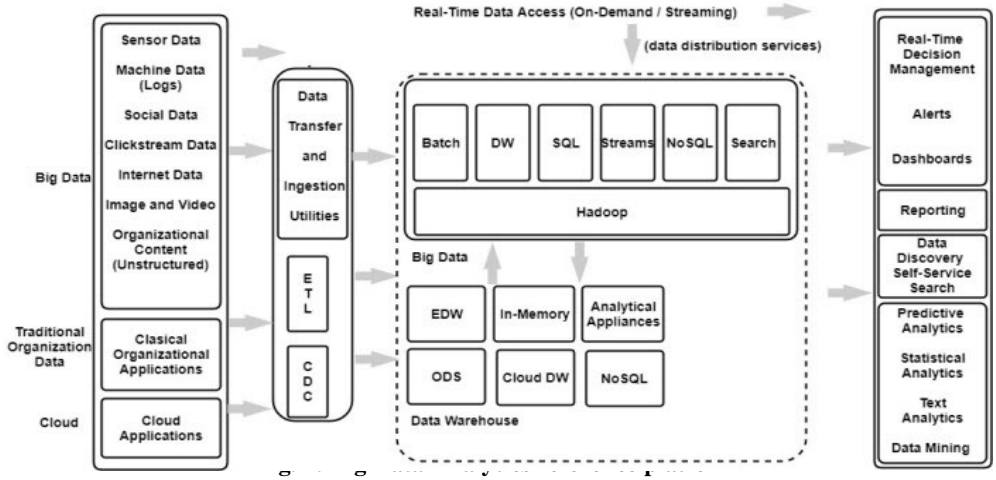
Management and processing of large data sets as in Peek et al (2014) in the biomedical and health domains generate methodological and technical challenges related to data sources, infrastructure and analytics.

Data sources consist of health care records, administrative data, web search logs and social media. Health care records are data collected for patient care but used for other purposes such as research or quality assurance, and contain a wide range of data such as demographics, lab values, distributed medications, imaging, other diagnostic data, clinical interventions, clinical notes in text format. Health care records pose challenges for researchers, related to data quality and diversity, confidentiality of providers and patients, inaccuracy or lack of data. Administrative data is insurance data or payment claims, diagnoses, procedures, and access to these data is important for the research part but also for the patient's safety improvement. The challenge of working with administrative data consist in the fact that data are heterogeneous and multivariate and difficult to collect (many data for a patient, hard to create a single analysis file from the multitude of data with many attributes, lack of clinical details) and therefore the solution is to link them to clinical data or to other healthcare data. Web searches logs are also useful for detecting side effects associated with pharmaceuticals. Searching and mining social media raise challenges related to nonstandard languages and representations used on social networks and related to, extracting significant information from these data sources. The volume of large data sets is a challenge along with the speed at which data is collected and their diversity. In the biomedical domain, batch processing and real-time data processing technologies are used. Structured data (electronic health records) and unstructured data (clinical images) are stored in databases as mentioned in Wang et al (2016). Storage can be done using file systems or database systems. In the case of file system storage, one option takes into account the data storage and calculation performed on the same machine, such as Hadoop. HDFS (Hadoop Distributed File System) from Hadoop has been used to store biomedical data. Data is stored for data analysis, backup or archiving. Alternatively, storage with database systems provides interrogation and recovery capabilities. For large volumes of heterogeneous data sets, non-relational databases (NoSQL databases) are preferred, providing efficient and flexible interrogation mechanisms.

Data acquisition is an important challenge for the platform as reported by Augustine (2014), so a requirement is low latency in capturing data and using simple queries for data processing. Apache Hadoop offers data processing technology in a distributed and data storage environment at the original location. In the case of clinical data, their analysis requires statistical and exploratory approaches. In order for the clinical data analysis platform to quickly deliver the expected results (cost savings, time reduction, optimized results for different research, smarter diagnostics leading to precise decision-making) it must provide reliability and scalability for data storage and processing according with Augustine (2014). Another challenge in the healthcare industry is to protect patients' data. In biomedical applications also, data security and confidentiality must be taken into account, whether applications are hosted in cloud or traditional environments. When processing large batch data sets, the Hadoop ecosystem is the most widely used architecture. Systems that process a large number of predictive modeling clinical methods use Hadoop to simplify the implementation of

complex activities. The processing of medical images from different sources is a challenge in the healthcare industry as described by Augustine (2014), and Hadoop offers solutions for medical imaging analysis and extracting important diagnostic data.

In all these cases of large data sets analysis, statistical methods, machine learning, NLP (natural language processing) and semantic methods in accordance with Peek et al (2014) should be used. Mainly, these are based on three components of data analysis conform with Wang et al (2016): Hadoop Map / Reduce, stream computing and in-database analytics. Mapreduce is a programming model for processing in batch form and analyzing data in a parallel processing environment. Stream processing supports stream data processing in real time with very useful prediction capability. In-database analytics is a data mining approach which offers parallel processing, scalability and optimization futures for big data analytics as observed by Wang et al (2016). It is a challenge according with Ola and Sedig (2014) for the public health workforce to efficiently use data with different formats that are available for limited periods of time and in transformation. In order to perform operations such as health records, filtering data to eliminate irrelevant data, identifying the relationships between different environmental factors in order to make the best decisions for citizens, there is a need for tools to support them, such as packets for data acquisition, data analysis, data monitoring, and data viewing, and which can be installed on a platform for clinical data analysis as reported by Ola and Sedig (2014).



4 Architecture for Big Data Visualization and Analytics

Currently there are clinical decision support systems (CDSS) that assist healthcare professionals in clinical activities, but most do not work with data generated continuously as observed by Balladini et al (2015). Storage space is required to store patient archived data in order to extract knowledge from them and to develop personalized predictive algorithms as mentioned in Balladini et al (2015). The tools used in Big Data Analytics make it easier to store and analyze clinical data.

4.1 The Reference Platform

We selected as a reference the Big Data Analytics Platform presented in Fig 1. The data managed by the platform can be classified in three major categories: Big Data (massive heterogeneous data coming from a large number of devices and/or external sources), Organizational Data (data collected from the applications running in the organization environment) and Cloud Data (data collected from cloud applications outputs). The data transfer to the Big Data platform can be done with specific data ingestion components, ETL (Extract Transfer Load) tools which are used for transforming the data into the format required by the data warehouse, and CDC (Change Data Capture) tools, used for tracking data transfer activities into the warehouse. The Big Data storage system will consist in a Hadoop ecosystem accompanied by a warehouse composed of NoSQL and SQL databases. This warehouse will provide the data for the Mapreduce specific processing and also for different tools like analytical appliances, search engines, data stream engines, batch processing, etc. These tools and utilities support predictive analytics, text analytics, data mining, statistical analytics and data discovery, and will generate reports and alerts for the end users.

In the next sections, we will present our adaptation of a Big Data Analytics Platform for the healthcare domain, along with the tools we consider important for clinical analytics.

(Source: Alberto (2016))

4.2 SQL and NoSQL data integration

Our proposed platform for clinical data analytics features a big data platform capable of storing SQL and NoSQL data, a data analysis tool, a web interface used for visualization of the analyzed data and tools for data acquisition from various medical data sources. The healthcare data used to be acquisitioned by this platform will come from medical equipment, healthcare staff and EHR data of a patient. Medical equipment and the equipment used by the healthcare staff for transferring the data to the platform will connect to an internal gateway which will then send the data to the platform. The EHR data should be stored in real time in the platform. The SQL database will store any SQL type of medical data of the patients and also will include information regarding the caretakers of those patients. The SQL database will be linked to the NoSQL database in order to understand which patient belongs the NoSQL data.

The platform will be connected to a web interface that healthcare staff and patients can access to visualize their reports. The reports will be generated by a data analysis tool that will be used by doctors or data analysts.

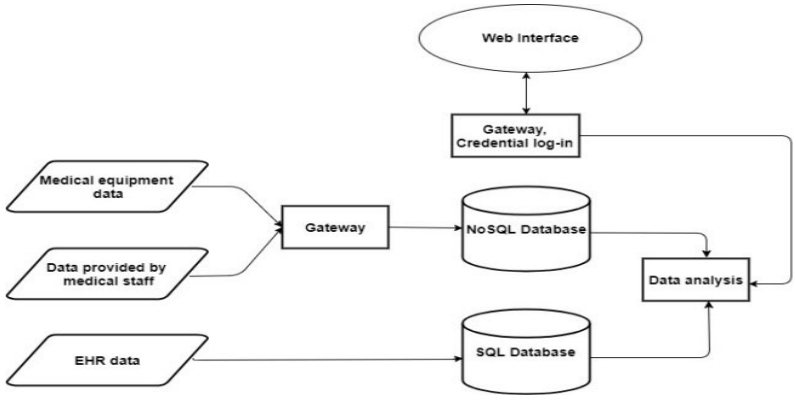


Fig. 2: The proposed architecture for a clinical Big Data platform

As seen in the Fig 2, the medical data sources are: EHR data, which are the patient data from their healthcare state records (such as clinical card), healthcare staff records: the data that the healthcare staff (such as nurses or doctors) will manually introduce based on their observation on a specific patient, and the medical equipment data: gathered directly from medical equipment such as MRI (Magnetic Resonance Imaging) or other clinical equipment used for investigation or measurement of different patient clinical parameters. The EHR data will be send directly to the SQL database because of its structure, while the medical equipment and healthcare staff data will be send to NoSQL database. The gateway is used for connecting the medical equipment in order to store the data provided by them.

The user interface that will permit the visualization of the results of data analysis performed on the proposed platform will be a web interface that permits two types of log-ins (one for the clinical staff and one for patients). This interface will permit patients to review their healthcare records, and permit the healthcare staff/data analysts to review their patients records and various statistics or recommendations that resulted from data analysis performed on the platform. The healthcare staff will also have an option to use the data analysis tool (for example RapidMiner or KNIME).

The data analysis on the platform will be possible to be made across multiple patient records and not only on those of which are patient to a specific doctor. For example, a doctor can choose to analyze the data of his patient against all the patient data of a specific age range, a specific sex type or with some specific diseases. Based on that analysis, the doctor will have the results of all the treatments that had success on a specific disease or will have statistics of future evolution of the specific disease.

4.3 Data analytics in the proposed platform

In the next figure we will present the data analytics flow process in our proposed clinical platform.

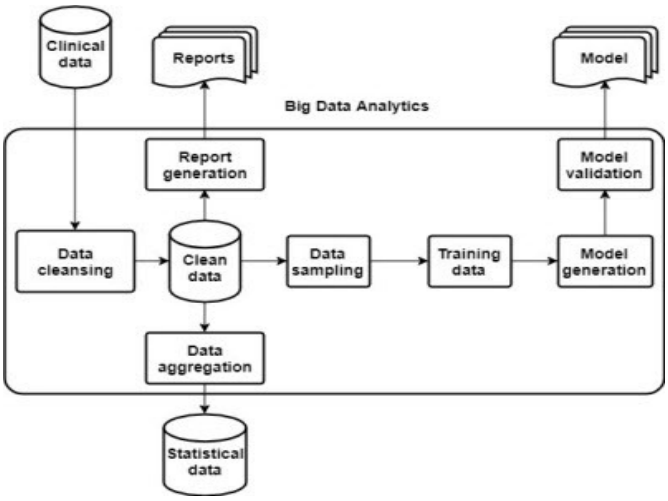

Fig. 3: Data analytics flow process

As we see in Fig 3, the start process of data analytics is the clinical data warehouse. The first step in data analytics is data cleansing. Data cleansing is a process in which the data entered is altered in order to making sure it is correct by amending or removing the incomplete, incorrect or duplicate data. After data cleansing process, the resulted data will be stored in a separate warehouse, that will only contain clean data and reports will be generated stating what data was altered or removed. Using the clean data warehouse, the data aggregation process can sort the clean data for the purpose of obtaining statistical data about patient based on specific variables such as age, profession, sex, type of illness, etc.

Data sampling process refers to the selection of the types of data that needs to be analyzed. For example, a data analyst can select a representative subset of data for further analysis.

The training data process informs the model on how it should work and how it should make decisions, while the model validation will be made by testing the generated model against the testing data. After the validation, a model will be generated for the user review.

5 Conclusions and Future Research

Taking into account the current healthcare situation where the interest in investing in Big Data Analytics and the experience in using analytics is low, the architectural considerations, challenges and key requirements for a Big Data clinical analysis platform have been addressed, to emphasize the benefits that modern technology implementation can bring to health organizations and third parties. Reducing mortality among patients, better quality of life, lowering costs and improving healthcare services are goals that both data scientists and physicians, and government must take into account in day-to-day work.

An analysis of open source components dedicated to such a platform in the form of an experiment will be the subject of further research.

Modern Technology and Internet Use In Learning in the Czech Population

Jitka Vaculíková, Research Centre, Tomas Bata University, Zlín, Czech Republic, vaculikova@utb.cz

Abstract

The objective of the current study was to investigate the use of modern technology (i.e., computer, laptop, or tablet) and the internet (i.e., Moodle, Elportal, e-learning and online interactive programs, YouTube, Google or Seznam, etc.) in learning in the Czech population. The research instrument consisted of a self-rate questionnaire developed by the author. The sample consisted of 1,008 participants selected according to gender, age, education, and region of residence to represent the Czech population. The sample scored average in terms of modern technology and internet use while learning. This trend was considerably lower the higher the age, regardless education level. Moreover, females used printed study materials more often than males. The relationship between the use of modern technology, internet, and preferred form of study materials were further examined with selected variables, i.e., gender, age, education level achieved, size of place of residence, region, and economic activity.

Keywords: technology, internet, learning, ICT, Czech Republic

1 Introduction

Modern technologies are one of the basic elements characterizing today's society that are not only products of contemporary time and culture, but also factors that make a significant contribution to society and everyday life. Their ongoing rapid development has allowed their use in all areas of human activity. Younger populations in particular use these technologies extensively during their leisure, work, or learning time. Furthermore, the use of modern technology has become a natural environment for today's youth born into the era of digital life. Today's youth are often referred to as digital learners (Gallardo-Echenique et al., 2005), digital natives (Gottwaldová, 2015), digital youth (McPherson, 2008), or youth of the net generations (Oblinger & Oblinger, 2005).

Although the older generation also uses modern technologies in their lives, the position of these technologies is different. Their social maturation, including the integration of different tools, media, and technologies into behavior patterns and lifestyles took place before those technologies emerged. On this basis, modern technologies are becoming incorporated into existing models of life. As a result, the range of activities such as leisure or working time that are accessible through modern technologies varies by generation. Findings showing the extent that this era of modern technology is reflected in learning for the entire society (from adolescence to old age populations) in the Czech sociocultural environment remain uncertain. Moreover, use of internet not only for social connection and entertainment, but also for academic studies and lifelong learning, has become the aim of presented research studies on the use of modern technology and internet in learning.

The term “modern technology” is defined as the use of a computer, laptop, or tablet during learning activities in various environments, i.e., at home, at school, or in other institutions and environments. The concept of modern technology was chosen for its colloquial meaning, which is generally understood by the whole population and was perceived as a synonym for information and communication technologies (ICT) commonly used in the literature. Furthermore, use of the internet while learning was defined as the use of Moodle – a learning platform designed to provide learners with a single robust, secure, and integrated system creating personalized learning environments (Moodle, 2016), Elportal (an e-learning

portal of courses and all other forms of e-learning), online interactive programs, YouTube, Google, or Seznam, which is a well-known Czech catalog search server.

The process of learning investigated in this research was conceived in congruence with Zimmerman and Schunk (2011) as self-regulatory oriented learning processes, whereby learners personally activate and express cognitions, effects, and behaviors that are systematically oriented toward the attainment of personal goals not strictly tied only to the school environment or formal institutional activities. Moreover, learning in this perspective was considered an intentional process in which an individual had to decide what to learn, when, how, with what tools, and where, i.e., at home, school, online, or offline.

1.1 Implementation of modern technology and internet in the Czech society

Modern technology (ICT) began its integration into the Czech education system in the 1990s. Infrastructure equipment and its use in education, as well as its financing, was at the initiative of individual schools. There was no national program or project at that time to coordinate or methodically manage schools in the integration of digital technologies into their lives. The issue of modern technologies was reflected in public and educational policy only after the creation of documents for the National Education Development Program in the Czech Republic entitled White Paper (MŠMT, 2001), State Information Policy (VČR, 1999), and Concept of State Information Policy in Education (MŠMT, 2000).

Whilst the declarations of the White Paper were very general, the key strategic areas were outlined in the remaining documents. The first area was to ensure the availability of digital technologies (infrastructure) to all learners involved in education (schools, continuing education, or lifelong learning). The second wave of ICT development consisted of the creation of a basic framework for integrating ICT into education at all levels of schooling with a focus on the importance of teacher preparation. An additional document approved by the Ministry of Education, Digital Education Strategy by 2020 (MŠMT, 2014), anticipated the gradual involvement of modern technologies in the formal education. It was in this document that the full incorporation of modern technologies into the teaching of all subjects was seen by the state as a necessary shift within education systems, from the simple memorization of facts to an emphasis on digital literacy, communication skills, and computational and logical thinking (Jelínek, 2015).

The year 1992 is considered to be the beginning of the "internet era" in the Czech Republic (Kasík, 2012). The largest increase in the proportion of households connected to the internet and owning a computer is dated to the year 2008. 67% of households owned a computer and only two percent fewer households were connected to the internet (CSO, 2014b). At the forefront of internet use was the age category of 15 to 30 years, which spent an average of 17 hours a week on the internet (Koledárová & Tomek, 2012). In terms of number of internet users, the population with higher education, i.e. university graduates, were the second most numerous group. Most users (96%) used email, with almost two thirds using it daily. The second most widespread online activity was searching for information. Social networking quickly struggled from the outset to become one of the most popular online activities, however, only 5% of online users used social networks during most of their time spent online (ibid).

The social profile of computer users has changed with advanced ICT implementation. The turning point for the development of computer literacy was the "Internet to Schools" project. The project equipped elementary schools with computers and internet access. This period was also known for "generation inversion," where children taught their parents and grandparents to work on and with computers (Sak, 2000; Arnesh, Erstad, Jahaňák, & Zounek, 2016). Computer literacy and the general availability of technologies were indirectly influenced by age and directly dependent on education and family income. However, with the considerable shift from fixed to mobile internet use (Fišerová & Horáček, 2015) the

absence of a computer or internet connection in the household is nowadays more of an exception. More specifically, mobile internet is preferred by three quarters of connected Czechs (ibid).

1.2 Research on Modern Technology and Internet Use in Education

The attitudes of Czech, Polish, and Slovak university students (n = 260) towards the personal computer and its role in lifelong learning and leisure were compared by Chráska (2014). The findings indicated that the concept of the PC was perceived in a similar way among Czech and Polish students as an irreplaceable means of work, lifelong learning, communication, and leisure time. Moreover, Czech students achieved the highest frequency of use of the PC for educational purposes. The authors attributed this finding to the most extensive use of an online learning management system (LMS) and computer-aided teaching by the Czech university.

Kolesárová (2014) extended the context of use of ICT to include the identification of typical characteristics of lifestyles within the Czech population. A representative sample of the Czech population over 15 years old (N = 1,818) was used. The author identified a cyber-developmental lifestyle that most strongly demonstrated a computerized character, i.e. predominant computer activity while studying. The cyber-developmental lifestyle was associated with life beyond marriage in younger generations (the average age = 23 years) as reflected by female students or university graduates.

The field of ICT research in education has a wide platform of application (Milková, Pekarková, & Salem, 2016) covering the areas of computer-aided personalized and collaborative learning (Mamat & Yusof. 2013), seamless learning systems (Ogata et al., 2015), and online game-based learning in school education (Jong, 2015). Moreover, students benefited from the application of ICT in the learning of foreign languages (Klimová Frydrychová & Poulová, 2014). Also, combining mobile devices (laptops, tablets) and social networks (Facebook, Instagram) was seen as an attractive refreshment of education in schools, increasing pupils' motivation to learn (Maněna, Dostál, Hubálovský, & Hubálovská, 2016).

Moreover, Zounek and Tůma (2014) mapped the representation of ICT in education covered by Czech scientific journals between 1990 and 2012. In twenty-two years, only nine empirical studies and only thirteen survey studies were published. However, these lacked a focus on the learning processes of individuals, their relation to modern technologies, and offered no information as to whether learners used computer skills and knowledge acquired from the school environment outside school and vice versa.

According to the findings of a systematic review of international literature on emerging technology (ET) in education between 2006 and 2016, all studies aimed to improve and transform the different educational processes through the incorporation of ET (Neira, Salinas, & Crosetti, 2017). Out of 288 selected studies the most affected population were students in higher education contexts with the objective of improving critical thinking, followed by problem solving, collaborative work, creative thinking, and decision-making. Qualitative research was the most commonly used methodological approach with Web 2.0 technologies.

Dogruer, Eyyam, and Menevis (2011) concentrated on students' use of internet in their academic studies. The participants (n = 100) were international students who studied at different levels in English Preparatory School. Students believed that they could easily use the internet as an educational tool, an online search engine, or a resource of knowledge and discussion about shared school subjects. However, more sophisticated activities such as the use of educational journals and databases, wikis, and e-learning portals were more problematic.

Since coherent information describing the use of modern technology and internet in studying in a representative sample of the Czech population is still lacking, the primary focus of this research study has been set at the descriptive level. Three main objectives are being investigated. First, to find out to what

extent modern technology (e.g. PC, laptop, tablet, etc.) is used during the learning process by the Czech population, and what characterizes those respondents who never use modern technology while studying. Second, to find out to what extent the internet (e.g., Moodle, e-learning, online interactive programs, YouTube, Google or Seznam, etc.) is used during the learning process by the Czech population and the discipline most commonly studied by respondents online. And lastly, to find out the preferred format of study materials.

2 Methodology

Nowadays the use of modern technology (ICT) and the internet is an integral part of every mature society. As work with computer, laptop, or tablet reaches almost all disciplines, it is finding its way to becoming a mediator in the process of learning. However, the extent to which the Czech population uses modern technology during learning and how this usage is influenced by gender, age, region, education and other socio-demographic variables has not been fully explored. Therefore, the purpose of this study is to fill this gap and bring the following information across a representative sample of the Czech population. More specifically, the research answered the following questions:

(1) To what extent is modern technology (e.g., PC, laptop, tablet, etc.) used for studying within the Czech population? The fact that a number of citizens or groups do not use modern technology is significant in terms of social cohesion and exclusion. Therefore, respondents who never use modern technology while studying were described further.

(2) To what extent is the internet (e.g., Moodle, e-learning, online interactive programs, YouTube, Google or Seznam, etc.) used in studying within the Czech population and what is the most common discipline that respondents study online?

(3) What is the preferred form of study materials?

We also investigated whether there was relationship between use of modern technology, use of internet, and preferred form of study materials against selected variables, i.e. gender, age, education level achieved, size of place of residence, region, and economic activity.

2.1 Research and Data Collection Methods

Given the nature of the research questions the research was based on a quantitative methodological approach using exploratory methods. To gather the data, a survey including selected items developed by the author was part of a wider Omnibus random data collection using a CAPI (Computer Assisted Personal Interviewing) method facilitated by trained interviewers implemented in Autumn 2016.

The survey included socio-demographic items covering gender, age (in years and also expressed in age categories: 15-29 years; 30-44 years; 45-59 years; 60 and up), education (basic; secondary without leaving examination (vocational); secondary with leaving examination; university level education), size of place of residence (up to 4,999 inhabitants; 5,000–19,999; 20,000–99,999; 100,000 and up), region (Prague; Bohemia; Moravia), economic activity (economically inactive vs. active), and professional career specialization (e.g., economics and administration, pedagogy, building construction, etc.).

Specific items were designed to be used in analyses as single items of nominal or interval nature. These variables were considered manifest variables that can be observed directly. More specifically, respondents answered the question concerning the usage of modern technology (e.g., PC, laptop, tablet, etc.) and the use of the internet (e.g., Moodle, e-learning, online interactive programs, YouTube, Google or Seznam, etc.) during their learning process on a seven-point Likert's scale ranging from 0 (*never*) to 6

(*very often*). The findings on internet use during learning have been expanded to identify the field in which respondents most often engaged in their study online. The International Standard Classification of Education (ISCED 1997) was used to select the field of study (i.e., foreign language, computer science, general education programs, etc.). Lastly, preferred form of study materials was investigated (printed study materials; electronic study materials; no preference).

2.2 Data Preparation and Statistical Analysis

Influential multivariate outliers and the possible occurrence of missing values were checked. First, descriptive statistics of the individual socio-demographic variables were calculated. Second, the general assumptions (i.e., level of measurement, random sampling, independence of observation, normal distribution, and homogeneity of variance) that apply to parametric techniques were investigated. The Kolmogorov-Smirnov test and the Shapiro-Wilk test were used to confirm ($p < .05$) the application of nonparametric statistics (U test, K-W ANOVA, Chi-squared test, and Spearman correlation). Effect size for all tests was calculated (η^2, Cramer's V, r^2). The null hypothesis was rejected given the significance level of .05. However, multiple comparisons were checked using Bonferroni correction to reduce the likelihood of incorrect rejection of the null hypothesis (Type I error). SPSS v. 24 was used for all presented analysis.

2.3 Participants

The research sample included a representative sample of the Czech population (N = 1,008). The sample was randomly selected based on quota for gender, age, education, and region of residence. The mean age of the sample reached 45.3 years (SD = 17.05) ranging from 15 to 89 years. The gender distribution was quite even with 482 (47.8%) males with an average age of 44.3 years (age ranged from 15 to 89 years, SD = 17.52) and 526 (52.2%) females with an average age of 46.3 years (age ranged from 15 to 85 years, SD = 16.56). The distribution presented also corresponded to the general gender distribution of the Czech population (CZSO, 2014a).

Most respondents had acquired secondary education either without a leaving examination (37.6%) or with a leaving examination (33%), followed by university (16.2%) and elementary school graduates (13.2%). Almost two-fifths of respondents (37.1%) lived in a place of residence with up to 4,999 inhabitants. More than half of respondents (63.4%) were economically active, with the region of the capital city Prague most represented (12.6%). As far as the professional career specialization of the respondents was concerned, mechanical engineering (117, 11.6%), economics and administration (84, 8.3%), business (66, 6.5%), pedagogy (61, 6.1%), building construction (58, 5.8%), and healthcare (52, 5.2%) were the most frequently profiled professions in the sample. The socio-demographic distribution of the sample is shown in Table 1.

Table 1: Socio-demographic distribution of the sample

Socio-demographic characteristics		Frequency		Socio-demographic characteristics		Frequency	
		N	%			*N*	%
Gender	Male	482	48	Size of place of residence	up to 4,999 inhabitants	374	37
	Female	526	52		5,000–19,999	183	18
Age	15-29 years	224	22		20,000–99,999	239	24
	30-44 years	268	27		100,000 up	212	21
	45-59 years	263	26	Region	Prague	127	13
	60 up	253	25		Bohemia	480	48
Education	Elementary	133	13		Moravia	401	40
	Secondary without leaving examination	379	38	Economic activity	active inactive	639 369	63 37
	Secondary with leaving examination	333	33				
	University	163	16				

Note: For a general overview, relative percentages are presented here and after without decimal places.

3 Results

The level of use of modern technology during learning processes is important information for the future planning of both national and international forms of education. The results of the aforementioned research questions are presented chronologically below.

3.1 To what extent is modern technology (e.g., PC, laptop, tablet, etc.) used during the learning process?

The central values (M = 3.3, SD = 2.44) of the seven-point scale used in the survey ranging from never (point 0) to very often (point 6) lie just above the midpoint of the scale. The results suggest that on average respondents used modern technology while studying. However, two main groups of respondents stood out compared to other respondents included in the survey: (1) those who never used modern technology while studying (276, 27%), and (2) those who on the contrary used PC, laptop, or tablet very often while studying (318, 32%). Apart from these two opposite trends, the middle point three was the point reached most frequently (12%) followed by a high frequency (11%) of answers on the right side of the scale (point five of the seven-point scale).

Age of respondents had a high statistical and interpretive influence on the level of modern technology use while studying. The use of state-of-the-art technology (i.e., PC, laptop, or tablet) was considerably lower the higher the age, regardless of **education level**. This trend was found in all age categories. University graduates, while reaching the highest level of modern technology involvement in their learning, used less modern technology while studying at younger ages.

276 (27%) of the sample size (1,008) **never used modern technology while learning.** More specifically, 47% (129) males and 53% (147) females were represented by the oldest age group (60 years and older). Out of these respondents, 52% (144) of respondents reached secondary education without leaving examination (vocational), followed by 74 respondents (27%) who obtained a diploma from secondary school with leaving examination, 41 (15%) of respondents who completed elementary education, and 17 (6%) university graduates. Based on a comparison of the absence of use of modern technology by region, 22 (8%) lived in Prague, 100 (36%) lived in Bohemia, and 154 (56%) in Moravia. Slightly lower use of

modern technology was shown by economically inactive respondents (153, 55%) vs. economically active (123, 45%).

3.1.1 What is the influence of the selected variables on the level of modern technology use?

The proportion of use of modern technology by **males** (Md = 4, n = 482) was not significantly different from the proportion of **females** (Md = 4, n = 526), U = 126150, z = -.14, p = .891, r = .004. The **age** of respondents reached a statistically significant difference, $x^2(3, n = 1{,}008) = 173.36$, $p < .001$, $\eta^2 = .18$. The youngest age group (15-29 years) recorded the highest use of modern technology while studying. The effect size calculated using Eta^2 showed the percentage of variability in the dependent variable explained by the test variable. It was found that quite high proportions (18%) of the change in modern technology usage could be accounted for by the age of the respondents.

Studying across four different **education** groups also significantly influenced use of modern technology while studying, $x^2(3, n = 1{,}008) = 76.51$, $p < .001$, $\eta^2 = .08$. Higher level of education achieved was associated with higher use of modern technology. Moreover, a larger **size of respondent's place of residence** was associated with higher use of modern technology, $x^2(3, n = 1{,}008) = 12.60$, $p < .01$, $\eta^2 = .01$, with the largest use of modern technology in the **region** of Prague, $x^2(2, n = 1{,}008) = 21.66$, $p < .001$, $\eta^2 = .02$. Lastly, there was a small negative correlation between **economic activity** and use of modern technology while studying (r_{rho} = -.20, $p < .001$, r^2 = 4%). Use of modern technology decreased with economic inactivity.

We also wondered whether the use of modern technology while studying went hand in hand with studying online, and how this usage differed across the age categories of the respondents (see Table 2). The findings showed a large negative correlation between age and use of modern technology while studying (r_{rho} = -.48, $p < .001$, r^2 = 18%) and use of internet (r_{rho} = -.43, $p < .001$, r^2 = 18%). High levels of use of modern technology and online studying were associated with lower age of respondents. A perfect correlation was found between the use of modern technology and use of internet (r_{rho} =.90, $p < .001$, r^2 = 81%). These results were not surprising since the internet can only be used together with modern technology. However, modern technologies such as PC, laptop, or tablet could be used for studying purposes in general without necessarily surfing the internet, i.e. studying online.

Table 2: Average values and intercorrelations between selected variables

Variables	Average values (SD)	Age	Modern technology
Age	45.3 (17.05)	1.000	
Modern technology	3.3 (2.44)	**-.418****	1.000
Internet	3.2 (2.47)	**-.433****	**.901****

** = p < .01.

Moreover, a partial correlation was used to explore the relationship between use of modern technology and internet, while controlling for the most influential variable, i.e. age of respondents. On this basis, the significant partial correlation between use of modern technology and internet, controlling for age, r = .89, n = 1.005, $p < .001$, remained almost unchanged. High levels of modern technology use were associated with high levels of studying online, suggesting that controlling for age had no significant effect on the strength of the relationship between these two variables. Where modern technology was used, the internet was concurrently used by the interviewed respondents as well.

3.2 To what extent is the internet (e.g., Moodle, e-learning, online interactive programs, YouTube, Google or Seznam, etc.) used during the learning process and what is the discipline that respondents most commonly study online?

Respondents used the internet on average (M = 3.2, SD = 2.47) as a learning tool. Likewise, as presented above in relation to use of modern technology, there were two main groups of respondents: (1) those who never used the internet while studying (294, 29%), and (2) those who used it very often (317, 31%). The age of the respondents had a high interpretive influence on the level of the internet use while studying. The youngest age category (15-29 years) used the most internet on average while learning (e.g., Moodle, e-learning, online interactive programs, YouTube, Google or Seznam, etc.).

Most of the respondents **devoted their online studying** to developing personal skills (213, 10%), studying foreign languages (192, 9%), using computers (101, 5%), and (98, 5%) to trade, management, and administration (finance, banking, insurance, accounting and taxation, etc.).

3.2.1 What is the influence of the selected variables on level of internet use?

There were no significant differences in the use of internet between **males** and **females**, U = 124391, z = -.53, p = .60, r = .02. However, statistically significant differences in use of internet were detected across four different **age** groups, $x^2(3, n = 1{,}008) = 179.63$, $p < .001$, $\eta^2 = .18$, with greater use of internet associated with younger age (see Table 3).

Table 3: Examining use of internet according to gender and age

	Gender		Age							
Variable	male	female	15-29	30-44	45-59	60+	r	p	x^2	p
Internet	3.2	3.2	4.5	3.9	2.9	1.7	.02	.596	179.63	**.000*****

*** = $p < .001$.

Education level achieved also influenced the use of internet, $x^2(3, n = 1{,}008) = 67.16$, $p < .001$, $\eta^2 = .07$. Respondents with a university degree used internet to the greatest extent. **Size of respondents' place of residence** was not associated with a difference in the internet use, $x^2(3, n = 1{,}008) = 7.02$, $p = .071$, $\eta^2 = .01$. Furthermore, the findings revealed a statistically significant difference in use of internet while studying across three different groups of the **region**, $x^2(2, n = 1{,}008) = 12.26$, $p < .01$, $\eta^2 = .01$. Those respondents who lived in Prague reached the highest level of internet use for studying. Moreover, there was a small negative correlation between **economic activity** and use of internet while studying ($r_{rho} = -.18$, $p < .001$, $r^2 = 3\%$), with high levels of internet use associated with economically active respondents.

3.3 What is the preferred form of study materials?

The area of modern technologies and internet is also related to preference for type of study materials (i.e., printed or electronic). Therefore, it was tested whether (1) respondents have a preference and, if so, whether (2) this preference was influenced by the gender, age, or education level achieved of the respondents.

3.3.1 What is the influence of the selected variables on the preferred form of study materials?

In general, a quarter of respondents (257, 25%) had **no preference** for study materials. Half of the respondents (525, 52%) **preferred printed** study materials and the last quarter of respondents (226, 22%) **preferred electronic** study materials. The proportion of **males** was significantly different from the proportion of **females** in their preference of type of study materials, $x^2(2, n = 1{,}008) = 12.24$, $p < .01$,

Cramer's V = .11. Females used traditional printed materials more often than males and vice versa (see Figure 1). Also, the **oldest** respondents (60+ years) preferred printed study materials, which were on the other hand the least preferred form by the youngest respondents. The opposite trend can be seen in electronic study materials (see Figure 2). These differences were statistically significant, $x^2(6, n = 1{,}008) = 53.78$, $p < .001$, Cramer's V = .16. Although both differences were statistically significant, the strength of the relationship (a post-test Cramer's V = .11 and .16) indicated that the relationship was weak. Knowing the independent variable (i.e. gender and age) did not help in predicting the dependent variable (i.e. preferred form of study materials).

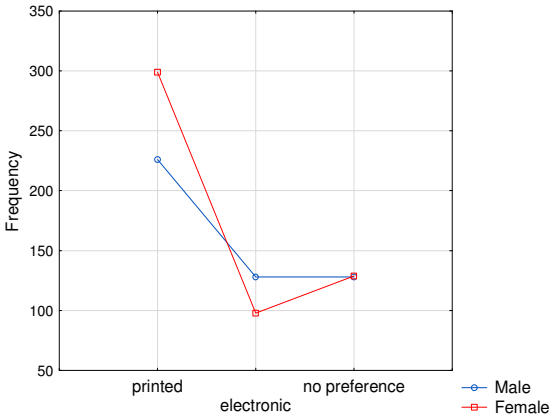

Fig 1. Absolute values of preference of study materials by gender

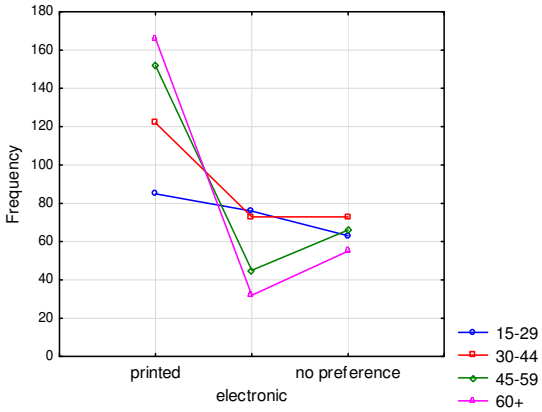

Fig 2. Absolute values of preference of study materials by age

Surprisingly, there were no significant differences between **education** groups and respondents' preference of form of study materials, $x^2(6, n = 1{,}008) = .86$, $p = .99$, Cramer's V = .02. However, in general printed materials were the most preferred from of study materials across all levels of education.

3.4 Research summary

The data revealed the following basic findings. On average, the Czech population (N = 1,008) uses modern technology and the internet while studying. However, there were two main groups of respondents. The first consists of those who never use modern technology or the internet while studying. The second consists of those who, on the contrary, use PC, laptop, tablet, and internet very often. The use of state-of-the-art technology (i.e., PC, laptop, or tablet) and the internet was considerably lower the higher the age, regardless of education level. Such a trend was found in all age categories. University graduates, although reaching the highest level of the modern technology and internet involvement, used less modern technology and internet sources while studying at younger ages. This finding highlights the fact that respondents born around the year 1957 and older most likely missed the era of rapid development of modern technology and are unable to catch up to this trend.

A third of the research sample never used modern technology while studying. Respondents aged 60 years and older represented the most frequent age category opting not to use PC, laptop, or tablet while studying. Surprisingly, respondents who never used modern technology while studying had most often achieved higher than elementary education, however, with just a few university graduates. Half of the respondents who did not use PC, laptop, tablet, or other modern technology while studying lived in Moravia, followed by respondents from Bohemia, with the lowest proportion of respondents from the capital city Prague. According to our data, the economic activity of the respondents did not have a

significant impact on those who never used modern technology while studying, indicating the financial accessibility of modern technology.

Out of the selected variables, age of respondents most strongly influenced the use of modern technology and internet while studying. Correspondingly, belonging to an age category helped explain 18% of the variance in modern technology and internet use while studying (see Table 4). Moreover, education, region, and economic activity significantly varied the level of use of modern technology and the internet. Size of respondent's place of residence also influenced the use of modern technology. The largest use of modern technology was detected among respondents with the largest size of place of residence (100,000 up). In contrast, gender did not vary the use of modern technology and internet as learning tool. However, in the case of preferred from of study materials, females used traditional printed materials more often than males and vice versa. Also, the oldest respondents (60 and up) preferred printed study materials, which in contrast were the form least preferred by the youngest respondents (up to 29 years). Although the differences in preferred form of study materials were statistically significant, the strength of the relationship indicated that the relationship was weak.

Table 4: Summary of test criteria and effect of size of tested variables on modern technology and internet use

Variables	Gender		Age		Education		Size of place of residence		Region		Economic activity	
	p	*r*	*p*	η^2	p	η^2	p	η^2	p	η^2	p	r^2
technology	.891	.01	**.000**	.18	**.000**	.08	**.006**	.01	**.000**	.02	**.000**	4
internet	.596	.02	**.000**	.18	**.000**	.07	.071	.01	**.002**	.01	**.000**	3

Furthermore, most of the respondents used internet while studying to develop personal skills, pick up a foreign language, learn how to use computers, or for future development in the fields of finance, banking, insurance, and accounting.

The research presented has several potential limitations. The first concerns the selected research technique. The questionnaires used measured probable statements by the respondents instead of real study activity. However, a general disadvantage of such an approach is the loss of control over the reliability of the data. This deficiency was balanced by the selection of a representative sample. The second limitation can be seen while working with nominal data in the form of comparison of frequencies (Chi-squared test). The results will always copy the proportion of the frequencies of nominal categories by gender, age, and other selected variables. However, the proportions in the data correspond to the proportions existing in the population. Lastly, it should be noted that in large data sets even small differences show high statistical significance. However, the post-tests were checked and interpreted. Despite all the limitations mentioned the presented findings represent unique information in the field of modern technology, internet, and type of study materials use in the Czech environment.

Conclusion

The current young generation is the first generation that is growing up and socially maturing through new technologies and social networking. Such a development creates differences across generations and makes a significant difference between those who have become familiar with new technologies in a later stage of life. This trend was also reflected by the predominance of the younger generation in the most affected age category by technology development (Kolesárová, 2014).

The competencies needed for the successful self-realization of each individual are different, and the ways in which these competencies can be achieved and developed nowadays differ considerably. Without a doubt, modern technology plays a crucial role and creates the need to re-evaluate educational goals and change practices in the education system. The Vision of the Digital Education Strategy by 2020 (MŠMT,

2014) is that the education system will ensure that every individual without discrimination will achieve the highest possible competencies that will enable him or her to succeed in the present and future information society through the option to use open education in the context of lifelong learning. Despite this effort, the current centralized education system has not responded with sufficient flexibility to information development.

The aim of this study was to find out how the Czech population uses modern technologies and the internet in learning. The results broaden the knowledge in an area still affected by new challenges and untapped opportunities. Hence, new initiatives are emerging (Arnesh, Erstad, Jahaňák, & Zounek, 2016) calling for increased attention to this area and motivating further theoretical and research activity in the area of ICT in Czech education.

Abstract

The development of the service sector is an outstanding feature of the world economy. In the non-favorable economic environment and increasing competition the main goal of Russian companies in the sphere of services is to increase their competitiveness. The solution of this problem requires the formation of a methodical approach to assessing and analyzing the real state of the competitiveness of enterprises. The article describes main features of the IT-service sector (the most promising and dynamically developing sectors of the Russian economy) and main problems of IT companies' activity. Practical methods for assessing the competitiveness of service enterprises are analyzed, and the disadvantages of these methods are revealed. A methodical approach to assess the competitiveness of IT companies is proposed, which takes into account the features of companies' functioning and includes an objective and labor-saving procedure of evaluation. At the first stage of the study factors determining the competitiveness of an IT company are defined: current efficiency and adaptability. The main characteristics of the factors are considered and their impact on competitiveness is analyzed. The key role of an adaptive component, used in evaluation of the competitiveness of IT companies in a rapidly changing external environment is proved. The adaptability of the enterprise is analyzed using the example of the 20 most successful Russian IT companies in terms of market share dynamics, and a graphic interpretation of the assessment is pro-vided by building a competitive field. The position of each company in the competitive field is revealed, a map of strategic groups is drawn up for quantifying the competitive position of competing enterprises. Analyzed enterprises are divided into the following groups: leaders, unstable leaders, persecutors and laggards. Based on the results of the competitiveness assessment, it was suggested to develop measures for further developing or changing the competitive position of a particular company in accordance with identified challenges.

Keywords: service sector, IT-sector, IT-industry, assessment of competitiveness, current efficiency.

Introduction

The service industry is one of the most promising and rapidly developing sectors of the economy. Analysis of international trends indicates an increasing role of services in the economies of many countries (for example, such countries account for more than 70% of GDP of the European Union (Growth, 2017)). The most rapidly developing sector is business services sector, which is presented by the following types: audit, research, logistics, information, marketing, advertising, consulting, etc. A significant growth in business services sectors is determined during last decade due to the growth of the transactional sector of the economy.

For its sustainable development service providers must promptly and adequately respond to all of the changes in the external and internal environment. A special role belongs to the companies operating in one of the most dynamically developing sectors of modern economy – the information technology sector (IT services).

In a rapidly changing external environment the importance of efficiency management mechanisms for such companies is significantly increased. These circumstances lead to the strengthening of the role of research and development aimed at improving the competitiveness of enterprises operating in the field of information technology as the most important for ensuring innovating development and growth of the Russian economy. Ensuring the competitiveness of enterprises in the sphere of IT-services is a challenging, dynamic and complex process requiring the adoption of rational management decisions. These decisions should be based on an assessment of the real state of the enterprise's competitiveness, which allows identifying the main problems of activity and outlining the ways of their solutions. The determination of the evaluation method of competitiveness of such enterprises should be specific to their activities, associated with the need for rapid reaction to changes in the external environment. The relevance of this study is determined by insufficient knowledge of practical and theoretical aspects of ensuring the competitiveness of enterprises in the information sector, as well as problems for effective implementation of the necessary tools of competitiveness.

The State of the Sector of Information Technologies

At present, the volume of the world information technology market is estimated at more than 1.7 trillion. US dollars, it is included in 25% of the fastest growing large markets in the world economy (Strategy, 2013). Information technologies increasingly penetrate into every industrial sector; their consumers are both end customers and corporate clients. Prospects for the development of the IT services sphere are connected not only with the expansion and involvement of an increasing number of industries and companies, but also with the constant need of existing users in support, updating and modernizing of used informational solutions.

IT industry has experienced two fundamental changes in the paradigm of its development, which is reflected in the theory of the three platforms (Jackson, 2014), the features of each of which are presented in Table 1, over relatively short time of IT sector existence. The transition from one platform to another is accompanied by a significant reversal both in technology development and in the user's new demand for certain types of equipment and information solutions provoked by new technologies.

Table 1: stages of IT industry development

Number of platform	Main characteristic	Amount of users
The first platform	Using mainframe and terminals	Thousands of users
The second platform	Usage of personal computers, Internet, client-server architecture	Millions of users
The third platform	Widespread use of mobile devices, big data, cloud services and social technologies	Billions of users

Such variability of demand and the market dependence on the introduction of new technologies is one of the main features of the IT industry, defining the direction of competition and the basic competitive advantage of existing companies. In conditions of a sharp change in the paradigm of the industry development some companies, with relatively high inertia and without ability to adapt to changes in the environment, leave the market. Another part of companies for continuing its development has to change after the market or, more preferably, to form changes of the market by itself. In the case of the company's adaptation, serious changes await all areas of its activity, up to a change of mission as the essence of the strategic vision. So, one of the most striking examples is the change in the mission of Microsoft in the transition of the industry to the third development platform.

It should be noted that for the information technology industry changes in a very high level are becoming routine, while in traditional industries cardinal breaking is extremely rare and takes a long time. An example is the change in the technological order during the industrial revolution. Change of players in the market also has been quite slow and sometimes fall into complete life cycle of the company. Today the IT industry that seemed to "tectonic shift" on a planetary scale is in everyday reality, so companies can't justify their failures critical scale and nature of the changes, and must be prepared to manage their competitiveness in a rapidly and significantly changing environment. For Russian IT companies (figure 1) the situation is complicated by the fact that they operate in adverse economic conditions. Medium - and short-term forecasts of development of Russian IT-market is far from optimistic. It is expected significant reduction of effectiveness, including by reducing the presence of foreign companies (TAdviser.ru, 2016). This is explained, on the one hand, the continuing decline of the Russian economy that makes consumers reduce their budgets, but on the other hand, competitive pressure from global IT companies (figure 1).

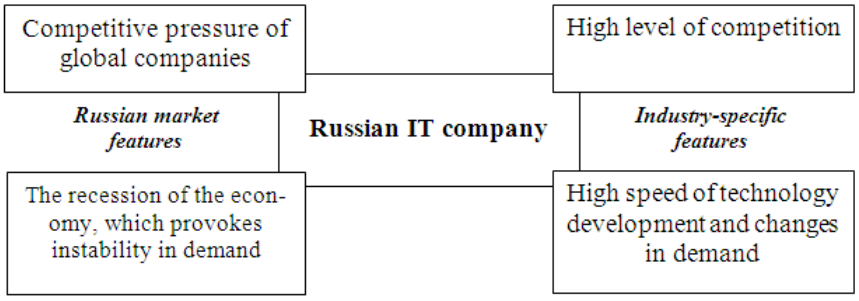

Fig.1. External factors influencing the activities of Russian IT companies

Domestic IT industry satisfies the requirements of the Russian market by less than a quarter, and largely due to service provision segment. Approximately 25% of all the software and about 80% of all IT services are produced in the domestic market, but all of domestic demand in the segment of providing equipment is fulfilled by imports.

In Russia, service companies are widely represented, which operate not only in the domestic market, but also in the markets of Europe, the United States and other countries.

Due to the high degree of variability of technology and demand for IT companies it is extremely important to be at the forefront in terms of technology, which is quite possible in the conditions of a constant inflow of financing and high rates of development of the industry. In this sense, the decline in demand in the Russian market amid growing global market is extremely unfavorable for Russian companies, since companies lose existing and potential competitive advantages due to falling volumes of financing of promising developments. In addition, we should note a higher initial level of development of the global companies (registered primarily in the US), which initially puts Russian firms in the position of "catch-up", and as practice shows, from the position of “catch-up” it is easy enough to move to the position of "laggards."

An objective assessment of Russian companies’ level of competitiveness for competent management should be provided in each specific period of time.

Methodological approach of evaluating of competitiveness of Russian IT companies

Based on the analysis of the conceptual framework, given in the publications of Russian researchers (Metelev, 2009; Pogonev, 2010), under the competitiveness of the organizations in business services sector we understand the superiority over competitors on a selected market segments in specific period of time determined by the range and quality of services, as well as the share of a particular market segment and competitive potential.

Studies show that currently in Russia there is no generally accepted methodology for assessing the competitiveness of enterprises in the sphere of business services. In general, the assessment is based on the same parameters as for industrial enterprises (Kuchina, 2016). Existing approaches can be divided into two large groups:

1. Approaches that assess the competitiveness of an enterprise on the basis of its financial performance;
2. Approaches based on the assessment of the competitive advantages of the enterprise with the help of expert assessments.

The authors believe that financial indicators reflect the current position of the enterprise in the existing environment, and competitiveness is defined as a dynamic concept. Therefore, only financial indicators are clearly insufficient for evaluating and forecasting the competitiveness of companies. Evaluation and calculation methods based on expert (ballroom) assessment allow you to compare competitors; however, these methods require the use of mathematical methods, which are quite complicated and expensive.

In this context, a methodical approach is proposed, which includes an objective and not-time-consuming procedure for assessing the competitiveness of IT companies using a small amount of initial information.

At the first stage of the study, which based on the previously noted features of the functioning of Russian IT companies, factors of companies' competitiveness are determined (figure 2).

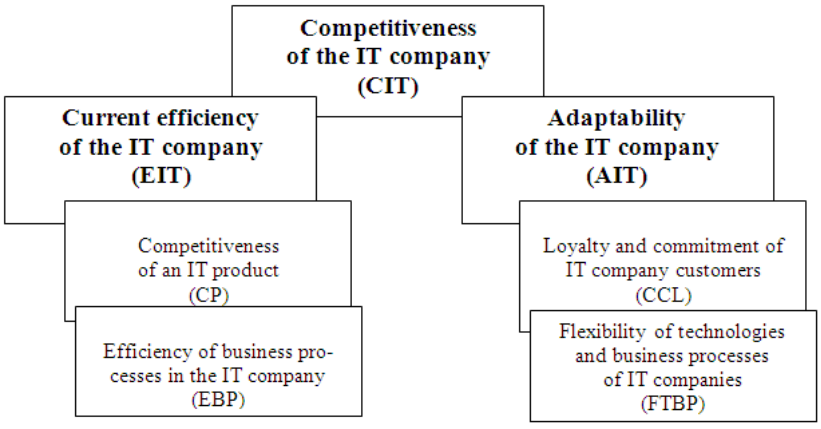

Fig.2: Factors determining the competitiveness of IT company

Current efficiency of IT companies is determined by the competitiveness of the IT product and the efficiency of business processes. To assess the competitiveness of the product there are indicators reflecting the performance characteristics of the product (usability, speed, productivity, reliability, etc.), product perception characteristics (design, image, etc.), infrastructure characteristics (support conditions, service level, availability modifications, etc.). The price of consumption of the product is formed under the influence of the following indicators: the price of its acquisition, the cost of operation and support, the cost of refusing to use it.

Evaluation of the effectiveness of business processes is conducted in three areas:

1. Efficiency of the use of resources (indicators of profitability and asset turnover, labor productivity, etc.);
2. Organization of flows and processes (coefficients of the rhythm of processes, indicators of supply and sales reliability, indicators of progressiveness of applied technologies, etc.);
3. Satisfaction of counterparties (the share of constant suppliers, the density of receipt of complaints, the turnover rate of staff, the characteristics of the credit history of the enterprise, etc.).

The current efficiency is related to the transformation of the strategic business process of competitiveness management into the operational one (Agilemanifesto.org., 2017).

The most important criterion of competitiveness is the ability to respond quickly to changes in the dynamically developing external environment. Therefore, the next important phase of evaluation of competitiveness of an enterprise is the analysis of the potential component of the competitiveness, namely, the adaptability of the enterprise. This indicator determines the ability of the enterprise to maintain its sustainability and the main development strategy in the conditions of changing the external environment and use the opportunities provided by these changes.

Adaptability of the IT company is a basic element of competitiveness. It consists of two characteristics: 1) the loyalty and commitment of customers; 2) the flexibility of the technology and business processes. The first characteristic of adaptability can be attributed to ways to ensure the company's sustainability to certain barriers that hinder the negative impact of global market changes on the performance of the company. Such braking in conditions of high speed and the likelihood of changes may not be so critical for the enterprise, since it gives time for adaptation and integration into new conditions without losing the main part of the client base. One of the most powerful tools for retaining and attracting clients strategically is definitely the strong brand of the company.

The second characteristic of adaptability demonstrates the company's ability to promote technology and business processes that are most attractive to its business in a changing environment. It should be noted there are several main areas of flexibility:

1) Diversification of the product portfolio as sold products and products under development.
2) Innovative products which give a good chance to be in the forefront of the market in a situation of the emergence of new technologies shaping the changing demand of users.
3) Daily use of flexible business processes that are focused on:
- constant monitoring of trends in technology and changes in consumer demand;
- simplification of procedures and speeding up the adoption and passing of managerial decisions related to the adaptation of the company to environmental changes;
- maintenance of technical, technological and organizational capabilities of the company's adaptation to environmental changes.

Authors believe that it is advisable to analyze the adaptive component of competitive-ness, using the indicator of market share dynamics for an objective assessment of the competitiveness of IT companies. The main advantage of this assessment is the high speed and ease of information collection.

The assessment of competitiveness based on the rating of Russian IT companies, included in the first twenty by the end of 2016 should be considered firstly (Ranking TAdviser100, 2017). The main indicator of the rating is revenue and its dynamics over the past few years. The set of the first 20 companies is made due to the fact that they own more than 83% of total revenue of one hundred the largest Russian IT companies. Table 2 presents the results of calculations of the relative market share of these companies in dynamics, and figure 3 shows its graphical interpretation.

Table 2: stages of IT industry development

Name of company	2016 year	2015 year	2014 year	Name of company	2016 year	2015 year	2014 year
1. Rosteh	19,27	21,73	21,62	11. RRC Group	2,71	3,57	3,14
2. NKK	15,72	14,53	16,09	12. SAP CIS	2,53	2,49	2,23
3. Lanit	10,98	10,60	10,80	13. Compulink	2,16	2,01	2,23
4. Softline	5,49	4,90	4,49	14. Asteros	2,05	1,97	2,38
5. TechnoServ	5,03	5,34	5,34	15. Sbertech	1,95	1,57	1,22
6. Kaspersky Laboratory	4,14	3,89	3,09	16. Infosystems Jet	1,84	1,69	1,70
7. 1S	3,58	3,71	3,81	17.Optima	1,51	1,25	1,32
8. ITG	3,50	3,67	3,93	18. Envision Group	1,26	1,33	3,31
9. I-Techo	2,85	2,95	2,81	19. Satel	1,24	1,20	0,00
10. Krok	2,73	2,84	3,12	20. AT Consulting	1,14	1,27	1,22

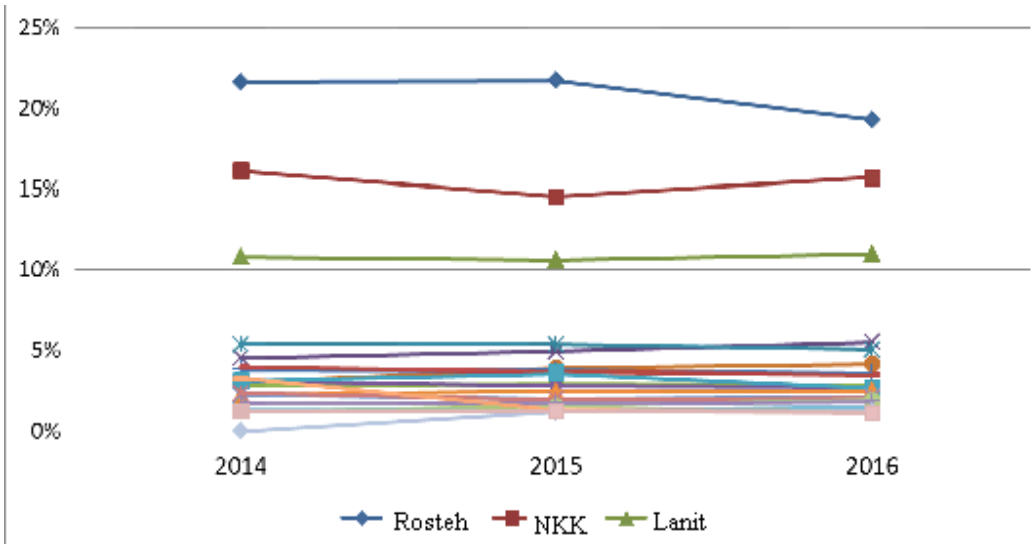

Fig.3: Dynamics of the relative market share of IT companies (top-20)

The presented data indicate the presence of three permanent leaders (Rosteh, NKK, Lanit), whose positions remain unattainable for the nearest competitors during the time being investigated. The dynamics of the relative market share of the remaining seventeen companies (positions 4-20 in the rating) is shown in figure 4. The majority of the companies has unstable dynamics, which indicates their insufficient adaptability.

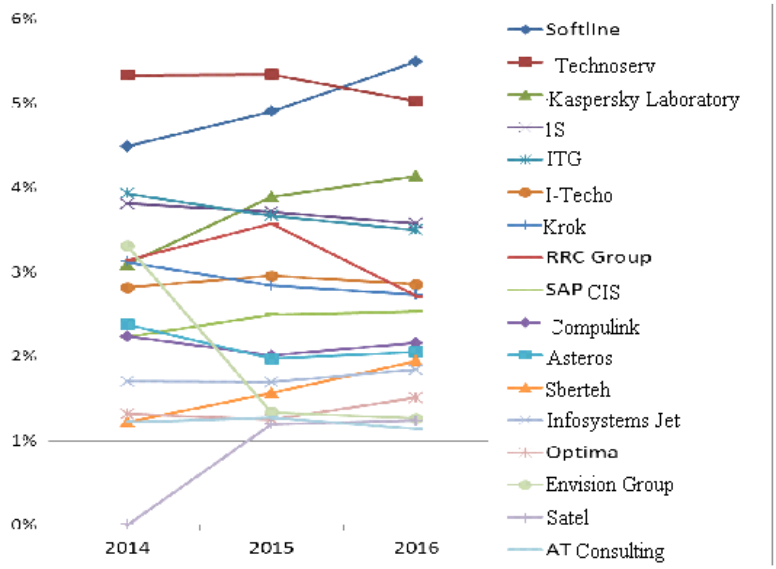

Fig.4: Dynamics of the relative market share of IT companies (positions from 4 to 20)

According to the calculated values of chain growth fractions (Table 3), we can distinguish:

- a group of relatively prosperous companies that demonstrate growth of up-market (1 - 5);
- a group of companies with a stable negative dynamics of market share change (17-20);
- a group of unstable companies, where all of the leaders are (6-16).

Table 3: Chain Growth of Relative Market Share, Points

Name of company	2016 year	2015 year	Name of company	2016 year	2015 year
1. Softline	0,59	0,41	11. Optima	0,26	-0,07
2. Kaspersky Laboratory	0,25	0,80	12. Rosteh	-2,46	0,11
3. SAP CIS	0,04	0,26	13. TechnoServ	-0,31	0,01
4. Sbertech	0,38	0,35	14. I-Techo	-0,10	0,14
5. Satel	0,04	1,20	15. RRC Group	-0,86	0,43
6. NKK	1,18	-1,56	16. AT Consulting	-0,13	0,05
7. Lanit	0,38	-0,19	17. 1S	-0,14	-0,10
8. Compulink	0,15	-0,22	18. ITG	-0,17	-0,26
9. Asteros	0,08	-0,41	19. Krok	-0,10	-0,28
10. Infosystems Jet	0,14	-0,01	20. Envision Group	-0,07	-1,97

To analyze the competitive situation in the IT market, we will assess the demonstrated competitiveness of the company based on comparison of market share and its dynamics (Baeva, 2010). Competitiveness assessment is carried out by a graphic method based on the construction of a competitiveness field consisting of four quadrants: in the quadrant "unstable leaders" there are companies with a high market share (vertical axis), but demonstrating its negative dynamics (horizontal axis); quadrant "leaders" should include companies with both high market share and positive growth; "laggards" are market participants with a declining small share; "catch-up" are companies that currently have a minor, but growing, share of the market, making them contenders for the leadership (figure 5).

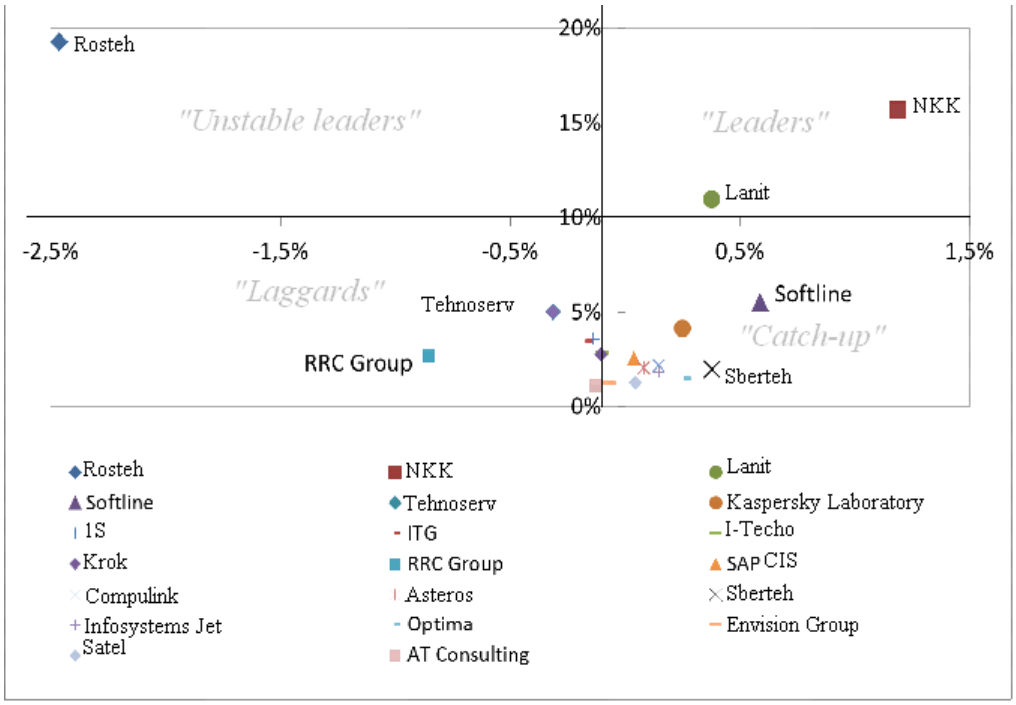

Fig.5: Distribution of IT-companies by the level of competitiveness in 2016

In the presented field of competitiveness there are three leaders of the industry: the NKK, Lanit and Rosteh. The first two companies show positive growth, the third one – negative. Despite the fact that the decline in market share of Rosteh is the maximum, this company remains the largest company in the whole market, and it allows taking her to the group of "unstable leaders". Most companies with insignificant market share are concentrated near the vertical axis, showing an increase close to zero. The affiliation of such companies to the group of "pursuers" or "laggards" is very conditional. In the group of "laggard" RRC Group can be identified; in the group of "laggards" there are Softline, Sberteh and Kaspersky Laboratory.

The result of a complex estimation of competitiveness of the enterprise in IT-sphere should be the development of a system of measures for further development or change in competitive position of the company in accordance with the identified problems and shortcomings of the existing system on the basis of the mechanism of ensuring competitiveness of the enterprise.

Conclusion

In conclusion, the proposed method for assessing the competitiveness of companies operating in the field of information technology allows a comprehensive assessment of competitiveness based on:

1. Current efficiency (IT product competitiveness and efficiency of business processes).
2. Adaptability (customer loyalty and commitment; and the flexibility of technology and business processes).

The proposed method is universal, quite simple to use, also it relies on a statistical basis, does not require complicated calculations, it can be used as a management tool at both the strategic and operational level. Using this method it is possible to carry out continuous monitoring of the activities of an IT company,

identifying its weak points, and to make informed decisions on the management of competitiveness. The advantage of this method is the possibility to determine not only the degree of the current competitiveness of enterprises, but also its real and potential willingness to participate in the competition.

Benchmarking to Adopt an Asap-Based Methodological Guideline for Software Systems Deployment

Dante Carrizo, Computer Science Department, University of Atacama, Copiapó, Chile, dante.carrizo@uda.cl
Liliana Sanchez, ICT Department, University of Atacama, Copiapó, Chile, liliana.sanchez@uda.cl

Abstract

Software-intensive information systems deployment is an activity informally carried out in most companies. However, many of the problems that show up during the operation of the software systems are due to lack of accuracy in this process. This work intends to enhance the importance of adopting formal practices of information systems deployment. To this aim, an ASAP-based methodological guideline is adapted for the deployment of any type of software system, and the gap between this proposal and the ones used before is established. The results of this benchmarking show that the deployments have been made complying with only some of the methodological guideline activities. This work has made possible to convince the organization of the need to formally adopt this methodology, and can help other people in charge of ICTs in this job.

Keywords*:* software systems deployment; methodology, ASAP, benchmarking

INTRODUCTION

From the beginning of software engineering, there have been many information systems development projects which have fallen out of use, and many others have extended their life, reaching high costs, not considered initially, as stated by Bohem (1981) and Davis (1993). The CHAOS report (2015) comprised a study of 50,000 projects all over the world, from little improvements to great projects. The results of this report showed that there is a lot of work to be done in order to have successful information systems development.

In the search to optimize its functionality, many organizations choose to buy packages of processes and procedures, thinking of a rapid computer solution, without a deeper analysis of their real needs. The purchase of an information system is a strategic decision which implies to evaluate the capacity of the company for its deployment. For this, critical factors concerning people, processes, and structure and resources must be taken into account, as Esteves and Pastor (2001)

With respect to People: choice of the project leader, high management support throughout the project, effective communication among all the actors, integration with the technical teams.

With respect to the Processes: to declare the vision and plan of the organization, revision of processes and adaptations to join up the system to the processes and vice versa, software validation, testing and solution of problems, monitoring and evaluating of results. Finally, about Structure and resources: change of plans and organizational culture.

Due to the high complexity and great impact of the information systems in the organizational environment, there arises the need to possess tools or guidelines that allow to assure the success in the deployment of a software-intensive system (hereinafter software systems).

This work is carried out in the context of the Atacama University, where many software have been acquired and developed but without following any formal process for its implementation. In some cases, such type of software operates with some difficulties which are overcome during their operation. But, in

some other cases, the difficulties are often so serious that lead to the removal of the software. These difficulties deal with the environment where they are distributed or simply due to the organizational culture, as declared by Cyrus and Nejad (2014).

These types of software systems are generally very promptly required and this means they must start operating without following any protocol. Nevertheless, the ICT Department is sure that the adoption of formal practices of deployment of software is a priority. To obtain convincing arguments to be presented to the organizational authorities, this work adapts a methodological guideline for software systems deployment, and carries out a benchmarking of the information systems deployments informally carried out.

The rest of the paper continues with the presentation of the work related to this research in section II. In section III, the authors' methodological guide proposal is described. In section IV, the evaluation of some deployments carried out in an educational institution is carried out to validate the necessity of the proposal. Finally, the conclusions of the paper are presented.

RELATED WORK

In Gutierrez et al (2013), there is an analysis of ERP deployment methodologies. In this work, an analysis of several deployment methodologies using a unified model is carried out. A summary of this study is shown on Table 1. The work presented in this paper is based on ASAP. Jithin (2013) work was relevant to understand the phases of this methodology. Another work by Tomé (2009) offers a global vision on the life cycle of a SAP solution based on the theoretical principles of the ERP methodologies, finding support on the ASAP standard methodology, but adapting it to the concrete needs of a certain deployment. This work made possible to analyze how the ASAP methodology was applied to a determined deployment going through all the phases mentioned in the methodology and the usefulness of the application of these methods and tools makes the project successful.

In Nagpal et al (2015) there is a new classification approach based on the ERP implementation strategy that can be categorized as custom-made, vendor-specific or consultant-specific. This research paper also conducts a comparative study of leading vendor-specific ERP implementation methodologies along-with their example cases. It then discusses how the principles of Agile Methodology as laid down in the Agile Manifesto are being incorporated in ERP implementations.

PROPOSAL OF A METHODOLOGICAL GUIDELINE

A. Accelerated SAP

The methodology for the deployment of ASAP software (Accelerated SAP), on which this proposal will be based, is the solution developed by SAP to make quick and efficient deployments. It was presented for the first time in the United States in 1966 and then was launched at a global level. Its aim is to coordinate all the necessary elements to guarantee the quick development and success of the SAP projects. SAP is an international German Company in charge of supplying ERPs to companies at an international scale and proposes its own methodology of ASAP deployment.

The ASAP methodology, shown on Fig. 1, comprises 5 phases of deployment and the main objective is to minimize time of the project, maximizing the resources and allowing to generate a model of procedures, as seen in Gullegde and Simon (2005). The first stage of this roadmap is the preparation of the project, in which the work plan is prepared, making sure that there is a common vision to reach the objectives of the deployment project. At this point, the scope of the project must be clearly defined, together with the setting up of the work teams, the assignment of roles and responsibilities and the setting of deliverables of each project phases. All of this is laid out in a document known as Project Charter. Finally, in this phase it is important to define the chronology of the activities, progress and application of corrective measures, a phase where all the consultants must have an active participation.

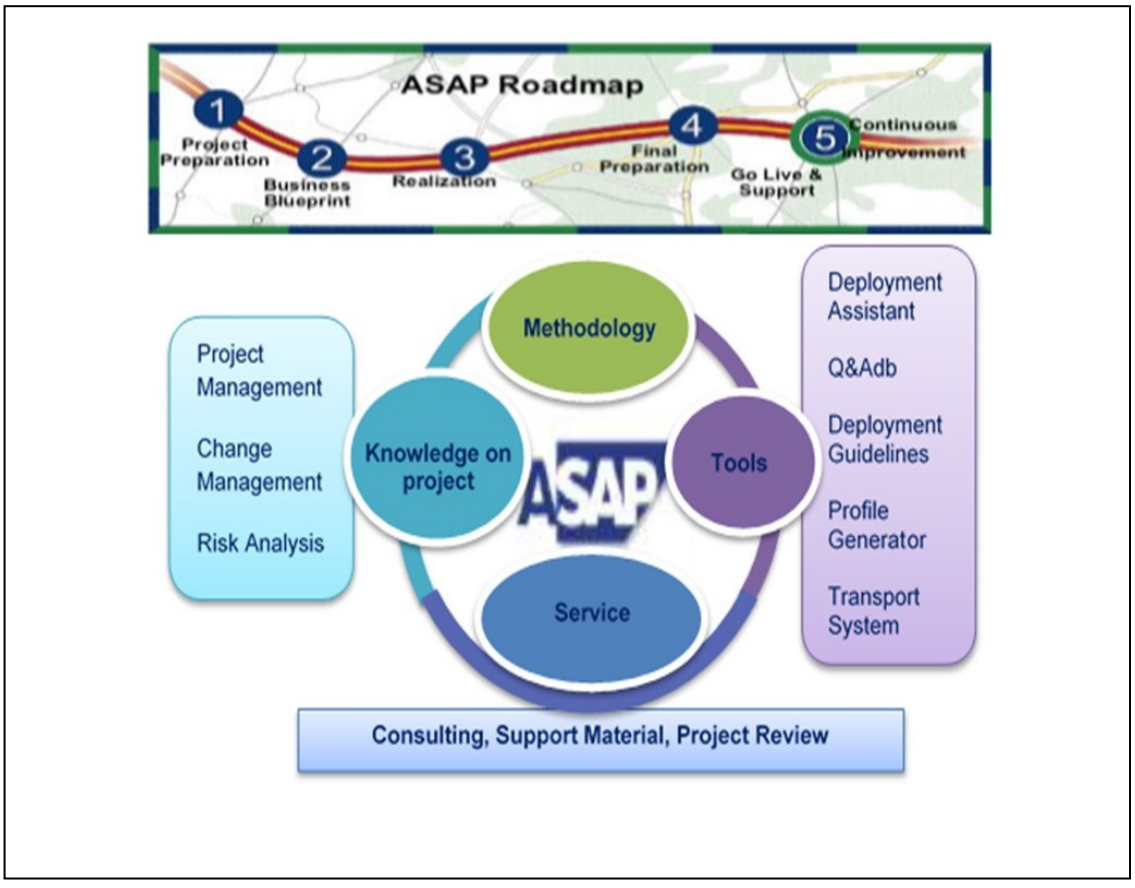

Fig. 1: ASAP Methodology (Accelerated SAP)

The second stage is Business Blueprint. At this stage of the project, the business objectives must be understood and the processes required to achieve the deployment of the system must be documented. Documentation and analysis of the information become the most delicate part of the Project. The way to document must be done at four levels, at least: Validation of the scope of the project, Organizational structure, Definition of the functional requirements, and Detail of system configuration. At this stage, the document known as Blueprint is created, which contains detailed documentation of the business processes, and defines the scope in detail and refines the objectives and work chronology. This document will be the base for the deployment of the system and its test.

In the Realization stage, everything which has been planned before is carried out, since at this point the following aspects become crucial: parametrization of the system and the development of interphases and programs, all of this based on the business model and technical models already designed.

Parametrization is the responsibility of the consultants, who will use, as a starting point, the designs already made in the previous stage, which must be validated by the user. At this point, minimal indispensable developments must be made in order for the deployment to be safe. The interphases must be developed, together with the programs of initial load, taking into account that it is necessary to have programmers with knowledge of the programming language of the older system as well as of the new system to deploy. It is at this point when a new training program is carried out to teach the technical user the parametrization of the system. Besides, the plans of the unitary and integral tests of the business processes must be conducted, and the documentation and training material for the final user must be constructed. Also, the roles and profiles of who will be the final users of the system are defined, and finally the cutover plan is described in detail.

The Final Preparation phase is prior to the production output. It is necessary to document the parametrization manuals, the users' manuals, the procedures manuals, and these must be accepted by stakeholders. Besides this, the technical user must be trained in all the models implemented of the system.

In the Go Live and Support phase, the training of the final users must be carried out, plus the unitary and integral tests to be performed in each of the processes. This will facilitate the user´s acceptance, or the correction of the errors that may appear. Finally, stress tests are necessary, of vital relevance since they will show whether the system is prepared for the operation in production. The massive load of data in the productive environment is carried out, and this information must be checked and accepted by the user, and previously purged. This step is essential for the output and must be previously planned since the loading of data usually takes some time. The users must be qualified in the operation of the system.

This phase has two immediate objectives, which will provide support for the operation and optimization of the system. The project team, at all levels, must be prepared to start helping the user to become an expert in handling the operation of the system and the new management procedures. This way, there has come the moment to make real the project and to start evaluating the benefits to the business as well as monitoring the satisfaction of the users' community. With the optimization of the system, producing and getting the results expected in the planning phase, successful deployment is reached.

B. Software Deployment Methodological Guideline

This Software Deployment Methodological Guideline (SDMG) is a basic tool for the deployment of any computer system, and in this way to successfully reach the objectives of any project of this kind in all organization. Therefore, this basic guideline will be useful to: reach clarity about the information collected during the deployment of the project; provide basic material for management and assessment; improve the way the deployment of systems is carried out; and document progress during a deployment project.

SDMG is not intended as a guideline for ERP deployments, as ASAP is, but as a guideline for every kind of software developed or purchased by an organization (ERP, Management Software, and Academicals Software, among others). The guideline will be standard and will have key points to be used as reference for any deployment (See Figure 2).

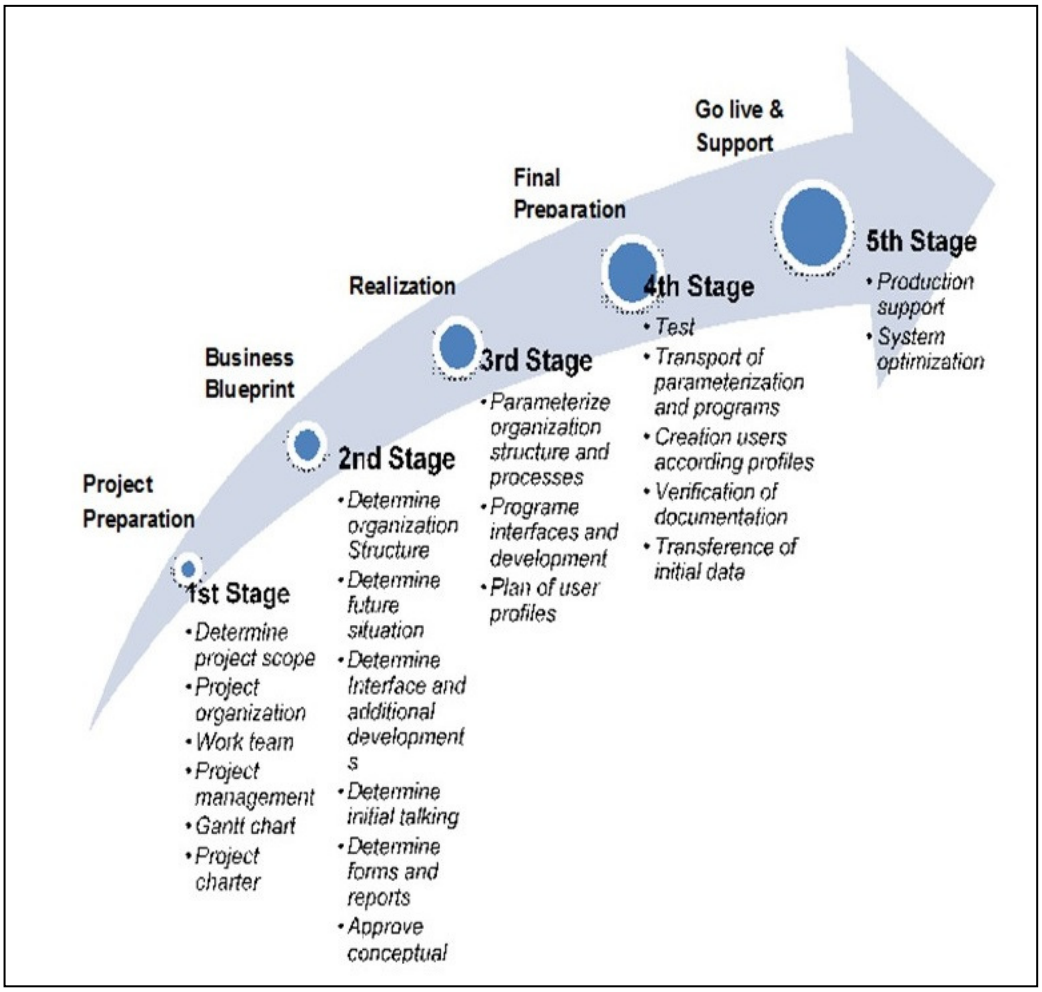

Fig. 2: SDMG phases and activities

Table 2 shows the deliverables at the different phases of SDMG, making it possible to keep a register and control of the activities performed during the deployment.

Table 2: SDMG deliverables

Stage	Deliverable
	Initial preparation
1	Project chart
	Gantt chart
	Set up of Development and Solution System, in place
	Training of the Project Team about software deployed
	Initial meeting, done
	Conceptual Framework

	Production Systems, proved
	Formal Announcement of Start Date of Production.
	Go Live and Support
5	Live Productive System
	Services of Users' Support
	Project closed

EVALUATING SDMG

To justify the adoption of SDMG, the authors conducted two types of expost evaluations of deployments of systems in the University of Atacama:

- Validation list to compare the deployment made with three software systems, as compared to SDMG, and
- Survey to deployers of other two software systems

C. Software Systems Evaluated

The five systems used for the evaluation of SDMG are described on Table 3.

Table 3: software systems used in benchmarking

Code	Name	Function	Year
S1	SIGA	Registration, Academic Register	2013
S2	ACREDITA FULL	Accreditation	2007
S3	SPDE	Prediction of Drop-Out Students	2015
S4	U+	Financial and Academic Management	2014
S5	POA	Control of Development Plan	2016

D. Validation List

This evaluation was made applying a validation list with three activities and deliverables of each of the phases of the SDMG guideline. The validation list, which can be seen in Table 4, shows whether the SDMG activities or deliverables were undertaken or not in the deployments of S1, S2, S3 softwares (W/I stands for "without information").

Of the three systems evaluated, System 1, "SIGA (System of Academic Management)" has 82% of the activities fulfilled, according to the validation list applied. In order to implement this system, a survey of the requirements and business processes of the University was carried out, as a first step, and from this point, there appeared the development to be implemented. Builder House Engineers, the firm in charge, provided the design documentation, users' manuals, process manuals, data dictionaries, and data models of

the project. As a company, they were in charge of controlling the changes of the project and held meetings with the people in charge of the project registering incidents and observations.

In relation to testing systems and loading historical information, they were made by Decom. This unit conducted validations information and system functionality, reporting all incidents encountered, for the company to make the corresponding changes to the deployment. We can say that this system meets a good percentage of the activities mentioned in this guide.

Regarding the S2 system "Acredita Full", developed by the Decom Unit, it emerged as a pressing need for the Undergraduate Unit, all this because of the lack of a system to register everything related to the tracking of cohorts of students that entered the university, information was needed from only one source to feed the Ministry of Education.

As can be seen, the evaluation of this implementation is 48% of all the validated activities. It can be said that this system was developed as was needed, so it was functionally deployed and then around this other features were added to have the system that is used until today.

This deployment in the first phase shows that the activities at this stage were not performed as part of the deployment. This is so because this system was designed between a user and a developer, emphasizing the product and not to the documentation, meetings, test plans and monitoring of deployment.

Table 4: results of validation list

PHASE	Name of Activity/deliverable	S1	S2	S3
Initial Preparation	Definition of the project team	Y	N	N
	Specification of the roles of the Project Team	N	N	N
	Technical requirements	Y	Y	Y
	Configuration standards of the software system	Y	Y	Y
	Knowledge transfer to the Project Team	Y	N	N
	Gantt chart of the project	Y	N	N
	Project chart	N	N	N
	Meeting of initial phase	Y	N	Y
	Communication plan	N	N	N
Conceptual Design	Identify and define business processes	Y	Y	Y
	Work meeting by modules	Y	Y	N
	Complete the conceptual design document, check it and get approval	Y	N	N
	Establish the schedule of users' training	N	N	N
	Determine the initial data conversions	Y	Y	Y
	Identifiy the reports requirements	Y	Y	N
	Identify the interphases requirements	Y	Y	N
	Identify developments	Y	Y	N
	Define forms and reports	Y	Y	N
	Identify the load requirements	Y	Y	N
	Design of cutover plan and change	Y	N	N
	Conceptual design document, submitted	N	N	N
Realization	Initial parametrization of the system	Y	Y	Y
	Document of users' profiles	Y	N	Y
	Definition of unitary tests plans	Y	N	Y
	Definition of integral tests plans	Y	N	N
	Aprove users' trainning plan	N	N	N
	Development of programs of retrieval and initial loads	Y	Y	N
	Data Preparation	Y	Y	Y
	Establish the functions of the system manager	Y	Y	Y
	Trainning on parametrization	N	N	N
Final Preparation	Interphase tests	Y	Y	N
	Making unitary tests	Y	Y	Y
	Making integrated tests	Y	N	Y
	Stress and volume tests	Y	N	W/I
	Dates for system shut down, approved	Y	N	N

	Formation of final users, done	Y	Y	W/I
	Assignment of users to profiles of the system	Y	Y	Y
	Users' manual	Y	Y	Y
	Procedures manual	Y	N	Y
	Final users' acceptation tests	Y	N	Y
	Load of initial data to the productive system	Y	Y	Y
	Productive system	Y	Y	Y
	Productive system, approved	Y	Y	Y
	Checklist for go live, verified	Y	N	N
Go live	Go live productive system	Y	Y	Y
	Support services for users	Y	Y	W/I
	Project, closed	Y	N	N
Control	Management of cost control	Y	N	N
	Management of risk control	N	N	N
	Training plan	N	N	N

The S3 "Early Warning System Retention" system displays 40% in activities validated from the list designed. IN this system developed by FORIS, the software encapsulates the predictive drop-out model. The deployment allows to make an advanced analysis of student desertion, as well as to take action on retention measures to apply to students with a high risk of dropping out.

A summary of the results can be seen on Table 5 and Figure 3.

Table 5: Evaluation Summary

	S1		S2		S3	
Stage 1	6	67%	2	22%	3	33%
Stage 2	10	83%	8	67%	2	17%
Stage 3	7	78%	4	44%	5	56%
Stage 4	14	100%	8	57%	9	64%
Stage 5	3	100%	2	67%	1	33%
Control	1	33%	0	0%	0	0%
	41		**24**		**20**	

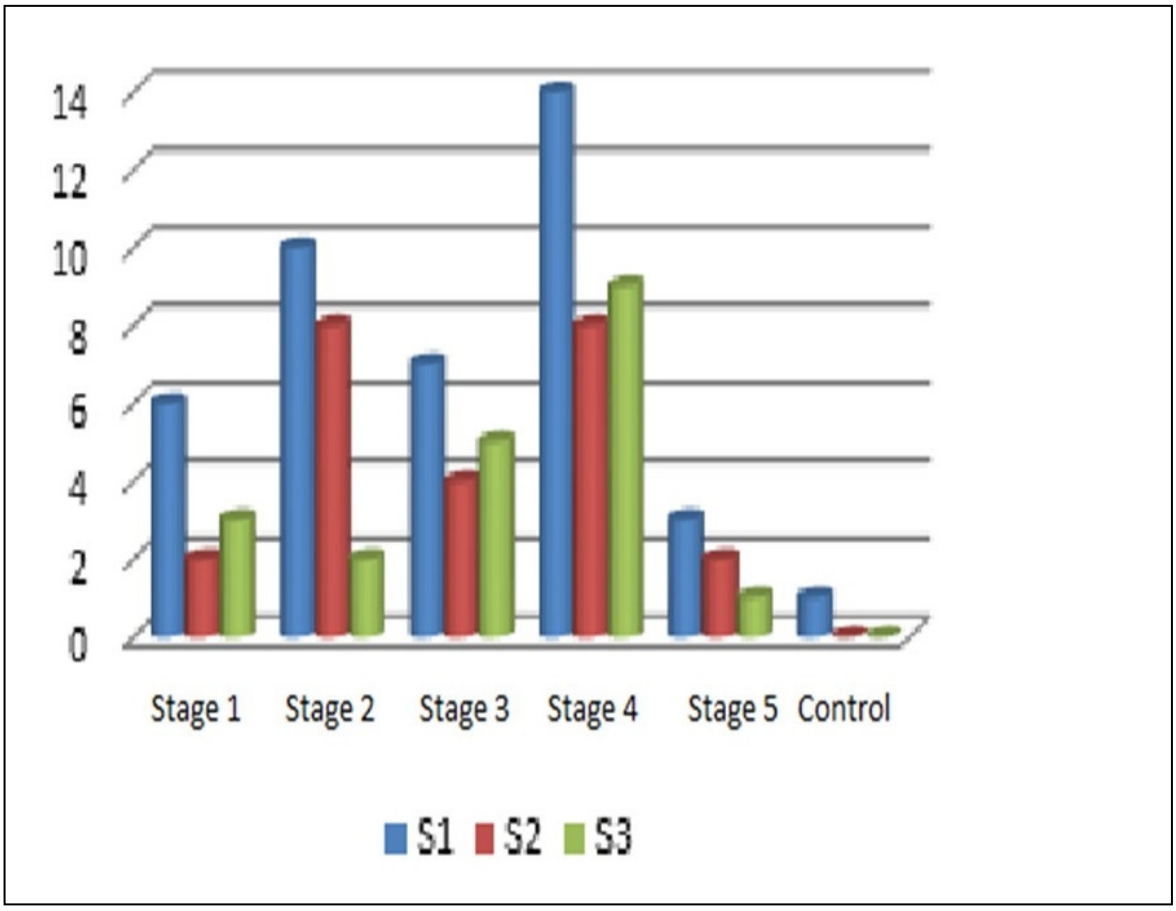

Fig. 3: Evaluation Summary

E. Survey

For systems S4 and S5, which were deployed by external personnel, a survey was conducted. This survey was divided into several items or dimensions containing questions related to deployment activities, proposed by the SDMG methodological guide. This survey is expected to have a vision of how the deployments of these new systems were handled in the institution.

The dimensions the survey consider aspects related to:

1) *The project initial preparation*
2) *The definition of business processes to implement.*
3) *The parametrization of the system, development of interphases and programs.*
4) *The final preparation of the deployment, previous tasks before the operation.*
5) *The deployment of the system.*
6) *The type of control taken during the deployment of the system.*
7) *The types of documents handled in the deployment process.*

Figure 4 summarizes the survey applied to the person in charge of the U+ system. It can be seen that 74% of the answers marked “fairly satisfied”.

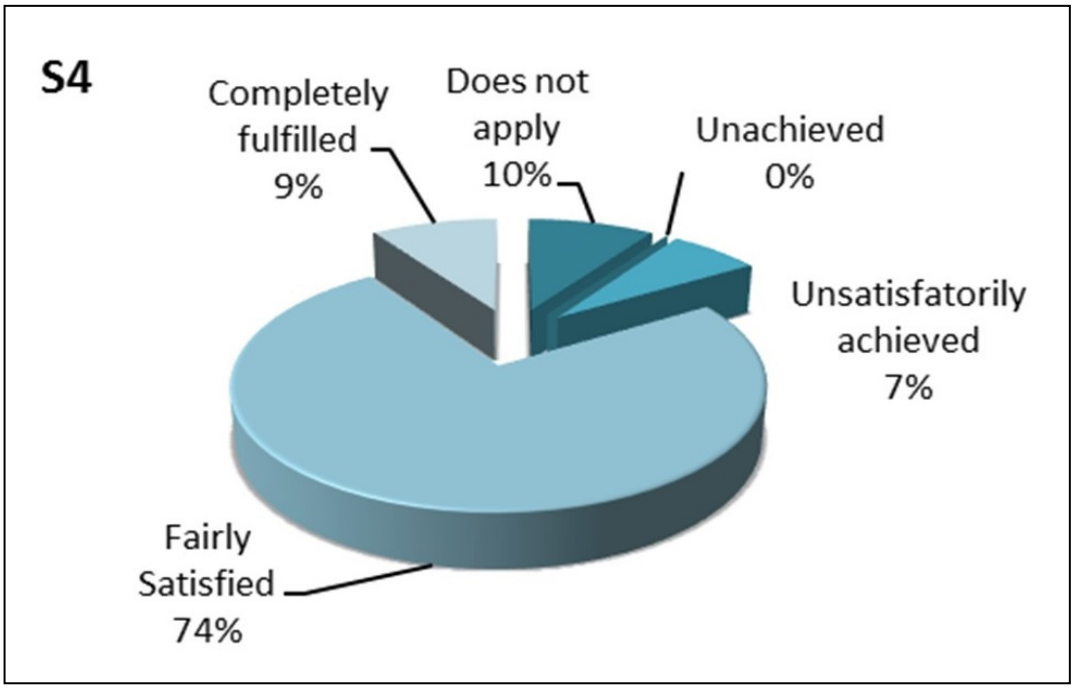

Fig. 4: Results of survey on system S4

Figure 5 shows the trend of the responses in the survey of the ERP system. It can be seen that most of the answers correspond to the criterion "Completely fulfilled" with a total of 47%; and 19% of the responses to the criterion "Fairly satisfied".

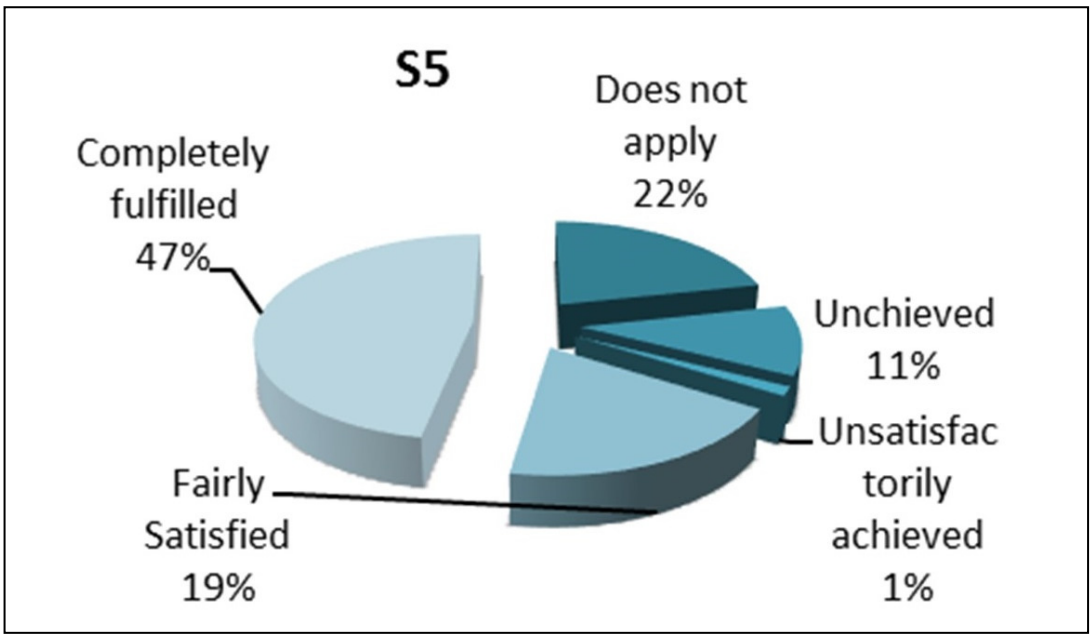

Fig. 5: Results of survey system S5

CONCLUSIONS

As there is no basic procedure for implementing software implementations, either ERP, management, or process support, in Atacama University, it is of paramount importance to lay the groundwork for this first guide to the deployment of software systems for the Institution. Therefore, some guidelines in this guide called SDMG were proposed in order to establish a way of working to successfully perform these types of implementation projects.

The ex post evaluation of information systems deployments carried out, showed that there were aspects not enough considered and that this can have an impact on the operation of software systems. In the first evaluation, it was observed that in the three systems deployed was not given much importance to the project communication plan, risk management and the process of change, which are relevant activities for a sound deployment.

The proposed methodology presented several advantages: it allows maximum utilization of resources, it incorporates a process-oriented scheme of work, it involves and ensures prompt acceptance of the system by users and the community in general, and it proposes a communication plan so that users feel part of the project and do not feel that they are at risk.

With this guide, the time of deployment of the systems can be reduced, as compared to the time initially defined. The way these deployments have been executed has exceeded the dates initially stated for them to be operative, leading to higher costs in time, personnel and resources, while the information for decision-making is not available when required.

A Case Study Regarding the Career Management Skills in the Romanian Context

Paulina Spânu[1], University POLITEHNICA of Bucharest, Bucharest, Romania,
pauspa16@yahoo.com

Abstract

The concept of „*Career management skills*" (CMS) has different meanings across European Union states. This paper presents an analysis of the concept of „Career management skills" (CMS) in different contexts and details a new proposal for a career management framework which can be used by the counselors or practitioners or can be adapted according to their needs. A lot of resources and tools for the new proposal of CSM framework were developed and some of them were made as Virtual Instruments using the LabView software. The virtual instrument described in this paper is a part of a more complex project that aims to provide applications for a lot of situations which the citizen could come across.

Keywords: career management skills, framework, LabVIEW,

Introduction

The concept of „*Career management skills*" (CMS) has different meanings across European Union states. The European Lifelong Guidance Policy Network (ELGPN) regards career management skills as competencies which help individuals identify their existing skills and necessary learning goals to improve their employability and social inclusion.

In Romania, the counselling and career guidance concept is regulated by the National Education Law no. 1/2011, at the Art. 350 - (1) „*Counselling and career guidance throughout the life refers to all services and activities that assist individuals of any age and at any moment of their existence to make choices in education, training or employment and manage their careers*".

Analyzing the actual context of CMS at European and national levels, a new proposal for definition of the CMS concept will be presented in this paper.

The European framework of key competencies for lifelong learning brought forward the idea that each citizen needs a wide range of key competencies for adapting flexibly to a rapidly changing world. At European level, CMS framework contains skills that are relevant throughout life and are pertinent at any stage of career development. In Romania, the need to define the methodological framework with specific theories and models for career guidance must be take into account as a priority. In this country there is no tradition in applying career counseling processes, which is an essential component of modern education and training. A new proposal for the career management framework described in this paper will meet some important needs of young people such as: ensuring access to educational provision, socio-professional integration of individuals, developing skills and competences required to make future changes personally and professionally. A lot of resources and instruments were necessary for the new proposal of CSM framework. Starting from this idea, a Virtual Instrument for obtaining the individuals` dominant personality type was developed using the Lab View software. The content of the personality test presented in this paper was adapted by Lana Bateman from Personality Patterns and published by Huntington House, Inc. Lafayette, LA. This content was only transposed into the Virtual instrument to help individuals to calculate rapidly and easier their dominant personality type.

The research on CMS in European and national contexts presented in this paper has been carried out within the project LEarning and Decision making Resources (LEADER), *project no* 2014-1-IT02-KA200-004105, funded with support from the European Commission, in the Erasmus+ programme.

Current state

European approach to Career Management Skills

The concept of „*Career management skills*" (CMS) has different meanings across European Union states, but in the European approach, many countries consider the following definition of the CMS available, according to research study by Sultana (2011): „*CMS refer to a whole range of competences which provide structured ways for individuals and groups to gather, analyze, synthesize and organize self, educational and occasional information, as well as the skills to make and implement decisions and transitions*". It is important to note that CMS aims to develop resources and key competencies for lifelong learning so that people manage better their life and career.

The European Lifelong Guidance Policy Network (ELGPN) regards career management skills as competencies which help individuals identify their existing skills and necessary learning goals to improve their employability and social inclusion. As a result of the researches undertaken within the LEADER project, the ELGPN definition of career management skills was adapted to the following definition: „*Career management skills (CMS) are competencies which help individuals to identify their existing skills, develop career learning goals and take action to enhance their careers"* (Neary, 2015).

In the research study by Sultana (2011) the career learning lends itself to formative types of assessment because career learning is arguably a different kind of area of knowledge than 'mainstream' curricular subjects, which tend to be more tightly 'framed' in terms of disciplinary content. A CMS programme is typically multi-disciplinary, drawing its knowledge and skills based on such areas as personal psychology, economics, sociology, ethics, and so on. CMS provision, by definition, tends to be tightly linked to the pragmatic consideration of helping unemployed persons finding jobs, and in some cases career learning is recorded and assessed in ways that facilitate recruitment. In such cases, assessment can become more goals oriented, and more summative in nature.

The European framework of key competencies for lifelong learning brought forward the idea each citizen needs a wide range of key competencies for adapting flexibly to a rapidly changing world. Since 2007, the EU Member States have been working on the theme of career management skills (CMS). At European level, CMS framework contains skills that are relevant throughout life and are pertinent at any stage of career development. Career management skills build on a range of pre-existing ideas and abilities of an individual, and intersect with other experiences.

Romanian approach to Career Management Skills

In Romania, the counselling and career guidance concept is regulated by the National Education Law no. 1/2011, at the Art. 350 - (1) „*Counselling and career guidance throughout the life refers to all services and activities that assist individuals of any age and at any moment of their existence to make choices in education, training or employment and manage their careers*".

The Romanian guidance and counselling system is mainly based on two networks:
- education;
- labor market.

Under the Law no. 1/2011, the Guidance System in Romania is focused on the following type of guidance service:

- **General education**. In this system, the counselling is provided by the School counselors and the clients are the pupils, parents and teachers. In Romania, the responsibility and administrative control of this service is assumed by the Ministry of Education, Research

and Youth, School inspectorates and Institute of Education Sciences. All of these institutions are funded by the state budget.

- **Higher Education.** In this system, the counselling is provided by the Guidance counselors and the clients are undergraduate students. In Romania, the responsibility and administrative control of this service is assumed by the Ministry of Education, Research and Youth.
- **Labor offices.** In this system, the counselling is provided by the Information officers and the clients are unemployed people or people searching for another job. In Romania, the responsibility and administrative control of this service is assumed by the National/County/Local Agency for Employment.
- **Civic Counselling.** In this system, the counselling is provided by the Information officers, civic counselor, juridical councilor and the clients are citizens. In Romania, the responsibility and administrative control of this service is assumed by the City Hall. There are many offices throughout the country. They provide information on employment opportunities, health services, child care, real estate, European integration, etc.

In Romania, there are also associations and centers which are interested in CMS:

- *National Resource Centre for Vocational Guidance.* The centre serves as link between the official sources of information (both European and national) and the beneficiaries of guidance and counselling activities (both individuals and organizations) www.euroguidance.ise.ro/
- *National Association for Educational and Vocational Guidance.* The association dealing in the field of Educational and Vocational Guidance and Counselling.
- *National Association of School Psychologists* - Training in educational and vocational guidance www.anps.ro/
- *Psychologists' Association of Romania* - Training in educational and vocational guidance www.apsi.ro/
- *Counsellors Association of Romania.*

Moreover, the law no. 1/2011specifies the types of activities that should be included in counselling and career guidance:

- *information about career*, which refers to all the information needed to plan, obtain and retain a certain job;
- *career education*, that takes place in schools through curricular area "advice and guidance". There are included , information about labor market, it is formed skills how to make choices about education, training, work and life in general, opportunities to experience different roles in community life or professional life, career planning tools;
- *career counselling* that helps people to clarify their aims and aspirations, understand their own educational profile, make informed decisions, be responsible for their own actions, to manage their career and transition process at different times;
- *employment counselling* that helps people to clarify their immediate goals on employment, learn about the skills needed to search and get a job;
- *placing at work*, which that helps people in finding a job.

In the national context, counselling and guidance are part of the national curriculum, starting with primary school. In the book by Mihai Iacob (2011), the national curriculum has the following content: self-awareness, communication and social competences, the management of the learning process, career management and development, life style.

A CMS framework is useful for individuals at any point in their lives, to identify their capacities, competences and interests to make educational, training and occupational decisions and to manage their individual life paths in learning, work and other settings in which those capacities and competences are learned and/or used. Guidance covers a range of individual and collective activities

relating to information-giving, counselling, competence assessment, support, and the teaching of decision-making and career management skills.

In Romania, career management is a focal point for both the employee and employer. Career management framework must include planning and career development. Career planning is a way to increase the overall level of performance and align business strategies with human capital present in the organization. There is therefore a need to establish appropriate educational and developmental programs for each employee to further develop the skills necessary to meet the short and long term career in line with the strategies of the organization.

In the case of CMS, the choice of assessment strategies presents specific challenges and issues given by the process of career planning and outcomes. Career planning is an important process of setting career goals, development and implementation of strategies, self-assessment and analysis of opportunities, and evaluating the results. The planning process engages both organization and individual responsibility. The individual can identify their aspirations, abilities and capabilities and, by evaluation and counseling, to understand which are the needed requirements.

The individuals can acquire career management skills in different ways and at different rates. Although career management skills can be learned, individuals need to learn in different contexts. The career management skills framework must be designed to support the development of carrier services in different context, for different people, for different groups, with different personalities and different needs. Therefore, the CMS framework should be adapted to the particular needs of specific individuals or groups (such as persons with disabilities, refugees, and early school-leavers, individuals with different religion, age and gender or minority status).

The study and research made in Romania has highlighted the fact that the following skills of the CMS framework are more relevant especially for the young people:

- realistic self evaluation of personal and professional potential;
- the efficient use of resources to identify, evaluate and select information about professional training, work and career;
- assuming lifelong learning;
- communication and social integration skills;
- skills necessary to achieve realistic career plans and adapting to labor market requirements;
- assuming realistic, achievable goals;
- stress management skills in case of job loss.

Therefore, at the national level, it is necessary to develop a CMS framework well organized and structured according to the needs of the people, adapted to the current national and European context to ensure a global approach of the individual, related to the dynamics of socio-economic development at local, regional, national and European level and to the changing demand of the labor market. Moreover, a CMS framework should be focused on the individuals` needs, developed according to their interests, preferences or aspirations.

Case study

The studies and results presented in this article are based on the researches made by LEADER partners from six countries in Europa: Romania (Politehnica University of Bucharest) Italy (University of Camerino and Centro Studi Pluriversum), Greece (Athens University of Economics and Business and Institute of Entrepreneurship Development), United Kingdom (CASCAiD and University of Derby), Spain (DEP Institut) Turkey (Cukurova University). Analyzing the current state of the CMS approach at European and national level in each country, it was developed the LEADER Framework for Careers with five main areas**:**

- ✓ personal effectiveness;
- ✓ managing relationships;
- ✓ finding and accessing work;
- ✓ managing life and career;
- ✓ understanding the world.

Under each of these five areas, the LEADER framework has a series of career management skills for which resources and tools were identified and implemented to support individuals in managing their careers according with their needs (http://www.leaderproject.eu):

- **Personal effectiveness**

- I know who I am and what I am good at.
- I'm able to reflect on my strengths and address my weaknesses.
- I make effective decisions relating to my life, learning and work.
- I remain positive when facing setbacks and I keep a positive orientation to the future.
- I make use of appropriate technologies to develop my career.
- I generate ideas that help me to achieve my goals.
- I am able to set SMART goals (Strategic, Measurable, Achievable, Relevant and Time bound).
- I can match my skills to labour market needs.

- **Managing relationships**

- I assess the pros and cons of formal and informal sources of information.
- I interact confidently and effectively with others.
- I build professional relationships and networks to support my career.
- I maintain my professional relationships and networks.
- I use social media networks to support my professional networking and my career.

- **Finding and accessing work**

- I learn throughout life.
- I can find work and successfully manage selection processes.
- I create opportunities and alternative career perspectives to build my career.
- I find and utilise information and the support of others.
- I know how to negotiate a job or collaboration.
- I can cope and negotiate successfully with changes and transitions in the world of work.

- **Managing life and career**

- I can decide on and set my career/life goals within appropriate timescales.
- I manage my goals, my time and personal finances in a way that supports my career building.
- I am innovative and creative in my thinking about work, learning and life.
- I maintain a balance in life, learning and work that is right for me.
- I can cope with adversities and changes which take place in life and career exactly at the moment they occur.

- **Understanding the world**

- I understand how changes in society, politics and the economy relate to my life, learning and work.
- I understand how life, learning and work change over time.
- I can act effectively as a part of society as a whole.
- I identify, create and capitalize on fortuitous/unforeseen situations, either positive or negative ones.
- I can act at an international level for issues relating to my life learning and work.

This new proposal for a career management framework was tested in Romania and the people involved in the testing activities made the following recommendations:

- They have considered the CSM model suitable to the actual needs of the young people. They appreciate the content and structure of the CMS considering that it is adequately and useful for their career guidance activities.

- The practitioners would like to re-design their guidance activities using the resources and tools developed according with CSM model tested. They appreciate especially the personality tests and the assessment methods.
- The resources and tools for counselling services relative to the dynamic changes of the labor market as well as the development of the available resources is imposed for decreasing the rate of university dropout and raising the rate of employment and professional integration of students and graduates.
- The career management skills framework must be improved to support the development of carrier services in different contexts, for different people, for different groups, with different personalities and needs.
- The LEADER Framework for Careers can be used in the European context because it has an innovative approach of the career counseling concept that will contribute to the development of career guidance skills for practitioners, consolers and teachers.

A lot of resources and instruments for the new proposal of CSM framework were designed and one of the most used and appreciated one by the users was made in LabView. The virtual instrument made in LabView is a part of a more complex project that aims to provide applications for a lot of situations the citizen could come across. Figure 1 shows the front panel of the Virtual Instrument for the personality tests developed using the Lab View software. The personality test presented in this paper was adapted by Lana Bateman from Personality Patterns and published by Huntington House, Inc. Lafayette, LA. The personality test has 40 items, each item being attributed to one of the dominant personality type: the popular sanguine, the strong choleric, the perfect melancholic, the phlegmatic calm.

The dominant personality type is obtained by assigning points for each personality trait grouped in the four dominant types and then by calculating the sum of the awarded points. The dominant personality type is the one that obtained the highest score.

Description of the virtual instrument functioning

The Virtual Instrument has two parts: one for the STRENGTHS" used for selecting sequentially or randomly the right answers for a certain personality feature and the other one for the Weaknesses.

To use the virtual instrument, the following steps must be followed:

- STEP 1 - Press the *RUN* button from the buttons toolbar.
- STEP 2 - From *"STRENGTHS*" select one option from the four available, pressing the R1,R2, etc tabs.
- STEP 3 - From „*WEAKNESSES*" select one option from the four available, pressing the R1, R2, etc tabs.
- STEP 4 - Click the "*Press for result"* button.
- STEP 5 - After the result is showed press the "*STOP*" button for stopping the application.

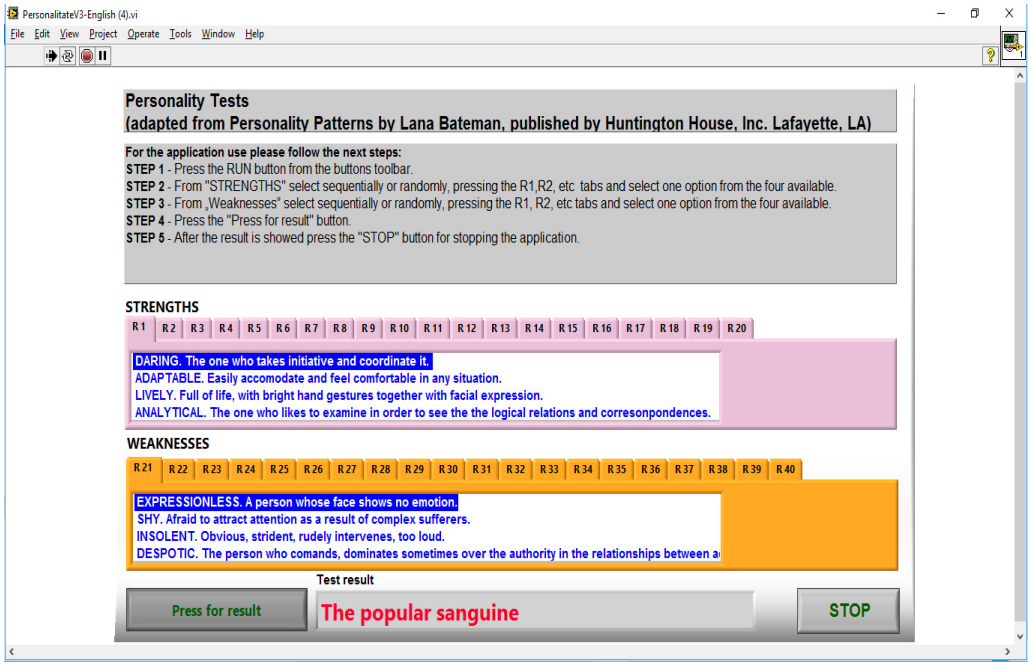

Fig. 1: The front panel of the Virtual Instrument

The application will run until the user will press the STOP button. This means, all functions from the block diagram are displayed into a While structure. The While structure repeats the subdiagram inside it until the conditional terminal receives the Boolean value from the STOP button. In order to select an option for the *STRENGTHS*" or for the „*WEAKNESSES*" the CASE structures were added inside of the While structure. The Case structures have four subdiagrams, one of which executes when the structure executes according to the numerical value wired to the selector terminal.

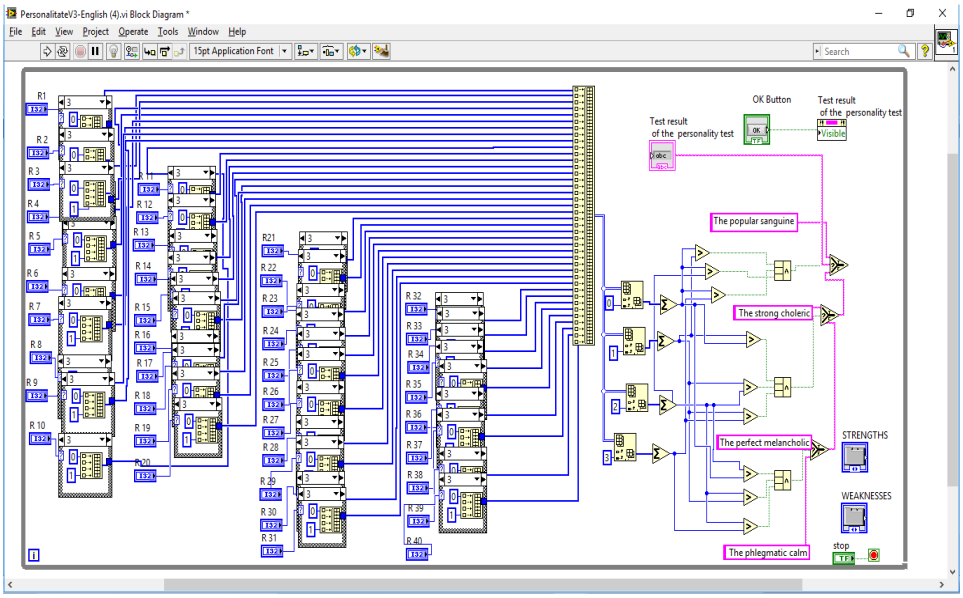

Fig. 2: the block diagram of the Virtual Instrument

The numerical value represents the number of the option selected by the user on the front panel. The application groups the numerical values into 2D Array using Build Array function. The Index Array functions were added on the block diagram of the virtual instrument to extract the numerical values only for one trait specifying the index of array. The sum of the numerical values from each array was calculated using Add Array Elements and then the results are compared between them to calculate the highest value. The dominant personality type with the highest score will be displayed into a String Indicator element when the application runs.

Conclusions

Based on the facts presented in this work, one can synthesize the following:

- The following definition of the concept of CMS could be available in the Romanian context „*Career management skills (CMS) are competencies which help individuals to identify their existing skills, develop career learning goals and take action to enhance their careers"*.
- The CMS framework is useful for individuals at any point in their lives, to identify their capacities, competences and interests to make educational, training and occupational decisions and to manage their individual life paths in learning, work and other settings in which those capacities and competences are learned and/or used.
- The new proposal of CMS framework is well organized and structured according to the specific and the needs of the people and is adapted to the current national and European context.
- The LEADER Framework for Careers can be used in the European context because it has an innovative approach of the career counseling concept that will contribute to the development of career guidance skills for practitioners, consolers and teachers.
- The Virtual Instrument for obtaining the individuals` dominant personality type has a simply interface that can be used by the individual as an executable file without Lab View software installed on their computers.
- The Virtual instrument helps individuals to calculate rapidly and with high accuracy their dominant personality type.
- The virtual instrument is a part of a more complex project that aims to provide applications for career guidance system.

Acknowledgement

The research work was performed under the project entitled "LEarning and Decision making Resources ", Project no 2014-1-IT02-KA200-004105, funded with support from the European Commission, in the Erasmus+ programme.

Abstract

This paper aims to study the way ethics influences business success. It is well known that many companies may go bankrupt because of lack of a well established overall strategy, poor quality of products, lack of innovation, focus on gaining immediate profit etc but is seems that nowadays ethics is strongly influencing business success. The study conducted reveals that implications of ethics in business are reaching a high level and they are more complex than presumed, ethical behaviour bringing significant benefits to a business.

Keywords: ethics, business success, qualitative research.

Introduction

Since ancient times, companies are searching for business success but it seems that, nowadays, more than ever, having success is not easy. Business success does not come unexpectedly in a company, it presumes efforts, wise strategies, risk assuming and sometimes failure provides the lesson for success. Many factors are implied in gaining business success (such as employees, processes, management, strategies, etc) and it seems that there is a strong connection between ethics and business success. Furthermore, code of ethics is seen as a pillar for business success, companies without ethics being not able to exactly determine what is right and fair within their business, therefore, ethical practices may lead a company to failure or success. We shall see in the following comments what ethics is, and what does business success means; we will explore the importance of ethics and closely study the way it influences business success.

Literature Review

What is Ethics?

Longman Business Dictionary (2017) defines ethics as "moral rules or principles of behaviour that should guide members of a profession or organization and make them deal honestly and fairly with each other and with their customers". Likewise, a company should apply ethics also when dealing with its stakeholders, in addition to its customers or employees (Cleveland, 2002). Moreover, some authors, Ferrel et al (2011) and Pauna et al (2014) have shown in their paperworks that fairness and honesty represent the heart of a moral business and there should be no discrimination when it comes about applying the rules within an organization. A code of ethics may help companies to improve their business activities, reducing ambiguities and communicating the ethical vision of the company to all interested parties. But what is a code of ethics? After reviewing several definitions of code of ethics, Schwartz (2004) issued that "a code of ethics is a written, distinct and formal document which consists of moral standards used to guide employee and/or corporate behaviour". Firms who operate at international level are more likely to have a written code of ethics; a study upon this was conducted

by McKinney & Moore in 2007. In the specialty literature, Kaptein (2004) and Kaptein & Schwartz (2008) clarified that for code of ethics there have been used other various names such as code of conduct, integrity code, business code, corporate credo, code of practice, business principles, corporate philosophy, corporate ethics statement.

What is Business Success?

There are many points of view about business success which shall be discussed below but what we know for sure is that success always brings an award for those who hold it. In fact this award is the one who triggers people for gaining success. But an exact recipe that would lead a company to success can not be set as success does not mean same thing to everyone: for some people, being successful means to reach a top position and have enough money to leave happy, without worries and fears regarding the future.

For others, having success may consists of being a top seller on the market. But business success is not only about selling products that suites the market. This is the result of having success and it starts with the leadership of the company. In his book, Baggett (2000) has shown that within a company, leaders should be the firsts who strive for companie's success and the best leader is the one who serves the others, thinks that finding a solution represents a higher priority than placing blame, understands the power of synergy, is flexible, open minded, fully accepts responsibility, shares knowledge, knows that employees want to be heard and understood, learns from failure, listens with his ears as well as with his heart, place effectiveness ahead of efficiency.

For other authors like Gagliardi (2006), business success means to be better than the competitors on the market and in its opinion the key of success is to develope dominating competitive positions that can not be attacked by competitors. In his book, Gagliardi presented nine formulas that describe how to build dominant positions and have business success.

Techniques for eliminating barriers to profitable growth, change management, business process improvement represents the basis of business success says Peter Cleveland (2002), senior vice-president at Ernst&Young. Case studies and methods that lead businesses to success can be found in Carstea (2016), Carstea et al (2014), David (2011).

As we can see, there are many points of view of approaching business success but one thing is clear: any company is searching for success and the way it reaches it, may differ from one to another.

Link between Ethics and Business Success

According to Ethisphere Institute, the global leader in defining and advancing the standards of ethical business practices, among 2016 world's most ethical companies list there are: Dell, Ford Motor Company, Intel Corporation, Levi Strauss & Company, L'Oreal, ManPower Group, Marriott International, Marks&Spencer, Royal Carribean Cruises, Starbucks, Xerox (the list includes 131 companies spanning 21 countries and 45 industries). All these companies are business successful thus showing us an implicit connection between ethics and business success.

In his article published by Forbes, Strauss (2016) mentioned that the goal of Ethisphere's ranking is to offer a model on how corporate entitities should manage themselves, improving their own activities and have business success. He said that this list "represents some of the best the international business world has to offer". Ethisphere (2017) evaluates firms upon 5 criteria considered as core for ethics, namely: ethics and compliance program; corporate citizenship and responsibility; culture of ethics; governance; leadership, innovation and reputation.

For this survey, there were also taken into account companies' size, geographic location, activity domain (industry), history of litigation, reputation, ethical track record, and other factors like risks exposure, sustainability, etc. Ethisphere does not take into account firms that deal in alcohol, tobacco or firearms (Strauss, 2016).

Another study conducted by Ethics&Compliance Initiative (2016) is Global Business Ethics Survey, a research project performed through online panels from 13 countries. This survey provides reliable insights about organizational ethics in global economies that are critical to business success on the basis of four key metrics: pressure to compromise organizational standards, observed misconduct, reporting of misconduct when observed and retaliation against reporters. Thus, ECI identified some principles common to High-Quality Ethics and Compliance Programs that may help company to reach business success, among which we mention: ethics and compliance are central to business strategy and leaders at all levels across the organization have to build and sustain a culture of integrity that prizes ethical decision-making.

Methodological Aspects of the Qualitative Research

In his book, Malhotra (2007) shows that qualitative research provides insights and understanding the problem setting, while quantitative research seeks to quantify the data.

Qualitative research aims to provide a deep understanding of people's contextualized behaviour. It aims to explain how and why people behave as they do, therefore there are examined beliefs, perceptions, motives, attitudes and opinions as mentionned by Bowie and Buttle (2004).

Survey Method. A survey consists of gathering data by interviewing people. The advantage of a survey is that information comes directly from the people you are interested in. The main limitation of a survey is that are opportunities for error in the construction of the survey questionnaire.

As stated by Etzel et al (1997), personal interviews are more flexible than phone or mails because more information can be obtained by personal interview and interviewers can probe more deeply if an answer is incomplete.

The purpose of this study was to determine the connection between ethical behaviour and business success, the general objective of the research being to learn about the concept of ethics in business.
In order to reach the above-stated aim, the following specific objectives were established:

1. *To identify individuals representing ethical models for the interviewed subjects;*
2. *To identify the factors influencing the unethical behaviour;*
3. *To identify the way in which breaking the principles of ethics affects the quality of work and products/services provided.*

In order to achieve the objectives listed above, a qualitative research was conducted, using the in-depth, semi-structured interview method. The sample was made of 20 subjects and the structure of the interviewed people is presented in Table 1.

Table 1: The Structure of Research Sample

Participant	Demographics					
	Seniority [years]	**Field of Work**	**Type of Company**	**Age**	**Gender**	**Studies**
S1	28	State public service	National	54	Female	Higher education
S2	27	Management, supply chain, import, distribution	National	47	Male	Post-graduate
S3	8	Furniture design	National	27	Male	Student
S4	20	Automotive, financial field	National	42	Female	Higher education
S5	20	Economics	National	40	Female	Higher education

S6	10	Non-profit, social, humanitarian and educational activities	National	38	Male	Higher education
S7	20	Services	National	44	Male	Post-secondary education
S8	20	Sales	National	42	Male	Higher education
S9	20	Culture	National	47	Male	Higher education
S10	5	Trade	National	25	Male	Student
S11	15	Technical	Multinational	33	Male	Higher education
S12	21	Industry	National	39	Female	Higher education
S13	21	Economics	Multinational	47	Male	Higher education
S14	5 months	Nutrition	Multinational	22	Male	Higher education
S15	1.5 years	Trade	Multinational	21	Female	Student
S16	6 months	Services	Multinational	22	Male	Higher education
S17	19	Automotive	Multinational	40	Female	High School
S18	2.5 years	Services	Multinational	28	Female	Higher education
S19	20	Services	Multinational	49	Female	Higher education
S20	1.5 years	SPA	National	20	Male	Student

The subjects interviewed were chosen taken into account their education and training but also their work experience (either students or graduates of economics faculties who studied subjects that dealt with concepts related to business ethics, or practitioners who were able to express an opinion from their own experience). The structure of the interviewed subjects by gender, type of organization they work for and their seniority is presented in figures no. 1, 2 and 3.

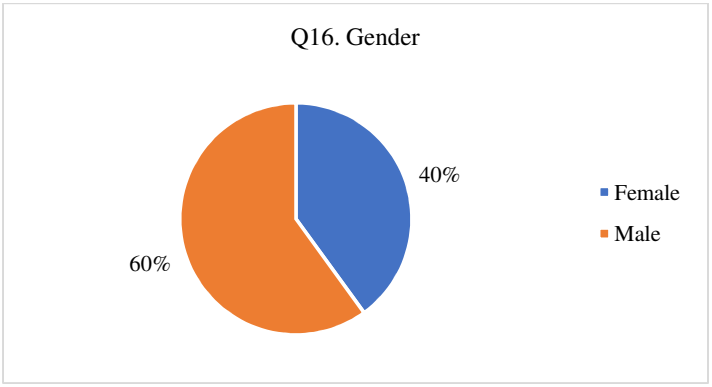

Fig. 1: Subjects Gender

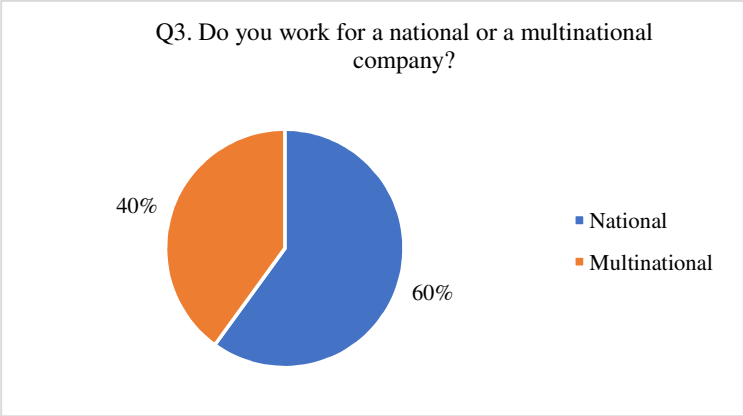

Fig. 2: Subjects Division by the Type of Organization They Work for

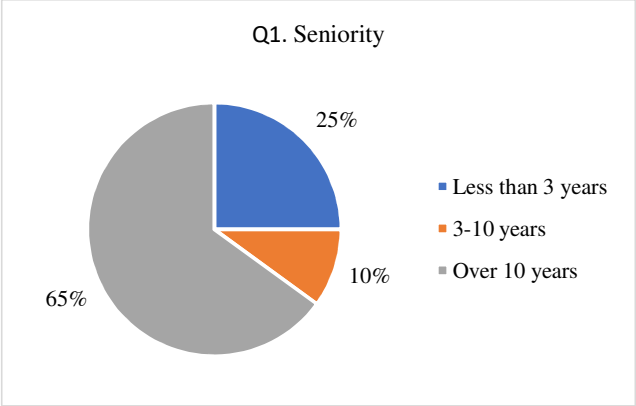

Fig. 3: Seniority of Interviewed Subjects

The interview guide, which included 18 questions, had both questions covering the general aspects under research, such as the awareness of the concept of business ethics and business success definition, and questions aimed to identify level of importance subjects give when it comes to complying with ethics and the potential correlation between business success, ethical behaviour and quality of provided work.

The qualitative research method used was the exploratory one, respectively exploratory investigation and as Constantin and Tecău (2013) mentionned, this kind of method is often used in order to investigate new and complex fields, collect information where secondary data is hard to get and when provision of a theory is intended.

In his book, Lefter (2004) stated that marketing qualitative research may rely on several investigation techniques such as direct communication techniques – which may be individual (structured, semi-structured or unstructured) or in group (debate group, focus group etc.) - or indirect communication techniques (projective techniques). In this case, we went for a direct individual communication technique namely semi-directive (semi-structured) in-depth interview.

The interviews were conducted between March 2017 and May 2017 and were afterwards transcribed in order to conduct a content analysis.

Content Analysis

In the content analysis, the questions of the semi-structured interview were correlated with the previously mentioned objectives.

For the first specific objective of the research correlated with the general objective (*"To learn about the concept of ethics in business"* and *"To identify individuals representing ethical models"),* all interviewed subjects asserted they knew what this concept meant and 45% of them considered they could identify individuals representing business ethical models (see figure 4). For instance, *S10* mentioned *Warren Buffet* as model of ethical behaviour, while *S13* went for *Mehran Tavakoli Keshe*.

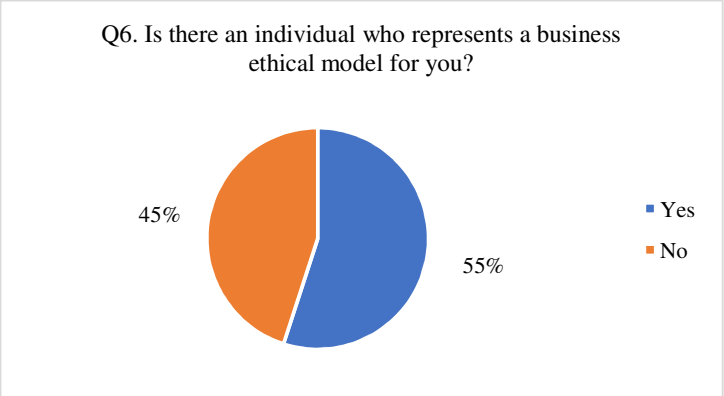

Fig 4: Share of Subjects Who Have an Individual as a Business Ethical Model

When it comes about defining the concept of ethics in business, we mention some opinions: S1 considers that business ethics is " *…a set of moral principles, methods and tools without which a business cannot develop ...*", S4 asserts that business ethics is correlated with "*adherence to moral norms",* and S19 defines the concept as *"promoting and implementing the moral principles within the company, in the relations from the internal and external environment (shareholders, employees, customers, suppliers, partners, authorities)".*

We also found interesting the subjects' answers to the question related to success definition *(What does success means to you?): S1 "the effort and abnegation towards achieving a goal", S15 "the capacity to succeed regardless of the situation" and S16 "to succeed in achieving all intended goals".*

Among the factors ensuring business success mentioned by our subjects, there are: *perseverance, profit, respect for competition, integrity, courage, seriousness, talent, profit reinvestment, quality, staying true to commitments, competent and moral people, professional training, correctness, honest partners, consistency, permanent adaptation to market needs, instinct, political stability, luck, notoriety, providing high quality products/services for competitive prices, money, work expertise, strategy, entrepreneurial spirit, trust in yourself and in what you do etc.*

In respect to the second specific objective *"To identify the factors influencing the unethical behaviour",* 51% out of respondents mentioned desire for gain, 16% the strong competition, 14% personality and 19% other reasons.

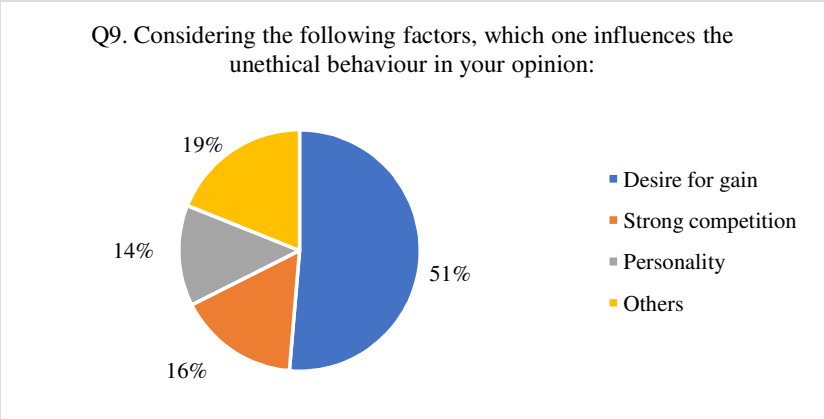

Fig. 5: Share of Factors that Influences Unethical Behaviour

The most interesting answers the subjects gave to question no. 10 ("*Which are in your opinion the consequences of an unethical behaviour?*") were: *maximum material profit for short period of time, achieved by breaking the ethical principles; corporate divergences; bankruptcy; corrupted company; personal benefits; legal and financial repercussions from authorities; perpetuation of negative values affecting the behaviour as well; customer dissatisfaction; image impairment, etc.*

Among the companies that subjects consider having an ethical behaviour we mention: *ICCO Clinics, Private Healthcare Network Queen Mary, Saint Constantin Hospital, Ina Schaeffler, Ikea, Apple, Emag, Vodafone, Orange, OMV, Telekom, Maurer Imob, Dacia Plant, Transilvania University of Brasov, Interbrands, Marketing&Distribution - P&G, Keshe Foundation, Albalact, Sergiana, Bit Software Brasov, Hutchinson, Gelu Bagel Shop etc.*

The elements that distinguish ethical companies from others were indicated by the answers to question no. 12 ("*Which elements distinguish in your opinion ethical companies from the unethical ones?*"). The elements mentioned by respondents were: *professionalism, correctness, management, care for customers, care for people/humanity, investment in employees, respect for partners, profit, compliance with law, social responsibility activities etc.*

The third specific objective - *"To identify the way in which breaking the principles of ethics affected the quality of work and products/services provided"* - got two of the 18 questions of the interview guide, namely questions 13 and 14.

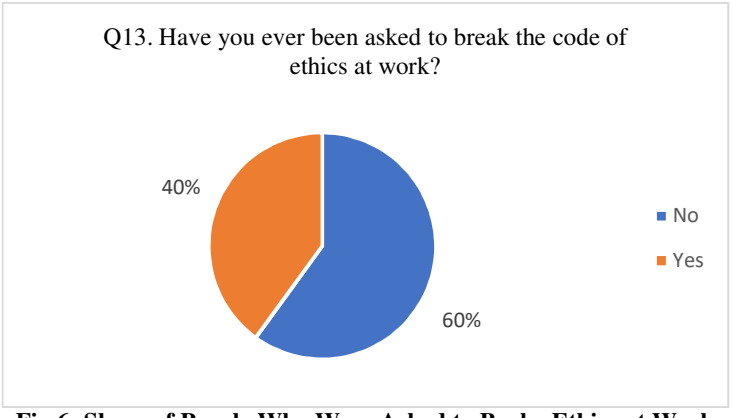

Fig 6: Share of People Who Were Asked to Brake Ethics at Work

As a result of our survey, 40% of the interviewed people answered that they were asked to brake ethics at workplace and among them 75% accepted it thus showing us that some employees do not

betrade companies own values. People at work were asked to offer bribery, sexual favors, imposing some people on certain job positions, omission of some items in the financial statements so that company may get included in a lower risk class by the bank, violation of government laws, delivery of a component made of material other than that requested by the customer, without informing him. Those who broke the rules said that this affected the quality of their work generating additional work effort (preparation of extra statements), stress affecting the personal well-being so as employees were tempted to look for another job.

Conclusions

The most important conclusions of the qualitative research are:

- all subjects interviewed stated that they knew what the concept of business ethics dealt with;
- 45% of the respondents stated that they could identify individuals representing models of ethics in business and they gave several examples in this respect;
- in respect to determining the factors influencing the unethical behaviour, 51% of respondents mentioned desire for gain, 16% the strong competition, 14% personality and 19% other reasons.
- in subjects 'opinion, there is a multitude of elements that distinguish the ethical companies from the unethical ones (*professionalism, correctness, care for customers, legal compliance, management, respect for partners, social responsibility activities etc.*).
- 40% of the subjects stated they had faced situations of breaking the ethics within the organizations they work/worked for. Those who broke the rules said that this affected the quality of their work generating additional work effort, and stress.

Therefore, culture of ethics should be embedded within a company from top down and all employees should be aware of it and apply it. Lack of ethics may cause serious problems in a business affecting employee performance, employee work relations, company's image and credibility.

The Phenomenon of Ad-blocking in the Light of Research Involving Individual Internet Users

Janusz Wielki, Opole University of Technology, Opole, Poland, Janusz@Wielki.pl

Abstract

This paper concerns a phenomenon with significant economic effects known as ad-blocking that has been rapidly growing for several years. The paper analyzes the causes and the scale of this phenomenon and its economic effects. In addition to the analysis of reports on ad-blocking, the survey conducted on a targeted group of individual Internet users was an important part of this project. It enabled to discover their motivations for using ad-block type solutions, the scale of their use on various devices, and the conditions on which they would be willing to give up their use. This made it possible to formulate some preliminary recommendations on the necessary directions of action.

Keywords: ad-filtering, on-line advertising, advertising model, electronic economy.

Introduction

Dynamically developing digital technologies cause profound changes in virtually all areas of the contemporary economy and its organizations (Wielki, 2015), and advertising was one of the first to experience this (Wielki, 2007). Since the advent of the first Internet banner in 1993, the digital advertising market has grown at an extremely fast pace (Jupiter, 2016). Its value was expected to reach $66 billion at the end of 2016 in the United States alone (IAB, 2016). The global value of revenue from digital advertising was estimated at $160 billion at the end of last year and to reach $285 billion in 2020 according to Jupiter Research estimates. This increase is primarily at the cost of traditional media, and ads related to mobile devices and so-called wearables will be the main contributor to its rapid growth in the coming years. In their case, spending on advertising will grow at a rate of 22% per year (Jupiter, 2016a).

Simultaneously with the dynamic growth of the organizations' spending on various forms of digital advertising, there has been a rapid growth of the phenomenon of blocking of advertising by targeted recipients, termed ad-blocking, over the past few years. It was already noticeable at the beginning of the second decade of this millennium, but its rapid growth became a fact in 2013 and intensified in subsequent years (Ryan et al., 2017). This phenomenon is beginning to raise the concerns of both advertisers and the entire advertising industry, hitting every entity in the digital advertising ecosystem and causing a rapid increase in economic costs in billions of dollars (Cookson, 2015; eMarketer, 2015; eMarketer, 2016; Manjoo, 2015; PageFair and Adobe, 2015; Searls, 2015).

Hence, given the importance of ad-blocking in the context of its impact on digital economy and its development, the main goal of this publication is to analyze the causes, scale, and dynamics of this phenomenon. In this context two basic research questions have been formulated:

- What are the main reasons for using ad-block solutions by individual Internet users?
- What are the conditions under which individual Internet users would be willing to stop using ad-block solutions?

The paper is based on data from reports on ad-blocking and own research conducted on individual Internet users.

Ad-Blocking: The Notion, Scale, Causes of Development, and Economic Consequences

The concept of ad-blocking and the historical aspects of the development of the phenomenon

Ad-blocking, also referred to as ad-filtering is, in the simplest terms, the blocking of Web advertisements. Various types of software are used to remove or alter the content of advertisements appearing on webpages and websites or in mobile applications. There are a variety of solutions used for this purpose (such as ad-blocking extensions, browsers, VPNs or DNS) that act as a firewall between the web browser and any known ad servers. In most cases, advertisements are blocked by end users using open-source web browser extensions (PageFair and Adobe, 2015).

As already mentioned, the phenomenon of ad-blocking began to be clearly visible in 2013. Figure 1 shows the dynamics of its growth. And so, the number of desktop devices blocking ads was 54 million in January 2013, and it already increased to 236 million in January 2017.

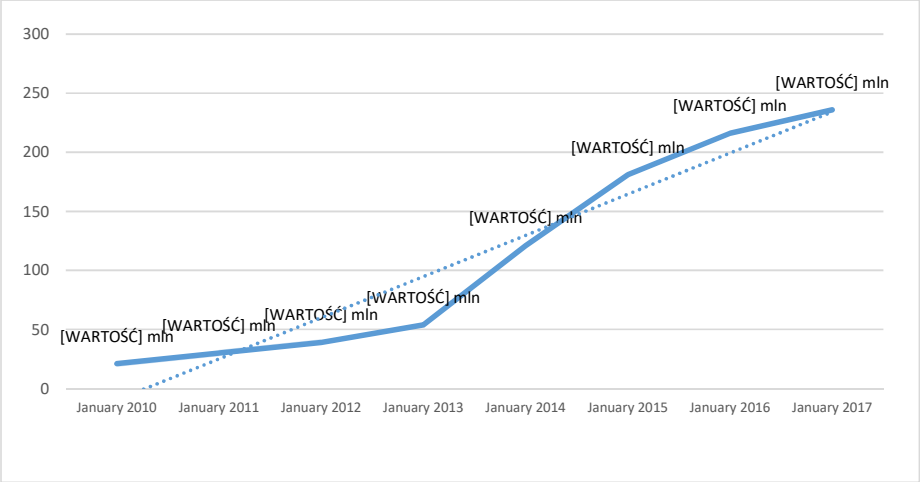

Fig. 1: Increase in the number of desktop devices blocking ads in 2010-2017

(source: PageFair, 2017)

At the same time, the number of mobile devices which block ads has also grown very rapidly. It was 145 million devices in January 2015, and 380 million two years later (PageFair, 2017– see Fig. 2).

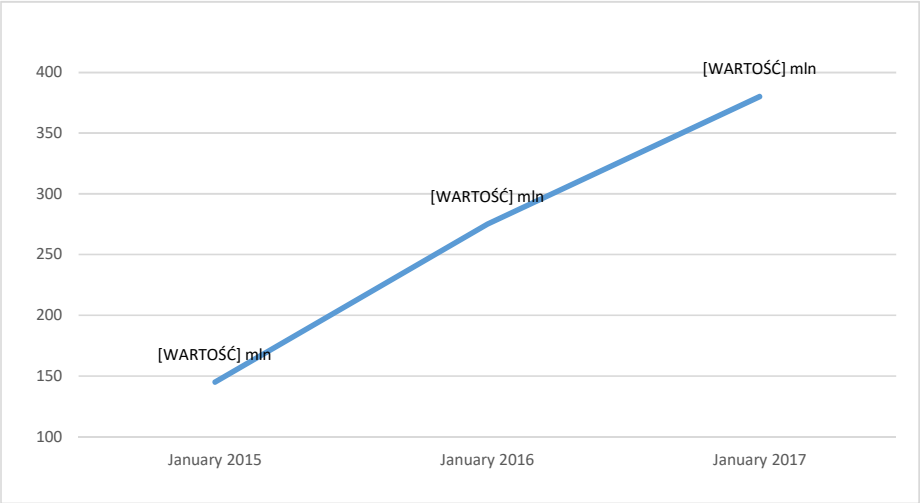

Fig. 2: The dynamics of growth in the number of mobile devices blocking ads in 2015-2017 (source: PageFair, 2017)

In the case of mobile devices, Asia-Pacific users definitely dominate, as 94% of global mobile adblock usage is in this region (PageFair, 2017. Data from November 2016 show that the majority of users are from three countries (Fig. 3).

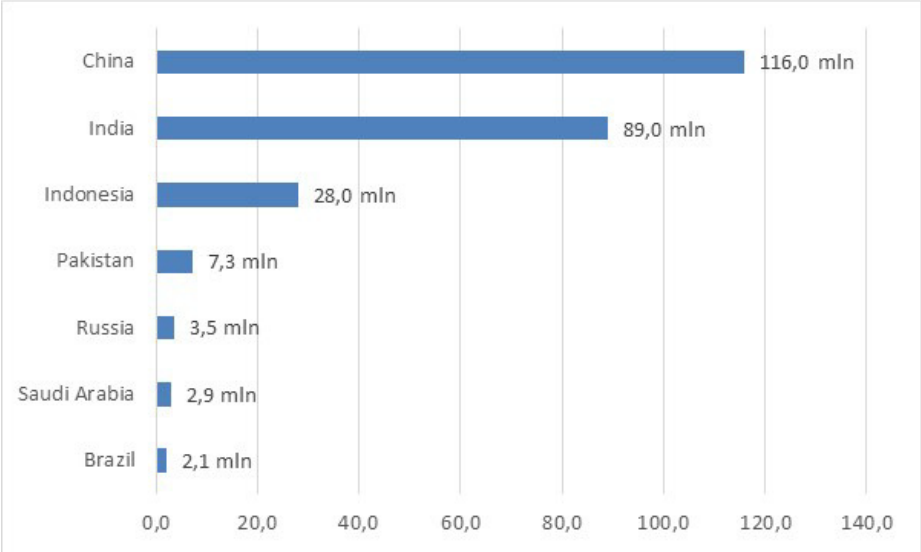

Fig. 3: Countries with the highest number of active mobile ad-blocking browser users in November 2016 (source: PageFair, 2016)

On the other hand, desktop adblock usage is dominated by Internet users in Europe and North America (68%). In Europe the majority are from Greece and Ireland (39%) and Poland (33%) (Fig. 4).

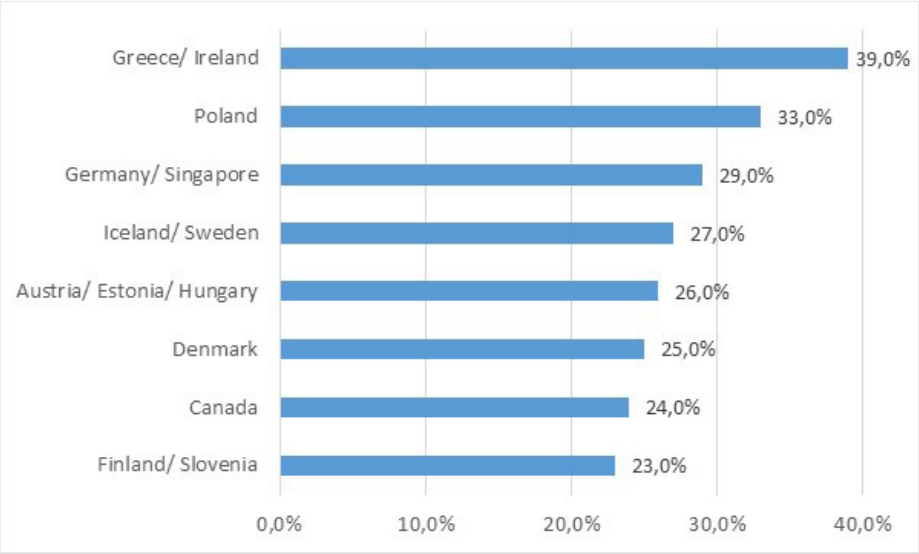

Fig. 4: Desktop adblock penetration per on-line capita % (source: PageFair, 2017)

The rate of growth of US ad-blocking users (% of Internet users) presents Fig. 5.

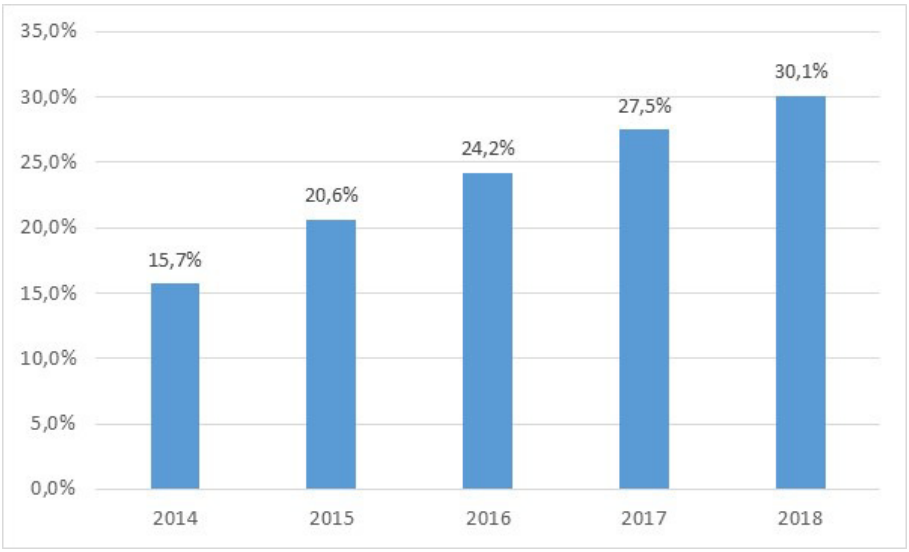

Fig. 5: US ad-blocking user penetration, 2014-2018 (source: eMarketer, 2017)

Main reasons for the growth of the ad-blocking phenomenon

There are a whole host of causes of the growth of ad-blocking in the world. Certain elements are common regardless of who did the study, however, some differences show up between them. According to the "2017 Global Adblock Report: The state of the blocked web" by PageFair, one of the most important factors that motivate users to use ad blocking solutions include (PageFair, 2017):

- Security (exposure to viruses and malware) – 30%.
- Interruption – 29%.

- Speed (slow website loading) – 16%.
- Too many ads on webpages – 14%.
- Privacy and tracking by unknown parties – 6%.

In contrast, the results of the survey among UK Internet users by AudienceProject in the third quarter of 2016 show the following reasons for blocking of ads by respondents (eMarketer, 2017):

- Websites are more manageable without banners – 31%.
- I want to avoid offensive or irrelevant messages – 31%.
- I don't want my behavior to be tracked – 23%.
- Websites load more slowly – 23%.
- I want to limit my data usage – 10%.

In turn, the results of the research conducted among the users of adblock-type solutions in Poland conducted in April 2016 show the following reasons for their use (eMarketer, 2016a):

- I'm annoyed by ads on the Internet – 74%.
- I can't see the page content because of the ads – 55%.
- It takes too long for pages to load because of the ads – 23%.
- I wasn't interested in the products presented in the ads – 15%.
- Ad blockers provide more privacy on the Internet – 19%.

The economic impact of the ad-blocking phenomenon

There are a whole host of causes of the growth of ad-blocking in the world. Certain elements are common regardless of who did the study, however, some differences show up between them. According to the "2017 Global Adblock Report: The state of the blocked web" by PageFair, one of the most important factors that motivate users to use ad blocking solutions include (PageFair, 2017):

- Direct costs.
- Hidden costs.

The first type of costs is those associated with "blocking" of revenues from advertisements (reduction of publisher revenue from advertising). In the United States alone, these costs amounted to $3.5 billion in 2013, and $20.3 billion in 2016 with advertising spending of $42.8 billion (2013) and $68 billion (2015), respectively. At the same time, global ad blocking costs were $7.2 billion in 2013 and were forecast at $41.4 billion in 2016 (PageFair and Adobe, 2015).

As far as the second type of costs is concerned, they primarily apply to small and medium publishers, and the mechanism for their creation is as follows. Blocking of ads results in a decrease in revenue from advertising for all publishers. This in turn reduces the chances of them investing in the content presented on the website. As a result, they become less attractive to recipients. As a result, traffic on a website decreases, resulting in reduced advertising revenue (PageFair, 2017; Ryan et al., 2017).

The Phenomenon of Ad-Blocking in the Light of Author's Own Research

With knowledge based on the analysis of reports on ad blocking and general trends related to it, it was decided to conduct in-depth research on a targeted group of individual Internet users. By choosing it, the following premises were followed:

1. Age of users.
2. Education.
3. Country of origin.

As for the first criterion, it was decided to choose a sample of people in the 19-25 age range assuming that they intensively or very intensively use the Internet. At the same time, as data from reports shows, people using ad-block type solutions are of a higher education (a bachelor's degree or higher) (see PageFair, 2017). Hence, the first, second, and third degree students were selected for the tests.

At the same time, the country of origin of Internet users was an important criterion. It was important that they came from a country where ad blocking is widely spread among Internet users. In this context, users from Poland, as the population which is the third most intensively using ad-block type solutions, were quite an obvious choice (see Fig. 4).

The study was conducted in the period of 01.02.2017–19.05.2017. These were surveys using Google Forms. 178 students of the Opole University of Technology and the University of Opole took part in the study (the majority of participants were students of the former – 176 people). The largest group of people who completed the survey were the students of the first (50%) and the second year (39.9%) of first degree studies in economics (51.7%), management (36%), and administration (10.7%). The majority of the respondents were women (77%).

There were the following subjects of interest in the study:

1. Internet access tools used.
2. Intensity of using the Internet.
3. The level of ad-block type solutions deployment across devices.
4. Reasons for using ad-block type solutions.
5. The conditions under which respondents would be willing to stop using ad-block solutions.

As for the first aspect, laptops and smartphones are definitely the two most popular tools for accessing the Internet (Fig. 6).

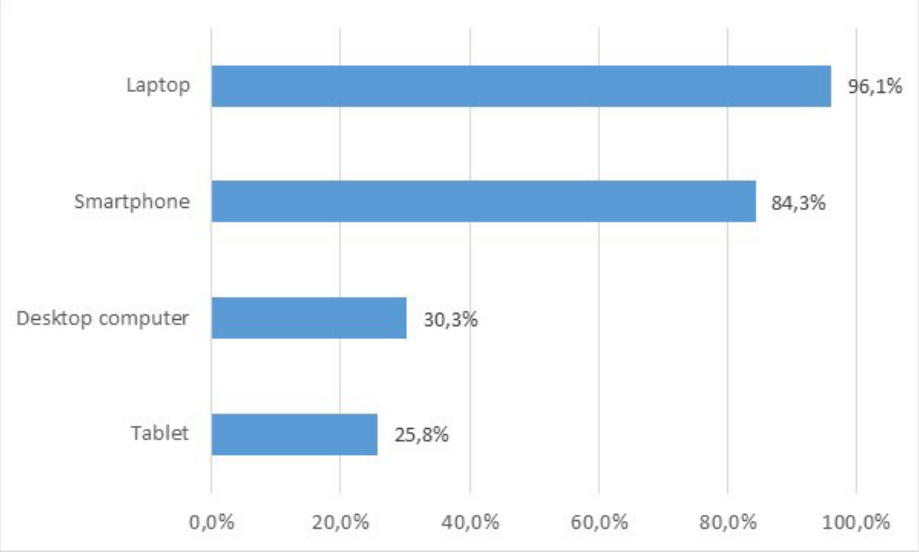

Fig. 6: Internet access tools used (source: own source)

The assumption regarding the time the respondents spent using the Internet proved to be accurate. The majority of the surveyed group uses the Internet intensely. It is over five hours in the case of nearly 40% of respondents and three to five hours in the case of 27% (see Fig. 7). At the same time, 54.5% of the respondents declare that they are connected to the Internet all the time (*always-on*).

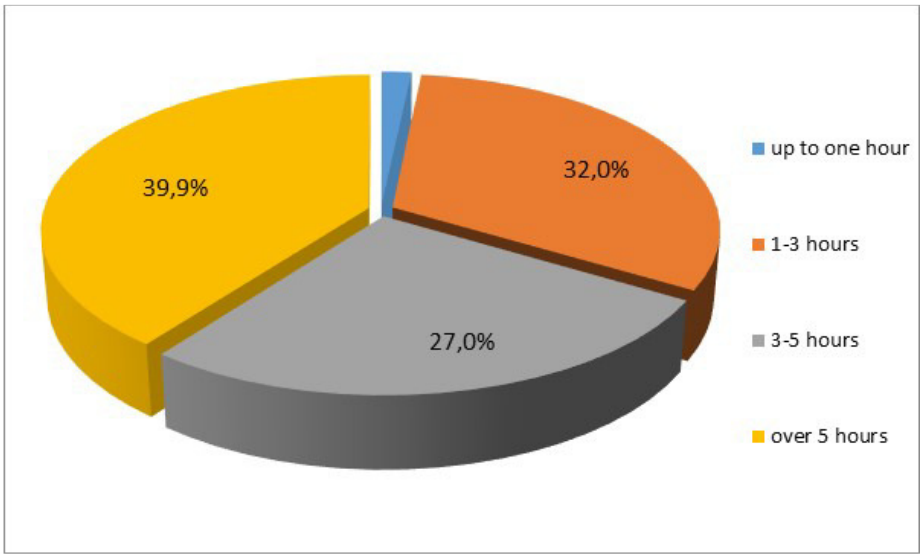

Fig .7: Intensity of using the Internet (source: own source)

Regarding the use of ad-block type solutions by respondents, it turned out that the majority (61.8%) uses them (see Fig. 8). This is almost double the average value for Internet users in Poland (33% – see Fig. 4).

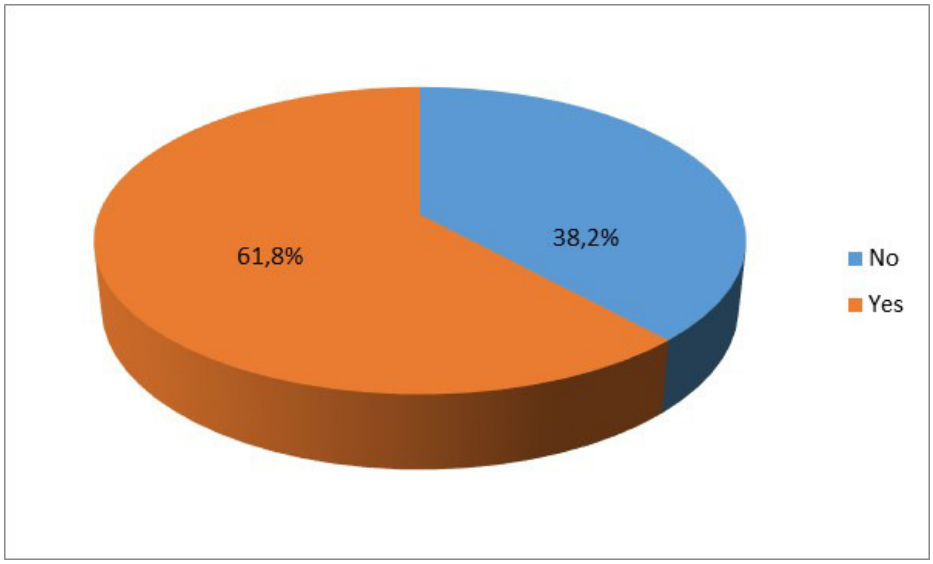

Fig. 8: Intensity of using the Internet (source: own source)

Another aspect of interest in the study was the question of which device(s) the respondents use ad-block type solutions on (see Fig. 9). It turned out that they are by far the most widespread in the case of laptops (90.3%). For smartphones, the second most popular Internet access tool, this percentage is low (less than 13%). However, this is not surprising in the context of the global trends shown above. We could even say that this is a relatively high level given the data regarding Poland shown in the report by PageFair (see PageFair, 2017).

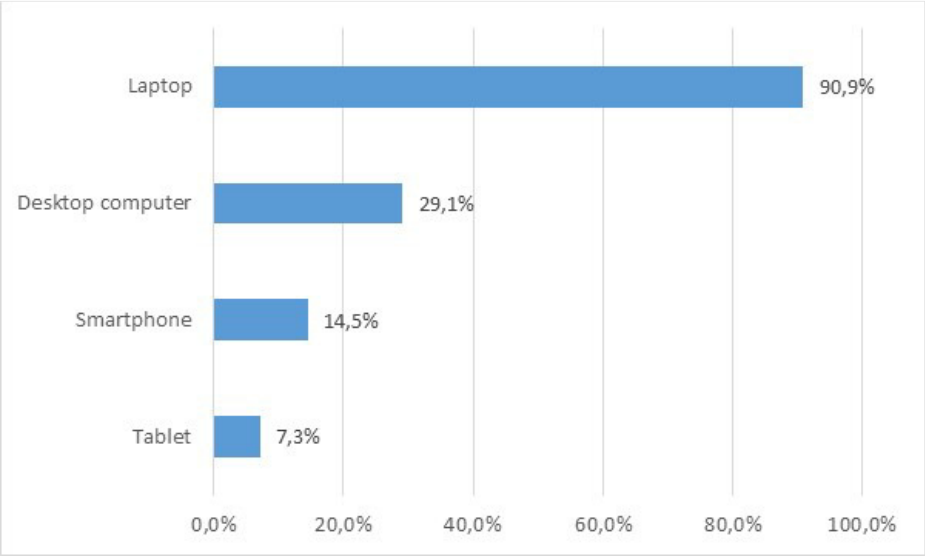

Fig. 9: Devices on which ad-block type solutions are used (source: own source)

It is remarkably important to know the motivations of Internet users to block ads in the context of the growth of ad-blocking (Fig. 10)

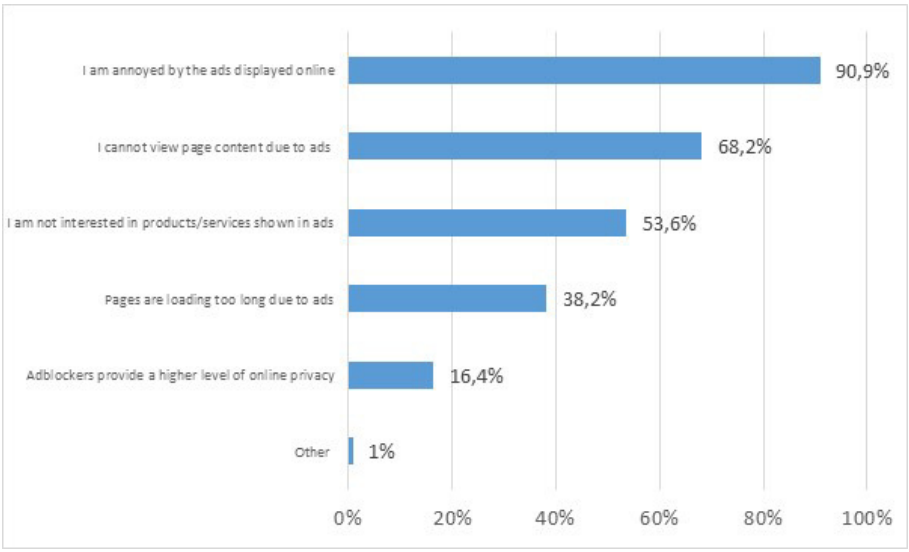

Fig. 10: User motivations in the context of using of ad-block type solutions (source: own source)

Definitely, the most important issue in this context has been the fact that online ads are annoying to Internet users (90.9%). Also, a significant percentage of the respondents (68.2%) indicated hindering the access to the content by the displayed ads. Both of these issues are undoubtedly directly related to aggressiveness of online advertising indicated by the Internet users in various studies. The third indicated issue (53.6%) concerns the lack of interest of Internet users in advertised products or services, which clearly indicates the lack of proper personalization of the presented advertising content. At the same time, it should be pointed out that the issue of online privacy was relatively minor (16.4%).

At the same time, knowing the reasons for blocking ads, it was also important to gain knowledge about in what services available online they are particularly annoying for respondents taking part in the study. It turned out that this was primarily the case for browsing Web content (68.2%). Also social media were highly ranked (66.4%). This is not particularly surprising since the respondents belong to a group of people who are particularly engaged in these media. However, a relatively low rank in online games or streaming is surprising (Fig. 11).

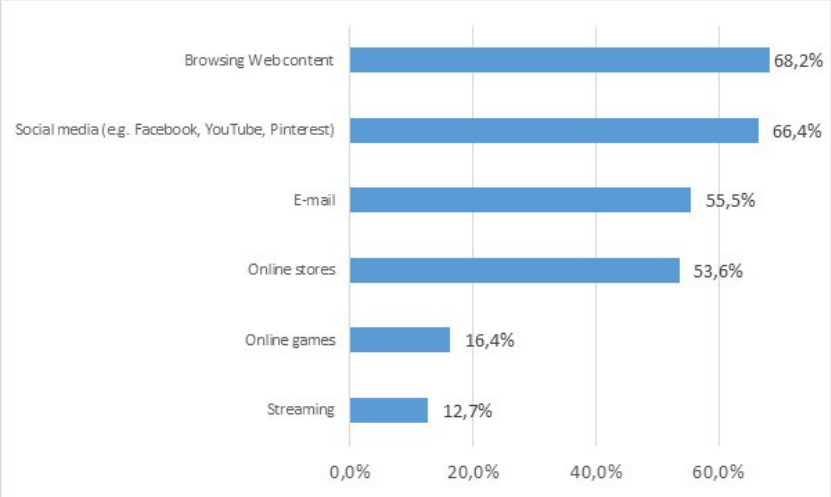

Fig. 11: On-line services where ads are particularly annoying (source: own source)

In the context of the results on the degree of use of ad-block type solutions by the respondents taking part in the survey, it was vitally important to know the situations in which they would be willing to give up their use (Fig. 12). The most important issues are lower invasiveness of online advertising (60.9%) and decrease in the number of Internet advertisements (54.5%). The following situations are also a strong incentive to uninstall ad-block type solutions: when payments are required for getting access to specific content (43.6%) and where blocking restricts access to certain content (37.3%).

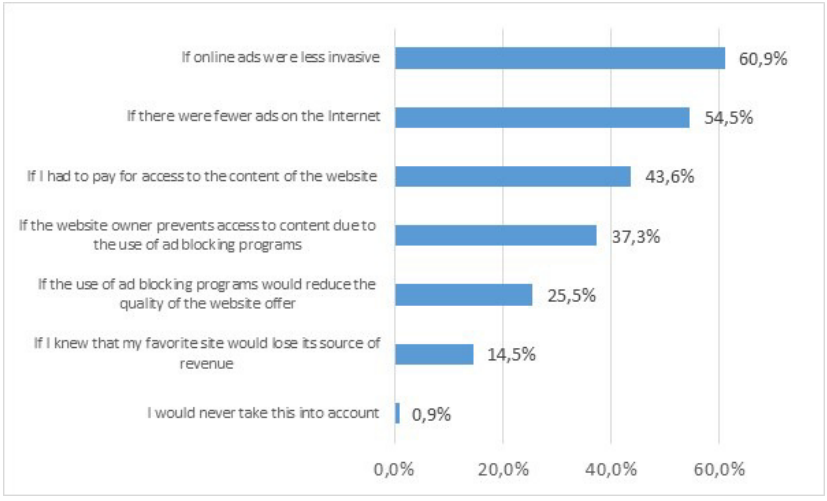

Fig. 12: Situations where it would be possible to uninstall ad-block type solutions

(Source: own source)

Respondents were also asked about their behavior when disabling ad-blocking programs was required to access certain content (Fig. 13). When analyzing the answer to this question, it seems surprising that only 32.7% of respondents in such a group are looking for alternative sites offering similar content or services. The vast majority (71.8%) decides to disable blocking programs.

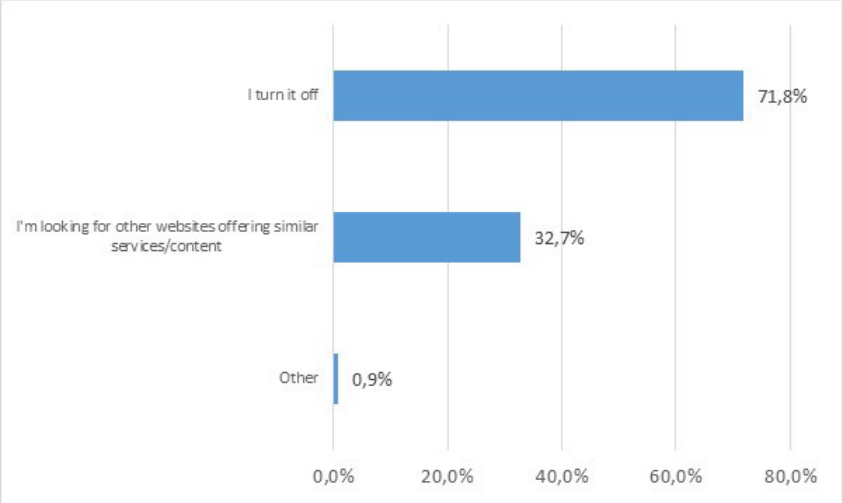

Fig. 13: User behavior when posed with the requirement to disable ad-blocking as a condition of accessing the content (source: own source)

Strategies of Organizations' Reactions to Ad-Blocking Phenomenon

As the presented analyses of secondary data and results of conducted own research show, ad-blocking phenomenon is the real challenge for organizations functioning in the ecosystem of digital advertising. On the other hand trends related to mobile devices indicate that the problem will escalate in the following years. Organizations take miscellaneous actions to counteract or reduce the phenomenon scale and its effects. Generally four strategies, observable in the market, can be distinguished. First three are reactive strategies, while the fourth is proactive.

Taking under the consideration the first strategy, it bases on persuading the users to cease using blocking solutions. This strategy is based on using by publishers different kind of technological solutions which allow them to discover whether consumer is using ad-block application. Then messages are sent to the users with argumentation that is meant to convince consumers to stop using ad-blocking solutions. Matter of effectiveness of such attitude is difficult to measure due to small number of available data (eMarketer, 2017).

The second strategy is to set up ad-block walls in the situation of using by consumers ad-blocking solutions. The effectiveness of this approach is shown by results of available research. It occurs that consumers when encounter the ad-block walls usually look for alternative content sources. Almost 74% of US ad-blocking users, surveyed in November 2016, left web pages when encountered ad-block walls. It is interesting that this kind of behavior was rare among younger consumers (eMarketer, 2017). This fact is confirmed by presented above results of own research.

The third of used strategies is based on presenting ads that cannot be blocked by the ad-block companies. Such strategy started to be used by many publishers including Facebook (ARF et al., 2017).

The last strategy is based on developing systemic solutions that considered both publishers and consumers interests. The result is creation of new model of functioning in digital advertising

ecosystem in which method, form and scale of advertising would be accepted by users. Coalition for Better Ads initiative, that associates the most significant entities in the market of on-line advertising, has made an attempt toward that direction. Within this association preliminary standards of new type of on-line ads have been created, which are being tested on more than 25 000 consumers (Coalition, 2017).

Conclusion

Ad-blocking phenomenon is rapidly becoming an increasingly challenging and economical problem in terms of the functioning and development of the electronic economy and business models used in it. This mainly applies to those where user access to specific on-line content depends on displaying of advertising material (the so-called ad-supported content delivered on-line). The problem becomes more significant when online advertising provides publishers more revenue than the access fees when using a paywalls based business model (Ryan et al., 2017). At the same time, the phenomenon of ad-blocking is rapidly expanding onto mobile devices where the dynamics of its growth is even greater than in the case of desktop devices. In fact it becomes the new form of the impact of elements of electronic space on organizations (see Wielki, 2007)).

In this situation, where publishers and other entities involved in digital advertising bear real and increasing economic costs, it is extremely important that stakeholders develop solutions which limit the scale of the ad-blocking phenomenon as much as possible. At present, publishers generally use three reactive strategies and the most common solution is to block access to content when users use ad-block type solutions.

Undoubtedly, besides this type of immediate activity, there is a real need to work out systemic solutions that take into account the interests of both publishers and consumers of digital advertising. The result should be the creation of a new digital advertising ecosystem based on ad-supported content delivered on-line, where the manner, form, and scale of displaying the advertisements will be acceptable to users. This particularly applies to the number of advertisements, their aggressiveness and the relevancy to individual interests of the recipients and the initiative undertaken by Coalition for Better Ads is such type of attempt.

At the same time, it is necessary to continuously monitor the ad-blocking phenomenon and further research on the subject as a very important issue for the e-economy. This also applies to the studies, whose results are shown in this article, which will continue in a broader scope and scale.

The Prerequisites for the Accounting Harmonization

Ionela Ivan, Accounting, The Bucharest University of Economic Studies, Bucharest, ROMANIA, ivan_v_ionela@yahoo.com;
Mihaela-Nicoleta Băcanu, Accounting, The Bucharest University of Economic Studies, ROMANIA, bacanu_mihaela90@yahoo.com

Abstract

Defining accounting harmonization is a good point to start and the perspective suggests an implementation of a unitary and uniform legislation according to the requirements and provisions of International Accounting Standards and European Directives. As a golden rule, before proceeding to harmonization there is important to assess the company's implementation capacity. In order for the information to be accurate, it is important to make it easily verifiable in terms of accuracy. Therefore, finding ways to present information so that it is easy to check and facilitate the checks implies having sufficient and appropriate evidence to support the accuracy and precision used in the context of measurement. The main purpose of the performed work is to answer to the question of the degree with which the accounting harmonization will enhance the credibility of the financial statements and add value to the company's business operations. In order to do this, we have performed a qualitative research by analyzing the responses of a group of 20 professionals - 10 auditors and 10 accountants, given in the distributed questionnaires during March-May 2017 within four companies, located in Bucharest. The results proved that the harmonization process is useful and brings multiple benefits to the professional's day-to-day activities and also every professional plays a very significant role in the process of harmonization by actively presenting various comparative analyses.

Keywords: - accounting, harmonization, standardization, taxation.

Introduction and Literature Review

Generally, the application of IAS/IFRS is a very complex process that can be due to the mandatory accounting regulations, the management's initiative, the request of the shareholders or the need to have comparative information.

Accounting harmonization is tightly connected to the international accounting standardization and standards can be written in clear language and have the required documentation for the implementation with proper training.

Among the advantages of the international financial harmonization there is the trust inspired by the financial statements prepared according to the International Accounting Standards.

The international harmonization of accounting principles is a topic of rapidly increasing importance as the jet age brings the financial centres of the world within a few hours of each other and improved means of data processing and of communication make the exchange of information almost instantaneous. Accountancy as the common language of business must keep up with this accelerated pace in order to maintain meaningful financial reporting (1967).

According to Nobes and Parker (2008), 'Harmonization' is a process of increasing the compatibility of accounting practices by setting bounds to their degree of variation. 'Harmony' is the state where compatibility has been achieved. 'Standardization' appears to imply working towards a more rigid and narrow set of rules. 'Harmonization' and 'standardization' have often been used interchangeably. However, standardization implies a narrowing down to one policy for any accounting topic, whereas harmonization implies that differences could be allowed to remain as long as the users of financial statements have a means of getting similar information from different statements. Harmonization is most useful when it concerns similar users who receive information from companies in different

countries. However there are some obstacles to harmonization such as the size of the present differences between the accounting practices of different countries, the lack of an international regulatory agency, the nationalism, the effect of 'economic consequences' on accounting standards.

Deegan (2009) provides theoretical explanations as to why, in the absence of efforts to globally harmonize or standardize accounting practices, accounting regulations and practices could be expected to vary between different countries. So, between countries are various differences, such as differences in culture, religions as a subset of culture, legal systems, financing systems, taxation systems, the strength of the accounting profession and accidents of history, which will also influence the accounting systems.

On the other hand, Beke (2010) describes and summarizes how the harmonized international accounting system can promote business decisions and influence economic environment. According to this, the unified, harmonized accounting system will lead to new types of analysis and data, furthermore with the possible integration of new indicators from the business management of certain countries. He classified the accounting systems, and in his opinion this classification should contribute to an improved understanding of: the extent to which national accounting systems are similar to or different from each other, the pattern of development of individual national systems with respect to each other and their potential for change, the reasons why some national systems have a dominant influence while others do not. The reason for differences in accounting principles between certain nations could be that they vary in the level of economic development, in the legal system, in the taxation system, in the intensity of capital market, so as in the level of inflation, in the typical methods of financing an enterprise, in the shareholder background, finally in the political and cultural traits, factors that are influencing accounting harmonization. Accounting diversity causes a series of problems such as the preparation of consolidated financial statements by companies with foreign operations, assessing to foreign capital markets, comparability of financial statements, the lack of high-quality accounting information in some parts of the world.

There are several studies analyzing the harmonization in different countries. The commitment by the European Union to mandate the use of IFRS for certain EU entities has generated a series of changes in global accounting that according to Gielen and Hegarty (2007) can only be described as revolutionary. They have shown, studying the case of nine EU Member States: Belgium, Denmark, Estonia, France, Germany, Luxembourg, Poland, The Netherlands, United Kingdom that strong statutory relationship between financial and tax accounting may have negative consequences, resulting in financial and/or tax accounting systems failing to achieve their objectives. However, a few additional considerations may help policymakers in evaluating the appropriate degree of relationship between tax and financial accounting given the circumstance of their Member State: the Member State's current situation (historical/tradition and economic); the case for associating tax and financial accounting.

Vallisova and Dvorakova (2011) detected the main differences between the Czech accounting system and IAS/IFRS and recovered further way of Czech accounting harmonization according to accounting global trends. The System of IAS/IFRS is from the beginning the purely accounting system and a range of financial and tax accounting are strictly separated. That is no longer in the Czech Republic, where financial profit is used as the basis for tax calculating and Czech accounting law is closely linked to the tax system.

Wysłocka (2008) presents the progress of harmonization of regulations concerning accounting, especially in Poland and describes functions performed by the accounting in market economy: reporting, evidential, optimizing, control, analytical. A relevant obstacle on this way is a high level of severity of Polish tax law.

Albu et al (2011) investigates the inter-play between institutions, routines and politics in the Romanian context and highlights the complexity of accounting change in an emerging country. According to them differences in the way IFRS will be applied in Romania and in other countries will remain, because of the environmental factors affecting the accounting system such as the

characteristics of a code-law country, a dominant position of the State and a reduced importance of the accounting profession.

The Benefits of Harmonization

The harmony is desired since it brings in more benefits and this mystery has shown all its clues. Each regulatory change had an important role in this process. The professional accountant has a dual role to play in relation to the set of alternatives that resulted after a number of changes to both accounting regulations and accounting standards.

The decision of adopting the IAS/IFRS should be based on a thorough investigation regarding related costs and benefits and whether this decision was justified from a cost-benefit point of view.

It is important to ensure that investors or managers take the proper decisions? Of course it is and factors in the situation that may trigger biases that the decision makers have need to be thoroughly analyzed.

The auditors rely only to a certain extent on the honesty of directors and no amount of regulation necessarily is going to ensure that dishonest people are going to be honest.

The application of IAS/IFRS can be due to the mandatory accounting regulations, the management's initiative, the request of the shareholders or the need to have comparative information.

Switching to IAS/IFRS can also generate costs related to training of personnel, double reporting, consulting services or even adjustment of computer information system, but the advantages of harmonization are multiple.

These costs should have been budgeted for even though the change of the relevant legislation would have been made fast.

All in all, the implementation of IAS/IFRS reporting offers a number of advantages:

-it offers relevant information to investors and therefore is an appropriate accounting system for listed companies

-it permits the access to the foreign financing market

-when in the process of decision making, the managers are offered a good information resource.

It is important to look at accounting harmonization as improvement and assess the accounting benefits in terms of whether new accounting practices satisfy better the interests of the users of economic information, and present the information in an understandable and fair way.

Different people may have different views regarding international accounting, which depend on the accounting practices used in the past and the construction of the concept of professionalism. Investigating the evolution and history of accounting brings into our attention the limits of harmonization.

In order to demonstrate the importance of harmonization, but also its limits we have distributed a questionnaire to a sample of professionals, which determines their position regarding the benefits of harmonization. The respondents completed and returned 20 surveys, based on which we performed an analysis of results using a scale from 1 to 5 (1 – totally disagree, 2 – disagree, 3 – neither agree nor disagree, 4 – agree, 5 – totally agree). The primary purpose of the study was to determine the degree of importance associated with the process of harmonization.

The questions based on which the results were analyzed are the following:

A. Does the new projects related to the changes in the accounting policies have a contribution to the enhancement of accounting harmonization?

B. Does the consistent application of accounting policies contribute to the true and fair view of the financial position and the performance results of an entity?

C. Can the process of harmonization lead to a development of the techniques and practices of creative accounting?

D. Are the needs of regulators limiting the process of harmonization?

E. Can the accountants improve the process of harmonization by actively presenting comparative analysis between the situation before and after harmonization?

The results of the questionnaire are presented below:

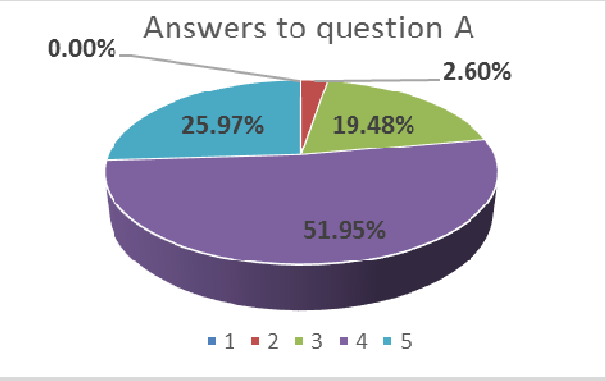

Fig.1: The results for question A (based on the answers received related to the changes in the accounting policies); Source: own analysis

51.95% of the interviewed professionals believe that new projects related to the changes in the accounting policies have a contribution to the enhancement of accounting harmonization, while only 2.6% are reluctant to these due to the flexibility involved in and the chances of making the wrong decision.

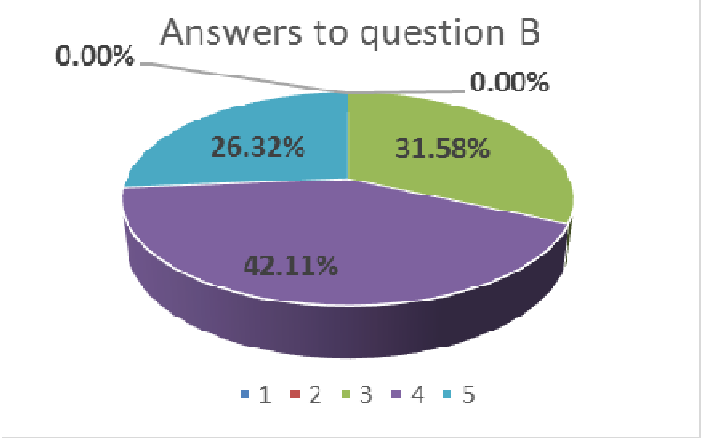

Fig.2: The results for question B (based on the answers received related to the consistent application of accounting policies); Source: own analysis

68.42% of the subjects agree the consistent application of accounting policies contributes to the true and fair view of the financial position and the performance results of an entity. This result might have a positive impact, since it can contribute to building proper measures to manage the suitable accounting policies in order to reflect the true achieved performance and not a fictional one.

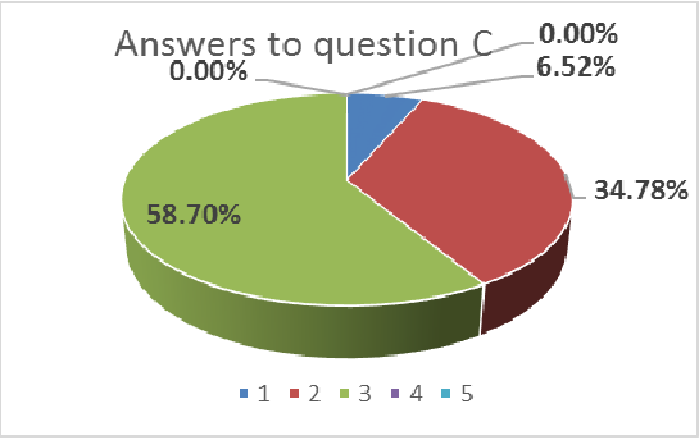

Fig.3: The results for question C (based on the answers received related to the process of harmonization); Source: own analysis

58.7% of the questioned professionals neither agree nor disagree with the fact that the process of harmonization could lead to a development of the techniques and practices of creative accounting, while 34.78% of the subjects disagree with this fact since the financial statements prepared in accordance with the local generally accepted accounting rules modified after harmonization proved to reflect the true and fair view of the financial statements.

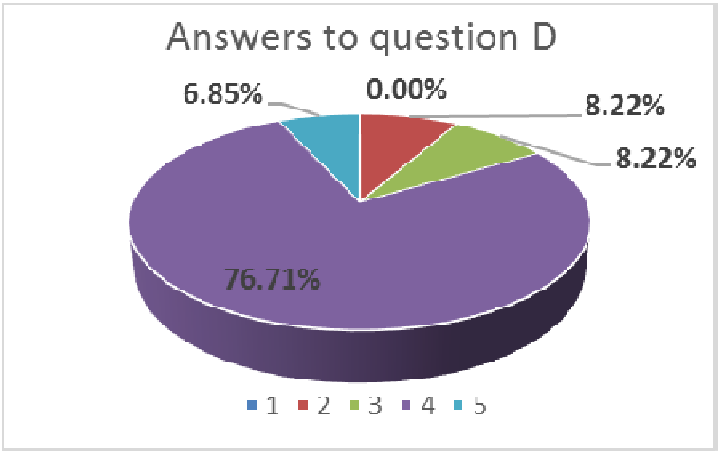

Fig.4 : The results for question D (based on the answers received related to the limits of the process of harmonization); Source: own analysis

84.56% of the subjects agree with the fact that the needs of regulators are limiting the process of harmonization since the primary needs to be satisfied are those of the financial information users.

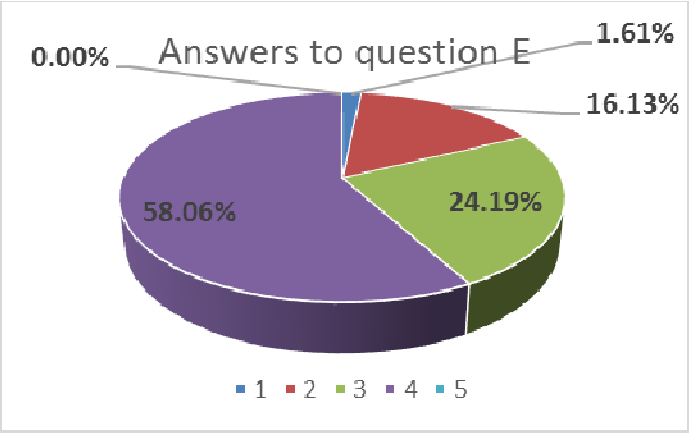

Fig.5: The results for question E (based on the answers received related to the improvements of the process of harmonization); Source: own analysis

From the answers received from the respondents, most of the professionals believe that they play a very significant role in the process of harmonization by actively presenting comparative analysis between the situation before and after harmonization.

58.06% of the questioned people believe that these analysis have a contribution to the enhancement of accounting harmonization, while 24.19% neither agree nor disagree to this statement.

Tax Implications upon the Process of Harmonization

The accounting harmonization process begins to reduce the differences between the accounting information provided by the companies from different countries. A cause for the differences between the countries is the tax system, and the degree of connection between the accounting and taxation.

There are countries that apply an Anglo-Saxon system for the accounting practices, which is characterised by a high degree of disconnection between the accounting and taxation and countries that apply a European-Continental Systems which is characterised by a closely connection between accounting and taxation.

Keeping separate tax and accounting records is in accordance with the financial needs of the companies and the link between tax and financial reporting rules can be used in favour of the company in order to create book-tax conformity.

Our research is concentrated on the impact of accounting harmonization and since taxation refers to fiscal policies in different context, situation and sector, its implications have to be measured accordingly.

It is impossible to split accounting from taxation because each one has an influence over the other and the interconnection has to be maintained.

The context in which the impact will be measured is Romanian legislation, which according to its accounting history, it started from European-Continental influences and finished at the moment by applying for a part of the companies the Anglo-Saxon influences.

The professional judgment is important in applying the accounting and taxation rules.

Conclusion

The process of harmonization can help in the construction of a better quality financial reporting system. The main findings focus on the important role each professional can have by following the opportunity to apply the stable, suitable accounting policies and by performing a thorough analysis that could assist investors and decision makers. The results reveal the fact that more than a half of the professionals questioned agree that the true and fair view of the financial position of a company is influenced by the consistent application of accounting policies, therefore this is a proof that the professionals are aware that they have an important role in building and manage the suitable accounting policies. Also, more than a half of the subjects believe that by presenting comparative analysis between the situation before and after harmonization, this will improve the process of harmonization. In this way their role in the process of harmonization is also important. The fact that the majority of the subjects believe that the needs of regulators are limiting the process of harmonization shows that they are aware that besides the fact that their role is important in the process of harmonization, this role is limited by the regulators. This limitation can influence the accounting policies, if we are looking from the point of view of the techniques and practices of creative accounting, which can be developed by some professionals. Therefore, more than a half of the questioned professionals neither agree nor disagree with the fact that the process of harmonization could lead to a development of the techniques and practices of creative accounting.

We can conclude that the increase in the relevance of the financial information will be more consistent after the harmonization process is complete and the IFRS adoption is realized worldwide.
If the accounting harmonization is successfully completed, there is a need to be analyzed what the taxation harmonization will imply in the future. We will further analyze the answers separately between auditors and accountants, by increasing the sample and aiming to obtain sufficient and appropriate evidence in order to sustain that the harmonization process will be complete once all the related parties act accordingly and work together in accomplishing this.

E-mail: Niculae.Mihaita@csie.ase.ro; niculae_mihaita@yahoo.com

Abstract

Using the title that was chosen above, it is a very ambitious project and I am aware that needs a lot of work to justice it. This paper will highlight analogies between second order cybernetics and Pierce's semiotics concepts applied to management techniques using quantitative methods under the umbrella of Informational Statistics.If we understand the Business Environment as a Semiotic Space, it looks like a multi-attribute living system revealing the life of existing or new developed signs, perceiving interpretation to accommodate yourself in this living (viable) space. As a Semiotic Space, the Business Room' noise, clamor like a sign, so easily to identify if you were there as visitor only one time. **Defining noise**: anything from the environment that does not exceed the everyday level of clamor and do not alert any single or multiple sensation requesting recognition as sign. **Defining Sign**: anything that can be recognized, calls, signals, shapes, drawings, *human beings as "signs for ourselves"*. Is used to map out systematised opinions or real life situations, reports, other marketing management documents. Here we follow his concepts and procedures. Just to see what outcomes one gets.

Dichotomic Alternatives and Informational Statistics For Risk taking Manager

Dr. Niculae V. Mihaita, Phd candidate Andrei Pericle NEGESCU Cybernetics, Statistics and Economic Informatics Faculty at the University of Economics of the Academy of Economic Studies in Bucharest, ROMANIA
E-mail: Niculae.Mihaita@csie.ase.ro; niculae_mihaita@yahoo.com

Abstract

The purpose of this paper is to illustrate some simple algebraic and Informational Statistics techniques gives knowledge from different meetings and situation emerging from the process of Decision-Making. The first part is shaped as a more personal or colloquial approach using the Second-Order Cybernetic concept of Observer INSIDE the black/grey BOX of the process he studied. The component shows that the uncertainties created by the mystery of the decision-making depend by the doubts created by those chosen to decide and no-one else. It illustrates how combination of simple quantitative methods reveals hidden scenarios and deals with true and false money assignments. It is written like a play, and like a mathematical riddle. Utility for this approach is made for better understanding of what is next to come in the second part of the paper. The paper content also has results and comments of an original algorithm of factorial experiments and Informational Statistics combination, adding more information to find States Reference Indexes System.

Abstract

This study seeks to clarify the interrelations between Volkswagen's innovation management, environmental sustainability, and market positioning as components of its corporate strategy in recent years. In 2015, Volkswagen became embroiled in an emissions scandal in the US and globally. The cornerstone of the diesel-scandal could be the fact that the german automobile industry has agreed on exhaust gas purification and technical standards. In the meanwhile, it is not just Volkswagen who circumvents the US Environmental Protection Agency's emissions guidelines by equipping its vehicles with devices that interfered with the operation of their emission control systems, especially for diesel under various brands.[1] This scandal may follow from there initial failure to develop an economically and environmentally sustainable business model. Both the backlash to this scandal and Volkswagen´s, Daimlers, Audi, Porsche and BMW´s recovery of its market share can be expected to be closely related to the market importance of sustainable consumption. While technological innovation already forms an important part of their business strategy, its market competitiveness has primarily rested on premium-brand car sales. This case study indicates that a successful repositioning of Volkswagen in the global marketplace will demand both a targeted, ecological sustainability-oriented deployment of VW´s technological assets and a reframing of VW's corporate image in environmentally friendly terms as a basis for the long-term economic sustainability of the firm.

Introduction

In year 2015 Volkswagen became involved in an emissions scandal in the United States in the course of which over 500,000 diesel passenger cars under its own brand and that of Audi have been recalled, while leading to a fall of over USD $16.9 billion in its market value. Since all of its diesel vehicles have dissimulated their diesel-exhaust emissions results, 11 million of these cars have been subject to recalls worldwide, while further depressing its sales and financial performance.[2] The cornerstone of the diesel-

scandal could be the fact that the german automobile industry has agreed on exhaust gas purification and technical standards. In the meanwhile, it is not just Volkswagen who circumvents the US Environmental Protection Agency's emissions guidelines by equipping its vehicles with devices that interfered with the operation of their emission control systems, especially for diesel under various brands.[3] Also Audi, Porsche, Daimler and BMW have used this method. The table below shos the revenues of Volkswagen group, Daimler and BMW group in billion euros of 2015.

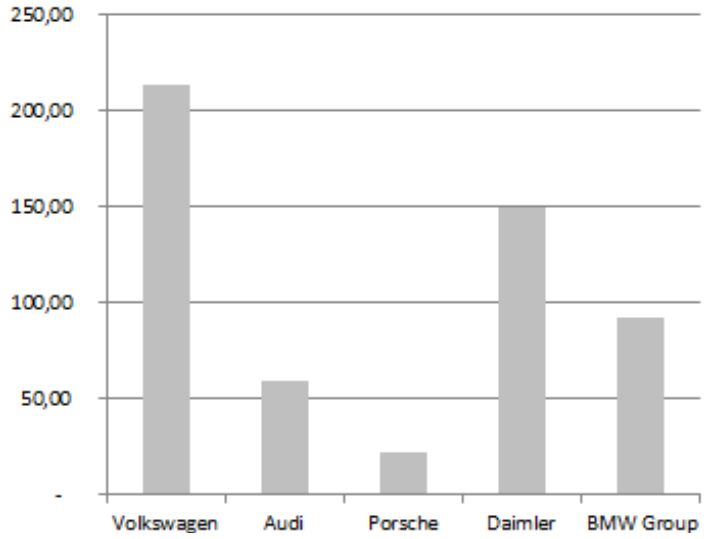

Chart. 1 Revenue comparison of Volkswagen, BMW and Daimler in FY 2016 (in million euros)

Source: Own presentation.
Basic Data: Statista database.[4]

At once, this case demonstrates not only the failure of the US and European emissions legislation regimes to increase the environmental performance standards of large-scale automakers but also the necessity to further inquire into company behavior in the automotive sector, especially on the firm level. Rather than responding to the influence of policy instruments or economic incentives, private firms can be expected to exploit the weaknesses of regulatory frameworks to secure their market position.[5] Moreover, this incident may spur the whole german automobile industry to further evolve its ecological innovation strategies by changing their direction toward the adoption of industry-wide environmental protection practices, such as an aggressive deployment of fuel cells technologies as engines of future innovation-based growth and profitability.[6] Also the whole german automotive sector is affected by the changing mobility-related consumer preferences and new market entrants, such as Tesla Motors, whose digitization-based innovations disrupt established business models. This is likely to call for a reorientation of firm-level innovation strategies.[7] In this respect, in the automobile industry, the adoption of environmental sustainability standards is increasingly considered by corporate decision makers and stakeholders not only as a means of avoiding public backlash and government-administered fines for ecological damage caused but also as a strategic approach for stimulating consumer demand, increasing market share and maintaining firm-level competitiveness, such as through the optimization of cost structures, the reduction of production-related waste and ensuring long term firm viability.[8] On the company level, strategic innovation and strategic behavior can be expected to be weakly interconnected and poorly understood in both theoretical and practical terms as drivers of company growth. This demands further research into the interrelations between corporate strategies, innovation practices and

organizational renewal.[9] In other words, the emissions-related scandal into which Volkswagen, Audi, Porsche, BMW and Daimler has become embroiled may follow from its initial failure to develop an economically and environmentally sustainable business model in view of the transformations that the automotive industry undergoes.

More specifically, emerging industry trends, such as car sharing, pose significant challenges for traditional business models in the automotive sector that have been slow to change in response to the arrival of new technologies, e.g., electric and hydrogen-powered vehicles. This may undermine the future sustainability amongst other of for instance Volkswagen's business strategies in rapidly changing market conditions. By contrast, emerging technologies can also provide the german automobile industry with opportunities for developing successful innovation-based business models that will eventually serve as the basis of its sustainable growth and competitive advantage.[10] Thus, this paper presents a case study analysis of Volkswagen's corporate management, marketing strategies, such as in relation to its various brands, and their interrelations in the context of its emission performance fraud scandal. This scandal also provides a background for this assessment of the crisis management strategies of Daimler and Volkswagen, Audi and Porsche on the basis of empirical data on Volkswagen's research and development budgets, economic performance and other indicators.[11]

Literature Review

The Audi, BMW, Daimler, Porsche and Volkswagen 2017 diesel emissions and syndicate scandal can primarily be considered a consequence of its failed innovation strategy. In this context it is demonstrated that the whole german automotive industry (particularly Daimler, BMW, Audi, Volkswagen and Porsche) used common arrangements about technology standards and emission regulation. It seems like that it is almost impossible to achieve the high emission guidelines within the predetermied time. Agreements are not forbidden. But it has to be prooven when they are against the law. Right now the European Commission is investigating syndicate suspicion. The cornerstone of the diesel-exhaust-scandal could be the fact that the german automobile industry has agreed on exhaust gas purification and technical standards. In the meanwhile, it is not just Volkswagen who circumvents the US Environmental Protection Agency's emissions guidelines by equipping its vehicles with devices that interfered with the operation of their emission control systems, especially for diesel cars produced between 2009 and 2011 under various brands. In the US and the global automotive market, this has proved a major competitive disadvantage, as during the Obama administration environmental regulations had become increasingly strict. By contrast, Volkswagen's competitors, such as Toyota, Opel, Ford, FiatChrysler or even Tesla, have successfully carved out a niche in the environmentally friendly automobile sector, while Daimler, BMW, Volkswagen (incl. Porsche and Audi) have primarily concentrated on refining its existing technologies.[12]

Especially since state-level environmental standards and consumer protection laws in the US are likely to increase their stringency, Volkswagen needs to reorient its business strategy rather than solely concentrating on damage control through compensation settlements.[13] In other words, the pre-crisis focus of Volkswagen's management on vehicle sales growth and branding-oriented product development may need to be expanded to include environmental sustainability.[14] The innovation strategy of Volkswagen, Audi and Porsche will need to be adjusted accordingly, even though it is already one of the more innovative automakers globally, as Volkswagen already vends plug-in and electric vehicles, implements lightweight material solutions for car body-shells and establishes joint ventures in emerging markets, such as China and South Africa.[15] While technological innovation already forms an important part of Volkswagen's business strategy, such as the introduction of modular automobile construction across its different brands in 2012, Volkswagen's market competitiveness has primarily rested on premium-brand car sales (e. g. the latest model 'Arteon'), such as those of Porsche and Audi, that has driven its profits based on new, innovative automotive products.[16] The Volkswagen group has largely failed to

capitalize on the potential of novel technologies related to ecological sustainability, such as electricity-powered vehicles.[17]

The import of this trend cannot be overestimated, as sustainable mobility defined as the societal ability to meet transportation and mobility needs without causing long-term ecological damage to the natural environment is increasingly incorporated into national and international policy frameworks.[18] Technological innovation alone may fall short of ensuring the achievement of these goals, especially since large corporations, such as Volkswagen, remain directly dependent on their market performance for their competitive positioning, rather than being influenced by ecological policy objectives. In addition, in the European Union (EU), efforts to prevent the clash of interests between policy makers and industry players such as Daimler, BMW and the big Volkswagen group have led to the creation of lax regional and national environmental environments that have acted as disincentives for ecological technological innovation.[19] Notwithstanding, these regulatory pressures have exerted a growing influence on Volkswagen's technological innovation strategy in recent decades, especially in relation to hybrid and electric propulsion motors.[20] Now, the emissions scandal has demonstrated the risks of failing to integrate environmental friendliness into corporate strategy, as in 2016 Volkswagen saw both its Moody's rating reduced and its market capitalization fall by 40% as a consequence of penalties and compensations, which has contributed to the competitive advantage of ecologically sustainable car makers, such as Tesla.[21] Anymore, in the course of the exhaust and syndicate scandal, Volkswagen's stock price fell from the recent years' record price of EUR 253 in 2015 to around EUR 128 in year 2017, Daimler´s stock price fell from EUR 93 to around EUR 60 in year 2017 and BMW´s stock price fell from around EUR 119 to around EUR 80 in year 2017. As already previous studies indicate, prior to 2015 Volkswagen consistently failed to integrate environmental sustainability priorities into its corporate strategy in the run-up to this scandal, since already in 2004 its diesel vehicles had become prohibited for retail in Maine, US, due to their low environmental performance.[22] This indicates that the pre-crisis innovation strategy of Volkswagen had been defined in relatively narrow technological terms rather than conceived of more broadly.[23]

Case Study Analysis

To assess germans car automotive industry management of the emissions scandal, it is important to assess its innovation management. As the below table demonstrates the passanger car production and registration in 2015.

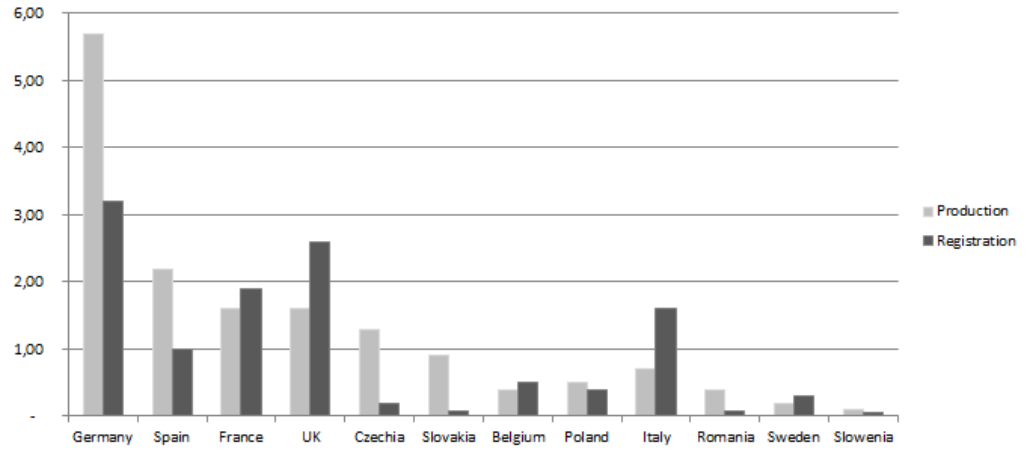

Chart. 2 : European passanger car production and registration 2015 (in Million)

Source: Own presentation.
Basic Data: Statista database.[24]

German products and the 'Made in Germany' label are associated with positive attributes such as quality, reliability, durability, efficiency, and safety. Now the exhaust and syndicate scandal is the maximum credible accident for the plausibility of the german automotive industry. Even as automobile manufacturer have to focus on upgrading the mobility and transportion features of their craft, stricter fuel economy regulations are closing in. By 2025, for instance, automobile manufacturer fleets in Europe and the United States will have to average upward of 60 miles per gallon, an ambition that becomes more difficult if oil prices remain low, stoking consumer interest in popular larger, less-efficient cars like sport-utility vehicles (SUV) or Pickups. Meeting these standards will need step-change amendments, not incremental ones. German vehicles continue to enjoy a globally positive image and are in high demand across the world.

A survey of Ernst & Young about 300 firms active in the European automobile industry finds Germany to be the most innovative automomile center in international comparison. The table below shows the assessment of the innovation power of Germany in 2013.

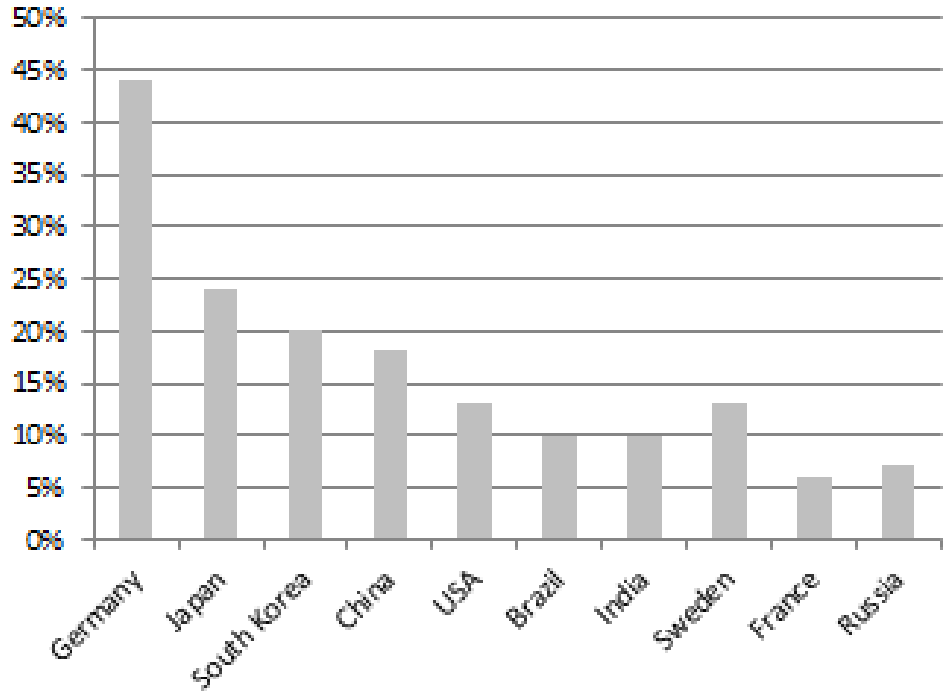

Chart. 3: Assessment of innovation power Germany 2013 (in %)

Basic Data: Statista database.[25]

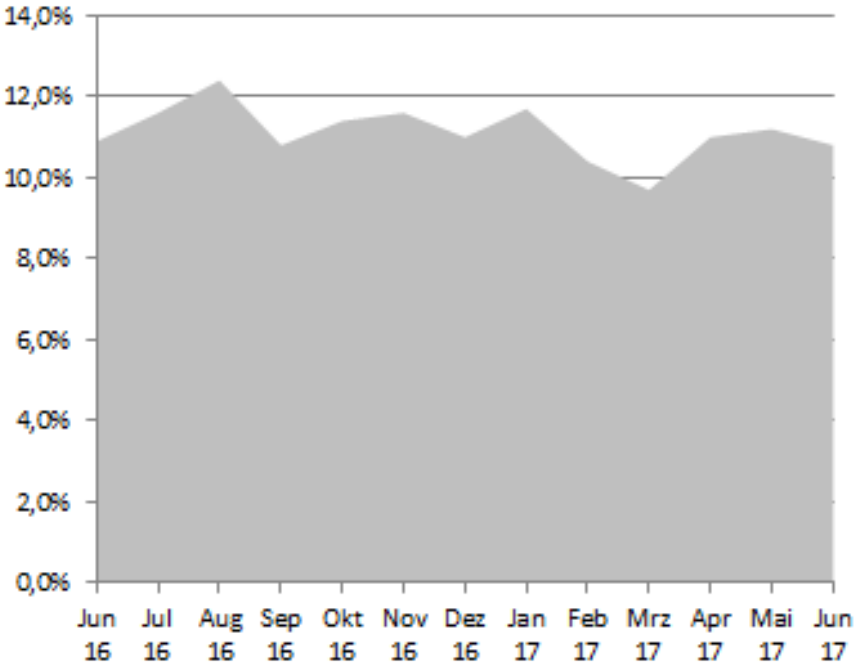

Chart. 5: Volkswagen´s share of new vehicle registrations in the EU from June 2016 to June 2017

Source: Own presentation.
Basic Data: Statista database.[26]

This data corresponds to the status of the Volkswagen group as the globally leading company in terms of research and development spending with a significant innovation-related advantage over Toyota as the nearest-ranking global automotive market competitor. As the table below shows, in the year in which the emissions scandal hit the headlines, the Volkswagen had significant innovation-related organizational resources with the help of which it could reorient its corporate strategy toward a greater degree of environmental sustainability.

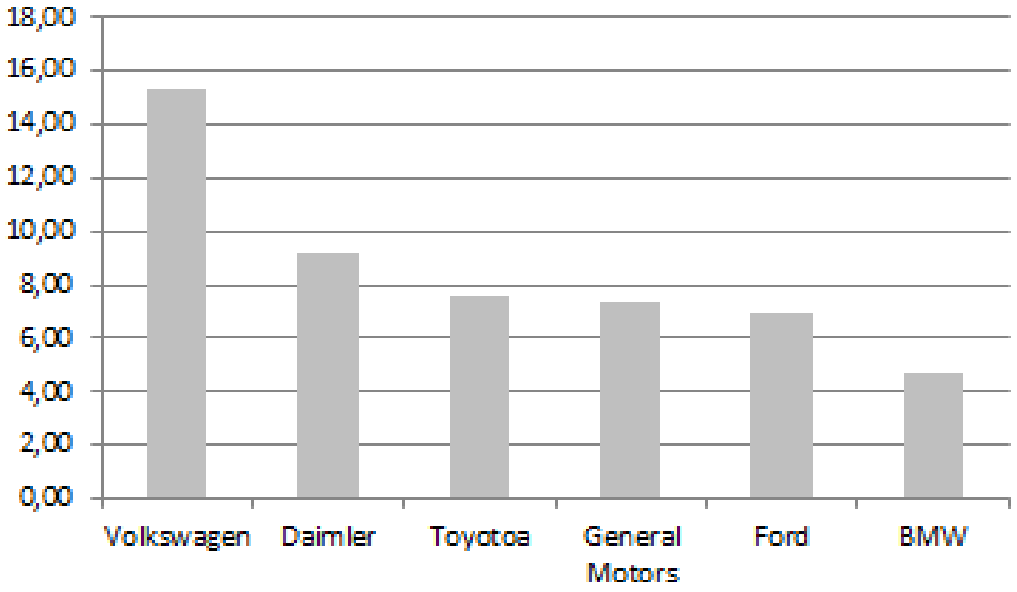

Chart 6 : Leading automotive firms by research and development spending worldwide in 2015 (in billion U.S. dollars)

Source: Own presentation.
Basic Data: Statista database.[27]

The new global market entrants, by way as example Tesla Motors, threaten the market positioning of the Volkswagen group, Daimler and BMW through their superior innovative capacity, as the below chart demonstrates. In other words, based on 2015 data, the research and development intensity of Volkswagen has been more than 2.5 times less than that of Tesla that has sought to position itself in the emergent sector of electric cars with a significant appeal to consumer conscious of environmental sustainability concerns.

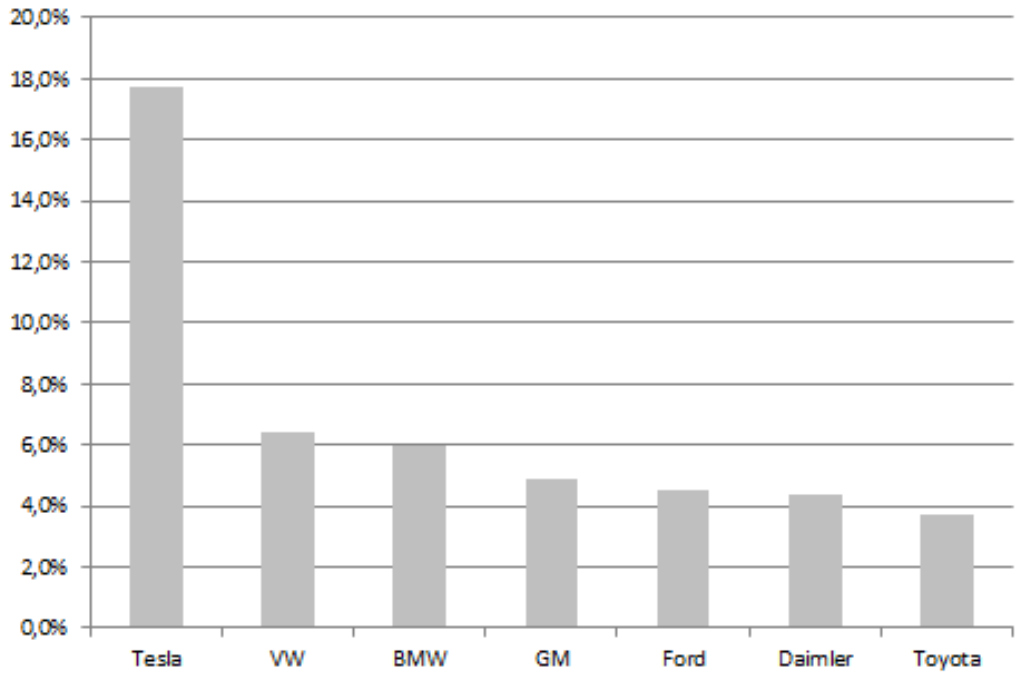

Chart 7 : Research and development intensity of german car manufacturers in 2015

Source: Own presentation.
Source: Statista database.[28]

None the less, VW, Audi, Porsche, Daimler and BMW consistently tops global research and development spending rankings across all consumer market segments, as the below table based on 2016 fiscal year figures demonstrates. This has likely contributed to the economic resilience of VW in the wake of the emissions scandal. Furthermore, immediately before the scandal broke out VW demonstrated one of the lowest ratios of research and development expenses to global yearly sales in the automotive sector, while Tesla has exhibited the highest ratio for 2014. Thus, as the below table shows, in this period Volkswagen enjoyed a significant advantage over its competitors in terms of sales performance. This can be expected to have assisted VW to cope with the financial consequences of the emissions scandal.

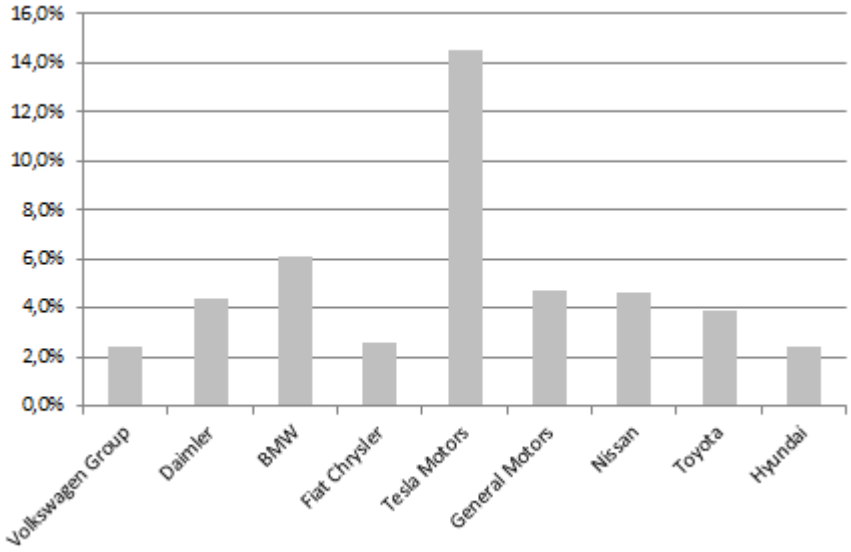

Chart. : 8 Selected automakers' R&D to sales ratio worldwide in 2014

Source: Own presentation.
Basic Data: Statista database.[29]

As well Volkswagen has one of the strongest intellectual property portfolios across all economy sectors worldwide. As the table below shows, Volkswagen belonged to the top 4 companies with the highest number of patent applications in the sphere of industrial design internationally in 2015. These intangible assets can be expected to have provided Volkswagen with technological resources for the reorientation of its business strategy toward a higher level of ecological sustainability in response to scandal-related governmental fines and company value reduction. According to 2017 data, in the US Volkswagen has to pay civil penalties related to its violation of the U.S. Clean Air Act to the amount of USD $1,450 billion dollars, which is far in excess of any penalties imposed on either domestic or foreign car manufacturers before or since 2015 in this country, as the table below indicates.

This penalty is disproportionate to the amount of vehicles affected, since only 584,000 diesel cars have violated the US environmental regulations. This is significantly less than 1,600,000 passenger cars of Honda's American division and 500,000 passenger vehicles of General Motors that were found to be in violation of the U.S. Clean Air Act in 1998 and 1995 respectively, as the below table shows. Notwithstanding, the impact of this emissions scandal on the market positioning of Volkswagen can be expected to be limited, since, based on global rankings, in 2016 two of the 12 most environmentally friendly vehicles were Volkswagen -made car brands. As the following table demonstrates, Volkswagen's E-Golf is considered to be fifth most ecologically sustainable car worldwide.

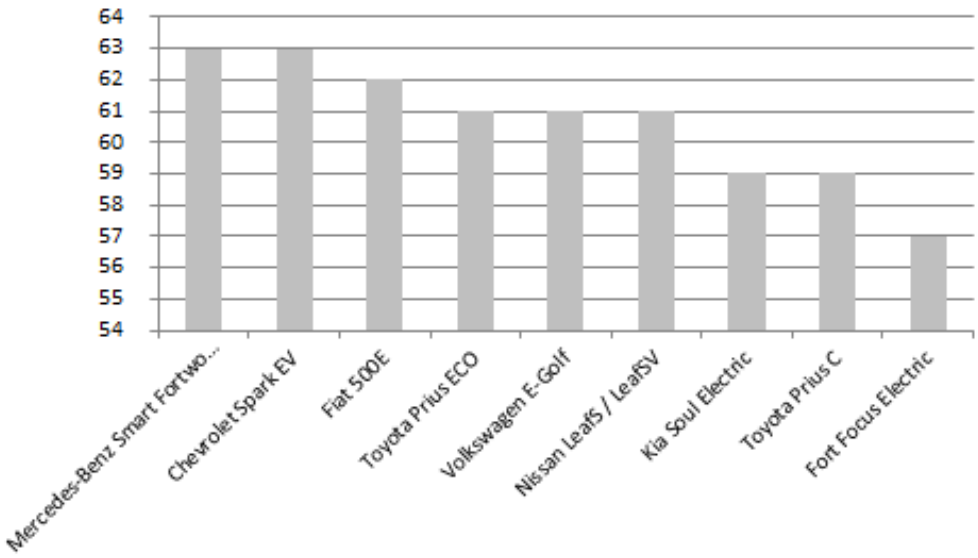

Chart. 9: Most environmentally friendly cars worldwide in 2016, based on index score

Source: Own presentation.
Basic Data: Statista database.[30]

As well, in the same year as the emissions scandal broke out, Volkswagen's E-Golf ranked among the top 5 best-selling electric vehicles in the US automotive market. At the same time, in 2015 with 25,700 units sold Tesla's Model S was the clear electric car market leader, while Volkswagen's E-Golf's sales constituted less than a fifth of this amount, as the table below shows.

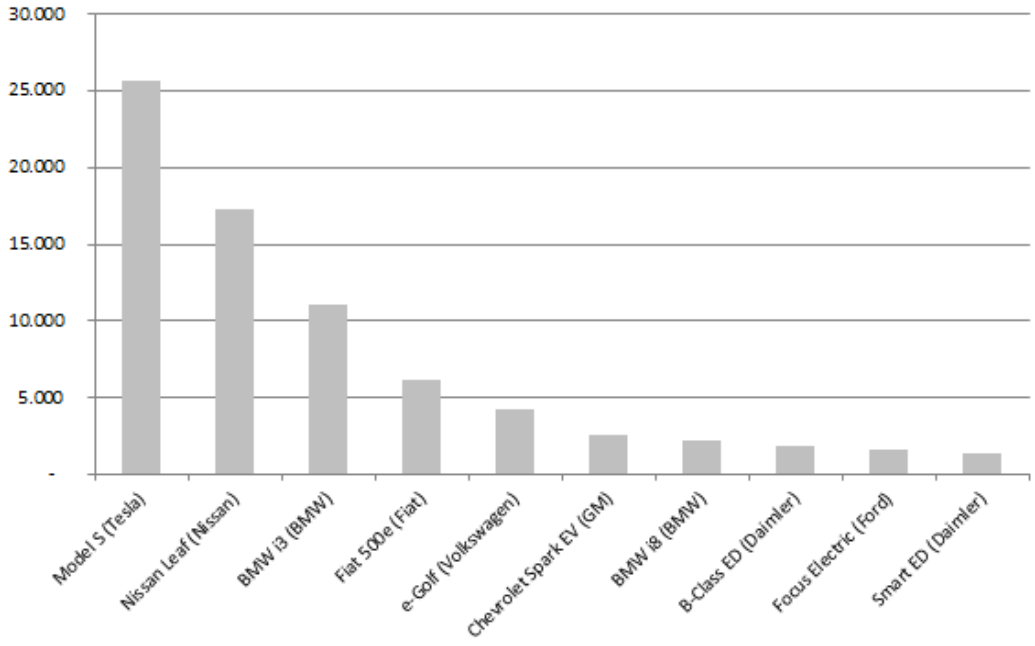

Chart. 10: Best-selling all-electric cars in the United States in 2015, based on sales (in units)

Source: Own presentation.
Basic Data: Statista database.[31]

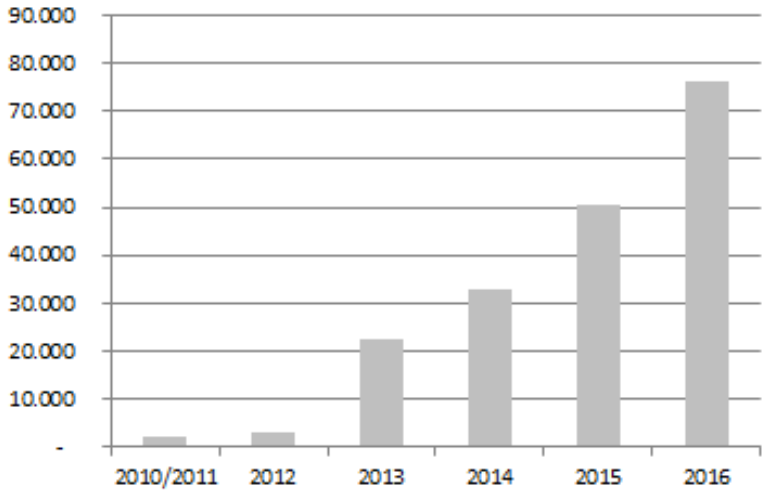

Chart.11 : Count of Tesla Motos abaout sold cars from 2010 to 2016

Source: Own presentation.
Basic Data: Statista database.[32]

Moreover, in 2015 Volkswagen was the third largest carmaker worldwide with 10.7% of the global automotive market share.

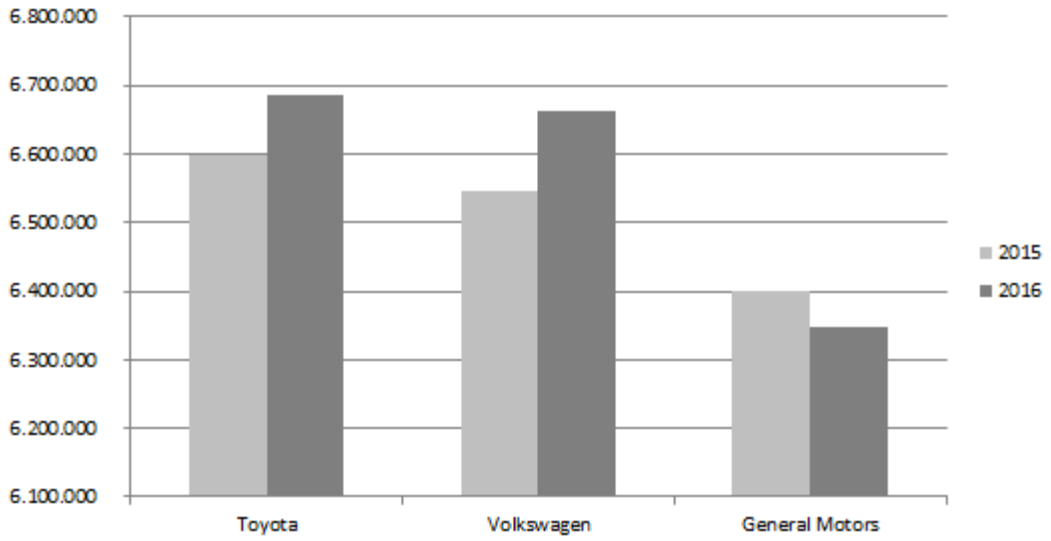

Chart. 12: Global car market share of the world's largest automobile OEMs in 2015

Source: Own presentation.
Basic Data: Statista database.[33]

At the same time, the official average CO2 emission levels for newly sold Volkswagen cars indicate that it has been consistently trailing behind the environmental friendliness of competing European and Asian automotive brands. While between 2012 and 2015, Volkswagen's CO2 gram per kilometer emissions performance improved significantly, the data for this period may fail to factor in the effect of the emissions fraud on the figures presented below. Moreover, the pace of the improvement in Volkswagen's cars' environmental performance does not appear to match that of its key competitors, such as Toyota. This is likely to be compensated by the global competitiveness of Volkswagen, especially in emerging markets, such as China for instance. In 2014, Volkswagen was perceived as the leading automotive brand among Chinese consumers. Presently, Volkswagen appears to have absorbed the majority of the costs that the emissions scandal has caused the corporation, as the following table demonstrates. Starting from 2018, Volkswagen will have mostly overcome the effects of this debacle, since the projected scandal-associated costs will fall from 62.79 billion in 2017 to 0.5 billion in 2018 (see the chart below).

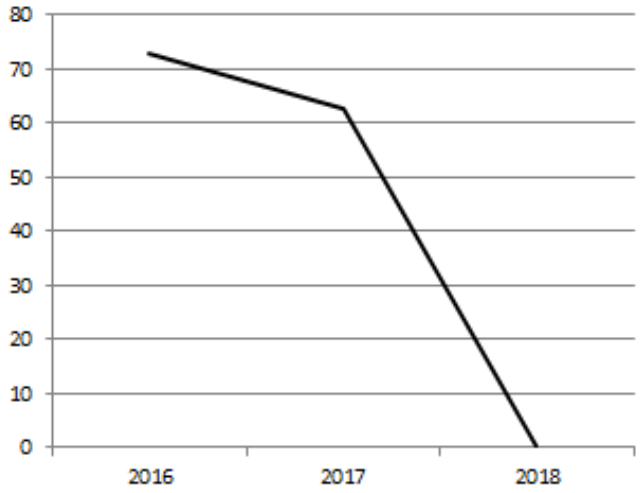

Chart. 13: Volkswagen's costs resulting from the diesel emissions scandal between 2016 and 2018 (in billion U.S. dollars)

Source: Own presentation.
Basic Data: Statista database.[34]

In its immediate impact, the emissions scandal has caused Volkswagen not only to sustain high litigation costs but also a significant decrease in its brand value, as except for Porsche it had not been listed among the top 10 most valuable automotive brands globally in 2017. The table below shows the most valuable brands within the automobile industry in 2017.

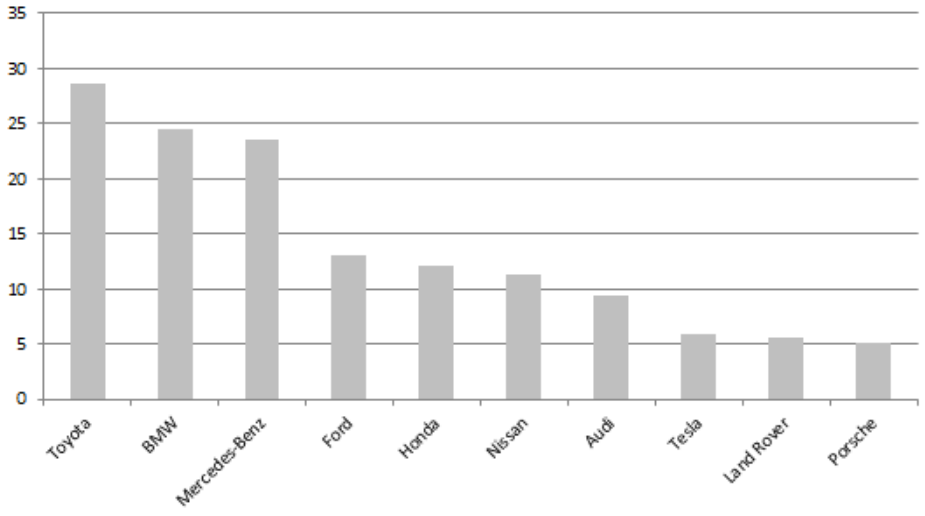

Chart. 14 : Most valuable brands within the automotive sector worldwide as of 2017, by brand value (in billion U.S. dollars)

Source: Own presentation.
Basic Data: Statista database.[35]

Nevertheless, in the same year Volkswagen remained the leading car manufacturer in the European market. Thus, in 2016 Volkswagen's European market share of 23.9% exceeded by over 10 percentage points that of its nearest competitor. In this market, Volkswagen enjoys a significant competitive advantage vis-à-vis international carmakers whose market shares range from 3.6% such as for Nissan to 7% such as for Ford.

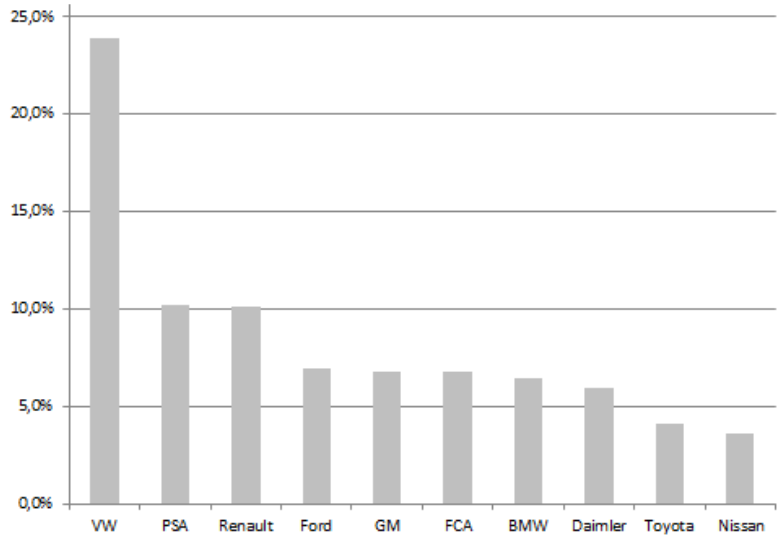

Chart 15: Selected passenger car manufacturers' European market share from January 2016 to August 2016, based on new registrations

Source: Own presentation.
Basic Data: Statista database.[36]

By opposite, presently in the US market Volkswagen only has the ninth largest market share of 3.6% as opposed to General Motors that as the local market leader holds 17.2% of the domestic automotive market, as the following table declares.

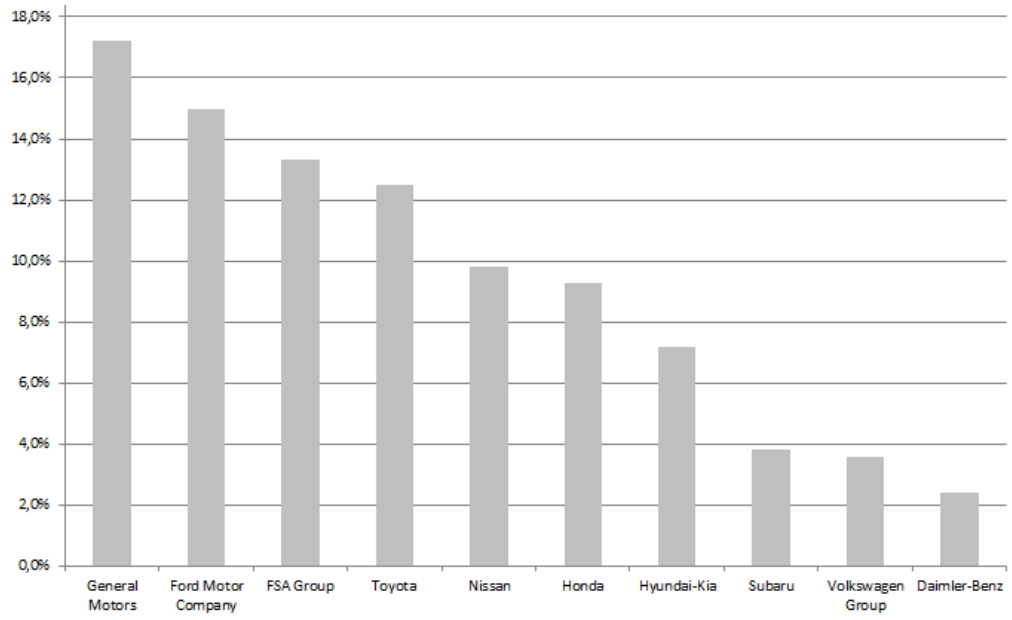

Chart 16: Market share held by selected automobile manufacturers in the United States in January 2017

Basic Data: Statista database.[37]

Discussion and Conclusions

Based on this case study, it is possible to argue that, as the 2015 emissions scandal recedes into the past, a successful repositioning of Volkswagen in the global marketplace will demand both a targeted, ecological sustainability-oriented deployment of Volkswagen's technological assets and a reframing of Volkswagen's corporate image in environmentally friendly terms as a basis for the long-term economic sustainability of this company.[38] Heretofore, the Volkswagen's primary aim has been sustainable financial performance defined in terms of car sales, whereas this scandal also highlights the importance of corporate social responsibility, especially as it applies to the compliance with environmental regulations, for its market positioning.[39] Thus, Volkswagen appears to be well positioned for the reorientation of its technological innovation toward the development of zero-emission electric drive engines announced in 2016, especially for its premium brands, such as Audi.[40] At the same time, branding alone may fail to restore the position of the global automotive market leader if it does not incorporate ecological friendliness imperatives into its long-term corporate strategy.[41] This is likely to be especially important for the market positioning of Volkswagen's luxury brands, such as Porsche and Audi.[42]

Abstract

The research investigates the client's perspective of outsourcing vendor information technology (IT) governance practices and service quality. The research uses a cross-sectional survey approach. A total of 100 survey questionnaires were distributed to employees at six client organisations in Malaysia that outsource selected IT functions to a local IT vendor. A total of 92 survey questionnaires were used for analysis. There is evidence to suggest that from client's perspective, vendor IT governance practices impact on service quality in IT outsourcing environment.

Keywords: IT outsourcing, IT governance, IT service quality, survey research, structural equation modelling

Introduction

The future of an organisation relies heavily on the quality of information services being used. Attempts to achieve sustainable competitiveness through information technology (IT), however, have placed a considerable burden on organisations as the scope and complexity of IT expands. Increasingly, organisations rely on outsourcing to focus on core competencies (Grover et al., 1996; Gupta and Gupta, 1992) and to manage their cost better (Ang and Straub, 1998; Claver et. al., 2002).

IT outsourcing is not a new concept for business.[1] Generally, IT outsourcing is the practice of contracting with a third party service provider (or vendor) for some or all of an organisation's IT functions. IT outsourcing has been practiced, notably in the United States of America (USA) since the late eighties. Significant examples of IT outsourcing are Kodak's outsourcing its IT functions to IBM[2] and General Motors' (GM) outsourcing its IT functions to EDS.[3] In the current global IT services environment, IT outsourcing practices are evolving as many organisations continue to identify opportunities and benefits.

Gartner forecasted global spending for IT outsourcing services would be $251.7 billion in 2012. This was a growth of 2.1% over 2011 and a projected compound annual growth rate of 5.9% from

2012 through 2016.[4] More recently, it was reported that the global IT outsourcing market could expect Compound Annual Growth Rate (CAGR) of 5.84% by 2019.[5]

With IT outsourcing, organisations are challenged to manage a large spending on IT outsourcing and intricacies of outsourcing relationships. Organisations equally face risks of business frauds and natural disasters. The last two decades witness continuous debates amongst practitioners and researchers on best practices in IT governance as organisations face these challenges. Accordingly, regulatory frameworks are instituted in assuring sound business systems and adequate internal controls. Sarbanes-Oxley Act (SOX) 2002, in particular, was enacted to enhance corporate governance, foster organisational responsibilities, strengthen internal controls and increase accountabilities (Damianides, 2004). Concurrently, the industry and academia saw the emergence and participate in the development and adoption of IT governance principles, standards and framework (e.g. COBIT, ITIL, PMBOK, ISO 27001). Each framework addresses specific objectives. Each framework defines specific top management level responsibilities and requires that they exercise due diligence in their roles. This governance development is largely driven by the need for transparency in managing organisational risks and safeguarding of shareholder value. The general concern of IT governance framework in implementation and monitoring of performance of IT investments includes IT control structure, protection of IT investment, security and control of IT, assurance of information integrity and quality of IT service delivery (Mohamed and Kaur, 2012).

IT vendors recognise the need to position themselves in responding to such challenging trend. Concurrently, client organisations need to consider how their vendor fits into the mix including areas outsourced. This challenge is further heightened by the popularity of selective outsourcing or multi outsourcing procurement models. The need for effective governance increases dramatically and the success of outsourcing contracts is critically dependent on the quality of the governance framework between the service recipient (client) and vendor. Increasingly, vendors are expected to demonstrate that their services align with IT governance best practices.

Prior literature shows a growing discussion among researchers on the impact of IT governance on organisational performance (Mohamed and Kaur, 2012; Mangalaraj et al. 2014; Lunardi et al. 2014; Pang, 2014; Tsai et al. 2015). While financial performance, balanced scorecard and strategic alignment are among the most common measure for organisational performance in IT governance impact research, outsourcing does not appear to be a key research context. In a recent literature, Tsai et al. (2015) investigated the mediating effects of IT governance on service quality and Enterprise Resource Planning (ERP) performance. While the research considered vendor service quality and consultant service quality, the research, however, confined to the implementation of ERP system. Further and more recently, there is a call for IT governance research to connect to information systems effectiveness as IT governance research in the past appears to place a greater emphasis on internal control and compliance (Mangalaraj et al. 2014).

Therefore, this paper aims at presenting empirical findings in encouraging additional research in IT governance. IT service quality is chosen as an impact of IT governance in the context of IT outsourcing in responding to identified gaps in prior research and to this recent call. The research aspires to advance understanding of the impacts of outsourcing vendor IT governance practices on service quality.

Hence, the research question (RQ) is:

RQ: Do extensive outsourcing vendor's IT governance practices impact on client's perceived IT service quality?

The objective of the research is to develop and test a theoretical model on vendor IT governance practices and IT service quality from client's perspective. The research aims at gaining insights into client's perspective of vendor IT governance practices and IT service quality in an IT outsourcing arrangement.

Literature Review

This section reviews the literature on IT governance and IT service quality.

IT Governance

The word governance is derived from the Greek verb *kubernao* meaning to steer. According to the IT Governance Institute (2005), IT governance is the responsibility of the board of directors and executive management. This is an integral part of enterprise governance. Van Grembergen (2000) refers to IT governance as the ability of organisations to achieve specified goals or organisational capacity, exercised by the board, executive management and IT management to control the formulation and implementation of IT strategy and to ensure the fusion of business and IT. Essentially, IT governance consists of leadership and organisational structures and processes that ensure the organisation's IT sustains and extends the organisation's strategies and objectives (De Haes and Van Grembergen, 2004; 2005).

Symons et al. (2005) defined IT governance as the process by which decisions are made around IT investments. IT governance covers the practice of how decisions are made, who makes the decisions, who is accountable for the decisions and how the results of decisions are measured and monitored. Executive commitment is vital in ensuring the role that IT plays in enabling and executing the enterprise's strategy. IT governance does not exist in isolation; IT governance is a subset of enterprise governance (Korac – Kakabadse and Kakabadse, 2001). It is the responsibility of not just of the IT management but of the board of directors and executive management (Peterson, 2004). Concurrently, Weill and Ross (2004) support the notion by requiring senior levels to specify decisions rights and an accountability framework to encourage desirable behaviour in the use of IT. The activity of governance itself improves the understanding and thus the working relationship between IT and the rest of the business. As a result, organisations that institute best practices in IT governance could expect business value and benefits (Kan, 2003) that are readily identified and that include increased revenues, profits and a balance struck between value creation (i.e. risk taking) and security (i.e. risk managing) (IT Governance Institute, 2000; Symons et al. 2005). Research indicates that board-level IT governance influence organisational performance regardless of IT needs (Turel and Bart, 2014) and that firms adopting IT governance practices improve their profitability (Lunardi et al., 2014).

Extant literature indicates poor governance and management of outsourcing relationships as the primary reason for the failure of outsourcing ventures (McFarlan and Nolan, 1995; Kern and Willcocks, 2000). A good structure of governance in an IT outsourcing relationship refers to the development of a good contract (Barthélemy, 2003). The outsourcing contract provides a detailed specification of "the exchanges of services and products, financial matters, assets and staff transfers, communication and information exchanges, service enforcements and monitoring methods, key personnel, dispute resolution procedures and other formal issues" (Kern and Willcocks, 2000).

Perceived It Service Quality

Service quality refers to the overall support delivered by a service provider. This is regardless whether such support is handled by the IT department, a new organisational unit or outsourced to an Internet service provider (DeLone and McLean, 2003). The quality of service is thought to be the core criterion for overall customer service (Parasuraman et al., 1991). Service quality has been reported to be significantly related to costs, profitability, customer satisfaction, customer retention, behavior intention and positive word of mouth communications (Cronin and Taylor, 1992). Over the years, the SERVQUAL instrument (Zeithaml et al., 1990) has been used to measure five elements of service quality:

Tangibles – appearance of physical facilities, equipment, personnel and communication materials.
Reliability – the ability to perform the promised service dependably and accurately.
Responsiveness – the willingness to help customers and provide prompt service.
Assurance – the knowledge and courtesy of employees and their ability to convey trust and confidence.
Empathy – caring, individualised attention which the organization provides to its customers.

Research Hypotheses and Research Model

The objective of the research is to investigate the client's perspective of outsourcing vendor IT governance practices and service quality. Accordingly, the research aims at answering the research question of whether outsourcing vendor IT governance practices impact on its IT service quality. Figure 1 shows the conceptual research framework.

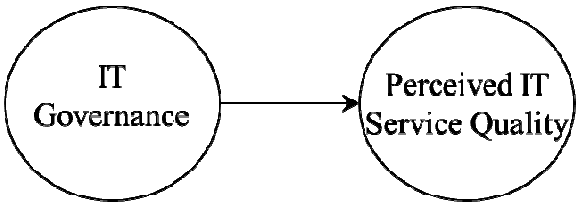

Fig 1: Conceptual research framework

Based on the aforementioned review, the research aims at developing a research model and testing a set of hypotheses. This is in seeking out an evidence for the relationship between IT governance and perceived IT service quality in an IT outsourcing arrangement. IT governance in the research comprises vendor's involvement at the top level in IT planning with the client, IT governance processes to ensure smooth execution of plans and adequate monitoring, and vendor-client outsourcing relationship. In this research, perceived IT service quality comprises soft issues that cover responsiveness, assurance, empathy and reliability. Accordingly, the hypotheses are listed below:

H1a: Vendor's IT governance structure is positively associated with its IT governance processes.

H1b: Vendor's IT governance structure is positively associated with its IT governance relational mechanism.

H2a: Vendor's IT governance processes are positively associated with its responsiveness to the client.

H2b: Vendor's IT governance processes are positively associated with its assurance to the client.

H2c: Vendor's IT governance processes are positively associated with its empathy to the client.

H2d: Vendor's IT governance processes are positively associated with its reliability to the client.

H3a: Vendor's IT governance relational mechanism is positively associated with its responsiveness to the client.

H3b: Vendor's IT governance relational mechanism is positively associated with its assurance to the client.

H3c: Vendor's IT governance relational mechanism is positively associated with its empathy to the client.

H3d: Vendor's IT governance relational mechanism is positively associated with its reliability to the client.

The research model is in Figure 2.

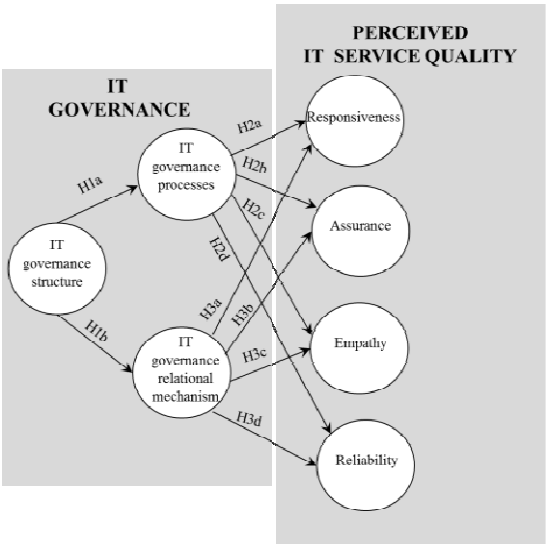

Fig 2: Research model

Methodology

This section discusses the research context, data collection and instrument, and data analysis approach for the research.

Research context

The research aims at finding empirical evidence on the relationship between vendor IT governance practices and IT service quality from client's (end user's) perspective. A total of six client organisations were selected for the research. All client organisations are based in Malaysia. The outsourcing vendor is a leading public listed company who has been providing IT outsourcing services since the 1980s. Malaysia was selected as the research context due to its potential to

further expand its IT service offerings within the Southeast Asia region. A recent newspaper report indicates that the IT outsourcing industry in Malaysia was set to double in growth by 2017 with a CAGR of 15% from its current 2012 revenue of US$1.7billion.[6]

Data Collection and Instrument

The research used a survey questionnaire as data collection approach. The survey questionnaire is in English and is divided into three parts: Section A, Section B and Section C. Section A of the questionnaire seeks to gain information about the profile of the respondents. This section covers personal information such as age, gender, education and job level, duration of work experience and whether respondent is from the IT unit of the organisation. Section B of the questionnaire contains questions about respondent's perceived IT service quality of the vendor. For this section, a five point Likert scale was used. A five-point represents "strongly agree" while a one-point represents "strongly disagree". Section C of the questionnaire contains questions about respondent's perception of vendor IT governance practices. A five point Likert scale was also used for this section. A one-point represents "not at all", a two-point represents "a little", a three point represents "moderately", a four-point represents "extensively" and a five-point represents "very extensively". Survey items using Likert scale were based on prior studies. IT governance measures were adapted from De Haes and Van Grembergen (2008a, b). Perceived IT service quality measures were adapted from Pitt et al. (1995) and Sherman (1997).

In line with the research context, only those from the supervisory, middle management and senior management in the client organisation were selected as respondents to the survey questionnaire. Target respondents should have regular interaction with staffs representing the outsourcing vendor. Respondents were from either the IT unit of their organisations or other non IT units. IT outsourcing services rendered by the vendor include helpdesk and desktop management services, and IT back end infrastructure services which cover servers, applications and network operations management.

A pilot test of the survey questionnaire was conducted among 40 respondents. Cronbach's Alpha coefficient is used to determine reliability of measures. A coefficient above 0.70 indicates internal consistency (Hair et al. 1998; Nunnally 1978). The result of reliability analysis indicates that all items were reliable (Table 1).

Table 1: Pilot test reliability analysis

Constructs	No. of items	Cronbach's Alpha
Perceived IT service quality	9	0.916
IT governance	11	0.901

A total of 100 survey questionnaires were distributed to respondents of six targeted client organisations. All six organisations are large in size having more than 500 employees. Each organisation has different business focus. The research used convenience sampling in view of fulfilling the criteria as set out to be in line with the research context as discussed earlier.

Each respondent was briefed about the purpose of the research, and was given a week to provide responses to the questionnaire and to return it to the researchers. A total of 92 questionnaires were received and used for data analysis.

Data analysis

Data collected from the respondents were first entered, coded, cleaned and analysed using SPSS Statistics 17.0. Analysis at this stage covers gaining insights into respondent's profile (descriptive statistics), profile of variables (descriptive statistics) and checking for group differences (due to the participation of respondents from several organisations). Descriptive statistics will be discussed in the subsequent section. Using Kruskal Wallis test (each sample within an organisation is fewer than 30), all except two items show no significant difference among the cases. The two items ($p<0.05$) were (i) the outsourcing vendor gives prompt services (measures responsiveness) (ii) corporate internal communication addressing general IT issues (measures IT governance relational mechanism). As these two items constitute only 10% of total items, the researchers considered all cases as one sample. Subsequently, data were analysed using Smart PLS Version 3 to determine the relationship among variables in answering the research question.

Results

This section presents and discusses the results of data analysis. Data analysis covers descriptive statistics and assessment of measurement and structural model.

Profile of Respondents

Table 2 shows the profile of respondents.

Table 2: Profile of respondents

Characteristics	Item	Frequency	Percentage (%)
Age	20 - 29	25	27.2
	30 – 39	45	48.9
	40 – 49	20	21.7
	50 – 59	2	2.2
	Total	92	100.0
Gender	Male	40	43.5
	Female	52	56.5
	Total	92	100.0
Years / current job	1 – 5	55	59.8
	6 – 10	23	25.0
	11 – 15	10	10.8
	16 – 20	2	2.2
	More than 20	2	2.2
	Total	92	100.0
Job level	Non-Executive	24	26.1
	Executive	41	44.6
	Supervisor	6	6.5
	Manager	16	17.4
	Senior Manager	5	5.4
	Total	92	100.0
Highest education	Up to equivalent	36	39.2

	grade 12 education		
	Bachelor's degree	50	54.3
	Master's degree	6	6.5
	Total	92	100.0

In terms of age group, 25 respondents (27.2 %) were between the age of 20 and 29. The remaining (72.8 %) are 30 years and above. In terms of gender, there were more female respondents (56.5%) with male respondents being the remaining (43.5 %) proportion.

The number of respondents in the range from 1 to 5 years in their current job is 55 (59.8 %). This represents the majority in work duration. Only four (4.4 %) of the total respondents have been in the current job for 16 years or more. The remaining proportion (35.8 %) has served in their current job between 6 and 15 years.

A majority of the respondents (73.9 %) are in management positions ranging from supervisory to middle management and/or senior management. Out of the total respondents, 5.4% represent the senior management.

A high proportion of the respondents (60.8 %) were educated at the Bachelor's degree or higher. The rest (39.2%) of the sample had at least an equivalent of grade 12 education. Based on the predominant age group that is above 30 years of age, educational background, job level and experience in the current job, the respondents would be generally familiar with management evaluation process.

Profile of variables

Table 3 shows the profile of perceived IT service quality variables.

Table 3: Profile of perceived IT service quality variables

Code	Item	SD	D	N	A	SA	Mean
	The outsourcing vendor:						
OV 11	gives prompt services *(measures responsiveness)*	0	3 (3.3%)	23 (25%)	50 (54.3%)	16 (17.4%)	3.86
OV 12	is always willing to help *(measures responsiveness)*	0	2 (2.2%)	13 (14.1%)	56 (60.9%)	21 (22.8%)	4.04
OV 13	is consistently courteous to me *(measures assurance)*	0	0	19 (20.7%)	55 (59.7%)	18 (19.6%)	3.99
OV 14	has knowledge to answer clients questions *(measures assurance)*	0	2 (2.2%)	27 (29.3%)	53 (57.6%)	10 (10.9%)	3.77
OV 15	gives me personal attention *(measures empathy)*	0	6 (6.5%)	29 (31.5%)	46 (50%)	11 (12%)	3.67
OV 16	understand my needs and those of my work group *(measures*	0	4 (4.3%)	29 (31.5%)	42 (45.7%)	17 (18.5%)	3.78

	empathy)						
OV 17	delivers when promises to do something *(measures reliability)*	0	5 (5.4%)	25 (27.2%)	46 (50%)	16 (17.4%)	3.79
OV 18	show sincere interest in solving problems encountered by myself or others in my work group *(measures reliability)*	0	8 (8.7%)	21 (22.8%)	49 (53.3%)	14 (15.2%)	3.75
OV 19	performs services right the first time *(measures reliability)*	0	6 (6.5%)	36 (39.2%)	37 (40.2%)	13 (14.1%)	3.62

Overall, majority of respondents were inclined towards agreeing with each measure of IT service quality. The mean ranges from 3.62 (the outsourcing vendor performs services right first time – measures reliability) to 4.04 (the outsourcing is always willing to help – measures responsiveness).

Table 4 shows the profile of IT governance variables.

Table 4: Profile of IT governance variables

Code	Item	NAA	AL	M	E	VE	Mean
	The IT outsourcing vendor practices:						
VP20	documentation of business and IT governance alignment tasks *(measures structure)*	0	7 (7.6%)	47 (51.1%)	30 (32.6%)	8 (8.7%)	3.42
VP21	involvement of their senior members in our organization at the IT steering committee/executive/senior management level for evaluation/prioritization of IT investment *(measures structure)*	1 (1.1%)	11 (12%)	42 (45.6%)	34 (37%)	4 (4.3%)	3.32
VP22	making available security/compliance function *(measures structure)*	0	3 (3.3%)	33 (35.9%)	50 (54.3%)	6 (6.5%)	3.64
VP23	working jointly with us in development and execution of our strategic information systems planning blueprint *(measures structure)*	1 (1.1%)	10 (10.9%)	41 (44.5%)	32 (34.8%)	8 (8.7%)	3.39
VP24	IT performance measurement (e.g. IT Balance Scorecard) in their service delivery *(measures process)*	0	8 (8.7%)	40 (43.5%)	33 (35.8%)	11 (12%)	3.51
VP25	conformity to Service Level Agreement (SLA) delivery *(measures process)*	2 (2.2)	3 (3.3%)	39 (42.4%)	34 (36.9%)	14 (15.2%)	3.60

VP26	project governance management methodologies for managing IT projects delivery *(measures process)*	2 (2.2%)	4 (4.3%)	48 (52.2%)	28 (30.4%)	10 (10.9%)	3.43
VP27	IT budget control/reporting in their performance reporting delivery *(measures process)*	3 (3.3%)	13 (14.1%)	46 (50%)	24 (26.1%)	6 (6.5%)	3.18
VP28	IT governance control framework (e.g. COBIT/ITIL) delivery *(measures process)*	2 (2.2%)	3 (3.3%)	46 (50%)	32 (34.7%)	9 (9.8%)	3.47
VP 29	Knowledge management (on IT governance) delivery *(measures relational mechanism)*	2 (2.2%)	4 (4.3%)	41 (44.6%)	33 (35.9%)	12 (13%)	3.53
VP 30	Corporate internal communication addressing general IT issues on a regular basis *(measures relational mechanism)*	1 (1.1%)	1 (1.1%)	37 (40.2%)	43 (46.7%)	10 (10.9%)	3.65

The mean score for IT governance measures ranges from 3.18 (IT budget control/reporting in their performance reporting delivery – measures process) to 3.65 (Corporate internal communication addressing general IT issues on a regular basis – measures relational mechanism). Findings indicate that respondents evaluated the vendor IT governance practices as moderate in line with the use of scale around the mid-point (as defined in earlier section of the paper). There is evidence to suggest that the vendor, from client's perspective does not yet reach extensiveness in IT governance practices.

Measurement Model and Structural Model

The subsequent step was to analyse the convergent validity. Convergent validity is achieved when loadings of the measures to respective constructs are at least 0.60 (Bagozzi and Yi, 1988; Kline, 2005), composite reliability (CR) of all constructs are above 0.6 (Bagozzi and Yi, 1988; Kline, 2005) and average variance extracted (AVE) are above 0.5 (Fornell and Larcker, 1981). Table 5 shows the loadings, composite reliability and average variance extracted.

Table 5: Loadings, Composite Reliability and Average Variance Extracted

Construct		Item	Loading	CR	AVE
Perceived IT service quality	Responsiveness	OV11	0.893	0.891	0.804
	Responsiveness	OV12	0.90		
	Assurance	OV13	0.847	0.844	0.73
	Assurance	OV14	0.863		
	Empathy	OV15	0.868	0.877	0.781
	Empathy	OV16	0.899		
	Reliability	OV17	0.898	0.90	0.751
	Reliability	OV18	0.851		
	Reliability	OV19	0.85		
IT governance	Structure	VP20	0.83	0.848	0.651

	Structure	VP21	***0.418***		
	Structure	VP22	0.788		
	Structure	VP23	0.792		
	Process	VP24	0.806	0.876	0.587
	Process	VP25	0.791		
	Process	VP26	0.835		
	Process	VP27	0.698		
	Process	VP28	0.689		
	Relational mechanism	VP29	0.871	0.848	0.736
	Relational mechanism	VP30	0.845		

Item VP21 highlighted in italic and bold (involvement of their senior members in our organisation at the IT steering committee/executive/senior management level for evaluation/prioritisation of IT investment) that measures structure in IT governance does not meet the cut-off loading. Therefore, the item is dropped from further analysis. The rest of the items meet the cut-off loading. The inter-variable correlations (Table 6) were then examined.

Table 6: Inter-variable correlations

	Structure	Process	Relational	Responsiveness	Assurance	Empathy	Reliability
Structure	**0.807**						
Process	0.795	**0.766**					
Relational	0.618	0.753	**0.858**				
Responsiveness	0.46	0.586	0.614	**0.897**			
Assurance	0.559	0.608	0.592	0.686	**0.854**		
Empathy	0.606	0.606	0.587	0.63	0.726	**0.884**	
Reliability	0.635	0.615	0.654	0.696	0.733	0.757	**0.867**

The correlation among IT governance structure, process and relational mechanism ranges from 0.618 to 0.795. This provides empirical evidence that IT governance measures correlate among each other. The correlation among perceived IT service quality ranges from 0.63 to 0.757. This provides empirical evidence that the measures for perceived IT service quality correlate among each other. The square-root AVE (highlighted in bold) were higher than correlations suggesting that the construct was more closely related to its own measures thus supporting discriminant validity (Kline, 2005).

The researchers then proceeded with bootstrapping to determine support for hypotheses (Table 7).

Table 7: Support for hypotheses

Hypotheses	Path	ß	Standard deviation	t-Statistic	Support?
H1a	Structure -> process	0.80	0.033	24.242	Yes
H1b	Structure -> relational	0.621	0.075	8.287	Yes
H2a	Process -> responsiveness	0.289	0.147	1.966	Yes

H2b	Process -> assurance	0.374	0.134	2.795	Yes
H2c	Process -> empathy	0.371	0.134	2.776	Yes
H2d	Process -> reliability	0.287	0.135	2.129	Yes
H3a	Relational -> responsiveness	0.397	0.137	2.892	Yes
H3b	Relational -> assurance	0.311	0.141	2.2	Yes
H3c	Relational -> empathy	0.314	0.134	2.339	Yes
H3d	Relational -> reliability	0.438	0.142	3.081	Yes

H1a suggests that vendor's IT governance structure is positively associated with its IT governance processes. Support was found for this relationship (ß=0.80; t-stat=24.242).
H1b indicates that vendor's IT governance structure is positively associated with its IT governance relational mechanism. Support was found for this relationship (ß=0.621; t-stat=8.287).
H2a proposes that vendor's IT governance processes are positively associated with its responsiveness to the client. There was support for this relationship (ß=0.289; t-stat=1.966).
H2b proposes that vendor's IT governance processes are positively associated with its assurance to the client. There was support for this relationship (ß=0.374; t-stat=2.795).
H2c suggests that vendor's IT governance processes are positively associated with its empathy to the client. Support was found for this relationship (ß=0.371; t-stat=2.776).
H2d proposes that vendor's IT governance processes are positively associated with its reliability to the client. Support was found for this relationship (ß=0.287; t-stat=2.129).
H3a suggests that vendor's IT governance relational mechanism is positively associated with its responsiveness to the client. There was support for this relationship (ß=0.397; t-stat=2.892).
H3b proposes that vendor's IT governance relational mechanism is positively associated with its assurance to the client. There was support for this relationship (ß=0.311; t-stat=2.2).
H3c suggests that vendor's IT governance relational mechanism is positively associated with its empathy to the client. Support was found for this relationship (ß=0.314; t-stat=2.339).
H3d indicates that vendor's IT governance relational mechanism is positively associated with its reliability to the client. There was support for this relationship (ß=0.438; t-stat=3.081).

Figure 3 shows the theoretical path results.

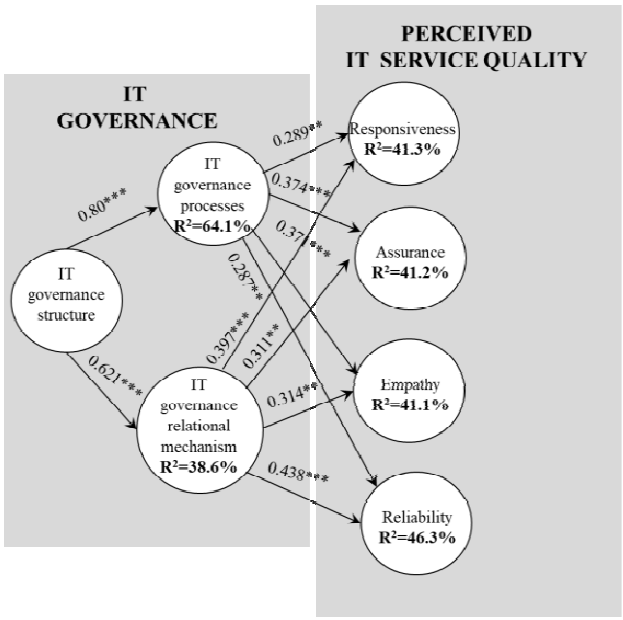

Fig 3: Theoretical path results

Note: -> significant path. **, *** Path is significant at p<0.05 and at p<0.01 respectively.

A total of 64.1% variation in IT governance processes is contributed by IT governance structure alone. IT governance relational mechanism is explained through 38.6% variation contributed by IT governance structure. A total of 41.3% variation in responsiveness is jointly contributed by IT governance process and relational mechanism. Assurance is explained through 41.2% jointly contributed by IT governance process and relational mechanism. A total of 41.1% variation in empathy is jointly contributed by IT governance process and relational mechanism. Reliability is explained through 46.3% variation jointly contributed by IT governance process and relational mechanism.

Discussion and Conclusion

IT outsourcing is a strategy for organisations who strive to manage IT costs and focus on core competencies. Equally, organisations nowadays struggle to manage risks and safeguard shareholder value as they engage into IT outsourcing relationship. Organisations are continuously challenged with outsourcing relationship intricacies while striving to attain organisational performance. The research sets out at gaining insights into client's perspective of vendor IT governance practices and IT service quality in an IT outsourcing arrangement. At the onset, the researchers formulated the following research question (RQ): ***Do extensive outsourcing vendor's IT governance practices impact on client's perceived IT service quality?***

The objective of the research was set out to develop and test a theoretical model on vendor IT governance practices and IT service quality from client's perspective. The research used survey approach. A total of 100 survey questionnaires were distributed to employees at six client organisations in Malaysia that outsource selected IT functions to a local IT vendor. A total of 92 survey questionnaires were used for analysis. The research has fulfilled the objective. The subsequent section discusses the major findings, research contributions and limitations and suggestions for future research.

Summary of Major Findings

The research reaffirms that vendor IT governance practices comprise governance structure, process and relational mechanism in IT outsourcing context. IT governance and IT service quality measures used in the research indicate reliability across time in outsourcing environment. The research provides evidence on the importance of vendor's having in place IT governance structure. This assures the client that vendor is capable to support client in development of IT planning blueprint, in providing secure and compliant function, and in catering to relevant documentation needs. In outsourcing context, IT governance structure requires joint involvement of vendor's senior management with the client in leading and managing critical IT function for the client.

Vendors who have more extensive IT governance structure (through top management's involvement and assurance of compliance) would experience greater drive in promoting appropriate internal control framework (reporting, service level etc.) and better relationship with clients (through meetings and communications). Clients could expect better control of their own performance and vendor's performance when vendor practices appropriate IT governance structure. This includes establishing standards for vendor performance and implementing relevant performance measurement tools when outsourcing. Regular communication and knowledge sharing between client and vendor about IT governance and issues arising in outsourcing are essential. This finding resonates McFarlan and Nolan, (1995), Kern and Willcocks (2000) and Barthélemy (2003).

In this research, perceived IT service quality was conceptualised as the impact of IT governance. IT service quality is measured through client's assessment of vendor. There is evidence to suggest that vendor extensive IT governance process and IT governance relational mechanism contribute to higher IT service quality from client's perspective. Client would experience greater responsiveness from vendor (in terms of willingness to provide prompt services and assistance) for vendor that practice more extensive IT governance. Further, there is indication that vendor practicing more extensive IT governance is more courteous to client and is better able to demonstrate knowledge on client's outsourcing concerns. Besides, client could expect vendor that practice more extensive IT governance to pay greater attention to client, to better fulfill promises and to deliver services right the first time. In sum, this finding is in support of Turel and Bart (2014) and Lunardi et al. (2014).

Research contributions

From a theoretical perspective, the research identified perceived IT service quality as impacts of IT governance. The research has developed a theoretical model that explains IT governance and perceived IT service quality from client's perspective in IT outsourcing context. Notably, the research lends support for the role of IT governance in explaining perceived IT service quality. As the measures demonstrate internal consistency, IT vendors could adopt the measures. This contributes to practice. The use of structural equation modelling is demonstrated for IT governance research thereby adding to methodological contribution.

Limitations and suggestions for future research

The first limitation of the research is the small sample size of 92 respondents. The small sample was a limiting factor in determining group differences for IT governance practice and perceived IT service quality. Secondly, a convenience sampling was used for the research. Thirdly, data was collected at a point of time. Future research could consider higher number of respondents, other client and vendor organisations and a longitudinal approach.

Abstract

This study critically examined the effect of corporate social responsibility on the profitability of Nigerian banks using the ECOWAS bank (popularly known as ECO Bank) and First Bank of Nigeria as case studies. The objectives of the study were to: examine the relationship between environmental concerns and return on investment; investigate how corporate governance affects the gross margin of consumer banks; ascertain whether suppliers' reward improves return on equity of Nigerian consumer banks. The questionnaire was adopted as the instrument for data collection, and the responses derived from the questionnaire were analyzed using simple frequency tables, Pearson correlation, regression analysis and ANOVA test statistics using the Statistical Package for Social Sciences (SPSS) version 23. Findings from this study indicate that corporate social responsibility has a positive influence on the profitability of banks operating in Nigeria, given the institutional deficiencies in the country. It is concluded that an investment into social responsibility positively influences the bank's reputation and image, thereby leading to stronger customer loyalty. It is therefore recommended that banks operating in especially developing countries like Nigeria look beyond financial profit to social profit derived from social responsibility.

Keywords: Corporate social responsibility, profitability, consumer banks, environmental concerns.

1.0 Introduction

The focus of Corporate Social Responsibility in several industries, such as the banking sector has moved from an effort to be solely ethical to ensuring an ethical performance orientation in all aspects of business operations. Banks have found the need to contribute to the environment of their operations by merging social responsibility to their profitability strategies (Dhaka & Ullah, 2012). The concept of Corporate Social Responsibility (CSR) is one of moral and ethics, which entails maintaining principled leadership and conduct that create solution to societal issues (Mohammed, Hassan & Kazi, 2009). Although the major purpose of all commercial banks and generally any business organization is to make

profit, there has become a rising recognition of the impact of banking operations on the employees, customers, government, competitors, partners, investors and environment. It is posited that commercial banks should concentrate their consideration on both expanding its main concern and being a decent corporate citizen (Pacific Continental May, 2013; Nurn & Tang, 2010).

Objectives of the Study

The broad objective of this study was to explore the effect of Corporate Social Responsibility on the Profitability of the Nigerian banking industry. However, the specific objectives were to;

i. Investigate how corporate governance affects the gross margin of the banks.
ii. Examine the relationship between environmental concerns and return on investments.
iii. Ascertain whether suppliers reward improves the return on equity of a bank.

Research Hypothesis

Hypothesis one

$H_{01:}$ corporate governance practices do not influence banks gross margin.

H_{a1}: corporate governance practices influences banks gross margin.

Hypothesis two

$H_{02:}$ there is no relationship between environmental concerns and return on investments.

H_{a2}: there is a relationship between environmental concerns and return on investments.

Hypothesis three

H_{03}: suppliers reward does not influence return on equity of a bank in any way.

H_{a3}: suppliers reward influences return on equity of a bank in various ways.

Like all business organizations, consumer banks profit by having revenues in excess of their expenses. The major portion of the bank's profit comes from the fees that it charges for its services and the interest that it earns on its assets, while its major liabilities accrue from the interest paid on its liability (Johansson, Karlsson & Hagberg, 2015). The issue of corporate social responsibility and its effect to bank profitability is crucial, as it is hypothesized that a successful Corporate Social Responsibility endeavor enhances an organization's reputation, leads to higher productivity and innovation among employees, boosts sales revenue through improved customer goodwill, attracts new customers and balances power with responsibility (Asemah, Okpanachi & Edegoh, 2013). Based on the above, this study attempts to create a relationship between CSR and profitability in commercial banks by studying the impact of Corporate Social Responsibility (measured using community development, corporate governance, environmental concerns and suppliers rewards) on profitability (measured by sales growth, gross margin, return on investment and equity).

2.0 Literature Review

White (2012) observed that the awareness for CSR is becoming a major cause of concern worldwide, and while several organizations are finding it difficult to deal with this concern, several other organizations are benefiting from the CSR wave. Commercial banks play an important role in the shaping of any economy – developing and developed. In the Nigerian economy, given the direct link between the

prosperity of the banking sector and the development of the economy, Nigerian banks are now under more pressure to exhibit responsibility and sustainability (Johansson, Karlsson & Hagberg, 2015).

Since the establishment of the idea of CSR, there has been a distinctive assessment in the matter of what CSR is proposed to fulfill for a firm. According to Cheng (2014), CSR has the capacity to strengthen the connection between a business organization and it's respective stakeholders. It is posited that as an act of being socially responsible, commercial banks can lower their loan constraints through better access to bank credits for small and medium enterprises, thereby contributing to the growth of the economy. In return, the bank is perceived to have the interest of the general populace at heart (Hanke & Stark, 2009).

The Case Study

The study reviewed the CSR practices of two consumer banks in Nigeria: First bank of Nigeria and Ecobank. The choice of both banks is as a result of the noticeable CSR practices engaged by both banks in their various branches in the country.

2.1 Empirical Framework

Corporate Social Responsibility Dimensions

The expansiveness of the concept of corporate social responsibility has created the need to break down the term into sizeable chunks to ensure business organizations are able to fully engage in social responsibility. The triple bottom line concept creates an easy to adopt approach to engaging CSR. It indicates that the concern of the business organization is mainly financial (costs versus pay), such that the business organization is concerned about how it can create value as regards three different entities: profit, people and planet, commonly referred to as the 3Ps (Dyllick & Hockerts, 2002). Profit explains how the business organizations (commercial banks in this case) produce economic benefits to the society, in terms of finance. The people aspect of the triple bottom line explains the bank's relationship with its employees, while planet refers to the commercial bank's responsibility to the environment.

In recent literature, the 3Ps have been alluded to as the social, environmental and financial scopes of an organization's CSR execution (Slaper & Hall, 2011).

Environmental Dimension

The environmental dimension of the triple bottom line approach to CSR is referred to as the business organization's commitment to reducing the negative environmental impact of its operations. This is usually achieved through appropriately disposing of outflows and waste, accomplishing energy effectiveness and efficiency, and generally diminishing practices that may adversely influence the sustainability of natural resources (Yeung, 2011). Rodriquez, Fernandez and Simonetti (2015) highlight the following as the main elements of environmental responsibility:

i. Adopting environmental performance measures and guidelines that are subjected to international environmental protection standards.
ii. Aiding nation-wide environmental development goals and initiatives
iii. Promoting environmental mindfulness
iv. Initiating community-focused discourse on environmental issues.

Social Dimension

The social dimension views the business organization's relationship with its various stakeholders – consisting dominantly of the shareholders, customers, employees, government bodies and community members. There is a rising pressure for business organisations, especially key entities such as the

commercial banks, to give more attention and resources to its relationship with its stakeholders, especially community members, as stakeholders have become more aware of their social rights and do not hesitate in anyway to push their social demands on the bank (Dylick & Hockerts, 2002). It is posited that the bank's main areas of portraying social responsibility from the social dimension perspective, is by ensuring fair employment and labour practices, and by proffering solutions to community challenges, thus creating better social relationship with its stakeholders.

Economic Dimension

The economic dimension of CSR deals with understanding the economic influences of the bank or company's operations, which entails understanding the firm's impact on the economy, as regards finances. It indicates how resources for the generation of merchandise and enterprises are conveyed inside the social framework. Several CSR authors such as Carroll (1991) in the pyramid of CSR, have inferred that of all dimensions of corporate social responsibility, the economic dimension is the most important. In the case of consumer banks, the economic dimension of CSR goes beyond the banks recording employment figures and debts in their CSR report, but entails core economic issues such as the multiplier effect of the firms' operations, it's contributions to the economy through taxes and very importantly, avoiding actions that damage trust (Jucan & Sabina, 2010).

The Consumer Banks' Cost and Benefits Evaluation of Corporate Social Responsibility

In the present world system, where consumers place more emphasis on the reputation of a firm than the perception of their products and services, consumer banks have not been left out from this system, as bank managers have begun to incorporate sustainable business practices into their daily operations, to fully benefit from good corporate citizenship (Dhaka & Ullah, 2012).

Investment in corporate social responsibility portrays the bank as one that is interested in people, planet and profit, and not solely its monetary bottom line. This reputation can be very attractive, not just to customers or clients, but also to investors, suppliers, vendors, employees and government. In situations where the employees and other key stakeholders align to this shared values and vision of positive impact, it can lead to better working relationships and increased loyalty, which often results in increased financial gain (Pacific Continental May, 2013). CSR prompts more noteworthy corporate budgetary execution and furthermore encourages the unmistakable benefits of pulling in improved representatives, diminished turnover rate, more significant profitability and decreased working costs. Summarily, the benefits of CSR to the banks include:

i. Higher productivity and innovation among employees
ii. Increased sales revenue
iii. Improved customer goodwill
iv. Ability to attract new customers
v. Improved balance of power with responsibility
vi. Enhanced reputation in the workplace (Asemah, Okpanachi & Edegoh, 2013; Nurn & Tang, 2010).

2.2 Theoretical Framework of Corporate Social Responsibility

The Stakeholders' Theory: Supporting the firm's engagement in CSR practices that encompasses the business organisation's relationship with its various stakeholders is the stakeholders' theory, which has for the most part been utilized while examining corporate social responsibility and its effect on the firm's stakeholders. The stakeholders' theory basically engages the concept of how stakeholders should be engaged in the running of the business organisations' operations, such that every decision made in the organization as regards corporate social responsibility outlines the impact (positive and negative) on the

firm's various stakeholders, which usually constitutes of any body that is affected by the firm's operations, such as the suppliers, customers, employees, government amongst others (Mitchell, Agle & wood, 1997).

3.0 Methodology

The descriptive and survey methods of research were adopted in this study. The survey research method was chosen to determine the factors influencing the profitability of Nigerian banks that are engaged in corporate social responsibility. The survey instrument; the questionnaire, was designed using likert categorical scale to measure respondents' attitude towards the important factors of the study. The **Sample Size** for this study includes all the employees of First Bank and Eco bank in Nigeria.

The **sample frame** used for this data would be based on convenience sampling. Using the formula postulated by awokemi (2003), we are able to get the sample frame in which the questionnaires would be administered because not everybody in the organization would be reached. The sample frame for this study is Eco bank and First Bank. Since all the population cannot be met the questionnaires were distributed to the customers and the community.

Due to inadequate records keeping, the exact number of these employees are not known, but are estimated to be above 10,000. Primary data for this study was collected using the questionnaire, while secondary data was gotten from the Internet, journals and articles. Data gathered from the questionnaire were analysed using correlation and regression tools of the statistical package for social sciences (SPSS). The Pearson correlation tool was utilized to investigate the quality of connection between two continuous variables and the regression analysis was used to determine the effect of the independent variable on the dependent variable.

The **Research validity**, questionnaires included a variety of questions on the knowledge of corporate social responsibility and its impact on the profitability of Nigerian banks. The questionnaire is designed in such a way that information gained would provide answers to the research questions and hypothesis. The questions were formulated in simple language for clarity and ease understanding. Clear instructions were given to the respondents. The questionnaires were shared to the employees in Ecobank transactional incorporated and they were all filled in the presence of the researcher.

Reliability of Research Instruments

Table 3.1 Reliability Statistics

Cronbach's Alpha	N of Items
.727	16

A coefficient of 0.727 indicates the research instrument is reliable, as it is above 0.7, which is the benchmark for testing reliability.

3.1 Corporate Social Responsibility practices of First Bank of Nigeria

First bank of Nigeria is acclaimed to be one of the leading banks with strong corporate social responsibility practices in Nigeria. Of their numerous community engagements the following are the most natable ones:

i. The creation of the First bank foundation: The first bank foundation is the unit of the bank that is concerned with the strategising of the bank's corporate social responsibility practices. The aim of creating the foundation was to ensure careful and well thought out engagement between the bank and their customers.
ii. Partnership with several organisations: First bank partners with several organisations to ensure a better societal reach. Such organisations as Cadbury Bournvita, Alexander Forbes amomg others for several projects. In recent times, they partnered with these organisations to sponsor the 'God's Children Got Talent' program, a talent show for young children, in collaboration with the Redeeemed Christian Church of God province 4
iii. Investment in educational growth opportunities such as the e-registration forms initiative for the November/December 2014 West African Senior School Certificate Examination (WASSCE).
iv. Partnership with health care initiatives such as the Sebeccly Cancer Care and Support Centre, to build awareness about cancer, pledge action amongst women to get screened and give access to quality cancer care. FirstBank is also supporting the Centre's Light Lagos Pink Campaign, an annual statewide fundraising campaign to promote breast cancer awareness and raise funds to support breast cancer treatment (First bank foundation, 2017).

3.2 Corporate Social Responsibility Practices of Eco Bank

Just like First Bank of Nigeria, The Ecowas bank (commonly known as Ecobank) is top on the lst of business organisations in Nigeria that have CSR at the fore-front of tehir operations. Some of the Ecobank's CSR initiatives include:

i. Support for the promotion of education in the country through several initiatives, such as the build of over a 100 seater ultra-modern lecture theatre at the Chukwuemeka Odumegwu Ojukwu University (formerly Anambra State University), as part of its corporate social responsibility (CSR) initiatives in 2016. In line with its main startegy of promoting education, Ecobank also committed resources to building classroom blocks for three schools across the country; namely, C&S primary school, ikorodu Lagos; Government secondary school, Kubwa; Abuja and Eastern academy onistsha, anambra state in 2013.
ii. Ecobank has an Environmental and Sustainability unit within its Group Risk Management department. This unit has the primary responsibility for all environmental and sustainability management, including environmental and social risks, sustainability business development, adoption of green initiatives, energy conservation and carbon footprint management (Ecobank, 2017).

4.0 Presentation of Result and Analysis

The data used here were gotten from the hypotheses tested, which were derived from the research hypotheses listed in the introduction. This study made use of three sets of hypotheses as seen below:

4.1 Test of Hypotheses

4.1.1 Hypothesis one: The influence of corporate governance practices on banks gross margin

Table 4.1.1.1 Model Summary

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate
1	.234[a]	.055	.044	.60552

a. Predictors: (Constant), Corporate governance has a positive effect on the bank's gross margin

Table 4.1.1.2 ANOVA[a]

Model		Sum of Squares	df	Mean Square	F	Sig.
1	Regression	1.925	1	1.925	5.251	.024[b]
	Residual	33.365	91	.367		
	Total	35.290	92			

a. Dependent Variable: There is a relationship with the bank and its customers

a. Predictors: (Constant), Corporate governance has a positive effect on your banks gross margin

Table 4.1.1.3 Coefficients

Model	B	Std.Error	Beta	t	Sig
(constant)	3.782	.382		9.909	.000
Corporate governance has a positive effect on your banks gross margin	.200	.087	.234	2.291	.024

a.Dependent Variable; There is a relationship with the bank and its customers

Source: Field Survey 2017

Interpretation: At a significance level, which is less than 0.5, the result shows that corporate governance practices does influence the bank's gross margin. Therefore, the null hypothesis was therefore rejected. The model of the influence of corporate governance explained the extent to which it influences the gross margin of banks as 5.5% at 0.024 level of significance where the null hypothesis was rejected.

4.1.2 Hypothesis two: The relationship between environmental concern and return on investment

Table 4.1.2.1 Correlations

		Has your banks involvement with the environment improved their returns	Banks that are highly involved in their environment tend to have more return on their investment
Has your banks involvement with the environment improved their returns	Pearson Correlation	1	.206*
	Sig. (2-tailed)		.048
	N	93	93
Banks that are highly involved in their environment tend to have more return on their investment	Pearson Correlation	.206*	1
	Sig. (2-tailed)	.048	
	N	93	93

*. Correlation is significant at the 0.05 level (2-tailed).

Source: Field Survey 2017

Interpretation: The relationship between the variables (Banks' involvement with the environment and return on their investment) was examined using Pearson correlation. The result from the test of the relationship between environmental concerns and return on investment shows that (Beta=0.206, p<0.01). This means that environmental concern has a .206 or 20.6% relationship with return on investment. The R-square was 0.0424 which amounted to 4.24% of the variation between environmental concerns and return on investment. It indicates a high relationship between environmental concerns and return on investments. Therefore, the null hypothesis was rejected.

4.1.3 Hypothesis three: The influence of suppliers reward on return on equity

Table 4.1.3.1 Model Summary

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate
1	.438[a]	.192	.183	.44012

a. Predictors: (Constant), An efficient suppliers reward can help a bank increase its ROE

Table 4.1.3.2. ANOVA[a]

Model		Sum of Squares	df	Mean Square	F	Sig.
1	Regression	4.179	1	4.179	21.576	.000[b]
	Residual	17.627	91	.194		
	Total	21.806	92			

a. Dependent Variable: A rising ROE suggest that a bank is increasing its ability to generate profit

b. Predictors: (Constant), An efficient suppliers reward can help a bank increase its ROE

Table 4.1.3.3 Coefficients

Model		Unstandardized Coefficients		Standardized Coefficients	t	Sig.
		B	Std. Error	Beta		
1	(Constant)	2.712	.336		8.071	.000
	An efficient suppliers reward can help a bank increase its ROE	.356	.077	.438	4.645	.000

a. Dependent Variable: A rising ROE suggest that a bank is increasing its ability to generate profit

Source: Fieid Survey 2017

Interpretation: The result from the test of hypothesis three, showed that suppliers reward influences return on equity. The model disclosed that supplier's reward significantly influences the return on investments of banks at 19.2% and with a 0.000 level of significance. Therefore, the null hypothesis was rejected.

4.2. Sustainable Solution Practice Index for First bank and Eco bank

This section reveals the results of the SSP index of each bank and the results of statistical procedures performed**.** The sustainable practice index (SSPI) result was derived from each bank and was gotten as follows; SSPI = Total score gotten from the individual banks x 100/ Total score obtainable.

Table 4.2.1 sustainable solution practice index for First bank and Eco bank

S/N	Bank	Economic	Social	Environmental	General	SSP Score	SSPI index	Interpretation	ranking
1	**First bank**	**5**	**8**	**0**	**3**	**16**	**80**	**substantial**	**1st**
2	**Eco bank**	**2**	**2**	**3**	**2**	**10**	**50**	**High**	**2nd**

Source: Published accounts of the selected banks based on their CSR practices 2014

Interpretation: - The results above show that First Bank had the highest SSP score index of 80, which is considered to be substantial. Eco bank had a high SSP score as well because they are presently no accounting principles in Nigeria on sustainability reports. The result shows that the banks were mostly involved in social responsibility with a score of 12 over the total score 31 representing (39%). The economic responsibility amounted to a score of 9 over the total 31 representing (29%). The general responsibility amounted to a score of 5 over the total 31 representing (16%) and the environmental responsibility amounted to a score of 4 over the total 31 representing (13%). Overall the four sustainability practices were well represented.

Table 4.2.2 Corporate Social Responsibility expenditure of First bank and Eco bank

First Bank of Nigeria Plc			EcoBank Nigeria Plc	
Year	CSR N' 000	PAT N' 000	CSR N' 000	PAT N' 000
2006	119,887,000	3,2164,000	4,147,000	9710000
2007	315,883,000	36,679,000	6,102,000	10096000
2008	438,729,000	12,569,000	7,193,000	(8980000)
2009	1,229,513.816	3,622,000	4,812,000	(5944000)
2010	887,743.640	29,170,000	6,123,000	2120000
2011	904,136.120	44,785,000	6,380,000	(4249000)
2012	924,613.810	46,124,000	5,907,000	3,165,000
2013	552,700,000	31,238,627	5,510,000	11,658,000
2014	849,256,000	11,940,000	6,623,000	29,733,000
2015	59,460,000	43,175,435	4,719,000	11,304,000
2016	734,654,400	55,735,220	6,671,000	26,45373

Source: Published Annual Reports of the Selected banks from 2006-2016

Interpretation: - This research study showed that First Bank Plc has the highest corporate social responsibility expenditure of N1,229,513,816 in year 2009 while Eco Bank has the lowest CSR expenditure of N4,147,000 in year 2006. This means that first bank is the leading commercial bank when it comes to CSR and it reveals that there is a significant relationship between corporate social responsibility on expenditure and profitability. First bank has always been contributing large donations to their CSR practices and it shows in their profitability, as they make bigger profits each year. Eco bank puts in smaller amount of money or donations to their CSR practices and it also shows that the bank does not make profit all the time, as they were making loss in the year 2008-2011. Although CSR brings about a decline in the profit after tax, it also encourages more involvement which leads to profit. Therefore, contributing to CSR improves the sustainability part of the banks financial statement which includes social responsibility. It should be noted that the banks have responsibility to several group of a company's investors both internal and external.

5.0. Summary of Findings

The research findings are divided into two; namely theoretical findings and empirical findings.

Theoretical Findings

The stakeholder theory identifies the business actions and decisions that must be taken into consideration towards the shareholders, managers, community, customers and employees. Shareholders and investors are one of the major stakeholders in the business and they are directly affected by decisions taken by the business. CSR is a reflection of stakeholders' theory as regards the business actions and how it affects their profitability. In order for a business to be sustainable in the long run they need to consider the environment as a major decision making point. Newton (2014) said that the key to CSR is trust and an economic driver of a business is its corporate image, which is what investors and shareholders look at, and maintaining it should be an ethical priority.

Empirical Findings

The empirical findings which was based on the analyzed objectives, specifies the following:

The role of community development in enhancing the sales growth of the bank

The empirical findings based on this objective are stated as follows

i. Banks involvement in community development can enhance their sales growth.
ii. Banks non- involvement in community development can affect their sales growth positively.
iii. Most banks are involved in community development.
iv. Banks have gained more customers through community development.

Corporate governance practices affect the gross margin of the bank

The empirical findings based on this objective are stated as follows

i. Corporate governance has appositive effect on their banks gross margin.
ii. Banks have a relationship with their customers.
iii. The principles and regulations put in place by the bank has improved the gross margin ratio.
iv. The policies in the bank are in the favour of the customers.

The relationship between environmental concern and return on investment

The empirical findings based on this objective are stated as follows

i. The banks involvement with the environment improves their returns.
ii. In the long run the bank gains more customer loyalty because of their involvement with the environment.
iii. The banks that are highly involved in their environment tend to have more return on their investment.
iv. The banks have improved the welfare and environment in which they are located in.

Suppliers' reward improves the return on equity

The empirical findings based on this objective are stated as follows

i. An efficient supplier's reward can help a bank increase its return on equity.
ii. A rising return on equity suggests that a bank is increasing its ability to generate profit.
iii. The growth and profitability of banks are better optimized through information, financial and physical suppliers reward.
iv. A banks return on assets can increase if their supply chain is as good as the relationship with suppliers.

6.0 Conclusion and Recommendations

This research concludes that corporate social responsibility has a strong positive effect on the profitability of consumer banks in Nigeria. It was observed that banks in Nigeria gain such benefits as improved reputation and image, enhanced customer loyalty and ultimately improved profitability when they align their operations with social responsibility in the aspect of their relationship with their various stakeholders. Based on the above conclusion, it is recommended that commercial banks engage active CSR practices with their various stakeholders, banks should also make it a priority to include their stakeholders in their decision making. Also banks should be prompt in handling ethical issues involving their transactions and activities, and should be very transparent in their dealings with the public, if they

intend to be sustainable. On the part of the government, policies and duties concerning CSR practices for commercial banks should be clearly outlined and enforced. Summarily, the relationship between corporate social responsibility and organisational profitability cannot be over emphasized, as such managers, scholars, government and other stakeholders should invest resources into unravelling the concept.

An Efficient 3D Point Cloud Coarse Registration based on Convex Hull

Mouna Attia, Université de Tunis El Manar -Faculté des Sciences de Tunis -Labotory: URAPOP- 2092, Tunis, Tunisie, Email: mounaattia.info@gmail.com

Yosr Slama, Université de Tunis El Manar-Faculté des Sciences de Tunis-Labotory: URAPOP-2092, Tunis, Tunisie, Email: yosr.slama@gmail.com

Abstract

Non-rigid registration is a crucial step for many computer vision applications such as dimensional control in manufacturing, pattern recognition, etc. Generally, such application accuracy depends strongly on that of the registration step. In this paper, we propose a new method to determine an efficient Coarse Registration that can be refined using Iterative Closest Point (ICP) algorithm. Firstly, two projection planes corresponding to the model and reference point clouds are determined using point dispersions. Secondly, all the points of each cloud are projected onto the corresponding planes. Then, two convex hulls are extracted from the two projected point sets and then matched optimally. Next, the non-rigid transformation from the reference to the model is robustly estimated through minimizing the distance between the matched points pairs of the two convex hulls. Finally, this transformation estimation is refined using ICP algorithm. The experimental results based on synthetic data show that the proposed algorithm outperforms standard ICP in terms of execution time and precision whether with a normal or a large transformation.

KeyWords: 3D point cloud, Convex Hull, Iterative Closest Point (ICP), Principal Component Analysis PCA, Non rigid registration

I. Introduction

Non-rigid 3D point cloud registration is an active research area in computer vision. It consists in finding the best transformation to align two clouds. 3D point cloud registration is widely used for reverse engineering, manufacturing process, virtual reality and map building in robotics. So far, nonrigid registration has been regarded as an on-line process. Therefore, we need to find an accurate transformation in a short time. In the literature, there exist many algorithms capable of aligning 3D point clouds such as Iterative Closest Point (ICP) [Besl and McKay, 1992], Normal Distribution Transform (NDT) [Magnusson, 2009], Ransac [Fischler and Bolles, 1981] and Softassign [Gold et al., 1998]. The execution time of these methods increases proportionally to the treated cloud points number. Moreover, all of the methods are iterative and their convergence quickness depends on the efficiency of the initial transformation estimation they use. For these reasons, a two-stage registration strategy is recommended: coarse and fine.The Coarse registration (CR) stage aims to compute an initial estimation used by the fine one to obtain, as possible, the most accurate solution.

Several studies are interested in finding a good method for coarse registration and improving the fine registration. In this context, Ma et al. [Ma et al., 2009] improve the step of coarse registration using the convex hull. In fact, they extract feature points by Harris corner detector. Then, they use a correlation method to match convex hull points of the pairing sets to establish the transformation parameters.

Carlos et al. [Torre-Ferrero et al., 2012] introduce a novel approach to find a rigid transformation that coarsely aligns two 3D point clouds. The algorithm proposed by Carlos determines 2D descriptors. The latter represents an ordered cloud of radial contours that are extracted around an interest-point within the point cloud. Then, a similarity measure correspondence between descriptors is determined. The search for correspondences is done iteratively following a cell distribution that allows the algorithm to converge to a candidate point. Burlacu et al. [Burlacu et al., 2016] propose a tensorial method to choose the initial guess of the ICP algorithm. This method is strongly connected to the parameters that can be used to describe the displacement of rigid bodies.

Fan et al. [Fan et al., 2013] introduce a robust approach based on convex hull for medical images registration. First, point sets on the medical image surface are extracted. Then, a 3D convex hull is constructed. After that, triangle patches on the surface of convex hulls are specified by predefining their normal vectors. Each edge of the referenced triangle is compared with all the triangle edges in the other point set to find the congruent pair set. Thereafter, the transformation parameters of each triangle pair are optimized by minimizing the Euclidian distance between the corresponding vertex pairs. The transformation is obtained iteratively by measuring the similarity between triangles. Global optimization is achieved through RANSAC. This method is improved in [Fan et al., 2016]. In fact, Fan et al. propose a novel convex hull aided registration method (CHARM) to match two point sets subject to a non-rigid transformation. Firstly, two convex hulls are extracted: the first from the model and the second from reference point cloud. Then, all points of the clouds are projected onto the reference plane through each triangular facet of the hulls to extract invariant features. The latter is matched optimally and a transformation is robustly estimated by the random sample consensus (RANSAC) scheme through minimizing the distance between the matched feature point pairs.

Other researchers implement non-rigid registration by minimizing the difference between the descriptors and invariant features among the potential correspondences between 3D surfaces [Chen and Koltun, 2015].

At present, the research on non-rigid registration techniques focuses mainly on feature extraction using the convex hull in 3D space but none among the proposed techniques shows interest in the shape topological structure. The use of a convex hull in 2D space is another point not taken into consideration in literature even if it may facilitate the search of correspondences.

In this context, we propose a new method to find an accurate transformation in a short time. It consists in applying first a coarse registration to find an initial transformation, and second a refinement method to improve the accuracy. The main contribution in this paper is the transformation of the 3D point cloud registration problem into a registration between two plane objects. The algorithm steps can be summarized as follows: (i) Projection of each point cloud onto a convenient plane, (ii) Determination of the convex hull for each projected point cloud, (iii) Matching between the two projected point clouds, (iv) Computation of the transformation estimation and (v) Refinement of the transformation using ICP algorithm. Our method is highly robust particularly with large transformation since it is based on a two-step procedure: coarse registration in the first step and fine registration in the second. Furthermore, the proposed method is computationally efficient because the number of points on the convex hull is significantly smaller than that in the original point cloud.

The remainder of this paper is organized as follows. In Section 2, we detail our registration method. In Section 3, we validate our proposed algorithm through different criteria and metrics. Finally, we conclude our work and suggest future works in Section IV.

Ii. Method

In this section, a detailed description of our method will be presented. First, we give an overview of the 3D point cloud registration. Let suppose that we have two point clouds to be registered.
Let $U = \{u_j | j = 1..n\}$ be the model data where $u_j \in IR^3$ and $V = \{v_i | i = 1..m\}$ be the reference data where $v_i \in IR^3$. n and m are the points number of U and V respectively. The $3D$ point clouds registration is the process of finding the transformation Trans that aligns two sets of data in the same coordinate. Trans is the matrix that matches V to U. It depends on six parameters, namely a translation vector $T = (tx,ty,tz)^T$ and a rotation vector $R = (\alpha,\beta,\gamma)^T$. α denotes the rotation angle relatively to the x axis whereas β and γ are the rotation angles relatively to the y and z axes. Therefore, the registration problem can be seen as the minimization of the objective function in eq. 1.

$$\sum_j \left\| \overrightarrow{V_j} - R\overrightarrow{U_i} + T \right\| \quad (1)$$

To have an overview of our approach, Fig. 1 shows the flowchart of the proposed method which is divided into coarse and fine registration. The coarse registration is determined through four steps:

- Projection plane determination: This step is the core of our algorithm. It consists of defining a plane in which the point cloud projections preserve the topological structure of the object.
- Point clouds projection: A set of new point clouds of the model (resp of reference) is then generated by projecting the entire model (respectively the entire reference) onto each projection plane.
- Convex hull determination: the convex hull of the projection points is created by extracting the smallest convex set that contains the entire model.
- Convex hull Matching: Points of the two convex hulls are matched and non-rigid transformations between these two clouds are estimated.
- Transformation Estimation: Estimate the transformation between the pairing matched in the previous step.

The fine registration is obtained by applying the iterative closest point (ICP). Our method is very sensitive to noise and outliers. Hence, the accuracy and precision of our method risk to be affected. For this reason, it is necessary to apply a smoothing module and a filter to eliminate the noise before any processing. Another condition is also applied to reduce the impact of noise when defining the convex hull: If the distance between two closing points is considerably larger than an epsilon value, the neighboring point is deemed as an outlier and removed.

A. Projection plane determination

The most important step in our approach consists in searching a two-dimensional plane which preserves the 3D point cloud shape when projected onto plane. Hence, in order to take into account the points dispersion, we use Principal Component Analysis (PCA) to define a plane. PCA is a statistical method widely used in image registration and pattern recognition. To compute the principal components, PCA operates according to the following three steps:

- Compute the mean of Point cloud U: The mean of each dimension is computed as follows:

$$\bar{u} = \frac{1}{n}\sum_{i=1}^{n} u_i \quad (2)$$

- Compute the covariance matrix: The covariance matrix, denoted $CovU$, is a square matrix of size n computed as follows :

$$CovU = \frac{1}{n}\sum_{i=1}^{n}(u_i - \bar{u})(u_i - \bar{u})^T \quad (3)$$

- Compute the eigenvectors and eigenvalues of the covariance matrix: To compute the eigenvectors and eigenvalues of the covariance matrix CovU, we compute A the diagonal matrix of the CovU eigenvalues. Then, we determine the matrix E of eigenvectors which diagonalizes matrix CovU i.e.

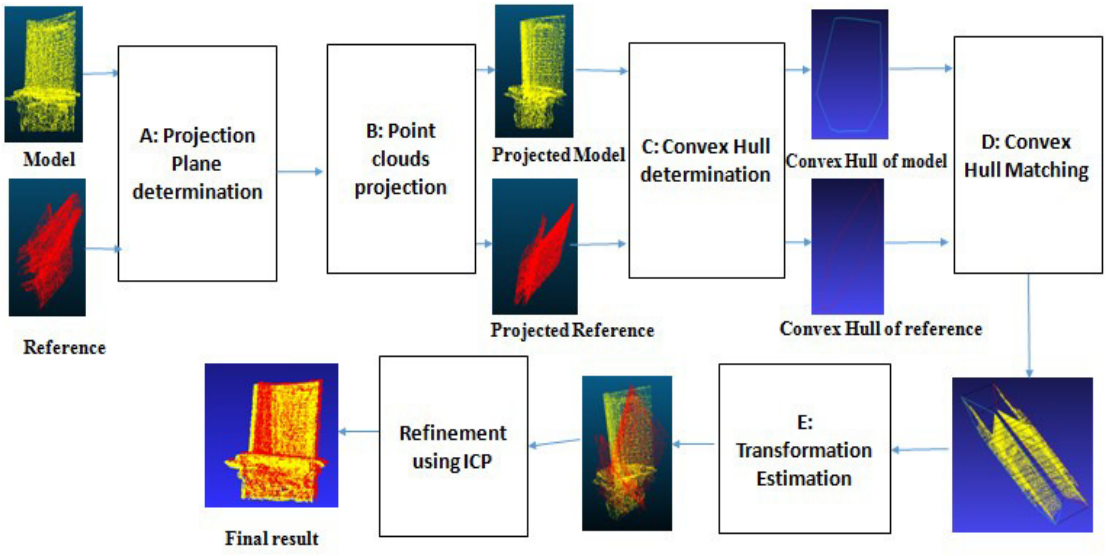

Fig. 1: The flow-chart of the proposed method for the 3D point cloud registration

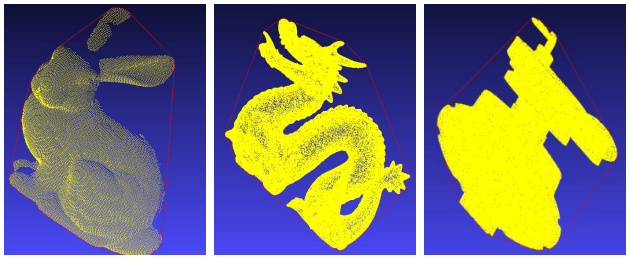
$$E^{-1}CovUE = A \qquad (4)$$



The eigenvectors E of matrix CovU are the principal components of the point cloud U. In our case, this method gives three eigenvectors which represent the principal components of our data. In fact, it turns out that the eigenvector having the largest eigenvalue is the main component of the point cloud. The eigenvectors are ordered according to their correspondent eigenvalues and sorted in increasing order. This gives us the components ordered according to their significance in relation to points dispersion. We decide to ignore the less significant components and consider the plane defined by the two first largest components. In fact, we may lose some information, but if the eigenvalues are small, we wont lose a lot. The measure of the data representation quality set by the two first principal components is given by the percentage of the total inertia contained in the corresponding space.

B. Point cloud projection

The principle of the point projection is to project all the points onto a plane. The projected clouds preserve the real cloud topology and the distribution of the entire model. This projection process is similar to observe a 3D point cloud from a certain viewing direction. This step is achieved in shorter time. The point cloud projected has the same original point cloud intensity distributions but in the plane. Matching between projection views can significantly improve registration effectiveness since processing with shapes in plane is always easier and generates lower noise.

C. Convex hull determination

The convex hull of 3D point cloud is the minimum convex combination that contains all points. These points are commonly used to represent the global structure of the point clouds. In fact, the geometric structure of the entire model can be represented by a limited number of points on the convex hull. The convex hull is unique for a point cloud and its structure is invariant. It can be achieved effectively by using numerous iterative algorithms [Berg et al., 2008]. The computational complexity of the convex hull is $O(nlog(h))$, where h denotes the number of vertices on the corresponding convex hull. The topological structure of convex hull can be affected by outliers. For this reason, we need a preventive condition to have a consistent and uniform convex hull. A point is considered as outlier if the distance between this point and its neighbors is considerably larger than an epsilon value. Fig. 2 shows the convex hull (represented by the red color line) of some point clouds used in experimental study.

(a) (b) (c)

Fig. 2: Convex hull and projected point of bunny, dragoon and E Piece

D. Convex hull Matching

Once the convex hull is obtained, it can be used to determine the corresponding point pairs between different models. Hence, the transformation parameters between the two convex hulls can be effectively estimated by detecting and matching the pairs. In fact, a set of the best-matching candidates is determined by minimizing the Euclidean distance between the two convex hulls.

E. Transformation estimation

Once the matching step is finished, a transformation between pairing is estimated. In this step, many optimization methods can be used. In our model, we use the Singular Value Decompostion to estimate the transformation.

F. Algorithm

Algorithm 1 describes formally the five steps of the proposed method.

Algorithm 1: Coarse and Fine registration
Data: U, V : two clouds
Result: T and R :final Transformation
begin

1 Compute $CovU$ the covariance of U and $CovV$ the covariance of V :

$$CovU = \frac{1}{n}\sum_{i=1}^{n}(u_i - \bar{u})(u_i - \bar{u})^T$$

$$CovV = \frac{1}{m}\sum_{i=1}^{m}(v_i - \bar{v})(u_i - \bar{v})^T$$

2 Compute λ :eigenvalues of $CovU$
3 Compute eigenvectors:

$$EU = [E_{\lambda_1}; E_{\lambda_2}; E_{\lambda_3}]$$

4 Compute : eigenvalues of $CovV$
5 Compute eigenvectors:

$$EV = [E_{\gamma_1}; E_{\gamma_2}; E_{\gamma_3}]$$

6 Compute the plane normal N_u and N_v

$$N_u = E_{\lambda_1} \wedge E_{\lambda_2}$$
$$N_v = E_{\gamma_1} \wedge E_{\gamma_2}$$

7 Project Points onto planes
8 Compute the two convex hull
9 Match convex hull
10 Estimate Tansformation trans
11 Apply ICP for refinement using trans as initialization
end

Iii. Experimental Study

To evaluate the performance of the proposed algorithm, a set of experiments is designed based on real models acquired using 3D scanner device from 3D scanner repository [link, a]. The proposed method is compared to original ICP implemented in libICP [link, b], for non-rigid registration and applied to a large rotation, translation and normal case. The synthetic transformation is generated using the parameters selected randomly as follows: α, β, and γ over the range of [0,180], *tx*, *ty*, and *tz* over the range of $[0,10 * D]$, where *D* is the largest dimension of the object. The algorithm is implemented in C++ under Windows 7 using Visual Studio 2010. All the experiments are conducted on a relatively lowcost PC with 4 GB RAM and intel core i3.

The registration accuracy is evaluated by the standard deviation (stdv) error. This latter is computed as the sum average of the Euclidian distances of every corresponding point pair between the model and reference point clouds. The computation time is measured by milliseconds. A successful registration is defined as the registration having the stdv error closest to 0. To represent the experimental result in histogram, we use a semi-cologarithmic scale (i.e. the abscissa is unchanged and the ordinate is replaced by its cologarithm e.g. 10E03 is represented by 3 to represent the standard deviation in the histogram). Moreover, we use a semi logarithmic to represent the execution time. The algorithm having the highest

value in the histogram of accuracy (Precision) is the best one whereas the algorithm having the lowest value in the histogram of execution time is the best one.We applied our algorithm and the standard ICP algorithm on 50 clouds. Due to space limitation, we restrict to excerpts from the experimental results. We have chosen five clouds which are blade, nm, E, bunny and dragon. These latter may be considered as representative of the whole. We have to add that the used the blade benchmark for a detailed analysis.

A. Projection plane choice evaluation

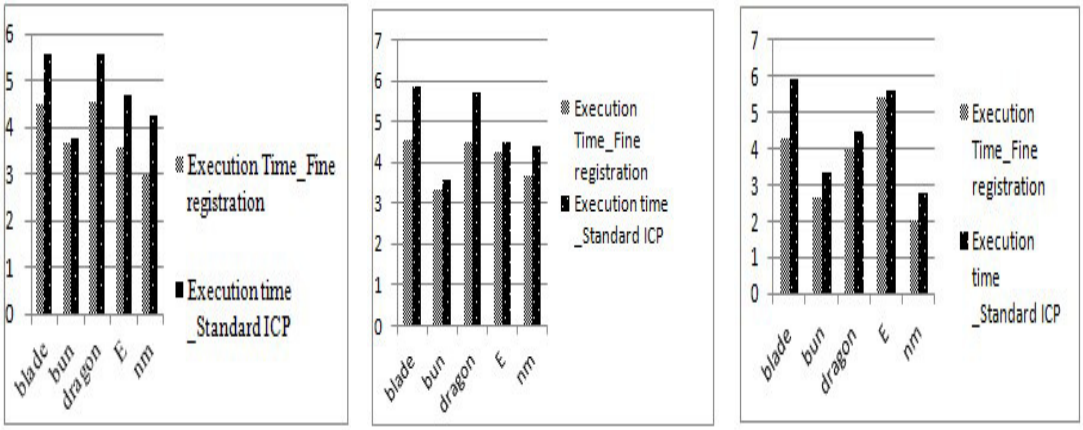
To evaluate the perfection for each projected plane choice, a mathematical score is computed for each projected plane. In fact, our algorithm uses the two first principal components (PC) determined by PCA method. Each PC is associated with a score value which is the eigenvalue. The similarity measure between the real shape and the shape projected onto plane is computed by the ratio between the sums of the two first eigenvalues and the sum of all eigenvalues (see eq. 5). If the ratio is equal to 1, we have the same shape in projection and in reality. The success of our approach returns to the fact that in most cases, we choose the best projection plane that represents the shape. Table 1 summarizes the obtained results. For bunny, blade and dragon, the ratio value is upper than 90%. The eigenvalue of the third component is in general very low. Thereafter, it has a negligible impact on the obtained transformation estimation.

$$(PC1 + PC2)/(PC1 + PC2 + PC3) \qquad (5)$$

Table 1: Principal components for five point clouds

Clouds	PC1	PC2	PC3	ratio
blade	0.913	0.0503	0.0363	96.37%
bun	0.632	0.307	0.0612	93.88%
dragon	0.639	0.294	0.0672	93.28%
E	0.474	0.31	0.216	78.38%
nm	0.5474	0.31	0.1426	85.74%

B. Computational time execution evaluation

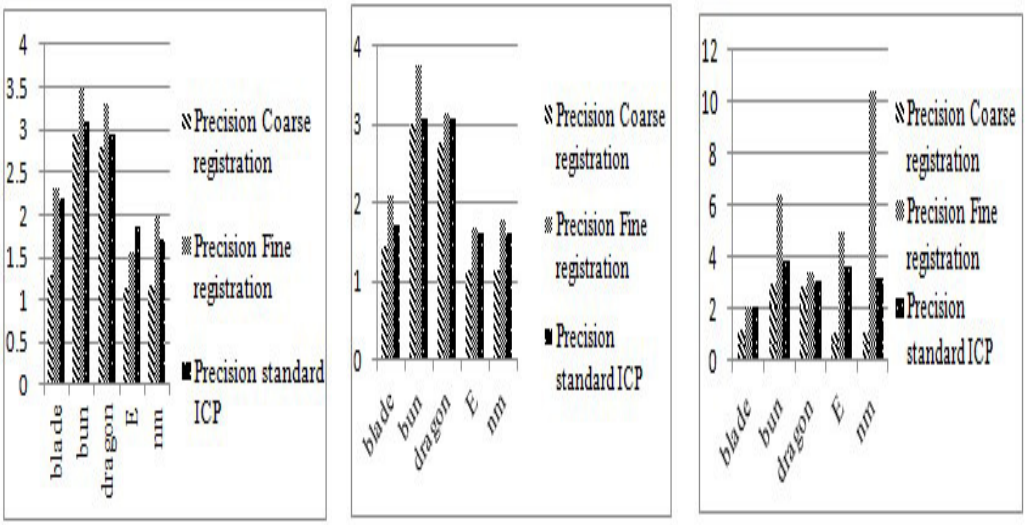


The execution time is very important for application in real time. For this reason, it is very important to accommodate this aspect. Fig. 3 shows the computational time of standard ICP and the proposed method applied on point clouds in the case of large translation, large rotation and in the normal case. It can be clearly seen that the proposed method requires less computational time than standard ICP in all cases. This returns to the fact that ICP searches iteratively the correspondences and updates the estimation in many iterations for a large amount of points. In contrast, the proposed method establishes a small set of point matches between the convex hulls of the two point clouds. Then, it estimates an initial transformation (see table 2). The latter is refined by ICP which iterates in fewer time to get a search result. Therefore, the proposed method exhibits higher computational efficiency and reduce the number of iterations. For the coarse registration, the execution time is very reduced to around 0.2 second for 400000 points. Table 2 gives an overview of the number of points and the execution time for the coarse registration (Computation time of the convex hull, projection points and computation of the PCA). The number of points used to compute the coarse registration is about 150 points for a blade shape (with 400000 points).

Table 2: Execution time of coarse registration(cr)

Clouds	Nb points	Nb points of CH	CR Execution time
blade	403624	155	281
bun	40256	46	30
dragon	79423	27	46
E	437645	84	328
nm	392941	102	345

C. Precision Evaluation



The point clouds registration is usually challenging due to a number of factors: large translation and large rotation. Hence, in this section, we investigate the convergence and robustness of the proposed method to these factors. Fig. 4 shows the precision comparison of coarse registration, fine registration and standard ICP applied to the point clouds subject to different transformations(large translation, large rotation and normal case). In most cases, fine registration gives the best precision. Thus, the proposed method is highly stable for the point clouds registration subject to random transformations with large translation, large rotations and in normal case. This proves that the proposed method is effective for the registration of point clouds in most cases.

(a) (b) (c)

Fig. 3: Execution time of Fine Registration and Standard ICP in (a)case of large translation, (b) large rotation and (c) normal case

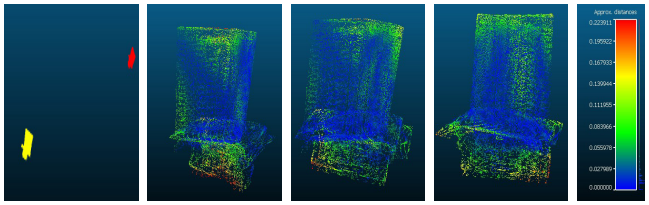


Fig. 5 shows the registration results of blade subject to large translation. The yellow blade in (a) is the model, whereas the red blade is the transformation of the model with the specified translation between 0 and 10*D. Fig. 6.b ,Fig. 6.c and Fig. 6.d show the mean error using coarse registration, fine registration

(a) (b) (c)

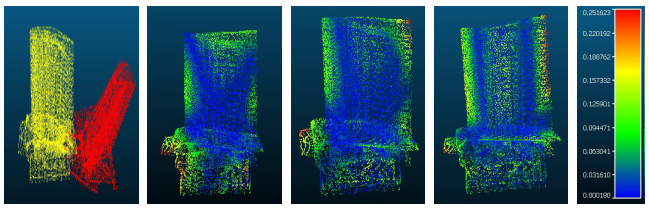

Fig. 4: Precision of Coarse Registration, Fine Registration and Standard ICP in (a)case of large translation, (b) large rotation and (c) normal case

and standard ICP, respectively. The points in blue show the mean error that is limited to zero. The errors increase as the point approaches to the red color. The mean registration errors of all the point matches in fine registration are between 0.001 and 0.027. For standard ICP, the number of blue points is approximately the same that green points. Thus, the proposed method is more stable for the data sets registration subject to random transformations with large translation. By comparing Fig. 6.b to Fig. 6.d, we remark that the error is nearly the same. Fig. 7 represents the registration results of blade subject to large rotation. It can be seen clearly that for fine registration, most points are colored in blue and the number of green and red points is greater in Fig. 6.d (standard ICP) than in Fig. 6.c (fine registration). In Fig. 7 which is the registration results of blade in the normal case, the blade is perfectly aligned (see Fig. 7.c) using fine registration. In order to have an overall view on the whole tests (in the 50 clouds), we give in Fig. 8 the number of times (in%) where fine registration gives the best precision among all tested point clouds. The obtained results are 89%, 95% and 82% in the cases of large translation, large rotation and normal case, respectively. We conclude that with the most point clouds, fine registration gives approximately 90% of the best results.

Iv. Conclusion

In this paper, a novel two-step 3D point cloud registration algorithm is proposed. In the first step, a coarse matching is performed to quickly detect the correspondences, giving thus an initial transformation. The latter is used by ICP point to point, in a second step, to refine the matching result and accurately find

the transformation. The proposed coarse registration step consists first in projecting the 3D clouds on convenient planes determined using PCA, second in computing the convex hulls (CHs) of the two projected clouds, and then in matching the obtained CHs which generally represent appropriately the cloud shapes.This new method is more accurate than standard ICP in most cases, especially when the transformation between clouds is large. Moreover, the time computation is very reduced thanks to the fact that the coarse registration is applied to a match smaller points number (convex hull points) than that of the original 3D cloud. The result of coarse registration is very close to that obtained using standard ICP, yet.

Two directions are subjects of future works. First, we plan to test similarity between edges of the convex Hull. To do this, we must test the length of edges and the boundary angles. Second, we aim at performing the step of noise elimination.

Abstract

This study aims at identifying Project Management (PM) techniques to increase productivity, quality, efficiency and customer satisfaction in telecommunication services in Lebanon. The study ranges from high-level approaches for improving project management techniques, to more detailed approaches for improving PM practices in the telecommunication industry. A set of questionnaires was conducted with the different quality and performance project managers at one of the leading telecommunication companies in Lebanon. The limitation of this study is that the set of recommendation may not be applicable for other companies. The results of this study can help telecommunication companies to improve their project management techniques for a specific project. It will help telecommunication business to have a leading edge over the competition by focusing on managing projects and adapt to changes more efficiently. This will result in improving service delivery and customer satisfaction. At the end, this will result in gaining market shares over competition and improve overall business conditions.

Keywords: project management, telecommunication management, network management, lean, Lebanon

Background to Research

A project is a temporary endeavor that has a definite beginning and end, that is carefully divided into several phases to give a unique output (Moder & Phillips, 1970). Projects are temporary that creates unique products (Cicmil, S., Williams, T., Thomas, J., & Hodgson, D, 2006) and are closed after attaining their objectives. Several million projects were developed and much more are planned according to ("PMI report", 2013). However, when projects are implemented in small to medium size companies, there is a clear lack of well-established project management methods (Ilincuta & Jergeas ,2003). This is often since small to large size companies lack the number of resources required so projects and resources might be given low prioritization in the organization (Rowe, 2007). The PMBOK (Project Management Book Of Knowledge) is viewed by such organization as complex and complicated to implement due to lack of budget in some cases and a low number of resource available. The objective of this research is to investigate the status of project management techniques used by telecommunication industry in Lebanon especially network implementation projects and evaluate different project management techniques (Klastorin, 2003) by providing a set of recommendations that can assist with implementing projects successfully.

Literature Review

Several research papers have been published on project management methods using different implementations approach. It is important that the project is delivered on time, within budget and with acceptable Quality of Service (QoS). Usually smaller teams are leaner and more efficient in terms of performance as discussed by (Terenghi, F., Kristensen, K., Cassina, J., & Terzi, S. 2014). In any telecommunication project management (Fazlović, S., dd Sarajevo, B. T., & Tuzla, R. D, 2012), timely delivery is important which requires telecommunication project managers to be highly skilled leaders with good communication skills across different teams that will lead to a successful project deployment. Project management methods look great on paper, but usually, fail when implemented due to different human-related factors. Usually, the human factor is not taken into consideration which will lead to failure like any economic factor (Brady, 2006). Research on project management was initially focused on adoption methods (Boehm, 2002; Nerur et al., 2005) and the use of having pair individuals for software development (Nawrocki and Wojciechowski, 2001; Williams et al., 2000). Later on, more research was focused on team dynamics (Moe et al., 2009) and the consequences of test-driven development (Erdogmus et al., 2005; Janzen and Saiedian, 2005) which includes adoption and post-adoption settings (B. Ramesh, L.A.N. Cao, K. Mohan, X.U., 2006).

Project Management Approaches

In project management methodologies (Kliem et al, 1997), there are several methodologies that we briefly discuss. The two most extreme approaches are the Waterfall and Agile project management methods, other methods are Kanban, Adaptive, Scrum and Lean.

The Kanban (Abdul-Nour, et al, 1998) focuses on minimizing the work in progress at any given moment because many activities are being performed at once which impacts the quality of each of them. Kanban also visualizes the work so each employee knows exactly what is needed and foresee issues before they start scaling.

In the adaptive methodology (Lévárdy, V., & Browning, T. R., 2009), the project scope is a variable and adjusted in order to get the maximum business value from the project within the given timeframe for the project.

The waterfall method (Hass, K. B., 2007), the requirement is that we need to complete each stage 100% before moving on to the next stage. For example, in network infrastructure deployment design, in the concept phase, we need to define what we want to make, and what all the features are. Also, we need to figure out the constraints, what are the budget, resources and time. In the design and concept phases, we make several assumptions that will be tested in the pre-production phase (Boehm, BW, 1988). When we get most of the features programmed, we go into the alpha phase. In the alpha phase, a small testing can be implemented to make sure some of the main features are working. Once we have all the features in, we go into the Beta phase in which we bring in more testers, then we go into the deployment phase. The issue with the waterfall model is that all the testing is done in the beta phase. It will be too late to change any design at this point in the beta release if we encounter a major issue during testing. Even if some testing is done in the alpha phase, the testing is still small and people involved in product testing is limited as compared to testing in the beta phase (Larman, C., & Basili, V. R., 2003). In many ways, the waterfall model is doomed to fail in production projects.

Project management (Duncan, W. R., 1996) consists of several phases such as planning, organizing, securing, motivating and controlling the resources to a successful product. This can define the "success" of a project. It may be hard to control a lot of things, but as a project manager (Rowe, SF, 2007), what can be done is to make some estimates and prediction plan accordingly and deal with them. It's basically predicting what needs to be done and how to do it. For a large customer project services releases, it's hard to manage to come out with a product on time, many projects come out late, over budget and maybe under delivering the shiny things that were originally mentioned and planned for. For example, in software games, they usually come out late as compared to what was planned for a release production date.

The mission of any telecommunication company is to increase its market share by anticipating market's needs and providing the best telecommunication service (Engwall, M., & Jerbrant, A., 2003). First, it is necessary to establish a product strategy that planned product will satisfy the market demand. The product plan should ensure customer need and satisfaction with both desirable and acceptable behavior. If no consumption is envisaged, there is no point in proceeding with product design. The demand for the service (4G and later the 5G internet) in the market may already exist (Adachi, F.,2001), and its volume can then be assessed by consumer research and sales figures for identical or similar commodities. In practice, the organization marketing department works by focusing on the product design while compromising between infinite variety on one side and the designer's concept of ideal design on another side. The strategy of the organization as represented by the Commercial and Marketing department focus on one main objective of advertising to expand the market (Moorman, C., Zaltman, G., & Deshpande, R.,1992). Expanding the market is normally achieved by:

- Providing general information about the existence of the product or service
- Providing technical information about its functional characteristics or utilitarian purposes
- Drawing the customer's attention to those attributes of the product that best suits them
- Winning undecided customers by exhibiting possible attractions to persuade their preference to the product in comparison with competitors
- Creating demand among a passive population of customers
- Educating customers by spreading the message of what they need
- Focusing on continuous product development and innovative designs

Lean development methods (Karim, A., & Nekoufar, S., 2011, Stevenson, W. J., & Hojati, M., 2007) focuses on delivering more value with less waste in the project environment. The focus on empowering people and creates an environment of self-accountability. It relies more on process compared to other methodologies especially in standardization and work breakdown structure, which helps streamline team workloads.

Lean project management focuses on delivering value to customers. Lean was originated by the book "The Machine That Changed the World" by MIT (James Womack, 2007). Two of the authors (James P. Womack, Daniel T. Jones) went on writing another book called "Lean Thinking", in which they emphasized that Lean thinking can be used by and implemented in any organization. Lean project management consists of five main points:

- Value Definition
- Identify and Map the Value Stream

- Control flow while eliminating waste
- Response to customer pull
- Perceive Perfection

The trend continues the moves toward the convergence of information content, delivery, and entertainment. This requires significant capital investment, cost-cutting initiatives, partnering with innovative solution providers for creating and delivering contents. In addition to building long-lasting loyalty through effective customer service interrupted into superior value to the end consumers. Telecommunication companies that can manage this effectively and intelligently will not just compete but out-compete. The popular misconception about Lean (Ballard, G., & Howell, G., 2003) is that it is suited only for manufacturing. It is not a tactic or a cost reduction program, but a way of thinking and acting for an entire organization. The word transformation or lean transformation is often used to characterize a company moving from an old way of thinking (Waterfall project management approach) to a lean thinking. It requires a complete transformation on how a company conducts business. This takes a long-term perspective and perseverance. The term "lean" was coined to describe Toyota's business during the late 1980s by a research team headed by Jim Womack, Ph.D. (James Womack, Lean Enterprise Institute), at MIT's International Motor Vehicle Program. The characteristics of a lean organization and supply chain are described in *Lean Thinking*, by Womack and Dan Jones, founders of the Lean Enterprise Institute and the Lean Enterprise Academy (UK), respectively. While there are many very good books about lean techniques, Lean Thinking remains one of the best resources for understanding "what is lean" because it describes the thought process, the key principles that must guide actions when applying lean techniques and tools (Cicmil, S., et al , 2006). Even in the most structured organizations, many workplace processes are chaotic and disorganized. This is an opportunity for process improvement using lean principles. Eventually, cost savings are realized due to efficient processes and workflows leading to profitable business results. Implementing lean process improvement can become quite detailed. However, the basic principles (Karim, A., & Nekoufar, S., 2011) are simple and straightforward:

1. Focus on customer values: Ultimately, what all customers want is value. Value creation occurs when the quality of services received is perceived as high compared to their cost. What does the customer want and how to provide it better, faster, and cheaper? The type of network hardware required to achieve high customer satisfaction with minimum cost.

2. Figure out how the work gets done in a given period of time: There is a lot of assumptions about how work get done that don't mirror exactly what happens. After all, during the daily grind, the company doesn't think about how the work is done, given that they often do it.

3. Remove inefficiencies and waste: waste is defined by anything the customers are not willing to pay for and anything that doesn't add up to customer values (Ronald Mascitelli, 2012). Once it is known what the workflow looks like, take a second look at any step in the process that doesn't directly create value for customers. Manage, improve, and smooth the process flow to eliminate non-valued-added activity.

4. Track numbers and manage by evidence: Sometimes we need to examine the processes, collect data on how well it is working, highlight and eliminate errors, and seek continuous improvements in value.

5. Empower the people operating the process: The best person to improve a process is the person who carries out the process. Utilize employee's full skill sets by doing more. If the process is improved, employees will likely have time to take on a higher level of work.

6. Improve in a systematic way: The process is not perfect and it won't last forever without changes. Changes will occur in any process. Being able to replicate the steps of process improvements is the key to delivering long-term and sustained value.

It's clear that Lean approach emerges due to limited resources, time and capital investment. Using the Lean method approach which is implemented for network infrastructure deployment focuses on building customer values, eliminate waste, integrity, build a learning experience, localize responsibility, delay commitment, and deliver fast and optimized products.

Project Management in Telecommunication Network

Project Management (Meredith J.R. and Mantel S.J.Jr., 1995) has been used for many years before it became a profession to be taught in universities. For example, a construction project in middle centuries was oriented around project management skills. Building the pyramids in Egypt was also organized and synchronized in a way like implementing project management skills nowadays. Large engineering projects (Cicmil, S, 2006) introduced to project management to enable the start and completion of any project within expected time frame and expected deliverables. One of the most popular tools introduce in project management for engineering project was the Gantt chart which was introduced by Henry Gantt in 1910. His argument was people were more focused on execution and making quick profits instead of focusing on the production of end goods. More tools were developed later such as the Performance Evaluation and Review Technique (PERT, found in most GUI-based PM software) tool and Critical Path Method (CPM) (Fondahl, John W., 1961) where it shows the start and end of the project with different tasks and sub-tasks involved. The PERT chart is used to draw all activities involved in the project and their sequence. A PERT chart is only as good as the assumptions inherent in the critical path represented on the chart. PERT is closer to a lean approach (Sutherland, J., 2001). Each task must have a weight such as duration of each task as shown in Figure 1.

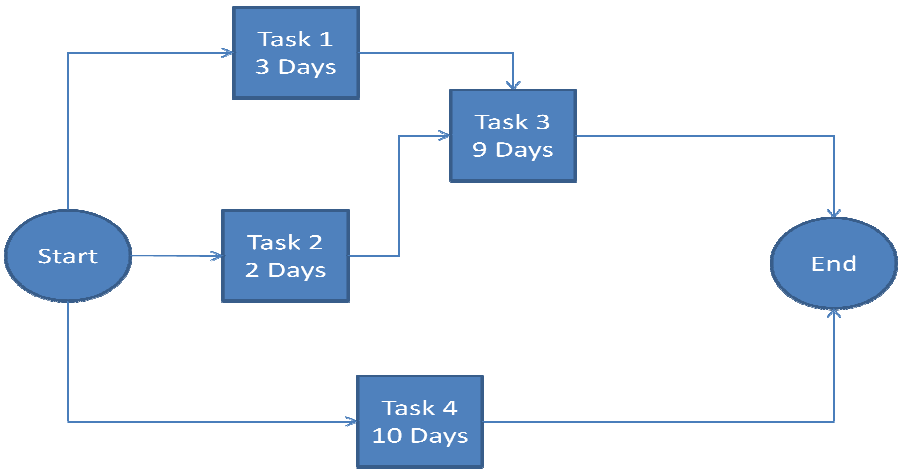

Figure 1: PERT Chart Example

Any project has a specific beginning and ending time frame. Telecommunication project (Sherif, Mostafa Hashem, 2009) consists of three categories, the first category is the business part which is the objectives and deliverables being generated for the project, the second is the Product and Service part and the third is the project management deliverables. Telecommunication project consists of different software and hardware components such as firmware, website, content, databases, underline infrastructure (routers, switches, bridges, and cables). Also, it requires network infrastructure (wireless and wired), security and storage and disaster recovery as shown in Figure 2.

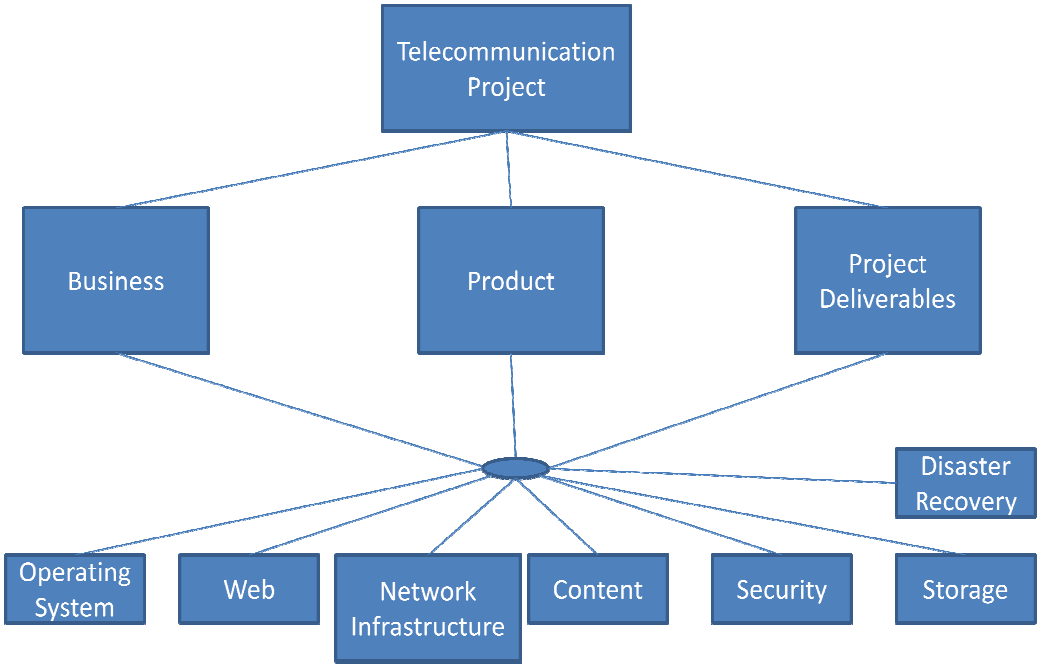

Figure 2: Typical Telecommunication Project Components

Each of these components is a project by itself. Project management, in general, is the aspect of applying good practices in any telecommunication project (Alfred Sankara, 2010). If requires the understanding of different essential elements such as leadership role for the project manager, project planning, control and risk management. The telecommunication project manager is required to balance between getting the maximum performance possible versus an acceptable reality performance metric. There are several requirements to start with telecommunication project; the first step is to acquire all information needed about the project requirement. The implementation part of telecommunication project requires the knowledge of what is the project, who will get affected in terms of the number of users, time frame requirements to complete the project and the hours of operations for people involved in implementing the project as well as hours of operations for users who are impacted by this change. Next step is to figure out who will be part of the project team.

In any telecommunication project (Alfred Sankara, 2010); there are common issues that must be addressed. The number of suppliers, partners, and vendors for hardware and software components is a common issue. Each supplier has his own expectation, constraints, and assumptions. This should be included in the overall project plan. In telecommunication, the change in software requirement is more dynamic and frequent, so changes in software versions.

Telecommunications in Lebanon

In June 1994, the Lebanese government launched an international public auction for a tender of two contracts knows as Build Operate and Transfer (BoT) contracts signed with France Telecom and Telecom Finland to develop the mobile network industry. In August 2002, the Lebanese government terminated the BoT contracts before the expiration date and transferred the network owner to its custody. In June 2004, the Minister of Telecommunications (MoT) awarded two new management agreements for operating the two networks. On the expiration of the agreements, the Lebanese Ministry of Telecommunications signed in January 2009 another two new management contracts between Orascom Telecom Holding S.A.E. and Mobile Telecommunications Company KSC. The Lebanese government owns the current two mobile telecommunication networks with outsourcing management agreements. A monthly variable management fees as stated in contracts represent the share in return to management operations for both contracts.

Telecommunication in Lebanon (Telecom in Lebanon- Fact book, 2015) has been driven by massive investments (estimated $500 Million in 2016) due to the increasing demand in mobility and number of mobile subscribers in the past several years. The objective of both major mobile network companies in Lebanon Touch and Alpha as well as OGERO is to make fiber optics as well as 5G available throughout the country by 2020 (Telecom in Lebanon- Fact book, 2015).

Project Management for the Telecommunication Industry in Lebanon

The process of change in the telecommunication industry in Lebanon and abroad is difficult to implement given the data and voice downtown associated with any change during the production phase. Even in the pre-production phase, any change will have a negative impact on service delivery date to customers and stakeholders. Project manager's plan is to avoid any disruption to business operations or delays in scheduled to release a product. There is a history of project delays for all telecommunication providers in Lebanon in which these providers failed several times to deliver competently and on time seems to be in worst shape in recent memory. One of the most factors contributing to not being able to deliver on time is the industry high pace of change. One factor contributing to this is the high turnover rate which leads to inadequately trained sales and technical people who lead to poorly delivered projects that will require time extensions to bring the project up to expectations.

Research Method

There are two main research requirements that need to be addressed in the method. First, we need to determine the population covered for people using and affected by network deployment. Second the interview questions and the type of people we are going to interview. For the first requirement, we covered about 50% of the telecommunication population in Lebanon given that there are only two telecommunication companies operating. Second, we decided to interview with several people (employees and managers) from the quality and performance department that can provide meaningful data for this research.

Results and Analysis

In this section, we discuss and analyze the results of two major types for project management, the Lean project management for network deployment. During the initial phase of this research, we found it beneficial to investigate the environment from more than one point of view. The interview was focused on understanding existing methods using in project management for different products and how do they adapt to any change whether demand or technological changes. The focus of this section is to investigate the primary research question:

> *What is your approach for schedule development and project management methodology used for network infrastructure deployment and service projects?*

To investigate this question properly, a comprehensive understanding of the company's different network infrastructure and service products need to be undertaken. This is an important step because the work will not be a repetition of work that has already been conducted and completed and to ensure the discussion is oriented around this key question.

This gave a rise to another key research question:

> *How are the changes in the market place incorporated in the company's products and features?*

This will give an idea which PM approach they use when the changes in market place (4G and 5G) additional to changes in customer service packages (i.e. student, family, lawyer's plans) are currently being adapted by the company.

The objective of this research is to identify the underlying principles and components that make up project management for telecommunication industry in Lebanon. This consists of Research and Development (R&D) activities and methods, PM methods and related discipline (Burke, R., 2013), and the importance to an application to R&D projects such as measurements, risk management and facilitating creative team activities. The 4G LTE rollout requires certain hardware enabling with carrier aggregation. This also requires transmission, antennas, routers, and power. Like any software and hardware products, it also requires tools upgrades for hardware and software. The company installed and enabled several new 3G sites including transmission, power, and antennas. This requires software and hardware licenses upgrade. Network infrastructure enhancement includes the Point-of-Service (PS) core upgrade. This also includes capacity and licenses, hardware upgrades licenses for new PS, software upgrade, features for commercial products. Core optimization requires improved redundancy, reduce utilization and enhance user experience.

In the year 2018, public safety 4G/5G LTE technology will reach the mainstream markets as trials and deployments gain momentum across the world. This expectation is based on the latest global market study by ABI Research (ABI Research 2016 Report). Hardware revenue is expected to grow by 30% annually reaching $540 million in 2025.The United States, UK, and South Korea markets will host the world's first three operational public safety LTE wireless networks by the end of 2017 or early 2018. The 5G infrastructure research and development targets lower latency far than 4G equipment and it also targets lower battery consumption for better implementation, but there is currently no standard for 5G

deployments. However, the Next Generation Mobile Networks Alliance (Alliance 5G Network Report, 2017) defines the following requirements that a 5G infrastructure standard should fulfill:

- Data rates of tens of megabits per second for tens of thousands of users
- Data rates of 100 megabits per second for metropolitan areas
- 1 Gbit per second simultaneously to many workers on the same office floor
- Several hundreds of thousands of simultaneous connections for wireless sensors
- Spectral efficiency significantly enhanced compared to 4G
- Coverage improved
- Signaling efficiency enhanced
- Latency reduced significantly compared to LTE

Recommendations for Network Deployment

The Next Generation Mobile Networks Alliance says that 5G should be rolled out by 2018 to meet business and consumer demands. In addition to providing speedy connection, researchers predict that 5G networks will cater for new use cases such as the Internet of Things (internet connected devices), as well as broadcast-like services and lifeline communication in times of natural disaster. Carriers, chipmakers, Original Requirement Manufacture (OEMs) and OSATs such as Advanced Semiconductor Engineering (ASE) and Amkor Technology Inc. are simultaneously preparing for the next-generation (5G) wireless standard. The network structure requires mobile systems and base stations with innovative and faster application processors, basebands and RF devices. Although updated standards that define capabilities beyond those defined in the current 4G standards are under consideration, those new capabilities have been grouped under the current ITU-T 4G standards. The U.S. Federal Communications Commission (FCC) approved the spectrum for 5G (Julius Knapp, 2016), including the 28 Gigahertz, 37 GHz and 39 GHz bands, on July 14, 2016, for vertical Industries:

- Connected Car
- Connected Robotics
- Connected Drone
- Mobile VR/AR
- Smart Manufacture
- Smart Home

The company is highly recommended to start preparing tender requirements for optimization of 5G network and expansion plan with the widest coverage across Lebanese territories. The company will bring together a coherent plan that effectively utilizes materials, capacity, resources, and knowledge available in the production facility. The project management study for the implementation of the 5G Network across all Lebanon shall maintain fast Internet to increase the profitability of the company. The company's project management system work must be well scheduled and controlled to produce the desired services.

Conclusion

In different telecommunication companies in Lebanon, lean project management methods are implemented for almost all types of projects, software, hardware, and services. However, when service projects are implemented in the telecommunication environment, these organizations often lack the rapid change in the service market due to different customer needs and competition. In this paper, we attempt to demonstrate that network infrastructure deployment project management can be conducted using the lean system approach which seems to be a fit for the network infrastructure deployment. In tough economic situation like in Lebanon where most companies are required to achieve great results with fewer resources, a lean project management approach can assist with reduction in expenses and project failures.

Abstract

The main objective of this study is to examine the microfinance services that improve the socio-economic welfare of urban households in Malaysia. We distribute questionnaires to 400 respondents across three different urban geographic areas in Malaysia in order to collect the relevant data for this study. Stratified random sampling is employed in the process of collecting the data. The results show that most of the services provided by the microfinance institutions including microcredit, micro insurance, training and social intermediation services have assisted the urban households to earn more income and enhance their socio-economic welfare. The recommendation of this study is detailed in the body of the paper.

Keywords: Microfinance; Socio-Economic Welfare; Financial Services; Non-Financial Services

Introduction

Malaysia is a middle-income country and covers two main regions: Peninsular Malaysia and East Malaysia (states of Sabah and Sarawak). The government of Malaysia embraced export-oriented industrialisation model in developing the country since the year 1970. The model, which emphasised on the manufacturing sector and has also successfully transformed the Malaysia's economy into an export-oriented one (Ministry of Finance, 2007). The government of Malaysia has set a long-term goal of becoming a developed nation by the year 2020. Thus, the government of Malaysia has formulated several policies and strategies to support the nation's economic growth. Those core policies are – New Economic Policy (1970), National Development Policy (1991), Vision 2020 (1991), National Economic Recovery Plan (1998), and Malaysia Plan (1971-2020). A special group of households namely B40 households was introduced by the Eleventh Malaysia Plan (2016-2020). B40 households represent the bottom 40 group with an estimated 11.7 million memberships or 40% of the population in Malaysia that live with a household income of up to RM 3,855 per month (Economic Planning Unit, 2015).

The economic development is essential to accomplish more equal income distribution among the different sections of the society. Nevertheless, there are still considerable concerns on the issue of income distribution in

Malaysia. The Department of Statistics Malaysia (2015) highlighted the general economic instability and the increasing gap between the rich and the poor. Inequality specifically poses a real challenge for Malaysia. The World Bank (2015) shows the income growth especially for the top 20% of Malaysian income earners has been strong for many years. However, the B40 of households has encountered the slowest income growth. According to Economic Planning Unit (2015), the top 20 urban households accounted for 45.9% of the total income, while the bottom 40 urban households accounted for only 17.1%.

Bank Negara Malaysia (2013) revealed that savings among the lower income households were insufficient due to lack of planning and saving for their post-retirement expenses. The B40 households are affected by high indebtedness as most of them always applied for personal loans to support their daily expenses. The people who earned RM 3,000 or below have debts that are about 700% of their earnings in 2013 (Bank Negara Malaysia, 2013). Moreover, B40 households face the issue of increment in living cost. It was reported that the B40 experienced 10.1% annual increase in the cost of living between 2009 and 2014 (Economic Planning Unit, 2015). The rising cost of living in urban areas is usually caused by the fact that they need to spend more on their daily consumption such as food, transportation and housing. The implementation of Goods and Services Tax (GST) throughout Malaysia has increased living costs in the country, especially on those who live in urban cities. Urban households need more income than rural households to stay away from poverty. In addition, they also need more resources to access basic amenities, healthcare, childcare and children's education. In particular, house rental in the urban areas account for half of the monthly salary earned by the poor urban households (Kaur, 2016).

Despite the implementation of many policies and programs by the Malaysia government to assist low income households, poverty is still visible in urban areas. Enhancing the socio-economic welfare among low income households requires microfinance services. Microfinance has been a part of poverty alleviation plans in helping the poor who usually would be disqualified from the mainstream credit sector. There are many poor households everywhere in the world which are already getting benefits and financial services from microfinance institutions (Morduch and Haley, 2002). Microfinance services are considered to be part of the tools in alleviating poverty in Malaysia. There are a total of three leading organisations working towards poverty alleviation, namely: (i) Amanah Ikthiar Malaysia (AIM); (ii) Yayasan Usaha Maju (YUM); (iii) Tabung Ekonomi Kumpulan Usahawan National (TEKUN, or The Economic Fund for National Entrepreneurs Group).

The first institution in Malaysia that provides micro finance services is Amanah Ikthiar Malaysia (AIM). AIM which was established in 17 September 1987 mainly emphasises on the provisions of loans to the poor in order to develop their business. AIM implements the Grameen Bank framework where the main objectives are to provide financing, guidance and training to the poor. AIM and YUM are institutions which only give loans to those people who are at or below the country's poverty line compared to TEKUN which does not only cover poor but also those above poverty line. AIM provides three types of economic loans for income-generating activities, namely: I-Mesra; I-Srikandi; and I-Wibawa. In addition, the organization provides: a recovery loan (I-Penyayang); an education loan (I-Bistari); and a housing/multipurpose loan (I-Sejahtera). The implementation of this program is based on the idea of 'trust' to monitor all members. AIM monitors the members, who are expected to attend weekly meeting organised by the institution. The meeting has promoted the capability of the participants to pay back the loans as the default rate was only 0.92% in year 2009. AIM provides free interest credits to the borrowers, which form themselves into groups of five and sequentially pledges against each other loans, in line with the model of the Grameen Bank. The total members of AIM as at April 2016 were 382,178 in Malaysia (Amanah Ikthiar Malaysia, 2016). AIM was chosen in this study to measure the effect of microfinance services in enhancing the socio-economic welfare among vulnerable households in urban Peninsular Malaysia because of its wide coverage.

The main objective of this study is to identify the effect of microfinance services on the socio-economic welfare of urban vulnerable households in Malaysia. There are total of five microfinance services provided by the microfinance institution, AIM which is microcredit, micro insurance, savings, training and social intermediation service. Likewise, this study would like to detect which microfinance services have the effect on socio-economic welfare on urban vulnerable households. Hence, there are two academic contributions in this study. Firstly, majority of the previous study only focus the socio-economic welfare on rural households.

Secondly, as income is part of the sources in enhancing households' socio-economic welfare. Also, it is evidenced that there is no previous research using income as mediating variable in their study. Thus, the focus of this paper is to investigate the how well the microfinance services effect on socio-economic welfare among urban vulnerable households in Malaysia and also using income as mediator in this study.

The following part of this paper is organised into few sections. First, this paper reviews the extant from previous literatures and discusses the relationship among independent, dependent and mediating variables. The empirical approach is presented next, followed by results and bootstrapping tests. Finally, this paper concludes by discussing the implications of the findings and acknowledging the limitations of this study

Literature Review

This section covers the empirical evidence on the linkage between microfinance services, income and socio-economic welfare in literature. Socio-economic welfare is defined as a condition whereby a person or groups is doing well or somewhat emphasises on a person's wellbeing or good (Frijerts and Van Prag, 1999). The low income households are likely to have low purchasing power, low expenditure, and low quality of life. Thus, there is a need for special assistance in improving the welfare of the low income households. Microfinance programs are the potential platforms in enhancing the socio-economic welfare in society. Microfinance services play a vital platform in alleviating poverty, eradicating poverty and creating wealth among poor people. These are among the objectives established by several microfinance institutions. The positive impact of microfinance services on poverty had been highlighted by Alam (1988). The financial services provided by the microfinance programs were crucial input to enhance productivity at household level. However, it has been claimed that the microfinance services had the ability to improve income levels and enhance employment of household members (Okurut et al. 2004). Also, Mahjabeen (2008) stated that microfinance institutions enhanced income and consumption stream of the households, lessened income imbalanced and welfare improvement. According to Mwewa (2013) and Mungai (2015), microfinance services could assist the poor in the creation of jobs because it provided the necessary capital for small scale enterprises.

There are studies that have considered the impacts of microfinance services on socio-economic welfare. One of the services that have been the focal point in the literature is microcredit. For instance, Wahid (1994) had stated that credit services were the crucial sources for the poor in assisting them to increase their capital in improving their standards of living through income investments. It was also agreed that credit is an essential tool in assisting borrowers from avoiding the poverty trap (Hermes et al. 2011; Mwangi, 2015; Owuor 2015). The credit from microfinance programs also assisted poor households to overcome their liquidity issue and fund investments in agriculture, trades and business, increase income, construct and improve employment among households. Microfinance services are effective developmental tools in poverty reduction, income distribution and achievement of millennium development goals. Salia (2014) analysed the effects of microcredit schemes on welfare in Tanzania, Africa. The findings revealed that participation in microcredit schemes could lead to poverty eradication among women clients and also financed children's education and health services.

Besides, Kireti and Sakwa, (2014) demonstrated that microcredit provided more income stream for the poor and liberated them from poverty circumstances. Microcredit improves the welfare of low income households as they lead to creation of jobs and generation income as well as increase in the household assets (Mokhtar, 2011; Nawai and Shariff, 2011; Hamdan and Hussin, 2012).

Few studies have also considered the role of micro insurance including Beattie (2000) that argued that micro insurance is a social protection tool, which assisted low income households in escaping from poverty circumstances. Besides, Matul (2005) also stated that the affordability to own insurance for low income households was not only linked to their income but also to the appropriate supervision of their financial sources which had a significant impact on their access to micro insurance. Similarly, Collins et al. (2009) also mentioned that micro insurance was gradually acknowledged to be similarly significant to microcredit as low income households must ensure a smooth flow of their daily cash and control their daily consumption in improving their future economic plan. Therefore, micro insurance is regarded as a powerful tool for low income households in enhancing their welfare.

Savings (micro savings) is increasingly recognised as equally important to microcredit because low income households must balance their cash flows in smoothening their daily consumption and future economic plan (Collins et al. 2009). Brannen (2010) conducted a study on the impact of micro savings on the welfare of the poor. The results showed that micro savings improved the welfare of the poor in Tanzania. Besides, Babajide et al. (2015) studied the influence of innovative micro savings service on welfare and business enterprise progress among low-income earners in Nigeria. The findings revealed that savings has a significant impact on welfare and also micro savings leads to poverty alleviation among low income households.

Training has also been considered in the literature. For instance, Hamdan and Hussin (2012) stated that the incorporation of entrepreneurial trainings had been considered as a powerful tool that can improve micro and small enterprises in South Africa and Malaysia. Previous studies also agreed with the fact that specific skills, and training will assist most of the recipients of microfinance in overcoming different obstacles (Karnani, 2007; Paul, Nyaga and Karoki, 2013). For instance, Saad (2010) conducted a survey of 1,800 members from AIM which were from the rural states of Kelantan and Perak only. The findings indicated that microcredit and training activities from AIM lessens poverty, develops the education level of their children and enhances the health status of its members. However, the study only focused on rural states in Malaysia and did not cover the urban states or entire nation of Malaysia. Furthermore, Al-Shami et al. (2014) consented to the point that AIM delivered a variety of training activities in enhancing their customer's talent to explore new income-generating activities, choosing suitable income-generating activities and enhancing their money management skills.

The perception of group lending from microfinance is a pressing need nowadays in supporting the poor to find jobs and increase their standard of living. The group lending assist the poor to access microfinance services to better off their expenditure, gain access to market information and boost the activities of entrepreneurship (Attanasio et al. 2011). The loan from social intermediation service could generate more income to lenders compared to the individual liability (Al-Shami, 2014). The study of Kireti and Sakwa (2014) examined the socioeconomic effects associated with the participation of women in the microfinance programs in Kenya. The findings revealed that the non-financial service of social intermediation service was able to smooth their income level and improve their socioeconomic welfare.

From the literature review, it is observed that a gap existed as most of the previous papers focus on the impact of microfinance institutions on the rural poor. Hence, it finds that income can also be part of the essential element for the research framework. This can be evidenced from the experts' feedbacks as the variable income can add value to academic contribution. Moreover, there is none of the previous study using income as mediating variable in such a related study. Hence, the variable of income was introduced as a mediating variable to the research framework. The study wants to detect the existence of income between microfinance services and socio-economic welfare came to be effective or not.

Methodology

The target respondents of this study are the household recipient of AIM's services in Penang, Kuala Lumpur and Johor Bahru. According to report from Department Statistics Malaysia (2010), Penang, Kuala Lumpur and Johor Bahru are considered as the 0top three urbanised states in Malaysia. Hence, total 400 respondents are equally selected from these three different geographic areas in Peninsular Malaysia. Primary data collection approach is used in this study. The data was collected via well-designed questionnaires in selected study areas. The approach of survey questionnaires was applied in this study as this approach provided an efficient way in collecting data. Patten (2016) indicated that the construction of questionnaire is superior to interview method because using questionnaire enables the researcher to collect data from several respondents simultaneously. Many of the previous studies such as Nawai (2011), Omar et al. (2012), Al Mamum et al. (2014) and others also used the survey questionnaire approach for data collection.

The stratified random sampling approach was used in this study. This is similar to the study of Al-Mamun (2012). Questionnaires were distributed to microfinance recipients. Furthermore, those qualified respondents from microfinance would be gathered by the administrators at the centers correspondingly. Questionnaires were then distributed to each respondent. They were given sufficient time to answer the questionnaire. Statistical Package for Social Science (SPSS) was used to measure the descriptive analysis

while structural equation modeling (SEM), Partial Least Squares in SmartPLS 3.0 was used to determine the path correlation between the variables. Figure 3.1 shows the research framework.

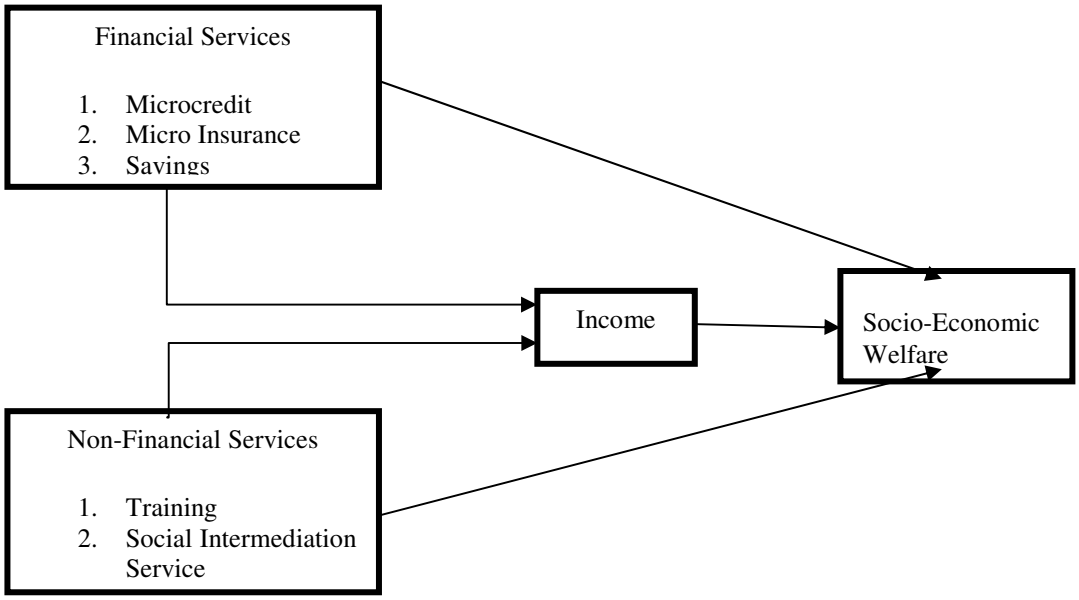

Figure 1: Research Framework

Data Analysis

The results in Table 1 reveal that about 75% of the respondents are between the age of 26 and 50 years. This indicates that majority of these household receivers' category are in need of the financial assistance. Nevertheless, only 2.4% of the respondents associating to the age group 61 and above were recorded. The percentage in age group 25 or below and 51 – 60 years are 5.3% and 17.8%.

Table 1: Distribution of Respondents by Age Group

Age Group	Frequency (N)	Percentage (%)
25 or below	21	5.3
26 - 35	84	21.0
36 - 50	214	53.5
51 – 60	71	17.8
61 and above	10	2.4

The results in Table 2 implies that almost two third of the total respondents have achieved secondary education and below as at the time of this study. This is followed by vocational and college diploma with 15.3% and primary education at 6.3%. The rest of the respondents with bachelor degree and above are up to 4.4% only.

Table 2: Distribution of Respondents by Education

Education	Frequency (N)	Percentage (%)
Primary Education	25	6.3
Secondary Education	296	74.0
Vocational / College Diploma	61	15.3
Bachelor's and above	18	4.4

Table 3 shows that majority (about 80%) of the respondents are self-employed while those that are unemployed and labourer are 7.5% and 13.3% respectively. For the terms of marital status, almost 84% of the respondents were married at the time of study. Only 6.0% are single while divorced and widowed are 3.8% and 6.2% respectively.

Table 3: Distribution of Respondents by Employment Status

Employment	Frequency (N)	Percentage (%)
Unemployed	30	7.5
Labourer	53	13.3
Self-employed	317	79.2

The results in Table 4 indicate that almost 85% of the respondents earn an income between RM 1,500 to RM 6,000. Only 10.8% of the respondents have earned less than RM 1,500 while 3.3% of the respondents earned between RM 6,000 to RM 10,000 during collection period. This is followed by those respondents with income of more than RM 10,000 with only 0.7%.

Table 4: Household Current Gross Monthly Income of the Respondents

Household Current Gross Monthly Income	Frequency (N)	Percentage (%)
Less than RM 1,500	43	10.8
RM 1,500 to < RM 2,500	120	30.0
RM 2,500 to < RM 4,000	157	39.2
RM 4,000 to < RM 6,000	64	16.0
RM 6,000 to < RM 10,000	13	3.3
More than RM 10,000	3	0.7

(a) Measurement Model

SmartPLS 3.0 was used to determine the measurement model of this study. The composite reliability and internal consistency assessed the reliability of construct measurement. The reliability of each construct was evaluated by the composite reliability with the cutoff value of 0.7 (Fornell and Larcker, 1981; Hair et al. 2016). On the other hand, the convergent validity was tested by Average Variance Extracted (AVE) with the recommended cutoff value of 0.5 and also each item loadings with the recommended cutoff value of more than 0.7 (Fornell and Larcker, 1981; Hair et al. 2016). This indicates adequate convergent validity as all items fulfill the requirements. Table 5 shows the results for items loading, average variance extracted (AVE)

and construct composite reliability (CR) on this study. The results reveal that all constructs' items loading, reliability and AVE are above the recommended levels.

Table 5: Items Loading, Average Variance Extracted (AVE) and Composite Reliability (CR)

Constructs	Measurement Items	Items Loading	AVE	Composite Reliability
Welfare	W2	0.724	0.560	0.836
	W3	0.732		
	W4	0.754		
	W5	0.783		
Microcredit	MC1	0.797	0.640	0.842
	MC2	0.848		
	MC3	0.754		
Micro insurance	MI2	0.726	0.551	0.830
	MI3	0.771		
	MI4	0.721		
	MI5	0.749		
Social Intermediation Service	SIS1	0.758	0.540	0.824
	SIS2	0.718		
	SIS3	0.739		
	SIS5	0.723		
Savings	SV2	0.729	0.566	0.839
	SV3	0.764		
	SV4	0.791		
	SV5	0.723		
Training	TR3	0.785	0.621	0.831
	TR4	0.794		
	TR5	0.785		
Income	IC3	0.779	0.628	0.835
	IC4	0.786		
	IC5	0.812		

Discriminate validity is a test to ensure that the value of AVE at least must be above the threshold value of 0.50 and the square root of the AVE also should higher than all other cross correlations (Fornell and Larcker, 1981; Chin, 1998; Chin 2010). Table 6 depicted the diagonal values (bold) are greater than the corresponding correlation values for each rows and columns. Thus, the discriminate validity was assured.

Table 6: Discriminant Validity Analysis

No.	Variables	Income	Microcredit	Micro insurance	Savings	Social Intermediation Service	Training	Welfare
1.	Income	**0.792**						
2.	Microcredit	0.517	**0.800**					
3.	Micro insurance	0.517	0.584	**0.742**				
4.	Savings	0.439	0.484	0.533	**0.752**			
5.	Social Intermediation Service	0.541	0.515	0.515	0.529	**0.735**		
6.	Training	0.457	0.405	0.445	0.507	0.501	**0.788**	
7.	Welfare	0.428	0.603	0.608	0.591	0.592	0.479	**0.749**
Diagonals (in bold) represent the squared root of Average Variance Extracted (AVE) while other entries represent correlations.								

(b) Structural Model

The structural model stipulates the information about the coefficients of sizes (R^2), predictive relevance (Q^2) and path coefficients of all variables. The results of Table 7 reveal that R^2 for dependent variable (welfare) and mediating variable (income) are 0.558 and 0.368, respectively. Hence, the research explained 55.8% of total variance of all predictors to welfare. Also, income was 36.8% determined by all independent variables. Q^2 represents a measure of how well-observed values are reformulated by the model and its parameter estimates. $Q^2 > 0$ shows that the model has predictive relevance (Chin, 2010). The results of this study implied that both variables are 0.247 (income) and 0.295 (welfare) which were more than 0. Hence, this model has predictive relevance.

Table 7: Coefficients of Sizes and Predictive Relevance Analysis

Variables	Coefficients of Sizes, R^2	Predictive Relevance, Q^2
Income	36.8%	0.247
Welfare	55.8%	0.295

The results in Table 8 illustrate the significance of direct path coefficients. The values of relationship as shown in t-statistics revealed that two relationships (TR->Income and SIS->Welfare) are lower than t-table value of 1.96 (p-value of 0.05) while remaining relationships are all positive relationship and higher than t-table value of 1.96 with p-value of less than 0.05. Also, the table indicates that Income->Welfare (β=0.439; p<0.001), MC->Income (β=0.191; p=0.001), MC->Welfare (β=0.276; p<0.001), MI->Income (β=0.194; p=0.001), MI->Welfare (β=0.204; p<0.001), SV->Income (β=0.241; p<0.001), SV->Welfare (β=0.187; p<0.001), TR->Welfare (β=0.195; p<0.001) and SIS->Income (β=0.145; p=0.007) were the only significant path coefficients. The relationship TR->Income and SIS->Welfare were not significant predictors to relevant variables. Thus, most of the direct path coefficients of this study were significant (p<0.001).

Table 8: Significance of Direct Path Coefficients

	Standardised Beta	t-statistics	p-values	Decision
Income -> Welfare	0.439	9.848	< 0.001	Supported
MC -> Income	0.191	3.465	0.001	Supported
MC -> Welfare	0.276	5.387	< 0.001	Supported
MI -> Income	0.194	3.368	0.001	Supported
MI -> Welfare	0.204	3.608	< 0.001	Supported
SV -> Income	0.241	4.327	< 0.001	Supported
SV -> Welfare	0.187	3.690	< 0.001	Supported
TR -> Income	0.05	0.879	0.380	Not supported
TR -> Welfare	0.195	3.508	< 0.001	Supported
SIS -> Income	0.145	2.686	0.007	Supported
SIS -> Welfare	0.041	0.866	0.387	Not supported

The results in Table 9 indicate the significance of indirect path coefficients. The mediating variable of income was added to five relevant paths of coefficients. It was found that income has a positive and significant impact on microfinance services towards welfare except for savings only. Despite the savings is not significant with $p>0.05$, the relationship between the remaining predictors (microcredit, micro insurance, training and social intermediation service) was intensely reduced with significant path coefficient (0.084, 0.085 0.063 and 0.106) ($p<0.05$) respectively.

Table 9: Significance of Indirect Path Coefficients

	Standardised Beta	t-statistics	p-values	Decision
MC -> Income -> Welfare	0.084	3.112	0.002	Supported
MI -> Income -> Welfare	0.085	3.234	0.001	Supported
SV -> Income -> Welfare	0.022	0.848	0.397	Not supported
TR -> Income -> Welfare	0.063	2.572	0.010	Supported
SIS -> Income -> Welfare	0.106	3.787	< 0.001	Supported

Conclusion and Recommendation

In a nutshell, microfinance institutions are required to be promoted to all low income households, persistently to extend its microfinance services. The microfinance services help to increase their source of income thus enhancing their socio-economic welfare and also reduce their level of poverty with the presence of microfinance institutions to develop national economic growth in line with the objectives of the New Economic Model Malaysia.

The main objective of this study was to examine the ideal microfinance services which enhance the socio-economic welfare of urban households in Malaysia. The results of this study confirmed the effect of microcredit, micro insurance, social intermediation service and training on socio-economic welfare. These results supported the hypothesis of the study by affirming the importance of microfinance services in enhancing the socio-economic welfare of urban households' poverty.

The study found out that majority of the households receivers are between the age group of 36 to 50. Most of them have at least secondary education with only minority having post-secondary education. In addition, this study found out that many of the urban households were engaged in self-employed businesses by starting up their own small businesses. This resulted in their gross monthly income to be between the ranges of RM 1,500 to RM 4,000 only.

The study also confirmed that most of the microfinance services provided by AIM are very significant in increasing their sources of income as well as enhancing their socio-economic welfare except for savings services. The fact shows that the amount of savings by the households for the microfinance programs is less than 1% out of the total loan amount (AIM, 2016). Hence, the amount of the savings does not really cater for the needs of the households.

This study is important as it assists to detect the most influential microfinance services in enhancing the socio-economic welfare on the urban vulnerable households in Malaysia. Microfinance services should not be treated as the only remedy to counter poverty in universal, but rather as an essential platform in eradicating poverty and subsequently, enhancing welfare of society too. Thus, the introduction of few policies by government of Malaysia such as National Urbanisation Policy, National Key Results Areas and Government Transformation Programme needs to be fully achieved in order to create developed country. Thus, this study is

able to assist government in achieving part of the goals of New Economic Model for Malaysia in which to be a high income economy which are both inclusive and sustainable. The government of Malaysia through AIM should extend promoting microfinance programmes in enhancing the wellbeing for the urban households in Malaysia. The government and relevant authorities have the responsibility in generating sustainable and favourable policy on microfinance institutions operations. The policy will assist them to inspire more urban households in participating microfinance programmes. This can indirectly have multiple effects on households' socio-economic welfare. Microfinance will perhaps likely to empower people by providing them with more confidence and assisting them financially in their businesses.

However, this study was limited only to the collection of selected states in Peninsular Malaysia only. There should be more geographic areas to be covered in future studies. Moreover, microfinance institutions should always strive to promote more on the quality of products and services to the extent of different needs of the borrowers. Hence, this may help to enhance the participation rate in their programmes in order to achieve poverty alleviation. Nevertheless, government should also be continuously funding the microfinance institutions in order to assist their operational maintenance. This will indirectly enhance the standard of living for the society too.

Factors determining housing price: case of St. Petersburg

Liudmila A. Guzikova, Professor of Peter the Great St. Petersburg Polytechnic University,
St. Petersburg, Russian Federation, guzikova@mail.ru

Ekaterina V. Plotnikova, Associate professor of Peter the Great St. Petersburg Polytechnic University,
St. Petersburg, Russian Federation, e-plotnikova@fido-polytech.ru

Abstract

In the framework of this study, the authors of the paper analyzed the construction sphere by the example of St. Petersburg. As a result, the main problems of housing construction financing were identified, an algorithm for financing construction sector was developed, correlation and regression analysis of the market value of housing was carried out and the main factors influencing its formation were identified.

Keywords: housing construction, housing, construction financing, housing prices, price factors

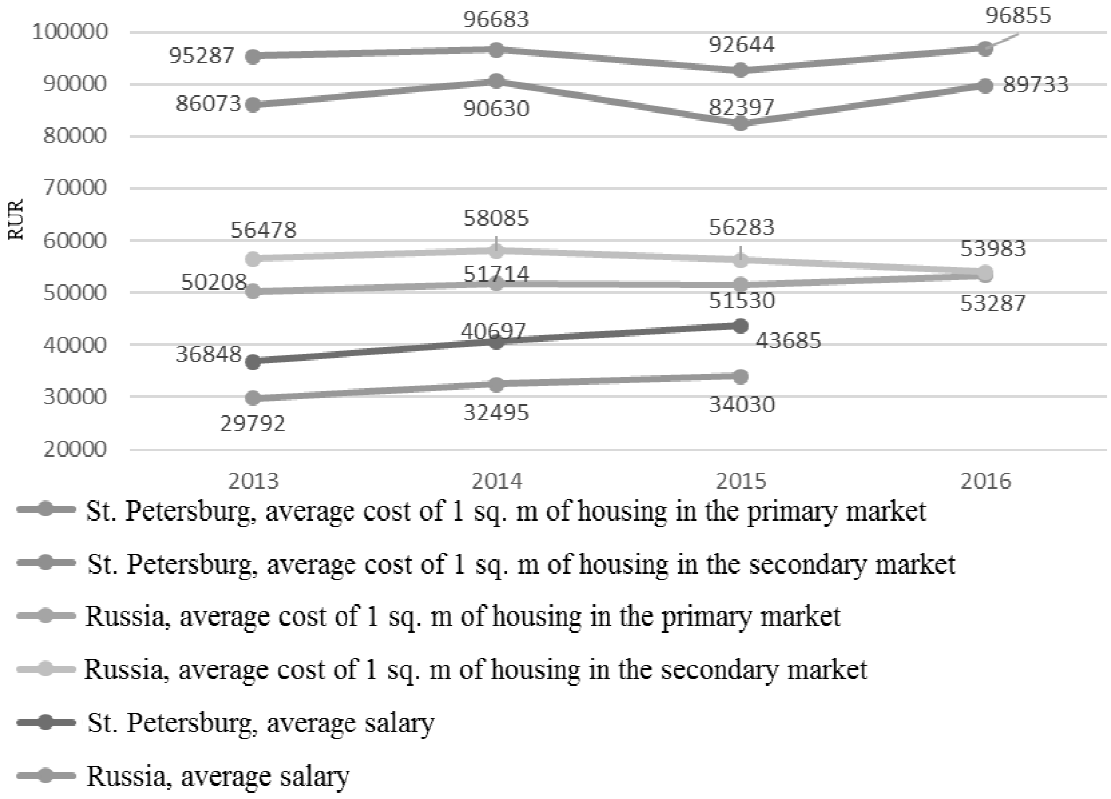
Introduction

Housing construction belongs to one of the most priority sectors of the national economy due to the fact that housing security is the most important indicator characterizing the citizens' level of well-being and the quality of life in general. There are two types of strategies for financial incentives for the development of priority industries: 1) strategies based on the stimulation of supply; 2) strategies based on the stimulation of demand.

Strategies of the first type go back to the historical period, when the production development level did not allow fully meeting the needs of society in every-day goods. During this period, the main task was to expand production, and a limited range of potential solvent buyers competed for the products in the market. The task of manufacturers was to ensure the production of the goods with minimal costs, which allowed expanding the range of customers due to lower prices.

With the development of production and the fierce competition in markets, a new type of incentive strategy has emerged. In the process of competition, manufacturers constantly increase production volumes, improve the quality of their products and expand its range, but the consumer, despite the desire to unlimited increase of the comfort level, is unable to pay the entire volume of output. Stimulation of demand becomes a reaction to the threat of a overproduction crisis.

In today's Russia the provision of affordable and comfortable housing for citizens is extremely acute issue, which forces to use a combination of the elements of strategies both the first and the second types in order to balance supply and demand. On the one hand, the increase in the volume of housing construction should be carried out by increasing the efficiency of the housing financing system and developing bank lending to developers and other incentive measures for producers. On the other hand, it is necessary to support the demand for housing, by means including, in particular, mortgage lending.
In connection with the mentioned above, the issues of financial support for housing construction as part of a set of measures aimed at housing problem solving are of high relevance and have priority from the standpoint of strategic socio-economic development.



The objective of the study is to identify the factors that have the greatest impact on the value of a square meter of housing in St. Petersburg which is analyzed divided by districts of the city. To achieve the goal, the following tasks were set and solved: 1) analysis of the situation in the housing market of St. Petersburg in order to determine the range of factors; 2) carrying out correlation-regression analysis in

order to reveal the dependence between the price of the housing as productive factor and the revealed factors.

It is supposed that the market price of the housing constitutes of two components - fundamental and conjunctural, and the first is dependent of the inalienable properties of the housing which stay unchanged for a long time.

Data and method

Analysis of the current situation in the housing market of St. Petersburg allows characterizing the state and identification the prospects for of housing construction. The most important factor determining the affordability of housing is the housing prices in the primary and secondary market in comparison with the level of the average salary in the investigated region (Fig. 1).

Source: compiled by the authors on the basis of the Regions of Russia (2016).

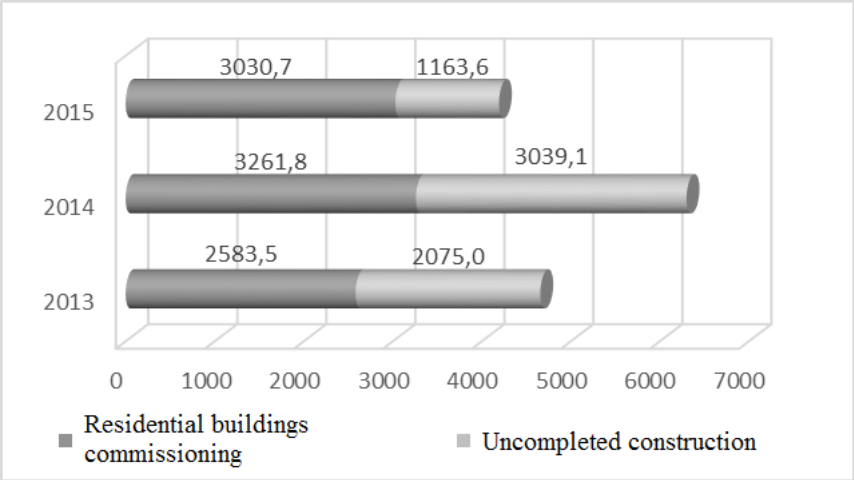


Fig. 1. The ratio of the average cost of 1 sq. m of housing to an average salary

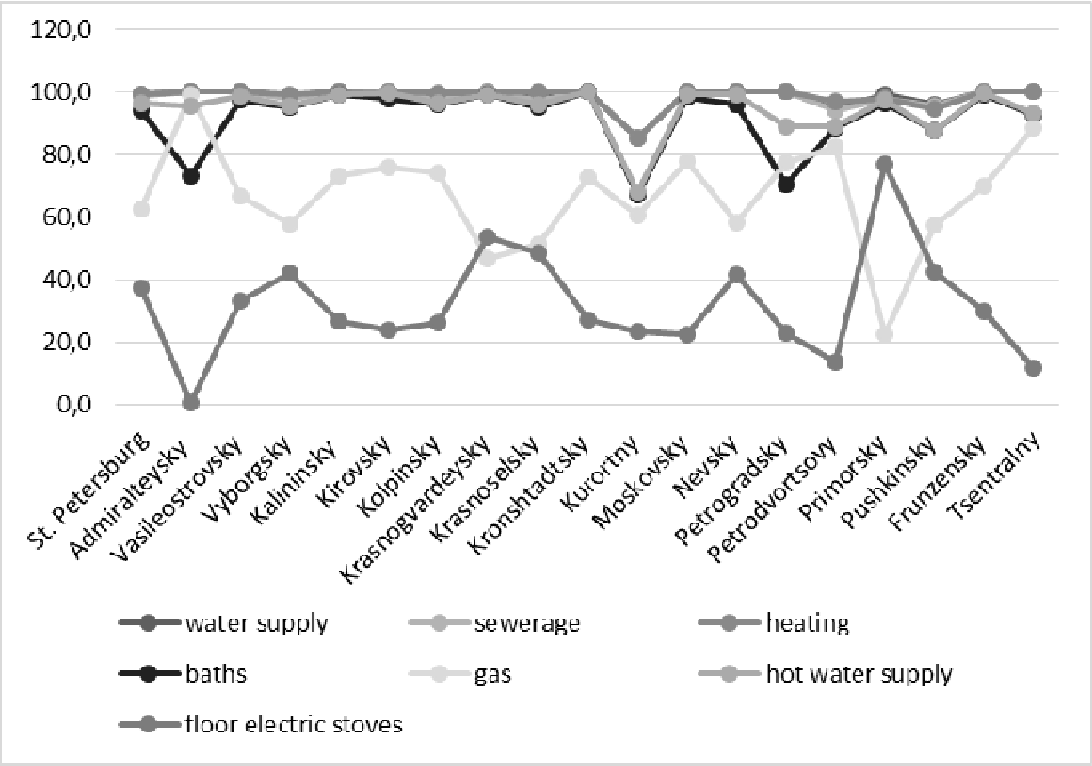
According to the data published by the state statistics bodies, during the analyzed period the cost of housing in the primary market of St. Petersburg exceeds the cost in the secondary market by an average of 8 thousand rubles per square meter of the total area. As a rule, the cost of housing in the secondary market is higher than in the primary market, which is confirmed by the situation on average in the country. This is explained by a number of factors: 1) the category of secondary real estate includes high cost apartments in houses built during the last five years; 2) buying a property in a house under

construction is perceived as a significant risk; 3) when buying a secondary real estate buyer can enter the house immediately; 4) mortgage rates on the constructed housing is lower by an average of 1% (Real Estate. "Secondary" vs new buildings: what and why is more expensive?, 2017).
The reverse situation prevailing in St. Petersburg can be explained by the saturation of demand for expensive housing in the secondary market and, as a consequence, the dominance of demand for mass housing of economy class.

Analyzing the dynamics of changes in the average monthly salary, shown in Fig. 1, we can conclude that the average salary does not match the cost of one square meter of housing, which significantly reduces the affordability – citizens' ability to purchase housing. So, in 2016, the average resident of St. Petersburg, having spent the entire amount of his/her monthly salary, could purchase 0.47 meters of housing in the primary market (0.53 meters - in the secondary market).

In 2016, the construction cost of a square meter of housing in St. Petersburg amounted to 59,294.8 rubles. (Housing in Russia, 2016), while the market value - 96 855 rubles. Thus, the cost of housing when it enters the market increases by an average of 63.34%. By the gap between the cost per square meter of housing and its market value St. Petersburg ranks second in Russia after Moscow.
Comparative dynamics of residential buildings commissioning and uncompleted construction in St. Petersburg for 2013-2015 is presented in Fig. 2.



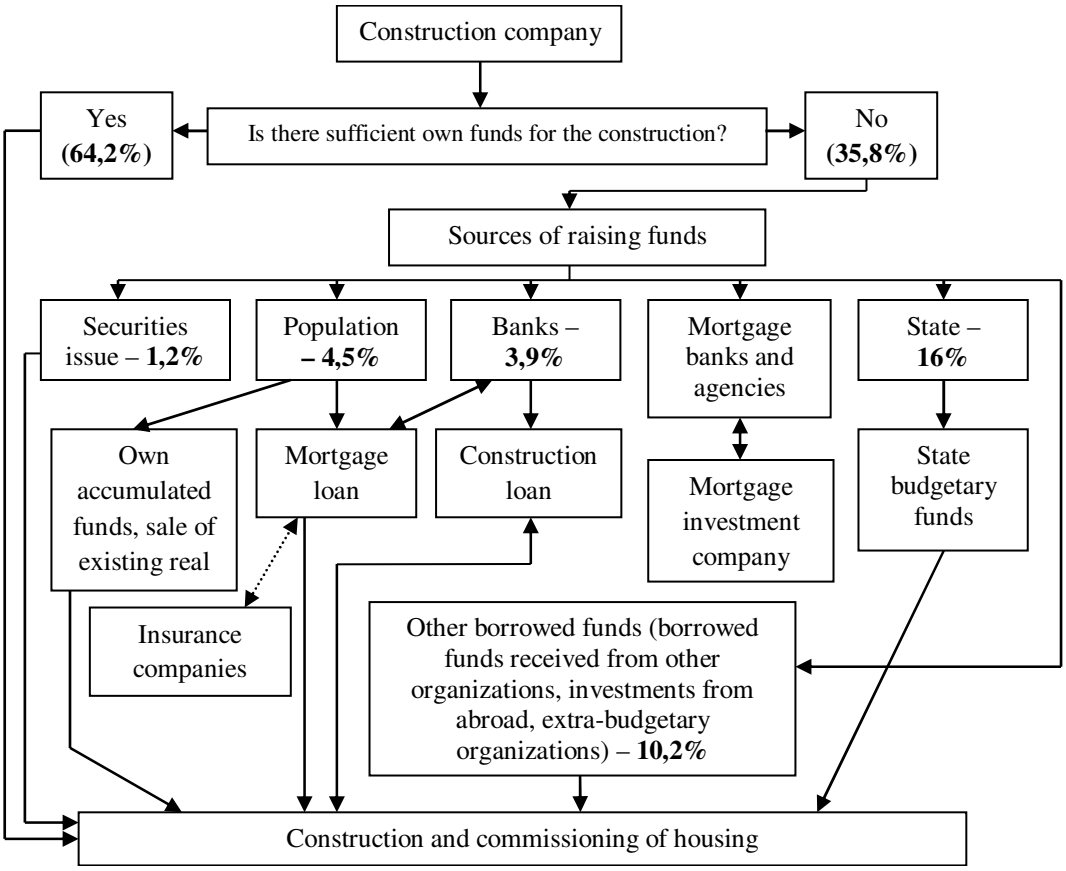
Source: compiled by the authors on the basis of the Regions of Russia (2016).

Fig. 2. Comparative dynamics of residential buildings commissioning and uncompleted construction (thousand sq. m)

An analysis of uncompleted construction of residential buildings in St. Petersburg shows that its volume is big and sufficient to significantly affect the economic development of certain territories of St. Petersburg and the Russian Federation as a whole.

The uncompleted construction of residential buildings is associated with a lack of money, changes in legislation, a currency crisis and other negative circumstances. In 2013 and in 2014, the volume of uncompleted construction was comparable to the volume of residential space commissioned and reached a huge size due to the deteriorated economic situation in the country. In 2015, construction in progress has reduced almost thrice. This is explained by the fact that along with the scheduled delivery of construction projects, a number of projects frozen during the crisis were completed.

Comfortable living conditions and accessibility of utilities are ensured by the equipment of residential buildings. To assess the trends in the residential buildings equipment, we will analyze proportions of the total area equipped with water supply, sewerage, heating, baths, gas, hot water supply, floor electric stoves in the districts of St. Petersburg in 2016 (Fig. 3).



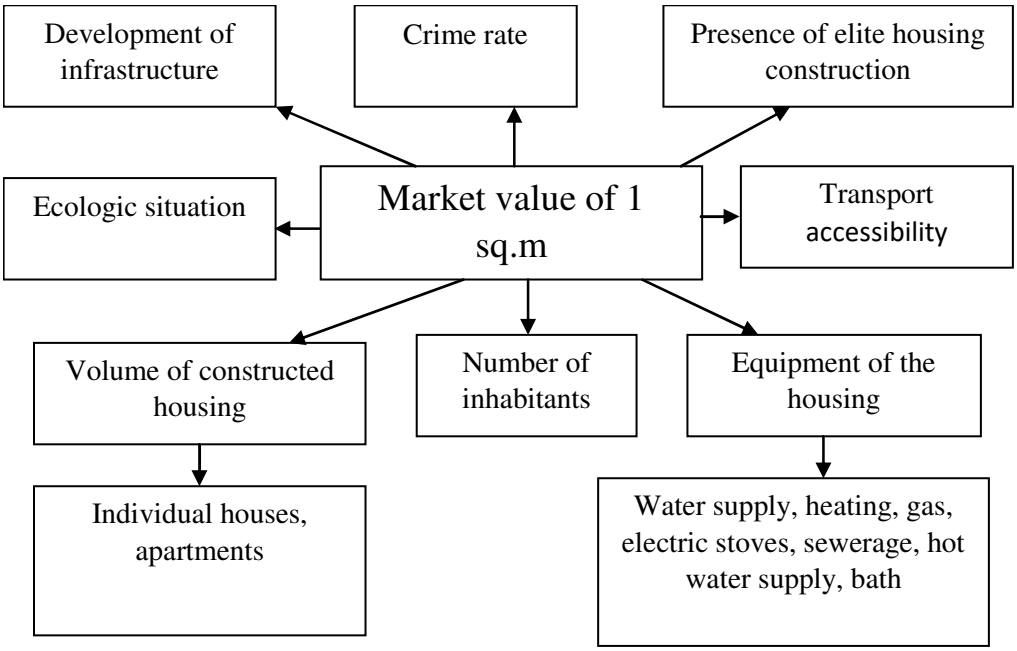
Source: compiled by the authors on the basis of Housing in Russia (2016).

Fig. 3. Equipment of housing stock in 2016 (%)

In the districts of St. Petersburg the equipment of residential buildings as a whole is in the quite high level. However, the Kurortny district has quite low indicators of residential buildings' equipment: only 68% of the total area is equipped with hot water supply, and 67.3% of the total area is equipped with baths (shower).

The analysis of the current state of the housing stock in St. Petersburg allowed revealing the following:
- huge gap between the construction costs and the market value of the housing stock;
- significant gap between the market value of housing and the average salary;
- positive trends in uncompleted construction, which made it possible to reduce its volume by almost three times in 2015;
- relatively high level of equipment of the housing stock.

Data representing investments in construction in St. Petersburg are shown in Fig. 4 by sources of financing.



Source: compiled by the authors on the basis of Badyranov (2009), Konkin et al (2016), Mataibaeva (2003), Sternik (2000).

Fig. 4. Structure of investments in construction by sources of financing (% of total)

Today the construction companies prefer to reduce potential risks, so 64.2% of construction financing is from own funds. This situation, in our opinion, has formed due to unstable situation in the economy. In the case of shared financing, construction companies lose part of the profit, selling the housing at a lower cost, so investments in construction through mortgage constitute only 3.9%. Another source of financing is budgetary funds (16%), which, as a rule, are being received on an irrevocable basis and are intended to build social housing. 4.5% of financing is carried out from the funds of organizations and participants of shared construction. The issue of securities constitutes 1.2%. 10.2% of financing is provided through other borrowed funds, including borrowed funds received from other organizations, investments from abroad, extra-budgetary funds, funds of superordinate organizations.

As a result of examining analytical reviews, statistical data and the current state of the housing market, a number of factors were identified which, in the opinion of the authors, should influence the formation of the resultant factor - the market value of square meter (Fig. 5).

Source: compiled by the authors.

Fig. 5. Factors of the market value included in consideration

Thus, the following indicators will be considered as factors affecting the market value of 1 square m of housing:

- equipment of housing (water supply, heating, gas, electric stoves, sewerage, bath, hot water supply);
- transport accessibility (presented in the form of an index which reflects how many times to travel from this or that region longer to center of city than from the Central District);
- volume of commissioned housing (the number of apartments in residential buildings and the area of individual houses);
- infrastructure development (determined by the availability of schools, hospitals, kindergartens, food stores within walking distance);
- crime rate (number of committed crimes);
- population (number);
- presence of elite housing construction (ranking position);
- ecologic situation (rating of the ecological situation in the districts of the city).

Analysis and results

Now let's investigate the factors that determine the market value of a square meter in the primary and secondary housing market in St. Petersburg. The market value of 1 square meter of housing in the primary and secondary markets of St. Petersburg will considered as resultant factors. Several indicators, reflecting the level of livability of housing, the number of built housing, the ecological situation of the area, transport accessibility, development of infrastructure, the availability of elite construction and number of inhabitants, were determined as attributive factors.

Correlation-regression analysis was carried out according to data published in public on various information portals, including websites of state statistics bodies (Regions of Russia, 2016), and reflecting

the situation in different districts of St. Petersburg in 2016. The results of the pair correlation analysis are presented in Table 1.

Table 1. Results of pair correlation analysis between the market value of 1 square m in the primary market and value factors

Factor	Correlation coefficient
Water supply	-0,058
Sewerage	-0,035
Central heating	-0,154
Bath (shower)	-0,409
Gas supply	0,117
Hot water supply	-0,304
Electric stoves	-0,151
Number of completed apartment	-0,059
Area of individual houses	0,428
Ecologic situation	-0,040
Crime rate	-0,127
Transport accessibility	-0,241
Development of infrastructure	0,591
Presence of elite housing	0,419
Number of inhabitants	-0,155

An attempt was made to construct multiple linear regression equation for the primary market price, based on the same factors. However, the results obtained are statistically insignificant. Table 2 presents the results of pair correlation analysis for the secondary market.

Table 2. Results of pair correlation analysis between the market value of 1 square m in the secondary market and value factors

Factor	Correlation coefficient
Water supply	0,046
Sewerage	0,070
Central heating	-0,029
Bath (shower)	-0,653
Gas supply	0,382
Hot water supply	-0,255
Electric stoves	-0,404
Number of completed apartment	-0,208
Area of individual houses	0,392
Ecologic situation	0,450
Crime rate	-0,228
Transport accessibility	-0,710
Development of infrastructure	0,713
Presence of elite housing	0,769
Number of inhabitants	-0,374

Based on the pair correlation analysis, four factors were identified that are most closely related to the market value of 1 sq. m on the secondary market:
- bathroom or shower room (x1);
- transport accessibility index (x2);
- infrastructure development (x3);
- ratio of elite and non-elite housing (x4).

On the basis of these indicators, the multiple regression equation was constructed showing how, in aggregate, the factors under investigation affect the market value of 1 sq. m. (Table 3-4). Note that during the analysis two variables (transport accessibility index and infrastructure development) were excluded as statistically insignificant.

Table 3. Regression statistics

Regression statistics	
Multiple R	0,983119282
R-square	0,966523522
Adjusted R-square	0,959084305
Standard error	4771,864717
Observations	12

The coefficient of determination is equal to 0.9665, therefore, the factors considered is determine the market value by almost 97%. The elimination of two indicators from multiple regression equation reduced the determination coefficient by 1%, which is acceptable.
The calculated value of F is 0.00000023. The calculated level is less than the selected significance level α = 0.05, therefore, this dependence is statistically significant.
Table 4 shows the P-values for the parameters of the regression equation. All P values are less than the selected significance level α = 0.05, which confirms the statistical significance of all parameters.

Table 4. P-value

	P-value
Y-intercept	0,000001
X 1	0,000013
X 2	0,000046

Thus, it was revealed that the availability of bath (shower) and the share of elite housing in the region by 97% determine the market value of housing in the secondary market.
As a result, in order to predict market value changes in the districts of Saint-Petersburg, the following equation was constructed: Y= -1416.14 * X1 + 3097.12 * X2 + 209699.53. This equation allows predicting the level of market prices for housing in the area based on two main indicators.

Discussion

Providing the population with housing is the most important socio-political and economic problem. The scale and pace of housing construction, the real well-being of people, their moral and physical well-being, political assessments and behavioral motivation largely depend on the approaches chosen to solve this problem. The results obtained in the paper can be used to predict the level of market prices for housing in the territory on the basis of factors determining housing quality in the wide sense, but they refer rather to the fundamental component of the market value than to its conjunctural component. So the latter should become the subject of further investigation.

Summary

At present, there is a huge gap between the market value of housing and the financial capabilities of population. In this regard, the tendency of construction growth is becoming dangerous, making newly constructed housing increasingly less affordable to the population and resulting the decrease of demand, and, consequently, the decrease of the construction volume. In the end, this can create a crisis of a systemic nature, markedly strengthening in the deteriorating economic situation in the country as a whole. In order to diversify the sources and mechanisms of financing, an algorithm for financing housing construction was proposed and the current distribution of financial flows in the construction industry was analyzed. As a result, it was revealed that construction organizations prefer to finance activities at their own expense, which provides them with financial stability and the maximum possible profit.

Correlation-regression analysis made it possible to identify factors that have a significant effect on the market value of a square meter in the secondary market. Such factors are the presence of a bath / shower - the inverse relationship, the ratio of elite and non-elite housing - a direct dependence. The fact of the inverse relationship between the presence of a bath / shower and the market value of a square meter in the secondary market can be explained by the fact that the most expensive apartments are located in the historical center of Saint-Petersburg, where the largest percentage of apartments was built in the end of 19^{th} beginning of 20^{th} century, and does not satisfy the modern requirements to equipment.

The scale of the problems of the housing construction development and construction financing, require the fastest possible measures to resolve them, to identify and make full use of the world experience and best practices of the Russian regions.

The Effectiveness of Funding the Activity of Russian Universities Project 5-100-2020

Liudmila A. Guzikova, Professor of Peter the Great St. Petersburg Polytechnic University, St. Petersburg, Russian Federation, guzikova@mail.ru

Ekaterina V. Plotnikova, Associate professor of Peter the Great St. Petersburg Polytechnic University, St. Petersburg, Russian Federation, e-plotnikova@fido-polytech.ru

Abstract

In the situation of the soaring demand for higher education, the topicality of global university rankings grows. Independently on the goals declared by their compilers, the rankings are recognized in academic society and beyond it as a comparative assessment of the educational institutions quality. Project 5-100-2020 was designed to provide financial support to Russian universities striving to maximize their competitive positions at the international level. The paper analyzes the effectiveness of Project 5-100-2020 financing in order to develop the most appropriate measures to achieve the goals. The effectivenessis evaluated with application of several criteria: necessity, performance to plan, costs, comparative characteristics. As the result it was found out that regulative provision of the project implementation is insufficient, the number of Russian universities participating in the project was projected up to the year 2020, recommendations are given to develop key indicators of Russian universities based on their comparison with the leading universities of QS rankings, inefficient use of financial means in the implementation of the project was identified.

Keywords: funding of education, effectiveness assessment, competitiveness, ranking of universities.

Introduction

Today education in its continual, organic interrelation with science is becoming one of the most important factors contributing to economic growth of the country.

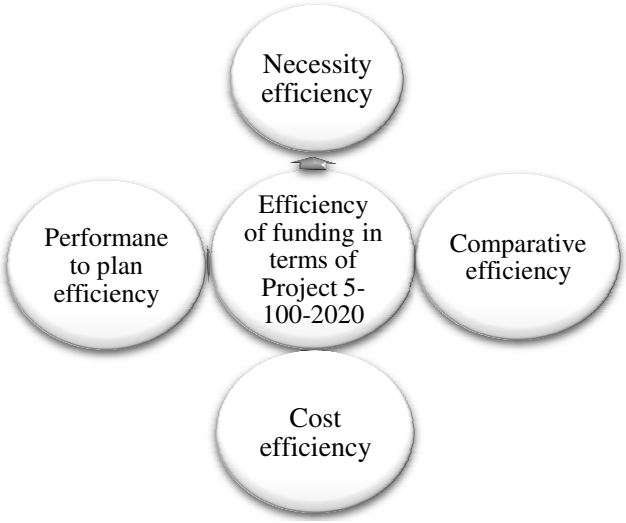
It should be noted that by the beginning of the 21st century, the prestige of the Russian educational system and university science turned out to be seriously disrupted. Socioeconomic and state political transformations of the late 1980s - early 1990s made a considerable impact on education in Russia, allowing making higher educational institutions academically autonomous, ensuring diversity of educational institutions and educational programs, developing the multinational Russian school and non-government sector of education. As a result of those transformations the influence of the state on the sphere of education decreased a lot, which doomed education to exist in the position of internal confinement and isolation from solving topical problems of the country's socioeconomic life.

Today Russia pays a lot of attention to the problems of training engineering, managerial and scientific cadres of higher qualification, which has been reflected in a number of official documents that set specific objectives and stipulate concrete actions aimed at improving the prestige of the Russian higher school at the international level. Now the attention of the state to the problems of the higher school is preconditioned by the fact that the prospects and dynamics of socioeconomic development of the country depend on the level of its intellectual potential while advancement in rankings is an indicator of progress, confirmation of the level of Russian education at the international level.

Development features and tendencies of modern education, its quality, as well as the criteria that influence the formation of ranking scores, were studied in detail in the papers by Russian researchers

(Rodionov et al, 2014-2016; Vorobyeva et al, 2017; Davidyuk et al, 2017; Efimova et al, 2017; Guzikova et al, 2014) and foreign scientists (Zahid et al, 2017; Shin et al, 2011; Dobrota, 2016).

According to the Presidential Decree in March 2013 the RF Government initiated a project with a working title 5–100–2020. Project 5–100-2020 is a state university support program aimed to promote and improve the prestige of Russian education. According to the Presidential Decree "On the measures for pursuit of state policy in the field of education and science" (No. 599, dated 7.05.2012), by 2020 five Russian universities must get into the top-100 best universities of the world according to the version of the leading international ranking called QS World University Rankings.



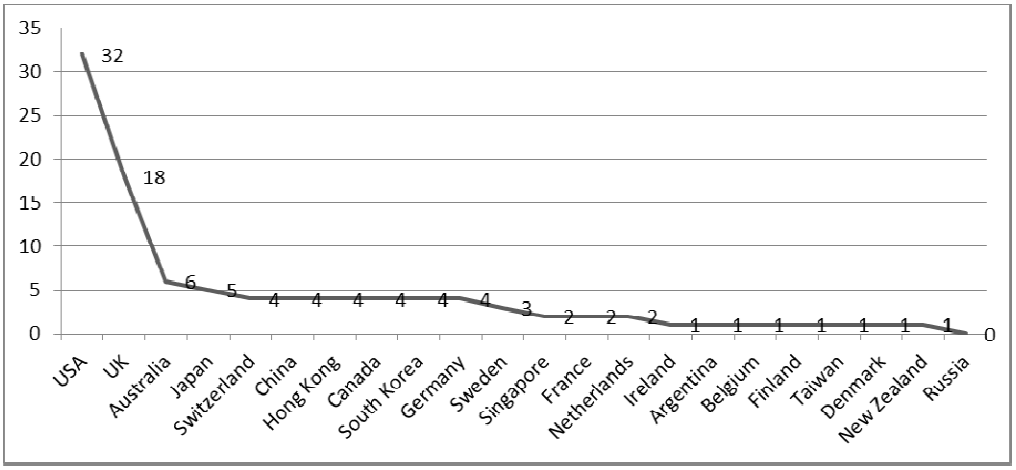
It has been 5 years since the project was started, which makes it possible to summarize the first outcomes, analyze the achieved results and evaluate how efficiently the goal of the project is implemented in terms of funding - maximization of the competitive position of leading Russian universities on the international market. Thus, the purpose of this paper is to evaluate the effectiveness of funding of Russian universities which obtain subsidies in the context of Project 5-100-2020.

In the first part a set of criteria is demonstrated. It has been used to assess the effectiveness of funding of Project 5-100-2020. The second part contains the results of effectiveness assessment and identifies problems and prospects related to the implementation of Project 5-100-2020.

The information basis for the research includes the RF Government laws and decrees, regulatory acts and materials of specialized, issue-related Internet resources, materials of the official and financial statements of project office 5-100-2020, statistic data.

Data and method

In order to assess the effectiveness of educational activity funding in terms of Project 5-100-2020 we will be using a complex of criteria which characterize program implementation from different angles. This complex of criteria shows to which extent the program implementation meets the goals and objectives that have been set. It can be used as a landmark for the project initiators in managerial activity, which directs this activity in the channel of substantiation, necessity, justifiability and sufficiency. Figure 1 presents a complex of criteria that will be used to assess the effectiveness of Project 5-100-2020 funding.



.**Figure 1 - Approaches to assessing the effectiveness of educational activity funding in terms of Project 5-100-2020. (***Composed by the authors)*

The above approaches supplement each other, so for a full-fledged assessment of the effectiveness of educational activity funding it is necessary to implement them as a single package. The complex of effectiveness evaluation criteria of educational activity funding includes the following approaches: necessity effectiveness, comparative effectiveness, cost-effectiveness, performance to plan effectiveness. Let us present each approach in more detail.

1. Necessity effectiveness. First of all, a logical criterion or common sense check-up should be noted as an effectiveness criterion. In terms of necessity, one should evaluate the feasibility of taking an action as a whole to see if it is reasonable to carry it out and to define the utility from taking it. In the context of this approach it is necessary to obtain an answer to the question: "what does it bring?" and "who stands to gain from it?". Despite the triviality of this criterion, a failure to comply with it can result in unprecedented consequences in practice. In terms of this research, the logical criterion implies calculation of an indicator which reflects the amount of money spent to improve a university's status by one position in the QS rankings for the period from 2013 to 2016.

2. Performance-to-plan-effectiveness. In order to assess the performance, such indicators are applied which characterize the degree of compliance with the planned and projected values, i.e. the "fact/plan" ratio, estimated on the basis of planned and accounting documents and statistical data. In this research we are going to use the goal of Project 5-100-2020 as a planned indicator, which prescribes entrance of five Russian universities to the ranking of 100 best universities in the world by 2020. On the basis of the actual data and identified trends, the position of universities in the rankings by 2020 has been forecast. This forecast in terms of the applied approach will be recognized as an actually achievable indicator.

3. Comparative effectiveness. The indicator is applied in the selection of the best option for solving an economic problem. The utility of comparative assessments depends on the objectives of a comparison and the soundness of the selection for comparison. A comparison will be useful only if consistent characteristics are compared, for example, indicators calculated by using the same methodology. Comparative analysis of effectiveness is made both as a whole and by individual directions and factors. Comparisons to foreign countries can make conclusions inaccurate because of differences in the registered and published indicators, methodologies for estimating indicators and unavailability of data for cross-over application of methodologies. As noted above, the goal of the program is that Russian universities will enter the number of 100 best universities in the world by the year 2020. Due to the above, the basis for comparison will include the countries whose universities have different positions in the top-100 of the QS rankings.
Application of the comparative effectiveness criterion is eased by the fact that usage of the data presented in the QS rankings implies a single methodology for acquisition, processing and analysis of information and presents comparable characteristics and factors.
Figure 2 presents the distribution of the participating universities which entered the top-100 of the QS rankings by countries in 2017.

Composed by the authors based on the QS World University Rankings.

Figure 2 – Distribution of the participating universities which entered the top-100 of the QS ranking by countries in 2017.

In order to estimate the comparative effectiveness, some countries have been chosen given the following logic:
1) the country which has the biggest number of universities in the top-100 of the QS ranking;
2) the country whose number of universities is a median value in the top-100of the QS ranking;
3) countries which have the smallest number of universities in the top-100 of the QS ranking;
Since there are as many as 7 countries which have only 1 university in the top-100 of the ranking, 2 countries, whose universities have the highest amplitude of the expected values of the criteria, have been chosen. Thus, comparison will be made by the following countries: the USA, Sweden, New Zealand and Taiwan.
The top-100 universities and the Russian universities participating in Project 5-100-2020 will be compared by such indicators as: academic reputation, employer reputation, faculty/student ratio, citations per faculty, international faculty ratio, international student ratio.
4. Cost-effectiveness. Achievement of the maximum result with constant costs. Calculation of cost-effectiveness is a mandatory condition for substantiating every action in terms of scientific research, project and production activity. In the research the estimation has been made in various forms and with a different degree of detailing. In this research we analyze the structure of costs on Project 5-100-2020 in Russia and make an assessment of their rational usage.

Analysis and results

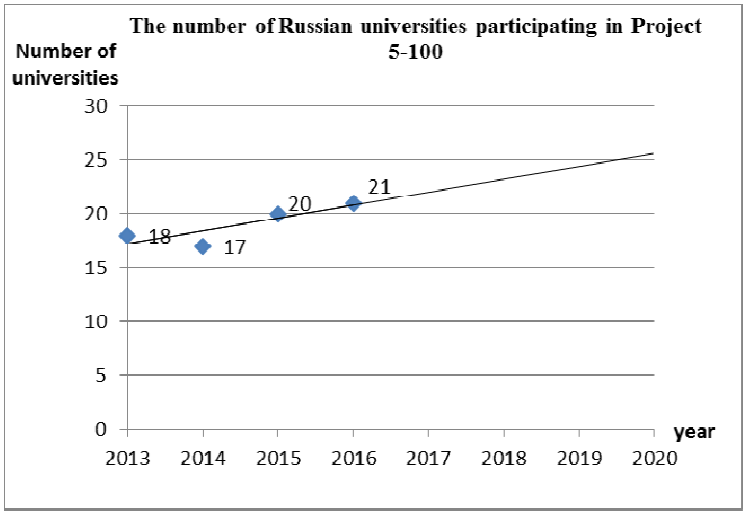
Below we present the results of the applied complex of criteria reflecting various approaches to assessing the effectiveness of funding in relation to the Project 5-100-2020.

1) Necessity effectiveness.

Project 5-100-2020 is financed from the funds of the RF federal budget. A project office was set up in order to organize analytical, methodological, informational, organizational and technical activity of Project 5-100-2020. The money is distributed between project participants and the project office through the Ministry of Education and Science of the RF. Every year, based on the RF Government executive orders, the amount of subsidies to participating universities is established. The specification of the total

amounts of funding granted to the universities participating in Project 5-100-2020 and the change in their general position in the QS ranking are presented in Table 1.

Table 1 – Specification of the size of funding granted to participating universities and change in their general position in the QS rankings.



Indicator	Year			Total
	2014	2015	2016	
Change in the number of positions in the Russian QS rankings	-	615	170	785
The amount of subsidies, m rubles.	8,700	10,150	10,140	28,990
Number of m rubles/ position	-	17	60	37

In the period from 2014 to 2016 the cumulative advancement of Russian universities in the QS rankings included 785 positions. The amount of subsidization for the same period was 28,990 m rubles. On average, the costs from the federal budget amounted to 37 m rubles in the context of Project 5-100 for improving the position of a university by one point in the international university QS rankings for the years 2014 - 2016.

The results of the effectiveness analysis in terms of necessity showed that:
1. The analyzed distribution of financial flows between participating universities sent by the Ministry of Education and Science in order to increase the competitiveness of universities shows that the regulatory support received for implementation of the project is not sufficient. For example, in 2014 the subsidy was too high for five universities and too low for 9 other universities. This fact bears evidence that there is no typical form of agreement on providing universities with a subsidy.
2. On average, in order to move by one position higher in the QS rankings a university needs 37 m rubles. Correspondingly, it can be assumed that universities which spend more money use it inefficiently. The following ones can be referred to as such universities: Moscow Institute of Physics and Technology (287.9 m rubles); National Research University "Higher School of Economics" (2 472.4 m rubles); Novosibirsk State University (60.8 m rubles).
The stipulated results bear evidence of inefficient implementation of Project 5-100-2020 in terms of necessity.

2) Performance-to-plan effectiveness.

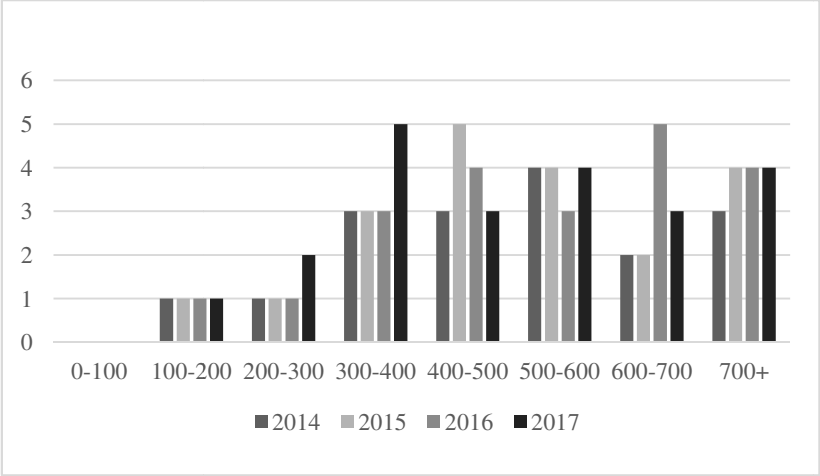


Figure 3 shows the dynamics in the number of Russian universities in the QS rankings.

Composed by the authors based on the QS World University Rankings.

Figure 3 – The number of Russian universities participating in Project 5-100

The analysis showed that by 2020 26 participating universities will be included in the QS rankings. Note that in the context of Project 5-100-2020 a goal has been set that 5 universities of Russia are to be introduced in the top-100 of the QS rankings. In order to see if Russian universities can enter the top-100, let us look into the distribution of Russian universities in the rankings for the period of 2014-2017 (Figure 4).

Composed by the authors based on the QS World University Rankings.

Figure 4 – Distribution of Russian universities in the QS rankings in the period form 2014 to 2017.

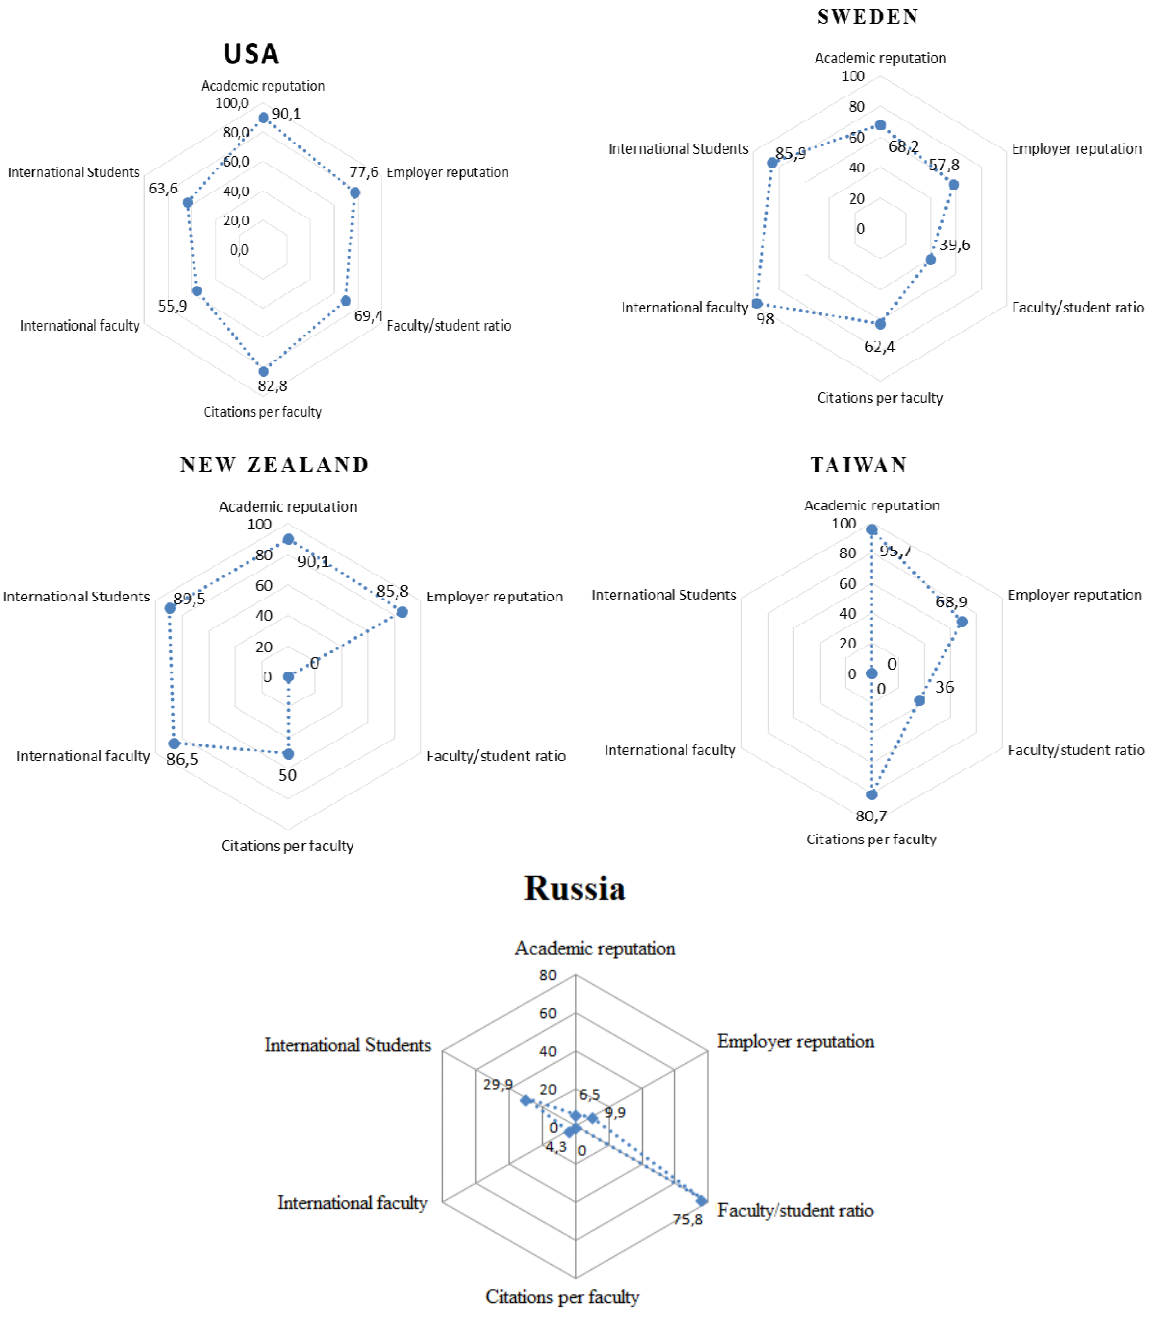
One university – Lomonosov Moscow State University – entered group "100-200" in the period from 2014 to 2017. It demonstrated consequent approaching of its positions to the top-100 of the rankings. In group "200-300", the number of universities remained the same throughout the examined period (1 university). The year 2017 became an exception: two Russian universities got into this group. In 2014-2016 there were three universities in group "300-400" and in 2017 the number reached five. Group "500-600" included 4 Russian universities. In 2016 there was a reduction in the group by one Russian

university, but as early as in 2017, the situation recovered. Group "600-700" included 2 universities in the period 2014-2015. In 2016 the number of universities increased to 5. However, as early as in 2017, the number of universities reduced to three. In group "700+" the number of universities was 3 in 2014. In the period 2015-2017, the number increased up to four universities. On the basis of the carried out analysis, it can be concluded that according to the revealed dynamics 1 university, at most, can get into the top-10 of the best universities of the world in the QS rankings.

The results of the effectiveness analysis in terms of performance to plan showed that:
1. The number of Russian universities in the top-100 of the QS rankings is equal to zero as of today. By looking into the dynamics of change in the positions of Russian universities in the rankings, it can be concluded that the goals and objectives of Project 5-100-2020 are not achievable in case the other conditions remain the same.
2. The projection of the number of universities in the period until 2020 showed that by this period about 26 universities will be included in the QS rankings.
Thus, the conducted analysis demonstrates the inadequacy of the planned indicators and, correspondingly, that of the goals and objectives set as part of Project 5-100-2020.

3) Comparative effectiveness.

In order to conduct a comparative analysis in the context of this research, it is necessary to compare the current position of Russian universities in the QS rankings to the universities which have positions in the top-100. The comparison results of universities by key indicators of the QS rankings are presented in Figure 5.



It is seen from the analyzed data that the biggest value in the rankings of Russian universities falls at "faculty/student ratio", which is 75.8 (the calculation methodology is presented in detail on the QS World University Rankings website. The lowest value was achieved by Russian universities by the value of such indicators as "citations by faculty" and "international faculty ratio". The "faculty/student ratio" is the main indicator for Russia allowing being included in the QS rankings. In 2015 the RF Government passed a Decree regulating the faculty/student ratio in educational institutions. According to the Decree one teacher must be accounted for 6 full-time students, or eight part-time students, or twelve students of a correspondence course. As a result of this Decree universities will have to reduce the number of teaching staff. Consequently, in the QS rankings Russian universities will lose their only advantage which has been obtained thanks to a high value of the key indicator "faculty/student ratio".

The results of the comparative effectiveness analysis showed that:

1. The universities in the top-100 of the rankings develop evenly and consistently each of the directions considered in estimation of their competitiveness. For example, for the US universities the lowest value of the criterion is 55.9 and the highest is 90.1. At the same time, for the Russian universities a high value is achieved only by one indicator – "Faculty/student ratio" (75.8).

2. As a result of the policy pursued in the sphere of education, Russian universities have to reduce the number of teaching staff. So, they risk losing the only indicator that has helped them occupy positions in the QS rankings.

Thus, the carried out analysis shows the imbalanced development of Russian universities by such indicators as citation, employer reputation, international faculty, international students and academic reputation. It is because of this imbalanced development that Russian universities cannot achieve the f top-100 of the QS rankings.

Composed by the authors based on the QS World University Rankings.

Figure 5 – Distribution of the key indicators of the universities included in top 100 QS in 2017, by countries

4. Cost-effectiveness.

Let us analyze the cost items in Project 5-100-2020 and make an assessment of their rational usage in order to achieve the best result.
The amount of project funding in 2013-2015 is presented in Table 2.

Table 2 – The amount of Project 5-100 funding (m rubles) in 2014-2016

Year	Participating universities	Project Office	Total
2016	10,140	349.913	10,489.913
2015	10,150	370.474	10,520.474
2014	8,700	220.771	8,920.771
Total	28,990	941.158	29,931.158

According to the data from the table, it can be concluded that from 2014 to 2016 the total amount of Project 5-100-2020 financing was almost 30 billion rubles from the funds of the federal budget.
The number of purchases of Project 5-100-2020 in 2015-2017 (until 31.05.2017) is presented in Table 3.

Table 3 – The number of purchases of Project Office 5-100-2020 in 2015-2017 (until 31.05.2017)

Item	Year					
	2015		2016		2017 (until 31.05.2017)	
	Number of purchases (pcs.)	Total amount of purchases (rubles)	Number of purchases (pcs.)	Total amount of purchases (rubles)	Number of purchases (pcs.)	Total amount of purchases (rubles)
Purchase from a single supplier	86	103,843,899	27	56,806,652	17	9,888,386
Price request in electronic format	-	-	-	-	5	1,345,630
Price request	6	4,407,763	18	13,330,009	-	-
Open tender	5	56,120,000	3	29,630,000	1	4,950,000

According to the State Purchase Portal, in the period from the year 2015 to 2017 (until 31.05.2017) Project Office 5-100-2020 held 9 open tenders. As a result of the tenders, contracts were made for the amount of 90,700,000 rubles. From 2015 – 2017 (until 31.05.2017) Project Office 5-100-2020 made a direct purchase (purchase from a single supplier). Following this purchase, contracts were made for the amount of 170,538,938 rubles. Within the years 2015 - 2016, the operator of Project Office announced price request 24 times. As a result of this procedure, contracts were made for the total amount of 17,737,772 rubles, and price request was carried in electronic format for the total amount of 1,345,630 rubles.

During analysis of the funds spent by Project Office 5-100-2020, it was registered that there were cases of inefficient and wasteful purchase operations. For example, the purchase of "Consulting the Customer on the matters of (budget) accountancy and tax book-keeping, application of tax legislation" (purchase register number No.31502592994, 31603349200). After studying the documentation, it was found out that the enterprise paid 1,100,000 rubles for the services that are already part of the chief accountant's responsibilities. The doubtful state purchases of Project Office 5-100-2020 include expensive flights, increased prices, double payments to contractors and contractors' employees - these facts suggest inefficient usage of the budget funds.

Thus, the carried out cost analysis gives evidence of the ineffectiveness and wastefulness of Project Office 5-100-2020.

Discussion

The obtained results can be used as a tool to assess educational activity funding. It can be applied in a complex effectiveness assessment, namely: in terms of necessity, in terms of performance to plan, in terms of costs, comparative assessment. The conducted assessments make it possible to define the range of problems in the sphere of education which prevent universities from developing at the international level.

Summary

When analyzing the effectiveness of the project a number of problems have been revealed. They do not allow the project to achieve the goal which was set earlier, namely:

1) regulative and legislative provision insufficiency of the Project 5-100.
It is necessary to draw up a standard form "Agreement on subsidy provision to universities for a certain period". Thanks to such a form it will be possible to make the Project 5-100-2020 university funding mechanism consistent and substantiate the given distribution of resources. It should be noted that this agreement for the universities which participated in obtaining subsidies as part of Project 5-100-2020 should consider previous outcomes of their financing. Given this aspect, for example, it can be found out that in the period 2013-2015, NRU "Higher School of Economics" was given subsidies in the amount of 2472.4 m rubles, but only rose in the QS ranking by 1 position. This fact gives evidence that the allocated funds are used inefficiently;

2) Insufficient substantiation of costs at the level of universities and weak mechanisms for cost control, no reference to results. So that a university could climb one position in the QS rankings, it needs 37 m rubles on average. It is suggested that costs should be strictly controlled and depositing mechanisms should be foreseen.

2) inconsistent and unrealistic goal-setting in the context of Project 5-100-2020
In case the QS ranking method and other conditions remain the same, about 26 universities will be included in the ranking by 2020. It has been more than 4 years since 2013 and so far no Russian university occupies a position in the top-100 of the rankings. Moscow State University, having the 108th position, is the best in the rankings. In terms of the revealed problem, some measures can be proposed to revise the set goals and objectives for this program. This aspect is related to the fact that on the basis of the forecast it is virtually impossible for Russian universities to achieve the top-100 in the rankings. So it is suggested not concentrating on funding the advancement of Russian universities in the rankings but instead on obtaining the so-called "QS stars", which reflect the degree of students' satisfaction with the quality of educational services, in particular, the quality of teaching.

4) comparative analysis revealed imbalance in the development of Russian universities by key indicators.
Actually Russian universities get into the QS rankings thanks to only one indicator – "Faculty/student ratio". This criterion has 20% share in calculation of the ranking. The criterion "Academic reputation", which accounts for 40% in the QS rankings, is 6.5 for Russian universities on average. Such criteria as "Citations per faculty" and "International faculty", which altogether amount to a quarter of the specific weight in the rankings, equal to 0.

5) inefficient and wasteful purchasing activity of Project Office 5-100-2020.
In order to exclude doubtful purchases, the following restrictions can be suggested:
– purchases made by Project Office 5-100-2020 should be correlated with the targets of the Project;

– the control process over purchases made by the Project Office must be toughened.

Thus, implementation of these measures will allow the best Russian universities to grow in the international rankings. However, it should be noted that the problem of university competitiveness on the international market is important not only for Russia, but also for the majority of European countries. This fact makes it possible to conclude that every year competition on the educational market will become fiercer, which will further complicate the advancement of Russian universities to the leading positions in the international rankings.

Moderation of problem-focused teams

Barbara Wasilewska, Opole University of Technology, Poland, b.wasilewska@po.opole.pl

Abstract

The aim of this article is to introduce the reader to the subject of moderating employee meetings in companies. The key rules for conducting such meetings are provided. The article also gives an example of the moderation of a problem-based team dealing with industrial practices. This case study is based on a number of methods that stimulate creativity.

Keywords: moderating, team, creativity, case study.

Introduction

The effective moderation of a team is beneficial to all the cooperating parties. An appropriate moderation can encourage innovative solutions, motivate the employees to undertake actions and develop their skills, and allow the team's work to be planned. A moderator should therefore be carefully selected to suit a given problem within a company. Moderators are frequently experts (advisers) in their fields. Their main tasks include:

- Directing the discussion;
- Ensuring that the meeting progresses correctly;
- Using creative competences (knowledge, skills and attitudes);
- Providing the necessary tools, methods, techniques and procedures.

Whether or not the moderator will be selected from within the company or hired externally depends on the additional requirements and needs related to the problem at hand, i.e. the complexity of the problem, the need for objectivity, duration of the meeting, particular talents, etc. A creative session that is conducted with a team that has a changing composition should be moderated by an externally-hired moderator; whereas a team with a permanent composition should usually be moderated by an internal employee.

A problem-focused team generally consists of 5–12 employees from the same department who meet for a few hours every week in order to discuss ways to increase the quality and efficiency of their work and improve their working conditions (Mulvey, Veiga, Elsass, 1996; Shonk, 1992; Verespej, 1992). Problem-based teams are one of the five most common types of working teams in companies (Robbins, DeCenzo, 2002). Figure 1 shows a problem-focused team in which all the members are asked to address a problem by sharing ideas and suggesting improvements.

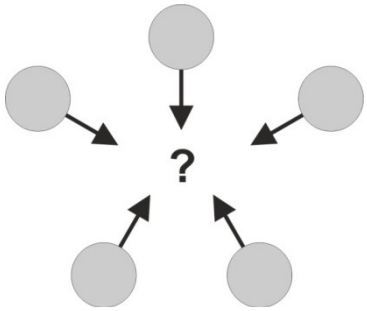

Fig. 1. Problem-focused team

To a large extent, the moderation can be planned in advance. However, the proceedings that occur prior to the actual moderation are vitally important. Before the planned meeting, its procedures should be agreed upon. The moderator should take into account all the reported expectations related to the problem and the arrangements regarding his or her role, and then adjust his or her own tools and methods accordingly. This will position the moderator within the dimensions of the problem in such a way that the team can focus on addressing the crux of the problem, while the moderator takes care of the meeting procedures. In a similar vein, in a study (Chybicka, 2006) that addressed the issue of directing the team-thinking process, the author translated exercises that would prepare the employees for creative work, group norms and creative thinking techniques into theoretical constructs, and described the effect of these constructs on a person's cognitive structure. Appropriately selected working techniques will frequently determine the successfulness of a team meeting, strategic workshop, decision-making session and a problem-solving session (Heidtman, Piasecki, 2017). The case study presented in this article was conducted by an external moderator who specialises in communication tools and methods for creative problem solving. The types of teams that have been moderated to date include (Karlińska, Knosala, 2013; Wasilewska, Knosala, 2014a; Wasilewska, Knosala, 2014b):

- Mixed teams composed of the representatives of different departments that were affected by the problem;
- Project-focused teams;
- Synectics teams.

It has been established that every type of team mentioned above requires different skills, knowledge and methods. This shows that the task of the moderator is specific to each case; although on the other hand, the basic stages of the employee meetings remain unchanged.

1. Stages of the moderation of a problem-focused team

Every process of the moderation can be divided into several common stages (CEO, 2012):
Starting phase (a discussion is initiated):

- The subject and schedule of the meeting is explained;
- Conditions are created for the participants to become familiar with one another (getting to know one another's role in the company);
- A method that will motivate the team to undertake an action is proposed.

Discussion development phase consisting of:

- Displays of interest;
- Free exchanges of opinions;
- Monitoring of the schedule and main subject;
- Paraphrasing of tasks and questions.

Ending phase (summary):

- A decision to conclude the discussion is made;
- Feedback is provided;
- Thanking one's fellow participants and goodbyes.

At every stage of the moderation, communication tools are used to motivate silent or unengaged persons to speak up. The questions should sometimes be directed to a specific person, and at other times to the entire group. The moderator can also use his or her tone of voice and gestures to direct the group's attention to key information and subjects.

The basic stages of the moderation involve the moderator's communication skills. Next, the tools and methods to be used for working with the team should be established. This comes before the main stage of the moderation. For example, in the studied moderation, the company had the following expectations in this regard:

- Workshops should be conducted that would improve the team's effectiveness (i.e. their cooperation and mutual expectations), and that would establish the roles within the team (each employee's role and the relationship between the employee and his/her department);
- Responsibilities should be established with respect to three ongoing projects, including: the owner of the recipe, the team's participation in the manufacturing tests (requiring at least three inspections), and the scope of the duties and their effectiveness;
- Support in determining the manufacturing capacity of the company with regard to the market and in determining the employees' attitudes toward the client;
- A formal framework for cooperation within the new team should be established.

The company and the moderator agreed that the moderator would:

- Organise a meeting and define its aim and working style;
- Prepare methods for stimulating the team's creativity;
- Initiate the discussion (control the group dynamics);
- Ensure the correct interactions;
- Provide further motivation during any impasse;
- Conduct an analysis and summary.

2. Example of a team moderation

The example provided in this article concerns the moderation of a team built up from two departments: the Product Development Department (PD) and the Manufacturing Department (C2). Previously, both departments worked independently from each other, and the moderated meeting was to constitute the first stage of building a permanent team. The tasks were undertaken during a meeting between the employees of a company that was responsible for manufacturing baby and child foods, and involved determining the capacity of the production line and developing a method for the cooperation between the departments. Methods that would support the moderation were suggested alongside these tasks. The representatives of each department were informed about the structure of the meeting, and a total of 11 persons worked on the tasks.

2.1. Task 1: Determine the possibilities of the production line

The moderator divided this task into three parts: overview of the production line structure; overview of its possibilities; and suggestions for changes. Table 1 describes the methods applied in the context of the problem.

Who: The Product Development Department (PD) and Manufacturing Department (C2).
Task 1: Determine the possibilities of the production line.

Suggested methods:

1. Establishing the structure of the production line: Terminology base (terminology map) (Buzan, 2005).

***2. Possibilities*:**

- Semantic analysis (Antoszkiewicz, 1992),
- Six Thinking Hats (de Bono, 1990),
- Crushing (Antoszkiewicz, 1992).

3. Changes:

- Creative assessment (Proctor, 2010),
- Generative Metaphor (Nęcka, 1994).

Table 1. Stages of the moderation and the methods applied

Stage of the moderation	Methods applied
Establishing the production line structure	Terminology base (terminology map): Do all members of the double-department team understand the problem in the same way? Is the terminology related to the process comprehensible?
Possibilities	Semantic analysis: The meanings of words are analysed to deepen the understanding of many complex problems or to discover a surprising relationship between the objects and problems or sub-problems. Six Thinking Hats method: The method involves using six different modes of thinking, which allows everyone to become familiar with various points of view and changes the team's outlook. Crushing: The team looks for disadvantages and solutions to each problem. This allows the team to establish what they know, what information they are missing, and who to ask for support (e.g. an expert or a layperson).
Changes	Creative assessment: The ideas are assessed according to the two criteria of finances and time. Generative Metaphor: A metaphor is established that will motivate the team to search for solutions.

Suggestions for solutions and the course of those solutions

Thanks to the application of the terminology base, the team was able to delineate the structure of the production line, define the most important terms and determine the crucial relationships

between those terms. This knowledge was shared by the workers in C2 and was complemented by the PD with an inventory overview. Next, the meaning of the word *possibility* was considered through a semantic analysis. The following synonyms were proposed: perspective, eventuality, opportunity, ability and permissibility. Thus, *possibility* was found to have many different meanings. However, exploring these meanings enabled a discussion about what eventualities the team could expect, whether the team was looking for innovations or minor improvements, what would be permissible and what the team was capable of. The team evaluated the production possibilities as extensive, which allowed for a greater degree of experimentation. Some of the team members suggested minor improvements, such as cleaning the machines in the middle of the week rather than once a week. Other team members suggested innovations, such as removing the mesh from a roller which would allow the facility to be used for the manufacturing of fragile products. In the terms of the permissibility, the team indicated an increase in the microbiological requirements as an issue to be addressed.

Subsequently, the Six Thinking Hats method was used to explore the different perspectives among the team. The team considered how the facility's manufacturing potential could be used to create benefits for the clients. The order in which the hats were 'put on' was not pre-established: anyone who wanted to speak up could choose any hat they wanted. The red hat, which was designated as the emotional hat that involved a dominance of feelings and moods, was the most popular one. The team shared their feelings, as well as anecdotes from their friends and clients, to indicate the needs that the products should satisfy. New ideas included:

- Quick meals for two (a mother and child);
- Anti-colic baby grits with a maximally simple composition;
- A stage-based line for women (pregnancy – breastfeeding – return to pre-pregnancy condition);
- A fitness series for adults who are engaged in sport and intense training.

In addition, the team drew attention to the choice of product packaging (small size, quick to open), the additions (spices) and the colouring (themed after the seasons of the year). The team moved on to the Crushing method without any major setbacks. Flaws in the products' quality, technology and design were analysed. The aim of this analysis was to adjust the focus of the team to the ideas that would potentially be implemented. The last method, a creative assessment, allowed the team to evaluate their ideas in terms of the financial and time requirements. Figure 2 shows the agreed-upon courses of action. It was decided that the company would forgo simple, quick solutions in favour of those ideas that are time-consuming and expensive but that have greater potential and a better chance to stand out against the competition. This decision agreed with the existing trends for health-promoting products and the increased client expectations and knowledge.

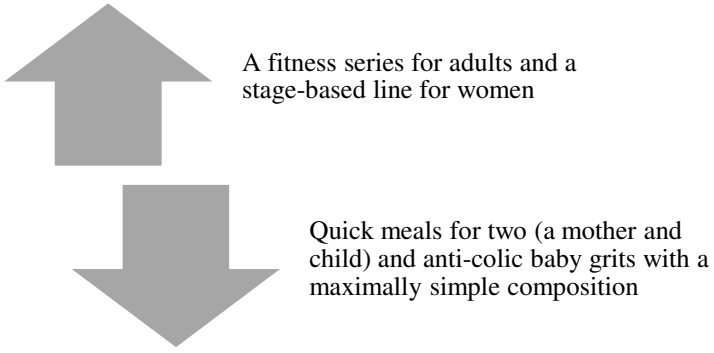

Fig. 2. Choosing ideas using the creative assessment method

The Generative Metaphor method used the metaphors of the military, education and health to promote the ideas for changes. The team indicated a number of aspects that were important for the company. The team also confirmed that the metaphors coincided with their corporate culture in terms of its rigorous procedures (military), its promotion of health education among the clients (education) and its selection of suppliers based on the company's quality policy (health).

2.2. Task 2: Determine the mode of cooperation between the two departments

The second part of the moderated creative session was divided into three parts: the mode; the actions to be undertaken; and the additional support tools. Table 2 shows an overview of the methods applied in the context of the analysed problem.
Who: PD and C2.
Task 2: Determine the mode of the cooperation between PD and C2.

Suggested methods:

1. ***Mode:***
   - Semantic analysis (Antoszkiewicz, 1992),
   - Purge (Nęcka, 1994),
   - Disney method (Noelke, 2008),
   - ALoU (Gawlik, 2001).

2. ***Actions:*** Six Shoes (de Bono, 1991).

3. ***Additional support tools:***
   - Provocation (de Bono, 2014).
   - Identification with an object (Nęcka, 1994): creative roles, i.e. the artist, the scholar and the jester;
   - Re-establishment technique (Kaufmann, Fustier and Drevet, 1975).

Table 2. Stages of the moderation and the methods applied in Task 2

Stage of moderation	Methods applied
Mode	Semantic analysis: Do all members of the double-department team understand the problem in the same way? Is the terminology related to the process comprehensible?
	Purge: Immediate ideas are discarded and the atmosphere among the employees is 'purged'.
	Disney method: Playing three different roles according to your own expectations.
	ALoU: Focus is put on the unique features of the team.
Actions	Six Shoes: Actions are chosen that are dominant in terms of the task at hand.
Additional support tools	Provocation: Theories are disputed on purpose, and situations are created that force the team to re-think the problem.
	Identification with an object: A particular role is assumed and the feelings related to it are expressed.
	Re-establishment technique: Familiar elements are reorganised without inducing changes to the functioning of the system.

Suggestions for solutions and the course of those solutions

The repeated use of a semantic analysis motivated the team to think about the meaning of the word *mode*. The following synonyms were suggested: method, algorithm, tactics and strategy. The team concluded that they needed something that would resemble an algorithm for their future course of action, i.e. they needed some permanent aspects of their cooperation. At the same time, they needed to establish different tactics so that the two departments could perform their roles together. The Purge method was used in order to allow the cooperation to begin *de novo*. Every team member criticised the previous, imperfect, relationship between the two departments and talked about ideas that could harm the cooperation. The aim of the method was to purify the atmosphere and to allow the team to be built afresh.

Next, the Disney method was used: every team member took turns assuming the role of a dreamer, a realist and a critic in order to find a mode of cooperation on their own. In this way, every participant was able to think about what they expected from the team. The Disney method helped to establish that the team members had similar needs, which was met with a great deal of surprise, as the employees had expected an argument or conflict between parties. Following this stage, the team was able to focus on three issues: the advantages of a team; the limitations of a

team and the methods for overcoming them; and the unique features (ALoU). The strengths of the cooperation were determined, where the advantages included the fact that every team member possessed different types of knowledge. However, the limitations included the time that needed to be dedicated for such meetings. The unique features (i.e. the features that made this particular team stand out among other teams) included the idea of combining departments that, at the time, had been working independently from each other, and that had viewed the same products manufactured by their company differently.

The discussion about the modes of cooperation allowed the team to develop a joint plan of action. Out of the types of shoes available in the Six Shoes method, the team chose grey sneakers and pink slippers, which helped them to establish particular guidelines. The team decided to show caring and understanding towards the members of the other department (indicated by the pink slippers), and to support each other, especially when one party lacks the knowledge about a particular scope of duties; but also to require the immediate execution of tasks, respect for each other's time and to avoid being overly demanding. Furthermore, the team decided that they would all come to the meetings prepared and (in accordance with the grey sneakers) they would gather objective information, hypotheses and theories as a preamble for their joint work.

These arrangements were complemented with additional support tools that the moderator found to be worthwhile for the completion of the task at hand. The Provocation method involved a team member who volunteered to assume the role of a provoker, i.e. someone who stimulates the team to view problems from an unusual perspective. From this point on, the same person would continue to play the provoker in any future meetings. The second support tool involved the identification with an object. The team members were asked to assume the following creative roles: an artist, a scholar or a jester. Every team member tried to establish which role suited them the most. The method was also practised through the identification of a client with a particular role. For instance, the moderator asked the team how they would interact with a client who was an artist, and what such a client would pay most attention to when buying the company's products, etc. The team suggested that the artist would not care about the price of the product, but would be more concerned about the design of the packaging. In turn, the scholar would be an educated client who makes informed decisions when buying products; while the jester would expect entertainment, gadgets and the joy that comes from having particular products. The final support tool was the re-establishment technique, which constituted a summary of the meeting. The arrangements from the meeting were written on a flip chart where both departments had to agree with every point that was written, and afterwards, each individual team member signed the flip chart. As a result, the team decided that the following re-organisation measures were required:

- A full understanding between both departments (with respect and no attempts at manipulation);
- Future 'trips' of the PD to the production hall to see the production process with their own eyes, and future trips of the C2 to the PD's design office to become familiar with their working methodology;
- Mandatory, systematic training covering the remit of the other department (to the extent required to complete a given task);
- Regular meetings;
- Coming to meetings prepared.

Thus, the problem-based team also became an interdisciplinary team. All that was left to do at this point before the arrangements for the cooperation could be implemented was to arrange the next meeting.

3. Summary

The aim of this article was to show how moderation works in practice. The moderating of employee meetings in companies requires both information and organisation. The tasks that were undertaken during the meeting used as an example concerned the possibilities of developing the company's production line and the development of a mode of cooperation between two departments. In this case, all of the parties found the moderated meeting to be satisfactory. In order to assess such a meeting, it worth considering the perspective of both the moderator and the participants. Other important considerations include the atmosphere among the employees and how the employees handle unexpected situations. Seifert (2009) lists three limitations that will affect the final results of a meeting: physical constraints, the group's efficiency, and the traits of the participants. The results may also be determined by a moderator who is equipped with the means to activate the group, such as asking the appropriate questions, applying reinforcements and signalling the transitions between the different stages (Łasiński, 2007). As various authors have pointed out (Seifert, 2009; Lenzen, 1999), skilful moderation over teams allows for the building of self-learning organisations. This indicates that moderation is a highly valuable process and is one that is needed in companies.

hefin.rowlands@southwales.ac.uk

Abstract.

Thirty years since the Brundtland Report put sustainable development firmly on the global political agenda, three of the nine planetary boundaries which represent a safe operating space for humanity have been transgressed through anthropogenic activity (Rockstrom, 2009). While today's global supply chains represent key arenas for environmental degradation, they also represent a field of opportunity for the achievement of sustainability. Thus, it is encouraging to see that a field of 'sustainable supply chain' (SSC) scholarship is experiencing geometric growth (Fahimnia et al, 2015). However, some have recently suggested that dominant assumptions within SSC scholarship have led to the prioritisation of economic goals over environmental or social protection, leading to a focus on managing supply chains to do 'less bad', rather than do 'more good' (Markman and Krause, 2016). Considering the reality of ecological transgressions and its social implications, this is no longer sufficient. Calls are therefore being heard for the need to 'think differently' about supply chains so that they may effectively contribute to the pressing goals of sustainable development. This working paper responds to those calls. It aims to propose the value of the metaphor perspective for: 1) helping to further explicate the problem, and 2) addressing the problem.

Keywords: Sustainability, Sustainable supply chain, Metaphor.

Introduction.

'It is difficult…to walk by a newsstand without seeing at least one magazine cover featuring alternative sources of energy, climate change issues or the iconic polar bear floating on a thin sheet of ice' (Carter and Easton, 2011, p.46).

The words of Carter and Easton (2011, above) paint a vivid picture of the place of 'sustainability' in twenty-first century society. Popular statements of anthropogenic impacts on the natural environment – such as global warming caused by industrial pollution or the destruction of natural habitats due to intense timber logging (Lele, 2013) - underpin a call for environmental protection that few now dispute.

Sustainability has therefore become an almost ubiquitous concept that permeates aspects of social, political and economic life (Redclift, 2005). It is most often characterised by reference to the 1987 report of the World Commission on Environment and Development, colloquially known as the Brundtland Report (WCED, 1987), which remains the most often cited source on the topic (Quental, 2011)[i]. It defined sustainable development as 'development which meets the needs of the present without compromising the ability of future generations to meet their needs' (WCED, 1987, p.8) and has been praised for having placed recognition of the dependencies between environmental and socio-economic issues on the global political agenda (Sneddon et al, 2008).

However, 2017 marks the 30th anniversary of the Brundtland Report's publication and despite widespread acceptance of the issues, alongside profound advancement regarding knowledge and technological capabilities (Lele, 2013), natural scientists have suggested that the environmental crisis is actually worsening (Rockstrom, 2009). A Swedish study has suggested that the safe operating limits of three of nine key environmental systems – relating to carbon dioxide, biodiversity loss and the nitrogen cycle - have already been transgressed (Rockstrom, 2009). The challenge of sustainable development therefore remains firmly atop the academic research agenda across multiple disciplines, from the natural to the social sciences.

Sustainable supply chain management (SSCM) has thus emerged as an important field of research. The effects of globalisation have interacted with management trends towards vertical disintegration leading to long and complex inter-organisational chains of supply and demand (Chen and Paulraj, 2004). Matthews et al (2016) have articulated the important place of supply chain management in sustainable development research highlighting that while supply chains. On the one hand they play a significant role in environmental degradation due to for example, the impact on carbon emissions of transport or network design decisions (Carter and Rogers, 2008). On the other hand, they also represent great opportunity for achieving the change required for sustainable development, for example by the responsible exploitation of power by supply chain leaders to instigate change within expansive and globe-spanning networks of organisations. However, the authors also suggest that dominant trends within sustainable supply chain scholarship have failed to provide adequate theoretical explanation for how supply chains can contribute to the challenge of 'returning the political-economic system from a state of ecological overshoot' (Matthews et al, 2016, p.83).

In this context, the present working paper sits at the juncture of sustainable supply chain scholarship and the metaphor perspective. It aims to propose the value of the metaphor perspective as a means by which to firstly, explicate and secondly, address the problems recently identified by SSCM scholars – a proposition, which to the author's knowledge has not previously been offered. In order to achieve the aim of this paper, the paper will first articulate the broad 'problem' in terms of key, reflexive SSCM literature through which issues have been highlighted. Secondly, it will introduce and defend the relevance of the metaphor perspective as a source of explication of the problem through exposing metaphoric enablers, as well as a potential solution through its facilitation of 'disciplined imagination' (Weick, 1989) for a new theory of sustainable supply chain.

The 'problem'.

The notion that environmental and social imperatives are not at odds with traditional economic goals of the firm has arguably been an important driver in the acceptance and continued pursuit of sustainable supply chain management (SSCM) practices (Walker and Jones, 2012). The logic of cost reductions associated with environmentally and socially responsible behaviour (such as reduced waste or reduced number of employee sick days) is longstanding in nineteenth and twentieth century industrial discourse (Desrochers, 2009). Porter and van der Linde (1995) suggested that the productive use of resources (physical or human) is essential for competitiveness in the modern context of globalisation and for environmental progress in a world of rapidly expanding population. Porter and Kramer (2011) have promoted a concept of 'shared value', contending that corporations should not consider sustainability issues an add-on to day-to-day business pursuits, but rather as a strategic opportunity for building business models around essential solutions to society's problems thus assuring competitive advantage. Illustrating this perspective in SSCM literature, Carter and Rogers (2008) used Elkington's (1994) triple bottom line conceptualisation of corporate sustainability as the foundation for their conceptual framework for SSCM. In their framework, sustainable supply chain activities sit at the intersection of three equally sized circles (representing each of the three dimensions) on the assumption that sustainability in the supply chain similarly constitutes win-win-win[ii] solutions (FIG 1). Shrivastava (2007, p.54) perhaps

crystallised the argument in declaring that sustainability 'is not just about being environmentally friendly; it is about good business sense and higher profits.'

Criticism of such win-win framing of sustainability in supply chain management however is beginning to emerge. While such framing assumes a theoretical balance between each of the three dimensions of sustainability, the practical reality of essential trade-offs between environmental, social and economic performance has been seen to have led to the prioritisation of economic over the environmental or social dimensions (Montabon et al, 2016; Markman and Krause, 2016). This suggestion may be seen reflected in wider observations of trends within SSC research output, such as the predominant concern with the question of whether or not sustainability 'pays' (Golicic and Smith, 2013), the proportional attention given to researching the environmental dimension (which may be seen as presenting more measurable economic benefits) over the social dimension of sustainable supply chain (Ashby et al, 2012), alongside Carter and Rogers' (2008) explicit questioning of the value of activities which do not explicitly address economic supply chain goals. The three ring model which intersects three circles representing the three dimensions offers a diagrammatic depiction of this win-win framing has thus received much criticism (Giddings et al, 2002; Griggs, 2013; Montabon et al, 2016) (FIG 1)

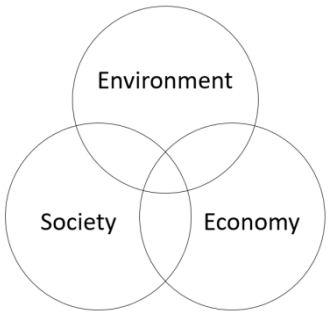

FIG 1. Common three ring model of sustainability.

To some minds, such win-win framing have led scholars and practitioners to seek mere amendments to supply chain management so as to do less harm (to be less unsustainable) rather than to do good (to be truly sustainable) (Pagell and Wu, 2009; Markman and Krause, 2016). This is reflected in Pagell and Wu's (2009) observation of a tendency to explore how existing supply chain 'best practice' can serve sustainability requirements. For example, studies have suggested that existing practises such as lean and total quality management (TQM) are congruent with the aims of sustainability because they endorse orientations towards more effective use of natural resources through the elimination of waste in supply chain processes (Simpson and Power, 2005; Dues et al, 2013). While this may be pragmatically considered as 'better than nothing', Pagell and Wu (2009) ultimately concur with Markman and Krause (2016) in suggesting that it does not prioritise the sustainability goal of environmental improvement to the extent of reversing significant ecological transgressions which currently risk the safety of future generations (Matthews et al, 2016). Pagell and Wu (2009, p.39) even suggest that such efforts towards win-win activity promote incremental improvement which may actually delay or prevent the more radical change that is required to become 'truly' sustainable. Indeed, Pagell et al (2010) have explored the suggestion that truly sustainable supply chain practise requires a fundamental reconceptualization of traditional supply chain practises. They showed that Kraljic's well-known portfolio matrix may in fact need re-thinking in a sustainability context. Reflecting wider disciplinary perspectives (e.g. Barbier, 1987) there is thus a growing acceptance within SSC discourse that trade-offs are an inevitable and essential feature of sustainability and therefore must be accommodated within supply chain management theory.

Common amongst these authors' reflections on the suitability of existing supply chain management practices and assumptions is the need to think differently about supply chains and their management (Pagell et al, 2010; Pagell and Shevchenko, 2014) in a way which puts ecological performance front and centre in supply chain scholarship (Markman and Krause, 2016; Matthews et al, 2016). Reflecting longstanding observations in organisational management and sustainable development research (Shrivastava, 1994, 1998; Gladwin et al, 1995; Daly 1996), Montabon et al (2016) have called for the replacement of the economically dominant logic in supply chain research with an ecologically dominant logic which prioritises ecological health over what is good for the firm or chain. Markman and Krause (2016, p.4) similarly conceptualised a new definition of 'sustainable practices' to prioritise the three dimensions 'whereby the environment comes first, society second, and economics third.' Montabon et al (2016) provided an example of a lighting fixture manufacturer which made the decision to source a particular component of their product – basic metal stampings which required low skill and simple equipment and thus could be sourced cheaply from overseas – in the high wage setting of the United States supply market because they prioritised the risk to the environment over the cost of their production. Such an approach has therefore been reflected in an alternative diagram of three nested circles which foregounds the environment by embedding the economic dimension within society, which is subsequently embedded within, and ultimately dependent upon, the natural environment (Giddings et al, 2002; Montabon et al, 2016) (FIG 2).

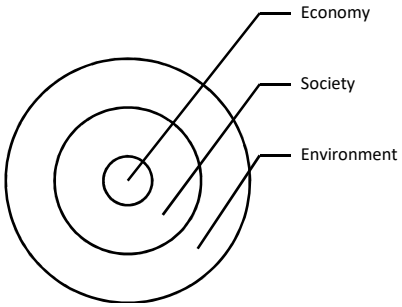

FIG 2. Nested model of sustainability.

Taking the words of Gladwin et al (1995, p.899), recent SSC literature seems to suggest that the problem for future SSC scholarship is the achievement of a 'new mind' among supply chain scholars and practitioners which is 'appropriate for a sustainable world': a new mind which accepts SSCM as more than simply a sub-set of SCM (Pagell and Shevchenko, 2014); which puts the natural environment at the top of the list of stakeholders (Montabon et al, 2016; Markman and Krause, 2016) and which seeks an answer for how supply chains can protect the environment for future generations (Matthews et al, 2016). Suggestions for achieving the change required have included calls for the adoption of alternative theoretical lenses (Touboulic and Walker, 2015) beyond the traditional sites of theoretical adoption such as economics. Matthews et al (2016) therefore proposes paradox theory as a means by which to address the tensions and complexity that are inherent within the essentially contested concept of sustainability (Connelly, 2007). However, the present author proposes that the achievement of a 'new mind' for SSC scholars must recognise the fundamentally constitutive nature of language in social construction, and therefore supply chain thought and action (Alvesson and Karremann, 2000).

A 'solution'? Proposing the metaphor perspective.

Popularly understood as stylistic devices, metaphors are more commonly associated with the work of Shakespeare than of scientists. Pinder and Bourgeois (1982) argued that if 'science' is about developing an accurate and literal description of physical reality, then what place is there for such figurative language

as metaphor (Grant and Oswick, 1996)? For educationalists, such a place for metaphor has been secured in terms of metaphor's ability to aid understanding of a relatively unfamiliar concept (in metaphoric terms, the target domain) through its comparison with a more familiar one (the source domain) - to compare an atom to a solar system is a classic example of the enlightening function of metaphor for students who are new to the field of physical sciences (Inns, 2002). 'Supply chain' and 'sustainability' may similarly be considered complex, intangible concepts which have benefitted from metaphorical explanation. In supply chain literature, the drum-and-rope buffer metaphor has been used to illustrate the abstract theory of constraints (Goldratt and Cox, 1984) and Earth as a greenhouse is a popular metaphor which illustrates the scientific principles of global warming (Romaine, 1996).

However, in recent decades, organisational and management studies' adoption of metaphor has reflected a theoretical perspective on the metaphorical nature of the human conceptual system (Lakoff and Johnson, 1980; Lakoff, 1993). In their seminal work, Lakoff and Johnson (1980) argued that our everyday behaviour reflects our metaphorical understanding of experience. More than simply a useful tool for education or a literary flutter, metaphors in fact shape and frame our thoughts and action (Lakoff and Johnson, 1980). Adopted within organisational studies by Gareth Morgan (1980, 1986), Morgan (1986) highlighted the paradoxical, liberating and dangerous nature of metaphor in organisational studies: offering a way of both 'seeing' and 'not seeing', they have the effect of both constraining and liberating new perspectives on organisational management (Jermier and Forbes, 2012).

In light of the multi-faceted nature of metaphor and the challenges in SSC scholarship outlined above, the author therefore proposes a metaphor perspective to firstly, further explicate the 'problem' through investigating the metaphoric enablers of such dominant SSC assumptions, and secondly, addressing the problem in terms of its potential for liberating new theoretical perspectives through new metaphors for sustainable supply chains. These propositions will be elaborated upon in turn.

Metaphors we die by.

Schoeneborn et al (2012) observe the irony of metaphor: it is the utility and success of metaphor in aiding comprehension of complex concepts that leads to their status as 'metaphors we live by' (Lakoff and Johnson, 1980), that is, metaphors which have become taken-for-granted as literal descriptions of concrete things. Organisational concepts such as 'customer' and 'market', 'teams' and 'strategy' have themselves become terms that are now used literally with little (if any) conscious recognition of their metaphorical origins (Peattie, 2004, Tsoukas, 1991) – they have become 'dead' metaphors. While some authors see dead metaphors simply as irrelevant, having lost their heuristic value (Black, 1979; Schoeneborn et al, 2016), others interpret deadness as dangerous normalisation that leads to false consciousness and the legitimation of certain actions over others (Tietze et al, 2003). The pervasiveness of the 'organisation as machine' and 'organisation as organism' metaphors are important examples in this regard. Despite Morgan (1986) famously proposing six alternative metaphors for organisation, Cornelissen (2005) found that organism and machine remain the dominant root metaphors in organisational science. Morgan (2006, p.13) thus decried the tenacity and familiarity of these metaphors as having now become taken for granted as second nature.

For the prospects of sustainability, this has been a cause for concern. A number of studies have suggested that such metaphors are incongruent with the requirements of sustainable development (Barter and Russell, 2013; Audebrand, 2010). Barter and Russell (2013) argue organism and machine metaphors for organisation have had the effect of de-humanising the biological creatures (humans) of which organisations are composed. Through these metaphors, humans have become mere functional components of the organisation, perpetuating an orgocentric view which, they argue, is fundamentally at odds with the interweaving of nature and humanity represented by sustainable development. Similarly, in the context of strategic management education, Audebrand (2010) argued that the requirements of sustainable development necessitated a re-appraisal of the root metaphor of 'strategy is war'. As a source

domain through which students reason about strategy, war prioritises adversarial relationships that undermine the collaboration required for sustainability.

Given the simultaneously damaging and protecting potential of global supply chains, there is considered value in critically reflecting on the metaphors that are currently used to reason about supply chains, supply chain management and sustainability. This is considered congruent with recent empirical and conceptual work which has suggested that traditional notions of power in supply chains are increasingly unsustainable (e.g. Pagell and Wu, 2009; Pagell et al 2010; New, 2015). The metaphor perspective may therefore help to further deconstruct embedded assumptions and expose metaphoric enablers of such assumptions (Inns, 2002). It is considered valuable to ask, what are the key metaphors through which scholars reason about supply chains and sustainability? And, what effect do such metaphors have on supply chain approaches to sustainable development? SSC scholars have suggested existing supply chain theory based on dominant win-win assumptions have failed to explain how sustainable SCM leads to the environmental improvement required for sustainable development. On the basis of the metaphor perspective therefore, it may be argued that if we don't change the supply chain metaphors we live by, they may well become the metaphors we die by (Norgaard, 1995; Romaine, 1996).

Metaphors we live by.

If the metaphor perspective supports a critical evaluation of the metaphors that are currently used to reason about supply chain in the context of sustainable development, it paradoxically also offers potential for liberating new perspectives on supply chain that may be more appropriate for the task of achieving sustainability. Through applying novel source domains to established target domains (such as supply chain), live metaphors are tools for what Morgan (1986) calls imaginization– creative thinking that can lead to theory-building. For example, since the publication of Morgan's seminal work, an extensive list of suggestions of alternative metaphors for organisation have been proposed within multivariate efforts at theory building. Organisations have been explored as spider plants, clouds and songs, and theatre (Tietze et al, 2003). More recently, Schoeneborn et al (2012) proposed the metaphor of insomnia to better explain inadequacies in organisational learning.

Akin to their educational value in making an unfamiliar concept more familiar to a student new to the field, so too can a new metaphor help a seasoned supply chain researcher see the supply chain from a 'different angle' (Inns, 2002). In this regard, organisational science has emphasised the potential of metaphor for facilitating 'disciplined imagination' (Weick, 1989) for the purposes of theory development (Cornelissen, 2005, 2006). Therefore according to Grant and Oswick (1996), the perspective of Pinder and Bourgeois (1982) which argued the need to 'purge' metaphor from scientific discourse simply reflect a non-constructivist perspective which prioritises theory testing over theory development. Weick's (1989) perspective meanwhile asserts that there is a greater chance of higher quality theory to emerge from a theorising process which begins with greater variety.

Foropon and McLachlin (2016) and Chen et al (2013) support the potential of theory-constitutive metaphors within the supply chain field, however, it has not yet been suggested in the context of SSC scholarship. Matthews et al (2016) have called for a conscious process-approach to theorising in SSC scholarship to develop normative as well as explanatory theory. It is proposed that the experimentation potential offered by metaphor (albeit accompanied by rigorous expectations of robustness that have been well discussed elsewhere e.g. Cornelissen, 2006) supports the charge for creatively considering how supply chains *should be* managed, instead of simply reflecting (and potentially artificially legitimating) ways in which supply chains currently are managed for sustainability (Matthews et al, 2016). This may be considered particularly pertinent in light of critical perspectives which emphasise corporate misappropriation of sustainability concepts for corporate gain (Springett, 2013; Milne et al, 2016). The challenge of achieving sustainable development may be encouraged by the opportunity to search for new

metaphors for supply chains which protect the environment for present and future generations and not just the economic performance of the chain – that is, metaphors we can in fact live by (Romaine, 1996).

Conclusion

The aim of the paper was to propose the value of the metaphor perspective as a means by which to explicate and address the problems recently identified in SSC scholarship. These problems relate to the dominance of particular economically dominant assumptions about supply chain and sustainability which are considered inadequate for the requirements of sustainable development. On the basis of the metaphorical nature of reasoning, it has been proposed that systematic analysis of the metaphors through which scholars reason about supply chain might help to deconstruct embedded assumptions in SSC scholarship by exposing their metaphoric enablers. Secondly, it has also been proposed that alongside its use in organisational and supply chain literature, the metaphor perspective constitutes a valuable approach to experimenting with new metaphors as a precursor to new theory for sustainable supply chains and their management.

[i] There are protracted debates on the relative uses and critical implications of the terms 'sustainability' and 'sustainable development' (see for example, Banerjee, 2003) however this is considered secondary for present purposes and the terms are therefore here used synonymously.

[ii] 'Win-win-win' solutions will henceforth be referred to as 'win-win' for brevity.

Public Catering Trends in Russia: The Case of a Megalopolis

Elena Ivanovna Sherbakova, South Ural State University, Chelyabinsk, Russian Federation, steklelena74@gmail.com

Abduvali Djabarovich Toshev, South Ural State University, Chelyabinsk, Russian Federation, toshevad@susu.ru

Anastasia Andreevna Rushchitc, South Ural State University, Chelyabinsk, Russian Federation, asuta80@gmail.com

Abstract

The article aims to review and analyze the state of public catering market as illustrated by the example of Chelyabinsk. Our study was based on the following methods: data gathering and analysis of secondary data; system analysis, statistical method, and method of comparison.We presented data on the development of the public catering network from 2012 to 2016. We analyzed changes in number of different types of establishments for the indicated period. We gave information on the closed and operating establishments of Chelyabinsk for 2016. Basing on the research, we formulated the main modern catering trends in Russia.

Key words: public catering establishments, services market, proportion, consumers.

Introduction

Public catering is an integral part of a consumer market and a socially significant sector of economic activity. Public catering services are formed to a greater extent by business initiative oriented towards the purchasing power. More and more people prefer to eat out. Public catering contributes to the solution of many social and economic problems: it helps to better use the country's food resources and provides the population with high-quality nutrition, which maintains good health, increases labor productivity and improves the education quality; it allows an effective use of free time, which is an important factor. One of the functions of public catering is to manage leisure time and social activities of the population [9].

State of the public catering market in Chelyabinsk

Nowadays, the organization of public catering is undergoing cardinal changes, namely, the period of work with imported products, which has lasted for more than twenty years, is finishing. An increase in the use of domestic raw materials after the food embargo has led to a change in tastes and cooking technologies.

From the standpoint of the development of mass catering market, large cities are of a particular interest. We propose to consider the state and prospects for the development of this market by the example of Chelyabinsk.

Chelyabinsk is a city with over a million dwellers and the administrative center of the Chelyabinsk region; it forms part of the Ural Federal District of the Russian Federation. The population of

Chelyabinsk, as of 01.01.2017, was 1198858 people, which is the second largest in the Ural Federal District and the seventh in Russia [3].

Modern Chelyabinsk is a large industrial megalopolis, and business, scientific and cultural center of Southern Ural. It is among the top five industrial cities of the country. It is also the largest transport hub connected with the entire Eurasian continent. The capital of Southern Ural has the international airport "Balandino", which provides aviation communication with the largest Russian cities and near-abroad and far-abroad countries. The Chelyabinsk railway branch is the largest transport hub of the Trans-Siberian Railway.
76 public catering establishments were opened in the city in 2016. The catering industry is constantly changing under the conditions of market transformations and is characterized by the following data (Table 1).

Table 1: Development of catering networks in Chelyabinsk

Type of establishment	year 2012		year 2013		year 2014		year 2015		year 2016	
	total number	seating capacity	total number	seating capacity	total number	seating capacity	total number	seating capacity	total number	seating capacity
restaurants	94	8810	98	9798	108	11196	106	11427	107	11324
cafés	219	11818	241	14243	266	15130	270	14998	271	15464
snack bars	170	5949	155	5592	154	5543	152	5498	142	5094
others (bars, lunchrooms, cafeterias, coffee houses, cake shops)	211	6072	210	6612	231	6925	234	6898	228	6642
canteens	40	2147	46	2335	48	2419	53	2446	67	3010
Total for open networks	734	34796	750	38580	807	41213	815	41267	815	41534

As of 01.01.2017, in Chelyabinsk there were 1175 public catering establishments with seating capacity of 81492 places, including 815 (69,4%) open network establishments with seating capacity of 41534 places [10].

Comparing the data of the following years with that of the previous ones, we established that the number of restaurants in 2013 and 2014 increased by 4% and 10% respectively, in 2015 it decreased by 2%, and in 2016 there were no changes; in 2014 the number of cafes increased by 10%, in 2015 by 1,5%, and in 2016 there were no changes; The number of snack bars decreased by 9% in 2013, by 1% in 2014, by 1,3% in 2015, and by 6.6% in 2016; the number of canteens increased by 15% in 2013, by 4% in 2014, by 10% in 2015, and by 26% in 2016; the number of other types of establishments increased by 10% in 2014, by 1% in 2015, and decreased by 3% in 2016 (Figure 1).

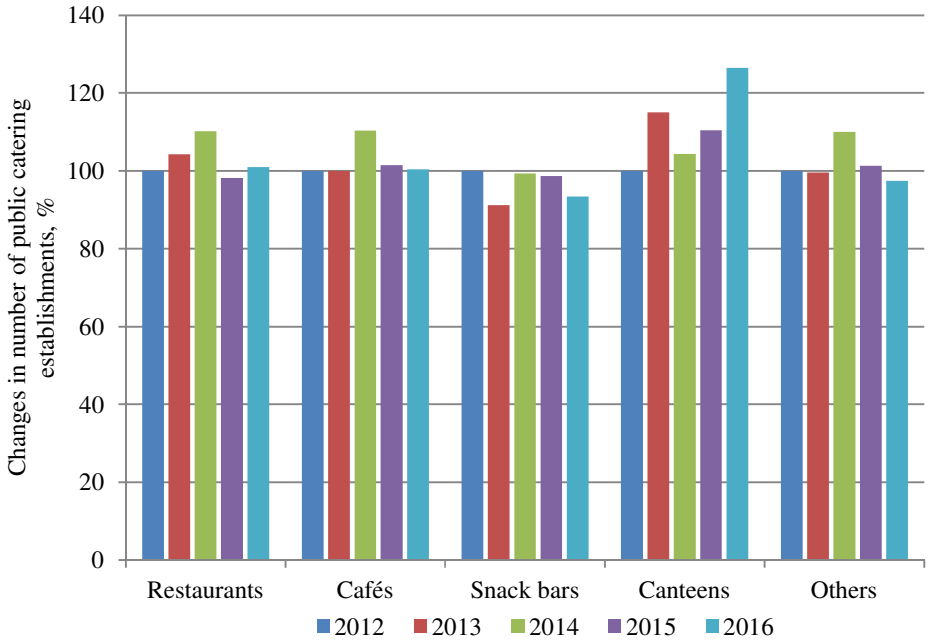

Figure 1. Changes in number of public catering establishments in Chelyabinsk

The turnover of public catering increased in 2016; it amounted to 2,535.0 million rubles, which equals 107,6% (in comparable prices) of the turnover by the corresponding period in 2015 [10].

About 70 public catering establishments closed last year in Chelyabinsk. Veranda restaurant, MixPizza, PizzaHouse, and LikePizzaGut pizzerias, and Lunnny svet bar are among others. The Megapolis Holding Company partially cut its network and namely, Dzedo sushi bars, which were located in the city (outside shopping malls).

At the same time, new restaurants, bars, and cafes (more than 40) opened in Chelyabinsk in 2016; these are Oliver, Ryobryshkovaya, Rodnya, Double L, and GraftBeerHous restaurants, and Nasha komanda pizzeria. The network of street food, mini-cafes, and bakeries expanded and 8 cake shops opened. The level of service rises every year, the range of options expands, promising forms and techniques of service are introduced. Heads of enterprises and sole traders, who provide public catering services, take measures to maintain and increase the volume and quality of the services provided.

Chelyabinsk restaurateurs continue to actively develop the segment of national cuisine. Caucasian, Ukrainian, Georgian and other cuisines are widely spread in the city, and the sector of oriental cuisine is expanding. This trend is of current importance, because such establishments are easier to supply with raw materials due to the food embargo [4]. In addition, public catering establishments of Azerbaijani cuisine are becoming very popular, as nowadays there are more than ten thousand Azerbaijanis living in Southern Ural [2, 7, 8].

Every year there are summer cafes and summer halls which open and operate in the city's territory. They are arranged in conformity with the functional system that provides for the network formation according to the main directions of population flow, pedestrian and transport systems of

the city, that is, in parks, recreation areas and crowded places. For example, in the summer of 2016 there were more than 50 seasonal establishments in the city.

Retail customer service continues to develop in trade networks of Chelyabinsk as they sell catering products from the counter (Teorema, Spar, Magnit, Prospekt and other hypermarkets) [5, 6].

To sum up the foregoing we can conclude that the catering industry keeps on gaining ground in Chelyabinsk.

Thus, there have been significant changes in the public catering market lately. The level of service is growing, the range of options is expanding, and promising service forms and techniques, such as off-premise catering, are being introduced. New catering establishments are distinguished by a wide range of services and modern high-performance equipment.

Trends in the development of the Russian public catering market

At the same time, the influence of the economic crisis on the development of this sphere cannot be left unmentioned. The profitability of restaurant business under these conditions ranges between 0 and 15% [9]. Restaurateurs' main task during crises is to keep the business. Practically all enterprises have investment plans and ideas for development (this is also facilitated by the appearance of a large number of vacant premises at low prices).

Basing on our research, we have formulated the main trends in the development of the modern Russian catering market:

1. Presently, there are more affordable establishments which have simple interior and service, but offer good and delicious food at low prices.
2. Newly opened establishments are most often based on a so-called monoconcept, i.e., their menu is formed with the use of a single product (mostly with some kind of meat). Monoconcept is a kind of fashion, although it is not devoid of a serious economic sense, because it allows the reduction of costs by purchasing one product in large quantities and working with one supplier, the reduction of menu making costs, etc.
3. Regeneration of Russian cuisine. Nowadays there are many different interpretations of Russian cuisine, such as classical, old, modern, and boyar variety. This is a natural development of the process of market's switching to Russian products, the result of reducing the distance between the place where the raw materials are grown and the place of their use.

It is noteworthy that restaurants of European cuisine, especially Italian ones, experience considerable difficulties under modern economic conditions due to the switch of food enterprises to domestic products, since it is impossible to engage in national cuisine without proper national products. According to market experts, the released niche of national cuisine is getting occupied by new food enterprises with Pan-Asian cuisine of different Asian countries of the world.

Conclusions

Thus, catering services are of specific importance and scale. They are an integral part of the sectoral consumer services market, form an effective mechanism to meet the population's individual and personalized needs not only in catering services, but also in leisure activities. Some services are integrating into the life and becoming traditional at one stage or another of our country's economic

development, while others are only emerging. Catering services represent a historically developing and changing phenomenon of a consumer services market.

The 5 P of the 21st Century

People, Planet, Prosperity, Peace and Partnership

PhD(c) Otilia Manta- scientific researcher, Romanian Academy- "Victor Slăvescu" Centre for Financial and Monetary Research, Bucharest, Romania, otilia.manta@rgic.ro

Abstract

Development is the process that gradually progresses to a different stage, usually more advanced and more mature, through gradual changes and expansions. The old developmental paradigm, focusing on prosperity and economic growth, has often neglected the other aspects of life and society, such as the subjective aspects of human and social well-being, crucial to human happiness and social quality, the latter being not significantly correlated with income levels and economic welfare. In this context, certain clarifications are required, such as: delimitation between economic development and economic growth; the distinction between different types of economic development indicators; the assessment of economic development must take into account the spatial, social and temporal context; the existence of key development indicators for different areas, sectors, countries and regions; the existence of differences in the interpretation of development and life standards, and last but not least the delimitation of current values of nonvalues as mentioned at the UN General Assembly on 12 August 2015: People, Planet, Prosperity and Peace. Based on these considerations and correlating with the overall objective of the EU and FAO to reposition the family farming on the outskirts of agricultural, environmental and social national agendas, we can say that now on a global scale we are in a position to promote a shift to a more equal and balanced development. Worldwide, it is intended to promote the directions to: generate discussion and cooperation at local, national, regional and global level; raising the awareness and understanding of the challenges faced by small farmers; contributes to identifying effective ways to support small farmers such as microfinance.

A question that is put in and we are trying in the limelars of knowledge to answer is if there are real chances for mankind to identify those solutions both for the limited resources of the Planet and for the aceler growth of the population but especially solutions for peace in the context of the current wars, all in an experiment of partnership and prosperity.

Keywords: Globalization, People, Planet, Prosperity, Peace and Partnership

Introduction

On 7-8 June 2017 , Europe's leading forum on international cooperation and development launch its eleventh edition. A large and influential group of speakers, stakeholders and participants took part in the multi-faceted programme. In 2017, the activities are based around three main themes: Investing in ***People*** and ***Planet***, Investing in ***Prosperity*** and Investing in ***Peace*** and ***Partnership.*** The three themes are directly linked to the 2030 Agenda for Sustainable Development and the diferent topics highlighted during each session provide insights into the most pressing issues facing the global development community and the various approaches to dealing with these. As we know, ***The 2030 Agenda for Sustainable***[i] it is about transforming our world. This Agenda is a plan of action for people, planet and prosperity. It also seeks to strengthen universal peace in larger freedom. It recognise that eradicating poverty in all its forms and dimensions, including extreme poverty, is the greatest global challenge and an indispensable requirement for sustainable development. All countries and all stakeholders, acting in collaborative partnership, will implement this plan.

The 17 Sustainable Development Goals and 169 targets which announced demonstrate the scale and ambition of this new universal Agenda. They seek to build on the Millennium Development Goals and complete what these did not achieve. They seek to realize the human rights of all and to

achieve gender equality and the empowerment of all women and girls. They are integrated and indivisible and balance the three dimensions of sustainable development: the economic, social and environmental.

Materials and Methods

Regarding the methodology of research on financial environment, complexity and diversity of the issues addressed have required the use of methods, techniques, tools, and procedures of scientific investigation and interpretation to which it's attached particular importance:

- ✓ Documentation, namly, accessing and studying general and specialized bibliography, domestic and foreign, state approach to knowledge issues investigated financial environment and scientific substantiation of the research;
- ✓ Rational method, used as an instrument of knowledge, reflection, analysis, organization, and ongoing scientific research approach;
- ✓ Integration of forms, methods, and logic operations research carried out through the use of analysis and synthesis, abstraction and concretization, comparison, generalization, and systematization;
- ✓ Statistical methods, through the use of descriptive statistics and statistical analysis;
- ✓ Observation method, carried out systematically and analytically;
- ✓ Discussions with experts from institutions and national and international institutions, but also the beneficiaries of financial products and services;
- ✓ Data analysis and interpretation, using graphs, tables, and figures to highlight various developments in financial environment.

Using the classic instruments of scientific research, based on analysis and synthesis, induction and deduction, general and particular, and adding modern methods, authors achieved substantial and pertinent analyses and studies on financial environment main ways, both internationally and especially national. Contributions of authors on investigated issue are highlighted during the research work and theoretical and applicative significance value resulting from the conclusions and proposals that they have formulated and promoted.

The research results are presented using formulas, tables, figures, and graphs. The theoretical information needed for the research was taken from literature and specialized works in the field of financial environment investigated, from home and abroad. Statistical information and concrete data on how financial environment works were taken from reports and statistics of institutes involved in financial environment in the country and abroad as well as to public bodies and private specialist.

This method of analysis provides a more rigorous substantiation of the decision-making process and also maximum reduction in uncertainty.

The primary data and information sources have been correlated with the secondary information resources, regards: economic analysis, reports of the local, regional, national and international level, institutions websites, and report analysis.

The research strategy of the researcher based on the use of a mix of information resources in accprding with the reports and analysis: "the action researcher does not become an independent observer, but becomes a participant, and the process of change becomes the subject of research".

Results and Discussions

The goals and targets will stimulate action over the next fifteen years in areas of critical importance for humanity and the planet:

People. Determination to end poverty and hunger, in all their forms and dimensions, and to ensure that all human beings can fulfil their potential in dignity and equality and in a healthy environment. The Earth Globe population has experienced a steady growth, often accelerated, reaching 6.1 billion inhabitants in 2000, and currently at 7 billion inhabitants, the living standard has also risen corroborated with the average life expectancy of the population.

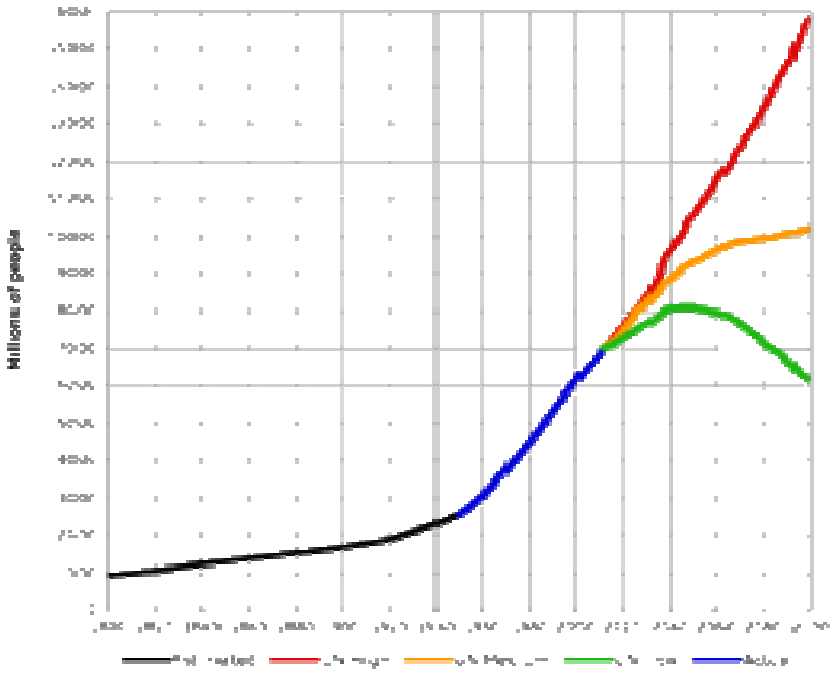

Table no.1 Average population estimates in 2012 from United Nations (millions)

An	Total (mlrd.)	Asia	Africa	Europa	America latină + Caraibe	America de Nord	Australia + Oceania
2010	6.916	4.165 (60,2%)	1.031 (14,9%)	740 (10,7%)	596 (8,6%)	347 (5,0%)	37 (0,5%)
2015	7.324	4.385 (59,9%)	1.166 (15,9%)	743 (10,1%)	630 (8,6%)	361 (4,9%)	39 (0,5%)
2020	7.717	4.582 (59,4%)	1.312 (17,0%)	744 (9,6%)	662 (8,6%)	376 (4,9%)	42 (0,5%)
2025	8.083	4.749 (58,8%)	1.468 (18,2%)	741 (9,2%)	691 (8,5%)	390 (4,8%)	45 (0,6%)
2030	8.425	4.887 (58,0%)	1.634 (19,4%)	736 (8,7%)	717 (8,5%)	403 (4,8%)	47 (0,6%)

Graph no.1. Estimates / projections of the Earth's population by the year 2100

Source: The population of the planet over the years 1800 - 2100 according to several statistics established by UN 2004 projections.

Moreover, the indicator of growth of the population of the Globe is interdependent with the indicator of the increase in the average life expectancy, ie if in 1900 the average life expectancy was 30 years, in the year 2000 due to the increase of the living standard (food at higher costs Accessible, and three times cheaper the cost of food than in 1957 and the more developed drug industry, respectively, to prevent and combat certain diseases), the global average life of the population has reached 65 years.

Planet. Determination to protect the planet from degradation, including through sustainable consumption and production, sustainably managing its natural resources and taking urgent action on climate change, so that it can support the needs of the present and future generations.

As a result of global industrialization, Earth resources have become increasingly limited, their balance being the primary objective of supporting living organisms on Earth. This balance has to be between the main resources, namely air, water, soil, forests and radiation. The evolution of the urban population has seen a growing dynamism over time, reaching in 2000 the urban poll to be about 50%. The World Health Organization's Air Quality Studies have shown in 1988 that about 1.8 billion people in the urban area were affected by air quality, inspiring toxic substances harmful to the human body (sulfur dioxide, fungicides, dust and other chemicals).

We are currently witnessing many scientific debates on global warming, with temperatures rising by 1-5 degrees Celsius, with the consequences we are currently witnessing: increasing sea levels, spreading tropical epidemics, flooding and droughts, failing Flora and fauna species, melting glaciers and slowing down the Golf Stream (North Atlantic Ocean). The main purpose of scientists is to significantly reduce carbon emissions, emissions that have a direct effect on climate change.

Reducing forest areas has a direct impact on the ecosystem as well as on Terra life ", according to estimates, over the past ten thousand years the total area of forests in the world has been reduced by 15 to 50%. In Africa and Asian monsoon, there are only a third of the wooded areas ten thousand years ago; Two thirds of the Russian forests remain, and three continents of the American continents. Half of the deforestation of the last ten thousand years has been achieved only in the 20th century, and half of them have only affected tropical areas since 1960. At present there are no more than three large wooded areas in the world: in northern Eurasia, From Sweden to Sahalin, North America, Alaska to Labrador, and South America, in the Amazon and Orinoco rivers. If the actual deforestation rate is kept, a quarter of the existing forests will disappear within the next fifty years."

The soil was, is and will remain an active landmass of the Earth, and the impact of industrial chemicals (fertilizers) with a direct impact on food production (pro-active factor) and soil erosion (negative factor).

At present, the wealthiest states are those that have fresh water sources (clean water). This aspect has been known since 1920 when the wealthiest cities of the lime were those that provided the inhabitants with drinking water. Excessive water consumption as a result of industrialization, increasing the level of comfort of residents, and massive pollution of water sources, draws attention to specialists in reducing fresh water sources on Terra, which implies identifying technological solutions to optimize sources existing so as to avoid certain constraints on people.

With regard to the impact of radiation on Earth at the beginning of the 21st century, scientists' efforts are focused on finding a process by which to fuse two hydrogen atoms into a helium atom to use the resulting energy. Fuel would be seawater, and the secondary effect would be scattering small amounts of radioactive emissions. Despite twenty billion dollars of investment, only 10% of the huge temperatures needed to get energy through hydrogen fusion failed. "

As a result of the richness between rich and poor countries worldwide, the wealthy countries do not feel safe and secure compared to the poor population living in the subsistence (survival).

Prosperity. Determination to ensure that all human beings can enjoy prosperous and fulfilling lives and that economic, social and technological progress occurs in harmony with nature.

Several scientists' scenarios show us that new scientific and technological discoveries lead us to the hypothesis that a first solution would be that of a "viable global society" that would ensure the balance of resource use on Earth. Three great specialists of the moment (Donella Meadows, Jorgen Randers and Dennis Meadows) point out to us that in order to create global society "mankind should act immediately and simultaneously in three directions: it should limit the population, reduce industrial production, Improve technologies ".

Peace. Determination to foster peaceful, just and inclusive societies which are free from fear and violence. There can be no sustainable development without peace and no peace without sustainable development.

At global level, we are currently witnessing a great many military conflicts that often result in resource losses. Therefore, the G20 coutries members, since the economic crisis with the objective of making decisions on peace, economic stability in the world, and implicitly regulating financial markets. Different opinions have emerged globally about group members, one of which was Joseph Stiglitz, the winner of the Nobel Prize for Economics, who has been calling for a "G192" for a long time, including all UN member states. Another opinion of Poland, Was like the EU executive, representing the EU at the G20. At present, the European Union is officially represented at the G20 meetings of the country holding the EU presidency at the time and by the European Central Bank (ECB). To put global order, global stability and global welfare, world leaders should unite on the 5Ps' goal: "Yes, we can".

Partnership. Determination to mobilize the means required to implement this Agenda through a revitalised Global Partnership for Sustainable Development, based on a spirit of

strengthened global solidarity, focussed in particular on the needs of the poorest and most vulnerable and with the participation of all countries, all stakeholders and all people.

As noted in "Peace", cooperation must exist globally between strong and less powerful (even poor) countries through group decisions transposed into international co-operation agreements, integrated stability programs, integrated programs Sustainable development in financial regulation packages, as well as government policies implemented at the level of each state, having as its primary objective the balance of the universe.

So, here are the ***Sustainable Development goals:***

1. End poverty in all its forms everywhere;

2. End hunger, achieve food security and improved nutrition and promote sustainable agriculture,

3. Ensure healthy lives and promote well-being for all at all ages;

4. Ensure inclusive and equitable quality education and promote lifelong learning opportunities for all;

5. Achieve gender equality and empower all women and girls;

6. Ensure availability and sustainable management of water and sanitation for all;

7. Ensure access to affordable, reliable, sustainable and modern energy for all;

8. Promote sustained, inclusive and sustainable economic growth, full and productive employment and decent work for all;

9. Build resilient infrastructure, promote inclusive and sustainable industrialization and foster innovation;

10. Reduce inequality within and among countries;

11. Make cities and human settlements inclusive, safe, resilient and sustainable;

12. Ensure sustainable consumption and production patterns;

13. Take urgent action to combat climate change and its impacts;

14. Conserve and sustainably use the oceans, seas and marine resources for sustainable development;

15. Protect, restore and promote sustainable use of terrestrial ecosystems, sustainably manage forests, combat desertification, and halt and reverse land degradation and halt biodiversity loss;

16. Promote peaceful and inclusive societies for sustainable development, provide access to justice for all and build effective, accountable and inclusive institutions at all levels;

17. Strengthen the means of implementation and revitalize the global partnership for sustainable development.

In Europe, the family farmers manage 63 percent of all farmland and guard the agro-biodiversity of soils, water, forests and fish stocks—resources that future generations will need in order to survive. Despite the differences among the countries in Europe, there are issues that are common to all of us, and this includes the challenges of strengthening sustainable family farming and small-scale production.

Romania is part of a growing international movement to recognize the economic, environmental and cultural value of family farms. Very important for food security acoording with

5Ps is to have technical and financial solution for small farms (including family farms) and small entrepreneur. Romania has already taken clear and concrete steps to support its estimated 700,000 smallholders. But there is always more to be done:

- ✓ Supporting and invigorating smallholder agriculture requires a comprehensive platform of policy and development initiatives that are tailored to the unique and diverse needs of family farmers.
- ✓ To preserve the long-standing tradition of family farming, favourable policy and regulatory environments are needed.
- ✓ Improving access to land, water, markets and credit – as well as standardizing land use and property laws – creates a sound foundation for productivity, solid ground on which farmers can and will invest in the future of their farms.
- ✓ Public investment in rural infrastructure, public services, training and education can give smallholders the help they need to be competitive in an increasingly globalized marketplace.
- ✓ Empowering women and young people to participate in agriculture will guarantee the long-term viability of family farming.

The family farming includes all agricultural activities family and is related to many areas of rural development. Family agriculture is a means of organizing forestry, fishing, agricultural production, pastoral and aquaculture, which is managed and operated by a family and work predominantly dependent family, including both women and men. Both in developing countries and developed countries, agriculture is the predominant form of family agriculture in the production of food. Family agriculture is the most common operational model of agriculture in Europe and therefore of great importance in the EU. Most of the 12 million EU farms are family farms passed from one generation to another, and contribute to sustainable socio-economic and environmental development of rural areas. There are a variety of family farms in the EU in terms of their size, the activities they engage in, resource availability, the degree of market integration, competitiveness etc. They operate in different economic contexts, agro-ecological and social ensuring food security while meeting the growing expectations of society for food safety, quality, value, origin and diversity of food, and thus contribute to smart, sustainable and inclusive. In developing countries, most poor people live in rural areas. Social studies and statistics show that today almost 40% of rural inhabitants are exposed to ongoing famine. Apart from projections issued by some analysts, specialists in rural areas continues to support the need for a true national development strategies for agriculture, who should have as a starting point thee causes of involution investment process in rural areas and especially those that put farmers unable to accumulate financial resources or access to microcredit/microfinance.

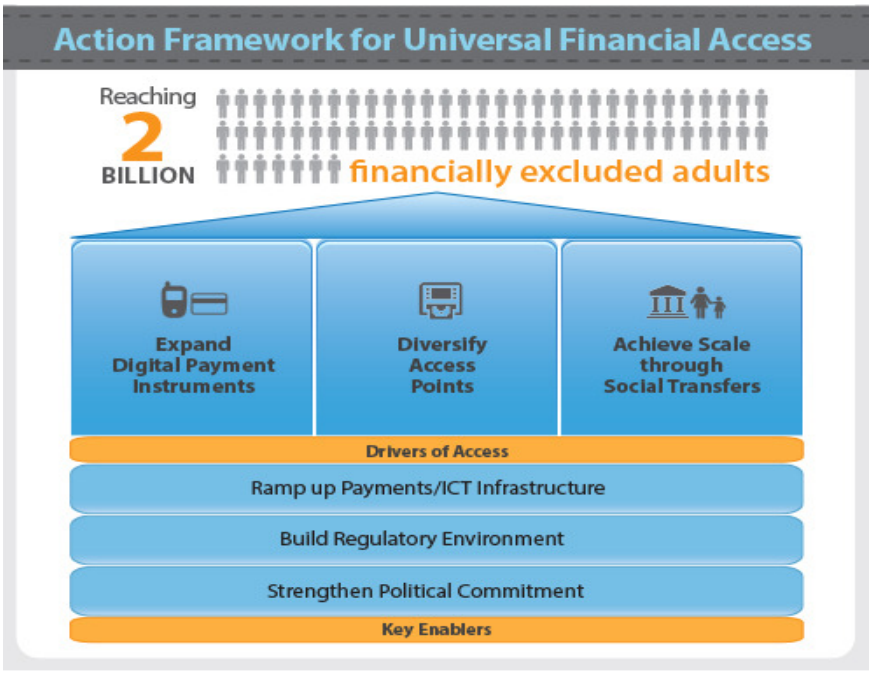
Finalizing a strategy for economic development of rural areas must be based on the truth that, under the circumstances, a great chance to ensure food security of the nation lies in restoring production and trade in the area of family farms. In the context of the reality of activities in rural areas, desideratum is a kin to help the development of models of microfinance to respond to these realities and to contribute to the current phenomenon of social inclusion and financial, as well as sustainable development of farms and support non-agricultural activities.

The financial development of the financial sector has a relevant influence on the long-term performance and growth of the economy, measured by factors such as the size, depth, access, efficiency and stability of the non-banking financial institutions sector (IFN), the financial system as a whole. The higher the degree of development of the sector, the more extensive the availability of the financial services offered, which allows diversification of the risks. Financial development is a process of strengthening and diversifying the provision by IFN of those services that meet the requirements of economic subjects in an efficient and real way.

Moreover, the financial development of IFN can be systematic, with the outflow or the continuous entry, without great variation, of various institutions on the market, ensuring the

uninterrupted and unlimited service provision. The development of IFN depends on the following factors: institutional environment, business environment, financial stability, financial markets, availability and access to capital.

The access to safe financial services is a component of financial inclusion that has proven vitally important for economic and social development and of critical importance in reducing extreme poverty, fostering common prosperity and supporting inclusive development. The lack of availability of affordable and adequate financial products is, however, a global barrier to full financial inclusion. The young generation faces more challenges in accessing affordable and affordable financial services than adults because of their social status due to regulatory issues and other intermediaries in flexible financial services. Several countries have already adopted flexible measures on their financial regulations for financial institutions. These new elements have been fundamental in the development and implementation of favorable national policies for financial inclusion and financial education for children and young people.



Therefore, a first attempt to analyze the innovative offers of available savings products and deposit accounts for children and young people, as well as the financial education programs provided by financial institutions in connection with such accounts in Armenia, Belarus, Croatia , The Czech Republic, and Moldova. In these case studies, with the exception of the Czech Republic and Croatia, the regulation allows those under the age of 18 to open and operate independently. However, banks still generally do not have adequate products available for young people. Despite these efforts, the development of adequate financial products for the needs of the most vulnerable consumers category are key strategic objectives for young people's integration. However, the subject of financial inclusion should be directly linked to the policy of guarantee and protection measures for disadvantaged groups. Guidelines, principles and rules should be created and respected, especially when working with vulnerable groups such as children and young people. The most appropriate economic instruments should be used to promote market transparency and prices that reflect the real economic, social and environmental costs of products and services (fair pricing). Their potential to reconcile environmental protection and smart growth and exploit win-win opportunities should be recognized.

Financing and economic instruments - The EU will seek to use the full range of fiscal policy instruments in implementing its policies. The most appropriate economic instruments should be used to promote market transparency and prices that reflect the real economic, social and environmental actual products and services (getting prices right). Their potential to reconcile environmental protection and smart economic growth and exploit win-win opportunities should be recognized. In addition, suitability should be evaluated against a set of criteria, including their impact on competitiveness and productivity. Member States should consider further steps to shift taxation from labour to resource and energy consumption and/or pollution, to contribute to the EU goals of increasing employment and reducing environmental impact in a cost-effective manner. The Commission should present a roadmap for reform, sector by sector, of subsidies that have considerable negative effects on the environment and are incompatible with sustainable development, with a view to gradually eliminating them. To ensure that EU funding should be used in an optimum way to promote sustainable development, Member States and the Commission should coordinate to enhance complementarities and synergies between various strands of Community and other mechanisms for co-financing, as such as cohesion policy, rural development, Life + program for research and technological development (RTD), the competitiveness and innovation Programme (CIP) and the European fisheries Fund (EFF).

Related to the access of poor people to financing sources it is good to recall the recent *UFA2020 Overview: Universal Financial Access by 2020 Report. A*ccording to this study the IFC estimates that more than 200 million formal and informal micro, small and medium enterprises (MSMEs) in developing economies are either unserved or underserved in terms of their financing needs. In some cases, the lack of access is because banking outlets are too few, too far or unwilling to serve the poor, but more often it’s because many with meager incomes think they’re too poor to be able to benefit from financial services. There is progress toward financial access.

Between 2011 and 2014, 700 million people became account holders at banks, other financial institutions or mobile money services providers, decreasing the number of financially excluded individuals by 20%, from 2.5 billion to 2 billion adults. Extending access to financial services is necessary to reduce world's poverty and increase prosperity.

Figure no. 1. Action Framework for Universal Financial Access

Source: UFA2020 Overview: Universal Financial Access by 2020, The World Bank Report

Microcredit, as defined by by the EC, is under € 25,000 loan given to support the development of microenterprises and self-employability. It has a double impact: the economic one, as a means of creating income generating activities and social one, as a means of social inclusion and therefore financial inclusion. 91.8% of businesses in the EU are micro level, comprising over 2/3 of the workforce. Micro and small enterprises are the engine of the European economy. However, creation and development of micro businesses in Europe is a cumbersome process. People from disadvantaged groups such as long-term unemployed, economically inactive young people, single parents (usually women), immigrants, the elderly (seniors) or disabled face difficulties for starting a small business or become self-employed (self-employed). In addition to administrative barriers, another major problem for them is access to finance. Commercial banks are reluctant to grant small loans because the administration costs are large while the profit margins are small. This discourages banks to provide loans under € 25,000. Also, the self-employed and micro-entrepreneurs are considered too risky by banks, using the scoring method based on credit history and provide safeguards for securing the loan. Most times people from disadvantaged groups have no collateral and no business track record. Moreover, the financial crisis and economic downturn became more expensive for financing debts and the wave of regulations (especially Basel II reform) have made more difficult the access to financing. Banks are gradually retiring from local and mutual economy as a result of increasingly stringent banking regulations. Therefore, the EU has made a priority of small and micro enterprises, through its internal policies, regional and employment. Europe 2020 Strategy with ***2008 Small Business Act*** aims to improve regulation and access to finance for small firms by Single Market Act and the new Structural Funds programs. Micro crediting is operational by 2007 JASMINE technical assistance program followed the European Progress Microfinance Facility 2009, providing 200 million euro to European microfinance institutions in the form of loans, guarantees and equity. A global definition presents the microfinance as providing basic financial services to low-

income people who traditionally have lack access to banking services definition (CGAP), including: credit, micro-savings, micro-insurance and micro leasing. In EU the focus is on micro crediting, defined as loans under € 25,000 which addressed to two groups:

- ✓ Microenterprises, defined as companies with fewer than 10 employees;
- ✓ Disadvantaged persons (unemployed and other inactive persons, social assistance, immigrants, etc.) who wish to become self- employed but don't have access to traditional banking services.

Thus, a distinction is made between micro lending and inclusive lending. The crediting of microenterprises is targeting the clients almost bankable (start-ups or existing companies) by amounts close to the maximum limit of 25,000 euro. On the contrast, the inclusive crediting is targeting the non-bankable clients, people who most likely will remain excluded from the banking system in the medium and long term. In fact, the unemployed and economically inactive people who want to take the first step in winning an independent income often seek loans under 5,000. So, there are those people who want to make the transition with small financial steps from the informal economy or jobs with small income to self-employment. Since the cost of administering of small loans is high and target groups often need additional counselling and support services for their businesses, the European microfinance programs are hardly sustainable, requiring government support. Even itself the microcredit operations that could be financially sustainable requires pre- and post-counselling subsidizing lending. Entrepreneurship and self-employment are activation instruments of the labour market. Many people, especially the ESF target groups (unemployed, immigrants, women, people over 50 years, youth) are hard to find a job, but could be very good entrepreneurs. Helping them to start a business or conversion into self-employed, in addition to reducing unemployment period is a way to develop creativity and innovative potential of a person who generates a sense of trust and usefulness. Well-designed, the entrepreneurship policies improves the economic and social inclusion. There is a very interesting problem: lending of micro-enterprise versus the social inclusive crediting.

The definition of European Commission Recommendation 2003/361 / EC of 6 May 2003 is: "A micro-enterprise is any enterprise with fewer than 10 employees and a turnover under 2 million euro." Lending the micro-enterprise target the top level of the micro financing market, by providing loans for bankable or nearly bankable microenterprises. The inclusive social lending are turning to self-employed individuals without access to banking services because of their economic and social status. These accesses loans in significantly lower. These two types of Micro financing are not mutually exclusive. About 63% of European organizations can be classified as "social inclusion lenders". Their work includes promoting business start-ups, job creation, and social support for persons excluded, reduce poverty. We have to say also something about Social Return on Investment (SROI). This indicator for entrepreneurship and microfinance programs shows that the amount of public funds granted for the scheme is part of the amounts saved in terms of social benefits which have not been granted those persons, as they became self -employed or have found employment through microfinance program in question. Such assessments show the economic and social usefulness of microfinance schemes. SROI analysis is a process of understanding, measuring and reporting the value of social, economic and environmental created in an organization. SROI shows how is translated the social and environmental results in tangible monetary value, supporting organizations and investors to see the full picture of the benefits of spending their time, money and other resources. This investment can be further seen in terms of value created for individuals, communities, society and the environment. SROI indicator allows a comparison of the value generated by intervention and investment required to achieve that impact. SROI = *net present value of benefits / net present value of the investment.* At European level, there are different models of micro crediting, sector which began to develop in 2000 in the western part and in the 1990's in the central and eastern. In the western part of Europe because of strict regulatory framework that allows banks to grant credit only prevail the linkage model: support organizations accompany clients and cooperate with banks for pulling credit. Although the linkage model often generates longer procedures for granting and firing longer, have some clear advantages: while banks obtain specific information on customer segment and may outsource part of certain operating costs, the nonprofits organisations support the target group with a broad of products alongside with learning the techniques

of scoring and evaluation of bank customers. In the countries from Central and Eastern Europe, the microfinance operations began in the 90s as a private initiative supported by international donors. In Romania and Bulgaria the microfinance organizations have a specific status of non-bank financial intermediaries and have the right to lend. Credit unions provide microfinance, savings and insurance.

In the UK, the community development financial institution (CDFIs) credits small businesses and individuals from disadvantaged areas. Types of micro crediting organizations in Europe:

- ✓ Non-governmental organizations specialized in microfinance (integrated non-financial services);
- ✓ Microcredit banks (converted from non-governmental organizations and foundations);
- ✓ Non-governmental organizations focused on specific groups (acts at small scale);
- ✓ Credit cooperatives (with special legal status);
- ✓ Non-banking financial institutions (microfinance institutions);
- ✓ Institutional support programs (part of the existing programs of development banks);
- ✓ Community development financial institution (CDFI - UK only).

The European Microfinance market is heterogeneous, immature and fragmented. There is not a common business model. The microloans value ranges between 220 - 30.000 euro, the largest being granted by banks, non-banking institutions and government organizations. The most pressing problem of such institutions is the lack long-term funding sources. It is however noted a trend of professionalization, efficient and self-sustaining. A growing number of unemployed people represents a source of demand for micro credits. Anyway, without access to stable funding, the growth perspectives are limited. It is expected that during the next period, European commercial banks to further reduce lending for financially excluded people, small and micro start-up enterprise. Microfinance is an important tool to combat the financial crisis and to sustain an inclusive growth. The legal framework for microfinance in Romania exists since 1993, currently being over-legalized.

The Romanian microfinance sector is competitive, being the 5th largest in the European Union with experience in accessing decentralized programs. On the other hand, in Romania there is no coordination between training programs in entrepreneurship and access to microfinance programs.

Beneficiaries, They are micro-businesses, including freelancers, sole proprietorships, family associations, small, new companies (start-up) companies, innovative enterprises, farmers.

Institutions, involved are: donors (EU, European Investment Fund), the fund manager, non-bank financial institutions, experts, consulting firms, microfinance institutions, and guarantee funds.

The benefits of the activity of microfinance for Romania mainly consist of: improving access to finance for all recipients listed above, improving the quality of financial services and support for business development offered by participating institutions, SME development and the creation / maintenance of jobs, revenue growth business of the beneficiary companies, while increasing the value of micro-credits granted. Thus, microcredit can be a breeding ground for the interbank market to creditworthy customers.

Conclusions

What should be done to promote access to microfinance in rural areas in the context of sustainable development? The issue of interventions with the objective of building sustainable access to microfinance in rural areas has been taken in the direction of development research in a comprehensive and systematic way and outlined what matters in rural areas and microfinance.

First of all: the customer experience - Clients who have experience in credit-donor projects can become poorer or richer: starting with large and short-term financial loans, as initially supported by projects supported by donors and who ultimately failed; only short-term short-term loans could allow investment to be made at a reasonable risk; to test their ability to borrow, invest, restitute and save; to move on to more profitable investments; to grow rapidly with increasing internal and external resources. Once they are successful, they need a banking partner that responds to their growing financial needs. This allows them not only to move beyond the poverty line, but also to create jobs for the poor. People in disadvantaged groups face particular difficulties in setting up a small business or becoming self-employed as long-term unemployed, economically inactive people, young people, single parents (usually women), immigrants, the elderly Seniors) or with disabilities. Besides administrative barriers, another major problem for them is access to finance. As a final conclusion it is considered that the microfinance in the complexity of the financed activities must achieve an optimal combination of the presented sources of financing and their destination, having as final objective the socio-economic development of the small entrepreneur.

Following the 5Ps on macroeconomics, microeconomics is of equal importance. How are business cycles related? Why are there periods of growth and decline? Which way function, operate and collaborate monetary policies, financial institutions, and markets?

Adam Smith's scarcity of resources is at the heart of microeconomics. How do organisations and individuals make decisions to invest or spend their resources and which effects do these decisions have on the economy? These are decisive questions and it is very obvious, how important this is, latest when news report about reducing consumer trust, spending cuts or low investments by companies. Each of them impacts, but also there is an interdependence leading to specific cycles of economic development and welfare.

Frequently called Theory of Prices, microeconomics also and additionally deals with price developments, inflation rates or employment. While much of it is national level, the global stream of money, goods, and services is of significant influence as well.

Much recent solution for sustainable local developments use on online banking services. While underlying reasons are understandable for both sides of the market, retail banking remains an important aspect. That not only for economic, but also societal reasons. In addition, it should not be forgotten that online banking is retail banking as well, only in a different form and through an alternative channel. Banking is part of the service industry, but the important instrument for sustainable development. Frequently banks speak about their products, but there is a decisive difference between 'real' products and services called products. That difference is not only about customer experiences, it also has a very different theoretical underpinning and it is about a different set of operations influencing, how retail banking works and what its servicing staff needs to understand.

What to do next?

Creation of a mechanism accordint with 5Ps (***People, Planet, Prosperity, Peace and Partnership***) is to help stimulate the creation of a value-added manufacturing chain more higher, so turnover is to ensure both current manufacturing costs and pay old debts.

The funding mechanism structure is adapted to the specific needs of SME's financing in agriculture (seasonal production, risk of natural disasters and other unforeseen events, mixt of the financial instruments, minimum guarantees, etc.).

In the "History of the World from Big Bang to the Present," by Cynthia Stokes Brown, there are mentioned questions to which so far scientists, implicitly new investigators, have not yet found an answer:

- "Will they generate current policies, a viable future or a collapse?

- Do new technologies have the power to influence the long-term trends of global systems so as to either increase or collapse?
- Is the free market capable of distributing resources so as to ensure a viable future?
- The market seems to allocate the riches of the rich and to accentuate the poverty of the poor. What changes this component of the global system, without which it seems impossible to stabilize the population growth?
- Can people in industrialized societies learn to live in harmony with nature?
- Can I share my wealth with the population of less industrialized countries? "

Are Institutions a Driver or an Obstacle to Development of Local Currency Corporate Bond Markets?

Teplova Tamara Viktorovna, PhD, Professor, School of Finance, Faculty of Economic Sciences; Head of Research and Training Laboratory of Financial Markets Analysis. National Research University Higher School of Economics. Moscow, Russia. tteplova@hse.ru

Sokolova Tatiana Vladimirovna, PhD, Senior Lecturer, School of Finance, Faculty of Economic Sciences; Analyst of Research and Training Laboratory of Financial Markets Analysis. National Research University Higher School of Economics. Moscow, Russia. tv.sokolova@hse.ru

Abstract

We analyze institutional determinants of the development of local currency (LCY) corporate bond markets in the period from 2010 to 2016. We consider a wide range of indicators of the quality of institutional environment: the Heritage Foundation's Index of Economic Freedom, the Worldwide governance indicators, the World Economic Forum's indicators of corporate culture, development and regulation of financial markets. Unlike most previous studies, we test not only static regression models (multifactor linear regressions), but also dynamic models based on the generalized method of moments, which allows to solve the problem of endogeneity of variables.

The results show that low quality of institutional environment, macroeconomic and financial instability stimulate growth of the share of LCY corporate bonds in the total issuance volume. In the periods of instability LCY corporate bonds become less attractive for foreign investors, and issuers are forced to raise capital in the domestic market. The most significant factors in both static and dynamic model specifications are the World Bank's indicators of regulatory quality and rule of law. A decline in sovereign credit ratings also gives impetus to the development of LCY corporate bond markets.

An original result is that more developed stock markets suppress the growth of LCY corporate bond markets: equity and corporate bonds are competing financing sources for companies from developing countries. A developed banking sector contributes to the growth of the LCY corporate bond market: banks act as dealers and market makers. Devaluation of the national currency has a significant positive influence on the explained variable.

Keywords: corporate bonds; quality of institutions; developing countries; local currency bond markets

JEL: E02, G10, G20

Introduction

In the period from 2006 to 2015 the volume of the world bond market doubled (reaching $126.2 trillion), while the volume of local currency (LCY) corporate bond markets of developing countries grew 4.4 times (reaching $ 6.4 trillion; source: authors' estimates based on the Bloomberg database). One of topical issues is the analysis of determinants of LCY corporate bond markets.

Results of previous works on the role of institutional factors in development of local currency corporate markets are mixed. On one hand,Eichengreen and Luengnaruemitchai (2004), Burger and Warnock (2006), Bhattacharyay (2013) showed that a higher quality of institutional environment and protection of creditors' rights stimulate development of LCY corporate bond markets (the volume of LCY corporate bonds outstanding to GDP increases).

On the other hand, Teplova and Sokolova (2016), Claessens et al (2007), Park (2016) revealed a negative impact of institutional factors on the share of LCY corporate bonds in the total volume of corporate bonds. In our opinion, a decrease in quality of institutions and setting restrictions on international capital flows may be favorable for LCY corporate bond markets. As an example, let us consider the market of ruble corporate bonds. In 2014, the USA and the EU imposed sanctions limiting the opportunities for key Russian companies to raise funding abroad. This gave an impetus to development of the domestic corporate bond market: the volume of ruble corporate bonds outstanding increased from 7.1% of GDP (December 2013) to 12.3% of GDP (December 2016, source: Bloomberg). Thus, the impact of institutional factors on LCY corporate bond markets is not unambiguous.

The aim of our research is to identify institutional determinants of development of LCY corporate bond markets on a cross-country sample. We have chosen the period from 2010 to 2016 characterized by macroeconomic and financial shocks: the debt crisis in the EU in 2010-2011 and instability in the world commodity markets in 2014-2016, which negatively affected economic situation of oil-exporting countries. We analyze a balanced panel on 15 emerging markets that were the leaders by issue volumes of corporate bonds in the pre-crisis year 2013. By means of econometric analysis, we examine the impact on the share of LCY corporate bonds of a wide range of factors - quality of development of political, legal and economic institutions, indicators of corporate culture and governance, quality of regulation of stock exchanges.

In most previous studies (Burger and Warnock (2006); Claessens et al (2007); Bhattacharyay (2013); Berensmann et al (2015)) there are applied only linear multifactor regressions. Thus, they do not take into account the fact that bond market development indicators, macroeconomic and institutional variables can be endogenous. Unlike previous works, we construct both static and dynamic (generalized method of moments, GMM) models, which allows us to solve the problem of potential endogenous variables.

Static methods and models (for example, the method of least squares, OLS) require the fulfillment of a number of conditions (for example, Gauss-Markov's). Similar assumptions are required when constructing models with fixed or random effects. GMM was proposed by Hansen (1982) and is a generalization of the methods of moments and of least squares. GMM is widely used in econometrics. The main advantage of GMM is that many econometric assumptions and requirements (about homoskedasticity, normality of distribution and absence of autocorrelation) are not obligatory.

Review of earlier research

Analysis of determinants of development of LCY government and corporate bond markets is performed by two main directions. The first direction is the analysis of influence of macroeconomic factors (Eichengreen and Luengnaruemitchai (2004); Eichengreen et al (2006); Burger and Warnock (2006); Fidora et al (2007); Batten et al (2012); Bhattacharyay (2013)). Eichengreen and Luengnaruemitchai (2004) revealed significance of the size of an economy, volatility of the exchange rate, competitiveness of the banking sector for development of LCY government and corporate bond markets. Burger and Warnock (2006) showed that countries with lower inflation and a larger size of the economy have larger domestic corporate bond markets. Fidora et al (2007) proved that countries with more stable inflation have larger corporate and government bond markets. Bhattacharyay (2013) revealed that the size of the economy, the level of economic development, the openness of the economy (in the sphere of international trade), the volatility of interest rates are significant factors determining the size of bond markets in Asian countries. In our study, the mentioned above and additional factors will be considered as control variables.

The second direction of research is the analysis of influence of institutional factors (Eichengreen and Luengnaruemitchai (2004); Burger and Warnock (2006); Claessens et al (2007); Berensmann et al (2015); Park (2016)). Conclusions of previous studies on the impact of institutional factors on the development of LCY bond markets are not unambiguous. On one hand, most researchers (Eichengreen and Luengnaruemitchai (2004); Burger and Warnock (2006); Park (2016)) conclude that institutional factors positively influence the volume of LCY bond outstanding (in % of GDP). On the other hand, Claessens et al (2007) and Park (2016) reveal that institutional factors can negatively affect the ratio of volumes of LCY and FCY bond markets. Berensmann et al (2015) conclude that the presence of foreign investors in the domestic bond market contributes to growth of LCY corporate bond markets, but may increase the volatility of international capital flows. In this regard, liberalization of capital markets in developing countries should be conducted in parallel with institutional development and strengthening of domestic financial markets.

The contribution of our study to the empirical literature is the analysis of a wide range of institutional variables, including Heritage Foundation's Index of Economic Freedom, indicators of the quality of development of political, legal and economic institutions (Worldwide Governance Indicators), indicators of corporate governance and culture (ethical behavior of firms, quality of auditing and reporting standards), indicators of ease of access to financing in the stock market and the banking sector, quality of regulation of stock exchanges by World Economic Forum (Global Competitiveness Reports).

As indirect factors of institutional development, we choose indicators of development of the stock market and the banking sector. In our opinion, a less protected equity capital in a country leads to a less developed stock market and a lower market capitalization to GDP. In the absence of incentives for entrepreneurship and growth of public equity, companies will choose debt financing. The more the concentration of business, the higher is the volume of publicly traded corporate debt (bonds). In the case of prevalence of small and medium-sized businesses and lack of strong regulation in the banking sector, the publicly traded debt will be replaced by bank loans. Thus, both the stock market capitalization and the level of development of the banking sector can be indicators of the quality of property protection institutions.

On the basis of previous works (Teplova and Sokolova (2016); Claessens et al (2007); Eichengreen and Luengnaruemitchai (2004)) we choose the following control variables: dynamics of the exchange

rate, economic growth, inflation (CPI and PPI), changes in sovereign credit ratings of leading agencies (Standard and Poor's, Moody's and Fitch). A detailed description of variables is presented in Table 1.

An originality of our study is in the applied methodology: unlike most previous works, we test not only static regression models, but also dynamic models based on the system generalized moment method (GMM), which allows us to solve the problem of a potential endogeneity of variables.

Methodology of our research

Based on previous works, we test the following research hypothesis:

(alternative) H1: Institutional factors have a significant impact on the share of LCY corporate bonds (in the total issue volume of corporate bonds).

Description of the dependent and explanatory variables (institutional factors and control variables) and the expected direction of influence are given in Table. 1.

Our analysis is performed on the basis of linear multifactor regressions and GMM models. We use quarterly data on corporate bond issues, macroeconomic and institutional factors in the period from 2010 to 2016. This allowed us to increase the number of observations in the sample in comparison with previous works (Bhattacharya (2013); Burger and Warnock (2006)).

Table 1: Description of variables

Variable	**Description**	**Expected direction of influence (+/-)**	**Source**
Dependent variable			
dom_cur_ bonds	Share of LCY corporate bonds in the total issue volume (%)		Bloomberg database, authors' calculations
Explanatory variables – institutional factors			
lnIEF	Logarithm of Heritage Foundation's Index of Economic Freedom (0 - minimum, 100 - maximum)	+/-	Heritage Foundation, http://www.heritage.org/
Political	World Bank's Indicator of political stability and absence of violence / terrorism (-2.5 - minimum, 2.5 - maximum)		World Bank database (Worldwide Governance Indicators)
Government	World Bank's Indicator of government effectiveness (-2.5 - minimum, 2.5 - maximum)		
Regulatory	World Bank's Indicator of regulatory quality (-2.5 - minimum, 2.5 - maximum)		
Rule	World Bank's Indicator of rule of law (-2.5 - minimum, 2.5 - maximum)		
Corruption	World Bank's Indicator of control of corruption (-2.5 - minimum, 2.5- maximum)		
Ethical	Index of ethical behavior of firms (1 - minimum, 7 - maximum)		Global Competitiveness Reports of World Economic Forum
Auditing	Index of quality of auditing and reporting		

Variable	Description	Expected direction of influence (+/-)	Source
	standards (1 - minimum, 7 - maximum)		
Financing	Index of financing on the domestic stock market (1 - minimum, 7 - maximum)		
Ease	Index of ease of access to bank loans (1 - minimum, 7 - maximum)		
Regul_ Secur	Index of quality of regulation of stock exchanges (1 - minimum, 7 - maximum)		
Indirect institutional factors			
lnCredit	Logarithm of domestic credit to the private sector (in % of GDP)	+	World Bank database
ln_MC	Logarithm of market capitalization (in $ mln)	-	World Federation of Exchanges
Control explanatory variables			
cur_usd	Change in the exchange rate of national currency (USD / unit of national currency) for the current quarter, %	-	Bloomberg database
GDP	Annual growth rate of real GDP in the current quarter (to the same quarter of the previous year)	+	Trading Economics, http://www.tradingeconomics.com/
inflation	Annual inflation rate (based on CPI), the average value for three months of a given quarter (%)	+/-	
PPI	Annual growth rate of the producer price index (PPI), the average value for three months of a given quarter (%)		
rating_SP	Change in S&P long-term sovereign credit rating: 0 - no change, +1 - rating upgraded, -1 - rating downgraded	+/-	Bloomberg database
rating_ Fitch	Change in Fitch long-term sovereign credit rating: 0 - no change, +1 - rating upgraded, -1 - rating downgraded		
rating_ Moodys	Change in Moody's long-term sovereign credit rating: 0 - no change, +1 - rating upgraded, -1 - rating downgraded		
rating	Change in one of long-term sovereign credit ratings (S&P, Moody's or Fitch): 0 - no change, +1 - rating upgraded, -1 - rating downgraded		
dAsian	Dummy variable of Asian countries	+/-	

In order to solve the problem of multicollinearity, institutional factors were included in the regression models separately. In addition, this construction of models allows us to rank institutional factors by significance of their impact on the dependent variable. A similar principle is chosen for variables of sovereign credit ratings: they are included in models separately.

We consider a balanced panel including 15 countries and 28 quarterly periods. At the first stage, we test static regression models with fixed effects:

$$dom_cur_bonds = \alpha + \beta_1 \cdot cur_usd + \beta_2 \cdot GDP + \beta_3 \cdot lnCredit + \\ + \beta_4 \cdot inflation + \beta_5 \cdot PPI + \beta_6 \cdot ln_MC + \beta_{7,k} \cdot rating_k + \beta_8 \cdot dAsian + \\ + \beta_{9,l} \cdot Institution_l + \sum \beta_{10,m} \cdot c_m + \varepsilon \quad (1)$$

where α - a constant, $\beta_1,..,\beta_{10}$ - beta coefficients, $rating_k$ *(k=1,…,4)* – one of variables characterizing changes in sovereign credit ratings, $Institution_l$ *(l=1,…,11)* – one of direct institutional factors, c_m *(m=2,…,15)* – country effects (dummies in models with fixed effects, *m=1* - Russia), other variables are described in Table 1.

At the second stage we test GMM-models allowing us to solve the problem of potential endogeneity between indicators of development of corporate bond markets and macroeconomic and institutional factors. We apply the system generalized method of moments (GMM-Sys model), proposed by Holtz-Eakin et al (1990), Arellano and Bond (1991), Arellano and Bover (1995), Blundell and Bond (1998):

$$dom_cur_bonds_{i,t} = \alpha \cdot dom_cur_bonds_{i,t-1} + \beta_0 \cdot X_{i,t} + \mu_i + \varepsilon_{i,t} \quad (2)$$

$$dom_cur_bonds_{i,t} - dom_cur_bonds_{i,t-1} = \\ = \alpha \cdot (dom_cur_bonds_{i,t-1} - dom_cur_bonds_{i,t-2}) + \\ + \beta_0 \cdot (X_{i,t} - X_{i,t-1}) + \varepsilon_{i,t} - \varepsilon_{i,t-1} \quad (3)$$

with additional conditions of the moment:

$$E[(dom_cur_bonds_{i.,t=s} - dom_cur_bonds_{i,t-s-1})(\mu_i + \varepsilon_{i,t})] = 0, \ \ s = 1 \\ E[(X_{i,t-s} - X_{i,t-s-1})(\mu_i + \varepsilon_{i,t})] = 0, \ for\ s = 1 \quad (4)$$

where *i* and *t* – a country and a quarter respectively, $X_{i,t}$ - the vector of independent variables (Table 1, model (1)), μ_i - country effects, $\varepsilon_{i,t}$ - the error.

Descriptive statistics on the sample

Initially, we chose for consideration the BRICS countries which are large economies with relatively large bond markets. In December 2016, the volume of LCY corporate bonds outstanding was 12.3% of GDP in Russia, 25.6% of GDP in Brazil, 43.8% of GDP in China, and 16.9% of GDP in India. It should be noted that the BRICS countries are characterized by different macroeconomic indicators but similar institutional indicators. For example, in 2010-2016 the average annual growth of real GDP was 1.4% in Russia, 1.4% in Brazil, 8.1% in China, and 7.4% in India. The average value of Heritage Foundation's Index of Economic Freedom in 2010-2016 was 51 in Russia, 57 in Brazil, 52 in China, 55 in India (the scale is from 0 (minimum) to 100 (maximum)). In order to identify institutional determinants of development of LCY corporate bond markets, we expanded the sample including both fast-growing bond markets of developing countries and bond markets of countries with a higher level of economic development (S. Korea, Hong Kong and Singapore) as benchmarks. So, we considered the top-15 developing countries by issue volume of corporate bonds (in LCY and FCY) in the pre-crisis 2013 (Fig. 1). Instability in world commodity markets in 2014-2016 had a

negative impact on GDP growth and stability of the local currencies of oil-exporting countries. In addition, we did not include the UAE in the sample due to an exceptionally low share of LCY corporate bonds (about 0.3%). Instead of the UAE, we chose Poland as one of the major emerging markets of corporate bonds in Eastern Europe. All the countries under consideration are characterized by certain difficulties in development of political and economic institutions and by elements of authoritarian rule.

So, we use a balanced panel data for 15 countries (Brazil, Hong Kong, India, Indonesia, China, Malaysia, Mexico, Poland, Russia, Singapore, Thailand, Turkey, Chile, S. Africa, S. Korea) from 2010 to 2016. The sample includes 420 observations.

Results of Empirical Research

The results of our empirical research demonstrate a stable negative impact of all institutional factors on the dependent variable in static and dynamic model specifications (Tables 3, 4). In static models (Table 3), all institutional variables are significant at the 1% level. Heritage Foundation's Index of Economic Freedom, regulatory quality, corruption control and rule of law have the most significant impact on the share of LCY corporate bonds.

In dynamic models, the significance level of variables is different (Table 4). Regulatory quality and rule of law are significant at the 1% level. Index of Economic Freedom, corruption control, the indices of quality of auditing and reporting standards, the quality of regulation of stock exchanges are significant at the 5% level. Government effectiveness is significant at the 10% level, and other factors are not significant.

Our results coincide with conclusions by Teplova and Sokolova (2016) regarding the Index of Economic Freedom and by Park (2016) regarding rule of law, but contradict results of other previous papers (Burger and Warnock (2006); Eichengreen and Luengnaruemitchai (2004); Claessens et al (2007)). It should be noted that Claessens et al (2007) revealed a positive, but statistically insingnificant influence of democratic institutions on the share of FCY government bonds. Burger and Warnock (2006) and Eichengreen and Luengnaruemitchai (2004) chose the volume of outstanding LCY government and corporate bonds (in % of GDP) as the dependent variable, whereas we consider the relative share of LCY corporate bonds in the total issue volume.

We explain the negative impact of the quality of institutions on the share of LCY corporate bonds by the fact that holders of corporate bonds in the domestic market are less sensitive to changes in institutional factors than global investors. The latter have wider opportunities for diversification of investments. In case of an increase in the level of institutional development, the FCY corporate bond segment develops at a faster rate than the LCY bond segment, because investment attractiveness of corporate bonds increases for global investors. In addition, higher quality of institutions stimulates issuers of corporate bonds to attract loans in foreign markets demonstrating lower rates and longer maturity. On the contrary, in cases of a decline in the quality of institutions, an emergence of barriers to the movement of international capital, a deterioration of the macroeconomic situation, national companies become less attractive for foreign investors and are forced to raise capital on the domestic market. As a result, the share of LCY corporate bonds increases.

In all considered model specifications market capitalization has a stable significant negative influence on the dependent variable. More developed stock markets suppress development of LCY corporate bond markets, because they are competing sources of financing for companies in emerging countries. This coincides with results of Teplova and Sokolova (2016). Unlike the stock market, a developed banking sector has a positive effect on the LCY corporate bond market. If companies prefer debt financing, larger ones issue bonds, and smaller ones attract bank lending. The variable *lnCredit* retains a positive sign in all model specifications, but it is significant only in static models (Tables 3, 4). Thus, conclusions of some previous works are confirmed (Eichengreen and Luengnaruemitchai (2004); Teplova and Sokolova (2016)), but this result contradicts to the work by Bhattacharyay (2013).

Notes. The significance level: *** — 1%, ** — 5%, * — 10%.

In all models (linear regressions and GMM), the change in the exchange rate has a stable negative impact (significant at the 1% level) on the dependent variable. Devaluation of the local currency stimulates development of LCY corporate bond markets, as debt denominated in FCY becomes more expensive. Changes in sovereign credit ratings significantly negatively affect the share of LCY corporate bond markets, and their impact is stable in both dynamic and static models. We explain this by the fact that an increase in sovereign credit ratings raises the country's investment attractiveness and facilitates attraction of FCY loans on the global market, but it is depressing for the LCY debt market.

In most model specifications, the dummy variable of Asian countries demonstrates a significant positive effect on the dependent variable, i.e. in Asian countries there is a tendency to issue a larger share of LCY corporate bonds.

In dynamic models, there is a significant positive effect of the lagged dependent variable *L1_dom_cur_bonds* (Table 4).

For other control variables, the results are not stable. In most of static and dynamic models, inflation (based on PPI) has a negative impact on the share of LCY corporate bonds, but this impact is not significant. This result coincides with conclusions of Burger and Warnock (2006), Claessens et al (2007), Teplova and Sokolova (2016). In static models, GDP growth rate significantly positively (at the 5% level) affects the dependent variable. On the contrary, in dynamic models, the direction of influence of GDP growth rate changes to be negative, and the factor is not significant. Burger and Warnock (2006), Teplova and Sokolova (2016) applied linear multifactor regressions and revealed a positive relationship between GDP growth and the size of LCY corporate bond markets.

Conclusions

We reveal institutional determinants of development of LCY corporate bond markets. We apply static (multifactor linear regression) and dynamic (GMM) models in order to solve the problem of potential endogeneity of variables (indicators of development of LCY corporate bond markets, macroeconomic and institutional variables).

In static models, all direct institutional variables, as well as an indirect factor of the development of the stock market, significantly negatively affect the share of LCY corporate bonds. The most significant factors are Heritage Foundation's Index of Economic Freedom, Worldwide indicators of regulatory quality, control of corruption and rule of law. In dynamic models, the influence of quality of institutional development is also negative, but the significance level of factors is different. Indicators of regulatory quality and rule of law are significant at the 1% level. Variables of sovereign credit ratings also negatively affect the share of LCY corporate bonds, but they are statistically significant only in linear regressions.

We explain the negative impact of the quality of institutions o by the fact that holders of corporate bonds in the domestic market are less sensitive to changes in institutional factors than global investors. The latter have wider opportunities for diversification of investments. In the case of an increase in the quality of institutions, the investment attractiveness of FCY corporate bonds grows, and this segment develops at a faster rate than LCY corporate bond segment. Openness of the economy contributes to the choice of issuers in global capital markets. A developed stock market limits growth of LCY corporate bond market, because in developing countries, stock and bond markets are competing sources of funding for national companies.

Financial and macroeconomic instability also stimulates development of LCY corporate bond markets. Devaluation of the local currency influences positively the share of LCY corporate bonds due to the rise in the cost of debt denominated in FCY.

The Economic Benefit of Fans of Luxury Fashion Brand Pages on Facebook

Jitka Novotová, Faculty of Economic, Technical university of Liberec, Liberec, Czech republic, jitka.novotova1@tul.cz

Lubica Cinkánová, Faculty of Economic, Technical university of Liberec, Liberec, Czech republic, lubica.cinkanova@tul.cz

Abstract

This article focuses on Facebook, specifically on the company pages of luxury fashion brands. The aim of the article is to find out why the users of this social network add luxury company pages and whether the fans of these pages constitute an economic benefit for companies. A quantitative survey was conducted using an online questionnaire sent via Facebook. Five hundred fifty-four Facebook users from the Czech Republic participated in the survey. The data obtained were analysed using exploratory factor analysis, ANOVY and the verbal variability independence test. The results showed that up to 70 % of luxury brand customers with Facebook accounts added company pages. The reason for adding the pages is, in particular, the opportunity to become a part of the luxury brand community and also to get the latest information on brands and upcoming collections. Additionally, it was found that fans of company pages are more likely to buy and spend more money than customers who have not added a company page. Thanks to this information, we can recommend that companies set up a company Facebook page and regularly communicate with their fans.

Key words: Facebook, luxury fashion brand, marketing communication, brand community

Introduction

For most people, luxury brands are an unattainable but fascinating world of expensive cars, handbags and clothing. Even though the luxury market is relatively small, it has exceptional economic results. In 2014, global sales of luxury goods and services amounted to EUR 850 billion, with the largest growth being in the luxury car (10 %) and luxury holiday (9 %) segments (D'arpizio, 2014). In 2016, it was already EUR 1.08 trillion (D'arpizio, et al., 2016). The growing group of so-called "High Earning, Not Rich Yet" people with high incomes but who are not yet wealthy is the main force behind this growth. There are ten times more customers in this category than truly rich people. These people want to at least occasionally enjoy something luxurious (Mediaguru, 2013). In the personal luxury goods segment (watches, cosmetics, shoes, handbags and clothing), revenues of EUR 223 billion were achieved in 2014, three times more than 20 years ago. The latest global economic crisis has slowed down sales growth, but unlike other segments, it has not recorded negative values (D'arpizio, 2014). Luxury goods are therefore a very promising segment, which is also addressed by a number of marketing experts. In this article I will focus on luxury clothing brands and on the Czech customers of these brands.

New channels of communication over the internet have become increasingly important for marketers in recent years, among which we can include social networks (Ungerman, 2016). The largest social network today is Facebook (Kopřiva, 2015). Facebook was founded by Harvard student Mark Zuckerberg on 1 February 2004. At the beginning, it was used by Harvard students to get to know each other. Once half of all Harvard students had created a profile on Facebook, it spread to other prestigious universities and high schools as well as leading corporations. In 2006, Facebook was opened to the general public (Treadaway and Smithová, 2011). Since 2007, many fan pages have been set up on Facebook to enable companies to promote their products or brands. Facebook users can add these pages to their favourites to show their friends what businesses and brands they are interested in (Kudeshia et al., 2016).

The purpose of this article is to find out what percentage of Facebook users add company pages of luxury clothing brands and whether communication on these pages affects purchase frequency and how much money customers spend on one purchase.

Based on this research objective we identified four research questions:

1) What percentage of Facebook users has added company pages of luxury fashion brands?
2) Why do fans add pages of luxury fashion brands?
3) Are there different reasons for adding company pages based on different demographic characteristics of fans?
4) Do company pages on Facebook have an economic benefit for companies?

The answers to these research questions were identified using a quantitative questionnaire survey, which will be presented in detail in the methodological part of this article. The theoretical part of this article will first familiarize readers with the generic term "brand", with the definition of "luxury brand" from the perspective of Czech customers, and will focus on Facebook as a marketing communication tool.

Theories

Brand

Brands have been used for centuries to distinguish the goods of individual manufacturers. The word *"brand"* originates from the word "*brandr*", which means *"burn",* because a brand or tag was used to mark and identify animals in a herd (Keller, 2007). In his definition, Keller compares brands to products: "*A brand is a product, but a product that delivers other dimensions that distinguish the brand from other products created to meet the same need"* (Keller, 2007, p. 34). Nowadays, the brand is a complex concept. The brand exists primarily in the consciousness of consumers and very often coincides with reputation. In other words, a specific brand is what the customer thinks of it (Healey, 2008). As Walter Landor, the pioneer of branding, memorably said: *"Products are made in the factory, but brands are shaped in the mind"* (Landor in Posner, 2011, p. 128).

The brand is thus a means of creating and changing the position of the product in the mind of the consumer (Vysekalová and Mikeš, 2009). For example, branded clothing is better rated by the consumer and reinforces the willingness to buy clothes. Brands generally provide a guarantee of unmistakability, especially in the sectors of very similar products such as clothing or electronics (Bristow and Mowen, 1998). The key element of branding is therefore that consumers perceive the differences between brands in the product category. The differences between brands often relate to the properties or benefits of the product itself. Other times, however, they can be guided by the less easily perceptible criteria of image. Whenever consumers decide between alternatives, brand plays an important role. For this reason, companies benefit from brands whenever consumers face the question of choice (Keller, 2007). Today, when there is a plethora of products and substitutes on the market, everyone can choose what product to buy. In this competitive struggle, therefore, each manufacturer strives to provide the customer with some added value, and this may be a brand (Dědková, 2014).

Luxury fashion brands

"Fashion is not just about clothing. Fashion is in the clouds, on the streets. Fashion is an idea, lifestyle and a current event." (Chanel in Brogi et al., 2013). This credo guided world-renowned fashion designer Coco Chanel, who set the tone for the world fashion industry until the mid-20th century and introduced one of the most luxurious brands in the world.

What is luxury fashion? There is no clear cut answer to this question. Luxuries are perceived differently not only by individual customers but also by residents of different countries. Research from the Czech Republic has shown that Czechs have a somewhat simplified view of the luxury

goods market. In their opinion, luxury above all demonstrates social status and satisfies the desire for recognition. Three-quarters of respondents perceive cars, jewellery and watches as symbols of luxury (Obruk, 2010). Among luxury fashion brands, Czech customers most often include Louis Vuitton, Prada, Versace and Dior. On the other hand, some of them perceive Guess, Lacoste or Michael Kors as luxury brands. These brands, however, are considered premium brands in countries such as the USA, Germany or France, which are characterized by lower quality and price (Novotová, 2016). The 2010 research also looked at the attributes of luxury brands. The most frequently mentioned attributes are exceptional quality, the social status that the brand brings to the user, global renown or high price (Obruk, 2010).

These results are practically identical with those from other countries. For example, Phau and Prendegast (2000) found that a luxury brand is a subjective notion that consists of exclusivity, expected quality, brand awareness and renown. According to Fionda and Moore, luxury brands can be divided into two levels from a customer perspective. The first is the material level, which includes brand history, quality and unique know-how. The second level is psychological and includes the exclusivity and prestige of the brand which affects the carrier's position in society (Fionda and Moore, 2009).

For the purposes of our research, these attributes of luxury fashion brands were used as the starting point, which were introduced to the respondents before filling in the questionnaire itself, as well as examples of brands that can be clearly considered luxurious. These measures ensured that the respondents had a good idea of what a luxury brand was and could correctly fill in a questionnaire dealing with the marketing communications of luxury brands on Facebook.

Facebook

Facebook is currently used not only for communication between friends, but also for communication between customers and companies (Gamboa and Goncalves, 2014). Companies can communicate with existing and potential customers on Facebook via company pages, news, events or paid ads (Janouch, 2011). Company pages bring businesses a number of benefits. Facebook users can add these pages to their favourites to show their friends what businesses and brands they are interested in (Kudeshia et al., 2016). Through these pages it is possible to build two-way communication between the company and a potential or existing customer (Janouch, 2011). Businesses should try to establish user-friendly relationships using the current page, responding quickly to customer inquiries, and listening to what users are saying. In other words, a company page must be a place where the customer likes to communicate and feels part of a wider community of fans (Gamboa and Goncalves, 2014). The advantage of company pages on Facebook is the ease with which fans of these pages are identified and the ability to create a strong customer bond with the brand (Shih, 2010). Whether this positive relationship also affects customer buying behaviour is the subject of much research. For example, Kang et al. (2013) claim that communication on company pages does not have an impact on product purchases. On the other hand, research in the Czech Republic has shown that communication on company pages motivates customers to buy (Novotová, 2017). It is also important for businesses to know what motivates Facebook users to add company pages. Rohm et al. (2013) identified five motivations. These include: entertainment, affiliation to a popular brand, access to customer services and content, the ability to get product information, and marketing communication which encourages them to add the page.

The motivations for adding the company pages of luxury clothing brands as well as the relationship between adding a page and purchasing goods will be dealt with in the practical part of this article.

Methodology

As was already mentioned in the introduction, the purpose of this article is to find out what percentage of Facebook users add company pages of luxury clothing brands and whether the communication on these pages affects purchase frequency and how much money the customer spends on one purchase.

Based on this objective, a quantitative research method was selected using an electronic questionnaire survey. The questionnaire was created through Google – Disk and distributed via Facebook. The main group of respondents were citizens of the Czech Republic who are over 18 years of age, have a Facebook profile and have bought a luxury clothing brand at least once. In this research luxury brands are defined as worldwide renowned brands such as Gucci, Prada or Versace. The sample was determined using the snowball nonprobability sampling method. This method was selected because of the narrowly and specifically defined sample base, which is poorly accessible. Individuals in the sample base have a higher family income and a specific lifestyle that leads them to purchase luxury goods. Due to the limited number and especially the poor availability of such respondents, the snowball sampling method was judged the only one possible. The research team selected suitable respondents who met all the criteria for the sample base. These respondents were sent an online questionnaire with a request to forward it to other suitable respondents.

The questionnaire contained closed selective questions and scaled questions. The results were evaluated using the statistical method of exploratory factor analysis, variance analysis (ANOVA), and the verbal variability independence test. These methods are briefly presented below.

1) Exploratory factor analysis

Factor analysis focuses on creating new variables and reducing the extent of data with minimal loss of information. For factor analysis to be performed, the Bartlett's sphericity test (P-value < 0.05) and the Kaiser-Meyer-Olkin (KMO) condition must be met. Under this condition, certain bands are defined to show the extent to which the use of factor analysis is appropriate. KMO ≥ 0.9 excellent, KMO ≥ 0.8 good, KMO ≥ 0.7 average, KMO ≥ 0.6 less suitable and KMO ≥ 0.5 borderline use (Meloun and Militký, 2006). For better interpretation of results, Varimax Rotation was performed in this article. It is a method that minimizes the number of variables that have high burdens with each common factor (Hendl, 2004).

2) ANOVA

The aim of the ANOVA analysis is to determine which of the qualitative or quantitative factors significantly affect the monitored quantities. ANOVA was used in this article after exploratory factor analysis. For this reason, and due to the large number of units in each selection, the normality of data was not verified (Churchill, 1987). A two-choice t-test was performed for two-value factors (Budíková, et al., 2010; Meloun and Militký, 2002). For both statistical methods, the H0 hypotheses of variance consistency and H1 hypothesis were determined by difference; the assertion was tested at a 95% significance level. If H0 was rejected and therefore H1 was accepted, it was further investigated which pairs of mean values were different at a given level of significance. To determine significant differences, Fisher's LSD post-hoc test was used (Šimonová, 2006).

3) Verbal variability independence test

It is used especially for verifying the dependencies of two verbal variables. The test assumes that data on two variables are a selection from an infinite two-dimensional set. The H0 hypothesis is tested on the independence of both variables against the alternative hypothesis H1, that these variables are dependent (Meloun and Militký, 2006).

Sample of respondents

A total of 554 respondents participated in the survey. Their demographic characteristics, including gender, age and highest level of attained education, are shown in Table 1. The vast majority of participants in the research were women (403), who buy luxury fashion more often. Men often did not know which clothing brands were considered luxurious, and therefore did not fill in the questionnaire properly. For this reason, a number of their erroneously filled in questionnaires were eliminated.

Tab. 1: Demographic characteristics of respondents (Source: the author)

Cathegory	Frequency	%
Gender		
women	403	72,7
men	151	27,3
Age		
Less than 20 years	18	3,3
20 to 29 years	357	64,4
30 to 39 years	101	18,2
40 to 49 years	51	9,2
50 to 59 years	19	3,4
60 to 69 years	8	1,4
Education		
primary	6	1,1
secondary without diploma	15	2,7
secondary with diploma	230	41,5
colledge	303	54,7

Respondents aged 20 to 29 and 30 to 39 were the most represented in the survey. People over the age of 50 often do not have a Facebook account and therefore cannot participate in the research. Most of the people involved in the research had a high school diploma or higher education.

Table 2 below shows the purchase frequency of luxury fashion goods and the amount of money that the average respondent spends on one luxury fashion purchase.

Tab. 2: Purchase frequency and money spent on one purchase (Source: the author)

Category	Frequency	%
Purchase frequency		
Only occasionally	143	25.8
1x per year	52	9.4
2x–3x per year	123	22.2
Once per quarter year	118	21.3
Once per month	80	14.4
Several times per month	38	6.9
Amount spent on one purchase		
up to CZK 10,000	227	42
CZK 10,001–30,000	227	42
CZK 30,001–50,000	54	10
CZK 50,001–70,000	18	3.3
CZK 70,001–90,000	12	2.2
CZK 110,000 and more	2	0.4

Table 2 shows that most respondents shop only occasionally. On the other hand, a relatively large group of respondents make a purchase once per quarter year or two to three times a year. Thus, we can say that both occasional customers and regular luxury brand customers are represented in the research. Most respondents spend a maximum of CZK 30,000 for one purchase (approximately EUR 1,154), and only two respondents spent more than CZK 100,000 (EUR 3,846).

Results

In the practical part we will first answer the first research question, which is:

1) What percentage of Facebook users has added company pages of luxury fashion brands?

Of all 552 respondents who are Facebook users, 389 or 70 % have accepted at least one luxury fashion brand page. This number is relatively high. It is important to note that all respondents who participated in the survey are customers of luxury fashion houses. Thus, we can state that up to 70 % of luxury brand customers have accepted at least one luxury fashion company page on Facebook.

The second research question asked about the reason for adding company pages.
2) Why do fans add pages of luxury fashion brands?

Based on the research team's deliberations, six reasons were identified that can cause Facebook users to decide to add a fashion page. The respondents assessed their agreement or disagreement with the reasons in the questionnaire using a seven-point scale where 1 = I totally agree and 7 = I totally disagree. The results were first evaluated using descriptive statistics. In the following Table 3, the reasons are ranked according to the averages reached from the lowest (largest agreement) to the highest. The most common reason is the need to keep up-to-date about one's favourite brand. The second reason is that people want to be inspired by the latest fashion trends. The third reason was simply that people want to be "in", and therefore add trendy fashion pages. People also add company pages because they want to be part of a group of fans of the brand that is created on the company page. Another reason is the ability to communicate on the page, i.e. to comment on posts or send queries to company representatives via chat. Lastly, people add a company page simply so that their friends can see that they have added it.

Tab. 3: Reasons for adding company pages – descriptive statistics (Source: the author)

	Brand information	Inspiration	To be IN	Fan community	Communi-cation	Friends
Average	1,6	1,9	3,4	4,1	5,1	5,3
Median	1	1	3	4	6	6
Modus	1	1	2	3	6	6
Standard dev.	0,87	1,22	2	1,93	1,8	1,81

For better clarity, the individual reasons for adding luxury fashion pages are presented in a box fence (Figure 1).

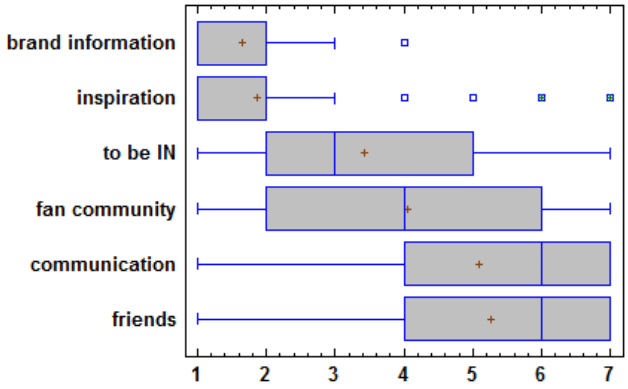

Fig. 1. Reasons for adding company pages – box fence

These six reasons were further tested using exploratory factor analysis. The aim of factor analysis was to summarize the information contained in a larger number of variables and reduce them to a few factors (Table 4).

Tab. 4: Reasons for adding company pages – factor analysis results (Source: the author)

KMO	0.744
Bartlett's test	0.000
Number of variables entering the FA	6
Number of factors	2
Cronbach's alpha	0.743

**Extraction method: main component analysis*
***Rotation method: varimax*

Kaiser-Meyer-Olkin's criterion was 0.744. This means that the use of factor analysis is good. Bartlett's test also came out (p-value < 0.05), so factor analysis could be performed. Cronbach's alpha was 0.743 for all variables, indicating the high consistency and reliability of the data. Table 5 summarizes the information about the overall explained variability and the numbers of the correlation matrix. The number of factors was chosen according to Kaiser's rule. This criterion is met by two factors, which together account for 66.8% of the overall variability.

Tab. 5: Reasons for adding company pages – results of main component analysis (Source: the author)

Faktor number	Eigenvalue	Percent of Variance	Cumulative Percentage
1	2,636	43,932	43,932
2	1,372	22,876	66,808

Table 6 shows the results of factor analysis. The table rows correspond to input items, columns represent factors. In order to better interpret the results, rotation was performed using the varimax method.

Tab. 6: Reasons for adding company pages – Factor Loading Matrix After Varimax Rotation (Source: the author)

	Factors	
	Brand community	**Information**
Brand community	0,861	0,023
Friends	0,832	-0,059
To be IN	0,731	0,259
Communication	0,724	0,126
Brand information	0,043	0,843
Inspiration	0,113	0,839

Table 6 shows that the first factor called the Brand Community consists of four reasons for adding pages, which are the possibility to be part of a brand community, the fact that my friends see that I have added a page, trying to be "in", and the ability to communicate on the page. The second factor called Information includes the ability to get up-to-date information about a favourite brand on the company page, and the opportunity to get inspiration about the latest fashion trends.

The third research question dealt with the possibility of different views on these two identified factors among different demographic groups of respondents.

3) Are there different reasons for adding company pages based on different demographic characteristics of fans?

This question was answered by means of a one-factor analysis of ANOVA variance, or the t-test, which examined the differences between the average response values of different demographic groups of respondents. Differences of gender, age and education were tested. Table 7 shows all the tests performed and shows both the F-Ratio / t statistic and the P-value.

Tab. 7: Reasons for adding company pages – ANOVA and t-test (Source: the author)

Factor	Characteristics	F-Ratio/t statistic	P-value
Brand community	gender	3,368	0,067
	education	7,646	**0,000**
	age	3,167	**0,024**
Information	gender	29,776	**0,000**
	education	0,992	0,397
	age	3,715	**0,012**

For the Brand Community factor, statistically significant differences were found in the characteristics of education and age. This factor was reported more frequently by people of lower age (under 30) and people with a high school diploma or university education. For the Information factor, a statistically significant difference was found for gender and age of respondents. More women and people under the age of 30 add the pages for this purpose.

The last research question focused on the economic benefits of company pages on Facebook. The research question was formulated as follows:

4) Do company pages on Facebook have an economic benefit for companies?

The economic benefit for companies was evaluated on the basis of two questions in the questionnaire. The first question related to the amount of money that customers spend on one luxury brand purchase, and the second asked how often customers buy luxury fashion. The economic benefit was therefore assessed on the basis of information provided by customers. The analysis was performed using the verbal variability test. First, it was tested whether there is a relationship between adding company page on Facebook and the amount of money spent on one luxury fashion purchase. The results of this test are presented in Table 8 below. The results show that there is a statistically significant relationship between the added page and the purchase amount.

Table 8: Tests of Independence (Source: the author)

Added page –	**Statistic**	**Df**	**P-Value**
Amount spent on purchase	60.778	4	0.000

The second test investigated the relationship between adding a company fashion page on Facebook and the frequency of purchasing luxury brands (Table 9). Here again, a statistically significant relationship between the two variables was demonstrated. So we can say that people who add the company pages of luxury brands are more likely to buy these brands.

Table 9: Tests of Independence (Source: the author)

Added page –	**Statistic**	**Df**	**P-Value**
Purchase frequency	42.411	5	0.000

Discussion and conclusion

This article dealt with the social network Facebook, specifically the pages that luxury fashion companies set up on Facebook. The first question asked what percentage of luxury brand customers has added at least one company page of these brands on Facebook. We have found that up to 70 % of respondents have added a company page. We discovered that this number is surprisingly large. It can be seen that customers are accustomed to adding company pages. There are many reasons why people add company pages. In this work, we defined six reasons that we reduced through exploratory factor analysis to two factors, namely Brand Community and Information. The Brand Community factor includes reasons such as the opportunity to be involved in a community of fans of the favourite brand, communications on the page, and the desire to be associated with a luxury brand. These reasons are especially important for the younger generation of Facebook users up to 30 years of age and for people with higher education (high school diploma, university degree). Therefore, companies should strive to create an appropriate environment for discussion amongst their fans. In addition, it is advisable to encourage brand awareness by means of appropriate communication. The second identified factor is Information. Fans want to get information on the latest fashion collections on the company's page and to peer behind the scenes of their favourite brands. Fans also expect the page to offer the latest fashion trends and tips on how to work with fashion. Fashion companies should focus on both identified factors if they wish to continue to expand their fan base.

In the last part of the research, we responded to research question number 4, which asked about the economic benefits of company pages. The results have shown that people who have added a company page typically spend more money on one purchase. Similarly, the purchase frequency is higher for fans of a company page than for people who have not added any pages. It cannot be clearly determined from the results whether page fans are so influenced by company communications that they are more likely to buy and spend more, or whether company pages tend to attract people who are loyal customers. Based on the results, we can only say that fans of company pages bring more revenue for companies than customers who have not added these pages. Whether the company page is the cause of larger and more frequent research is needed in further research. Based on our results,

we can state that company pages on Facebook have a large percentage of users today. The most common reasons for adding a company page are to be part of the brand community and the availability of brand information. Another important finding is that company pages cluster together customers who bring the largest revenue to companies. Based on these findings, we can recommend that companies establish a company page on Facebook and create a loyal customer base.

Acknowledgment

This article was created as part of a project to support excellent research teams at the Faculty of Economics of the Technical University of Liberec (EF TUL), which is funded by institutional support for the long-term conceptual development of EF TUL.

Liquidity Constraint and the Efficiency of Innovative Activities: The Results of Empirical Analysis of Industrial Companies

Dr. Arkady Trachuk, Doctor of Economics, Professor, the Financial University under the Government of the Russian Federation, Head of the Department of Management, Russia, Trachuk_A_V@goznak.ru;

Dr. Nataliya Linder: Candidate of Economics, Professor, the Financial University under the Government of the Russian Federation, Deputy Head of the Department of Management, Russia, NVLinder@fa.ru

Abstract

Research and development of new technology (R&D) is generally more beneficial for society than simply the profits made by an innovator, meaning that it produces a positive externality. Therefore, the key feature of an innovation analysis is consideration of the effects of floating: an enterprise does not receive the whole profit from the R&D completed, since other firms also obtain access to the developed technology (possibly with a time lag). For this reason, many firms tend to underinvest in R&D - particularly when a company experiences a liquidity constraint.

This paper highlights the results of research into the influence of liquidity constraint on corporate decisions on investment in research and development (R&D), and the efficiency of their innovative activities. The purpose of this research is to analyse the influence of liquidity constraint, expressed both in a tough version in which a company has no access to capital markets (for instance, due to a financial crisis or lack of property to secure collateral for credit) or in a softer version in which a company can raise credit, but the price of borrowed funds is higher than profitability of its activities - on the decision of companies to invest in R&D, the intensity of their investments in R&D and anticipated efficiency of innovative activities. This analysis uses a direct indicator of limiting credits and an econometric model defining a relation between a decision of companies to invest in R&D, intensity of those investments and efficiency of innovative activities. The results show that constraining financial indicators have a positive significant interrelation with the decision of firms to invest in R&D and has no influence on the intensity of those investments in case of a positive decision. Therefore, the liquidity constraint reduces the number of industrial companies deciding to invest in R&D, but does not influence the amounts of such investments. This can be explained by the fact that when companies decide to invest in R&D, availability of their own funds is more important than the possibility of raising credit.

There is also a cash effect: the effect of availability of extensive available funds at a large company facilitate its financing of R&D and innovation, and thus an inverse U-dependency between competition and innovation is confirmed.

It is concluded that small companies and companies in low-tech industries do not need to boost their R&D intensity, but need investment which facilitate the imitation of ready-to-use technology from the developed markets.

Key words: costs of research and development, innovation, liquidity constraint, result-driven innovative activities, financial status, two-dimensional probit-model.

Introduction

Given today's fast-developing situations and growing globalization, companies must regularly upgrade their production technology, create new products and form new sources of competitive advantages associated with the creation of intangible assets in order to keep their competitive positions and create new competitive advantages. All these things require huge research and development costs alongside generally financing innovative activities (Trachuk, Linder, 2016).

At the same time, most Russian industrial companies currently experience liquidity constraints due to the sanctions imposed on Russia by Europe and the USA after the RF reunified with Crimea. For instance, sanctions against the financial sector affect 60% of assets of the RF banking system and seriously limit the country's development. More expensive funding for Russian banks and organizations has resulted in an increase in interest rates and has made borrowing more expensive - which, in its turn, has had an inevitable impact on companies' investments in their current operations, including in investments in research and development.

Sanctions have a most deleterious impact on industrial companies since - , firstly - they reduce the options for cheap investments. In such cases, the State cannot provide such financing or meet the demands for all companies. Secondly, sanctions restrict access to new technologies, which cannot be substituted by either Chinese or Russian products over the short term. A ban on importing dual-purpose products, along with limitations on non-military higher technology imports may make Russia's technological inferiority to the world's leading countries even worse.

For this reason, research of the impacts of liquidity constraint - expressed both in a soft form where the rate of return on a company's operations is lower than the interest rate on loans or a tough form implying that a company has no access to the market of crediting - on companies' investment decisions in research & development, as well as the amounts of such investments and efficiency of innovative activities of Russian industrial companies, is highly topical.

Liquidity constraint impact on investments in R&D and innovation: overview of research

The results of such research of liquidity constraint on investments in R&D are ambiguous and contradictory. Most studies proved a negative effect of the liquidity constraint on investments in R&D (for instance, Aghion et al., 2012; Mancusi and Vezzulli, 2012; Bellone F. et al., 2013) and innovation (Savignac, 2008). However, a study (Czarnitzki and Hottenrott, 2011) shows that availability of in-house sources of funding is more important for a company deciding on investments in R&D; therefore, such decisions are not sensitive to liquidity constraint; a study by Mulkay et al., 2001, shows that decisions to invest in R&D are sensitive toliquidity constraint, but no more than decisions to invest in current operations. A study by Bond (Bond et al., 2003) argues that investments in research and development do not depend on cash flows and therefore financial constraints have no serious impact on decisions of firms to invest in R&D.

This article uses, for analytical purposes, the methodology chosen in studies (M. L. Mancusi, A. Vezzulli, 2010 and C. Altomonte, S. Gamba, M.L. Mancusi, A. Vezzull, 2013), which consists in using an index proposed by Whited and Wu (2006) considered below.

Study selection and analysed data

This study uses data on Russian industrial companies over the period of 2013-2016. The analysis encompasses industrial manufacturing companies, which were divided into high-tech, medium-tech, and low-tech ones. The study covered companies experiencing liquidity constraint:

- *due to a high cost of borrowings.* This group includes companies, whose rate of return on invested capital[1] was lower than the average interest rate on credits, in which case companies are divided into two groups: small and medium-sized ones employing up to 500 people and large ones with headcounts of over 500 people, which is due to a different cost of credits for these categories of companies. The RF Central Bank's statistics show that the average interest rate on credits in 2016 was as follows: 12.8% for large companies, 15.73% for small and medium-sized companies; in 2013 – 11.4% and 14.2%, respectively[2];
- *due to the poor financial condition of companies* and, for this reason, without access to the capital market. In order to select companies for this category, we selected a normative approach to determine the level of financial standing by comparing the estimated financial indicator with the normative value approved by laws.

Sources of information used: databases SPARK, Ruslana, Rosstat, in addition to information from the websites of industrial companies, indicators reflected in innovative development programs, statistical reporting form 4 "Innovation", supplemented by audit data. Small and medium-sized firms with unavailable financial indicators were not considered in the study.

970 industrial companies were analysed in total, 198 of which were selected (Table 1).

Table 1. Number of selected companies distributed by headcount

Companies with a headcount of	Total companies considered	Companies experiencing liquidity constraints		Total companies selected
		Companies whose rate of return is lower than the average rate on credits	Companies with an unstable financial position	
Up to 250	183	26	17	43
250 - 499	194	31	14	45
500 – 999	198	26	12	38
1,000 – 4,999	127	17	11	28
5,000 – 9,999	196	23	9	32
10,000 and more	72	14	5	19
Total	970	130	68	198

Table 2. Number of selected companies distributed by industry sectors

Sectors of manufacturing industry	Companies whose rate of return is lower than the average rate on credits	Companies with an unstable financial position	Total
High-tech sector	44	18	62
Medium-tech sector of a high level	31	9	40
Medium-tech sector of a low level	34	15	49
Low-tech sector	28	19	47
Total	137	61	198

The variables of analysis included: the size of a company, sphere of activity, investments in R&D and parameters of export operations. In order to reflect the liquidity constraint impact on innovation, we introduced the variable Rdint corresponding to the amount of innovation costs interrelated with total sales revenues in 2016. This permitted analysis of the impact of innovation costs on the level of demand for capital; companies' decisions to invest in R&D; and efficiency of innovative activities. Table 3 presents descriptive statistics of the

studied companies.

Table 3. Descriptive statistics of distribution of the studied companies

Industry Sector	R$D = 1 (% of companies)	EXP = 1 (%of companies)	Expint (average weighted value)	Standard deviation	RDint (average weighted value)	Standard deviation
Up to 250 people (43 companies)

Table 4 summarises all indicators used in the study.

Table 4. Variables used for the analysis purposes

Indicator	Interpretation
R$D	Fictitious variable equal to 1, if a company invests in R&D, and 0 if otherwise
EXP	Fictitious variable equal to 1, if a company has sales revenues on foreign markets, and 0 if otherwise
Capital investment (CI)	Equity investments (current and capital expenses), (RUB'000)
Expint	Share of revenues from export operations in the total sales revenue
RDint	Share of sales revenues aimed at innovation
LTF_2016	Total factorial output calculated for 2016
size	Company size measured by the average headcount
	Index measuring the company's demand for external funding

Research methodology

In order to analyse the liquidity constraint impact on companies' decisions concerning investment in R&D, and the intensity of those investments and efficiency of innovative activities, we used a system of simultaneous econometric equations - the technique of which implies that each independent variable y is considered as the function of the same set of factors x. Traditional indicators proposed in the studies of this subject were considered as independent factors: firm size, sales revenues from export operations (Expint), share of sales revenues used to invest in innovation (RDint), full factorial output of companies (LTF_2016), capital investments (CI).

The company size determinant was proposed by Cohen W. M., Klepper S. (1996), and this is explained by the fact that investments in R&D require quite extensive funding, which can be distributed by large firms for a large scope of products and, therefore, are unlikely to choose to reject participation in R&D. Furthermore large firms have better relationships with investors, and this additionally facilitates their access to financing. The full factorial output impact on investments in R&D and innovation is described in a study by Blundell et al., (2009), proving an important interrelation between the factorial output of a firm and a decision to invest in R&D. A study by C. Altomonte, S. Gamba, M.L. Mancusi, A. Vezzull, (2013) points out to a positive interrelation between export operations and investments in R&D; in order to analyse the effect of export operations, we introduced the variable Expint showing the share of revenues from exports in the total sales revenues.

Building an econometric model

The econometric model consists of three components. The first equation of the model evaluates a firm's demand for external funding. The second part consists of two equations explaining a company's decision to invest in R&D and amounts of such investments. The third component shows the interrelation between the efficiency of innovative activities and the amounts of investment costs.

Mathematically, the model appears as follows:

$$\begin{cases} \mathcal{WW}_i = \beta_{10} + \beta_{11}RD_\iota + \beta_{12}EXP_\iota + \beta_{13}LTF_{2014_i} + \beta_{14}size_\iota + \beta_{15}\mathrm{CI}_\iota + \upsilon_{1\iota} \\ Y_i = \beta_{20} + \beta_{21}WW_\iota + \beta_{22}EXP_\iota + \beta_{23}LTF_{2014_i} + \beta_{24}size_\iota + \beta_{25}\mathrm{CI}_\iota + \upsilon_{2\iota} \\ \omega_i = \beta_{20} + \beta_{21}WW_\iota + \beta_{22}EXP_\iota + \beta_{23}LTF_{2014_i} + \beta_{24}size_\iota + \beta_{25}\mathrm{CI}_\iota + \upsilon_{2\iota} \\ \mathrm{g}i = \beta_{30} + \beta_{31}WW_\iota + \beta_{32}RD_\iota + \beta_{33}LTF_{2014_i} + \beta_{34}size_\iota + \beta_{35}\mathrm{CI}_\iota + \upsilon_{3\iota} \end{cases} \quad (1)$$

Index of a firm's demand for external funding

In order to evaluate the liquidity constraint impact, we use an index proposed by Whited & Wu (2006) – WW, which measures a firm's demand for external funding. The WW index is obtained as a function of maximizing the structural investment model, and appears as follows:

$$\mathrm{WW} = -0{,}087 * \mathrm{CF} - 0{,}058 * \mathrm{DIVPOS} + 0{,}034 * \mathrm{TLTD} - 0{,}042 * \mathrm{LNTA} + 0{,}117 * \mathrm{ISG} - 0{,}028 * \mathrm{SG} \quad (2)$$

where,

CF = relation of the cash flow to the total value of property;
DIVPOS = a fictitious variable equal to one if the company pays dividend and zero if otherwise;
TLTD = relation of long-term debt to own resources;
LNTA: book value of the company's property;
ISG: growth of sales revenues;
SG: sales revenues.
The index was calculated based on data presented in Table 5.

Table 5. Descriptive statistics of variables used to calculate the index.

	Average weighted value[3]	Standard deviation	Minimum value	Maximum value
CF	0.3553	0.01637	0.1645	0.7644
DIVPOS	1 \0	-	0	1
TLTD	0.5302	0.02139	0.2332	0.7828
LNTA	8.1274	1.2576	3.7301	16.0951
ISG	0.0493	0.002596	0.03078	0.07134
SG	1.408	0.02174	0.1222	1.7444

Investment in innovation

The second component of the model evaluates the impact of factors on the decision to invest in R&D and - in case of a positive decision - the amount of investment in R&D per employee involved in research and development. The Hackman Censored Regression model was used for the purpose of analysis, enabling the evaluation of both the company's disposition to invest in innovation, and the definition of the amounts of such investments. The model consists of two components: the first one – a binary choice model determining whether "to invest/not to invest"; the second one – a linear model evaluating the amount of investments in R&D.

Therefore, the Hackman model has two latent variables explaining a decision of firms to invest in R&D:

$$\mathrm{y_i} = \begin{cases} 1 \quad if \quad y_\iota^* = \beta_{20} + \beta_{21}WW_\iota + \beta_{22}EXP_\iota + \beta_{23}LTF_{2014_i} + \beta_{24}size_\iota + \beta_{25}\mathrm{CI}_\iota + \upsilon_{2\iota} \quad > \tau \\ 0 \quad if \quad Y_\iota^* = \beta_{20} + \beta_{21}WW_\iota + \beta_{22}EXP_\iota + \beta_{23}LTF_{2014_i} + \beta_{24}size_\iota + \beta_{25}\mathrm{CI}_\iota + \upsilon_{2\iota} \quad \leq \tau \end{cases} \quad (3),$$

where $\mathrm{y_i}$ = an observable binary variable equal to one, if companies decide to invest in innovation, and zero for other companies;

y^*_i = latent (non-observed) endogenous variable measuring factors that affect a company's decision to invest in R&D. The latent variable may be interpreted as a choice criterion; in our case: the anticipated amount of the firm's profit from innovative activities;
= vectors of parameters;
$_i$ = residual member.

Accidental errors of the model are assumed to be normally distributed.

Companies decide to invest in research and development, if = the non-observed endogenous variable is higher than the defined threshold = anticipated amount of the firm's profit from innovative products.

The second equation of the Hackman model shows the amounts of innovation costs in case a decision is made to "invest", which is expressed as an amount of investments in R&D per employee involved in research and development:

$$w_\iota = \begin{cases} w_\iota^* = \beta_{20} + \beta_{21} WW_\iota + \beta_{22} EXP_\iota + \beta_{23} LTF_{2014_i} + \beta_{24} size_\iota + \beta_{25} \mathrm{CI}_\iota + \upsilon_{2\iota} \ , \\ if\ \gamma_\iota = 1 \\ 0,\ if\ \ \gamma_\iota = 0 \end{cases} \quad (4)$$

where = the non-observed variable evaluating the amount of investments in R&D per employee involved in research and development;
= vector showing the trend direction;
$_i$ = residual member.
If the option "not to invest" is chosen in the first equation, is considered equal to zero.

Results of innovative activities

The third component of the model shows a dependence of the results of innovative activities in the form of the following production function of innovation:

$$\mathrm{g}_\iota = \beta_{30} + \beta_{31} WW_\iota + \beta_{32} RD_\iota + \beta_{33} LTF_{2014_i} + \beta_{34} size_\iota + \beta_{35} \mathrm{CI}_\iota + \upsilon_{3\iota} \quad (5)$$

where g_i = results of innovative activities expressed in the scope of released innovative products;
= vectors of parameters;
and $_i$ = residual member.

Research results

Tables 6, 7, 8 show the results of calculations of the liquidity constraint impact on a company's decision to invest in R&D, amounts of such investments, and efficiency of companies' innovative activities.

3) robust standard errors are shown in brackets.

According to calculations, the company's size, export activities, and investments in innovation negatively correlate with the size of its demand for external financing, i.e., the larger the company's size, the lower the likelihood of liquidity constraints will be for a firm; this can be explained by the possibility large companies have to use available accumulations and established relationships with banks. Banks also prefer providing credit to larger firms due to a lower asymmetry in information. Smaller firms have more financial limits. Export operations also reduce the liquidity constraint impact of companies because exporters may be credited on both domestic and foreign markets.

These calculations show that liquidity constraints have a negative impact on companies' decisions to invest in R&D, and this dependence is most acute for companies operating in medium-tech industries of a high level (0.548) and low level (0.492). At the same time, this dependence is less typical of companies in high-tech and low-tech industries. At the same time, and for all industrial sectors. liquidity constraints more greatly influence a company's decision to invest in R&D than the "intensity" of a company's investments in R&D expressed as R&D costs per employee involved in innovative activities. Across all sectors, liquidity constraint has a minor impact on the intensity of investments in R&D - which can be explained by the fact that the availability of in-house funds is more important for the decision-making process. This is also confirmed by indicators of elasticity of an impact of investments in equity (0.311; 0.392; 0.255; 0.259, respectively).

All of this confirms the inverse U-dependence between competition and innovation. For instance, exporting firms are more likely to invest in R&D due to a higher levels of competition to which such companies are exposed. Besides, a sectoral analysis shows that in high-tech industries with a small number of players competition targets quality (creating good grounds for innovation) and a competition increase has a positive impact on the output; in the market of low-tech sectors with a large number of players competition targets prices and we can see an inverse trend where a company refuses to invest in R&D, substituting them with imitation.

As was anticipated, liquidity constraints have a negative impact on the results of innovative activities expressed by sales of innovative products. However, the highest impact of liquidity constraints is observed in high-tech and medium-tech sectors of a high level (0.772 and 0.857, respectively).

A positive correlation between competition of markets and efficiency of innovative activities is proved. Exporting companies are characterized by higher efficiency of innovative activities even in a situation of liquidity constraints. This dependence is expressed more strongly in high-tech and medium-tech sectors (0.472; 0.441; 0.315, respectively) and more feebly in the low-tech sector (0.201). Neither a large headcount, nor full factorial output have significant effect on the efficiency of innovative activities.

Conclusions and further research

Research and development of new technology (R&D) is generally more useful for society than profits gained by an innovator, i.e. it brings a positive externality. Therefore, the key feature of an innovation analysis is the consideration of an effect of floating: an enterprise does not receivethe entire benefit fromR&D carried out, as other firms get access to the developed technology as well (possibly with a time lag). For this reason, many firms tend to underinvest in R&D, particularly when a company experiences a liquidity constraint.

Our empirical model makes it possible to arrive at several conclusions concerning the interrelation of liquidity constraints, a company's decision to invest in R&D, and efficiency of innovative activities.

Firstly, we showed the cash effect: the effect of availability of substantial available funds at a large company, which facilitate its financing of R&D and innovation. The empirical results of research show that companies of a large size, which actively invest in current operations, are more likely to invest in R&D - even against a background of liquidity constraints. Smaller firms are more sensitive to liquidity constraints when investing in R&D than large firms, whose investments in R&D are not so sensitive.

Small companies most often cannot use their own in-house funds to finance R&D and experience such constraints. In this case, the infrastructure development by the state for supporting the financing of start-up projects and small businesses plays a large role in this case: business angels, venture funds, etc.

Another important conclusion is a more decisive role of own in-house funds for financing R&D. Thus, the higher the amount of current investments in operations of a firm, the higher the likelihood that it will invest in R&D.

Our analysis showed that liquidity constraints reduce the number of companies deciding to invest in R&D, particularly in medium-tech industries, and have a minor impact on a company's R&D costs per employee involved in innovative activities. This dependence is typical of all the considered sectors of the industry.

One further result is a confirmation of the inverse U-dependence between competition and innovation. For instance, exporting firms are more likely to invest in R&D due to the higher level of competition to which such companies are exposed. Besides, sectoral analysis shows that in high-tech industries with a small number of players, competition targets quality (creating good grounds for innovation) and a competition increase has a positive impact on the output; in the market of low-tech sectors with a large number of players competition targets prices and we can see an inverse trend where a company refuses to invest in R&D, substituting them with imitation.

It can also be concluded that small companies and companies in low-tech industries do not need to increase the intensity of their R&D, but need investments simplifying the imitation of ready-to-use technologies from developed markets.

At the same time, our research has a number of limitations. For our analysis purposes, we used a direct limiting factor of liquidity, which only indirectly identifies liquidity constraints (see an analysis of Kaplan-Zingales) because we have no deeper data on availability of credits for the subject companies and the actual extent of demand for external funding. For this reason, analysis should be subsequently focused on surveying companies of the industrial sector with more accurate evaluation of investment models - based on the Eiler equation, accelerator model or error elimination model, which enable definition of an "optimal model" of debt-to-equity ratio.

Abstract

Integrity and cyclical development of the world community allows to consider globalization, on the one hand as a process, on the other hand as the system located at a certain stage of development. Assuming that the world community - it is a system, so it can be told that it has properties of the system. This, in turn, allows authors to highlight in this system a subsystem - business. For management of resistance of subsystem, business authors propose to use the Solow growth model and its concept of economic evolutionary process: " ... the nonlinearity, instability, bifurcation and chaos in dynamical economic systems." Subsystem of business is in continuous harmonic oscillations, it means that the subsystem is unstable, because it does not return to its initial steady state, and therefore it has synergistic properties.

Based on the above, as a result of the study, the authors constructed a mathematical - economic dynamic model of stability of the subsystem business, considering inflation component. Entering in a formula particular data of the subsystem business, specific business model will be obtained, representing area of stability of the subsystem business in the context of globalization. In conclusion, it can be said that obtained economic-mathematical model with dynamic inflation component allows to control the stability of the subsystem business in the context of globalization.

Keywords: business sustainability, globalization, mathematical economic model, Solow model, Samuelson–Hicks model.

Introduction

Business in a globalized world represents a qualitatively new socioeconomic system. Today's global business community is now in the transition stage from multinational to global corporations. Multinational corporations produce and sell their products in different countries using different business strategies and tactics. Global corporations produce and sell their products in different countries using uniform strategy and tactics in all markets (e.g. Procter & Gamble, Nestle, Toyota, Coca-Cola and so on).In recent years, rapidly developing technology allowed scientists to address the problem of basis for sustainable development of our civilization and, as one of its components, the basis for sustainable economic development. The latter depends on the sustainable development of business, which represents different types of socioeconomic systems.

Literature review

To questions of a sustainable development of economy have devoted the works prominent Russian and foreign scientists - A. Marshall (1890), Y.A. Shumpeter (1911), J.M. Keynes (1936), R. Dofman, P.Samuelson and R.Solov (1958), L.I. Abalkin (1987), V.B. Zang (1999) ,V.V., R.A. Brazhe. (2002-2003), Martina K. Linnenluecke (2010), I. Rudskaia, L. Guzikova (2014), A.J. Silviusa, etc (2015), L.Nikolova, D.Rodionov & J. Kuporov (2015), O. Kalinina (2016), T. Kudryavtseva (2016), T. Shabunina, S. Shchelkina (2017), N. Afanasyeva (2017) and many others.

Harlem Brundtland (1993), who coined the term "sustainable development", explains it as follows: "Humankind is surely capable of making its development sustainable, i.e. ensuring that this development can fulfill the needs of the present and never puts at risk the capability of future generations to fulfill their future needs."

While analysing this problem, A.V. Pozdniakov (2002) showed that the essential possibility for sustainable development of socioeconomic process exists because this process has a range of features, as listed below:

1. "Development is an irreversible spacial-temporal direction of changes in the states of systems (including socioeconomic ones) where some of the elements of previous states are being denied in the posterior structure... If external conditions (including the environment created by the total of socioeconomic systems) alter, then alters the very structure of a socioeconomic system".
2. "Socioeconomic system growth rate is a number of times its structural elements are substituted per a unit of time. And growth intensity is defined by the growth rate and mass of the system (amount of systems involved in the process, amount of people, resources, etc.)".
3. "Sustainability of development is defined by the length and amplitude of oscillations, e.g. GNP, counted from the trend..."
4. "Social system develops sustainably if the wave amplitude (oscillation about the equilibrium point, trend line) reduces and the wavelength increases which is, for sure, possible only if the development (movement) rate is high..."

Further Pozdniakov says that sustainable development can only be possible due to unsustainabilities: "Unsustainability actuates, induces the tendency of the system toward a dynamically equilibrated state – dynamic sustainability..."

Thus, the sustainable development of economy, and business in particular, should not be regarded as something balanced and monotone, without oscillations and jerks, but as dynamically sustainable development with a positive trend which is overlapped by stochastic (i.e. probabilistic) oscillations related to changes in the system and its environs.

Methodology

Systemic approach is a basis for methodology, its key principles are used in the application of the dynamical systems theory (in most cases – theory of automatic regulation), methods of mathematical economic modelling, decision theory and methods, economic and financial analysis theory and methods, forecasting.

The theory of growth poles or growth centers serves as a basis for modern economic theory of business development in different countries. This theory represents an aggregate of three concepts – "dominant economy", "harmonized growth" and "universal economy". However, the growth poles theory remains raw, a range of important problems are still unsolved, in particular, the problem of population size in the growth centers, the problem of population functional hierarchy concerning the level of business development and its policy objectives. Issues of the poles theory are often eliminated by means of application of the evolutionary systems theory, which consists in the fact that the result of work of any system could be reduced to assessment of some integrated index – a value showing the reaction of a system to changes in various local values in the environment.

Here, the Gross National Product (GNP) is this value characterizing the reaction of a system to the changes in various local values in the environment.

When forming the mathematical economic model (the Model) of business sustainability in a globalized world we applied the synergetic approach to study this model.

In the study, we assume that the model of business sustainability is composed of two main subsystems: a scientific production system and a financial credit system. Each of the subsystems is self-organizing and developing which allows to consider any of their element as a feedback loop consisting of a controlled object and a controller. Elements, which form the scientific production subsystem and the financial credit subsystem, may be strategic or dynamic.

Conclusions

In the study undertaken in order to form mathematical economic model we used Robert Solow's Neoclassical Growth Model (Fig. 1) where business is considered as a closed unified unstructured entity producing a single universal product, which may be consumed or invested. This statement may be interpreted as a representation of business as one complex dynamic element.

Solow in his model uses the Cobb-Douglas Production Function in order to describe business.

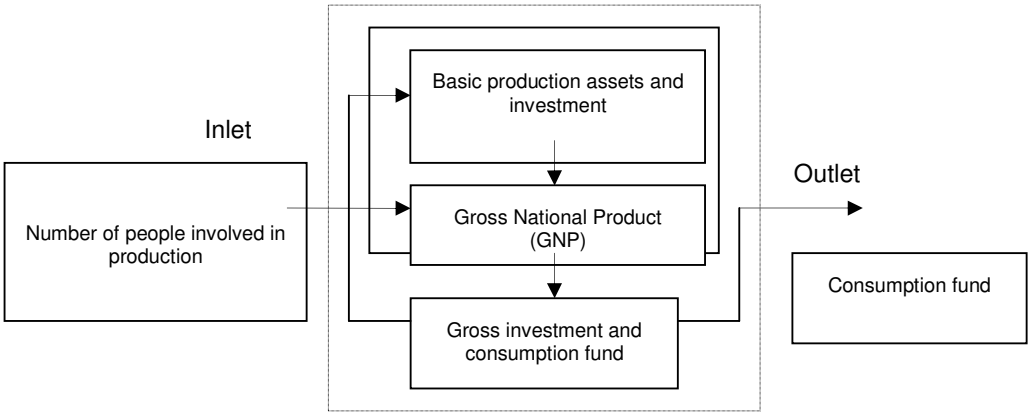

Fig. 1. Solow Business Description Model

This model considers five macroeconomic indicators (endogenous variables): Gross National Product (GNP); Gross Investment; Consumption Fund; Basic Production Assets (BPA; number of people involved in production.

Business system presented in the form of Solow Model is an unstructured dynamical system because it contains dynamical elements. In business management, the most significant thing is distribution of GNP between savings (gross investment) and consumption. Our analysis made it possible to conclude that business is a dynamical system. Also, it was stated that business economics is non-linear because the relation between output and resource spend is shown as a non-linear production function.

Among the most important aspects of economic evolution process the authors name "... non-linearity, unsustainability, bifurcations and chaos in dynamical economic systems".

As a result, the study outlined the variant of analysis where all GNP growth for the year is entirely used for investment, business development. Dynamics of this process is shown in business mathematical economic model, the ideology of which was developed by Samuelson-Hicks (1).

Samuelson-Hicks's approach allowed to present the business system model as a system in simple harmonic motion (at r=1), i.e. the system is unsustainable because it doesn't return to the initial sustainable state and, therefore, is synergetic.

In the plane (η, u) of phase variables, the system track will look like a canonical ellipse (Fig. 2):

$$\frac{\eta^2}{a^2} + \frac{u^2}{b^2} = 1, \qquad (1)$$

where

a – share of gross investment in GNP;
b – changes in the share of gross investment in GNP considering the time factor;
r – growth of demand for investment when GNP is increased by one;
η – change in GNP value at given amount of investment;
u – GNP growth speed.

As a result, we have got that GNP will range between $y^E \pm \rho,$ (gross investment plus-minus share of investment), consumption will stay constant and equal to the stationary value $y^E - 1,$ and investment will be experiencing non-damping self-oscillations according to the equation $I_{(t)} = I + \eta(t)$ - (investment plus changes in GNP value at given amount of investment at a time).

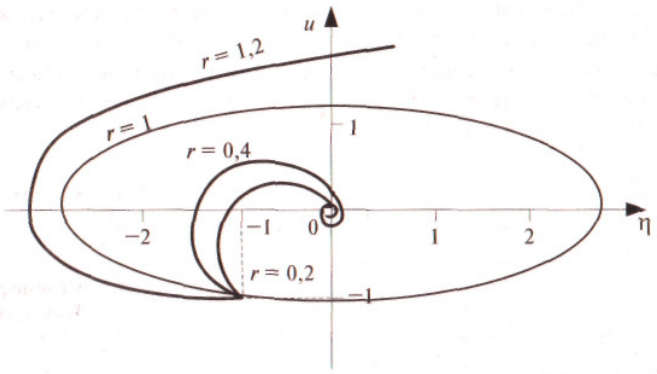

Fig.2. Dynamics of changes in the state of business economics

Therefore, the study found that the business system model has synergetic properties.

Following the study, we concluded that in order to create a 3D dynamical mathematical economic model of business sustainability in a globalized world, it is necessary to introduce the inflationary component (P) into the Samuelson-Hicks Model (1).

$$\frac{\eta^2}{a^2}+\frac{u^2}{b^2}-\frac{P^2}{c^2}=1, \qquad (2)$$

where P – inflationary component;

c – the calculation step.

Upon introduction of inflationary component, the mathematical economic model of business system will represent a one-sheeted hyperboloid.

Economic interpretation of the model: the lower part of the hyperboloid is the area of sustainable development of a business system model (inside a truncated cone), while the upper part of it is the area of stability (outside of the cone).

Application of scientific achievements of recent years allowed the authors to find basis for sustainable business in globalized world and build a mathematical economic model of its development.

Impact of Regional Conditions on Innovativeness Of Enterprises in Poland

Alfreda Kamińska
Warsaw Management University, Warsaw, Poland,
alfreda.kaminska@wsm.warszawa.pl

Abstract

The dynamics of the processes of innovation and of various factors that condition them imply the need for systematic research to identify the factors that determine the innovativeness of enterprises. Aside from the micro- and macroenvironmental factors, mesoenvironmental regional conditions, largely dependent on local authorities, are becoming ever more prominent. This paper seeks to systematise regional factors and present the severity of their impact on innovativeness of enterprises. The conclusions are drawn from a survey performed in Poland on a sample of 265 small, medium, and large enterprises from the Kuyavian-Pomeranian voivodeship and 259 small, medium, and large enterprises from the Silesian voivodeship.

Keywords: innovativeness of enterprises, regional conditions of innovativeness

Introduction

Knowledge and innovativeness are the foundation of any modern, competitive, and growing economy. Innovativeness has had the full attention of business and science and has been perceived as the driving force of development of economies and societies for many years now (Schumpeter 1961), but the innovativeness level of Polish economy and enterprises is still unsatisfactory. In global and European rankings, Poland scores low on innovativeness and like other Visegrád countries (Czech Republic, Hungary, Slovakia) is listed among "moderate innovators" (European Innovation Scoreboard, 2017).
Europe's regions are grouped into four innovation performance groups according to their performance on the Regional Innovation Index relative to that of the EU:

• The first group of "innovation leaders" includes 53 regions with performance more than 20% above the EU average.
• The second group of "strong innovators" includes 60 regions with performance between 90% and 120% of the EU average.
• The third group of "moderate innovators" includes 85 regions with performance between 50% and 90% of the EU average.
• The fourth group of "modest innovators" includes 22 regions with performance below 50% of the EU average.
Poland includes 16 regions: Mazowieckie, the capital region, is the most innovative region and the only "moderate innovator"; seven regions are "moderate" and nine regions are "modest innovators" (Regional Innovation Scoreboard, 2017). One of the causes of low innovativeness of regions is the low

innovativeness of enterprises. Research conducted as part of the Community Innovation Survey (CIS) points to a persistent low level of innovativeness in Polish enterprises (EIS, 2017).

Within this paper, innovativeness of enterprises means the capacity of companies to pursue innovation in order to introduce new products, processes, marketing ideas and organisational concepts (Hult, Hurley & Knight, 2004; OECD & Eurostat, 2005).

The matter of conditions of innovativeness of enterprises is one of the most frequently analysed issues in the study of innovativeness, however, the literature on it usually only considers microeconomic and macroeconomic circumstances. Meanwhile, we can see at present that the mesoeconomic context, understood as a collection of factors that come into play at a regional level and create conditions that are more or less conducive to innovative activity by organisations within a given region (voivodeship in our case), is becoming ever more important.

The interdisciplinary nature of research into regional impact on innovativeness of enterprises generates interest from geographers, economists, management researchers, sociologists. The literature mostly features the regional context of conditions of innovativeness as seen from the level of a city, an urban area, or a metropolis, that is, from a local level. Urban centres, particularly metropolises, are considered the most important locations for innovation, as they offer a large potential for it in a small area. Polish and global literature has relatively few overviews of the regional context of the processes of innovation (Porter, 2001; Nowakowska, 2009, 2011; Jewtuchowicz, 2005; Bellman et al., 2013). In particular, many works deal with the impact of innovativeness on economic development within a given region and analyse regional innovativeness systems (Strahl, 2010; Stawasz, 2006; Świadek, 2007, 2011 and others).

This paper considers the impact of regional conditions on innovativeness of enterprises in Poland. As the Oslo Manual notes, "identifying the main characteristics and factors that promote innovation activity and the development of specific sectors at regional level can help in understanding innovation processes and be valuable for the elaboration of policy" (OECD & Eurostat, 2005).
The chief purpose of the paper is to attempt to answer the following questions: how large is the impact of regional conditions on innovativeness of enterprises and what is the relationship between innovativeness in enterprises and the assessment of the importance of regional factors. The main goal is the attempt to systematise and determine the role of regional factors that impact innovativeness in enterprises.

Regional conditions of innovativeness of enterprises: overview of literature

There are a great number of diverse types of factors impacting innovativeness of enterprises. The literature on it usually divides them into two major groups: endogenous and exogenous. Endogenous factors are a result of material and non-material resources available to the company, while exogenous factors are related to the broadly-understood environment – which is a part of the microenvironment, mesoenvironment, and macroenvironment, as well as the global environment. At a time of increasing globalisation, the role of regions is, contrary to expectations, increasing, while the economists outline a new and independent field of study called the mesoeconomics (Gorynia, 2008), which researches economic phenomena that occur at the level of sections, branches, economic sectors and regions. This paper analyses mesoenvironmental factors in a regional context, and a region is understood to be a given voivodeship.

One of the first scholars to notice the impact of outside environment on enterprise creation and innovativeness of enterprises was Aydalot (1986), who declared in the 1980s that the source of innovation is the environment (*innovative milieu*) that the company operates in. As Guinet (1995) and other scholars of innovation accurately pointed out, innovative activity is interactive, a result of relationships within the enterprises and between it and outside agents such as clients, suppliers, research and development units, local authorities, financial institutions and any and all other supporting companies.

Sternberg and Arndt (2000) believe that the most important regional determinants of innovativeness of enterprises include local availability of qualified personnel, research and development facilities, technology transfer, appropriate economic structures, and soft factors (facilities etc.), institutional support, and innovative policy factors in the macro- and mesoenvironment (including support for operations growth and R&D cooperation). The list of regional factors impacting innovativeness of enterprises was expanded with local and central government initiatives, macroeconomic trends, financial support, education, economic structure, knowledge and technology transfer, infrastructure, values, and norms (Sternberg & Litzenberg, 2004).

Porter (2002) lists four main groups of regional determinants: 1) factor (input) conditions: high quality specialised inputs such as human and capital resources, knowledge and technology, physical, administrative, and information infrastructure, natural resources; 2) demand conditions: sophisticated and demanding regional customers, local demand in specialised segments; 3) related and supporting industries: access to capable, locally based suppliers and firms in related fields, inter-industry cooperation (clusters); 4) context for firm strategy and rivalry: local context that encourages investment and sustained upgrading (including protection of intellectual property), competition among locally based rivals.

Sosnowska, Poznańska, Łobejko, Brdulak, Chinowska (2003) point to factors resulting from the location of the enterprise, such as the economic situation of the region, market access, collaborative connections to other firms, cooperation with local authorities, contacts with higher education facilities and R&D facilities, infrastructure layout, environmental protection restrictions.

Innovativeness of enterprises is shaped by regional politics, actions of institutions from the business environment, and technological, social, and economic structure of the region (Jasiński & Wiatrak, 2010).

Meanwhile, Broekel and Brenner (2011) researched an astounding 70 variables describing the socio-economic situation of a region, divided into 12 groups of factors influencing innovativeness in a region.

Kosała and Wach (2011) have projected the innovative potential of a region based on a number of metrics, including research and development spending and its sources, research and science workers per 1 000 employed, gross value of research tools, the number of R&D units, reported inventions and patents granted, foreign trade balance in cutting edge technology products, share of innovative enterprises in the overall number of companies.

In Nowakowska's (2011) view, innovative processes are determined by the potential of the R&D sector, academic potential, activity of institutions supporting the innovation processes, technology transfer and presence of clusters.

Meanwhile, Świadek (2011) has analysed the impact of the following factors: distance from urban areas, distance from and relations with the competition, suppliers, buyers, the number of suppliers and buyers, interactions between and within sectors, access to capital, employee skills. Bellmann, Crimmann, Evers and Hujer (2013) have pointed out the importance of human resources – namely, STEM graduates – as well as the distance from research and technology centres and tertiary education facilities, and the unemployment rate in the region.

The review of the subject literature and own experiences and observations give reason to name five main, codependent groups of regional conditions, which have been assigned 27 factors determining innovativeness of enterprises. They are listed in Table 3.

Inasmuch as the list cannot be considered complete or exhaustive of the all the possibilities of a region's impact on innovativeness in enterprises, it does provide a toolkit for the identification of the most important conditions and for an assessment of the extent of their influence.

Research methodology

The aim of the research was to determine the impact regional conditions of innovativeness of enterprises have and the links between the level of innovativeness in companies and the assessment of the importance of those factors. The research was conducted in Poland, in enterprises located in two Voivodeships of different innovativeness level and different economic situation, namely, Silesian and Kuyavian-Pomeranian.

Silesian Voivodeship was ranked fourth in the country in innovativeness, while Kuyavian-Pomeranian came fourteenth (RIS 2017). RIS values position the latter in the weakest EU regional innovation bracket (i.e. *regional modest innovators*), while Silesian is ranked among *regional moderate innovators*. In terms of economic development measured by GDP per capita, the Silesian Voivodeship is fourth in the country, while Kuyavian-Pomeranian is tenth (GUS, 2016).

Empirical research has been performed by survey augmented with extended interviews with the management of the enterprises. The research tool for the survey stage was a questionnaire prepared by the author, while the research was conducted by the Centrum Badania Opinii Społecznej (*Centre for Public Opinion Research*, CBOS). The interviews were conducted according to the CATI (Computer Assisted Telephone Interview) method – a quantitative research method. Like in Eurostat research, company size was accepted as a criterion for assigning the companies in question to groups (of small, medium, or large enterprises). The sample was selected according to the recommendations of the Oslo Manual "that the stratification of random sample innovation surveys should be based on the size and principal activity of the units" (OECD & Eurostat, 2005). Ultimately, empirical research was conducted on a sample that was representative both in terms of size (due to the number of employees) and in terms of sectional activity (as per the Polish Activity Classification – PKD), which included 265 small, medium, and large enterprises in the Kuyavian-Pomeranian Voivodeship and 259 small, medium, and large enterprises in the Silesian Voivodeship. The structure of enterprises analysed as part of the research is proportional to the structure of all enterprises in the regions (Table 1). The number of research samples and their structure allow an assumption that the conclusions drawn from the work presented in the paper on the impact and

importance of regional conditions on innovativeness in enterprises are very likely to be representative for the entire populations of enterprises in the Kuyavian-Pomeranian and Silesian Voivodeships, aside from any micro-scale units.

Table 1: Structure of surveyed companies

Criterion	Kuyavian-Pomeranian Voivodeship		Silesian Voivodeship	
	No. of enterprises	% of N=265	No. of enterprises	% of N=259
Number of employees:				
10-49	223	84.0	222	85.5
50-249	37	14.0	32	12.3
250 and more	5	2.1	6	2.2
Activity type:				
Manufacturing	113	42.7	108	41.7
Services	76	28.8	84	32.4
Commerce	42	15.8	58	22.4
Mixed	34	12.8	9	3.4

The general research was performed between October and December 2016. When preparing the survey questionnaire, the author drew from subject matter literature and her own experience from years of work at various enterprises. Moreover, in order to better understand the problems that fell within the scope of the research and to capture the elements most important to entrepreneurs and the economy, she interviewed managers about the regional conditions of innovativeness of enterprises. As per procedure for surveys, it started with a pilot study, which allowed for a test of the research tools, clarification of any ambiguities and an assessment of the time needed to conduct the survey.

Results and discussion

Assessment of innovativeness in surveyed enterprises

In order to achieve the main goal of determining the importance of regional conditions of innovativeness in enterprises and their influence its level, it was necessary to assess the level of innovativeness in the surveyed subjects in both Voivodeships.

Based on the subject literature quoted earlier, several crucial markers of the innovativeness process in enterprises were named. These included: the number of innovativenesss in product, in process, in marketing, and in organisation over the past three full years (i.e. 2013, 2014, and 2015), the degree of novelty of the innovation (on a five-step scale: novel for the enterprise, locally novel, regionally novel,

novel for the country, novel internationally), and a subjective assessment of the innovativeness level of the enterprise by the survey respondent.

Depending on the number and novelty of the innovations introduced between 2013 and 2015, every enterprise was assigned to one of six groups based on their level of innovativeness: "very high," "high," "average," "low," "very low" or "non-innovative." To measure the appropriateness of the accepted criteria for the assessment, the results were cross-referenced with the resulting enterprise structure and the self-assessment of the level of innovativeness of enterprises performed by the respondents.

Table 2 presents the innovativeness structure of the entire surveyed sample. The analysis shows that both voivodeships have a similar innovativeness structure in enterprises. Non-innovative companies, which had not introduced any innovation in product, process, marketing, or organisation in the period surveyed, represent more than 50% of the firms in the survey. Around one in five enterprises (20.1%, 21.2%) introduced between one and three enterprise-level innovations, putting them in the group of companies with a very low innovativeness level. Higher levels of innovativeness show insignificant differences between the two voivodeships. The Silesian Voivodeship has a 2.1 percentage point lower share of medium innovativeness firms (4-10 company, local, regional innovations, 1-10 national innovations) and a 1.9 percentage point higher share of very high innovativeness firms (more than 10 national or sub-national innovations). It also has a 5.6 percentage points higher share of low innovativeness firms (1-3 local or regional innovations). The very high percentage of companies that had introduced no innovations in the researched timespan and of those at a very low level of innovativeness testifies to a low general level of innovativeness in enterprises in both voivodeships in question.

Table 2: Innovativeness structure of companies in the research sample (N=265, N=259)

Innovativeness level	**Kuyavian-Pomeranian Voivodeship**		**Silesian Voivodeship**	
	No. of enterprises	**As % of N=265**	**No. of enterprises**	**As % of N=259**
Non-innovative	156	58.8%	145	56.1%
Very low	53	20.1%	55	21.2%
Low	22	8.3%	36	13.9%
Average	25	9.4%	19	7.3%
High and very high	9	3.4%	4	1.5%
Total	265	100.0%	259	100.0%

Impact of regional conditions on innovativeness of enterprises

To determine the importance and impact of regional conditions on innovativeness of enterprises, the respondents were asked to evaluate 27 regional variables divided into five groups. They were asked to evaluate their importance on a five-step scale: very large (5), large (4), average (3), small (2), unimportant (1). These factors were then ranked based on the average evaluation score, as shown in Table 3.

Table 3: Impact of regional conditions on innovativeness in enterprises – average scores

	Kuyavian-Pomeranian Voivodeship	Silesian Voivodeship
FINANCIAL SUPPORT OF REGIONAL AGENTS BY LOCAL GOVERNMENT		
Financial aid for investment in permanent assets	3,28	3,22
Subsidising and development of financial institutions, facilitating access of enterprises to capital	2,95	2,93
Financial aid for autonomous R&D activities in enterprises	2,72	2,65
Financial aid for purchase of consulting services, licenses, patents and so forth	2,71	2,73
Financial aid for cooperation with scientific research institutions	2,63	2,72
Financing for creation and development of special economic zones	2,50	2,52
Financial support for creation and development of scientific research institutions and innovation centres	2,35	2,29
ORGANISATIONAL AND ADVISORY SUPPORT OF REGIONAL ECONOMIC AGENTS BY LOCAL GOVERNMENT		
Organisational and advisory aid for enterprises (including them in projects, organising conferences and training)	3,36	3,34
Engaging innovation centres in pro-innovative activity	2,87	2,79
Public procurement of innovative goods and services by local authorities	2,64	2,48
Investment in public-private partnership	2,43	2,30
PROMOTING COOPERATION BETWEEN REGIONAL AGENTS BY LOCAL GOVERNMENT		
Price of services offered by institutions supporting innovation	3,53	3,66
Local government aid for interregional and international cooperation (organising fairs, meetings, study visits etc.)	3,34	3,45
Facilitating cooperation with training and consultancy centres	3,25	3,33
Tailoring the offer of business environment institutions to the needs of companies	3,00	3,05
Location of institutions supporting innovativeness	2,98	3,08
Facilitating cooperation between enterprises and science	2,87	3,03
Facilitating cooperation between enterprises and innovation centres	2,86	2,99
Facilitating access to services of research institutions and laboratories	2,76	2,82

Local government aid in the functioning of connection networks between enterprises and pro-innovation institutions, including clusters	`2,71	2,52
CREATION AND AUGMENTATION OF OTHER NON-MATERIAL RESOURCES OF THE REGION		
Local government aid for development of human capital	3,45	3,60
Creation of knowledge centres within the region and providing free access to market analyses, databases, information sources etc.	3,24	3,38
Promoting entrepreneurial and innovative attitudes in the region	3,22	3,29
Increasing the capability of public administration to handle innovation and improvement of functioning of local administration	3,01	3,23
CREATION AND AUGMENTATION OF OTHER MATERIAL RESOURCES OF THE REGION		
Development of transport infrastructure	3,88	3,91
Development of communications and computing infrastructure	3,65	3,71
Making the region more attractive for foreign investment	3,18	3,40

Financial conditions are an important group of factors determining innovative activity of enterprises. Research shows that financial limitations are one of the most important barriers to introducing innovation (Kamińska 2016). According to the answers from both voivodeships, the most important financial factor for the realisation of innovative processes is financial aid for investment in permanent assets. This factor was given an average score of 3.28 in the Kuyavian-Pomeranian Voivodeship and 3.22 in the Silesian Voivodeship. The second most important factor – per the answers – is the financing and development of financial institutions (including lenders and guarantors, high-risk capital) and facilitating access to capital. This factor was rated at 2.95 and 2.93, respectively – a lot lower than financing enterprises.

The assessment of the following factors shows little difference between the voivodeships. The Kuyavian-Pomeranian Voivodeship respondents place financial aid for autonomous in-house R&D to be the third most important condition (average grade of 2.72), while those in Silesian greatly prefer cooperating on R&D with outside institutions (same grade). The surveyed find financial aid for the purchase of consulting services, licenses, patents to be less important, as it was rated respectively at 2.71 and 2.73. Respondents in both voivodeships are largely in agreement on the least important factors of this group. They put financing the creation and development of special economic zones as second to last, with an impact score of 2.50 and 2.52, while – in their opinion – the least important boost for innovativeness of enterprises is financial support for the development and creation of scientific research institutions and innovation centres (2.35, 2.29).

Analysis shows a notable correlation in the Kuyavian-Pomeranian Voivodeship between financial factors and innovativeness level of specific enterprises when evaluating the importance of capital aid for

permanent investments. This type of financial aid is more important for companies at a higher level of innovativeness, with Spearman's rank correlation coefficient (r_S) of 0.216 at probability value (p) of 0.001. Meanwhile, according to more innovative enterprises, subsidising and development of financial institutions such as loan funds, which is understandable, as these companies tend to have a better access to bank loans. In the Silesian Voivodeship, important correlations between the innovativeness level and the assessment of importance of financial factors are more frequent. Enterprises with a higher innovativeness level placed more importance on six out of seven surveyed financial factors, with the correlations being absent only on the subject of subsidies for special economic zones.

The respondents from both voivodeships have returned an identical ranking of factors in the organisational and advisory support group. They consider direct aid for enterprises, including enlisting them in innovative undertakings and passing on necessary knowledge and information in conferences and training seminars, to be the most important element for increasing innovativeness, with a rating average of 3.36 in Kuyavian-Pomeranian and 3.34 in Silesian. Many enterprises believe that a broad engagement of innovation centres in pro-innovative tasks translates into a higher level of innovativeness in firms, and therefore they place that factor in second place, with a respective rating average of 2.87 and 2.79. According to the respondents, public bids from local government have little impact on innovativeness, thus the average rates of 2.64 and 2.48. The last of the surveyed factors – development of investments in public-private partnership (PPP) – has been listed as the least relevant (2.43 and 2.30), which is appropriate considering the current situation in Poland in this regard, with one in five answers stating that is has no impact on innovativeness of enterprises. It is not a surprise that organisational and advisory aid for enterprises, including bringing them onboard in innovative projects and providing training, has been rated the highest. The dynamics of the changes in the current business environment imply the need for a constant refreshing of knowledge and new, up-to-date information, and research indicates that entrepreneurs are aware of this fact.

The assessment of the importance of organisation and advisory factors varies based on the level of innovativeness of a given enterprise. Those at a higher level of innovativeness see involving innovation centres with pro-innovative activities and local government procurement of innovative products to be more important. This occurs in both voivodeships.

As for the promoting of cooperation of regional agents group, the respondents from both voivodeships decided that the three most important factors for increasing innovation were: the price level of services rendered by innovation-supporting institutions (ratings in voivodeships respectively 3.53, 3.66), local government aid for interregional and international cooperation of enterprises (3.34, 3.45) and facilitating access to training and consulting support (3.25, 3.33). The results of a lot of research conducted in Poland indicate that a high price of services from business environment institutions is one of the principal barriers to innovativeness and development of enterprises (Kamińska, 2016a, 2016b).

Today, when costs are constantly being cut and price is seen as a major element of competitive advantage, the price factor is unsurprisingly rated highly. What is interesting, however, is that the entrepreneurs surveyed – even though the range of their activity is currently very limited (mostly to local and regional market), think in the long term and want to find new markets in other regions and countries, which is why organising fairs, study visits, and other meetings that contribute to establishing new contacts is so

important to them. Noticing the need for training and new knowledge (third-highest-rated factor in the group) is also a good trait of the surveyed managers.

The other factors are ranked similarly in both voivodeships – the entrepreneurs see similar value in facilitating collaboration with the science sector and innovation centres. In the last place comes the help of local governments for clusters and other forms of cooperation.

When considering the differences in evaluation of different factors in this group and their correlation with the innovativeness level in enterprises, it appears that in both voivodeships companies with a higher level of innovativeness place a much greater focus on facilitating access to research institutions (r_S in the Kuyavian-Pomeranian of 0,307 with *p* below 0,0005, in Silesian, 0,299 with *p* below 0,0005).

Another investigated group of regional conditions were the various activities related to the creation and augmentation of non-material resources of the region. The analysis of answers from both voivodeships points that out of this group, the largest importance is attributed to local government actions for the development of human capital, rated in both voivodeships at 3.45 and 3.60, respectively. That these activities placed this high testifies to the entrepreneurs' understanding that knowledge and skills of employees are key to inspiring innovativeness. Companies are aware of the need for broad knowledge and information in order to introduce innovation, and of their own lacks in that regard, which is why they rank the need for knowledge centres in their regions and free access to any and all analyses and data helpful for innovative undertakings as the second most important factor in this group. In the view of the respondents, promoting entrepreneurial and innovative attitudes in a region is more important than increasing the capabilities of public administration in innovation and improving its functioning. It is worth highlighting that projects accomplished as part of efforts to promote innovativeness and entrepreneurship are not costly and their introduction frequently depends solely on the will and activity of the local authorities. Of note are the high average notes of the factors in this group (average above 3.0) compared to other sets of conditions.

Referencing the evaluations with the innovativeness level of enterprises brings important conclusions. It appears that the relatively high rating of these factors is independent of the actual level of innovativeness a given company exhibits.

According to the answers, all the listed material assets of a region are very important to innovativeness of enterprises. In this section, the highest rank went to the development of transport infrastructure, rated, respectively, at 3.88 and 3.91. Second place went to the development of communications and computing infrastructure, where average grades were also high, standing at 3.65 and 3.71. Therefore, entrepreneurs believe that the development of innovative economic activity is very tightly connected to transport and information network, which allow for either face-to-face or computer-mediated communication with other agents, including suppliers and clients. Respondents from both voivodeships give a high mark to actions intended to make a region more attractive to foreign investments (average ratings 3.18 and 3.40). This shows they are not afraid of competition from abroad, while remaining aware that foreign investment may contribute to the development of their enterprises and regions. We also do not notice any correlation between the assessment of specific factors and the level of innovativeness in a given company.

Conclusions

The changing nature of the business environment and the low level of innovativeness in Polish enterprises give cause for systematic research to identify the factors that determine the innovativeness of enterprises with a view to regional factors. The results produced by the research are congruent with the findings of RIS 2017 and point to a low level of innovativeness of enterprises in the regions in question. The research presented here has identified the relatively most important factors influencing innovativeness in each of five groups of region-level conditions:

1. In the group of factors related to financial support from the local government, both the respondents from the Kuyavian-Pomeranian Voivodeship and from the Silesian Voivodeship declared that the most important element is financial aid for investment in permanent assets as well as subsidising and development of financial institutions so as to facilitate access of enterprises to capital.

2. As for the local government organisational and advisory support, the most important factor was involving the enterprises in projects, organising conferences and training, and engaging innovation centres with pro-innovative activity. The assessment of the two most important factors in this group varies greatly, as enterprises in general prefer aid that is offered directly to them and not other institutions. For this reason, involving companies in innovative projects directly and allowing them to obtain necessary knowledge and information is considered by the survey respondents to be the most important condition of innovativeness.

3. Among the factors serving to inspire cooperation between various subjects in a region, the most important ones included the prices of services rendered by institutions supporting innovativeness and local government aid for companies in interregional and international cooperation.

4. Among the factors creating and reinforcing non-material resources of a region, involving the local government in developing the human capital (by handing out grants, stipends, organising training, promoting talent, tailoring education to fit the needs of the region and so forth) was deemed the most important. Another factor of great relevance of this group is the creation of knowledge centres in regions and free access to market analyses, databases, information sources necessary to bring about innovation processes.

5. In both voivodeships, development of transport and telecommunications infrastructure was named the most important factors in the creation and augmentation of a region's material resources group. Of note are high ratings given to this group of factors underpinning effective operations of enterprises.

When comparing the importance of the five groups of regional conditions, entrepreneurs place the creation of material and non-material resources in the first place. In turn, they attribute the least importance to financial support of regional agents, aside from subsidising investment in permanent assets of enterprises. Considering the high importance placed on financial factors on the micro- and macroeconomic level, it is a piece of information of both interest and importance for local governments who seek to conduct a policy of supporting innovativeness. At the same time, none of the factors reviewed in the survey received an average note of less than 2.0, which would mean that it is of very little importance.

In both voivodeships, the more innovative companies find the following factors more important than the less innovative companies do:

- financial aid for investment in permanent assets,
- financial aid for cooperation with scientific research institutions,
- Subsidising and development of financial institutions, facilitating access of enterprises to capital,
- Engaging innovation centres in pro-innovative activity,
- Public procurement of innovative goods and services by local authorities,
- Facilitating access to services of research institutions and laboratories,
- Facilitating cooperation with training and consultancy centres.

Therefore, more innovative companies are more open to their environment and willing to cooperate with it. They appreciate the need to use knowledge and services of research, training, and consulting institutions. These correlations are present in both voivodeships. Although the two regions differ in their level of social and economic development, only in 3 out of 27 cases do their assessments conflict, pointing to a more or less universal nature of the factors in question and the need to take them into account while designing and pursuing regional innovativeness policies, while at the same time noting the specifics of any given area.

The research has allowed a systematisation of the most important regional factors and an assessment of their impact on innovativeness in the regions in question. It is, however, limited by the subjective nature of the responses when evaluating the importance of regional conditions of innovativeness of enterprises, although attempts were made to minimise any potential errors in replies by a number of measures, including selecting respondents among the management. The impossibility of taking into account all regional factors and the overlap of factors from various levels of business environment as well as applying a scale for the level of innovativeness of given enterprises are the further limiting factors of the study. An important research question for the future is the diagnosis of the impact of regional conditions on the effectiveness of companies.

Abstract

The Member States of the European Union are affected by the same or very similar factors influencing employee motivation. In the article, we analyse the level of employee motivation in V4 countries. We assume that the level of economy of these states is similar and efficient, after 27 years of labour market development and accession to the European Union. Our research was conducted in 2016 and 2017. In sociological research 2183 respondents from manufacturing companies were involved in the questionnaire by the correspondence method. Respondents are made up of 898 men and 1295 women of different age and education, with different practices and different job positions. In the tests, we examined the significance of the difference in arithmetic mean and the standard deviation of the motivation factors of the observed samples at significance level = 0.05. Subsequently, we tested the samples by the Tukey's HSD test. Based on the research results, we have defined four most important motivational factors in the analysed countries. We conclude that the requirements for motivating employees in industrial enterprises are highly similar in the V4 countries. The most important factors are basic salary, good working team, work atmosphere and job security. Other factors include manager access, fair employee evaluation, additional financial evaluation, and workplace communication. Despite the similarity between countries, there are statistically significant differences. The biggest difference can be observed between Hungary and other countries when looking at motivational factors such as workplace atmosphere and good working team. Between the Czech Republic and the other countries, there are also differences in the basic salary factor. In the case of job security factor, we observe statistically significant differences between the Slovak Republic and Poland.

Keywords: motivation of employees, Republic of Poland, Czech Republic, Republic of Hungary, Slovak Republic, Tukey's HSD test.

Introduction

The Visegrad Group (known as V4) represents an informal grouping of four Central European countries - The Slovak Republic, the Czech Republic, the Republic of Hungary and the Republic of Poland. It is a lively and informal regional structure of four EU and NATO member states that claim the same values, have a common history, culture and geography. V4 is a dynamic regional grouping of EU member states that provides scope for strengthening the coordination and consultation mechanism to find common positions and opinions on topical issues of foreign and European policy, regional development, economic and cultural cooperation. The Visegrad Group is an expression of the Central European countries' efforts to cooperate on a number of areas of common interest within the framework of pan-European integration. The Czech Republic, Hungary, Poland and Slovakia have always been part of the same civilization based on the same cultural and intellectual values and the common roots of religious traditions that they wish to preserve and further strengthen. The Visegrad Group was formed on 15 February 1991 when the cooperation between the four nations (after the break-up of Czechoslovakia also the states) was renewed in order to support the process of European integration and the transformation of economies. The regional cooperation of V4 has been successfully developing for more than 20 years in the sector / interdepartmental area, economy, infrastructure, energy, cross - border cooperation, cultural - scholarship exchanges, coordination of foreign policy positions and the promotion of common interests both in the EU and in relation to third countries / regions. V4 co-operation is coordinated by the Ministries of Foreign Affairs and National Co-ordinators of Visegrad. The program is based on the program of the presidency, which is approved by the country's presidents at V4 Summits.

The integration of the Slovak Republic, the Czech Republic, the Republic of Hungary and the Republic of Poland into the European Community has led to the integration of their labour market into Europe (Virglerová et al., 2017). Member State markets should be affected by the same or very similar factors influencing staff motivation (Felsead et al., 2015). This is supported by the facts such as similar levels of gross domestic product growth per person, cost of living, and average wage (www.etrend.sk/ekonomika).

Literature Review

Work satisfaction is one of the most accurate indicators of work motivation (Lorincová, Schmidtová, Javorčíková, 2016). The lack of work motivation still does not lead to dissatisfaction, but only to a lack of satisfaction (Sacchetti, Tortia, 2013). Satisfaction with work is supposed to encourage and motivate a person to perform better (Dugguh & Ayaga, 2014, Roos & Van Eeden, 2008).

Both current and potential employees are the subject of human resources management. It is necessary to constantly invest in their development (Drábek, Lorincová, Javorčíková, 2017, Kucharčíková, 2014, Semann and Farkašová, 2015). Each managerial decision is original and specific and it is also its information support (Potkány, Krajčírová, 2015). Employees are the source of the transformation process, and the principle of efficiency should be respected (Vetráková, Smerek, 2016). Motivation (as a force that strengthens behaviour and gives way to behaviour) triggers a tendency to continue. This explanation proves that individuals need to be sufficiently energetic and clear about their goals in order to achieve their goals. These are internal units to satisfy unmet needs and the will to achieve them (Lorincová, 2015). Motivation is a procedure that stimulates goal-oriented performance through physiological or psychological stimuli. The principle is to close two interface products, namely personality behaviour and

organizational uniqueness. This symbolizes those psychological procedures that stimulate the steps and determine deliberate goal-oriented action (Shukla, 2012). Motivation is also supportive target behaviour. It is the inner strength that causes personal and organizational activity. For an enterprise, motivation of employees is the most important in terms of the employment of employees. It can be defined as human behaviour targeted and based on the claim that motivation is the inner force of a being shifting individual behaviour in different directions (Mura, Horvath, 2015). Employee motivation becomes a competitive advantage in many successful businesses (Remeň, Sujová, 2017). When the company's goal is to improve employees' engagement, this should necessarily motivate its working groups because motivated groups makes efforts, work is finished faster, co-operation increases with greater intensity and has a positive impact on business productivity (Lorincová, Potkány, 2016). The relationship between employee motivation and employee engagement is bi-directional. If an enterprise wants to improve employee motivation, employee engagement should be improved, too (Evangeline, 2016, Gopal, 2016). Also, according authors Urbancova and Urbanec, the performance depends largely on many factors related to motivation. These factors include assessment of employee performance motivation, employee satisfaction, reward, education and development of occupational safety, organizational structure and more. The field of study is focused only on employee motivation, with this attribute greatly affecting the performance of employees (Urbancová, Urbanec, 2016). Employee motivation is one of the policies leading to the improvement of quality and employability in the performance of employee obligations in enterprises. A motivated employee is usually perceived according to the ultimate goals he has to achieve and therefore directs his efforts in this direction (Teplická, 2004). Providing the best and most appropriate work even in tedious conditions is one of the most stable challenges for employees, and it may be the object of their motivation (Nedeliaková, Sekulová, Nedeliak, 2015). Motivation is also one of the major issues in behavioural sciences, therefore, by virtue of its essential role, it plays an important role in managing human resources to achieve the goals of society (Barzokiet et al., 2008, Stacho, Stachová, 2015). Highly motivated employees will have a higher level of organizational commitment as their attitudes, related to work and behaviour, are developed positively. Employees believe that their work is important, and this faith leads them to work harder. These workers tend to create higher work as well as organizational performance. Therefore, it is less likely that they will leave their job but enjoy more job satisfaction (Smerek, 2017). Trying to understand and explain job satisfaction is motivated by calculated reasons as well as humanitarian interests. Satisfied employees tend to engage in altruistic behaviour that exceeds the formal requirements. On the contrary, unhappy employees have a high tendency to counter-productive behaviour. Academics and managers have defined the conditions for motivation and job satisfaction. Specifically Chatzopolou (2015) defines motivation as a predisposition to behave purposefully to achieve specific, unmet needs. According to Luthans (1998), motivation can be defined as a process that stimulates, delivers energy, manages and maintains the behaviour and characteristics of employees. On the other hand, he argues that motivation can be defined as "an internal force that activates individuals to achieve personal and organizational goals". Job satisfaction is the emotional response of an individual to the current state of work, while motivation is a driving force to seek and meet some needs (Chatzopoulou, 2015).

Materials and Methods

At the beginning of the 1990s, the analysed countries had a similar starting level in transforming into democratic landscapes. After 27 years of developing labour markets and after joining the European Union, we assume that they have very similarly performing economies even today. The accession of the

V4 member countries to the European Union, agreed in referendums in these countries, took place on 1 May 2004. The only organization within the V4 platform is the International Visegrad Fund based in Bratislava and established in 1999. All activities of the Visegrad Group are aimed at strengthening stability in the Central European region. Member States understand their mutual cooperation as a challenge for themselves and their success as the best proof of their ability to integrate into structures such as the European Union (www.visegradgroup.eu).

Since the V4 countries have had a long-term common history, they are intensively cooperating in the economic area; they have had a common starting transformation position. The aim of the paper is to evaluate two working hypotheses:

WH1: The importance of motivation factors is similarly high in the Czech Republic, the Slovak Republic, Hungary and Poland.
WH2: Statistical differences in the level of motivational factors in the Czech Republic, the Slovak Republic, Hungary and Poland are statistically insignificant.

We used the questionnaire method to determine the level of motivation and to analyse the motivation factors in the monitored enterprises. The questionnaire consisted of closed questions (Hitka, 2009). The first part of the questionnaire examined socio-demographic characteristics and qualifications of employees in enterprises compared. In this way, we have obtained basic data on respondents about their age, gender, work-life in the company, completed education and employment. The second part of the questionnaire included questions about motivational factors that can be used to find out about the characteristics of the work environment, the working conditions, the system of assessment and remuneration in the company, the personal work in the company itself, the social care system and the employee benefits as well as information about employee satisfaction or dissatisfaction, value orientation, relationship to work, colleagues and the enterprise as a whole.

We analysed the motivation factors in terms of financial evaluation (basic salary, additional financial evaluation, fair evaluation of the employee), social security (social benefits, company vision, prestige of the company name, development of the region, the relationship of the enterprise to the environment, free time); working conditions (physical labour demand, workplace safety, job security, content and type of work performed, work performance report, working time, work environment, work performance, psychological burden), career development (work experience, skills, prestige, self-decision, self-realization, education and personal growth, work recognition) and interpersonal relations (workplace atmosphere, good working team, workplace communication, The individual motivation factors were arranged according to the alphabet for reasons of not influencing the respondents. Employees could assign one of five grades to the scale of the Likert scale, where 5 was the maximum and 1 minimum, for each question.

In the years 2016 and 2017, 2193 respondents from V4 manufacturing companies (Slovakia - 763, Czech Republic - 633, Hungary - 366, Poland - 431) participated in the research by the correspondence method. Respondents (898 men, 1295 women) were of different age and education, with different practice and different job positions. The data were obtained by the simple random selection method from the entire territory of the monitored countries. The detailed characteristics of the respondents are in Table 1.

Table 1: Characteristics of respondents

Country	Slovak Republic		Czech Republic		Hungary		The Republic of Poland		The total percentage of respondents
Gender	**Number**	**Percentage**	**Number**	**Percentage**	**Number**	**Percentage**	**Number**	**Percentage**

white-collar worker	317	41.55	238	37.60	114	31.15	423	98.14	49.79

Source: own processing

Further, we processed the data obtained by evaluating the questionnaires using statistical software STATISTICA 12 (StatSoft Inc., 2014). Descriptive statistics have been used to characterize sample files. Given the selective nature of the data, we tested the differences between the arithmetic mean values of the motivation factors' importance in selected countries using the Tuke's HSD (honest significant difference) method at the significance level =5% . Tukey's HSD test is a single-step multiple comparison procedure,

which is also adapted for different numbers of observations in each group. The assumption is the independence between the levels of factors, the variance of consistency and the normality. It can be used on raw data or in conjunction with an ANOVA (Post-hoc analysis) to find means that are significantly different from each other.

Results and discussion

We have defined the motivational factors assessed in all the countries surveyed as most important using descriptive statistics. This group of factors consists of a workplace atmosphere, a good work team, job security and a basic salary (Table 2). These factors are among the top ten most important factors in all four countries.

Table 2: Average values of the most important motivating factors in the monitored countries

Slovak Republic	Ø	**Czech Republic**	Ø	**Hungary**	Ø	**Republic of Poland**	Ø
Basic salary	4.595	Supervisor's approach	4.542	**Atmosphere at the workplace**	4.727	**Basic salary**	4.703
Good working team	4.591	**Atmosphere at the workplace**	4.509	**Basic salary**	4.634	**Good working team**	4.638

a) Analysis of the motivational factor - atmosphere at the workplace

"Atmosphere at the workplace“ as a motivational factor was most often rated by importance level 5 (very important) where up to 65.8% of all respondents identified this option (Table 3).

Table 3: Frequency of motivational factor - the atmosphere at the workplace

d) Analysis of the motivational factor – basic salary

The motivational factor "basic salary" is the most important of the analysed factors. It is more than 68.58% of the respondents for whom this factor is highly (Table 9).

Table 9: Frequency of motivational factor - the basic salary

Country	Basic salary					Total
Scale	**1**	**2**	**3**	**4**	**5**

Within the achieved results, a high similarity in the level of motivation of employees in the V4 countries can be seen. Basic salary, good workforce, workplace atmosphere and job security are among the most important factors. Other factors include supervisor's approach, fair appraisal system, further financial reward, and workplace communication. Despite the similarity among these countries, there are statistically significant differences. The greatest differences exist between Hungary and the other countries, in the case of motivational factors - workplace atmosphere and good working team. We see other differences among the Czech Republic and other countries, these differences consider the basic salary. Looking at the "job security" factor, there are statistically significant differences between the

Slovak Republic and the Republic of Poland. We can partly attribute these differences to the structure of respondents in terms of age, education and practice. In Hungary, 59% of respondents are under the age of 30. This causes a different perception of the atmosphere in the workplace than in other countries. We can claim that this is caused by the generation Y and its perception of the surrounding world. From the perspective of Polish respondents, we can say that most of them work in enterprises for more than 10 years. In Poland, there are a high proportion of white-collar workers. In Tables 3, 5, 7, and 9, the absolute and relative abundance of the respondents in the V4 countries are described according to motivational factors and their preferences in the area of importance. Using Tukey's HSD test, the tatistically significant differences within the analysed motivational factors among countries, is defined in Tables 4, 6, 8, and 10. Statistically significant differences among the monitored countries are observed in the motivational factor of "atmosphere in the workplace" between Hungary and the Czech Republic, and Hungary and the Slovak Republic (Table4). Statistically significant differences can be observed between the Slovak Republic - Hungary, the Czech Republic – Hungary, and the Republic of Poland - Hungary (Table 6), for the motivational factor called "good working team". Within the factor "job security", we see a statistically significant difference between the Slovak Republic and the Republic of Poland (Table 8). In the case of the "basic salary" motivational factor, there are statistically significant differences between the Slovak Republic – the Czech Republic, the Czech Republic - Hungary, the Czech Republic – the Republic of Poland (Table 10). This means that despite the high similarity of the analysed factors in the V4 countries, the respondents in particular countries attribute these factors different, statistically significant level. Paradoxically, the statistically significant difference is observed in the basic salary among the Czech Republic and other countries. The Czech Republic has the highest level of average salary from the monitored countries.

Conclusion

Based on the comparison of the most important motivating factors of the analysed countries, we conclude that there are very similar requirements of employees of the production enterprises for the motivation in the V4 countries. Based on the descriptive statistics, it can be stated that in all V4 countries, employees demand the same motivation areas from their employers. Thus WH1 was confirmed. Looking at the results in more detail, it can be concluded that despite the high similarity of the analysed motivation factors in the V4 countries, respondents attributed them different, statistically significant importance in particular countries. So WH2 was not confirmed.

For this reason, we recommend further investigation. Creating an incentive program is a demanding and costly activity for all businesses in these countries. Its effectiveness is based on a thorough and targeted analysis of employees. Based on our analysis, the following conclusions can be stated: In the V4 countries, employees are similar in terms of satisfying their motivational needs. However, the level of importance varies between these countries. For this reason, it can be said that there are differences in the level of motivation among employees in the V4 countries. At present, it is very important for employers to ensure their employees job security and to create trustworthy relationships among them – this can be achieved through efficient communication processes. Employers, however, have not paid careful attention to this need yet. Research shows that employers rarely allow their employees to satisfy their needs and this can have a significant demotivating effect.

The Relationship between GDP And It's Resources in Romania's Economy

Agatha Popescu, University of Agricultural Sciences and Veterinary Medicine, Bucharest, Romania, E-mail address: agatha_popescu@yahoo.com
Livia David, University of Agricultural Sciences and Veterinary Medicine, Bucharest, Romania, E-mail address: livia_david@hotmail.com

Abstract

The paper analyzed the dynamics of GDP and its structure by category of resources in Romania in the period 2007-2016 pointing out the relationships existing between GDP and its components based on the simple linear regression and multiple linear regression econometric models, correlation coefficients, and coefficients of determination, the validity of the model being checked by Fisher's test. In the analyzed period, GDP increased by 82 % grace to the contribution of all the economic branches. The main contributors to GDP are Other services (31.8 %), Industry (23 %), Trade (18 %), and Financial intermediation and communication (17%), which all together totalize about 90 % of the resource supply. The simple linear regression equations and also the multiple linear regression equation showed the strong influence of various economic branches on GDP. This aspect was also confirmed by the determination coefficient, R^2= 0.999, meaning that 99.9 % of GDP variation is explained by the variation of the independent variables, and also by the high positive coefficient of multiple correlation, r = 0.999. H1 hypothesis was accepted as long as Fisher's calculated value was higher than its tabled value, reflecting that the regression model was correctly computed. The development of Romania's GDP should be supported by ***services*** (professional, scientific, technical, administrative activities, public administration and defense, social insurance, education, health, social assistance, shows, culture and recreation activities), ***industry*** (mining and quarring, manufacturing, electricity, gas, steamed and air conditioning, waste management), as well as trade, transport, and tourism.

Keywords: dynamics, GDP, resources, linear regression, multiple regression, Romania

Introduction

GDP is a macroeconomic aggregate that measures the value of the goods and services produced by a country in a specific period, adjusted for inflation and is calculated based on the value of all products achieved in an economy using average prices in a specific year.
GDP is used by Governments as a comparison tool to analyze the purchasing power of the economy over time to describe the economic health of a country which is a guarantee of the living standard. It is also commonly used to compare the productivity of various countries with a high precision. In order to compare GDP level from a year or a quarter to another, GDP is adjusted for inflation. It reflects whether an economy is expanding or contracting, reflecting either economic growth or decline (Investopedia, 2017).

According to Eurostat, six sectors forms the condensed economic structure of the EU since 2010 as follows: *Agriculture:* Products of agriculture, forestry, fisheries and aquaculture; *Manufacturing:* Products of mining and quarrying, manufactured products and energy products; *Construction:* Constructions and construction works; *Trade:* Wholesale and retail trade, repair services, hotel and restaurant services, transport and communication services; *Business services*: Financial intermediation services, real estate, renting and business services; Other services (Eurostat, 2011).

This condensed structure of the economic sectors supplying GDP was adopted by National institute of Statistics of Romania and is presented in its methodology SEC 2010, CAEN Rev2.

According to National Institute of Statistics in Romania, GDP is defined as the main macroeconomic aggregate of national accounting, representing the final result of the production activity of resident producer units. GDP is approached in three ways as follows: *(i)Production approach*: GDP = GVA + TP + D - SP, where: GDP = Gross domestic product (market prices), GVA = Gross value added, (basic prices), TP = Taxes on products, D = Import duties, SP = Subsidies on products; *(ii) Expenditure approach:* GDP = FC + GFCF + CS + (E - I), where: FC = Final consumption, GFCF = Gross fixed capital formation, CS = Change in inventories, E = Exports of goods and services, I = Imports of goods and services; *(iii)Income approach:* GDP = C+ GOS + OTP - OSP+TP + D - SP, where: C = Compensation of employees, GOS = Gross operating surplus, OTP = Other taxes on production, OSP = Other subsidies on production, TP = Taxes on products, D = Import duties, SP = Subsidies on products (National Accounts, Romania, 2013; Romanian Statistical Yearbook, 2012).

In 2015, Romania's GDP was Euro Billion 160 and in 2016 it reached Euro Billion 169.07, (+ 4.8%), placing the Romanian economy on the 17th position in the EU. At present, Romania's economy is almost similar to the economies of Czech Republic, Greece and Portugal, (Eurostat, 2017).

The growth of GDP was determined by the important contributions of all the economic sector, less agriculture, forestry and fishing. In 2016, compared to 2015, the growth rate of various sectors in the economy was as follows: wholesale and retail trade, repairs of vehicles and motorcycles, transportation and storage, hotels and restaurants (+1,8%), information and telecommunication (+0.7%), professional, scientific and technical activities, administrative services and support services (+0.6%), industry (+0.4%), and net taxes on product (+0.5%)(Tilica and Arustei, 2017).
In 2016, the lowest share in GDP was achieved by agriculture, just 3.9%, industry contributed by 23.1%, constructions by 6%, trade by 18.1%, information and communications by 5.6%, real estate by 8.2%, and public administration and defense by 10.2%, the remaining representing the share of other sectors (Tudor, 2017).

According to the World Bank, Romania's GDP/capita, adjusted at the purchasing power parity increased 4 times in the period 1998-2015 placing the country on the 8th position in the world. From this point of view, Romania is on the top position in the EU, increasing its GDP/inhabitant 3.5 times in the last 18 years (Amariei, 2016).

Romania is a member of the EU-28, and considered a fast developing, upper-middle income mixed economy with a very high human development index (HDI) and a skilled labor force, the 16th largest in the EU by total nominal GDP and the 13th largest based on PPP (purchasing power parity)(World Economic Outlook Database October, 2009) .

Taking into account the current economic growth it is expected as Romania's GDP to reach 1 trillion of USD PPP before 2035. Among the CEECs, Romania continues to be one of the leading nations attracting foreign direct investment, only FDI totalizing more than $170 billion since 1989. Romania is on the top among the CEECs for electronics manufacturing, and has become a major centre for mobile technology and information security, and automobiles and its economic growth is 3 times higher than the EU average.

Romania has various natural resources such as: iron, ore, oil, salt, uranium, copper, natural gas. IT and motor and vehicle production make this country a leader at regional level. Vehicles, machineries, chemical goods, electronic products, electrical equipments, pharmaceuticals, transport equipments, basic metals, food products, and rubber and plastics are the top 10 products exported by Romania. While exports increased by 7.6 %, imports increased by 9.3% in 2016 compared to 2015 (Economy of Romania, Wikipedia).

The relationship between GDP and its factors has been studied by many authors using regression models.

In the CEECs, labor quantity and quality, information and communication technology capital services, total factor productivity, foreign direct investment inflow, investment on research and development, have a positive impact on GDP growth (Pokrivčák *et al*., 2016).

In Lithuania, the increase of fixed capital consumption could explain the changes of GDP. (Bobinaite *et al.*, 2011).

In India, financial development has a stronger role in the growth of GDP (Ray, 2013). Also, in India, FDI, Net FII equity and Import have a positive impact on GDP development. (Jain *et al*, 2015).

In Pakistan, GDP is deeply and positively influenced by national expenditures, goods exports, gross saving and final consumption expenditure, and in Bangladesh, national expenditures, external debts stock total, goods imports and exports have positive effect on the GDP. (Mehmood, 2012). Also, in Bangladesh, population, imports of goods and services, agriculture value added, manufacturing value added and labor force have positive effects on GDP (Hasan *et al*., 2016).

In Romania, final consumption and the turnover of companies in retail trade have a positive influence on GDP increase (Anghelache *et al*., 2017). Also, privatization has an important role both in the contribution of administrations and various economic branches to GDP (Anghelache *et al*., 2013). The increase of unemployment could led to a decline of real GDP (Dumitrescu *et al*., 2009).

In this context, the paper aimed to analyze the evolution of GDP and the dynamics of its structural components, the degree of determination of GDP by all the economic sectors, using linear and multiple regression models.

The paper objectives are:
(a)Analysis of the dynamics of GDP and its categories of resources in Romania's economy the period 2007-2016;
(b)To study the relationships existing between GDP and its supplying resources by means of linear regression analysis and correlation coefficients;
(c)To study the relationship existing between GDP and its categories of resources by means of multiple regression analysis.

The structure of this paper is the following one: *Introduction* which presents the empirical literature on GDP and its structural components in the vision of the EU Commission and National Institute of Statistics in Romania, *Materials and methods* present the source of the data collection, the selected economic variables taken into consideration, the mathematical models, the methodology used in this research, *Results and Discussions* which mention the results of the calculations based on the utilized econometric models and the corresponding comments and interpretations, and finally *Conclusions*, where the main ideas resulting from this research are briefly exposed.

Materials and Methods

Data collection. The study is based on the empirical data provided by the National Institute of Statistics, Tempo-online Database, National Accounts for the period 2007-2016.

The data refer to the following indicators: GDP at Romania's level, considered the dependent variable Y, and GDP created by various categories of resources, considered the independent variables: X1, X2, ..., X7, whose significance is the following one: X1- *Agriculture*, forestry and fishing; X2-*Industry*, including: mining and quarring; manufacturing; electricity; gas; steamed and air conditioning production and supply; waste management and decontamination activities, X3-*Construction*, X4- *Trade,* including: whole sale and retail trade; repair of motor vehicles and motorcycles; transport and storage; hotel and restaurants; information and communication; X5-*Financial intermediation* and insurance; real estate activities; X6-*Other services:* professional, scientific and technical activities; activities of administrative and support services; public administration and defense; social insurance of public sector; education; health and social assistance; shows, culture and recreation activities; repair of household goods and other taxes on product; import duties; X7- Subsidies on product.

Methodology. The study is based on the general mathematical model for GDP, Y, the dependent variable:

$$Y= f (X_1, X_2, X_3, X_4,X_5,X_6,X_7, \varepsilon) \quad (1)$$

whose meaning has been already explained above. These values are in Lei Billion, the national currency, presented according to *SEC 2010 Methodology of production, in current prices, CAEN*

Rev2 by category of resources, used by National Institute of Statistics (National Institute of Statistics, 2017).
GDP and its components by resource category were studied as follows:

(a)Dynamics across the period of reference, establishing the growth rate. The comparison between the value of the variables in the last year and the value in the first year of study was made based on *Index Method,* calculating the index with fixed basis (I_{FB}), according to the formula:

$$I_{FB} = (X_n / X_1)*100 \quad (2)$$

where X is the analyzed indicator and n = 1,2,3.....i the number of years in the chronological series of data.
The evolution was studied graphically both for GDP and its components.
(b)Descriptive statistics was set up for each indicator: Mean, Standard error, Median, Standard deviation, Minimum and Maximum values, and coefficient of variation.
(c)Trend analysis both for GDP and its categories of resources.
(d)GDP structure by category of resources pointing out the share of each resource in GDP.
(e)Linear Regression *Analysis* of GDP, Y, depending on each category of resource, X1, X2, ...X7, according to the formula:

$$Y = a + bX + \varepsilon \quad (3)$$

where, a and b are the estimators of the regression parameters, whose values were determined solving the linear system of equations by means of Least Square Method, and ε is a variable, reflecting the error.
The significance of the regression model was verified by Fisher's test.
(f)Pearson correlation coefficient was used to identify the links existing between pairs of indicators, divided into two categories: (i) $GDP*X_1$, $GDP*X_2$, ...$GDP*X_7$, and (ii) X_1*X_2, X_1*X_3,..... X_6*X_7, i.e. all the possible combinations between resources.

$$r = \frac{\sum (x - \bar{x})(y - \bar{y})}{\sqrt{\sum (x - \bar{x})^2 \sum (y - \bar{y})^2}} \quad (4)$$

The values of the correlation coefficients were interpreted according to Evans (1996).
(g)Multiple Regression Analysis was used to identify the relationships between all the categories of resources and GDP. The only difference between simple linear regression and multiple regression analysis is the number of predictors, " X" variables.
The formula of multiple regression is:

$$Y = b_0 + b_1 X_1 + b_2 X_2 + \ldots\ldots\ldots\ldots\ldots\ldots + b_i X_i \quad (5)$$

where b_0 is the intercept, the control, i.e. the value of the dependent variable Y without the influence of the independent variables X1, X2, ...X7, b_1, b_2, b_3, …, b_i are the regression coefficients analogous to the slope in linear regression equation, and i=1,2,3,...n, the number of variables in the chronological series.
The interpretation of regression coefficients is given by the value b_i, which shows the expected increase of the dependent variable Y if X_i increased by 1 unit.
Multiple regression analysis involves other parameters such as:
-***Multiple correlation coefficient***, which reflects the relationship between the dependent variable and the independent variables:

$$r = \frac{n(\sum_{i=1}^{n} x_i y_i) - (\sum_{i=1}^{n} x_i)(\sum_{i=1}^{n} y_i)}{\sqrt{[n(\sum_{i=1}^{n} x_i^2) - (\sum_{i=1}^{n} x_i)^2][n(\sum_{i=1}^{n} y_i^2) - (\sum_{i=1}^{n} y_i)^2]}} \quad (6)$$

-***R squared (coefficient of determination)*** shows in what measure the variation of the dependent value Y depends on the variation of the independent values, Xi.

$$R^2 = 1 - \frac{\sum_{i=1}^{n}(y_i - \hat{y}_{icalc})^2}{\sum_{i=1}^{n}(y_i - \bar{y})^2} \in [0,1] \quad (7)$$

-***Adjusted R-squared*** indicates how well the terms fit a curve or line, but adjusted for the number of terms in a model. When more useless variables are in the model, adjusted r-squared will decrease. When more useful variables are added in the model, adjusted r-squared will increase.
Its formula is:

$$R^2_{adj} = 1 - \frac{(1-R^2)(n-1)}{n-k-1} \quad (8)$$

where: n is the number of points in the data sample, and k is the number of independent regressors, i.e. the number of variables in the model, excluding the constant.

- *Standard error(SE)* is very similar to standard deviation, reflecting the spread of the data.

$$S_{est} = \sqrt{\frac{\sum (Y_i - Y_{icalc})^2}{N-2}} \quad (9)$$

-ANOVA table includes:

-DF= degrees of freedom, in our case k=7 for Regression, n-k-1=10-7-1=2 for residual, and n-1= 10-1=9 for Total.

-SS=Sum squared, which represents the value of the variation for each of the three items: total, factor explained by regression, and random factor (unexplained by regression).

-MS-Mean squared, which represents the dispersion value corrected by the number of degrees of freedom, respectively MS(i)/df(i), where i is the variation source: Regression, Residual, and Total.

-SS***regression*** is the sum of the squares of regression deviation, i.e. variation explained by regression.

$$SSregression = \sum_{i=1}^{n}(\hat{y}_i - \bar{y})^2 \quad (10)$$

-SS***residual*** is the sum of the squares of the errors, i.e. the variation unexplained by regression.

$$SSresidual = \sum_{i=1}^{n}(y_i - \hat{y}_i)^2 \quad (11)$$

-**SS*total*** is the sum of the individual deviations from the mean, i.e. total variation.

$$SStotal = \sum_{i=1}^{n}(y_i - \bar{y})^2 \quad (12)$$

SS***total*** **=** SS***regression*** **+** SS***residual*** equivalent to the formula:

$$\sum_{i=1}^{n}(y_i - \bar{y})^2 = \sum_{i=1}^{n}(\hat{y}_i - \bar{y})^2 + \sum_{i=1}^{n}(y_i - \hat{y}_i)^2 \quad (13)$$

F = the calculated value of Fisher's Test = MS (*Regression*)/ MS (*Residual*). The calculated F value should be compared to the tabled value of F (α, df1, df2), where α is the level of confidence (0.05), df1= k=7, and df2=n-k-1=2.

Significance F is the risk that allows to accept the H1 hypothesis, that is the model is good.

If SignF is smaller than α, this means that the risk to accept the H1 hypothesis is smaller than the proposed risk, and as a consequence the model is good.

P-value represents the risk calculated to accept H1, and if P-value < α, therefore the calculated risk is smaller than the assumed risk, considered acceptable, we may accept H1, meaning that the parameters are different than 0.

Results and Discussions

Dynamics of Romania's GDP. In the analyzed period, GDP increased by 82 %, from Lei Billion 418.2 in the year 2007 to Lei Billion 761.5 in 2016, reflecting a continuous development of the economy (Fig.1.)

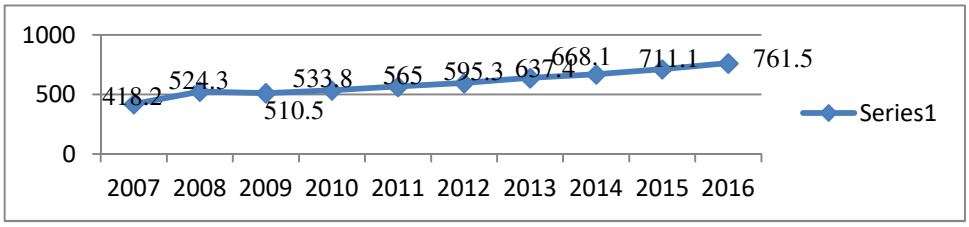

Fig.1.The dynamics of Romania's GDP, 2007-2016 (Lei Billion)

Source: Own design based on National Institute of Statistics, Tempo on line Data Base.

GDP trend analysis reflects the evolution of this indicator too (Fig2.).

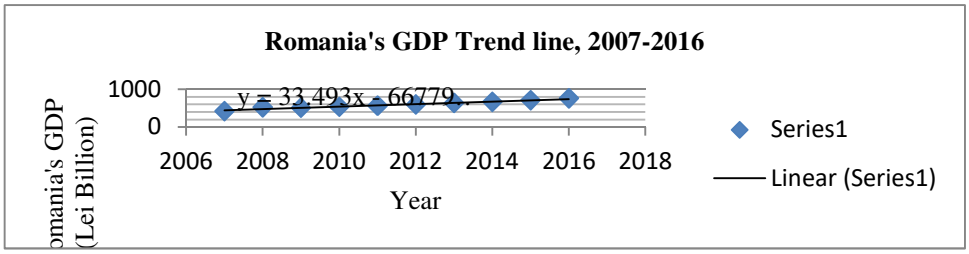

Fig.2.GDP trend analysis, 2007-2016

Source: Own design based on National Institute of Statistics, Tempo on line Data Base.

Dynamics of GDP created by various resources. The positive dynamics of GDP was influenced by the contribution of each of its resources as shown in Table 1 and Fig.3.

Table 1: GDP by category of resources, Romania, 2007-2016 (Lei Billion)

	2007	2008	2009	2010	2011	2012	2013	2014	2015	2016	2016/2007 %

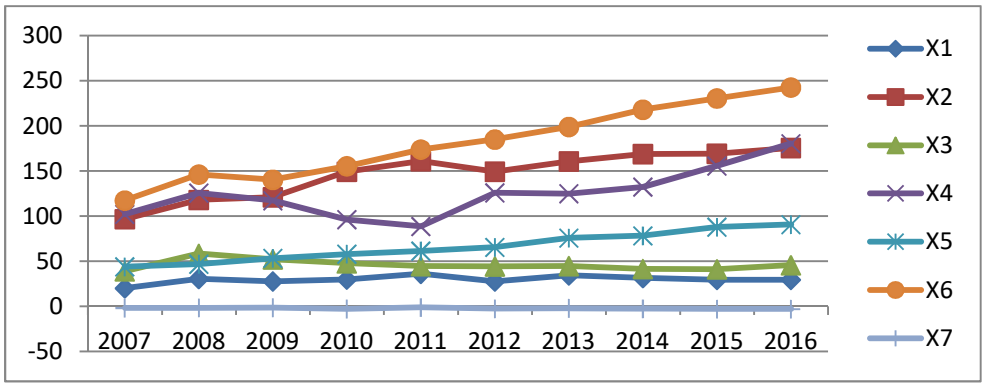

Fig.3.GDP by category of resources, 2007-2016 (Lei Billion)

Source: Own design based on National Institute of Statistics, Tempo on line Data Base.

Agriculture, forestry and fishery (X1) contribution to GDP increased by 46.5 % from Lei Billion 20.2 in 2007 to Lei Billion 29.6 in the year 2016.(Fig.4).

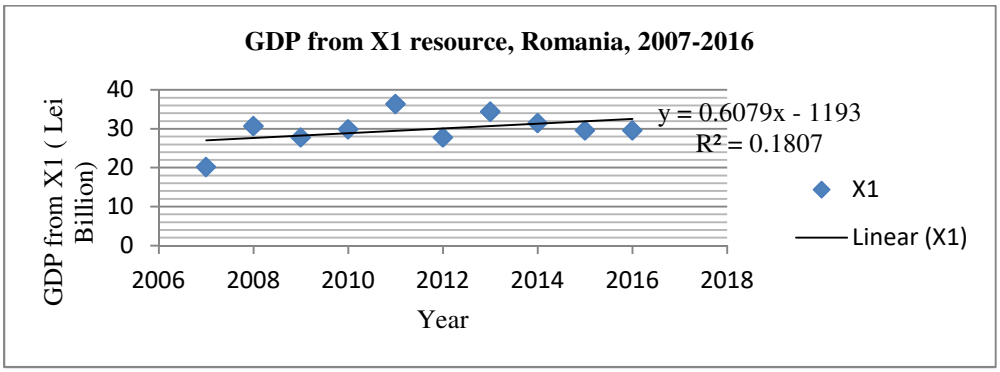

Fig.4.Trend analysis of GDP created in agriculture, forestry and fishing, Romania, 2007-2016 (Lei Billion)

Source: Own design based on National Institute of Statistics, Tempo on line Data Base.

Industry (X2)'s contribution to GDP grew up by 81.4 % from Lei Billion 96.7 in 2007 to Lei Billion 175.5 in 2016, taking into account the development of mining, manufacturing, electricity, gas, water supply, sewerage and waste management (Fig.5).

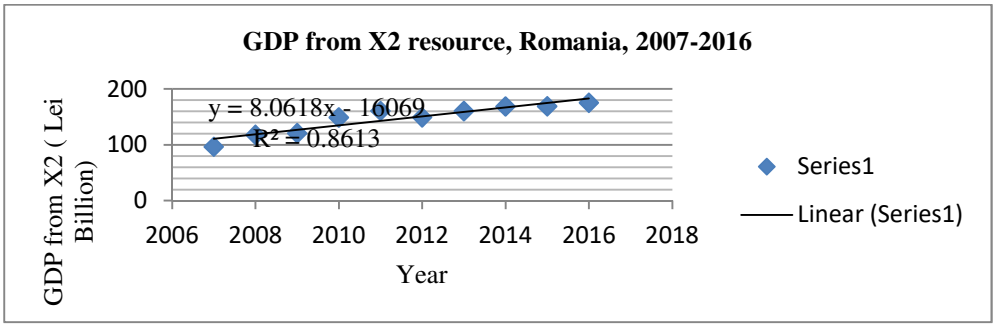

Fig.5.Trend analysis of GDP created in industry, Romania, 2007-2016 (Lei Billion)

Source: Own design based on National Institute of Statistics, Tempo on line Data Base.

Constructions (X3)'s contribution to GDP recorded a variable growth across the whole period, but with a general trend of decline. However, in the year 2016 the value of GDP produced in the field of construction was by only 17.4 % higher, accounting for Lei Billion 45.7 compared to Lei Billion 38.9 in 2007 (Fig.6).

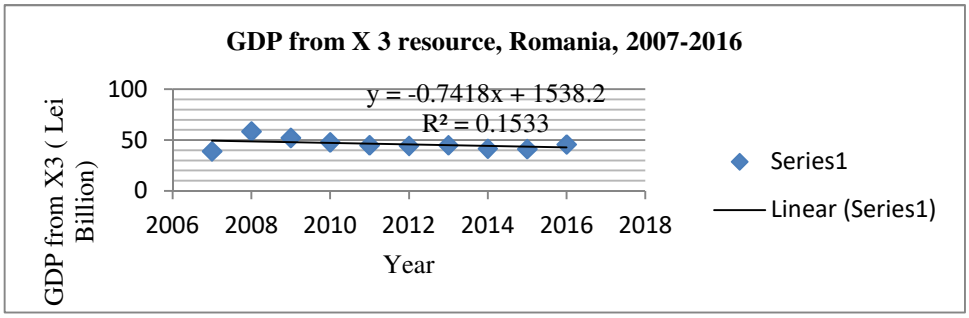

Fig.6.Trend analysis of GDP created in constructions, Romania, 2007-2016 (Lei Billion)

Source: Own design based on National Institute of Statistics, Tempo on line Data Base.

Trade (X4)'s contribution to GDP was by 70.5 % higher in 2016, reaching Lei Billion 138.3 compared to 2007 when it accounted only for Lei Billion 81.1. This growth was determined by the development of wholesale and retail transactions, the activity of repairs of vehicles and motorcycles, and tourism in hotels and restaurants (Fig.7).

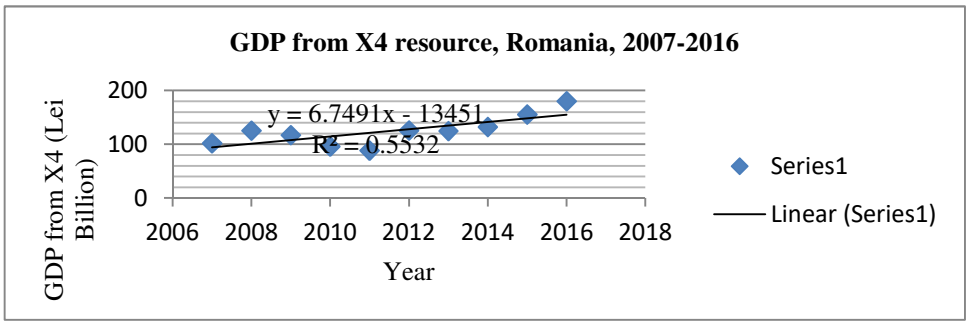

Fig.7.Trend analysis of GDP created in the field of trade, Romania, 2007-2016 (Lei Billion)

Source: Own design based on National Institute of Statistics, Tempo on line Data Base.

Financial intermediation and IT (X5) increased their contribution to GDP by 104.4 %, from Lei Billion 64.9 in 2007 to Lei Billion 132.7 in 2016. This growth was stimulated by the development of activities of financial intermediation and insurance, and real estate, but also due to the development of information and communication (Fig.8).

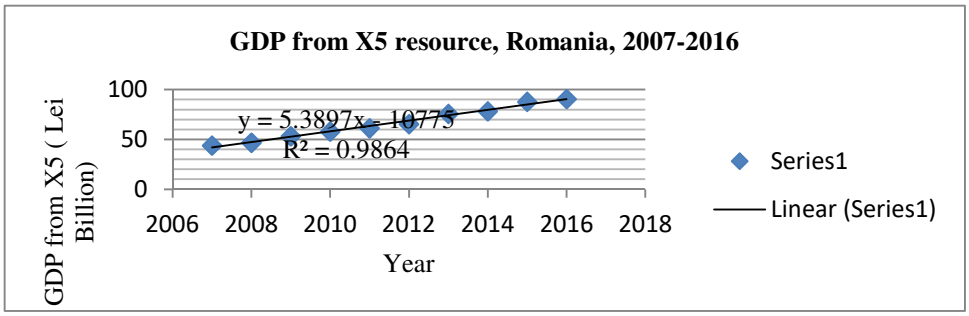

Fig.8.Trend analysis of GDP created in the field of financial intermediation, real estate and information and communication, Romania, 2007-2016 (Lei Billion)

Source: Own design based on National Institute of Statistics, Tempo on line Data Base.

Other services, including administrative and support services, research services, public administration, social insurance, education, health and social assistance, shows, culture and recreation activities, taxes on product and import duties, carried out 106.7 % increase in the analyzed period from Lei Billion 117.3 in 2007 to Lei Billion 242.5 in 2016 (Fig.9).

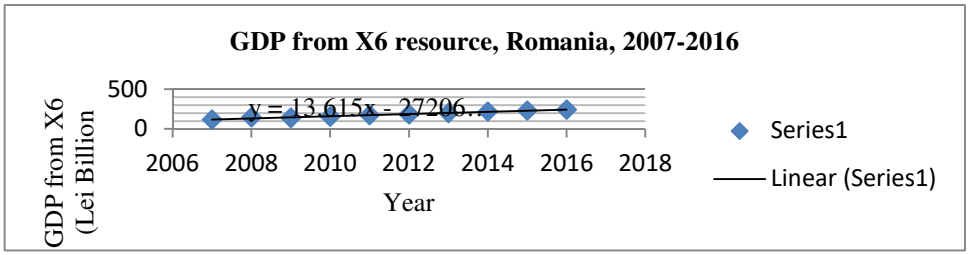

Fig.9.Trend analysis of GDP created by other services, Romania, 2007-2016 (Lei Billion)

Source: Own design based on National Institute of Statistics, Tempo on line Data Base.

Subsidies on product (X7) have brought a weak and negative contribution to GDP, but their value increased by 75 % in 2016, reaching Lei Billion 2.8 compared to Lei Billion 1.6 in the year 2007 (Fig.10).

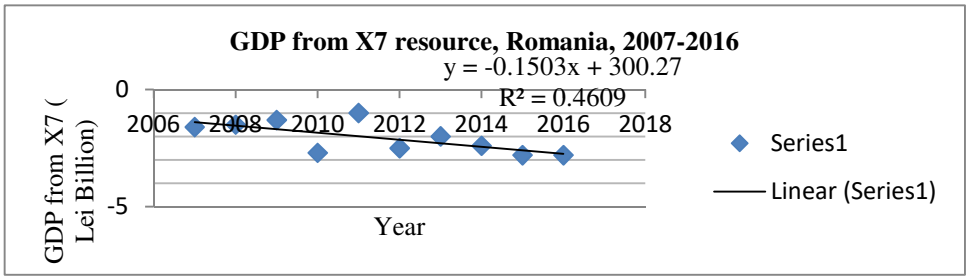

Fig.10.Trend analysis of GDP created by subsidies on product, Romania, 2007-2016 (Lei Billion)

Descriptive statistics in terms of mean, standard error, median, standard deviation, minimum and maximum values and coefficient of variation for GDP and its resources is presented in Table 2.

Table 2: Descriptive statistics for GDP and its resources, Romania, 2007-2016 (Lei Billion)

	Mean	St. Error	Median	St. Dev.	Min.	Max.	Coeff. of var. (%)
GDP	592.52	32.71	580.15	103.45	418.2	761.5	17.45
X1	29.79	1.36	29.75	4.32	20.2	36.4	14.50
X2	146.92	8.31	154.95	26.30	96.7	175.5	17.90
X3	46.02	1.81	44.90	5.73	38.9	58.5	12.45
X4	124.86	8.68	125.25	27.47	88.6	180.3	22.00
X5	66.19	5.19	63.45	16.43	44	90.7	24.82
X6	180.73	13.14	179.35	41.57	117.3	242.5	23.00
X7	-2.06	0.21	-2.2	0.67	-2.8	-1.0	32.52

Source: Own calculation based on National Institute of Statistics, Tempo on line Data Base.

The values of the variation coefficients have been $v \leq 35\%$, reflecting that the series of data are homogenous, the variations are relatively small and the mean is enough representative.

GDP structure by category of resources reflects the shares of various resources in GDP. In 2016, the share of each resource in GDP in the decreasing order was the following one: 31.8 % X6, 23 % X2, 18 % X4, 17.4 % X5, 6 % X3, 3.8 % X1, and a insignificant contribution X7 (Table 3).

Table 3: The structure of GDP by category of resources, Romania, 2007-2016 (%)

	2007	2008	2009	2010	2011	2012	2013	2014	2015	2016
GDP	100	100	100	100	100	100	100	100	100	100

In the analyzed period, it was noticed a decreasing share in GDP in case of agriculture (X1), constructions (X3) and trade (X4), a relatively constant share in case of industry (X2), and a continuous increase of the weight of financial intermediate and communication (X5) and other services (X6) to GDP.

Linear regression of GDP depending on each resource category is presented in Figures 11, 12,13,14,15,16, and 17 which are given below. The graphics illustrate that in the analyzed period, GDP was positively influenced by X1-Agriculture, X2-Industry, X4-Trade, X5-Financial intermediation and communication, and X6-Other services, but it was negatively influenced by X3- Constructions and X7-Subsidies on product.

The coefficients of determination reflected that GDP variation was determined in a small amount by the variation of X3- Constructions 5.10 %, and X1-Agriculture 21.3 %, in a moderate amount by X7-Subsidies on product 43 %, and in a high amount by the variation of X6-Other services 98.2 %, X5- Financial intermediation and communication 94.9 %, X2- Industry 81.4 %, and X4-Trade 66.2 %.

The main parameters characterizing linear regression of GDP depending on its categories of resources are presented in Table 4.

Table 4: Main aspects in linear regression analysis of GDP depending on its resources

	Regression function, Y	R^2	St. Err.	F	Sign. F.
$Y=F(X_1)$	$Y=11.03\ X_1+263.92$	0.213	97.34	2.16	0.179
$Y=F(X_2)$	$Y= 3.54\ X_2 + 71.03$	0.814	47.29	35.06	0.00035
$Y=F(X_3)$	$Y= - 4.089\ X_3 + 780.7$	0.051	106.87	0.433	0.528
$Y=F(X_4)$	$Y= 3.065\ X_4 + 209.75$	0.662	63.72	15.71	0.0041
$Y=F(X_5)$	$Y= 6.135\ X_5 + 186.42$	0.949	24.66	150.32	0
$Y=F(X_6)$	$Y= 2.46\ X_6 + 146.7$	0.982	14.40	456.0	0
$Y=F(X_7)$	$Y= - 101.22\ X + 384$	0.430	82.83	6.038	0.039

Source: Own calculation based on National Institute of Statistics, Tempo on line Data Base.

Taking into account the linear regression function between GDP and its resources, the interpretation of the results is the following one: $Y=F(X_1)$ regression function shows that for 1 unit increase of X_1-Agriculture, GDP will go up by 11.03 monetary units; $Y=F(X_2)$ regression function shows that for 1 unit increase of X_2-Industry, GDP will grow by 3.54 monetary units; $Y=F(X_3)$ regression function shows that for 1 unit increase of X_3-Constructions, GDP will decline

by - 4.089 monetary units; $Y=F(X_4)$ regression function shows that for 1 unit increase of X_4-Trade, GDP will grow up by 3.065 monetary units; $Y=F(X_5)$ regression function shows that for 1 unit increase of X_5-Financial intermediation and IT, GDP will grow up by 6.135 monetary units; $Y=F(X_6)$ regression function shows that for 1 unit increase of X_6-Other services, GDP will grow up by 0.246 monetary units; $Y=F(X_7)$ regression function shows that for 1 unit increase of X_7-Subsidies on product, GDP will decrease by - 101.22 monetary units.
Fisher's test and significance F have confirmed that the linear regression models are valid (Table 4).
The Pearson coefficients of correlation for all the combinations between GDP and its resources X1, X2, ...X7, and between all the pairs of resources are presented in Table 5.

Table 5: Pearson coefficients of correlation between GDP and its resources and between all the pairs of resources

	GDP	X1	X2	X3	X4	X5	X6	X7
GDP	1							
X1	0.480	1						
X2	0.902***	0.669**	1

Source: Own calculation based on National Institute of Statistics, Tempo on line Data Base.
***Significance for 5 %.

The values of the correlation coefficients reflected a positive correlation between GDP and all its categories of resources. However, the intensity of correlation differs among various pairs of indicators as follows: *a very strong positive correlation*, $r > 0.8$ was found between (GDP, X2), (GDP, X4), (GDP, X5), (GDP, X6), (X2, X5), (X2, X6), and (X5, X6); *a strong positive correlation*, $0.6 < r < 0.79$ was found between (GDP, X7), (X1, X2), (X4, X5), (X4, X6), (X4, X7), (X5, X7) and (X6, X7); *a moderate positive correlation*, $0.4 < r < 0.59$ was found between (GDP, X1), (X1, X6), (X2, X4), (X2, X7), and (X3, X5); *a weak positive correlation*, $0.2 < r < 0.39$ was found between (GDP, X3), (X1, X3), (X1, X5), (X2, X3), (X3, X6), and (X3, X7); *a very weak correlation*, $0 < r < 0.19$ was found between (X1, X4), (X1, X7), and (X3, X4).
Multiple regression analysis. The results regarding multiple regression analysis are presented in Table 6.

Table 6: Results of multiple regression analysis between GDP (Y) and its resources (Xi)

10.000	761.4843	0.0157

Source: Own calculation based on National Institute of Statistics, Tempo on line Data Base.

The equation of the multiple regression is:
Y= 2.2512 + 1.0771 X1+ 1.0066 X2+ 0.9169X3 + 1.0247 X4 +0.9742X5 + 0.9819X6 +0.8851X7, where:

2.2512 = b_0, the value of the dependent variable, Y=GDP; b_1= 1.0771 which shows the expected GDP growth for the increase of X_1 by 1 unit; b_2= 1.0066 which shows the expected GDP growth for the increase of X_2 by 1 unit.... b_7= 0.8851 which shows the expected GDP growth for the increase of X_2 by 1 unit.

The coefficient of multiple correlation, r = 0.9999 shows a strong positive and direct relationship between the dependent variable Y= GDP and the independent variables, GDP resources, X_i.

The coefficient of determination R^2= 0.999 shows that 99.9 % of GDP variation is explained by the variation of the variables X_i.

F calculated value was 2316119 which was compared with the tabled F value (0.05,7,2) in Fishers' distribution, which was equal to 6.094. Because, F calculated value >F tabled value, H1 hypothesis is accepted, that is the regression model is correctly determined, as the variance explained by the regression model variables is higher than the variance unexplained by the model.

Significance F: 0<0.05, therefore the risk to accept H1 is smaller than the proposed risk, and as a consequence the regression model is good. In our case, we accepted H1, and the model is correctly determined.

P-value < α, therefore the calculated risk is smaller than the assumed risk, considered acceptable, and in this case we accepted H1, that is the parameters are different than zero (Table 8).

Table 8: P-value

	P-value
Intercept	0.021223107
X1	0.00142696
X2	0.00000000
X3	0.000825009
X4	0.000119936
X5	0.000228453
X6	0.000104912
X7	0.013345924

As P-value is smaller than 0.05 for all the variables X_i, we may accept H1 hypothesis, that is all the coefficients of the regression model are different than zero. Therefore, there is a significant relationship between the dependent variable Y=GDP and the independent variables X_i, GDP' s categories of resources, $i=1,\ldots,7$.

Conclusions

In the analyzed period, Romania's GDP increased by 82 % due to the contribution of all the economic branches. In 2016, the highest contribution to GDP was given by Other services (31.8 %), Industry (23 %), Trade (18 %), and Financial intermediation and communication (17%). The lowest contribution to GDP have the following sectors: Subsidies on product, Agriculture (3.8 %) and Constructions (6%).

Between GDP and its resources it is an important relationship confirmed both by the simple linear regression equations and also by the multiple linear regression equation, as well as by the determination coefficient whose value was R^2= 0.999 reflecting that 99.9 % of GDP variation is explained by the variation of the variables X_i and by the coefficient of multiple correlation, r = 0.9999 which shows a strong positive and direct relationship between GDP and its components.
A very strong positive correlation r >0.8 was found between GDP and Industry, Trade, Financial intermediation and communication, and Other services, a strong positive correlation 0.6 < r < 0.79 was found between GDP and subsidies on product, a moderate correlation was noticed between GDP and Agriculture, and a weak correlation 0.2 < r < 0.39 was noticed between GDP and constructions.

The equation of the multiple regression showed that for an increase of GDP created in Agriculture by 1 unit, GDP will grow by 1.0771, for an increase by 1 unit of GDP created in industry, GDP will increase 1.0066, for an increased of GDP by 1 unit in the field of constructions, GDP will grow by 0.9169, for an increase of 1 unit in case of trade, GDP will grow by 1.0247, for an increase by 1 unit in the field of financial intermediation and communication, GDP will grow by 0.9742, an increase by 1 unit in case of other services will led to a growth of GDP by 0.9819 and an increase by 1 unit in case of subsidies on product, GDP will increase by 0.8851.

The F calculated value was higher than F tabled value, which allowed to accept H1 hypothesis that the regression model is correctly determined and that GDP.

As a conclusion, the economic growth of Romania should be based on the development of services, industry and trade, which are the most important economic branches which could supply more than 73 % of GDP.

An Econometric Analysis between Tourism Income and Romania's GDP

Agatha Popescu, University of Agricultural Sciences and Veterinary Medicine, Bucharest, Romania, E-mail address: agatha_popescu@yahoo.com
Daniela Plesoianu, "Ovidius" University, Constanta, Romania
Email address: plesoianudaniela@hotmail.com

Abstract

The paper analyzed the dynamics of GDP, Tourism GDP, and tourist arrivals in Romania in the period 2007-2016 in order to determine the relationship between these indicators using a linear regression econometric model and correlation coefficients. Tourism GDP reached Lei Billion 39.3 in 2016, being by 100.5 % higher than in 2007. Tourism total contribution to Romania's GDP increased from 4.6 % in 2007 to 5.2 % in 2016. In 2016, total arrivals in tourist accommodation structures was 11 million, by 57.8 % higher than in 2007. About, 22.6 % of total arrivals belonged to foreigners. The regression model, Y = 11.617 X + 304.41, reflected that 1 unit increase in Tourism GDP will determine Romania's GDP to grow by 11.617 units. The regression function Y = 4.279 X - 8.7238 showed that 1 unit increase in Total Arrivals will increase Tourism GDP by 4.279 units, and the regression function Y = 17.041 X - 4.3905 reflected that 1 unit growth in foreign tourists' arrivals will increase Tourism GDP by 17.041 units. All these regression models were valid, as confirmed by Fcalc > 6.094 F value (0.05,7,2), and Sign F <0.05, and H1 hypothesis was accepted, meaning that Tourism GDP has a positive influence on GDP and tourist arrivals have a good impact on Tourism GDP. The determination coefficients and correlations confirmed the strong links between these indicators. As a conclusion, macroeconomic policies should promote tourism to increase arrivals, receipts and tourism contribution to GDP, employment, and investment, its benefic impact on economic growth.

Keywords: dynamics, travel and tourism income, GDP, regression analysis, Romania

Introduction

From the "art of travel for your own pleasure" as defined by M. Peyromarre Debord to "an activity run in the free time with the purpose to travel or live far away from the residence place for entertainment, relaxation, getting experience and knowledge about new cultures and civilizations as defined by Jan Medecin, nowadays, tourism is a mean destined to satisfy people's need to change the environment, to recover the status of health, to cultivate the feeling of admiration and respect for the beauty of nature, and all this is allowed by the development of trade and transportation means as affirmed Guy Freuler" (Negoescu *et al*., 1998).

Across the time, tourism has been continuously developed both as inbound tourism and outbound tourism. Today, tourism is the most dynamic sub-branch of international trade and the most dynamic branch of the world economy (Popescu Agatha, 2014a).

In 2015, the number of international arrivals reached 1,186 million and tourism receipts accounted for USD Billion 1,136 (UNWTO, Tourism Highlights, 2016).

Tourism is a complex phenomenon with a deep economic and social impact. In 2015, the direct contribution of Travel & Tourism to GDP was USD Billion 2,229.8, representing 3 % of GDP. This reflects that tertiary industry including hotels, travel agents, airlines and other passenger

transportation services as well as restaurant and leisure have given a direct support to the world economy. The total contribution of Travel & Tourism to GDP accounted for USD Billion 7,170.3, representing 9.8 % of the world economy (Travel & Tourism Economic Impact 2016, World).

Tourism has a deep impact on economic growth and social development by means of investments, employment, income, exports, infrastructure, local communities and cultural values. Tourism is an important driver in the EU economy, which is placed on the top position in the world regarding tourism attractions, number of arrivals and receipts (Athanasopoulou, 2013; Popescu Agatha, 2014b).

Various studies proved a close relationship between tourism indicators such as arrivals and receipts and GDP. Most of these studies utilize econometric models to demonstrate the link between tourism and economic growth in the EU, Latin America, Asia Pacific, and Arabian countries (Ajvaz, 2015; Mello-Sampayo, 2012; Eugenio-Martin *et al*, 2004; Kreishan, 2010; Skerritt *et al*., 2005).

In the developing countries, tourism revenue has a positive contribution to economic growth and as a consequence governments should develop economic policies to promote tourism which looks to be an important source of economic growth (Ekanayake *et al*., 2012).

A study on the empirical data for the period 1980-2005 belonging to 150 countries concluded that the countries specialized on tourism have not a higher growth rate than non-tourism based countries, with one exception for the period 1980-1990, when the data were not fully available (Figini et al., 2010).

In 85 countries with a high share of tourism receipts in their exports it was noticed that they are facing large fluctuations in tourism arrivals and consequently in the volatility in the annual GDP rate (Brakke, 2005). A similar conclusion was drawn for Greece, where the volatility of tourism income is 8 times higher than GDP volatility (Eeckels, *et al*., 2012). Bayramoğlu *et al*., (2011) found that foreign tourists' expenditures have a deep impact on the economic growth of Greece.

In India, tourism has a benefic impact on economic growth, even though the contribution of tourism to GDP, employment, visitor export, internal consumption, capital investment, foreign exchange earnings and government expenditure is still far away from the country potential (Anson *et al*., 2016; Bandekar *et al*., 2014).

In Nepal tourism has a bi-directional impact on GDP, and on GNI, exports, private consumption, imports, being therefore an important factor of economic growth (Paudyal, 2012).

In Iran, the use of the Johansen-Juseliusco integration test suggested a long-run positive relationship between the studied variables and tourism receipts, and Granger and Hsiao causality tests proved that between tourism income and GDP is a close link in the both directions. (Assadzadeh *et al*., 2012).

In China, it was found a positive relationship between tourist income and GDP, with a benefic impact on people's living standard in Guizhou Province (Wang *et al*., 2015).

A study on a panel of 135 countries pointed out that in Europe it is a bi-directional causality between tourism revenue and GDP compared to an unidirectional causality in America, Latin America & Caribbean and World. In case of East Asia, South Asia and Oceania, it was noticed a reverse direction of causality from tourism revenue to GDP, while in Asia, Middle East and North

Africa, Central Asia and Sub Saharan Africa, it was not found any causal relationship between these indicators (Çağlayan *et al*., 2012).

A study upon the causal relationships between tourism spending and economic growth in 10 transition countries in the period 1988–2011 affirmed that there is a direct causality between these two indicators in Cyprus, Latvia and Slovakia, a reverse relationship in the Czech Republic and Poland and neutral causality in case of Bulgaria, Romania and Slovenia (Chou, 2013).

Using regression models, the hypothesis that tourism development has a deep impact on economic growth was verified. Capital investment, labor and tourism contribute to economic growth for the Mediterranean countries (Gökovali *et al*., 2006).

In the Balkan countries, the impact of tourism on GDP differs from a country to another due to the national practices and legal framework. Tourism has not only a direct impact on GDP but also an indirect impact on a large range of socio economic categories, causing difficulties in their correct estimation (Gramatnikovski *et al*., 2016).

In Romania, based on an Input-Output model, it was found that there are close relationships between hotels, restaurants and travel agencies and other economic sectors. The development of tourism generates an increased demand of inputs from other sectors and also an increased supply to other economic sectors, proving that tourism supports economic growth (Surugiu *et al*, 2009).

In this context, the paper aimed to analyze the evolution of GDP created in tourism industry comparatively with GDP at country level and to identify the relationship between tourist arrivals and tourism receipts and contribution of tourism to GDP in Romania in the period 2007-2016, using a regression model.

The paper objectives are:
(a)To set up a comparative analysis of the dynamics of tourism GDP and Romania's GDP;
(b)To establish the evolution of tourism contribution to GDP;
(c)To analyze the dynamics of arrivals in tourism accommodation structures (total, of which foreigners and Romanians);
(d)To study the relationships existing between Romania's GDP and tourism GDP, and between tourism GDP and arrivals by means of linear regression analysis and correlation coefficients.

The paper is structured as follows: *Introduction* including the empirical literature regarding the impact of tourism on GDP and economic growth, *Materials and methods* presenting: the study area, the data collection, the selected economic variables taken into consideration, the econometrical model used in this research, *Results and Discussions* including the main results and their interpretation, and *Conclusions*, presenting the main ideas drawn from this research.

Materials and Methods

The studied area

Romania is situated in Southeastern Europe in the Balkan Peninsula. Romania is the 12th largest country in Europe as its surface accounts for 238,391 km^2, of which 231,231 km^2 land. The length of its frontiers accounts for 3,195 km and its border countries are: Bulgaria, Hungary, Republic of Moldova, Serbia and Ukraine. It also has a coastline of 245 km length at the Black Sea.
Romania looks like an "amphitheater" divided three parts: 31 % mountains, 33 % plains and 36 % hills. The highest elevation is over 2,500 meters while the lowest area is in the Danube Delta (Geography of Romania, Wikipedia).

Romania has a high tourism potential grace to its beautiful landscapes and old and rich history. The tourism patrimony includes: (a) the components of the natural heritage characterized by a various relief with high mountains with beautiful sceneries, glacial lakes, rich plains, attractive seashore at the Black Sea, the Danube Delta-the paradise of birds and fishes, a mild temperate-continental climate, a rich net of rivers and lakes, a diversified flora consisting of old forests, meadows, natural parks, dendrological parks, scientific reservations and a large variety of species forming its fauna, (b) the components of the anthropogenic heritage determined by the cultural-historical past including archeological sites of the Dacian and Roman cities, medieval fortresses and peasant fortified cities, historical and art monuments characterizing the local culture and civilization such as monasteries, castles, palaces, folk architecture, handicrafts, ceramics, wood processing, egg painting, carpet weaving, traditional folk music, dances, and suits, cultural and artistic institutions like concert halls, opera houses, museums, memorial houses of various personalities in the field of science, literature, art, music, libraries, touristic villages, roads crossing the mountains at high altitude, bridges, old medieval cities with a specific architecture and attractions.

Also, Romania is rich in natural factors suitable for spa tourism based on its mineral and thermal waters, mud and gases with therapeutic properties, salt mines used in the treatment of various diseases, and medicinal plants.

The large variety of seashore resorts offer a diversified program for tourists such as: seashore tours, cruises, nautic sports, fishing, swimming, scuba diving, yachting, helio-marine cure.

Touristic attractive itineraries offer the tourists the chance to climb the mountains, to practice winter sports, to discover caves, to enjoy tasting good wines, to enjoy visiting the cities and villages etc.

Therefore, Romania offers a large variety of tourism forms such as: entertainment tourism, leisure tourism, cultural and historical tourism, mountain tourism, coastal tourism, spa tourism, medical tourism, religious tourism with pilgrimage to important monasteries and churches, agrotourism, hunting, fishing, and chances to participate to important scientific, cultural and sport events, folk traditions etc (Matei, *et al*., 2001; Cocean, 2004; Popescu Agatha, 2014b).

Data collection

The empirical data used in this study are provided by the National Institute of Statistics, Tempo-online Database, for the period 2007-2016.

The data refer to the following indicators: GDP at Romania's level, GDP achieved in tourism including hotels and restaurants and agencies of tourisms activities, tourist arrivals: total arrivals, of which foreigners' arrivals and Romanians' arrivals.

Methodology

-*The graph method* was used to illustrate the dynamics of each indicator in the period of reference and identify the trend line.
-*The descriptive statistics* was determined for each indicator using Excel Data Analysis. In this purpose, there were determined: Mean, Standard error, Median, Standard deviation, Minimum and Maximum values, and coefficient of variation.
-*The linear regression* was the econometric model used in this study in order to identify the impact of tourism GDP, considered the independent variable X, on Romania's GDP, considered

the dependent variable Y. Also, linear regression was used to evaluate the impact of total tourist arrivals, X, independent variable on tourism GDP, considered the dependent variable Y.
The linear regression was determined using the formula:

$$Y = a + bX + \varepsilon \quad (1)$$

where, a and b are regression parameters, whose values are obtained using the Least Square Method to solve the linear system of equations, and ε is the error.
-*The Least Square Method and the following system of normal equations* were used:

$$\sum y = a\sum x + nb \quad (2)$$
$$\sum xy = a\sum x^2 + b\sum x$$

The parameters a and b from the normal equations system were calculated using the formulas:

$$a = \frac{\sum x \sum y - n\sum xy}{(\sum x)^2 - n\sum x^2} \quad \text{and} \quad b = \frac{\sum x \sum xy - \sum y \sum x^2}{(\sum x)^2 - n\sum x^2} \quad (3)$$

-*The standard error*, Sest, of the linear regression was determined using the formula:

$$S_{est} = \sqrt{\frac{\sum (Y_i - Y_{icalc})^2}{N-2}} \quad (4)$$

-*R squared (coefficient of determination)* was utilized to evaluate in what measure the variation of the dependent value Y depends on the variation of the independent values, X.
-*ANOVA* represents the analysis of the variance of Y, the dependent variable, due to X, the independent variable, Regression of Y due to X, residual variance due to the other factors, Residuals and Total variance due to all the factors.

In the ANOVA, we may find:
-*df (degrees of freedom*), k – number of variables X, for simple regression K=1, n-k-1 for residuals (10-1-1= 8 df and n-1 for total variation (10-1=9).
-*Sum for Regression and Residual* is equal to df per Total: k + (n – k – 1) = n – 1.
-*MS-Mean squared* represents the value of variance corrected by the number of degrees of freedom, respectively MS(i)/df(i), where i is the variation source: Regression, Residual, and Total.
-SS*regression* is the sum of the squares of regression deviation, that is the variation explained by regression, having the formula:

$$SSregression = \sum_{i=1}^{n} (\hat{y}_i - \bar{y})^2 \quad (5)$$

-SS*residual* is the sum of the squares of the errors, representing the variation unexplained by regression, according to the formula:

$$SSresidual = \sum_{i=1}^{n} (y_i - \hat{y}_i)^2 \quad (6)$$

-SS*total* is the sum of the individual deviations from the mean, that is total variation, having the formula:

$$SStotal = \sum_{i=1}^{n} (y_i - \bar{y})^2 \quad (7)$$

Finally, SS*total* = SS*regression* + SS*residual,* having the formula:

$$\sum_{i=1}^{n} (y_i - \bar{y})^2 = \sum_{i=1}^{n} (\hat{y}_i - \bar{y})^2 + \sum_{i=1}^{n} (y_i - \hat{y}_i)^2 \quad (8)$$

-*Fisher's Test* was used to verify the significance of the obtained regression model. F = the calculated value of Fisher's Test = MS (*Regression*)/ MS (*Residual*). The calculated F was

compared to the tabled value of F (α, df1, df2), where α is the level of confidence (0.05), df 1= k=7, and df 2=n-k-1=2.
-*Significance F* is the risk that allows to accept the H1 hypothesis, that is the model is good. If SignF < α, this means that the risk to accept the H1 hypothesis is smaller than the proposed risk, and as a consequence the model is good.

-*P-value* represents the risk calculated to accept H1, and if P-value < α, therefore the calculated risk is smaller than the assumed risk, considered acceptable, we may accept H1, meaning that the parameters are different than 0.
-The Bravais-Pearson coefficient of correlation was used to evaluate the relationship and its intensity between variables. It was calculated based on the formula:

$$r = \frac{\sum (x - \bar{x})(y - \bar{y})}{\sqrt{\sum (x - \bar{x})^2 \sum (y - \bar{y})^2}} \quad (9)$$

The Ho (null hypothesis) is that the two indicators Y and X are not linked between them, they are independent variables.
The H1 hypothesis (the alternative hypothesis) is that the two indicators Y and X are connected among them, GDP at country level is influenced by tourism GDP, which in its turn it is influenced by total arrivals.

Results and Discussions

The comparative analysis between the dynamics of Tourism GDP and GDP.

Romania has a dynamic economy as confirmed by the evolution of GDP in the analyzed period. From a GDP accounting for Lei Billion 418.2 in the year 2007, Romania reached Lei Billion 761.5 in 2016, reflecting an increase by 82 % compared to the level of the first year of the time series (Fig.1.)

Tourism GDP registered a variable evolution from a year to another in the analyzed period, but the general trend is an increasing one. GDP coming from travel and tourism increased by 100.5 %, in the year 2016 accounting for Lei Billion 39.3 compared to Lei Billion 19.6 in the year 2007 (Fig.1.).

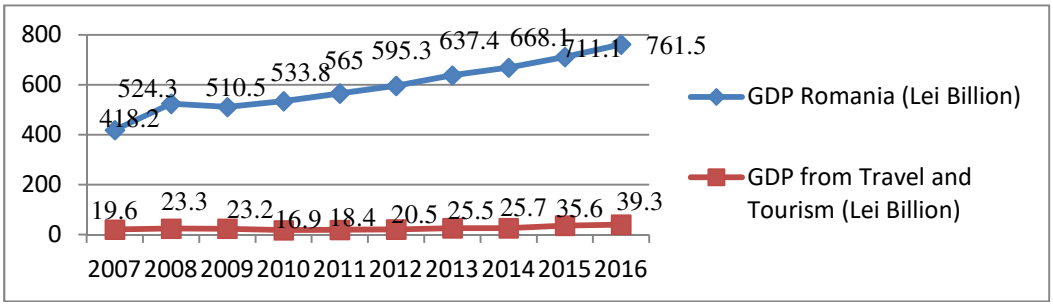

Fig.1.Dynamics of GDP and GDP from tourism, Romania, 2017-2016 (Lei Billion)
Source: Own design based on National Institute of Statistics, Tempo on line Data Base.

The evolution of tourism GDP is more dynamic compared to Romania's GDP as atested by the values of indices with variable basis shown in Fig.2. The growth rates from a year to another have been much higher in case of Tourism GDP compared with the growth rates recorded by Romania's GDP in the years 2009, 2011, 2013, 2015 and 2016. In the other years, tourism GDP growth rates

have been lower but not too much compared to Romania's GDP growth rates, except the year 2010. The most significant increase was achieved in the year 2016, (+10.4), compared to 2015.

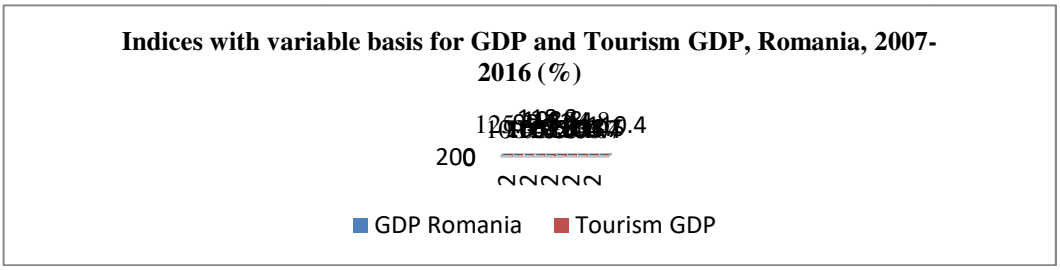

Fig.2.Indices with variable basis for GDP and Tourism GDP, Romania, 2007-2016 (%)
Source: Own calculations and design based on National Institute of Statistics,
Tempo on line Data Base.

The contribution of Tourism GDP to Romania's GDP has varied from a year to another, but the general trend was an ascending one. Thus, from 4.6 % in the year 2007, tourism contributed by 5.2 % to GDP in the year 2016. In the year 2010, it was noticed a slight decline to 3.2 %, but in the coming years the share of Tourism GDP has slowly recovered year by year increasing by 0.1 % till the year 2012 when it reached 4 %. In 2014, it was recorded a decline to 3.8 % again but in the next two years the weight of tourism GDP reached the highest level of 5.1 % and respectively 5.2 % (Fig.3).

In 2016, the direct contribution of tourism to GDP accounted for Lei Billion 10.1 (USD Billion 2.5), representing only 1.3 % of Romania's GDP.
In the same year, the total contribution of Travel & Tourism to GDP was Lei Billion 39.3 (USD Billion 9.7). The forecast for 2017 is Lei Billion 53.7 (USD Billion 13.3), representing 5.8 % of GDP in 2017.

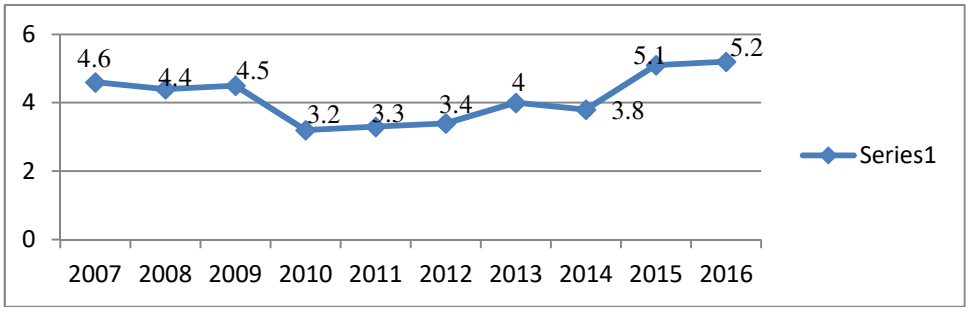

Fig.3.The share of tourism GDP in Romania's GDP, 2007-2016 (%)
Source: Own computation and design based on National Institute of Statistics,
Tempo on line Data Base.

For total absolute contribution to GDP (USD Billion 9.8), in the year 2016, travel and tourism places Romania on the 63rd position in the world. The total contribution to GDP is far away from the world average which accounts for USD Billion 57.3 and the EU average which accounts for USD Billion 60.1. (Travel &Tourism Economic Impact 2017, Romania, World Travel& Tourism Council).

Other contributions of Travel and Tourism in Romania's economy.

In 2016, tourism assured directly 197,500 *jobs* representing 2.4 % of total employment. For the year 2027, it is expected as tourism to support 219,000 jobs (2.6 % of employment). The total contribution to employment, including indirectly support was 513,500 jobs (6.2 %) and in 2017 it is expected to raise to 574,000 jobs (6.9 % of total).

In 2016, ***visitors exports*** assured Lei Billion 8.8 (USD Million 177.5), representing 2.8 % of total exports and in 2017, it is expected to reach Lei Billion 13.6 (USD Million 3,364.9), representing 2.9 % of total.

In 2016, tourism *investment* accounted for Lei Billion 14.7, representing 8.1 % of total investment and in 2017 it is expected to grow at Lei Billion 19.8 (USD Billion 4.9), meaning 8.4 % of total.
For these absolute contributions in the economy, Romania comes on the 63th position for employment, on 77th position for visitors exports and on the 35th position for investments. (Travel &Tourism Economic Impact 2017, Romania, World Travel& Tourism Council).

The dynamics of arrivals in tourist accommodation structures. The number of total arrivals increased by 57.81 % from 5.97 Million in the year 2007 to 11 Million in the year 2016.

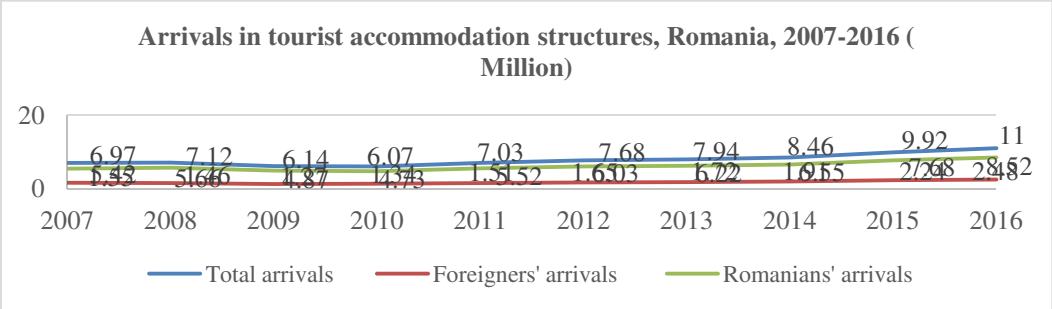

Fig.4.The evolution of arrivals in tourist accommodation structures, Romania, 2007-2016 (Million)

Source: Own design based on National Institute of Statistics, Tempo on line Data Base.

The number of foreigners' arrivals registered also a positive trend line, increasing by 60 % from 1.55 Million in the year 2007 to 2.48 Million in the year 2016. A similar remark is available in case of Romanians' arrivals which increased by 57.1 % from 5.41 Million in 2007 to 8.52 Million in 2016. Therefore, the arrivals of foreign tourists looks to be a little more dynamic than Romanians' arrivals (Fig.4).

As a result, the foreigners' share in total arrivals remained relatively constant about 22 %, but with a slight growth from 22.2 % in the year 2007 to 22.6 % in the year 2016. Romanians keep the highest share in total arrivals, 77.8 % in 2007 and 77.4 % in 2016, and also in 2008 and 2009, 79.5 % and respectively 79.3 % (Fig.4).

Descriptive statistics for the studied indicators in terms of mean, standard error, median, standard deviation, minimum and maximum values and coefficient of variation for GDP and its resources is presented in Table 1.

Table 1: Descriptive statistics for the analyzed indicators

	GDP	Tourism GDP	Arrivals-total	Foreigners' arrivals	Romanians' arrivals
Mean	592.52	24.8	7.83	1.71	6.12
St. Error	32.71	2.31	0.50	0.12	0.37
Median	580.15	23.25	7.4	1.6	5.84
St. Deviation	103.45	7.31	1.58	0.39	1.19
Min.	418.2	16.9	6.07	1.27	4.73
Max.	761.5	39.3	11	2.48	8.52
Variation coeffic. (%)	17.45	29.5	20.1	22.8	19.4

Source: Own calculation based on National Institute of Statistics, Tempo on line Data Base.

The series of data have been homogenous and the values of the coefficients of variations have been v ≤ 35%, reflecting small differences and that the calculated mean is representative.

Linear regression of Romania's GDP depending on Travel and Tourism GDP.

Taking into account the linear regression function between GDP and Tourism GDP, Y = 11.617 X + 304.41, we may conclude that 1 unit increase in Tourism GDP will determine Romania's GDP to grow by 11.617 units. The linear regression model is valid as confirmed by Fisher's test and significance F (Fig.5, Table 2).

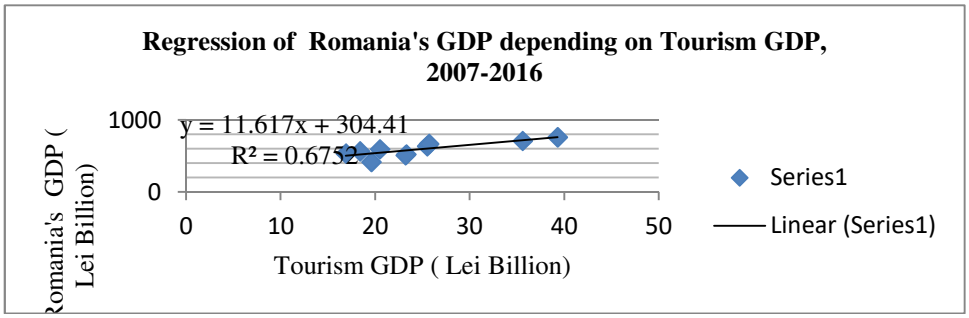

Fig.5.Regression of Romania's GDP depending on Tourism GDP, 2007-2016

Source: Own design based on National Institute of Statistics, Tempo on line Data Base.

The coefficient of determination R^2=0.675 reflected that 67.52 % of GDP variation was determined by the variation of GDP created in Tourism. The difference of variation is determined by other factors.

F calculated value was 16.6311 > 6.094 the tabled F value (0.05,7,2) in Fishers' distribution, therefore H1 hypothesis could be accepted, meaning that the regression model is valid because the variance explained by the regression model variables is higher than the unexplained variance.

As long as the Significance F = 0.003543 <0.05, the risk to accept H1 is smaller than the proposed risk, and this reflects that the regression model is good.

P-value is also < α, meaning that the calculated risk is smaller than the assumed risk. Therefore, H1 is accepted as the parameters are different than zero.

Linear regression of Tourism GDP depending on Arrivals Total. Taking into account the linear regression function between Tourism GDP and Arrivals total, Y = 4.279 X - 8.7238, we may conclude that 1 unit increase in Total Arrivals will determine a growth of Tourism GDP by 4.279 units. The linear regression model is valid as confirmed by Fisher's test and significance F (Fig.6, Table 4).

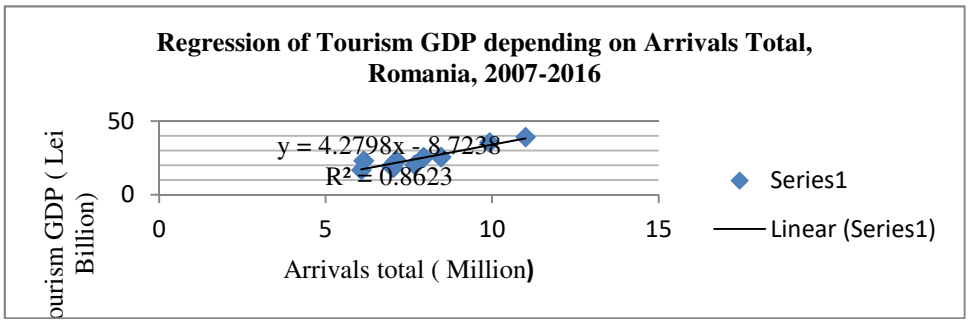

Fig.6.Regression of Tourism GDP depending on Arrivals Total, 2007-2016

Source: Own design based on National Institute of Statistics, Tempo on line Data Base.

The coefficient of determination R^2=0.862 showed that 86.2 % of Tourism GDP variation was determined by the variation of Total Arrivals.

F calculated value was 50.08755165 > 6.094 than the tabled F value (0.05,7,2) in Fishers' distribution, therefore H1 hypothesis is accepted and the regression model is valid.

Because the Significance F = 0.000104 <0.05, we may accept H1as its risk is smaller than the proposed risk. Therefore, the regression model is good.

P-value is also < α, meaning that the calculated risk is smaller than the assumed risk. Therefore, H1 is accepted as the parameters are different than zero.

Linear regression of Tourism GDP depending on International Arrivals.

The linear regression function, reflecting the relationship between Tourism GDP and International Arrivals, Y = 17.041 X - 4.3905 reflects that 1 unit increase in foreign tourists' arrivals will determine an increase Tourism GDP by 17.041 units. The linear regression model is valid as confirmed by Fisher's test and significance F (Fig.7, Table 6).

The coefficient of determination R^2=0.829 reflects that Tourism GDP variation was determined in a proportion of 82.91 % by the variation of foreign tourists' arrivals.

F calculated value was 38.8246945 > 6.094 the tabled F value (0.05,7,2) in Fishers' distribution, therefore H1 hypothesis is accepted and the regression model is valid.

Because the Significance F = 0.000250841 <0.05, we may accept H1 as its risk is smaller than the proposed risk. Therefore, the regression model is good.

P-value is also < α, meaning that the calculated risk is smaller than the assumed risk. Therefore, H1 is accepted as the parameters are different than zero.

The Bravais- Pearson coefficients of correlation.

The values of the correlation coefficients reflected a positive correlation between GDP and Tourism GDP, r = 0.821.
Also, between Tourism GDP and Arrivals total it was found a positive and very strong relationship, r = 0.928.
Finally, between GDP created in Tourism and International arrivals is also a positive and strong correlation, r = 0.910.
All the coefficients of correlations have a high significance for 5 % confirming the strong position connection between the analyzed pairs of tourism indicators as presented in Table 8.

Conclusions

The paper made a comparative analysis of the evolution of Tourism GDP and GDP in Romania proving that travel and tourism is an economic branch with a high dynamics in the period 2007-2016. Also, the study presented the evolution of tourist arrivals (total, arrivals of foreign tourists and arrivals of residents) in tourist accommodation units. The relationship between these indicators was studied using linear regression econometric model and Bravais-Pearson correlation coefficients.

The hypothesis of the paper was that tourism GDP has a positive influence on GDP, and the number of tourist arrivals has an important impact on Tourism GDP.

While Romania's GDP increased in the analyzed period by 82 %, tourism GDP increased by 100.5 %. In the year 2016 Tourism GDP accounted for Lei Billion 39.3 compared to Lei Billion 19.6 in the year 2007.

The Tourism total contribution to Romania's GDP had a general ascending trend, with some variations from a year to another. From 4.6 % share in GDP in the year 2007, tourism contributed by 5.2 % in the year 2016. The direct contribution of tourism to GDP was Lei Billion 10.1, representing only 1.3 % of Romania's GDP.

Tourism development was stimulated by the increased number of tourists visiting the country. In 2016, the number of total arrivals in tourist accommodation structures was by 57.8 % higher than in 2007, accounting for 11 Million, of which 22.6 % belonged to foreigners and 77.4 % to residents. The international arrivals increased by 60 % reaching 2.48 million in 2016, while Romanians' arrivals raised by 57.1 % accounting for 8.52 million.

The regression function of GDP, considered the dependent variable Y, and Tourism GDP, considered the independent variable X, was Y = 11.617 X + 304.41, which could be interpreted that 1 unit increase in Tourism GDP will determine Romania's GDP to grow by 11.617 units.

Fisher's test proved that F calculated value was 16.6311 > 6.094 the tabled F value (0.05,7,2) in Fishers' distribution, and significance F confirmed that the linear regression model is valid, therefore the H1 hypothesis was accepted, meaning that between Romania's GDP and GDP created in Tourism is an important positive relationship. This was also attested by the coefficient of determination which reflected that GDP variation was determined only in a proportion of 67.52 % by the variation of Tourism GDP.

The regression function reflecting the relationship between Tourism GDP and Total Arrivals was Y = 4.279 X - 8.7238, meaning that 1 unit increase in Total Arrivals will determine an increased Tourism GDP by 4.279 units. F calculated value was 50.08755165 > 6.094 the tabled F value (0.05,7,2) in Fishers' distribution, and Significance F = 0.000104 <0.05, therefore, the regression

model was good and H1 hypothesis was accepted. More than this, the coefficient of determination proved that 86.2 % of the variation in Tourism GDP was determined the variation of Total Arrivals.

The regression function characterizing the relationship between Tourism GDP and International Arrivals was Y = 17.041 X - 4.3905 reflecting that 1 unit increase in foreign tourists' arrivals will lead to increased Tourism GDP by 17.041 units. F calculated value was 38.8246945 > 6.094 the tabled F value (0.05,7,2) in Fishers' distribution, and Significance F = 0.000250841 <0.05, reasons to consider the regression model a valid one, and to accept the H1 hypothesis. About 82.91 % of the variation of Tourism GDP was caused by the variation of foreign tourists' arrivals. Very strong positive correlations were found between GDP and Tourism GDP, r = 0.821, between Tourism GDP and Total Arrivals, r = 0.928, and between Tourism GDP and International arrivals, r = 0.910.

As a conclusion, in Romania, tourism has been continuously developing in terms of tourist arrivals and GDP, having a positive impact on GDP at country level.

The economic growth of Romania should be based on macroeconomic policies which have to promote tourism expansion, besides other services components of trade, as tourism is a dynamic economic branch.

The large variety of tourist attractions and high quality services of accommodation, transportation, entertainment offered by Romania could increase the number of arrivals, overnight stays, and income coming from travel and tourism, as well as the contribution of tourism to GDP, employment, visitors exports and investment.

Abstract

The terminology of modularization is to be found in many branches of industry as an integral part. This fact will continue to rise in the future. This can be inferred from some market trends which reinforce the causes of modularization. For this reason, the motives for the use of modularization also play an increasingly important role in the industry.

Thus, the objective of this research is to review the reasons for the most significant motif for modularization which are complexity and diversity of variants that support the use of modularization strategy. Besides the literature research of external and internal reasons for complexity and diversity of variants, 100 questionnaires on the same subject have been taken into account These questionnaires have been completed by 60 professional buyers, 20 experts from the strategy department and 20 persons working in the field of modularization. Furthermore, 50 experts in modularization and professional buyers have been interviewed separately.

As a result of the research, cost pressure, complexity and organizational effort were stated as the three most important reasons for the complexity and diversity of variants. In addition, a comparison of the primary data and the literature showed that the results were consistent. The authors therefore emphasize the findings from literature research. Moreover, the two surveys highlight that the topic of modularization has gained more and more importance due to the causes of complexity and diversity of variants throughout the past five years. This means that applied science provides additional input and results for the business analyses in the future.

I. Introduction

The terminology of modularization is to be found in many branches of industry as an integral part. This fact will continue to increase in the future (Wildemann 2014b). The reason for this is the fact that a target conflict between individual products, which is demanded, for example, by the personal wishes of the customers and the required standardization. This standardization is to be strived for by the company (Wildemann, 2012, 2014a; Wildemann, 2017b). The latter point mentioned leads to cost savings by purchasing many identical parts, which can be purchased more favorably from the respective supplier due to larger order quantities and thus to offer favorable sales prices for customers. The described conflict has played an increasingly important role for several years (Buchmüller et al., 2017). This forecast is based on market trends, on the one hand. Here, the increase of the customers' individual requirements (Stang, Hesse and Warnecke, 2002), the decrease of innovation and shortening of the product lifecycles (Waltl and Wildemann, 2014; Wildemann, 2014a; 2014b, Krampf, 2012), the continuous increase in vehicle models and vehicle derivatives within the past ten years (Daimler AG, 2013; Volkswagen AG, 2013; CAR Uni Duisburg-Essen, 2012; Waltl and Wildemann, 2014) and the transformation from a seller's market to a buyer's market (Waltl and Wildemann, 2014; Wildemann, 2014a; 2014b; Baum and Hüttenrauch, 2008) need to be taken into account Also, the stagnant or even declining demand in the triad markets (industrial East Asia, NAFTA and EU) are to be mentioned in this context. Instead, growth continues to be reported in the ASEAN and BRIC markets (Waltl and Wildemann, 2014; Hab and Wagner, 2012; Baum and Hüttenrauch, 2008). Another two market trends are the increasing environmental consciousness in society (Baum and Hüttenrauch, 2008), which have been prevalent since the mid-1990s, as well as the decreasing brand loyalty in the automotive sector (Wolters, 2012). Finally, reference should be made to the exponential increase in complexity in the context of the expanded range of products, the increasing importance of corporate services (Wildemann, 2014a; 2014b) and the need for more cooperation caused by great, monetary or non-monetary synergy effects that are not being used (Wildemann, 2014a; Hab and Wagner, 2012).

On the other hand, a global extension of the production network (Wildemann, 2014a; 2014b) and the existence of high cost pressure through competitors (Baum and Hüttenrauch, 2008) need to be taken into consideration, too.

Based on these presented trends and developments, the following research investigate the exponential increase in the complexity of the increasing number of product offerings and its causes because it has been a continuous increase of vehicle models and derivatives in the automotive sector within the last ten years (Car Uni Duisburg-Essen, 2012). In addition, an almost explosive increase of variant diversity has been observed (Wildemann, 2014b). Using the example of the model series or variants, respectively, of the German passenger car market, this development is depicted in the two charts below.

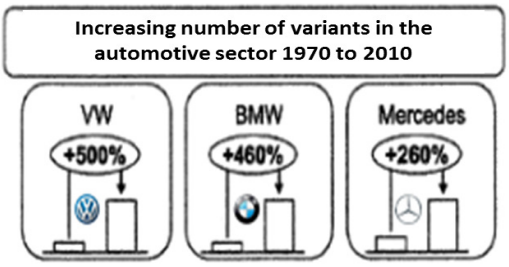

Fig. 1. Variant development of 1970 compared to 2010
Source: Adapted to Wildemann, 2014b, p. 14

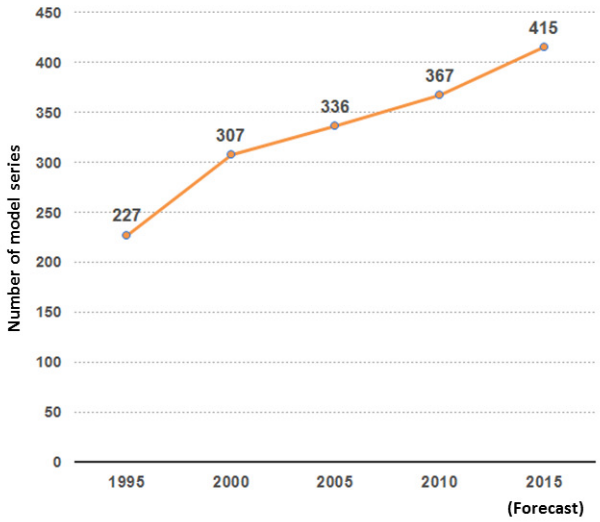

Fig. 2. Number of model series in the German passenger car market
Source: Car Uni Duisburg-Essen, 2012

Apart from the automotive sector, a continuous increase of the number of variants can also be observed in other industries. Here, examples are plant engineering (Schuh and Schwenk, 2017), the manufacturers of mobile phones which differ from each other only marginally (Renner, 2007), as well manufacturers of sneakers or contacts lenses (Baum and Hüttenrauch, 2008).

In addition Schuh and Schwenk (2017), for many corporates, the degree of complexity has come to a point where coordination and control costs get out of hand (Schuh and Schwenk, 2017). This latter fact strongly supports the following investigation of the causes

II. Literature Research

Definition of Modularization

Modularization is a method for structuring products based on defined aspects. Modularization ensures the independence of the individual elements by diminishing their interdependence and decreases the amount of interfaces (Göpfert, 2009; Canales Salacerry, 2006; Buchmüller et al., 2017). The method can be compared to the construction of a Lego vehicle. The method indicates that the construction process requires a certain amount of components (Buchmüller et al., 2017).

Definition of complexity and variant diversity

Since the terms 'complexity' and 'complexity control' often are used in the same context as 'variants', 'variant diversity' and 'variant control' (Wildemann, 2017a), the definitions of 'variant diversity' and 'complexity' will be given below.

According to Firchau et al. (2002), variant diversity describes the number and diversity of different variants of a component, a product, and an assembly group (Firchau et al., 2002; Renner, 2007). Heina (1999), on the contrary, focuses on diversity on the level of the end product and establishes a classification of the term. The external diversity is equivalent to the variety at product level, whereas internal diversity is given within a corporate's production sector at the level of components and assembly groups. Due to the prevalent interdependency between the different levels, the expansion of product diversity leads to more variance at subordinate levels. Conversely, this means that modifications and innovations entail an increase of product variety at the component level (Heina, 1999). In addition, the following definition should be mentioned as well. Variant diversity corresponds the number of variants of a specific type but it ignores largely their differences because it is difficult to clearly determine them anyways (Renner, 2007).

In contrast to 'variant diversity', there is no generally accepted definition of the term 'complexity'. However, the term is used in many different ways and highly specific definitions can be found (Renner. 2007). The term 'complexity' is derived from Latin describes the total of all measures and features or multidimensional nature (Duden, 2010).

Lindemann defines complexity as non-transparency, i.e. condition of a system that is hard to understand (Lindemann, 2005). Precisely, this non-transparency is caused by the features relations, element and dynamic, and is increased by a lack of clarity concerning both the current specification and the distinction of single elements and relations as well as through a lack of knowledge (Lindemann, 2005).
In addition, the production-technical point of view of Adam (2004) should be taken into consideration as well. They understand complexity as the multidimensional nature of all features of a production concept (Adam, 2004).

The two terms of complexity and diversity are very closely linked. Complexity reflects a feature of the system, and diversity is the corresponding measuring unit (Schuh and Schwenk, 2017). Due to this connection, the two terms cannot be considered separately, and therefore will be dealt with together in the following (Renner, 2007).

External reasons of complexity and variant diversity

A company that aims at generating revenues by selling and offering products, finds itself in an area of conflict that consists of different factors. Each of these factors has an impact on variance at product level in the corporate (Renner, 2007). These factors can be divided into four areas.

- Market and customer complexity (Wildemann, 2014a; 2014b; Baum and Hüttenrauch, 2008; Krampf, 2012)
- Globalization and internationalization (Renner, 2007; Wildemann, 2014a; 2014b; Baum and Hüttenrauch, 2008; Wiesener et al., 2016; Ehret, 2008)
- Standards, regulations, ergonomic requirements, laws and guidelines (Renner, 2007; Wildemann, 2014a; 2014b)
- Technological progress (Renner, 2007; Wildemann, 2014b)

A continuous increase of market complexity poses a new challenge for each and every corporate. On the part of the market, there is only a stagnant demand for standard products, whereas the demand for individual products continues to increase (Stang, Hesse and Warnecke, 2002). This means that on globally saturated markets (Wildemann, 2005b) only those corporates will remain on the market in the middle turn that continuously meet the needs of the customer – which tend to become more and more complex (Wildemann, 2014a; 2014b; Krampf, 2012; Renner, 2007). However, if this customer focus is not properly understood, this can lead to an explosive increase of the number of variants and therefore cause numerous economic problems. Another factor that needs to be mentioned in connection with the market is the lack of possibilities of streamlining product ranges (e.g. through discontinuing of earlier models). Because this could have a negative impact on the image or spare parts stock required by the customer (Renner, 2007).

The ongoing globalization and internationalization of the markets leads to country-specific product requirements and, thus, causes variances. These country specifications are changing values in terms of design, equipment, quality, handling or costs and political and social structures of the individual countries as well. Furthermore, globalization and deregulation leads to rising competitive intensity and dynamic which, in turn, leads to shorter development cycles in combination with a sharp increase of product quantity in order to remain competitive (Renner, 2007, Wildemann, 2014a).

Apart from market complexity and globalization or internationalization, the different ergonomic requirements on a product also play an important role for the number of variants. There is a number of differences in connection with different climate conditions (e.g. lubrication and cooling), and also in terms of differing regulations, standards, laws and guidelines, e.g. voltage and hertz of the power supply system (Renner, 2007), country-specific certification (Görbert, 2014), labeling of measuring units, languages, and left-hand or right-hand traffic (Renner, 2007)). Moreover, there often are different “de facto standards” (Renner, 2007, p. 25) and habits which require modified variants. The cup holder is one example. The habits differ very strongly. Whereas Europeans usually do not require a cup holder, most Americans want to have one in their car. Or, the majority of vehicle owners require a cup holder that is round and provide a filling capacity of up to 1,5 liters, whereas square formats with a filling capacity of 0,2 liters are required in Japan (Renner, 2007).

The last external reason is the fast, technological progress (Wildemann. 2014a). It is necessary to remain competitive. As a consequence, the variant diversity keeps increasing which can be seen very clearly in the sector of computers and mobile phones (Renner, 2007).

Apart from these aforementioned external reasons for the prevalent variant diversity, there are internal reasons, too, which will be looked upon in the following.

Internal reasons

Reasons for unnecessary variant diversity emerging from the internal area are a result of existing deficits in organizational and technical framework conditions within the company (Renner, 2007; Wildemann, 2014b).

In detail, the increase of diversity can be explained by the following factors (Baum and Hüttenrauch, 2008; Wildemann, 2005a; Wildemann, 2005b; Wildemann, 2014a; Wildemann, 2014b).

- Non-use of existing experience
- Existing diversity of variants
- Existing process variety
- Non-transparency of the existing organization
- Lack of awareness of the employees
- Very slow generation of variants in the work progress
- Lack of access to relevant information
- Lack of interconnectivity and integration of experts
- Communication deficits in the areas of development and construction
- Description of product structure is not sufficient
- No superordinate strategy for continuous improvement processes
- Standardization of components is conducted too late
- The change management in many parts of the corporate is disorganized
- IT-technical and construction-methodical tools to ensure effective and fast development or component parts are missing
- The prevalent dominance of sales over the areas of production and construction

This means that development and construction have a crucial share in the number of variants (Renner, 2007).

III Research design and methodology

This research is based on one hand on literature research of the causes for the most important reason for modularization – the complexity and variety of variants. These identified reasons are subsequently evaluated by a quantitative survey and also checked by qualitative interviews. Both results include

reasons for the complexity and eventually for the implementation of the modularization method. The results of both research works will be compared in the end.

For quantitative research, a questionnaire was sent out and completed by 100 persons. 60 participants work in the procurement department, 20 in the strategic department, and another 20 persons are experts in the field of modularization. The questionnaire consists of five questions. The questions include some demographic and general questions concerning modularization strategy and also a specific question about the reasons for modularization or the complexity and diversity of variants (Table 1).

Table 1: Questionnaire for the quantitative research

Question	
1	How old are you?
2	What is your profession?
3	How long are you working on the field of the modularization strategy?
4	How did the importance of the modularization strategy for companies during the last 5 years? (Characteristics: decreasing; equally; increasing)
5	Please evaluate the following reasons if they are crucial for the implementation of the module strategy (Characteristics: certainly not (1); probably not (2); maybe (3); probably yes (4); certainly yes (5))
5.1	Complexity (in market or customers segment)
5.2	Globalization and Industrialization
5.3	Laws, standardize and regulations
5.4	Organizational and technical conditions
5.5	Technological progress
5.6	Cost pressures

Source: Own presentation

In parallel with the quantitative research described above, short interviews were conducted. For this qualitative research, 50 persons were interviewed. 25 of the participants are experts in the field of modularization and 25 are professional buyers who are well versed in the topic of modularization strategies. Like the questionnaire introduced above, these interviews include five questions. For the main part, the questions are basically the same one which were asked in the quantitative research as well. However, the last question is different, as shown in the table below (Table 2)

Table 2: Questionnaire for the qualitative research

Question	
1	How old are you?
2	What is your profession?
3	How long are you working on the field of the modularization strategy?
4	How did the importance of the modularization strategy for companies during the last 5 years? (Characteristics: decreasing; equally; increasing)
5	Which reasons are crucial for the implementation of the module strategy

Source: Own presentation

Over the course of the period of May 2017 to July 2017 the authors have examined a global company with multiple production facilities and subsidiaries. The activities of the company are aiming for profitable growth and a sustainable increase in value in order to ensure the long-term success. The customers, suppliers, and society recognize the company as a competent and reliable partner regarding the entire, common value chain.

IV. Results

The research revealed that the persons consulted in both research strands were of an average age of 32,9 years (questionnaire-based research) and 31,4 years (interview-based research). Furthermore, it was discovered that all participants have been working for more than 2 years in the field of modularization strategies; which is an average of 4,7 or 3,9 years.
Moreover, the two research strands provide a point of reference in terms of the development of the importance of the modularization strategy because the majority of the persons interviewed found this topic to be increasingly important (see chart 3).

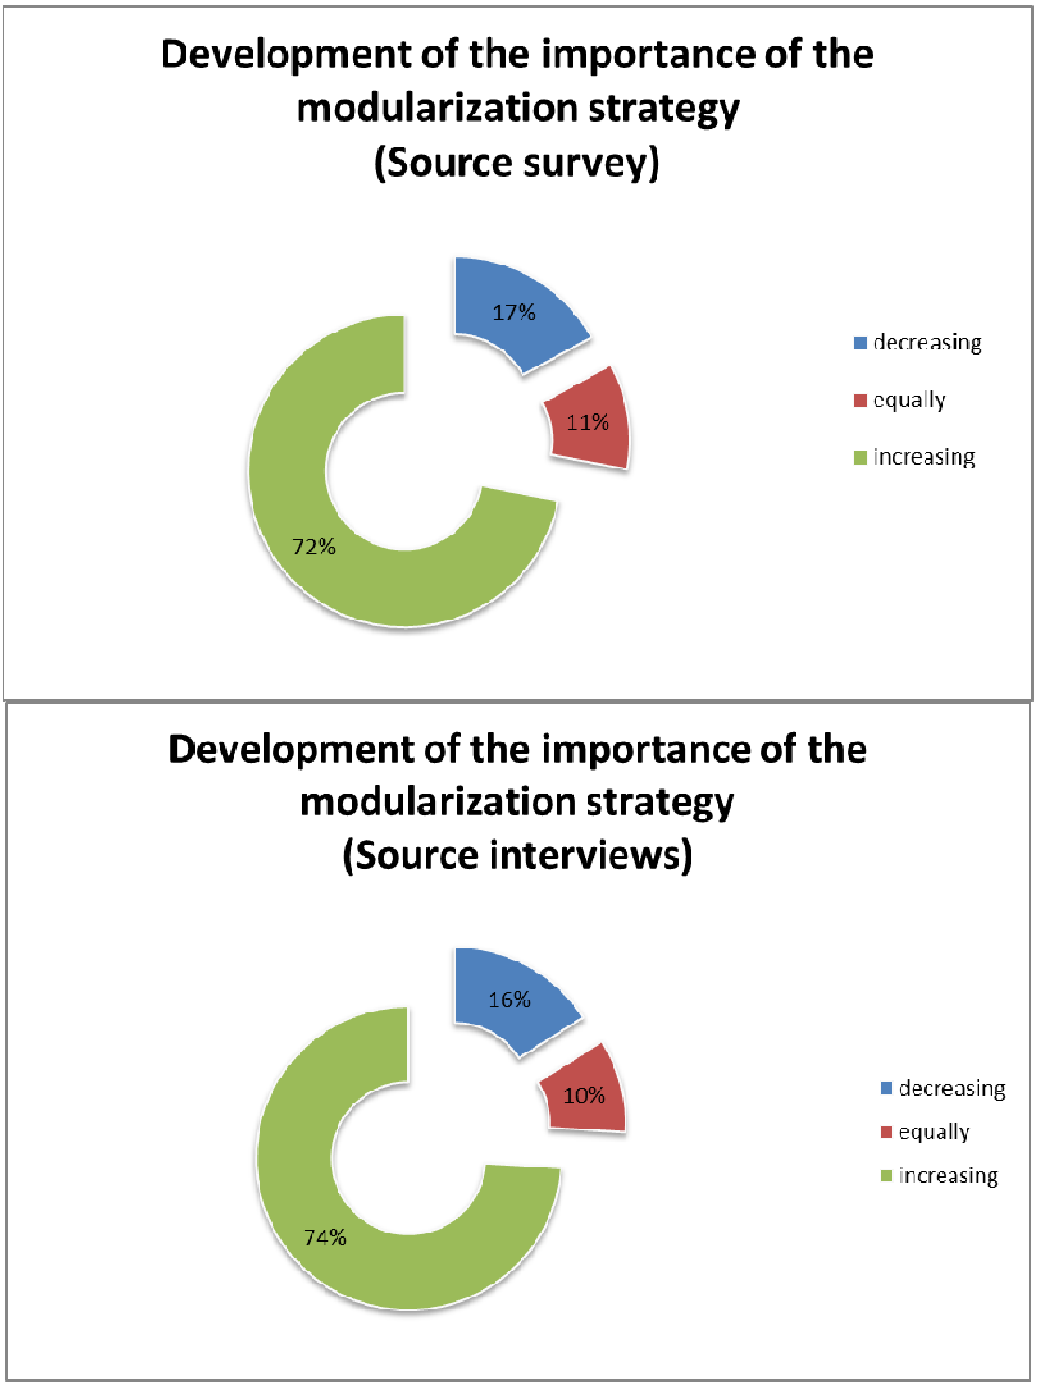

Fig. 3. Development of the importance of the modularization strategy

Source: Own presentation

In order to obtain a significant result for the last question, the weighting of the reasons derived from literature are reported first. Here, it is obvious that complexity, cost pressure and organizational and technical requirements are the highest-rated reasons (rating >4 points). This is followed by the aspects of

technological progress and laws, standards and regulations with a rating of >3,2 points. Then comes globalization and industrialization with a rating of >2,8 points (chart 4)

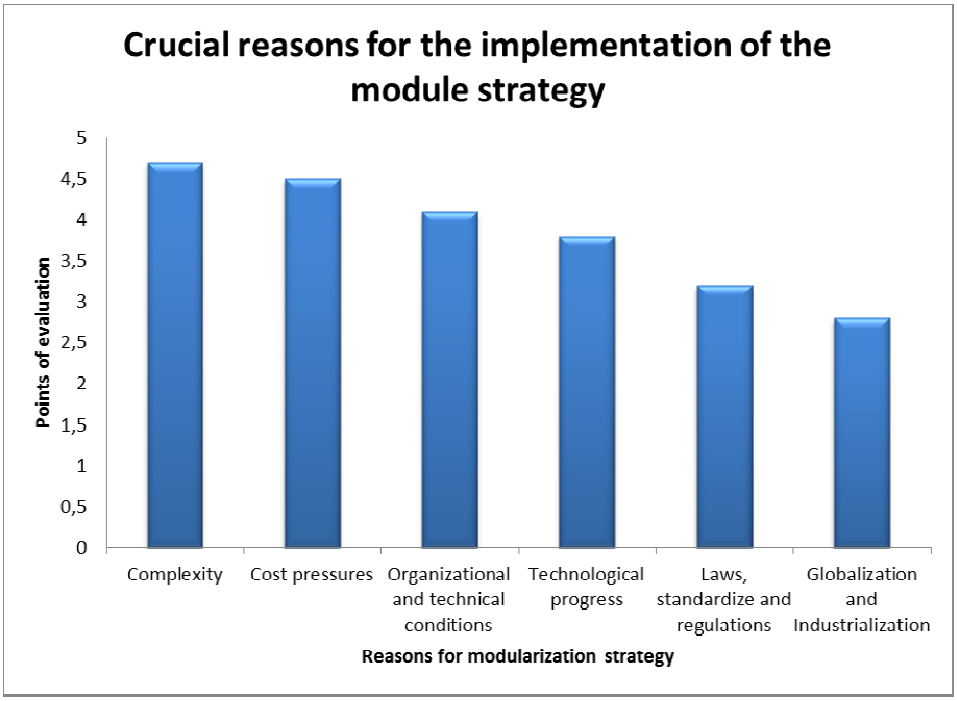

Fig. 4 Crucial reasons for the implementation of the modularization strategy

Source: Own presentation

After the reasons given in the questionnaire had been analyzed, the different reasons given in the interviews could be taken into consideration. At this point, the following six crucial reasons have been stated (sorted by frequency of mention):

- Cost pressure (36)
- Reduction of complexity (30)
- Organizational effort (27)
- Quality (25)
- Technical aspects (24)
- Competitive pressure (21)

Integrating both results, it is obvious that in both surveys the factors cost pressure, complexity and organizational effort can be identified as the most important reasons. At the same time, the factors technical aspects as well as standards, regulations and quality are present in both surveys.

V Discussion

When the literary findings are compared to the results of qualitative and quantitative research, it can be seen that the primary research results confirm and complement the literary findings. The complementt corresponds with the factors of quality and competitive pressure. All these results are shown more clearly in the following table under the column "Results of the comparison".

Table 3: Comparison of theoretical aspects and results of primary research

Theoretical Aspects	Quantitative Research Results (Average value)	Qualitative Research Results (mentions)	Results of the comparison
Complexity (in market or customers segment)	Complexity (4,7 → certainly yes)	Complexity reduction(30/50)	✓
Globalization and Industrialization	Globalization and Industrialization (2,8 → maybe)	X	(✓) Consistency not qualitative
Laws, standardize and regulations	Laws, standardize and regulations (3,2 → maybe)	X	(✓) Consistency not qualitative
Organizational and technical conditions	Organizational and technical conditions (4,1 → probably yes)	Organizational conditions (27/50)	✓
Technological progress	Technological progress (3,8 → probably yes)	Technical Aspects (24/50)	✓
Cost pressures	Cost pressures (4,5 → certainly yes)	Cost pressures (36/50)	✓
X	X	Quality (25/50)	Additional aspects from primary research
X	X	Competitive pressure (21/50)	Additional aspects from primary research

Source: Own presentation

VI. Conclusions

Based on the two research strands conducted, it can be reported that the importance of individual reasons for the implementation of a modularization strategy can be reviewed and its value determined. The results of this study confirm and complement the reasons and findings already published in literature.

Hence, this paper emphasizes the importance of specific aspects which have an impact on corporation and therefore can lead to the implementation of modularization. Moreover, this study can support further research in this field.

Future Development of Cooperation between Russia and Iraq in the Sphere of Investment and Construction

Natalia Vasilievna Gorodnova, Ural Federal University, Ekaterinburg, Russia,
n.v.gorodnova@urfu.ru
Anastasiya Alekseevna Peshkova, Ural Federal University, Ekaterinburg, Russia,
np91@list.ru

Abstract

This article deals with prospects of cooperation between Russia and Iraq in different spheres of economics. The focus is made on the investment and construction sphere. The article shows main criteria of building socially-oriented economic in Iraq. Also, it presents an analysis of current social and economic conditions and assesses significance of implementation of social projects on integrated territory development in Baghdad. The conclusion is made that attracting foreign investments, including those from Russia, may become an important factor facilitating successful implementation of major infrastructural projects.

Keywords: cooperation, Russia and Iraq, investment and construction projects.

Introduction

Trade and economic relationships between Russia and Iraq have a long history and started from 1958 (The Ministry of Economic Development of the Russian Federation, 2003). Since then, the countries signed several bilateral treaties, including the Agreement of June 13, 1986, under which the most-favored-nation treatment was granted. Up to 1990, Iraq was the biggest trade partner of Russian in the Middle East. In 1989, the goods turnover exceeded 2 bln US dollars. In the early 1990s, cooperation between the countries experienced difficulties due to the international sanctions regime imposed on Iraq by the United Nations Organization because it occupied Kuwait. It gave rise to a problem of financing major joint projects, mainly, in the oil and gas industry as well as the power industry. For example, implementation of the contract signed in March 1997 for development of the West Qurna 2, the biggest Iraqi oil field, in cooperation with Lukoil was actually stopped (The Ministry of Economic Development of the Russian Federation, 2003). According to current assessment of Iraq, this oil field is the second in the world in terms of oil stock, and its oil reserve is measured at 14 bln barrels (Kable Intelligence Limited, 2014). Notwithstanding problems in relationships, there were negotiations on the issues of trade and economic cooperation between two countries held in August 1993 in Baghdad, the capital of Iraq; during those negotiations, the Agreement on Establishment of Russian and Iraqi Committee for Trade, Economic and Scientific and Technical Cooperation was signed. In recent years, a political dialogue between Russia and Iraq becomes especially active.

Future development of relationships between Russia and Iraq is mainly determined by their cooperation in the oil and gas industry. In 2009, after a long break, development of the West Qurna 2 oil field was resumed by a consortium within Lukoil, a Russian corporation, together with Statoil, a Norwegian company (Kable Intelligence Limited, 2014). In January 2013, an additional agreement to the contract was signed; it provides for extension of the contract duration for up to 25 years. It is expected what the estimated project capacity of 1.2 mln barrels will be achieved by 2022.

Besides Lukoil, Rosneft and Gazpromneft, both Russian companies, also operate in Iraq. Gazpromneft, in its turn, develops the Badra oil field in the Eastern Iraq as well as holds exploration works within a

consortium together with a Korean, Malaysian, and Turkish companies in the Kurdistan Region. The share of the project participation of Gazpromneft comprises 30% (Gazprom Neft Badra, 2017). Commercial oil export started on September 1, 2014.

From January to November 2015, after a long decrease, the goods turnover between the two countries got back to the point of 2 bln US dollars (The Federal Customs Service of Russia, 2015). Presently, as one of the main tasks of relationships development is the trade diversification. The major share in the goods turnover comprises Russian export; it its structure, the main share of supplies is presented by machines, equipment, and vehicles; metals and metal products; wood, cellulose and paper products; food products and agricultural raw materials (The Federal Customs Service of Russia, 2017). In Iraq export to Russia, the main share of supplies is presented by chemical products, machines, equipment, vehicles, and mineral products (The Federal Customs Service of Russia, 2017).

Representatives of the Ministry of Economic Development of the Russian Federation believe that trade and economic relations between Russia and Iraq have a significant potential for growth not only in the oil and gas industry but also in the agricultural industry, education, social and cultural sphere. In particular the matter of participation of Russian companies as general contractors or sub-contractors in major infrastructural projects implementation was considered; it will facilitate development of Iraq as the whole country (Tsybulskiy A., 2016).

Future development of cooperation between Russia and Iraq in the sphere of construction

Presently, there is an acute lack of the basic infrastructure units in Iraq, including that in the sphere of water supply, water waste disposal and electric power generation. Mainly, implementation of the infrastructural projects is restrained by a low level of economic and political security. An institutional transformation of Iraq domestic economy is needed, including development of mechanisms to engage the private sector to implementation of prioritized national projects and programs. This article's authors developed the main criteria for building socially-oriented economics in Iraq (table 1).

Table 1: main milestones to build socially-oriented economics in Iraq

No.	Main quantitative standards/indicators	Indicators' values	
		As at 2017	Forecast (2030)
1.	Monthly income of a household (USD)	1000-2500	1500-5500
2.	Social standard of total floor space per a person (m^2)	19	35
3.	Age of retirement in years (males/females)	65 / 65	65 / 65
4.	Children per a woman (number)	3.5	≥ 4.5
5.	Housing growth per 1000 persons per year (m^2 / year)	700	1200
6.	Price of acceptable housing for 1 m^2 (USD)	550	600
7.	Average mortgage rate, %	11.3	7
8.	Index of the state social responsibility (ratio of constructed (financed) by the state ready housing that was purchased to the socially-required volume)	0.021	0.097
9.	Index of social responsibility of the private sector (ratio of housing financed by the private sector to the socially-required volume)	0.151	0.49

Recently, power infrastructure units in Iraq were significantly damaged. In many localities, it is still difficult to get to electric power supplies. Recovery of large electric power plants requires significant investment. The Iraq Development Program adopted in 2011 for 10 years provides for construction of several power plants with capacity of about 300 MW. For this purpose, the financing facility from 3 to 4 bln US dollars per year was provided. It should be noted that the Iraqi Government uses foreign investments as on of the financing sources. Thus, the cumulative amount of Russian investment on a number of projects in the sphere of power supplies, transportation, and machinery engineering of the Iraqi Republic is about 1.5 bln US dollars (Baliyev A., 2013).

The exchange rate of Iraqi dinar (ID) to US dollar in recent years was rather stable due to high oil proceeds and foreign investments. However, from 2013 we may observe non-stable conditions of US dollars selling. The Central Bank of Iraq (CBI) played an important role in keeping control over the situation by trading in the market and setting US dollar exchange rate on daily trading held by CBI. Currently, the exchange rate is about ID 1 to USD 1.2.

In Baghdad, one of the main trends is the integrated development of urban infrastructure carried out within the framework of the Global Strategy of Baghdad Development Until 2030 that provides for completion of the following tasks: development of a transport network subject to future growth of the city; maintenance of historical districts, agricultural lands; formation of a network of green, cultural and touristic units. As presented by the analysis of current social and economic city environment, the main share of population still faces the following problems:

1. Acute security issue. About 61% of households faced this issue.

2. Underdevelopment of the infrastructure. Many households experience insufficiency or lack of the main infrastructure (there are no water waste disposal facilities in 47% of residential buildings; also, there is no electricity in 33% of residential buildings).

3. Low income of households. Presently, Baghdad is characterized by a lack of high professional/managerial employment of inhabitants because the state-controlled economic system is at the stage of transition to the market basics. An average salary rate in Baghdad does not exceed that in other countries of the Persian Gulf. Income of 54% of households is lower that the minimum subsistence income that is 673 US dollars per month. To mitigate the situation, the state provides 99% of households with state subsidies for basic food products and materials.

4. High level of unemployment in Baghdad that is about 23% for males and 35% for females.

5. High level of prices on food products and good of first priority (79% of the total family income); only 21% are spent on other things (education, healthcare, and recreation).

6. A car is still a luxury for most of Baghdad households. Only 16% of households have cars that is much less that an average rate in the country.

According to the Central Statistical Organization in Iraq, Baghdad population at the moment is about 6.5 mln. As forecasted, by 2030, its population will exceed 11.5 mln that will require construction of large housing buildings. Presently, the integrated development of Baghdad territory has been started. The article's authors together with Iraqi scientists developed two investment and construction projects one of which is focused on construction of housing clusters in Iraqi capital center, and another one is the project of integrated development of the territory in the Western Baghdad.

Presently, implementation of housing clusters construction involves construction of housing and commercial property as well as construction of necessary infrastructure, including, educational, healthcare, and recreational units. Total area of development is 1 mln sq. m, it includes 28 city clusters. According to preliminary evaluation, implementation of this project will provide from 3 to 4 mln people with housing with the city identity and unique structure reserved.

The total capital investment is calculated in a simplified form according to the engineering and economic characteristics of the project, it amounted to 3 bln US dollars, including costs of transport corridors, parking lots and garages comprising 80 mln US dollars. Basing on an expert's opinion, it is forecasted that by the twentieth year of the project implementation, the operating expenses will amount to 0.03 bln US dollars, including expenses on technical maintenance of the housing complex, and other expenses (incidental expenses, advertising costs, and unexpected costs).

During the project implementation, to finance the project, a loan of 3 bln US dollars will be required. Bank interest rate on a long-term loan (in US dollar equivalents) in average amounts to 11.3%. The loan term is 20 years. It is supposed that profit taxation at 27.8% will be applied.

It is expected that the full capacity of the whole project will comprise 19,964 apartments with an average floor space of 140-200 m^2 and the price of 600 US dollars for 1 m^2, 24,668 parking lots and garages. According to the expert's opinion, it is forecasted that in the current conditions, by the twentieth year of the project implementation, profit will comprise 80% of the full load of residential and commercial spaces, parking lots and garages, private child day-care centers, water pools, and other infrastructural units subject to an optimal plan of development.

For the optimal plan of operation development, a discount rate of 13% was taken. As a basis of the discount rate calculation, the forecasted inflation rate of 4% was used. Besides, the risk of decline in demand (1%), risk of an error in calculations (0.5%), risk of error in forecasted purchase prices of goods, work and services (0.5%), unexpected risks (1%), risk of aggravation of the global financial and economic crisis, and change in the economic environment (6%) were taken into account.

Basing on the calculations made, the financial project profile subject to the optimal plan was developed (fig. 1).

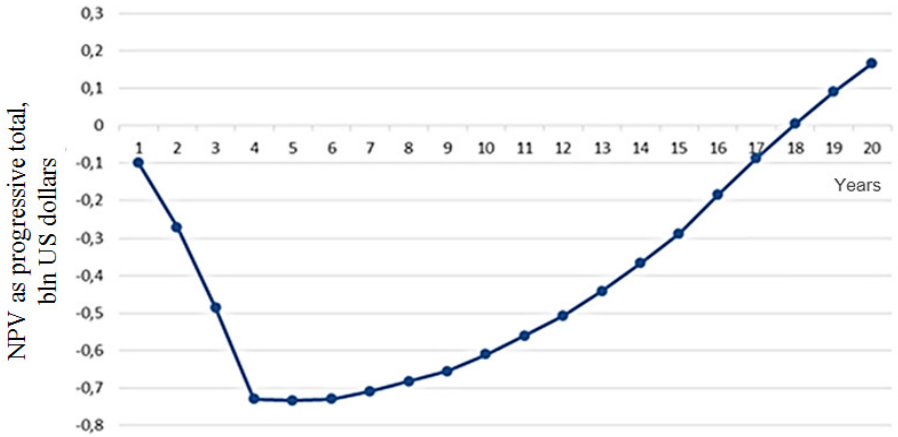

Fig.1. Financial profile of housing clusters construction project subject to optimal plan of development

Indicators of efficiency of the investment and construction project are shown in table 2.

Table 2: indicators of efficiency of a project of housing clusters construction subject to the optimal plan of development

No.	Indicator description	Value
1.	Net present value (billion US dollars)	0.167
1.1.	compliance with assessment criterion	+
2.	Internal standard of profitability, %	2.66
2.1.	compliance with the assessment criterion	-
3.	Profitability ratio	1.06
3.1.	compliance with the assessment criterion	+
4.	Repayment period (years)	17.9
4.1.	compliance with the assessment criterion	+

Mainly, the values presented in table 2 comply with the criteria figures that is a favorable factor and draws us to the conclusion that the investment and construction project is efficient.

As compared to the project under consideration, the project of integrated territory development is not so large-scaled. Development of the housing complex will be carried out over the area of 170 acres; it will comprise 120 buildings each of those contains 43 apartments.

The project will be implemented in 3 years and require 413 mln US dollars of capital investment, the average current costs will comprise 1.294 mln US dollars per annum. According to an expert's opinion, it is expected that by the fourth year of the project implementation, the complete load of the spaces will be achieved, and the proceeds of sale will comprise 576 US dollars.

For an optimistic plan of development, the discount rate of 3.5% was taken. As the discount rate basis the forecasted inflation rate of 2% is used. Besides, the risk of error in calculations (0.5%) and unexpected costs (0.5%) are taken into account.

Figure 2 contains the graph of the financial profile of the project based on the net present value as progressive total in millions US dollars.

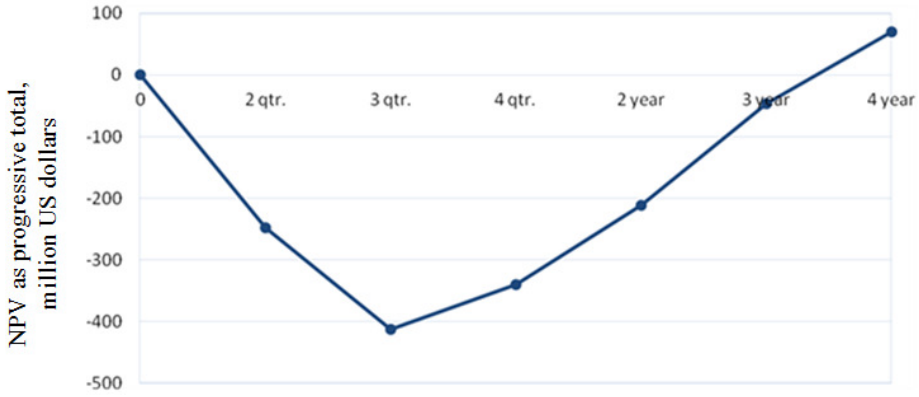

Fig. 2. Schedule of the project financial profile, an optimistic plan

To assess efficiency of the project, table 3 is prepared.

Table 3: schedule of economic efficiency values of the project of the integrated territory development

No.	Value description	Optimistic plan
1.	Net present value (million US dollars)	69.809
1.1.	Compliance with the assessment criterion	+
2.	Profitability ratio	1.17
2.1.	Compliance with the assessment criterion	+
3.	Period of return (years)	3.5
3.1.	Compliance with the assessment criterion	+

Therefore, subject to the optimistic plan of operation development, the project is efficient because its main values comply with the criteria values.

Due to implementation of the projects presented, it will be possible to reach the balance between the social and economic needs of the society and interests of the private sector subject to available support of the state and its participation in regulation of necessary processes. In the area of investment and construction, Iraq takes a number of measures to raise private investment: it improves laws, provides benefits and land plots. In future, the modern Iraqi economy may feel the need for mechanisms that could be based on the principles of partnership between the state and private sector.

Conclusion

One of reliable ways to form sustainable economic relations between Russia and Iraq is mutual investments. Long-term cooperation between the countries is formed in the oil and gas industry, in particular in the sphere of Iraqi fields' development. In the mid-term prospects, Russian companies may enter such spheres and housing construction, transportation, and modernization of Iraqi industry. In his interview for RIA Novosti, Russian Information Agency, Mazhar Mohammed Saleh, an economic adviser to Iraq's Prime Minister explained that Russian companies may enjoy significant benefits and advantageous law on investments (RIA Novosti, 2017).

The basis of cooperation between Russia and Iraq in various branches of economy may be a united scientific and engineering potential by means of arranging education and training of personnel in the sphere of science and engineering as well as active scientific cooperation in implementation of program and taking measures of interdisciplinary character which results may be used in the course of implementing joint projects.

Research held by this article's authors together with Iraqi scientists in the sphere of assessing efficiency of investment projects on integrated development of Baghdad territory confirm their social and economic significance for population of Iraqi capital that is one of the factors of increasing economic security in the country and the society in general. Construction of housing complexes will significantly improve living and operation conditions of urban inhabitants. Provision of large cities inhabitants with available and comfortable housing becomes one of the main trends of Iraq state economic policy. The raising of foreign investments, including those from Russia, may become an important factor that facilitate successful implementation of the large infrastructural projects.

Public Procurement: World Experience and Russian Practice

Natalia Vasilievna Gorodnova, Ural Federal University, Ekaterinburg, Russia, n.v.gorodnova@urfu.ru
Anastasiya Alekseevna Peshkova, Ural Federal University, Ekaterinburg, Russia, np91@list.ru

Abstract

This article describes the world experience and Russian practice of implementing state procurement. We held a comparative analysis of certain aspects of the public procurement system used in different countries. The focus was made on the protection level for domestic producers. We highlighted positive as well as negative characteristics of the public procurement system and main problems that impede to increase its efficiency in Russia.

Keywords: public procurement, world experience, Russian practice, public-private-partnership.

Introduction

The continuing functioning of economics branches depends on many external and internal factors. The defining significance for national economy development is vested in the state economic politics that is based on objectives principles and categories, takes into account the existing trends and interests of social groups, and the approaches used differ country to country.

Balanced regulation of economy in the market economic management is a difficult task for the state. The role of the state in distributing resources for the public production is significant and may be expressed by the use of fiscal tools to influence or exploit the money impacts.

In emerging markets, the transition to the efficient production process that ensures the products that are competitive in the world scale requires that the state implement consistent structural transformations in the economy. The development vector shifts to creation of technologies related to production of information products as well as scientific and technical innovations.

To keep competitive, basic branches of industry, especially, high-tech industries, significant state funding is required. One of the main mechanisms to spend budgetary funds is a public contract. Mainly, this mechanism is applied in the sphere of fundamental scientific research, production for the military industrial sector, and social services. Financing of projects through the public procurement system significantly influences on the functioning and development of companies, especially those of them that operate in the branches where the state is the only customer.

In many countries, public procurement constitutes a significant share in percentage correlation to the volume of the gross domestic product. In average, this figure varies from 10 to 15%; in developed countries, it may comprise 30% or more. In Russia, this figure comprises 25% (more than 30 trn rubles) (OECD, 2015). The Ministry of Economic Development of the Russian Federation notes that in 2015 the most budgetary funds were spent on procurement of construction work (2.07 trn rubles) and medical

products and pharmaceuticals (486.6 bln rubles). Considering significant volume of the public procurement, it is important to build an efficient system of procurement activities regulation (Artemyev I., 2016).

World experience and Russian practice in the sphere of public procurement

In many countries, in the sphere of public procurement a certain institutional environment is created that is formed by administrative regulation through legislative system as well as by economic regulators. In this matter, a great role is given to financial institutions that establish certain rules of the procurement procedure using the funds issued by them as loans. For instance, the world practice shows a wide use of procedures that are set by the World Bank.

The building of an efficient system of public procurement must be accompanied by formation of a regular competitive environment and guarantee that the state is impartial in selecting an organization as a service provider. As the world practice shows, a competitive procurement mechanism annually saves from 10 to 25% of budget funds intended to be spent (Zakharov A. N., 2011). A subject of competitive procurement may be orders to deliver (complete or render) various products (work or service), from unique to bulk goods. As we can observe, the subject matters of international bids may include delivery of several packs of nails as well as construction of ready-to-operate greatest industrial and civil buildings (Zakharov A. N., 2011).

In Russia, the public procurement system was introduced relatively not so much time ago; it is mainly regulated by federal laws. Presently, the legal framework for public procurement in the country is Federal Law No. 44-FZ On the Contract System in the Sphere of Goods, Work, and Services Procurement for Federal and Municipal Needs dated April 5, 2013, that commenced on January 1, 2014. This law replaced a previous law that was not so efficient; it is focused on detailed regulation of procurement among federal and municipal institutions.

Besides, no less important in this sphere is Federal Law No. 223-FZ On Procurement of Goods, Work, and Service by Certain Types of Legal Entities dated July 18, 2011, that sets rules for: organizations in which the Russian Federation holds more than 50% interest; companies engaged in controlled types of activities (water supply, power industry, etc.); natural monopoly holders (railways, oil companies, gas companies, etc.); budgetary organizations that hold procurement procedure using extra-budgetary funds (owned funds, funds from subcontracting, grants awarded, etc.). This law regulates general principles of the procurement procedure. The mentioned customers must independently develop regulations on procurement activities applicable to their organization that sets requirements to suppliers and possible ways to determine the winner of procurement bids.

Systems of legal regulation of public procurement used in various countries are similar in a combination of their principles on which they are based: openness and transparency of the process, faithfulness and equality of rights of all members to the procurement, equality of conditions for all candidates (OECD, 2015). However, there are some differences in the public procurement process itself.

For example, ways to publish the information on public procurement differ. In the Russian Federation, there is the website (zakupki.gov.ru) where notices of forthcoming procedures must be published. In

many other countries, law requires that publications are made in several sources at a time: Internet, newspapers, printed media (Vedeneev G. M., Goncharov E. Yu. and Kobzev G. N., 2005). Besides, it should be noted that there is a variety of procurement procedure means in Russia (fig. 1): electronic auction, request for proposals, request for quotes, open bids, closed auction, restrictive tendering, multi-staged competition, closed competition, closed competition with restricted participation, procurement from a sole supplier. For foreign systems, as a rule, the only procedure is open bids (Vedeneev G. M., Goncharov E. Yu. and Kobzev G. N., 2005).

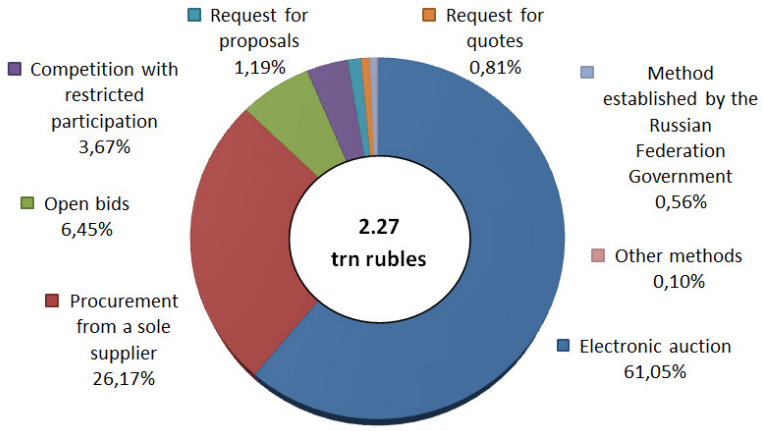

Fig. 1. Total volume of contracts concluded in the 1st half-year period of 2017 broken down by methods of determining suppliers (Russia) (Ministry of Finance of the Russian Federation, 2017)

We suggest that the main difference in the public procurement systems is the level of protection of a domestic producer. Many countries take efforts in this sphere mainly as a reaction to the foreign trade liberalization and large-scaled markets opening. Thus, the People's Republic of Chine, after it was admitted to WTO in 2001, introduced preferences for local producers under the Law on Public Procurement.

In this paper, a comparative analysis of main principles of protecting domestic producers in the USA, Great Britain, China and Brazil was held (Table 1).

Table 1: main principles to protect domestic producers in various countries (Lucky J., 2012; Frizzo H., Oliveira P., 2016)

Country	Main principles to protect domestic producers	WTO membership	Accession to the Government Procurement Agreement
USA	If offerings of a domestic producer and foreign supplier are equal, the domestic producer is preferred. The foreign producer may become a winner in a tender if imported goods have prominent advantages to compare with the US products.	WTO member from January 1, 1995	January 1, 1996
Great Britain	No restrictions are imposed on foreign suppliers from members of the European Union and the World Trade Organization who signed the Government Procurement Agreement. In case of other countries, it depends on specific features of each individual situation and relationships between the member countries.	WTO member from January 1, 1995	January 1, 1996
China	Significant restriction of foreign companies' operation in the public procurement market. A foreign producer may become a winner provided that the products may not be purchased in China; domestic product may not be purchased on reasonable commercial conditions (its price exceeds 20% of a comparable import goods); the purchased goods are intended to be used abroad.	WTO member from December 11, 2001	Accession in progress
Brazil	When choosing from two equivalent goods, the priority is given to a local producer. A foreign producer may be admitted to the competition provided that it has a branch, representative office of a legal entity inside the country, or a joint venture company in which a domestic partner has the leading role.	WTO member from January 1, 1995	-

Russian law shows the striving for applying the unified regime to the goods of both local and foreign origin in cases and on conditions provided by international treaties of the Russian Federation. At the same

time, Russia as well as many other countries provides for relatively large number of preferences for local producers and sets certain restrictions on participation of foreign companies.

In particular Russian experience shows some restrictions in the sphere of public procurement of certain goods which substitutes are produced within the country, including foreign medications and medical equipment, goods for national defense and security, consumer goods industry and mechanical engineering. This includes about 132 items, from helicopters, column cranes, baggage elevators, foundry machines, automatic cranes, to tires, limestone, plaster, sand, clay, insulating glass units, cement, lime, plaster, asphalt products, and other products.

Price preferences are widely used in the sphere of public procurement of developing countries (Ssennoga F., 2006). Thus, they comprise up to 20% in China (European Chamber, 2011), 25% in Brazil (European Commission, 2014), 15% in Mexico (World Trade Organozation, 2013). In Russia, price preferences may vary. Within the terms of operation as provided by Federal Law No. 223, offerings for delivery of Russian products are considered by the customer with a decreasing coefficient of 15% for the price criterion. In terms of procurement of medications for companies that carry out the complete cycle of medications production in the member countries of the Eurasian Economic Union, this figure comprises up to 25%.

The mentioned scope of preferences and restrictions applicable in Russia significantly facilitated achievement of a share up to 31% (to compare with 2015) of domestic products in the public procurement segment in 2016.

Russian law in the sphere of public procurement is aimed at creation of favorable conditions of operation not only for large corporations who may satisfy federal or municipal needs for procurement to a larger extent but also for small businesses. Thus, according to Federal Law No. 44, customers must purchase at least 15% of goods and services of the total annual purchases from small businesses. A small business may participate in any procurement provided that it complies with the customer's requirements and is able to fulfill the contract. Initial price of such procurement may not exceed 20 mil rubles.

Notwithstanding the intention of Russian legislative bodies to ensure favorable conditions for procurement activities, there is strict control of relationships between service providers and customers, and its violation is subject to a system of penalties developed. Thus, if a public customer violates requirements of Federal Law No. 44, its procurement will be annulled and it will be imposed a fine, and participants' organization may be recorded in the Register of Bad-Faith Suppliers.

Basing on the research held a number of advantages and disadvantages of the public procurement system in Russia (table 2).

Table 2: advantages and disadvantages of the public procurement system in the Russian Federation for participants

Advantages	**Disadvantages**
1. An opportunity to find any procurement interested and obtain any required document for it. 2. All participants of the procurement procedure enjoy equal rights and obligations. 3. No hindrances for participation in procurement in any region of the Russian Federation as well as no restrictions on their number. 4. Clear legal governing of bids procedure provides for an opportunity to track the procedure and further actions up to the completion and execution of the contract.	1. Corruption and "kick-back schemes" in the sphere of public procurement. A customer may prepare documents specific to a supplier in which it is interested. 2. Indirect restriction of competition in some competitive procedures, especially in terms of a request for quotes. Often, customers set inappropriate deadlines for executing contracts that is almost impossible to appeal in a regulatory body. 3. Great risk of being included in the Register of Bad-Faith Suppliers that bans a company and its founder for two years to participate in any public procurement.

In developed and developing countries, there is one more serious problem in the sphere of public procurement, namely, signs of corruption (The Commission To The Council And The European Parliament, 2014). As assessed by the Transparency International (Campos E., Pradhan S., 2007), at least $400 bln are annually lost in the world as a result of bribery and corruption in the sphere of public procurement; it increases public expenses to 20-25%. Experts say that up to 1 trn rubles are annually stolen in Russia out of budgetary funds allocated for public procurement (The First Anti-corruption Media, 2012). This results in a number of accompanying problems for competitors who have to spend extra resources and time on participation in the bids that are knowingly losing to them.

Besides, there is a problem of strengthening the presence of cartels in the bids; total damage of their activities (in commodities markets, public procurement and government-owned companies' procurements, bids for alienation of state property and titles, etc.) may amount in Russia up to 1.5-2% of GDP. Activities of these anti-competitive entities threaten the national economic security and significantly damage the state budget; they shake the foundations of the market economy. Russian Federal Antimonopoly Service stated that foreign companies more often engage in cartel activities, they illegally penetrate, among other things, strategically important branches of economy (Federal Antimonopoly Service of the Russian Federation, 2017).

To increase efficiency of their operation, Russian companies that are potential candidates for completion of public contracts try to improve the internal system of procurement management. They take measures to improve the organizational structure of the company, acceleration of the process of managerial decision making, increase in labor productivity, development of the quality management system, and search for reserves to decrease costs of procurement processes, including by means of decreasing transaction costs. Efficiency of the measures taken may be assessed using the following system of indicators calculated for a given period:

1) Total share of terminated contracts:

$$S = {}^{C_t}/_{C_c} \cdot 100\%, \quad (1)$$

where Ct – number of terminated contracts;

Cc – number of concluded contracts.

2) Losses resulting from termination of contracts:

$$L = C_t \cdot V_{av} + F, \quad (2)$$

where Ct – number of terminated contracts;

Vav – average value of contracts;

F – amount of a fine.

3) Potential profit of measures:

$$P_p = L_0 - L_1, \quad (3)$$

where L0 – level of losses before the measures were taken;

L1 – level of losses after the measures were taken.

4) Cost effectiveness of the measures:

$$E = {}^{(P_p - C)}/_{P_p} \cdot 100\% \quad (4)$$

where Pp – potential profit;

C – all costs.

5) Lost profit:

$$P_l = N_{p.l.} \cdot V_{av}, \quad (5)$$

where Np.l. – number of procedures lost;

Vav – average value of contract.

Interaction between the state and private sector in the sphere of investments and construction in Russia may be ensured by means of applying law on public procurement as well as by applying public-private partnership (P3) that has gained popular recently and is considered an important tool of financing infrastructure projects. According to data of the Center for Private-Public Partnership Development (Center for Public-Private Partnership Development, 2017) at the beginning of 2017, there are about 2,000 P3 projects underway in Russia; the most significant of them are150 projects the cumulative investment in which amounts to 1.5 trn rubles. Mainly, the projects are implemented in the sphere of transportation (584.6 bln rubles) and public power supply (387 bln rubles).

Under Russian law, establishment of rights and obligations between P3 parties may be effected by means of conclusion of an agreement on P3 or a concessionary agreement. The structure of an agreement on P3 was introduced not so much time ago, from January 1, 2016, compared to concessionary agreements which are in use for a relatively long period of time. The amount of investments under concessionary agreements concluded in 2016 comprises about 67.6 bln rubles out of which 62.4 bln rubles are private partners' funds (Center for Public-Private Partnership Development, 2017).

One of important specific features of concessionary regulations as compared to the public procurement system is that financial contribution of the state may be only partial that is directly regulated by Federal Law No. 115-FZ On Concessionary Agreements dated July 21, 2005. However, authorities sometimes abuse their right to co-finance concessionary projects (Federal Antimonopoly Service of the Russian Federation, 2017) and undertake to provide funds using only budgetary funds; it constitutes a violation of P3 laws and results in non-efficient spending of budgetary funds as well as unreasonable increase of costs of the infrastructural projects. In this case, such agreements must be classified in compliance with contracting procurement system laws.

While it is necessary to increase efficiency of state financial administration, it is important to spend those funds rationally, especially subject to forecasted deficit of GDP of 3.2% (2.753 trn rubles) in 2017. One of the recent analyses held by Russian Ministry of Economic Development states that the budgetary funds saved due to procedures provided by contractual procurement laws in quarters 1-3 of 2016 amounted to 290 bln rubles (gain of 21% to compare with the same period in 2015). Also, the average increase in price of procurement amounted to 8.4% (The Ministry of Economic Development of the Russian Federation, 2016).

The saved amount is determined as a sum of all placed procurements in the Unified Information System (that is the amount of starting (maximum) contract prices, or SMCP) less the final contract price. Assessment of justification of the saved amount that was stated is largely dependent on the SMCP calculation method as set by Federal Law No. 44:

- comparable uncontrolled price method (market analysis);

- standard cost method;

- tariff method;

- design and estimate method;

- cost method.

Subject to article 22 of Federal Law No. 44, the comparable uncontrolled price method is a preferred one from the mentioned methods; according to it SMCP is calculated using the following formula:

$$SMCP = \frac{v}{n} \cdot \sum_{i=1}^{n} P_i \,, \qquad (6)$$

where v – quantity (volume) of the purchased goods (work or service);

n – number of values used in calculations;

i – number of the price information source;

Pi – price of the goods, work or service per unit as provided in the source under no. i as adjusted for coefficients (indices) used to re-calculate prices subject to differences in characteristics and/or financial conditions.

Figure 2 shows statistics under an average quantity of applications filed depending on the procurement volume.

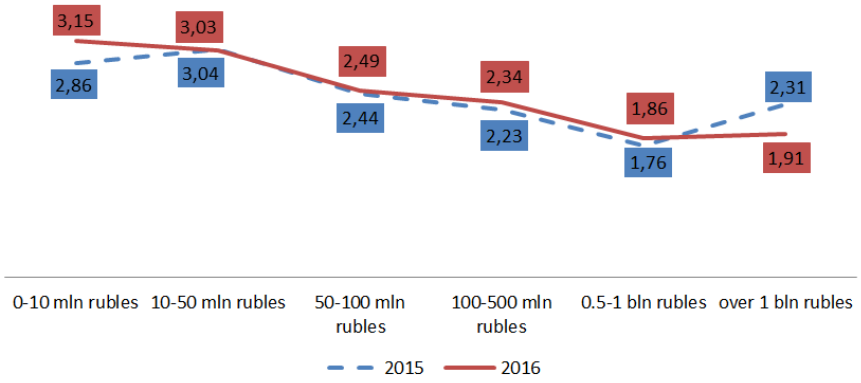

Fig. 2 – Average number of applications filed depending on the procurement volume as per results of quarters I-III in 2015-2016 (Russia) (The Ministry of Economic Development of the Russian Federation, 2016)

The figure allows us to conclude that the most competitive procurement exists at the stage below 50 mln rubles; participants usually decrease the price to the real market price. The least competitive procurement is presented in the segment from 500 mln to 1 bln rubles; as a rule, suppliers here may win the contract at an increased price because they may be sole suppliers. Taking into account that the share of procurement from a sole supplier comprises a significant portion in the total volume (26% as at the 1st half-year period in 2017), it is unlikely to ensure much savings in budgetary funds.

In one of its more recent reports, the Ministry of Economic Development of the Russian Federation demonstrated the following offers to improve current law on public procurement (The Ministry of Economic Development of the Russian Federation, 2016):

Implementation of a catalogue of goods, work and service for procurement of federal and municipal needs;

Bringing the Unified Information System in compliance with technical standards for an information and analytical system of monitoring and control in the sphere of medications procurement;

Introduction of liability for unreasonably increased or decreased SMCP or incorrect procedure of its calculation;

Centralization of procurement and justification of SMCP to specialized organizations.

We expect that the mentioned measures will improve transparency of the public procurement system, increase corruption risks and customers' costs, and increase the level of competition in the market.

Conclusion

Within a framework of the research, we concluded that one of the prioritized tasks in the current context must be an increased efficiency of the public procurement system. Budgetary funds must be spent subject to the balance between interests of the state, society, and private sector with simultaneous assurance of financial saving and maintenance of quality of the procured goods, work and service. Mainly, it depends on creation of a regular competitive environment in the country.

As it was demonstrated by the world practice analysis, in different countries the systems of legal regulation of public procurement are similar in a combination of their principles on which they are based. At the same time, there are many differences in the process of procurement activities itself, starting from common methods of procurement procedures and ending with ways of publishing information about public procurement. One of the most prominent difference is the level of protection of a domestic producer that is expressed in volumes of preferences granted or restrictions imposed on participation in procurement in respect of foreign companies.

Major systemic issues that impede promotion of competition in public procurement in Russia include:

- cartelized economy and corrupt practices threatening the country's economic security and damaging the state budget;

- loss of quality of goods purchased for state and municipal needs and increase in their value for the consumer.

Things went from bad to worse for the legislative imperfections in Russia in public procurement, poor demonstration of the strategic function, formalism and various conflicts of a number of laws.

A way out of the existing situation was the public procurement reform and entry into force on January 1, 2014 of the new federal law, the content of which attracted increased attention from the professional community. However, the new law did not throw light on the validity of limits of legal regulation over procurement, contracting, planning, monitoring and auditing. In our view, it shows the redundancy of legal regulation and the complexity of some legal rules, which may hinder law enforcement practice and increase transaction costs.

The implementation of a systematic approach to the making, allocation and performance of public (municipal) contracts will establish the basis for a new and novel institutional environment. The most comprehensive assessment of positive effect of the new law can only be given in the medium-term perspective.

The Economic Results of a Company with a Code of Ethics

Zdeněk Caha, Mgr., MBA, PhD., Department of Management, Institute of Technology and Business, České Budějovice, Czech Republic,
E-mail address: caha@mail.vstecb.cz

Abstract

The aim of this paper is to verify the possibility of a connection between a company's code of ethics and its economic results using a sample of 607 companies in the Czech Republic. There are two contradictory opinions on the influence of a code of ethics on a company's economic results, and these opinions incline either towards the positive influence of a code of ethics on business results, or a negative influence, in particular in the short term. However, it is our belief that the presence of a code of ethics has no influence on the economic results of a company (Caha & Vokoun, 2017). The following hypothesis was set and subsequently confirmed: The presence of a code of ethics has no influence on the economic results of a company. The statistical tests performed on the basis of the results of the questionnaire survey showed that the presence or absence of a code of ethics has no demonstrable influence on the economic results of a company, irrespective of its size.

Key words: code of ethics, economic results, company

Introduction

The purpose of a code of ethics and similar guidance is to cultivate a particular company environment and culture. A code of ethics defines in detail the moral principles of a company and their application to company practice. According to Remišová (2011), a code of ethics should not be perceived as a legal document and should be comprehensible, communicable, specific, up-to-date and enforceable. Singh (2011), for example, recommends that codes of ethics should be evaluated and revised every two years, whereby all company employees should be informed of any changes through training sessions. New employees should also be familiarized with the code of ethics, namely prior to the commencement of their employment.

According to Ho (2010), a code of ethics only has a positive influence on the ethical behaviour of employees if it is presented in an appropriate way.

Codes of ethics are also subject to criticism. Their poor efficacy, poor enforceability, formalism and high level of generality are particularly reproached, as is the fact that the behaviour of individuals is more or less determined by the values they acquire during childhood (Putnová and Seknička, 2007). The question as to what extent a code of ethics is useful for small companies and small entrepreneurs with a fixed organizational culture that works mainly on the basis of informal relations, is also disputable (Čaník and Čaníková, 2006). A code of ethics is also not necessarily accompanied by an improvement in company ethics. Several empirical studies have revealed that codes of ethics give companies a negligible advantage, if any advantage at all. Research conducted by McKendall, DeMarr and Jones-Rikkers (2002) is an example of one of these studies. In their research, Kaptein and Schwartz (2007) also concluded that the efficacy of codes of ethics was relatively low. A global survey conducted by KPMG (2008) points to the worldwide trend for increasing numbers of companies to define and implement a code of ethics. The research showed that in 2008 the proportion of companies with a code of ethics stood at 86%. It is clear from the above that in recent years a code of ethics has become a standard basic tool for ethics programmes within large and renowned companies. This is also backed up by an informal survey conducted by IBE in 2012, which showed that a code of ethics was implemented by 92% of those companies with the highest market capitalization based in Great Britain whose shares are traded on the London Stock Exchange (IBE, 2012). The IBE survey (2012) also reported that in 2012, 73% of all companies had a code of ethics. In 2016, according to a worldwide survey conducted by PwC, the largest of its kind, in which 6,337

companies from 115 countries participated (including 79 prominent companies from the Czech Republic), on average 82% of companies had a formally established code of ethics (PricewaterhouseCoopers, 2016). One of the latest surveys was conducted in 2016 by Dow Jones and Metricstream (2016) and showed that 96% of the 330 questioned companies had a code of ethics. The aforementioned surveys indicate the growing trend towards the introduction of codes of ethics in business practice. However, it is important to highlight the fact that not all these surveys are compatible. In actuality, the results depend on numerous factors, in particular on the structure of the respondents. Whilst a higher proportion of large US based companies have codes of ethics, this proportion is smaller for small and medium-sized companies and those operating in Asia. It is therefore clear that only global surveys with large numbers of respondents from all business sectors and companies of different sizes will provide the relevant information required. Unfortunately, such surveys are difficult to perform.

According to a survey conducted by the Association of Chartered Certified Accountants (ACCA), one in five managers or accountants in the Czech Republic has had to deal with a serious ethical dilemma in their work. This only confirms the necessity of the introduction of effective ethical management tools (Transparency International – Czech Republic, 2015). Džbánková (2003) concluded, on the basis of her smaller, less representative survey conducted in 2002, in which 60 representatives participated from middle and top management in companies operating in Prague and Central Bohemia, that 35% of the questioned companies had a code of ethics in place and 22% were considering drafting and implementing one. In contrast, Transparency International – Czech Republic in conjunction with the Economic University in Prague, conducted a very representative survey in 2005, which was repeated in 2006. The surveys sought to determine the degree to which codes of ethics were applied in companies that operated on the Czech market. The conclusion was that in the second half of 2005 only 59 companies (i.e. 10.3%) of the 574 questioned had a code of ethics in place. This situation was similar when the survey was repeated in the first half of 2006, whereby only 104 companies (i.e. 8.4%) of the 1,240 in the sample set had a code of ethics in place. The survey also proved that the larger the company the greater the chance a code of ethics existed. Dytrt et al. (2011) state that in 2011, less than 15% of domestic companies had a code of ethics in place. In a more recent survey conducted by Transparency International in 2013, the results showed that this percentage had increased to 46% of domestic companies. In the Czech Republic, the presence of a code of ethics tends to be limited to larger companies and public institutions. Smaller companies are still only at the stage of exploring their options with regards to this ethical management tool.

Methodology

In cooperation with the Czech Statistical Office, a sample set of companies was selected from all size categories in compliance with EU nomenclature. The emphasis was placed on selecting companies that were representative of the basic spheres of the national economy. In total, 1,420 companies were included in the sample set. The empirical research, in the form of a questionnaire survey, was conducted in the second half of 2016 among the heads of personnel departments. In addition to acquiring basic information about the respondents (company name; contact data; area of business activity; economic results), the questionnaire contained eight items with respect to codes of ethics. All the respondents were guaranteed anonymity with regards to the presentation of the research results. The questionnaire survey was conducted by students and academic staff. The majority of respondents replied in electronic form by means of an electronic reference within the Google – disc web platform. The paper form was used to a minimum extent. The targeting of heads of personnel departments resulted in 607 completed and returned questionnaires i.e. a return rate of 42.75%. For the analysis, four categories of companies were identified, namely large companies ($\geq$ 250 employees), medium-sized companies (50 – 249 employees), small companies (10 – 50 employees) and micro-companies ($<$ 10 employees). The purpose of the analysis was to determine the relationship between the presence of a code of ethics in Czech companies and their positive economic results for the last three years, and to determine how widespread the presence of a code of ethics is. Within the sample dataset of 607 companies, there were several companies that gave no response to the question “Does your company have a code of ethics?” It was decided to assign the answer “No, we do not miss it” to these cases on the basis of the assumption that omitting to answer the question automatically showed that the company did not have a code of ethics. In addition, our interest was

only in whether a company did or did not have a code of ethics. As a result, it was decided, for this analysis, to combine the number of responses for "No, we do not miss it" and "No, we miss it" into one group "No". As part of the analysis of the relationship between the presence of a code of ethics and a company´s profit or loss, it was necessary to exclude companies which failed to declare whether their economic results were positive, balanced or negative. In these cases it was impossible to automatically assign any other option. In this work we focus on profitability, so we were only interested in the companies which are profitable, rather than those which are breaking even or making losses.

Tables and charts of the absolute and relative frequencies were created to illustrate the results of the questionnaire survey for the monitored areas. A two-selection test was subsequently carried out on the identity or difference between the two proportions and the interval estimates calculated. MS Excel was used for the preparation of the tables and charts. R statistical software was used for the relationship tests and the calculation of the interval estimates. All the statistical tests and calculations of interval estimates were performed at a confidence level of 95% (i.e. at a significance level of 0.05).The hypothesis was tested separately for each category of company size. A table was put together of numbers in which the companies were divided according to size, whether they have a code of ethics, and whether they make a profit/loss. The number of profitable companies with a code of ethics was calculated as a proportion of all the companies with a code of ethics. This process was repeated for those companies that do not have a code of ethics. The proportion of profitable companies is highlighted in bold in the tables below. A two-selection test was subsequently performed to show whether the difference in the proportions for the profitable companies is dependent on the existence or non-existence of a code of ethics, and whether this is statistically significant. If the difference was not statistically significant, then this would mean that the existence of a code of ethics does not influence the economic results of a company. From the point of view of the formulation of the hypotheses, it was necessary to test whether the proportions in both groups were the same against the alternative that the proportions were significantly different. The proportions were tabulated as decimal numbers rather than in percentages because the R statistical software works with decimal numbers. The results of the statistical test were evaluated on the basis of the determined p-value and from the interval estimations for the differences in the proportions. If the p-value was higher than the chosen significance level (in this case 0.05), or if the interval estimation contained zero, the difference in the proportions is statistically insignificant. This means that the existence of a code of ethics does not significantly influence profitability.

Confirmation of the hypothesis

The presence of a code of ethics has no influence on the economic results of a company.

a) Micro companies

Table 1: Frequencies

Presence of a code of ethics	Economic results			
	Break-even	Positive	Negative	Total
No	32	83	7	122
Yes	3	13	1	17

Source: authors

Table 2: Proportions

Presence of a code of ethics	Economic results		
	Break-even	Positive	Negative
No	0.262	0.680	0.057
Yes	0.176	0.765	0.059

Source: authors

Table 3: Results of the two-selection test

Z - test	0.7588
p - value	0.448
Interval estimation of the difference in proportions	(-0.134; 0.302)

Source: authors

As the p-value is higher than the significance level of 0.05 and the interval estimation contains zero, the statistical test proves that the presence of a code of ethics has no influence on the economic results of micro-companies.

b) Small companies

Table 4: Frequencies

Presence of a code of ethics	**Economic results**			
	Break-even	**Positive**	**Negative**	**Total**
No	30	101	5	136
Yes	8	30	3	41

Source: authors

Table 5: Proportions

Presence of a code of ethics	**Economic results**		
	Break-even	**Positive**	**Negative**
No	0.221	0.743	0.037
Yes	0.195	0.732	0.073

Source: authors

Table 6: Results of the two-selection test

Z – test	-0.139
p – value	0.889
Interval estimation of the difference in proportions	(-0.165; 0.143)

Source: authors

In small companies, the situation is similar to that in micro-companies. The p-value is substantially higher than the significance level and in the interval estimation there is a zero near its centre. The test results also therefore prove that the existence of a code of ethics has no influence on the economic results of small companies.

c) Medium-sized companies

Table 7: Frequencies

Presence of a code of ethics	**Economic results**			
	Break-even	**Positive**	**Negative**	**Total**
No	17	73	10	100
Yes	14	44	1	59

Source: authors

Table 8: Proportions

Presence of a code of ethics	Economic results		
	Break-even	Positive	Negative
No	0.170	0.730	0.100
Yes	0.237	0.746	0.017

Source: authors

Table 9: Results of the two-selection test

Z – test	0.219
p - value	0.827
Interval estimation of the difference in proportions	(-0.125; 0.157)

Source: authors

The numerical characteristics of the statistical tests show that the situation among medium-sized companies is almost identical to that found in small companies. The p-value, as well as the interval estimation, clearly show that even in this case the existence of a code of ethics has no influence on the economic results of medium-sized companies.

d) Large companies

Table 10: Frequencies

Presence of a code of ethics	Economic results			
	Break-even	Positive	Negative	Total
No	4	36	0	40
Yes	14	64	4	82

Source: authors

Table 11: Proportions

Presence of a code of ethics	Economic results		
	Break-even	Positive	Negative
No	0.100	0.900	0.000
Yes	0.171	0.780	0.049

Source: authors

Table 12: Results of the two-selection test

Z – test	-1.814
p – value	0.0696
Interval estimation of the difference in proportions	(-0.249; 0.0095)

Source: authors

Although the p-value and the interval estimation at the significance level of 95% show that the existence of a code of ethics in large companies has no influence on their economic results, the conclusion is borderline. The p-value is 0.0696, which is very close to the critical value of 0.05. It is visible on the interval estimation that zero, which represents a negligible difference in the proportions of profitable companies with a code of ethics and those without one, is at the very edge of the interval, as the upper limit of the estimation is 0.0095, which is nearly zero. The lower limit of the estimation suggests that the difference may be up to 0.249, which is almost 25%. The conclusion is therefore on the edge of the given liability. The values show that the hypothesis is not confirmed as

definitively as in the previous cases. If the difference were to be considered as significant, the results of the research would show that there is a higher proportion of profitable companies without a code of ethics.

Conclusion and discussion

The statistical tests performed on the basis of the results of the questionnaire survey show that the presence or non-existence of a code of ethics has no demonstrable influence on the economic results of a company, irrespective of its size. Nevertheless, the conclusion drawn for large companies was based on borderline results. If the difference for this category of companies were to be considered significant, the conclusion would have to be drawn that the proportion of profitable companies without a code of ethics is higher than for those without.

In our opinion, further research should focus on the differences between groups of companies based on technical efficiency, labour productivity, research and development expenditures, and profitability. MANOVA would also shed some light on the odds of a relationship using interactions of economic results, the size of the company and the existence of a code of ethics. Non-financial performance variables like employee satisfaction should also be taken into consideration. These variables can contribute to the better understanding of the total performance evaluation of an ethical culture within companies.

Abstract:

Regarding the seasonal adjustment of Romanian GDP, there are some inconsistencies between the GDP growth rates computed based on the sum of seasonally adjusted components and the one computed based on the direct seasonal adjustment of the GDP. This paper provides a better understanding of the differences between the direct and indirect method of seasonal adjustment of economic time series and illustrates a possible solution to the problem encountered. Moreover, the seasonal adjustment procedure for TRAMO-SEATS and X13 will be tested using JDemetra+ 2.1. The choice between direct and indirect approach is made taking into account the quality of the seasonally adjusted data, the magnitude of revisions and consistency between the aggregates and the overall GDP. Although both methods provided satisfactory results, TRAMO-SEATS gave better results with regard to quality and revisions. Some key benefits of choosing the right method are the possibility of comparing economic series from month to month and making accurate predictions.

Keywords: seasonal adjustment, direct/indirect approach, JDemetra, TRAMO-SEATS, X13

Introduction

With regard to seasonal adjustment of macroeconomic aggregates, two approaches emerged: direct method (adjusting the aggregates independently) and indirect method (adjusting the subcomponents of an aggregate and sum up to obtain the seasonally adjusted aggregate). Yet, as Hood and Findley (2001) point out, the direct and indirect seasonal adjustment results for an aggregate are usually different.

The problem of choosing direct or indirect adjustment appears when users take into account the consistency of disaggregated and aggregated data. According to the theoretical evidence one cannot say that a method is better than another, *a more detailed analysis of the data being required* (Eurostat, 2015, p. 33).

From a practical point of view, a mix of the two methods is usually used: according to Foldesi et al. (2007), 21 out of 31 European countries use the direct method for more than 50% of the series and 7 countries use the indirect method. According to the same source, 8 countries apply exclusively the direct method and 2 countries the indirect one.

Strictly considering national accounts, the direct method is preferable among European countries. This approach is used by countries such as Albania (Institute of Statistics of Albania, 2015), Austria (Scheiblecker, Steindl and Wüger, 2007), Bosnia and Herzegovina (Agency for Statistics of Bosnia and Herzegovina, 2013), Bulgaria (National Statistical Institute of Republic of Bulgaria, 2017), Czech Republic (Czech Statistical Office, 2008),

Estonia (Statistics Estonia, 2009), Latvia (OECD, 2001), Lithuania (Statistics Lithuania, 2008), Ireland (Central Statistical Office, 2016), Luxembourg (Haas et al., 2009), Hungary (Hungarian Central Statistical Office, 2012), Malta (National Statistics Office Malta, 2008), Poland (Central Statistical Office of Poland, 2016), Sweden (Statistics Sweden, 2010), Netherlands (Statistics Netherlands, 2006), Romania (The National Institute of Statistics Romania, 2017), Slovenia (Statistical Office of the Republic of Slovenia, 2017). The indirect method is used in the following countries: Andorra (Department of Statistics of Andorra, 2017), Denmark (Graversen et al., 2008), Germany (Federal Statistical Office Germany, 2006), France (National Institute of Statistics and Economic Studies France, 2012), Republic of Serbia (Statistical Office of The Republic of Serbia, 2011), Greece (Hellenic Statistical Authority, 2016), Italy (Italian National Institute of Statistics, 2008), Cyprus (Statistical Service of Cyprus, 2008), Portugal (Statistics Portugal, 2007), Finland (Statistics Finland, 2014), Norway (Statistics Norway, 2014), Iceland (Central Bank of Iceland, 2012), Croatia (Croatian Bureau of Statistics, 2014), Switzerland (Swiss Federal Statistical Office, 2016), Turkey (Turkish Statistical Institute, 2009).

There are different factors which influence the choice between one method or the other (Foldesi et al., 2007). Firstly, according to the authors, user requests and data characteristics must be taken into account. Secondly, the indirect method is used when the seasonal patterns of the component series are different from each other or when the seasonal adjustment can be performed on each series. Moreover, one can use this method to preserve consistency in data. Last, the direct method is usually used when the components cannot be adjusted individually.

Maravall (2005) emphasizes the importance of using the direct adjustment, explaining that the dynamic composition of the series modifies through aggregation. Moreover, he points out that the constraints between the series will not be the same after the seasonal adjustment, which is a non-linear process. Rodriguez and Brathaug (2012) affirm that the direct approach is more efficient than the indirect method for seasonal adjustment of GDP, as it does not require many revisions. On the contrary, Central Bank of Iceland (2012) points out that the indirect method is more accessible to the users as it provides the same additive relationship between seasonally adjusted components as the raw series.

In the case of Romanian National Accounts, seasonal adjustment of the GDP is performed using the direct approach and the GDP components are seasonally adjusted indirectly. This article proposes a framework in order to find a consensus between the two approaches.

Assessing consistency among growth rates for seasonally adjusted data

Data and formulas for the Romanian GDP and its components can be found at http://www.insse.ro/cms/en/content/gross-domestic-product (accessed February 09, 2017), as follows:

- GDP production aggregates = Total gross value added + Taxes on products – Subsidies on products.
- GDP consumption aggregates = Final consumption + Gross Fixed Capital Formation + Changes in Inventory + Exports of goods and services – Imports of goods and services.

For the purpose of this paper, data for all aggregates and subcomponents in millions of lei average prices of 2000 were considered.

As one can observe from the data available at this link, major seasonally adjusted aggregates are computed as a sum of smaller aggregates, thus using the indirect method. According to Eurostat (2016), a major drawback of this method is the presence of residual seasonality, therefore before proceeding to consistency assessment, a test with regard to this issue will be performed. After performing seasonality tests on these aggregates, one can observe that no residual seasonality is present. Therefore, there is no concern about the quality of seasonally adjusted data.

Table 1: Seasonally adjusted GDP major components – autocorrelation at seasonal lags test; Source: designed by the authors using Seasonality tests in JDemetra+ 2.1

Aggregate	Autocorrelation at seasonal lags p-value, 2011q1 – 2016 q3	Autocorrelation at seasonal lags p-value, all data available
Total gross value added	0.4544	0.5
Taxes less subsidies on products	0.8166	1
Final consumption	0.4526	0.1405
Actual individual consumption of households	0.4069	0.7051
External balance of goods and services	1	0.9802
Exports of goods and services	1	1
Imports of goods and services	1	1

Astolfi et al. (2003) point out that when comparing the direct and indirect seasonal adjustment methods the aggregate and the components should deliver the same message in terms of the sign of the growth rate. Therefore, consistency between GDP growth rate (direct seasonal adjustment) and GDP growth rate using the sum of the aggregates is analysed, based on data and formulas available at http://www.insse.ro/cms/en/content/gross-domestic-product (accessed February 09, 2017).
The growth rate for the third quarter 2016 compared to the second quarter 2016 was analysed. For the consumption side, there is a major inconsistency between the GDP growth rates computed based on the sum of seasonally adjusted components (-4%) and the one computed based on the direct seasonal adjustment of the GDP (0.6%). With regard to the production side, the two growth rates deliver a fairly similar message (1% compared to 0.6%).

Choosing the time span, decomposition method, package and ARIMA model

Romanian National Accounts quarterly data are available since 1995. UNECE (2012) points out that a time series should be at least 3 years long for monthly data and 4 years long for quarterly data, warning that a too long time series can be inconsistent. Moreover, according to UNSD (2010), the most suitable length for seasonal adjustment of quarterly time series is 5 years. Thus, for the purpose of this article, time series will be considered since the first quarter of 2011.

The decomposition method can be assessed using graphical inspection following the instructions provided by UNSD (2010): a pure additive model should be used when the seasonal component is not affected by the series level, while a multiplicative (log additive) model should be used when the seasonal component evolves with the series level. Graphs in annex 1 are used in order to assess what decomposition method should be used for each series.

- The log-additive model should be used for the following series:
  - Total gross value added;
  - Agriculture, forestry and fishing;
  - Construction;
  - Wholesale and retail; repair of motor vehicles and motorcycles; transport and storage; hotels and restaurants;
  - Financial intermediation and insurance;
  - Real estate activities;
  - Professional, scientific and technical activities; activities of administrative services and support services;
  - Public administration and defence; social insurance of public sector; education; health and social assistance;
  - Taxes less subsidies on products;

  - Taxes on products, Final consumption expenditure of households;
  - Final consumption expenditure of Non-profit institutions serving households;
  - Individual final consumption expenditure of General government;
  - Collective final consumption expenditure of General government;
  - Exports of goods and services;
  - Exports of goods.
- The additive model should be used for the following series:
  - Mining and Quarrying; manufacturing; electricity, gas, steam and air conditioning production and supply; water supply; sewerage, waste management and decontamination activities;
  - Information and communication;
  - Shows, culture and recreation activities; repair of households goods and other services;
  - Subsidies on products;
  - Final consumption;
  - Actual individual consumption of households;
  - Gross fixed capital formation;
  - Change in inventories;
  - External balance of goods and services;
  - Exports of services;
  - Imports of goods and services;
  - Imports of goods;
  - Imports of services.

Astolfi et al. (2003) again point out three issues that should be addressed when comparing different seasonal adjustment approaches:

- the necessity of working with cleaned time series (without calendar effect and outliers);
- defining seasonal adjustment policy criteria;
- finding a common set of quality indicators for X13 and TRAMO-SEATS.

With regard to the first issue, according to Grudkowska (2015), JDemetra+ 2.1 TRAMO-SEATS and X13 packages incorporate tools for both calendar adjustment (Easter effect, Leap year, trading days, working days) and outlier detection and adjustment. For the purpose of this article a specific calendar for Romania has been defined comprising of all legal holidays in this country.

Considering the second issue, Mirică et al. (2016) point out that seasonally adjusted series should be as stable as possible, namely with very small revisions for growth rates. In order to assess the magnitude of varying revisions, two criteria will be used, according to Grudkowska (2015): root mean square error, an indicator that measures the magnitude of revision and number of revision points for which the relative differences between the initial and the final estimation are larger (in the absolute terms) than 2 times the root mean squared error of the revisions (red revision points). Moreover, Scheiblecker (2014) points out that inconsistency between components and the aggregate may not be acceptable for the users.

The third issue can be easily addressed as JDemetra+ 2.1 offers a vast majority of common diagnostic tools for TRAMO-SEATS and X13 including a summary tool that incorporates all diagnostics, so it would not be any problem in comparing the results of X13 and TRAMO-SEATS. Nevertheless, there may be situations where one must decide between models with similar general diagnostics, a choice that can be based on various criteria (Kadane and Lazar, 2004). If that is the case, one can use the Out-of-sample Mean Squared Error test and the AIC criterion. As Pena (2001) points out, one of the main features of any model is to provide forecasts as accurate as possible, therefore the Mean Squared of forecasts errors must be assumed closed to the Mean

Squared of in sample residuals. Moreover, the AIC criterion is successfully used when we need to select a model that best fits an unknown reality (see for example, Olofsen and Dahan (2013), Dziak (2012)).

The automatic procedure for both TRAMO-SEATS and X-13 will be tested with regard to the three issues defined above. Moreover, we will apply the seasonal adjustment procedure to all major aggregates and check for consistency between the GDP growth rates computed based on the sum of seasonally adjusted components and the one computed based on the direct seasonal adjustment of the GDP. Also, consistency will be checked among the growth rates of the major aggregates computed based on the sum of the seasonally adjusted subcomponents and the one computed based on their direct seasonal adjustment. If the obtained results are unsatisfactory, one should manually set the ARIMA Model parameters and decomposition method.

Why the automatic procedure in JDemetra+?

According to the Eurostat and European Central Bank joint letter, issued in 2014, JDemetra+ is recommended as the official software for conducting seasonal adjustment of official statistics within ESS and ESCB (Eurostat and ECB, 2014).

Although, the program offers a wide range of options that can be set manually, the automatic procedure may be preferred in practice, due to several reasons. First, as Eurostat (2007) points out, seasonal adjustment is very time consuming and usually seasonally adjusted series must be submitted in a very short amount of time. Second, the major features of the automatic procedure in JDemetra+ both TRAMO-SEATS and X13 include automatic choice of decomposition method, outliers, ARIMA model and calendar detection.

Results

Tables 2 and 3 present the results of the X13 automatic procedure with regard to the three issues stated above and tables 4 and 5 present the results of the TRAMO-SEATS automatic procedure. 29 series were decomposed. Quality indicators as well as growth rates are presented.

From a technical point of view, one can observe that both procedures produced satisfying results for the seasonal adjustment process. The overall quality is good for both methods, with only two exceptions for X13 (one uncertain result and one severe result). The decomposition method is generally the same as the one chosen manually for TRAMO-SEATS (with one exception). For X13, it is different in 8 cases. The AIC looks better for TRAMO-SEATS in most of the cases. Also, the Out of Sample Mean test produced only one severe result in the case of TRAMO-SEATS and 2 in the case of X13.

The root mean-square root revision history for SA series is better with TRAMO-SEATS for Total gross value added and Final consumption, approximately the same for Taxes on products, Subsidies on products, Gross fixed capital formation, Exports of goods and services, Imports of goods and services and better for X13 for Change in inventories. This suggests that revisions would be smaller if TRAMO-SEATS would be used for Total gross value added and Final consumption and X13 for Change in inventories. No red revision points appeared, thus suggesting no major model instability.

Considering consistency between growth rates at the aggregates level, the results look much better for TRAMO-SEATS. Yet, for X13 growth rates are slightly more consistent between the GDP as sum of production aggregates and GDP directly seasonally adjusted as well as the GDP as sum of consumption aggregates and GDP directly seasonally adjusted. As one can observe, growth rates computed using the sum of production aggregates are 0.3 for X13 and 0.2 for TRAMO-SEATS, while growth rates computed using the sum of consumption aggregates are 1.3 for X13 and 1.8 for TRAMO-SEATS.

Conclusions

Eurostat (2015) highly recommends that the choice between direct and indirect approach should be based on statistical considerations with regard to quality and users' needs. In this paper we proposed a framework that addresses these two issues. First, we set up most important diagnosis criteria that can be used to assess the quality of the seasonal adjustment process (Overall quality, AIC and Out-of-sample MSE test). Second, we identified the criteria that seasonal adjustment of national accounts should comply with in order to address users' needs: consistency between seasonally adjusted aggregates, subcomponents and GDP. Third, we proved that all these can be addressed using an easy, fast, open-source tool: the automatic procedure in JDemetra+ 2.1. 29 series comprising quarterly GDP components of Romania were seasonally adjusted using this procedure with satisfactory results in respect to users' needs: good quality of the seasonally adjusted data, small revisions and consistency between the aggregates and the overall GDP.

TRAMO SEATS gave better results with regard to quality. Considering revisions, prospects are better for TRAMO-SEATS. If there is high demand of very small revisions from the users, the ARIMA model can be set manually using a set of simulations as described by Mirică et al. (2016). With regard to consistency, results are slightly better for X13 at GDP level but better for TRAMO-SEATS at aggregate level. A satisfactory level of consistency is observed between the aggregates and the GDP if the aggregates are directly seasonally adjusted and not computed as the sum of seasonally adjusted subcomponents.

This document illustrates the required style to prepare Camera Ready format for 14th IBIMA, in Microsoft Word document and Rich text format forms.

Abstract

The article discusses the outcomes of the existing innovation rankings for evaluating the level of the innovation system in St. Petersburg. It has been concluded that the principles of general innovation management should be applied in order to develop the regional innovation system (RIS) of St. Petersburg. The need for applying the procedure of regional innovation foresight is substantiated. The author has managed to define the key areas for enhancing the efficiency of RIS operation for the city of St. Petersburg.

Keywords: region, innovation systems, foresight, general innovation management, principle.

Introduction

Today the innovation way of developing the country and some of its regions is one of the most important priorities in the socioeconomic policies of the Russian Federation. It is the regional innovation system that is the factor of long-term competitive growth both for a region and for the entire country. An efficient innovation mechanism can be created regionally only in case there are cleverly determined trends for the RIS development. The paper looks into the RIS of the city of St. Petersburg.

St. Petersburg is one of the leading regions in the innovation system of Russia. This conclusion can be made on the basis of the ranking of complex socioeconomic and innovation development of cities called "AT Kearney Global Cities", 2016 [13], specialized ranking of innovation cities "Innovation Cities Index 2015: Global", and the ranking of innovation regions of Russia "AIRR" [7]. It is also proven by various national and international investigations.

According to the findings of the research study conducted by the author [8,9], as well as the statistics [10, 11] and data from other investigations, it can be generally concluded that the regional innovation system exists in St. Petersburg (i.e. there is a quite wide range of research institutions, universities and there are many industries where enterprises implement innovations, and innovation infrastructure organizations; the contributors to innovation activities interact a lot). The system has been operating efficiently in a short term. However, by some parameters of its

[1] The paper has been written under support of the Ministry of Science and Education of the RF (project No. 26.6446.2017/BCH).

operation one can judge about regression trends and shrinking innovation activities. In the long run (in the projection "R&D – R&D results – results of innovation activities"), the regional innovation system of St. Petersburg is inefficient, i.e. it can be stated that bigger investments in the initial phase of the innovation process - research and development - do not entail equivalently growing efficiency in the last phase - the share of innovative products in the GDP and innovation-based growth of the GDP.

The strategic development of St. Petersburg RIS

The sustainability of St. Petersburg regional innovation system is related to a wide basis for innovation development. However, fast developing new technologies, including biotechnology, artificial intelligence, big data processing technology, can change the situation in favor of new sectors, if no effective cooperation is ensured between the actors of the regional innovation system.

The strategic development of St. Petersburg RIS must rely on the principles of general innovation management. These principles include:

1-st principle Long-term horizon of RIS development strategy.

The tools of regional innovation foresight must be used to form the list of technologies which determine the region's competitive advantages for a long period of time (30-50 years), and to design regional innovation policies given the foresight outcomes. Fast development and competitiveness in the sphere of technology is only possible in case there is certain scientific and technological capacity, created by the region. In addition, favorable investment climate is needed to attract finances into perspective technologies.

Our investigations show that St. Petersburg is a leader of innovation development in Russia and the activity of region's enterprises in the field of innovation technology development is high. However, according to the results of technical efficiency simulation based on a two-phased envelopment analysis model[2], St. Petersburg is losing the signs of technical efficiency in both phases - in the first one, related to transformation of R&D outcomes suitable for commercialization and further utilization, and in the second one, related to commercialization of these outcomes. The inefficiency of the first phase can be eliminated if long-term technology priorities are formed and supported in the innovation policies of the region.

The entire scope of regional innovation foresight procedures is shown in Fig. 1.
As substantiated, it might be reasonable if a university (or a consortium of universities) is responsible for setting up a foresight project, since the third mission governs the active role of universities as an integrator in the regional innovation system.

[2] These investigations were made by the author in previous papers with application of Data Envelopment Analysis (DEA).

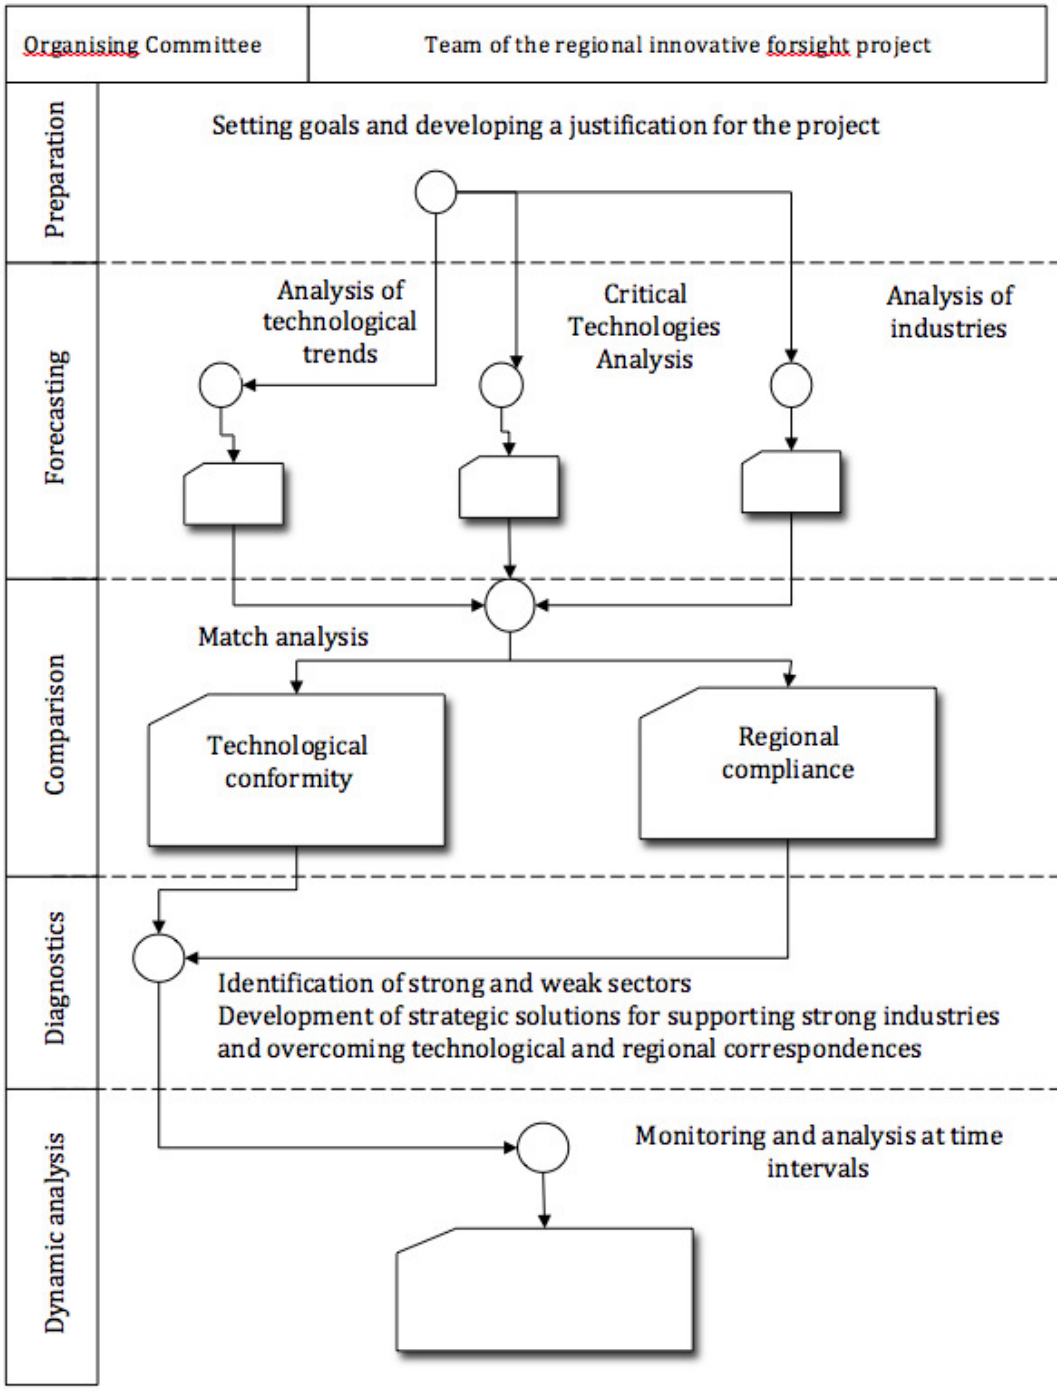

Fig. 1. The scope of regional innovation foresight procedures

The 2-nd the key role of technological innovations based in the interdisciplinary approach as the main source of sustainable competitive advantages.

As substantiated, it might be reasonable if a university (or a consortium of universities) is responsible for setting up a foresight project, since the third mission governs the active role of

universities as an integrator in the regional innovation system.
In case of St. Petersburg, it is reasonable if the role of project organizer is played by one of the leading universities, which have strong competences in the field of modern research in natural, technical and social sciences. The interdisciplinary requirement is mandatory, since convergence, which is one of technological development trends, is impossible without involving various branches of knowledge. Experts in social sciences should be involved for two reasons: firstly, the society have to accept new priorities, secondly, convergence of social studies and natural ones (such as bio-informatics, social informatics, artificial intelligence) is one of the key factors for the future development. Since no university in St. Petersburg is a sole holder of all the necessary competences (they develop in many universities, but leaders are needed to implement foresight), it is proposed that a consortium of universities should be set up, including St. Petersburg State University and universities that are members of the "5-100" project or have the status of a national research university. Before setting up the consortium, the competences of universities must be audited. It should be done by the project team of regional innovation foresight. In order to increase manageability, the team must be made up of representatives from one university and engage experts from other universities and research institutes for audit. St. Petersburg Polytechnic University can be a good choice as the base for setting up the project team. According to the recent QS ranking, St. Petersburg State University has the leading position (240 position) among St. Petersburg universities. However, since it is a federal university, SPbSU is not involved in the regional environment a lot. The next related to St. Petersburg university in the ranking is the Higher School of Economics. It is especially strong in sociology and among young universities of the world (51 position in the ranking of young universities). However there is only a branch of this university in St. Petersburg, whereas the head university has a federal and international focus in its research. Obviously, these universities have to be engaged and their expert competences must be used. However, a university involved in the regional environment must become the base. St. Petersburg Polytechnic University has the first positions in the ranking in the fifth hundred (401-410),with strong positions in physics and astronomy. This is the best result among St. Petersburg universities. This approach allows applying the second principle of general innovation management in reference to St. Petersburg RIS.

The organizational committee of the project should include, apart from representatives of SPbPU, members of other leading universities and non-profit-making organizations, which would convey the positions of the regional community and executive government bodies. The general structure of the organizational committee and consortium, as well as the key objectives are shown in Fig. 2.

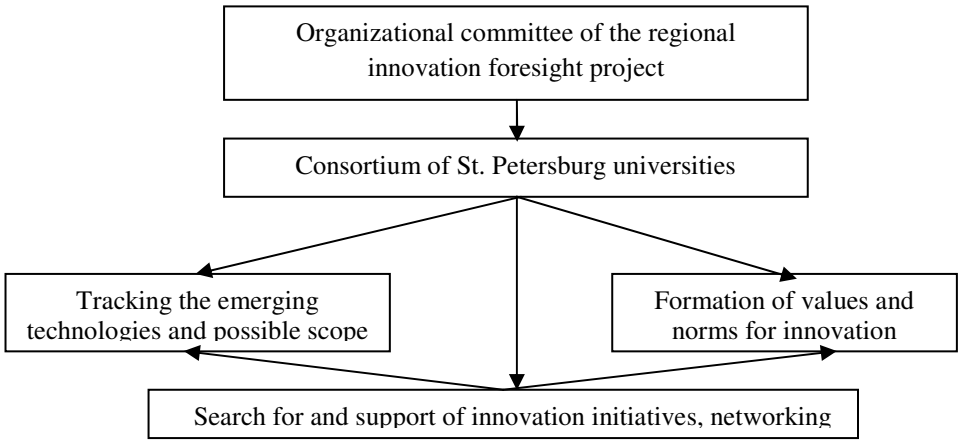

Fig. 2. University consortium as the basis for the project of regional innovation foresight of St. Petersburg

The 3-rd principle: introduction of innovation management as a tool of not only strategic but also operational management.

The organization of the regional innovation foresight project must embrace the time horizon relevant for managing the project. Since it is the issue of working out the guidelines for regional innovation policies, and investment in technology has a long-term nature, following the examples of other regions, it is reasonable that the time of the project should be limited by three years, given the results of regular monitoring over its implementation. The frequency of monitoring must be no less than once per 2 years, since today the life cycle of technology development is reducing and a two year period is the time proposed by many researchers.

In parallel with the regional innovation foresight project, other innovation initiatives should develop, as well as the legislation stimulating and regulating innovation activities. The most important statutes of St. Petersburg, regulating innovation project financing, are:
1. St. Petersburg Government Decree No. 355 as of 13.05.2014 "On the Economic and Social Development Strategy of St. Petersburg for the period until 2030".
2. St. Petersburg Government Decree No. 835 as of 28.06.2011 "On Complex Program "Science. Industry. Innovations" in St. Petersburg for the years 2012-2015". The total volume of finance for the program is 3.6 bil. RUR.

3. St. Petersburg Government Decree No. 495 as of 23.06.2014 "On St. Petersburg state program "Development of industry, innovation activities and agro-industrial complex in St. Petersburg" for the years 2015-2020". The total volume of finance for the program is 875.6 mil. RUR.

4. St. Petersburg Government Decree No. 496 as of 23.06.2014 "On the state program of St. Petersburg "Economic development and knowledge economy in St. Petersburg" for the years 2015-2020". The total volume of finance for the program is 4.5 bil. RUR.

At the same time St. Petersburg lacks the legislation which directly regulates innovation activities.
The fourth principle is *compliance of the innovation policies with the innovation culture in the region*. Since regional innovation foresight and regional innovation policies are the products of a wide consensus concerning the issues of St. Petersburg strategic development and given the strong science, technology and innovation potential, this issue calls for addressing the creation and enhancement of a culture contributing to the growth in innovation activities and acceptance of key development trends. Since the innovation policies of the strong region should contribute to expanding the base of competitive advantages, innovation culture must be focused on facilitating innovation activities in various sectors, revealing and setting up new clusters or other modes of interaction between agents of innovation activities.

An important principle is *market orientation*. Since the issue is about prospective areas of regional innovation development, the market for innovations should be not only monitored but also created and stimulated.

Conclusion

The findings of St. Petersburg regional innovation system monitoring, discussed by the author in previous publications [5], show that now the support given to innovation enterprises is low and does not stimulate innovation activities.
It should be taken into account that the financial infrastructure of innovation activities should be fostered so that innovation enterprises could enter the market. The region and the state do not provide innovation enterprises with sufficient finances to develop new key technologies and form a strong innovation system in the region.

Venture investors, together with the state, traditionally work as financing sources. However, the statistics from Russian and foreign venture funds prove that investing in large projects in new sectors, accompanied by a high risk, is not common for venture business. Investors are much more likely to invest in industries which are demonstrating a dynamic growth today. Thus, venture investors in Russia are mostly willing to invest in software engineering, e-commerce, new services, advertising and marketing, as well as new transport and logistics technologies [12]. Thus, the issue of searching for promising technologies by venture investors to invest funds remains to be one of the most acute. One of the tools to tackle the problem is the system of technology brokering in the region.

Thus, this research study of St. Petersburg innovation system allows marking out the key areas for improving the efficiency of the system. They include enhancing the quality of innovation policies, making interaction between the actors of innovation activities more intense, improving the efficiency of investments made into innovation resources, developing the innovation infrastructure and overcoming the existing disproportions. The key areas are substantiated for strategic development of St. Petersburg regional innovation system based on the implementation of a regional innovation foresight project. The project uses the principles of general innovation management and is implemented by a consortium of universities, whose objective is not only to define the technologies which drive regional development, but also to determine to what extent the community of the city is ready to accept and introduce these technologies.

CSR in the Logistics Sector and Its Analyses

Ing. Simona Činčalová
University of Pardubice, Faculty of economics and administration, Czech Republic
simona.cincalova@student.upce.cz

Abstract

This paper deals with one of the topical issues of each company, corporate social responsibility. CSR is a voluntary concept beyond the statutory obligations of an enterprise that encompasses the economic, social and environmental spheres and fulfills the goals of stakeholders. The history of CSR dates back to the early 1950s and it consist of three pillars – economic, social and environmental. As in any industry, it is important in the logistics sector of CSR. Logistics is analyzed using PESTLE analysis and Porter's five competitive forces model. Finally, the trends in CSR are defined.

Keywords: CSR, logistics, analysis

Introduction

At present, Corporate Social Responsibility (CSR) is becoming a topic that is increasingly being discussed. The public and the competitors are more aware of how the business behaves towards consumers, the social and the environment, the employees and the social needs of society. Successful companies are no longer enough to focus on making profits. Also, the popularity of social responsibility is growing in the Czech Republic, and the number of organizations involved in this concept is increasing. There are competitions of companies where social responsibility is the main measure, looking at how the enterprise is perceived by the public.

According to Jirásek (2007), "be good" is a sought after characteristic of a business - to be a good supplier, to be a good employer, to be a good neighbor, etc. It turned out that it may not be the biggest companies at all to take a significant place on this scale. Social responsibility not only does not stand against economic success but, on the contrary, belongs to it and acts as a motivating and reinforcing factor.

Corporate Social Responsibility

The notion of "Corporate Social Responsibility" (CSR), although discussed over half a century ago, currently has no globally valid and consistent global definition. According to Kašparová and Kunz (2013) this may be due to the fact that CSR is based on volunteering, it does not have strict boundaries, thus giving scope both for a broad discussion and for a very wide understanding and interpretation of this complex concept by individual interest groups. Mura (2011) even takes the view that if there is a certain unified and universally accepted consensus in understanding the concept of CSR, this is because the term CSR has different meanings for different stakeholders.

Trnková (2004) states that an interested party (group, individual) is any person or organization that has direct or indirect influence, whether positive or negative, to the functioning of the company or, on the contrary, the company influences it. Stakeholder analysis is a very important part of

strategic management in this time (Slabá and Fiala, 2014). These are the following groups of stakeholders (Mádlová, 2010; Trnková, 2004; Dědina and Malý, 2005):

- customers,
- employees,
- suppliers and business partners,
- owners and investors,
- managers,
- local community.

These groups always vary by organization. However, depending on the type, it is possible to estimate what their interest is and what they are trying to do. Customers can be expected to be interested in the quality of the product or service, the reasonable price of the product and after-sales service. Employees assess working conditions in the organization, reasonable wages and non-financial benefits, reconciliation of work and personal life. Owners and investors are interested in the profit, growth and prosperity of the organization. Business partners expect quality contracts and negotiations as well as timely performance of commitments. The local community assesses the impact of the company's business on the environment, and the goal of managers is above all to harmonize the legitimate interests of each of these major groups. (Steiner, 2008)

History of CSR

The history of CSR dates back to the early 1950s. The roots of this concept can be found in the United States, when Howard Bowen first used the term CSR in its Social Responsibility of Businessman (1953) to demand social management considerations.

In the 1970s, the United Nations took the first debates and formed the foundations for CSR content. The concept gained importance in the 1990s, when the European Union became interested in it. In 1996, CSR Europe, the most important European headquarters dedicated to CSR, was established. Its aim is to provide a Europe-wide promotion of CSR, to provide education and advice in this area.

Another milestone was the Lisbon Summit in 2000, where top EU officials agreed that CSR development across Europe needs to be strategically promoted and promoted.

One of the most important documents in the area of social responsibility is the so-called Green Paper issued in 2001 by the European Commission. The Green Paper contains the basic principles, tools and approaches to CSR, as well as the first official definition of CSR from the European Union, which is based on three pillars of socially responsible behavior. The Kunz Green Paper (2012) unleashed a wide-ranging debate amongst representatives of companies, non-profit organizations and the general public. It points out that CSR is not only a matter for large firms, but must also become an integral part of small and medium-sized enterprises (SMEs), because they also depend on the competitiveness of the future Europe. There is important finding from most studies focused on the link between firm growth and size that smaller firms grow faster than their larger counterparts (Fiala and Hedija, 2015).

In the following years, two important organizations - Multistakeholder Forum (2002) and European Alliance for CSR (2006) - have been formed that bring together European businesses to help develop CSR (exchange of experience, monitoring existing CSR tools, creating new jobs, etc.).

As part of the Economic 2020 Strategy, the European Commission issued a Communication on a renewed EU CSR strategy for 2011-2014. (Tetreva, 2017; Kunz, 2012)

Three pillars of CSR

According to some authors (Kunz, 2012; Zu, 2009; Mullerat and Brennan, 2011; Henriques and Richardson, 2004), CSR is built on three basic pillars (so called triple-bottom-line):

- economic (profit),
- social (people),
- environmental (planets).

Fig. 1: Three pillars of CSR. Source: Kunz (2012)

Within the economic sphere (see Table 1), attention is paid to the main goals - continued profitability, which subsequently enables the company to finance CSR activities such as management and control of the organization, the fight against information and corruption, money laundering. Furthermore, organizations focus on fulfilling commitments, payment morals, consumer protection and data, compliance with contracts, transparency, credibility, establishing ethical codes, including marketing and advertising ethics, and respecting the rules of fair competition. The social sphere includes the development of human capital, the reconciliation of the personal and working life of employees, as well as outplacement and health and safety at work. Environmental issues include, for example, eco-friendly production, ISO standards and waste management.

Tab. 1: Examples of CSR activities within individual pillars

Pillar	Examples
Economic Area	Ethics and Avoiding Corruption
	Way of corporate governance
	Credibility and transparency
	Relationships with customers and suppliers
	Behavior towards owners, shareholders
	Respecting the protection of intellectual property
	Innovation and sustainability
	Respecting the rules of fair competition
Social area	Creating the conditions for employees to reconcile their personal and working life
	Development of human capital
	Outplacement
	Employee policy
	Respecting equal opportunities
	Occupational health and safety
	Open and friendly business climate
Environmental area	Reducing negative environmental impacts
	Environmentally friendly production, products and services
	Environmental Management (ISO Standards)
	Investing in green technologies
	Waste management
	Creating conditions to minimize traffic load
	Protecting natural resources, reducing energy and water consumption

Source: own processing according to Kunz, 2012

Analysis of the logistics sector

According to Štůsek (2007), logistics is a common concept, which is understood as the doctrine of solution of supply and security problems in various branches of social life. In fact, it is a solution to all circulatory processes, regardless of the form of organization. The concept of logistics is closely linked to the supply chain. Logistics greatly influences and facilitates the creation of values between companies, in the form of electronic information and physical goods.

Tomek and Vávrová (2007) states that this term was used and applied originallyin the military, but since the 1960s it has become a very popular slogan, which has many meanings in it. The goal of logistics is to optimize material flow and thus logistics performance based on individual technical components, logistics services and logistics costs. Logistics management itself includes three dimensions:

- functions - buying, production, sales and associated activities,
- institutions - building a network of entities inside and outside the business organization,
- information processing - planning, management, implementation, control.

Logistics companies must strictly stick to "time is money" because they need it quickly and efficiently process a large amount of information to deliver the right goods to the right place at the right time. Key success factors are economy, fast response and flexibility.

To analyze the logistics industry, the author chose PESTLE analysis and Porter's model. Macro-environment analyzes focus on assessing the effects of the environment. PEST analysis is called by the initial letters of influence: political (political), economic (economic), social (social), and technological (technological). Johnson et al. (2006) suggests that variations such as PESTE, PESTEL, SLEPT, SLEPTE, STEEP or STEP are created by rearranging the letters and adding other (ecological, legislative) influences. The logistics industry, as well as all sectors, is affected by the factors (see Table 2) that cannot be affected.

Tab. 2: PESTLE Analysis for the Logistics Sector

Factors	Specific examples in logistics
Political	Current political situation Position and stability of the government Support for foreign trade
Economic	Trend of GDP, Unemployment, Inflation The amount of money in circulation The emergence of new companies Trend of international trade
Social and cultural	Level of education People's lifestyle - eating habits, attitudes to work and leisure, to ecology
Technological	Transport and Information Infrastructure needed to develop logistics Speed of fleet obsolescence Government support for research New discoveries, results in R & D
Legislative	Legislation, Tax Policy Antitrust laws Environmental policy of the state State regulation
Environmental	Waste Management Access to environmental protection

Source: own processing

Of great importance for the development of the strategy is the analysis of the company itself. Needed to realize the position it occupies in the business environment. Michael Porter identified five forces that decide on their own long-term attractiveness of the market or market segment: competitors in the industry, potential new entrants, substitutes, customers and suppliers. (Kotler, 2007)

The goal of the model is to understand the forces that work in the business environment and to identify what is of the greatest importance for the company and which can be influenced by strategic decisions. For an enterprise that wants to achieve success, it is necessary to recognize these forces, to cope with them, to respond to them and, if possible, to change their actions for their own benefit. Specific examples that businesses encounter in the logistics sector are illustrated in Figure 2. Industry's current competitors are the most powerful in the model. There is a large

number of logistics companies and it is difficult for them to increase their market share. Often they conclude contract contracts for a short time, also because they offer similar services and compete mainly with the price. Potential newcomers have easy access to distribution channels, and as there is more and more opportunities and no high starting capital, there are almost no entry barriers to the industry.

Negotiating power of suppliers depends on fuel prices, politics, taxes, land prices and others. Entrance prices have a large share of how profitable the business is. The negotiating power of buyers is related to the number of current competitors in the industry - there is a large selection of them, customers can easily compare the prices of the services provided and in some cases vertical integration with the manufacturers. Availability of substitutes is high (eg rail, air), but does it depend on the nature of the goods transported (bricks or frozen debris?).

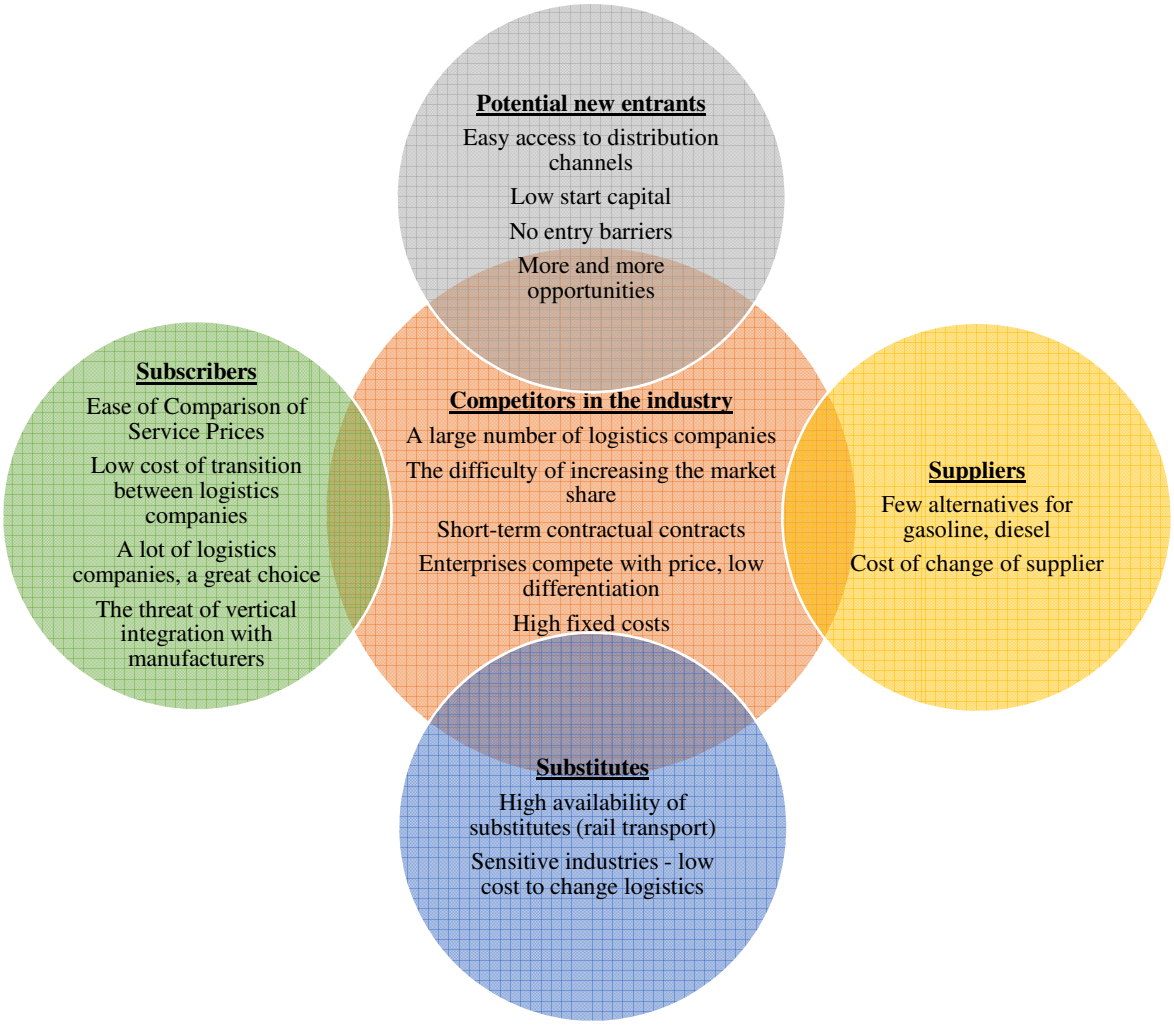

Fig. 2: Porter model for the logistics industry. Source: own processing

Conclusions

Corporate Social Responsibility (CSR) is among the appreciated features of an advanced society. The balance between profit and social responsibility becomes a strong link between business leadership and employees. And if the business wants to succeed in competitive struggle, it will gradually be forced to reconcile its economic interests with social and environmental issues, because it can only maintain its profitability in the long term and become competitive.

The long-term financial success of businesses is increasingly linked to corporate social responsibility and reporting. In the future, we can assume:

- the rapid development of modern technologies, which are increasingly demanding transparency (disclosure increases not only due to regulations, but also to better access to information and greater public interest);
- building consumer confidence through CSR activities,
- involving businesses in global challenges (education, environmental protection, health)
- employee involvement in decision making as they are the working capital of each enterprise.

Further research by the author will continue with a more detailed breakdown of CSR in the logistics sector and comparing the CSR activities of individual logistics businesses.

Crisis Management in Retail Sector. Cases of Russian Retail Chains

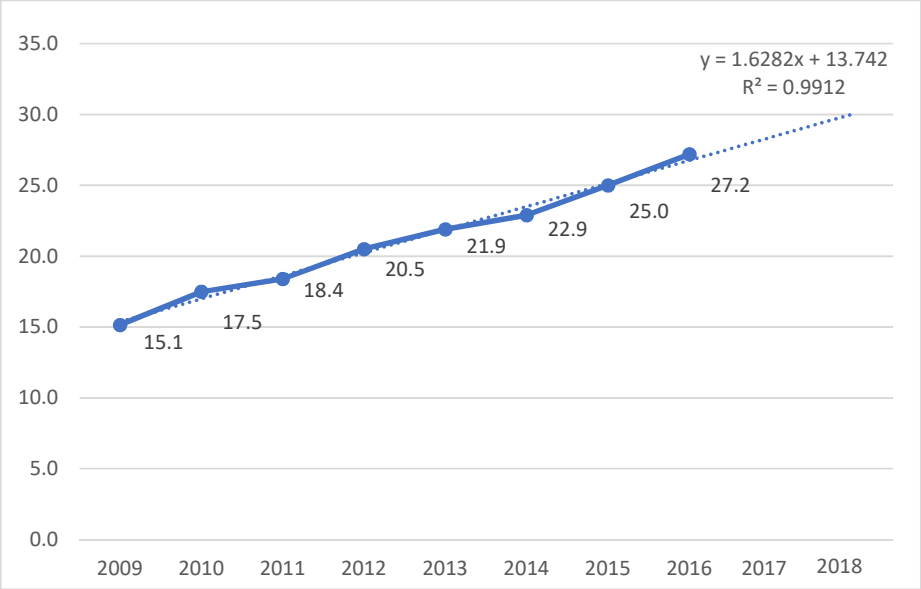
Veronika Panyukova, Associate Professor, Department of Management, Financial University under the Government of the Russian Federation, Moscow, Russian Federation, email: vpanukova@ya.ru

Abstract

Research in the field of crisis management in the retail sector is an interdisciplinary endeavour at the intersection of crisis management, marketing, logistics and finance. The current study is aimed at identifying an optimal set of anti-crisis measures allowing retailers to weather crisis and develop sustainably in difficult market conditions. Presently, chains are increasing their share of retail market in Russia. It is forecasted that they will account for 30% of total retail turnover by 2018. The paper provides analysis of anti-crisis measures carried out by Russian retail chains in 2014-2017. In crisis conditions all leading Russian retailers implemented organic growth and multi-format development strategies, and at the same time developed long-term partnership programs with manufacturers, financial institutions, etc. Such partnerships are instrumental in decreasing operational risks and overcoming downturn. The study outlines the types of synergies which retailers can achieve by concluding long-term partnerships with players from other sectors. Operational, financial, investment, communication and innovation synergies are being discussed. Synergies in supply chain are considered using the example of private labels programs. The paper also analyses vertical integration strategy aimed at securing reliable procurement of products. The current research project provides for subsequent efforts to assess how implementation of partnership programs influences retailers' effectiveness and performance in crisis environment.

Keywords: Crisis management, retail chain, strategic partnership

Introduction



Presently, retail sector executives and scholars are showing an increasing interest in development and implementation of anti-crisis programs.

During the last three years, Russian retailers have faced a number of major challenges:
- Fall in real disposable incomes and lower purchasing power of consumers (according to the Federal State Statistics Service of the Russian Federation, real disposable incomes were down by 0.7% year-on-year in 2014, 3.2% in 2015, and 5.9% in 2016);
- Decrease of working capital due to tightening of domestic fiscal policy and restricted access to international capital markets (Antipin P.A., 2015);
- Growing legislative pressure, such as amendments to the Federal Law Nr. 381-FZ "On Trade" regulating relations with suppliers;
- Disruption of procurement chains due to embargo on imports of certain products from a number of countries and government import replacement policy (Panyukova V.V., 2015).

The objects of the current study are leading Russian retail chains. Among domestic retailers they were the first to develop and implement anti-crisis policies.
By constructing a linear trend function based on the 2009-2016 data (reliability of approximation being 0.9912), it can be concluded that the share of chains in Russian total retail trade turnover will reach 30% by 2018 (fig. 1).

It is asserted that there is a steady growth of the chains' share in Russia's total retail trade turnover. The market power of leading federal retail chains is constantly growing as well.

This study seeks to identify optimal anti-crisis measures which could be instrumental for retailers as well as to assess effectiveness of retailers' partnership programs in challenging market conditions.

Source: based on Rosstat data for 2009 – 2016

Fig. 1. The share of chains in Russian total retail trade turnover, 2009-2018

The current research comes up with the following hypotheses:

1. Strategic partnership programs with manufacturers, financial institutions etc. are a powerful tool which retail chains can use to prevent and overcome crisis developments.
2. Strategic partnership programs within the retail sector are aimed at bringing operational, financial, communication and innovation synergies.

Literature review

Russian and foreign academic literature thoroughly analyses current trends in retail trade. Development and specific problems of retail chains are being addressed in the first place.

Foreign scholars discuss anti-crisis policies in retail trade based on evidence from certain regions or chains. For example, an interesting analysis of how crisis management influenced corporate reputation of Maxima retail chain, the largest in Latvia and Lithuania, was carried out in 2014. A conclusion was made that the organizations regardless of their type and size should pay significant attention to setting up crisis management systems, as well as obtain at least basic knowledge in this field as crisis significantly affects corporate reputation (Miglė Šontaitė-Petkevičienė, 2014).

Human resources management is one of the crucial elements of crisis management in retail chains. Foreign researches underline that in crisis conditions it is necessary to implement a time management policy as well as to form a special anti-crisis team with clear responsibilities defined for each of its members (Pelin Vardarlıer, 2016).

It is also pointed out that managing relations with suppliers and adapting supply chain play decisive role in development of anti-crisis programs (Stavros T. Ponis, Athanasia Ntalla, 2016). Choosing the right communication strategy has a noticeable influence on successful realization of anti-crisis programs as well.

Russian retail chains attempted to overcome the effects of the 2014-2015 crisis by realizing the following strategies: the strategy of growth, the strategy of achieving cost leadership, the strategy of developing multichannel sales, and the strategy of building customer equity (Bakharev V.V., 2016).

Our research shows that the problem of development and implementation of anti-crisis strategies by Russian retailers has not been comprehensively analysed. Moreover, strategic partnership programs and fields of their implementation have not been assessed in the framework of retailers' anti-crisis policies.
For this research, we assume that a strategic partnership "is a long-term partnership in the field of business and projects that have a strategic importance, which is formed by a limited number of participants and set up in practically any legal form" (Zobov A.M., 2012).

Research design and methodology

Russian (Ilkevich S.V., Shlapak V.S., 2014) and foreign (Dominic Elliott, Kim Harris, Steve Baron, 2005) scholars argue for using integrated, cross-disciplinary approach for drafting a long-term and sustainable business development strategy. We believe that within the services sector such strategy should include marketing activities, anti-crisis measures and supply chain management. The current paper is based on this approach.

The case study method was used in this research with an aim to identify crucial elements of Russian federal retail chains' anti-crisis programs and these programs' specific aspects. Case studies were conducted based on data available on official websites of the retailers (X5 Retail Group, Magnit, and Dixy Group), as well as information obtained from sector reports published by consulting companies and via monitoring of Russian and foreign media sources.

Results

X5 Retail Group, Magnit and Dixy Group are the largest players on the Russian FMCG retail market in terms of revenues and number of stores. An overview of these companies' operations and financials is presented in the table 1.

Table 1: Russian largest FMCG retailers in 2016

	X5 Retail Group	Magnit	Dixy Group
Market share	7,4%	8%	2,4%
Number of stores	9187	14059	2802
Retail space, thousand square meters	4301	5 068	952,5
Retail revenues, RUR billion	1025,6	1069,3	309,1
LFL change	7,7%	0,26%	4,4 %
LFL average check, %.	5%	0,9%	3,5%
Deloitte Global rank	71	61	198

**Source: compiled by the author based on data available at companies' official websites*

Russia's largest retailers reacted to crisis conditions (after the year 2014) in a different way compared to regional and local retail chains. Smaller retailers had to concentrate on survival and resisting downturn. At the same time, the leading players focused on development, achieving long-term competitive advantages and adjusted their anti-crisis strategies in these directions.

Table 2 presents main features of largest retailers' anti-crisis policies.

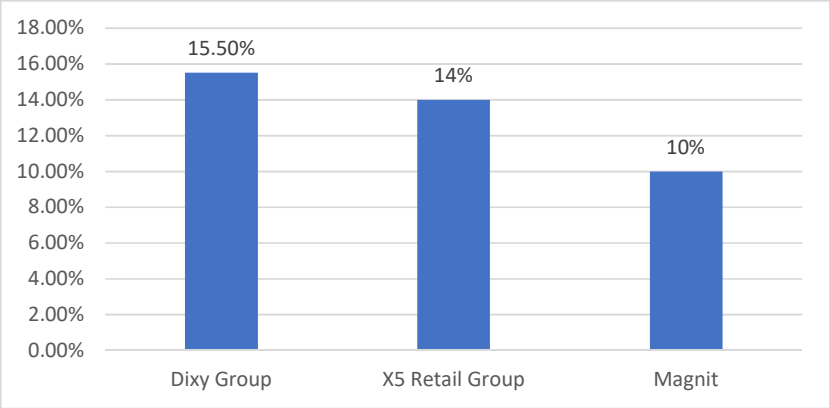
In response to the crisis, the three leading Russian retailers have chosen the organic growth strategy, which allowed achieving competitive advantages thanks to the economies of scale. Economically

viable opportunities for large-scale mergers and acquisitions in the sector did not emerge. According to Russian investment bank Aton, all the companies mentioned will demonstrate growth of retail space in 2017. It is expected that X5 Retail Group will expand its retail space by 21%, Magnit – by 15%, and Dixy Group – by 6%.

Table 2: Main features of largest Russian retailers' anti-crisis policies

	X5 Retail Group	Magnit	Dixy Group
Organic growth strategy	Aggressive organic growth strategy. Regional expansion.	Development of existing business model. Regional expansion and boosting retail space.	Plans regional expansion and boosting retail space. Closing down unprofitable stores.
Multi-format development strategy	Pyaterochka discounters, Perekrestok convenience stores and supermarkets, Karusel hypermarkets	Magnit convenience stores and hypermarkets, Magnit Family, Magnit Cosmetics, Magnit Wholesale (pilot project), Magnit pharmacy (pilot project).	Dixy convenience stores, Victoria supermarkets, CASH cash-and-carry store, Megamart and Minimart hypermarkets.
Private label management policies	Increasing the share of private label products to 20% of turnover at Pyaterochka.	Cutting down the number of private labels, optimising the range of goods. Increasing the share of private labels to 20% of turnover	In 2017, it is planned to increase the share of private label products in total turnover from 15,5% to 25%. Development of new private labels under umbrella brands.
Vertical integration	Abandoning the vertical integration strategy. Development of strategic partnerships.	In 2016, agreed to build an industrial park in the Krasnodar region. In 2017, acquired a Lipetsk region-based vegetables producer.	Integrating procurement of wholesaler Megapolis and retailer Dixy Group.

Source: compiled by the author based on data available at open sources



In environment characterized by changing state regulations and general economic difficulties, all the above mentioned retail chains revised approaches to procurement and terms of relations with suppliers. Entering into direct contracts with suppliers is now prioritized. For example, X5 Retail Group signed in 950 new suppliers in 2016.

In 2015-2016, as part of its anti-crisis strategy Dixy Group reconsidered its supplier lists and dropped a number of well-known brands. In an effort to optimize its range of products the company moved from shelves products with low turnover. However, such anti-crisis policy proved to be ineffective and disrupted operations. It should be underlined that Russian discounters and convenience stores traditionally carry a wider and deeper range of goods than foreign counterparts.

Synergy in the field of procurement can be achieved by developing and selling private label products. Private label programs play an increasingly important role in anti-crisis programs of the leading retail chains (information on share of private label products in leading retailers' total turnover is presented in fig. 2).

Due to falling purchasing power and changing terms of relations with suppliers, the share of private label products will have a tendency to increase. At the same time, it is necessary to carry out

continuing monitoring of demand for private label products and optimize the product range. Our analysis shows that Russian retail chains face a number of problems when realizing anti-crisis private label strategies: disbalance of private label offerings in specific product categories; inadequate pricing policy; lack of feedback from consumers; absence of quality control systems.

Source: compiled by the author on the basis of companies' official data

Fig. 2. Share of private label products in leading retailers' total turnover in 2016

In this connection, retail chains' managers should concentrate on the following main elements of private label development and promotion: distribution strength, pricing, communications system (Carmen Abril, Belén Rodriguez-Cánovas, 2016). Stability of relation between producers and retailers cooperating on private label products is usually higher compared to traditional supply agreements.

One of the approaches to achieving financial and investment synergy could be private-public partnerships. For example, the Russian Prime Minister, the Governor of the Krasnodar region and the General Director of Magnit signed a trilateral agreement in 2016. According to the agreement, the retailer will invest RUR 9 billion in developing an industrial park on a 146-hectare land plot located in the region. In the framework of the project, Magnit will build 14 production facilities, including a confectionary plant, a bakery, a tea and coffee packaging plant, an ice-cream plant, etc. In total, the company plans to build 40 new food production plants during the next 10 years.Such a business model allows the retailer to control and optimize its supply chain.

Synergy in the purchasing field can be also achieved by carrying out joint promotion activities. For example, in September 2016 Magnit organized in Volgograd a purchasing seminar for local suppliers, during which the retailer presented itself and its terms of cooperation, and at the same time provided a platform for local companies to promote their own products.

Synergy in operating activity can be achieved by implementing a vertical integration strategy. Cooperation between retailer Dixy Group and wholesaler Megapolis, which developed a joint project to deliver consumer products to non-chain stores, can be a good example. The synergy is expected to arise from merging procurement, logistics and distributions platforms of the two companies.

In its turn, marketing synergy can be attained by launching co-branding initiatives, such as offering joint banking products (debit and credit cards, etc.). One of the examples is a partnership between X5 Retail Group's Pyaterochka chain and Pochta Bank. Another example is presented by Dixy Group and Qiwi Bank which launched a joint project promoting usage of the bank's interest-free instalment plan cards Sovest in the retailer's stores.

Synergy in the communications field is achieved by implementing both multi-format development strategy and multi-channel marketing and sales. Agreeing with Chaplygin Yu.V., we consider multi-

channel marketing and sales as one of the options to achieve sales channels synergy and communications synergy (Chaplygin Yu.V., 2015).

In unstable market conditions, Magnit is implementing the diversification strategy introducing additional store formats. In 2017, the company launched pilot stores in two new formats – pharmacy and wholesale (Magnit-Opt).
This kind of synergy can be achieved both by the chain's autonomous development and by participation in partnership programs.

Marketing synergy can be attained by forming partnerships between retail chains and other service establishments. Such partnerships increase traffic, number of purchases, average check, and sales in general, which leads to financial and investment synergies. In 2017, X5 Retail Group announced a trilateral partnership agreement with private equity fund Acmero Capital and investment company Marathon Group to develop retail and services centres at transportation hubs (Passenger Service Centres). Each centre will include a Pyaterochka discounter, a pharmacy operated by Marathon Group, a food court operated by Acmero Capital, a ticket office, a parcel automat, an ABM, a payments terminal, etc.

Another example of marketing synergy could be a shop-in-shop arrangement. By 2021, The Central Union of Consumer Cooperatives of Russia plans to open on sublease conditions 5000 shops-in-shops to sell farmers' produce in X5 Retail Group's Pyaterochka stores. In addition, during the next two years the parties could open around 1000 stores under a joint brand, COOP-Pyaterochka. Besides marketing synergies, such cooperation will decrease risks connected to agricultural products deliveries and allow optimizing the supply chain.

Earlier, in 2015, Dixy Group signed a termless partnership agreement with Pharmacy Chain 36,6 giving the latter a priority right to open shop-in-shop pharmacies in Dixy stores.

The strategy of achieving innovation synergy via forming partnerships can be assessed using the example of cooperation program, which was agreed upon by X5 Retail Group and Internet Initiatives Development Fund accelerator in 2017. The Fund will be responsible for organizational and financial issues while X5 Retail Group will provide informational support, advice and a platform for approbation of the best innovation projects within the retail and services field. However, achieving innovation synergies in the retail sector requires size and market power, and could face obstacles such as low employee qualification.

Also in 2017, Dixy Group launched an accelerator for retail sector start-ups offering investments of up to RUR 1 million for projects, which promise to breakeven in less than half a year. The company is ready to consider projects aimed at improving effectiveness of sales process and customer service, as well as initiatives in the field of logistics optimization and new product delivery channels.

Innovation projects developed in the framework of partnership can be aimed at:
- introducing innovations into production processes (for private label products and at retailers' own production facilities, such as farms, etc.);
- procurement and supply chain optimization;
- improving customer service and increasing sales conversion;
- modernizing distribution centres, automating technological processes (for example, cooperation between retail chains and logistic operators);
- developing up-to-date business models for managing retail chains;
- optimizing retailers' business processes.

Conclusion

Partnership programs play an increasingly important role in retailers' crisis management systems. Such programs are aimed at strengthening market position, and at the same time are performing communication and marketing functions.

Case studies testify that strategies of the three leading Russian retailers rely on multi-format and multichannel development, organic growth and expansion of private label offerings.

This approach helps to achieve closer contact with consumers, identify clients' needs, and develop customer-focused offerings, i.e. greatly contributes to positive consumer experience, which is of strategic importance for all retailers.

Anti-crisis partnership programs being presently implemented by Russian retailers are targeted at procurement, operational, financial, investment, and innovation synergies.

During the subsequent research, it is planned to carry out a questionnaire survey and in-depth interviews with retail chains' executives to assess effectiveness of anti-crisis programs. Financial accounts of public retail companies will be used to evaluate the results of anti-crisis measures. Additional studies will be required to analyse vertical integration as an element of anti-crisis strategies in the retail sector.

Abstract

The entrepreneurial environment has been changing for years. The quality, cost and time requirements for companies have constantly increased and are still subject to the pressure, to adapt to the fast-paced and modified market demands. Shortened product life cycles as well as increased pressure for innovation due to increased and globally occurring competition are causing financial difficulties for suppliers Metze (2010). Through this described pressure for innovation, manufacturers and first-time suppliers, often referred to as the OEM (Original Equipment Manufacturer) in the automotive industry, and their suppliers, also called tier 1 and 2 suppliers, are moving closer together to optimize research, development and other costs, while improving adaptability to market needs in order to identify competitive advantages - www.vda.de (2016). As a solution, to reduce the financial difficulties, often companies install Supply Chain Finance as a tool to save their liquidity and restructure their financial structure. They install individual trade financing procedures and get more and more independend from their bank partner. This work is based primarily on expert opinions, which mostly come from press reports. It presents the positive effects that can arise, both for suppliers as well as for recipients of goods, with the optimization of supply chain finance by means of selected instruments and their mode of action or the optimization of the financial flow within the chain.

Keywords: Supply Chain Finance, Working Capital, Liquidity,

1 Introduction

To be able to cope with this challenge, companies see themselves compelled to adapt their financial flows to their value creation and to optimize their transactions in line with their needs - Huch / Fache (2015). This is where the Supply Chain Finance approach developed in North America and in Europe is taking place. The market volume which is to be used alone in France, the United Kingdom, and Germany, is about 470 billion euros, with Germany having the largest market potential of about 230 billion euros - Huch / Fache (2015). The global market for supply chain finance is subject to steady growth, whose market volume has increased in the past two years from 30 to about 40 percent. This can be attributed, among other things, to the very distinctive and capital-intensive automotive industry in Germany. The focus of this paper will be on how the various options will enable a better utilization of working capital. Furthermore, the work formulates that further positive effects, e.g. increased liquidity outside of traditional credit lines, are released and which leads to a stabilisation effect of the suppliers – Klüwer (2016).

2 Basics of Supply Chain Management and Its Content and Thematic Delineation

2.1 Definitions of the supply chain

In the literature, there are numerous interpretations and representation of the term supply chain. The Supply Chain (German supply chain) is a chain of successively connected suppliers that work

together within the value chain and work together in a coordinated manner until the final acceptance - Kortus-Schultes and Ferfer (2005).

> "The supply chain ... of a company consists of several departments, which can include purchasing and customer service. In this way, activities in a supply chain are associated with the organization of storage (material), the storage process itself, the supply and delivery of materials to the distribution of final products to end users - Kortus-Schultes, Ferfer (2005)."

Lukatsch formulates the concept supply chain as follows: It goes beyond the already mentioned interaction of a company and its suppliers and supplements these by the interaction with the customer, as so-called demand chain - Lukatsch (2010). The supply chain can be viewed as a link or integrated enterprise-wide organization in the value-added process, for the coordination of the entire value-added chain. The application fields of the supply chain generate the primary value added of a company and therefore represent a significant component in a company, regardless of location, size or industry.

2.2 Definitions of Supply Chain Management

The concept of supply chain management is not also clearly defined – Fettke (2007). However, the following consensus can be derived. Supply chain management emphasizes both the goal of increasing customer satisfaction as well as the cross-company perspective, which not only looks at its own company, but rather takes the entire value-added supply chain into focus. The coordination of the individual actors is decisive for a successful supply chain management. In addition, the goods, information and financial flows must also be taken into consideration - Metze (2010). Kümmer, Grün und Jammernegg interpreted this process as follows:

- "Strategic, collaboration-oriented and cross-company management concept
- The planning and control of the majority of the activities is demand-oriented (pull principle)
- It uses inter-organizational coordination mechanisms with the aim of integrating all value-added processes - Kummer / Grün / Jammernegg (2006).

2.3 Financial Supply Chain Management

In the case of working capital management, the management of financial resources in relation to transactions in procurement and sales is of paramount importance and this role is played by the so-called financial supply chain. In the Financial Supply Chain Management, two processes can be distinguished, the Trade Enablement and Trade Settlement. In trade enablement, the process steps of qualification, financing and pricing are focused on the business initiation between two partners in order to generate a successful completion. In the case of trade settlement however, the corresponding sub-processes such as invoicing, examination, complaint and payment, are taken into account – Lukatsch (2010). The financial supply chain management serves as an umbrella term for financial considerations within the supply chain. It enables the optimization of information and cash flow within the company and beyond. It leads to better use of working capital and helps to reduce the financing costs - www.jnm.com (2016.).

2.4 Supply Chain Finance

The term supply chain finance is not yet clearly defined - Huch / Fache (2015). The financial supply chain management is considered as a superordinate term of supply chain finance but supply chain finance is a sub-item, see Figure 1 - Metz (2010).

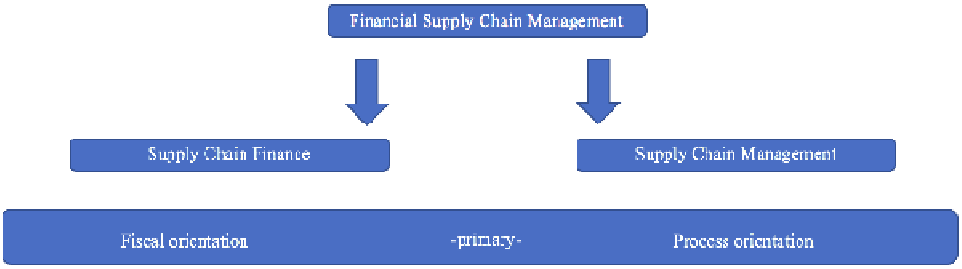

Figure 1: Structure of the supply chain finance (own graphic) .

Huch and Fache have defined the Supply Chain Finance (SCF) with respect to other notions as follows.

> "One way to fundamentally explain the concept of supply chain finance lies in the understanding that the SCF can be seen as a complement to the classical supply chain management (SCM). While the SCM is characterised by the optimization of logistical processes, supply chain finance focuses on the financial aspect of the supply chain and its optimization. At the core of the SCF is thus the question of which actor (e.g. supplier) in the supply chain finances what (e.g. stocks) and how (e.g. factoring) - Huch / Fache (2015)."

Even financial service providers are using the concept of supply chain finance to market different products in different versions - Huch / Fache (2015). The goal of supply chain finance is clearly to optimise working capital (net current assets) in order to increase profitability and ensure liquidity in the long run - Neuthinger (2016). The situation is different with suppliers and customers, on one hand, successful companies with enormous cash reserves achieve virtually no interest or even punitive interest rates in the current low interest rate environment while on the other hand, suppliers with structural liquidity fluctuations and high financing costs often act abstruse - N.N. I (2016.). The flow of payments and deliveries that occur within the value chain is often characterized by a strong divergence of the respective maturities. The supplier, standing at the beginning of the chain, makes his goods available and in return only refers after a previously agreed time (payment target) His consideration, the money for the goods or services. The supplier standing at the beginning of the chain makes his goods available and in return receives his reward, the money for the goods or services, only after a previously agreed time (payment goal). In the meantime, the recipient can in turn act on the market with the goods/services obtained. There often exists long payment terms between companies and in many cases even up to more than 60 days. Within this period, the producer's liquidity is created on one hand with a current negative interest rate of -0.318% in the short term (current money market interest rate – 3 months Euribor) - www.kurse.banking.co.at from (28.11.2016), on the other hand, the necessary funds for interim financing of the supplier are financed from 4% to over 10% p.a. via credit lines (overdraft loans) - N.N. I (2016). Managing payment targets and stocks has always been of great importance in working capital management. If the required liquidity is lacking, the entire supply chain comes to a halt or even to a standstill - Henke / Schulte (2016.).

The supply chain finance intervenes in order to ensure the liquidity of all actors during the entire process. Purchasing companies are interested in optimizing their liquidity, minimizing their financing costs, so as to benefit from optimal purchasing conditions in addition to the sold product. Long

payment targets and the associated high pre-financing costs are generally known to suppliers as a fundamental problem. With rebates and discounts, suppliers try to fight against them, but this usually has just a one-time effect - Henke / Schulte (2016). The approach of supply chain finance takes into account the interests of all players within the supply chain and creates a win-win situation for all parties involved - N.N.II (2016). The supply chain finance approach is owed to the entrepreneurial orientation of capital flows across the entire supply chain and synchronizes the physical and monetary transactions along the supply and value chain. Cooperative action between financial intermediaries (banks, factoring and similar financial service providers), suppliers and manufacturers, significantly reduces financing costs - Huch / Fache (2015). The various ways in which supply chain finance can be realized are presented in the following chapter; selected financing instruments and their effects.

3 Instruments for Optimizing Working Capital in Supply Chain Finance

3.1 Reverse Factoring

The supply chain finance concept is based on factoring or the reverse factoring approach, which is the reason why it is important to understand the basic system - Henke / Schulte (2016.). Reverse factoring is a special type of factoring. In classic factoring, a supplier sells his trade receivables to his end customer at a factor which in turn triggers a direct payment and in principle immediately becomes liquid. There is only a contractual relationship between a factor and its customer - Moonen I (2015). Figure 2 shows the interaction of the sequences. In the case of a so-called silent factoring, the end customer is not informed that the claim made to him is sold to a third party -Moonen II (2015).

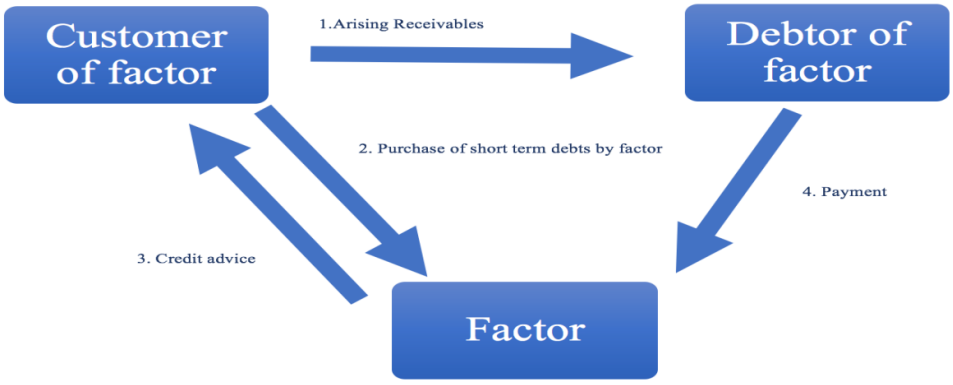

Figure 2: The factoring triangle (own graphic).

In return, Reverse Factoring is not aimed at the end customer but at the manufacturer's supplier. It is not considered the demand for the respective end customers, but rather the only concern is the sustainable connection between supplier and manufacturer. As can be seen in Figure 3, a joint framework contract is concluded with all three contracting parties. The supplier, the manufacturer (customer) and the factor are thus aware of the configuration and are aware of this. Reverse Factoring is also referred to as supplier or purchasing financing by the reverse function – Schaaf (2016.). In the case of reverse factoring, the bank assumes a form of interim financing of the supplier's claim. Thus the supplier receives his money directly within the agreed discount period and the buyer (manufacturer) has to pay only at the original maturity –Huch / Fache (2015).

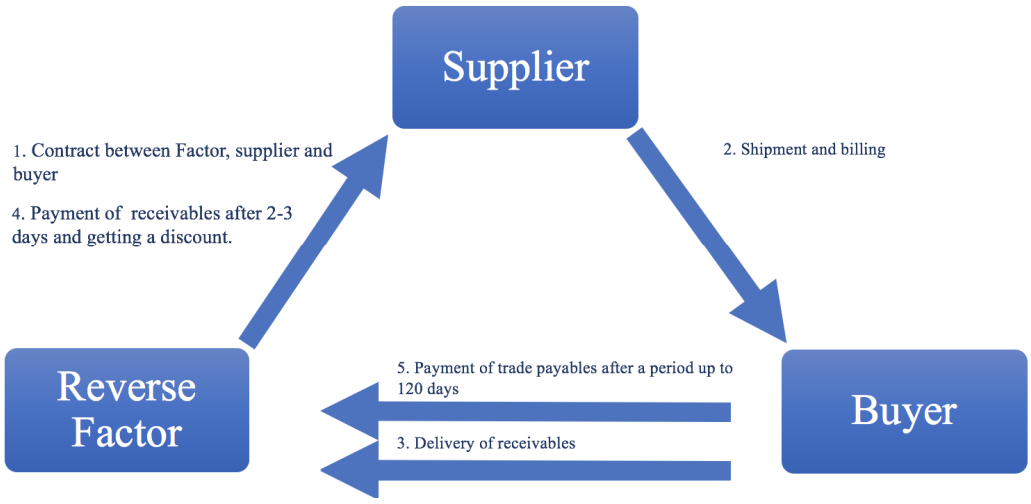

Figure 3: The Three Contracting Party Triangle for Reverse Factoring (own graphic)

The reverse factoring process consists of five stages. In the first stage, a basic contract is concluded between the three contracting parties, in which the most important components such as delivery and payment conditions are regulated. Then the delivery between the supplier and the manufacturer (customer) takes place. Third, after receipt and inspection of the goods, the delivery is released by the manufacturer and transferred to the factor by the supplier. In the fourth stage, the factor assigns the amount to the supplier within the discount directly after the request has been paid. After expiry of the previously agreed regular payment period, the manufacturer assigns the open amount to the factor. Reverse factoring programs are often directly used by original equipment manufacturers (OEMs) to facilitate customer retention and capital procurement for smaller suppliers - Henke / Schulte (2016). Factoring in all its facets, however, also has disadvantages or legal peculiarities to contend with. In the case of factoring transactions, the disadvantage of the industry-standard extended property is usually reserved - Klüwer, (2016). The extended retention of title refers not only to the delivered item, but also to the product in which the item was received. Thus, a possible resale of the product or the downfall of the item is also excluded in a new one - www.welt-der-bwl.de (2016.). For example, if raw materials or semi-finished products into a finished product, which has already been sold to a third party, the supplier's right of recourse (in the case of the factor) expires on the final product due to the good faith of the third party.

3.2 Finetrading or Reverse Factoring

Finetrading represents a further development of the reverse factoring. As a decisive difference, the lack of receivables is to be mentioned, unlike factoring. Here the Finetrader buys the goods directly from the supplier after the establishment of an intermediray trading company. In the end, the seller then supplies the goods directly to the client and not to the intermediary trading company. The established intermediary trading company acts only as a link between suppliers and manufacturers and does not influence the actual transformation process – Klüwer (2016.). The aforementioned problem of extended reservation of property may not be caused by the sale of the real merchandise which the Finetrader does. The Revers-Factoringpartner i.e. the intermediary company, can thus agree with the buyer on individual payment targets of up to 120 days - www.stenn.com (2016.). Figure 4 shows the detailed procedure of the process.

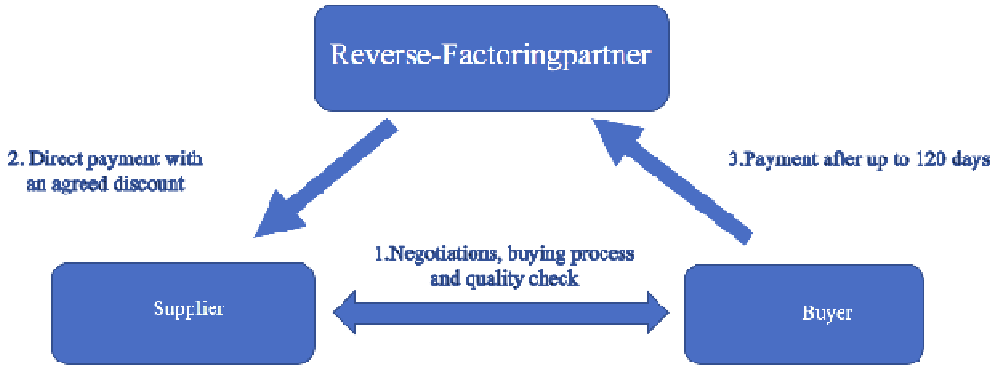

Figure 4: Reverse factoring procedure (own graphic).

Similar to reverse factoring, the Finetrading must have at least three parties with corresponding contractual relations and they must agree on the process as well as the corresponding conditions. This also necessitates a basic contract between all actors similar to that reverse factoring. The first step involves the negotiation between the customer and the supplier. Subsequently, the order as well as quality inspection and delivery are done out directly to the customer. However, the billing document about the delivery is not transferred directly to the client but rather to the Finetrader who appears to be the new owner after direct payment. Finally, the Finetrader invoices the same amount plus fees.

The 100% financing rate and the resulting flexibility with regard to the handling of the deliveries are often advantageous to different factoring forms. Another advantage of this is that elimination, which often occurs in factoring, crystallizes out in terms of sector and financing quotas - www.stenn.com (2016). Lastly, it should be noted that the collateralisation of volume in Finetrading is easier and more risk-free than factoring. Whilst finetrading is to be viewed as a classic commodity loan, factoring is used exclusively as collateral. The risk of bad debts has been passed on to the Factorer or its insurer.

Syndicated loans - www.bayernlb.de (2016) usually require a debt assignment to the financing banks. However, once such a factoring program has been issued, the factoring programs are usually no longer possible or only very limited and are possible with a high level of coordination with the bank holding the assignment - Klüwer (2016). Installing a Finetrading can also be useful if the supplier of the goods already uses classical factoring for liquidity reasons. The conflict of interest resulting from the already existing assignment of a claim assignment is circumvented by the concrete purchase of the Finetraders - Klüwer (2016.)

3.3 Working capital optimization through credit card financing

As one of the oldest forms of financing, the classic B2B credit card business can be included in the various supply chain finance options. Again, as in the previous cases, liquidity is quickly generated or a deferred payment is guaranteed. Similarly, as with the aforementioned possibilities, the user of the credit card generates classic credit. Again, there is a triangle relationship between the supplier, the recipient of the goods, as a classic borrower and the financer. The latter assigns his money to the supplier within a few days, while the buyer of the goods receives a longer payment target from his financer. In this way, intermediary-purchase financing also takes place in the credit card business which is both advantageous to the supplier and the buyer of the goods. One example is the classical Hamburger forwarding agency. This has annual toll fees of 350 T €, which of course severely limits the urgently needed liquidity. By using credit card financing, the forwarding agency is more flexible and can make the respective payments more flexible by deferred payments. Various kickback actions,

in the form of points and bonuses allows the company to refinance the fees incurred - Hülsbömer (2015). American Express for example, allows deferred of payments of up to 58 days. Depending on the sector, the type and extent of use of this form of financing may also result in a non-underestimated additional credit volume whose balance does not have a negative effect - www.business.americanexpress.com (2016)

3.4 CRX-Markets

The CRX markets are conceptually part of the FinTech approaches.

> "The term FinTech is composed of Financial Services and Technology and relates to technologies, financial services or their provision. This in addition to payment services includes technologies for the systematic analysis of large amounts of data (big data)." - www.wirtschaftslexikon.gabler.de (2016)

Even before supply chain finance, the introduction of digitisation has not stopped. In the USA, technology-based markets have already established themselves for the optimization of working capital - N.N. I (2016). In Germany, the conventional factoring have serious competition in the form of the CRX markets. The innovative instrument makes supplier financing more flexible than with the classic models, which leads to some advantages for the actors - N.N. I (2016). In principle, companies can use the digital supplier financing through market-based premature payments of invoices against additional rebates or discounts - N.N. II (2016). The market place creates a win-win situation for the successful transaction, both for the supplier and for the customer. As already discussed, there are currently hardly any lucrative investment opportunities for short-term surplus liquidity. The marketplace allows the stakeholders to enter into joint exchange in the sense of a bidding process after successful IT connection. The example in Figure 5 is intended to illustrate the procedure of the bidding process.

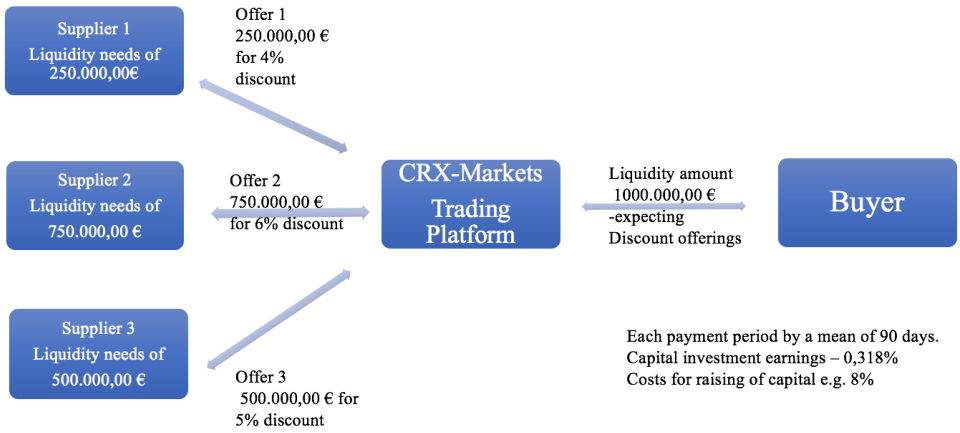

Figure 5: Functional example of a CRX market (own graphic).

The originally agreed payment terms between all stakeholders remain unchanged and the goods and services go as usual directly from the supplier to the customer. The purchasing company defines once a week how much free liquidity it can provide for the early payment of its suppliers. Each supplier gets a list of open items and can thus individually determine its worth for premature payments. The individual suppliers thus submit bids in the form of discounts to get their invoices prematurely paid by the customer. Since the different bids and the available liquidity are limited, it results in a market - N.N. II, (2016). In the above example, the available 1,000,000 euros would be distributed to Supplier II for an additional 6% discount to 750,000 euros and Supplier III would get prematurely paid for an additional discount of 5% to a pro rata amount 250,000. The prerequisite is that the individual invoice

items make this allocation possible. Vendor I, who only offered an additional discount of 4% for the invoice payment shown would not be awarded. The example demonstrates that the parties involved are subject to a win-win situation due to the bidding process. The suppliers reduce their credit costs, as all discounts granted are less than 8% of the capital intake costs no additional credits have to be included in the invoice payment shown. The customer obtains revenue from the additional discounts granted by the suppliers instead of creating the free liquidity at current negative interest rates. The IT bidding market is currently being used and extensively tested by companies such as Lufthansa and Vattenfall in order to optimize their working capital. In the event of insolvency, the stakeholders are not worse off than without the trading platform, since the platform has a non-committal payment promise by the debtor which can be transferred. This does not result in any additional risk for the participants - N.N. II (2016). The financing of the platform is generated by the brokerage fees incurred for transactions. At the moment, the system is still in its early stages because communication with suppliers is predetermined and everyone needs to implement the tool or the IT interface. The circle of users is still manageable, but is expected to grow in the future. Disadvantages of the new technology lie in the high cost of it interfaces and the long start-up times - N.N. II (2016).

4 Analysis of financial instruments and their impact

4.1 Balance sheet and financing effect of modern supply chain finance products

Liquidity and its exchange play the central role in supply chain finance. The ability to meet his claims at an early stage enables the vendor to compensate for his own rebate concessions by pulling cash discounts to his suppliers within the supply chain. For this purpose, an example account is created for the effectivity calculation.

- An invoice over 100,000 euros
- Payment term 90 days
- 3% cash discount for payment within 10 days

A credit of 8% would otherwise be required for the use of the cash account. A borrowing for the 80 days is worthwhile because the supplier's loan has a higher interest rate. If the supplier like in example 3.4 is lower, the effect will be even greater.

Cash discount-effectiveness calculation

1. Determenation of cash disc.amount	2. Determination of interest rate
z = Invoice amount-discount	p = (z * 100 * 360) / (K * t)
z = 100.000 EUR - 3.000 EUR	p = (3.000 *100 * 360) / (97.000 * 80 Days)
z = 97.000 EUR	p = 13,92 %

This is possible for the supplier in supply chain finance through the additional liquidity, even without additional bank financing in the case of a CRX market solution. Furthermore, all the instruments presented have the effect of debt reduction and thus the reduction of the balance sheet, provided that the new liquidity is used to reduce existing bank debt or supplier liabilities - Wöhe / Bilstein / Ernst / Häcker (2009.).

In the example of reverse factoring, receivables are taken from the balance sheet since the non-regressed purchase of receivables is a "true sale".. Due to the reduction in the balance sheet, the equity ratio is significantly increased, as shown in Example 7.

Balance sheet without factoring

A	Supplier balance sheet for... in Euro 1,000		P
Div. Assets	4.000	Equity capital	500
Recieveables from L&L	1.800	Miscellaneous liabilities	3.500
Bank	200	Liabilities	2.000
Sum	6.000	Sum	6.000

In the example, 90% of the receivables are purchased. The following balance sheet effect results from the purchase, coupled with the assumption that debts are settled in the form of liabilities with the additional liquidity.:

With a 90% sale of the receivables from 1.8 million euros, 180,000 euros still remains in the balance sheet (remaining 10%) afterthe sales -with the new liquid assets worth EUR 1.62 million, the liabilities of EUR 2 million were reduced to 380,000. The equity ratio thus improved from originally 8.3% to 14.16% (equity ratio).

Actual effect of the balance sheet redcution based on debt reduction

A	Supplier balance sheet for... in Euro 1,000		P
Div. Assets	4.000	Equity capital	500
Recieveables from L&L	180	Miscellaneous liabilities	3.500
Bank	200	Liabilities	380
Sum	4.380	Sum	4.380

Finetrading has a very similar balance sheet effect. The difference lies in the actual purchase of the goods by the intermediary company as a result of which no claim is made in the balance sheet (or only for a very short period due to the direct payment of the finetraders) of the supplier- The claim shall be payable in the accounts of the intermediary trading company. In the case of financing via CRX markets, the supplier balance sheets are also relieved by direct premature debt payments. All have one thing in common, the creation of additional liquidity or, in the case of the CRX market, through efficient use of the financial flows of suppliers and manufacturers, distribution of liquidity in favor of suppliers within the entire supply chain.

4.2 Win-win situation through professional supply chain finance

As the described instruments show, supply chain finance is essentially about creating a win-win situation in the process chain or at least optimizing working capital. For this purpose, the financial flows are being adjusted to supply flows or exchanged liquidity positions between the individual players. On average, buyers only pay their invoices after 30 to 90 days. The long-term payment targets lead to liquidity bottlenecks, especially for small and medium-sized enterprises (SMEs), and can have an effect on their existence. In most cases a low rating is accompanied by SMEs, which leads to poorer financing conditions - Henke / Schulte (2016). In addition, SMEs have a difficult access to capital markets, which highlights the importance of optimizing financial flows - Henke / Schulte (2016) Through targeted supply chain finance, the existing liquidity within the supply chains is released and thus provides an advantage over the value chain. The supplier benefits from the additional liquidity, the manufacturer from improved purchasing conditions and thus the material and payment flows can be approached in time - Henke / Schulte (2016). The coming together of the suppliers and the manufacturers creates, in addition to the financial competitive advantage, a closer

relationship with manufacturers, which strengthens the cooperation and reduces the risk of default on the part of the suppliers - Huch / Fache (2015). Final is aimed at reducing the total capital cost within the supply chain - Huch / Fache (2015).

5 Conclusion and Preview

The work discussed how supply chain finance is trying to present a win-win situation for the financial equipment of the entire supply chain. The fundamentals of the idea of trying to support the cost of capital throughout the cycle through both innovative new financing models, as well as the fair exchange of free liquidity reserves will benefit all stakeholders. In particular, the IT solutions and IT-based market platforms which are still in the early stages, still offer ample optimization and further savings potential. If, for example, the same approach is undertaken by competitors within an industry, the winner is the one whose supply chain finance has the best optimization. The old merchant's wisdom, "the profit is in purchasing" - Klopp (2016) also applies fully to the procurement of liquidity. Because of lower financing costs, sales prices can get reduced or higher profits with consistent selling prices generated.

Determining Project Management Practices for Enterprise Resource Planning System Projects

Tatjana Vasiljeva, RISEBA University, Riga, Latvia, Tatjana.Vasiljeva@riseba.lv
Elena Berezkina, RISEBA University, Riga, Latvia, Elena.Berezkina@riseba.lv

Abstract

The given research focuses on the study of enterprise resource planning (ERP) project management practice application in the context of choosing the most appropriate practice and improving an enterprise's business results. Organizations worldwide are dependent on ERP systems for their day-to-day operations, as this software allows enterprises to integrate a wide range of business processes throughout different functional areas to increase productivity, efficiency and their competitive advantage (Ramburn, Seymour and Gopaul, 2013). Grabot et al. (2008) outline the importance of ERP for any company and call it the 'backbone' of the information system.

Research methods applied: review of the literature; analysis of secondary data and primary data collected by interviews with industry experts. Through qualitative data and interviews with experts, project management (PM) practice was examined to determine the most relevant practice in ERP-related projects.

The findings of the empirical part include a list of five methodologies which are used or highly recommended for ERP projects; a classification of ERP projects types, which have different characteristics, work scope and duration; and a list of twenty factors important for PM practice determination. Recommendations from IT and ERP industry experts regarding the qualification of a project's internal and external factors are provided and an example of a matrix for PM practice determination is described.

The findings provide a basis for further studies in the PM field regarding the introduction of contemporary information technology and modern ERP to a business environment.

Keywords: project management, information technology, enterprise resource planning system

Introduction

ERP is a class of IT systems which has been developing rapidly since the beginning of the 1990s; Ray (2011) explains that 'enterprise' means any organization with a set of common goals. Hossein (2004) specifies that the system integrates and automates processes within the entire organization regardless of what kind of organization it is: a private company or a public or state organization. Successful implementation, support, maintenance and further development of ERP is vitally important for the existence of any organization. Elimination of problems related to the ERP system is essential for the secured functioning and development of the enterprise. The authors assume ERP projects have the same nature as any other software projects, acquiring the same signs of failure, success, risk and challenges. Ineffective project management techniques could be recognised as the intrinsic risk factors while accurate project management (PM) practice determination is definitely one of the key influencers of success. But the dilemma is how to improve the PM approach.

A wide range of literature sources recommend using Waterfall-based PM methodologies, which imply cascading, step-by-step realisation, a long planning period and delivering results at the end of the project. But the Waterfall-based approach should not be considered as the only valid methodology in a rapidly changing business environment as enterprises need to adopt and exploit flexible and dynamic methods and procedures of business process reengineering, bringing agility to ERP projects to ensure necessary changes in an acceptable timeframe.

Theoretical Basis of the Research

Hossein (2004) defines ERP as "an integrated computer-based system, which manages internal and external organizational resources". Ray (2011) offers a definition which is pretty much the same: "ERP is an integrated informational system built on a centralized database and having a common computing platform that helps in effective usage of an enterprise's resources and facilitates the flow of information between all business functions of the enterprise and external stakeholders". Both Ray (2011) and Hossein (2004) maintain that ERP-class software is not only about planning and that this term doesn't reflect the actual meaning and capabilities of the ERP system – the software helps run business functions throughout the whole organization.

Eckartz et al. (2009) recognizes three groups of ERP benefits: operational benefits, which include improved business processes, cost reduction, productivity and quality customer service improvement, and revenue increase; managerial benefits, which include improved decision-making and organizational performance; and strategic benefits, which include support of business growth, building business innovations, and cost leadership. Bradford (2015) added some other important advantages for organizations adopting ERP: data integration, real-time access to information, and standardization of business processes throughout the enterprise, including branches and subsidiaries. According to the Panorama consulting solutions report (2017), 17% of organizations would like to improve business performance by implementing ERP for better customer service (8%), preparing a company for growth (9%) and ensuring proper and timely reporting (14%).

Researchers mention the following project types:

- Initial implementation of an ERP system at an enterprise;
- Rollout, which is needed at large multinational companies for common business process support at branches and subsidiaries (Aloini et al., 2011);
- ERP upgrading (Munkelt and Volker, 2013; Bradford, 2015; Kalaimani, 2015) – regular ERP software version updates that could turn into a separate project as they may include not just technical but also functional updates. Ray (2011) named it a 'booming business' as the company regularly has to pay the vendor for software version updates that must be run by functional and technical consultants to ensure smooth day-to-day business activities;
- External maintenance and system support – to help users in the post-implementation stage for systematic monitoring of software performance and continuous improvements (Aloini et al., 2011, Ray, 2011) – is becoming a major source of revenue for vendors and consulting companies.

Large companies that have been using ERP for many years could still ask for constant enhancements, which are required due to fast-paced business development. ERP-related activities such as "data migration activity" and "consolidation and harmonization" might be considered as a separate project, but more often these tasks belong to the implementation project type. The concept "harmonization" could be data realized as "data harmonization" (Bradford, 2015) or harmonization of the ERP system with organizational business processes (Hurbean and Fotache, 2010) as well as harmonization of various software applications and data sources. If so, it can't be combined with consolidation projects as they have a different aim and include the opposite activities. Munkelt and Volker (2013)

acknowledge that implementation projects include different types of customization of ERP systems. They categorize sub-types of implementation project types, maintaining that there are codeless configurations, application development configurations and customized report configurations. If an organization has some specific business processes and there are some gaps in ERP software, it might be necessary to develop specific applications.

The authors completely agree with Hossein (2004), who pointed out the challenges of every ERP project: product complexity, which could require special consultancy; considerable time consumption; high implementation costs. The next common problem mentioned in many sources (Tarhini et al., 2015, Ray, 2011, Kimberling, 2012, etc.) which essentially impacts an ERP project is change resistance in the customer's organization. But there may also be other important aspects of ERP introduction: quality of business process design, establishing key performance indicators, measurement of performance, employee training, etc. Insufficient evaluation of these factors could lead the project to failure. According to Ray (2011), there have been several cases where implementation projects were not successful, but this seems to be an understatement. From many other sources, it is clear that ERP implementation is a real test for an organization. The International Project Management Association (2016) acknowledged such project failure criteria as going over the budget or deadline and lack of required quality delivered. Finishing the project within the budget is one of the main factors of success (Murray, 2009). For the success of every project, it is necessary to show the project's positive effect at the earliest stage, so the authors assume that splitting the project into smaller parts, which could be delivered to stakeholders as soon as they are implemented, might have a positive influence on the success of the whole project. Most ERP projects employ the old-school Waterfall-based project management approach that is recommended by a wide range of literature sources and vendors' methodologies (Ray, 2011, Capgemini, 2012, Harmon, 2016). This means that the company has to freeze its business processes for 17-25 months while the ERP project is executed, which is not possible in real life and could negatively impact business results, even dramatically deteriorate market shares and the satisfaction of customers. Responding to market demands, companies need to change their business processes regularly, and ERP projects have to be aligned to this strategy. The traditional Waterfall approach, with its long planning and realization cycles, can't be used as the only approach in such a sensitive area as business process automation. Companies should also employ new methodologies, which bring agility to ERP projects and support a flexible and dynamic attitude in strategy realization (Capgemini, 2012).

We completely accept the statement that in case an organization is changing the scope of business requirements during the lifecycle of the project, this could be the cause of ERP implementation project failure (Ray, 2011). Robson (2013) emphasizes that requirements identified at the gathering stage should be revised at the realization stage and the reason is usually the time difference between requirement elicitation, modelling and delivering. Users are unable to define their requirements precisely due to their lack of understanding of ERP system capability. Using a cascading, step-by-step ERP project execution framework inevitably leads to time and cost overrun, customer dissatisfaction, and lack of planned benefits. It is well outlined that organizations should have an effective PM approach to control all stages of realization (Al-Fawaz et al., 2008). Previous studies emphasize the role of PM among the critical success factors required for successful ERP implementation (Ramburn et al., 2013), stressing that poor PM is a main reason for ERP implementation failures.

Despite various previous studies in the ERP field, a clear procedure for PM practice determination related to ERP introduction at an enterprise has not yet been formulated. Many related questions appear when a company is facing the challenge of introducing new ERP or is trying to enhance the existing one: how to determine PM practice? What might be the consequences? How should they be treated? Which PM practice should be chosen considering the project's characteristics and conditions?

Research Design

In Figure 1, the conceptual model of the research is given.

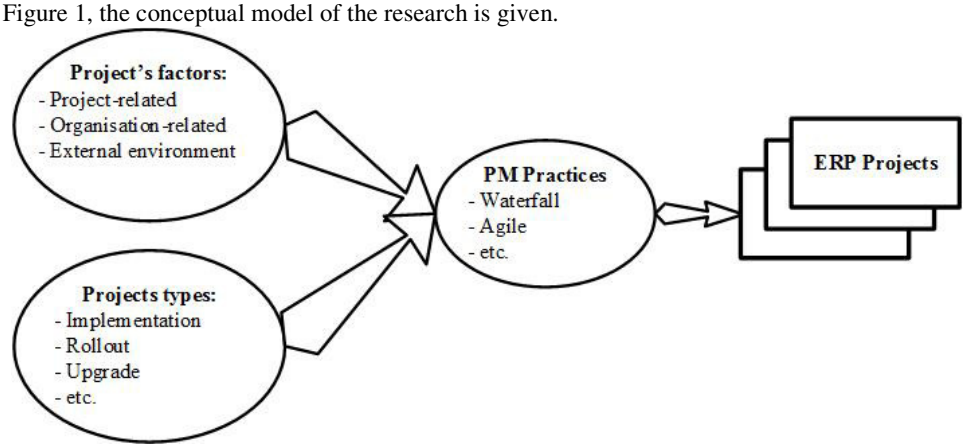

Figure 1: The conceptual model of the research: interaction of the dependent and independent variables for PM practice determination in an ERP project (created by the authors)

Three research questions (RQ) have been formulated.

RQ1: Which contemporary PM practices are applied for different types of ERP projects?
RQ2: What factors influence PM practice determination for different types of ERP projects?
RQ3: What ERP project types are performed on the ERP systems market?

This is an exploratory study; the empirical data were gathered in March-April 2017 during two series of interviews with experts in the project management and ERP system fields. Sixteen experts participated in the research; the respondents were considered as experts according to the following criteria:

- significant work experience in the field related to the research;
- a leading position and role at their companies;
- certification in the field of PM;
- experience in participating in international projects at leading international IT companies.

The research design is shown in Figure 2.

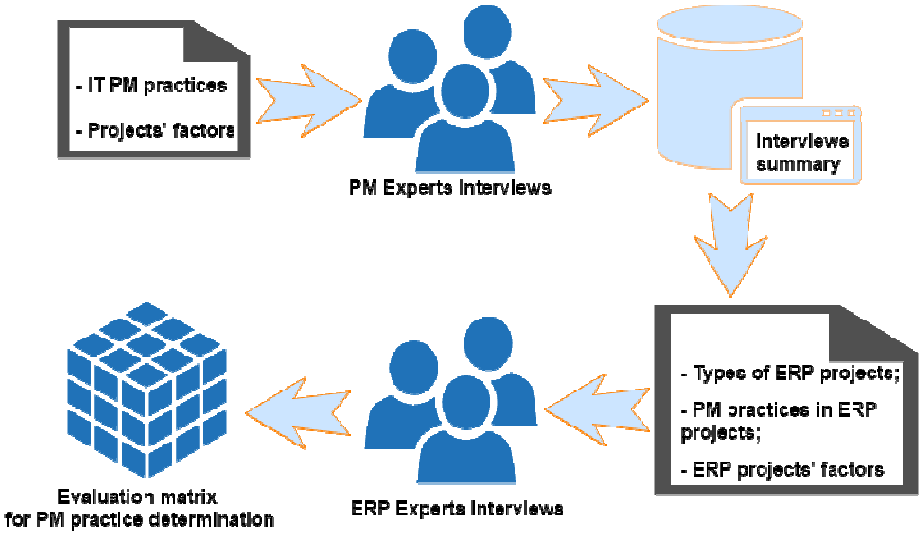

Figure 2: Research Design (created by the authors)

Two phases of research were conducted. In the first phase, the experts in the project management field were interviewed. The objective was to identify the main contemporary PM practices applied in IT projects and evaluate the factors influencing PM practice determination for IT projects. In the second phase, the experts in the ERP project field were interviewed. The objective was to identify ERP project types and factors influencing PM practice determination for application in ERP projects. All interviews were conducted directly by the authors in face-to-face meetings or Skype meetings. Semi-structured interviews with similar sets of basic questions for every set of respondents were accomplished, with some specific questions which were raised during every interview depending on experts' answers. The answers were documented in a specially designed template.

Research Results and Discussion

In this part, the authors state the main results of the empirical study, comparing it with theoretical literature sources for clarification as to what extent the results coincide with or differ from fundamental studies conducted by other authors.

RQ1: Which contemporary PM practices are applied for different types of ERP projects?

Cockburn (2005, 2007), Singhal (2013), Cobb (2016), Mills (2016), McLaughlin (2016), and Murray (2009) mention the main contemporary PM methodologies which companies use. They comprise the Agile project management philosophy and certain methods and methodologies in the Agile family, e.g. Scrum, Lean, Kanban, Extreme Programming XP, Crystal, the Dynamic Systems Development Method (DSDM), and Feature-Driven Development (FDD). The expert interviews conducted by the given research supplied the basis for defining a list of five methodologies which are highly recommended for use in ERP projects: Waterfall-based, Scrum, Kanban, Scaled Agile Framework (SAFe) / Enterprise Scrum, and a mixed Agile-Waterfall-based methodology. The experts defined two main PM approaches, Waterfall and Agile, emphasizing that the Waterfall concept is still in place in various cases. As a result, the empirical part of the research was devoted to the investigation of these two basic concepts.

Traditional PM practice is called Waterfall because of its cascade-like structure. In Waterfall methodologies, the project development process goes through several sequential phases from the

beginning till the end, and the customer can evaluate the work results at the very end of every phase, when it is already late to adopt changes. (Mills, 2016) Traditional plan-driven development according to Cobb (2016) is totally planned in advance, so there is a low level of uncertainty. Business users approve the well-defined requirements before the actual start of the project, the team meets the requirements within the schedule and budget, and any project scope changes are not welcome, making the project inflexible and very constant. Munkelt and Volker (2013) and Chow et al. (2016) maintain that project models for ERP system introduction resemble the traditional Waterfall approach to software development.

The main idea of the Agile ideology is the priority of high customer satisfaction, frequent software delivery for competitive advantage, and high motivation of the customer's representatives and developers who provide sustainable development of working software (Beck et al., 2001). Within Agile, practitioners outline the main Agile methodologies, also mentioned in fundamental literature: Scrum, Lean, Kanban, Extreme Programming XP, Crystal, DSDM, and FDD. All of them follow the same philosophy and practices, but "from an implementation standpoint, each methodology has its own recipe of practices, terminology, and tactics" (McLaughlin, 2016).

Most PM methodologies, frameworks and approaches described in the literature were also cited by the experts. They were encouraged to mention any number of relevant PM practices, and some experts were keen to give as wide a picture as possible. A list consisting of 17 methodologies, frameworks and approaches was obtained. The practitioners also mentioned that in some cases they employed their own, in-house-developed methodologies.

The most frequently used contemporary PM practices in software development projects in the international IT landscape according to the experts are given in Figure 3.

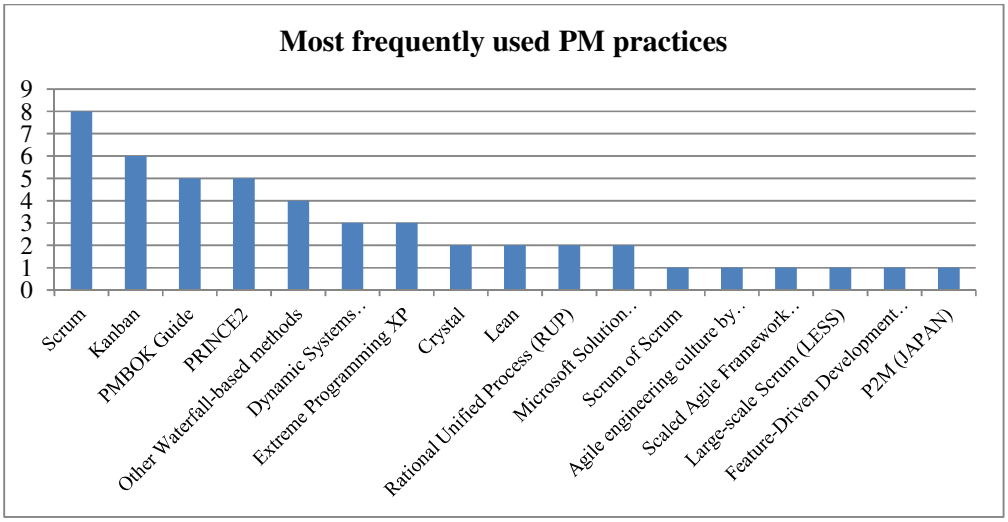

Figure 3: Most frequently used PM practices for IT projects (created by the authors)

RQ2: What factors influence PM practice determination for different types of ERP projects?

The project environment and various internal and external organizational factors have an impact on how projects are conducted. Major factors influencing the outcome of a project include the project's characteristics, environmental factors of the company and external factors (Murray, 2009). PMBOK

Guide, PRINCE2, and IPMA PEB have underlined environmental factors that may influence the project's performance and success.
All factors are categorized according to the following groups.

Project factor group:
- Stakeholders' level of engagement;
- Stakeholders' risk tolerances;
- Geographic distribution of facilities and resources, etc.

Organization factor group:
- Organizational culture (shared visions, mission, values, expectations);
- Organizational structure;
- Organizational governance, etc.

External factor group:
- Government or industry standards;
- Authorities' regulations;
- Quality standards.

Conducting the practical research, the authors found out which particular factors truly influence PM practice determination in an ERP project. The list of factors was offered to PM experts for discussion, evaluation and supplementation with other factors which are important for determining a methodology. The experts have extended the list with several factors related to the project, the customer's company and the external environment. The experts were asked to evaluate the factors on a scale of 1 to 10, where 1 = no influence on PM practice determination and 10 = significant influence. 0 means that this factor wasn't mentioned by the respondent at all. For the purpose of further research, it was decided to use only those factors which were evaluated with a score of 6 or more by at least three experts or evaluated with any score by the majority of experts. This theoretical statement was fully confirmed by the interviews' results, allowing the authors to compile a list of 20 factors influencing PM methodology determination in projects. These 20 factors were taken to the next step of the research for evaluation. The prioritized list of influential factors is given in Table 1.

Table 1: Factors influencing PM practice determination

Group of factors	Factor name	Average score
Project level	Level of project uncertainty	8.63
Organizational level	Flexible attitude to changes in tactics and priorities, readiness to adjust	8.00
Organizational level	Level of bureaucracy	7.88
Organizational level	Knowledge accessibility	7.75
Project level	Quality of definition of requirements	7.50
Project level	Team size	7.25
External environment	Market competition	7.25
Project level	Project planning perspective	7.13
Project level	Project risk level	7.13
Project level	Level of involvement of customer's team	6.75
Organizational level	Quality of the project's definition of objectives	6.38
Project level	Project stakeholders' geographical distribution	6.25
Organizational level	Stakeholders' risk tolerance	5.63
Organizational level	Resource availability / limitation	5.50

Group of factors	Factor name	Average score
Project level	Stakeholders' cultural differences	5.38
External environment	Government regulations	5.38
Organizational level	Alignment of project's objectives with company strategy	4.88
External environment	Product quality standards	4.75

For the clarity of the research, the expert's name and particular evaluation of every factor was excluded and only the average score of the factor was shown in Table 1. All factors in the list were arranged by average evaluation score. The factor "Level of project uncertainty" was evaluated with a score of 9 or 10 by the majority of the experts; the average score is 8.63. This means that most of the PM experts participating in the research recognized this factor as significant. The factor "Product quality standards" was evaluated with scores ranging from 1 to 9, and its average score is 4.75. This means that the importance of this factor for PM practice determination is not significant according to the experts.

RQ3: What ERP project types are performed on the ERP systems market?

The following types of ERP projects are mentioned in the literature: initial implementation, rollout, upgrading (software version updates), maintenance and support, and consolidation and harmonisation. This list is based on Ray (2011), Aloini, Dulmin, and Mininno (2011), Munkelt and Völker (2013), Vaman (2007), Bradford (2015), and Hurbean and Fotache (2010). But there was no clear, structured classification of ERP projects in the theoretical sources. Due to inconsistencies and contradictions in ERP projects type definitions, the authors found a research gap which this study aims to fill. Based on the expert interviews, the classification of ERP projects types was updated, each type having different characteristics, work scope and duration.

Implementation – Initial implementation of an ERP system at a company which did not have one before. SAP experts use the term 'greenfield'; Oracle experts qualify this type of project as a 'fresh' implementation. Both characteristics mean that there wasn't any serious level of business process automatization beforehand and an initial configuration of business processes in ERP is required. Customization of an ERP system may become part of initial implementation if the company's business processes differ significantly from standard ERP system business processes.

Rollout – In case an enterprise has branches / subsidiaries, all of them should have the same basis for communication, smooth business processes and document flow. Global corporations are keen on using the same software everywhere, supporting their business processes in all units by rollout of business processes installed at the headquarters. Consolidation projects may be considered as a subtype of rollout projects; they may happen if a company's branches and subsidiaries already had some ERP systems historically.

Maintenance and support – When an ERP implementation project is finished, the next stage is system monitoring, fixing bugs, change requests and realizing small ERP module enhancements. From the PM point of view, this type of project is the most flexible, enabling diversity in PM practices.

Upgrading (software version updates) – all experts included this type of ERP project in the list as ERP vendors constantly improve their software to increase productivity for better business outcomes, encouraging customers to move their business processes from obsolete software to new versions.

Consolidation, integration via harmonization – Ray (2011) proposed consolidation and harmonization integration as a type of ERP project, but the experts explicitly distinguished these two types of integration. The experts insisted that integration via consolidation of different applications on a single ERP platform is in fact a type of rollout project. As for integration-via-harmonization projects, most of the experts acknowledged that this constitutes an independent project type. Its purpose is the integration of systems built on different ERP platforms or on different versions of the

same ERP software. The aim is the harmonization and constant exchange of data originating from different sources.

Ray (2011) mentioned migration projects as one of the projects types; however, not all experts who participated in the research acknowledged this view. If a company transfers its business processes from one ERP system to another due to its natural growth or the need to move from a legacy ERP system, the consultant has to create all the settings in a new system. From the new ERP system team's point of view, this is initial or "greenfield" implementation. Data migration from an external source to the target system may be part of any project type above.

Based on the findings of the first phase of the research, ERP experts were asked which PM practices are applied in different types of ERP projects. Their answers demonstrated the very high level of conservativism in the ERP market and extremely slow pace of new trends and experience adoption. Of the great variety of PM practices, the experts mentioned just five, though every expert was permitted to give multiple answers – see Figure 4.

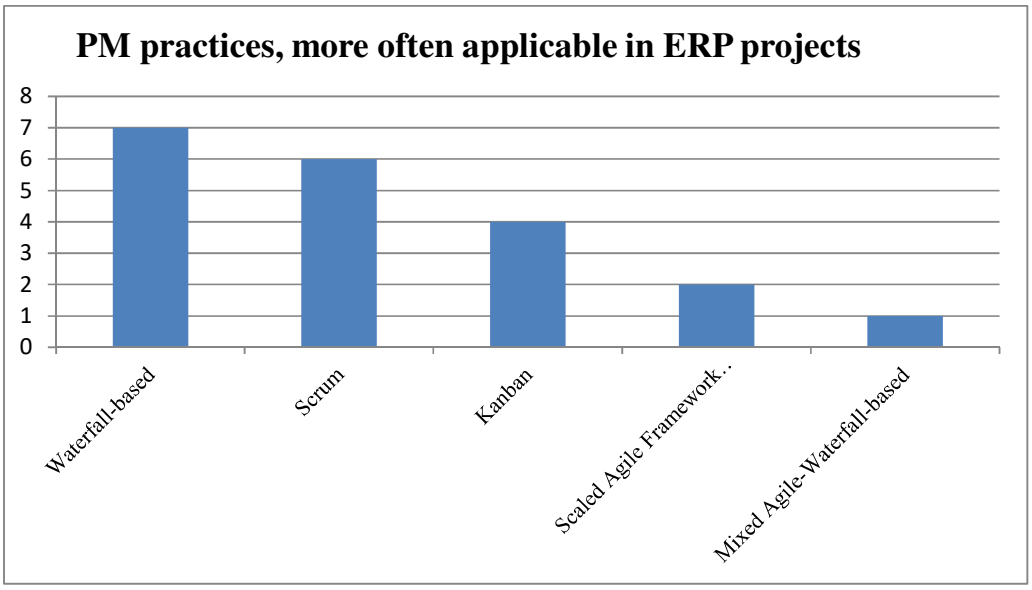

Figure 4: The most frequently applied PM practices in ERP projects according to experts' opinions (created by the authors).

As the next step, the authors compiled a list of factors influencing PM practice determination in IT projects. ERP systems experts indicated the possible values of these factors and identified the most appropriate methodology for each of the ERP project types. As a result, it was possible to find out the impact of every factor and every factor's values on PM practice determination and to construct a matrix for assessing project parameters (conditions) and project environments for PM practice determination. Some factors were evaluated as not applicable for particular projects types and were excluded from the summary tables. This means these factors have no influence on PM practice selection. For example, the factor 'Stakeholders' geographical distribution' doesn't have any effect on PM practice determination in implementation projects. A list of non-applicable factors for projects is given below:

- Stakeholders' geographical distribution;
- Stakeholders' cultural differences;
- Market competition in the project-related area;
- Alignment of a project's objectives with company strategy;
- Product quality standards;

- Quality of the project's definition of objectives;
- Stakeholders' risk tolerance;

The final step of the research was constructing a matrix for assessing project conditions and environments and for determining which PM practices are most suitable for a particular project. An example of a factor evaluation matrix for the implementation project type is given in Table 2 below.

Table 2: Example of a factor evaluation matrix for determining PM practice for implementation projects

Factor name	**Factor's value**	**Evaluation matrix**		
		Water-fall	**Scrum**	**Kanban**
Project planning perspective	Short-term (3-6 months)			
	Medium-term (up to 18 months)			
	Long-term	x		
Level of project uncertainty	High level		x	
	Medium level			
	Low level			
Quality of definition of requirements	Well defined	x		
	Poorly defined			
Level of involvement of customer's team	High level			
	Medium level	x		
	Low level			
Geographical distribution of stakeholders	Co-located			
	Located nearby (< 3000 km)			
	Located far away > 3000km)			
Total		**3**	**1**	**0**

The highest score is '3', for the Waterfall-based methodology that is recommended by the majority of experts for the chosen project type with appropriate conditions.

Conclusions

The significance of the given research lies in the investigation of arranging and managing ERP-related projects in the most appropriate way and increasing the effectiveness of relevant information technology use for competitive advantage. The comparison of empirical information with the theoretical background as well as the overall results the research obtained could assist an enterprise in choosing relevant PM practices for a particular project, achieving better business indicators and delivering an effective IT environment for business users and stakeholders.

Further research

The authors intend to continue research on the "Matrix for PM practice determination for ERP projects", test the matrix in different types of real projects, analyse the results and adjust the main parameters of the matrix to improve the PM practice determination process.

Acknowledgements

The authors would like to express gratitude to the PM and ERP experts who participated in the interviews. The results would not have been achieved without their passionate participation and input and valuable conversations and discussions during the interviews.

Preincubation as an instrument for increasing the entrepreneurship of young people- the case of Poland

Sławomir Jankiewicz, Faculty of Finance and Banking WSB University in Poznan, Poznan, Poland,
e-mail: slawomir.jankiewicz@wsb.poznan.pl

Abstract

One of the primary objectives of the economic policy in Poland is to generate a strong GDP growth rate. In order to maintain a long-term economic growth, it is necessary not only to secure capital for investments and introduce appropriate legal regulations. Another prerequisite is to prepare the society for challenges underlying the "informational revolution". State that the knowledge they gained in the course of their studies may not be sufficient to effectively manage in the current ever-changing economic environment. Nevertheless, such knowledge is a good foundation for development of entrepreneurship. Therefore, it is necessary to improve the practical skills and qualifications by promoting entrepreneurship among schoolboys. This is vital as graduates should learn how to independently operate on the market. This study provides an overview of an instrument which is to help to achieve the aforementioned objectives. The instrument comprises pre-incubators operating at school. With implementation of this project, the graduates of most peoples in the country will become more creative and prone to innovative ways of thinking, and that should make Poland more competitive.

Keywords: economic policy, entrepreneurship, preincubation.

Introduction

In the twenty first century there were structural changes in the functioning of the economies of the most developed countries. The result of which was economic growth, which was not accompanied by a correspondingly high increase in employment (Romer 2000, p. 476-513, 522-523; Kwiatkowski 2020, p. 7-8). Therefore, unemployment is a problem for many countries (including those in the EU), regardless of their political, economic or social policies (Uramova, Pala 2007). They differ only in terms of different character, scale and policy in this regard (Acoccella 2002, p. 15-158). However, the common point is that the highest impact has on youth. The difficulties finding a job by young people adversely affect the economy, especially local.

In Poland 28% of people (the most among OECD countries) are unemployed, including more than 71% of workers aged between 15 and 24 (ed. Jankiewicz, Pająk 2014). Which is not conducive to the social and economic development of the country. From a social point of view it is a threat to democracy and cohesion of society. It leads to poverty and its related negative effects (e.g. increase in crime, deterioration of health, etc.). Unemployment also causes "the violation" of human dignity and - in principle- limitation of its freedom (Jan Paweł II 1991). Looking for a job outside the country (as is the case in Poland) results in weakening of social and family ties (Jan Pawel II 1979).

The solution to this problem may be in the increasing of society. Therefore, the purpose of this article is to present the pre-incubation system as a tool for increasing the entrepreneurship of young people. It allows to shape entrepreneurial attitudes even at the level of the lower secondary school.

The article is descriptive and analytical, and is based on observation the functioning of two experimental pre-incubators operating in Poznan (whose author of this article was a co-author), critical analysis of literature and pre-incubator activities in practice. For its completion were used results of surveys conducted on entrepreneurship.

A survey of business support institutions was conducted to assess the potential of these organizations, the scope of support provided, and the forms of cooperation between organizations. The study covered more than 70 organizations supporting small business from the Poznan agglomeration. The point of reference for the verification of the assistance provided by these institutions was the information received from entrepreneurs about their preferences and expectations in terms of development support and the service available in this area. Data were also obtained through questionnaire survey on a randomly selected group of 90 SMEs. The largest group of surveyed companies were small enterprises employing up to 10 employees.

Further data were obtained throuh a study carried out under the project "Adjustment of training needs and qualifications of inhabitants from poviats: ostrowski, krotoszyński, pleszewski and jarocinski to the requirements of the regional labor market". In the aforementioned poviats, the study included entrepreneurs, labor office employees, post-gymnasium directors, guild leaders, and district office workers who were responsible for constructing educational offerings in schools (ed. Bondyra 2006). The aim was to assess the innovation potential in education, adjust the needs of education to the labor market, the scope of cooperation between the economy and education, and the impact of upper secondary education on the creative attitudes of young people.

Recent research made possible to determine the level of entrepreneurship among students and whether the process of teaching at higher education stimulates entrepreneurial attitudes. The survey was conducted among students of economics from the following universities: Poznań University of Economics and Business, Adam Mickiewicz University in Poznań, School of Communication and Management in Poznan, SGH in Warsaw, Wrocław University of Economics, PWSZ in Piła and PWSZ in Leszno. In the case of the five-year studies, the survey was conducted on fourth- and fifth-year students, while in the bachelor-level studies, students were asked to fill in a questionnaire for students in the last year of study. A total obtained 700 correctly completed questionnaires, which have been analyzed.

In addition, research was used:

- OECD - the analysis was conducted on the economic behavior of the inhabitants and the approach to economics. Poland took the last place and was overtaken by countries such as Thailand, Jordan, Albania, British Virgin Islands (OECD 2016a);
- NBP - conducted by Pracownia Badań i Innowacji Społecznych „Stocznia" and the IQS Group. Poles believe that they have a low level of knowledge about entrepreneurship and running their own businesses (as much as 69%), a market economy (63% think so) of financial institutions (64% of responses) and the use of investment vehicles (67% of indications). At the same time, 67% believe that they need the knowledge of economics, finance and economy (NBP 2015).

Unemployment of Young People as an Important Issue of Economic Development

Unemployment among young people is long-lasting and global. According to statistical data on the OECD countries, a dozen percent of young people find it difficult to get a job (e.g. 16.7% in 2009 and 15% in 2015) (OECD 2016b) which resulted in reducing the gross income (estimated in 2014) about 360-605 billion dollars a year, equivalent to 0.9-1.5% of GDP of the entire OECD area (OECD 2016c). This phenomenon was named - NEETs (not in employment, education and training), and includes all young people who are not working (because they cannot find a job matching their skills or expectations) or are afraid to start their own business (because of inability to make independent decisions, risk aversion and lack of passion and ideas for life) (Bynner, Parsons 2002, p. 289-309; Wilkinson 1995; York Consulting Ltd 2005; Harries, Roberts 2006; Akister, Mutty 2012; Sadler, Akister, Burch 2015, p. 508–520; Furlong 2006, p. 553–569). However, in different countries it covers a different age category of youth. At the EU level it is assumed that it affects people aged 15-24, although Eurostat statistics also include a group of people aged 15-29. Outside the European continent (e.g. in Japan and Korea) the NEET category covers a much wider group of young people, e.g. people between the ages of 15 and 34 (Furlong 2007, p. 101–121; OECD 2010, p. 45; OECD 2008, p. 40).

Due to the social problem that this group creates, synonyms for NEETs are eloquent (Quintini, Martin, Martin 2007; Bynner 1998, p. 29–54; ed. Bynner, Ferri, Shepherd 1997, p.10; Nudzor 2010, p. 16–17; e-journal of the British Education Studies Association 2016; ed. Strzelecki, Potrykowska 2012; Szcześniak, Rondon 2011, p. 241–251):

- going nowhere,
- Generation X,
- unregistered,
- omitted by statistics,
- lost youth,
- dismissed, discouraged, disappearing young people,
- uncommitted,
- "anti-anti" generation.

In Poland youth unemployment is one of the major problems. Reducing the activity of this social group on the labor market has the effect of not using the potential of labor resources and generating negative social, economic and demographic effects. They are due to:

- postponing the decision to become independent, start a family and run a household (EC 2012, p. 7);
- poverty, marginalization and, in extreme cases, even social exclusion;
- increase of social pathologies, such as crime, alcoholism, drug addiction, prostitution, etc.;
- economic emigration (often talented and educated people) (Work Service, Wrocław 2014);
- occurrence of disorders such as: insomnia, taking a lot of sedatives, apathy, nervous breakdown, suicide Plante 2010);
- disintegration of social bonds and social alienation;

- to adjust, after prolonged periods of inefficient searching, to live on benefits and supported by parents.

The first effects of the above described phenomena can already be observed in Poland. This happens because among the young long-term unemployed the lifestyle and work attitude are changing.

Employers also affected by this phenomenon, by losing potential employees. It has a major impact on the pace of economic development (for example, getting a job opportunity in the so-called The Old Union caused the emigration of young Poles at the level of about 2-3 million people). The unemployed young person does not earn (which has a negative impact on state budget revenue) and contributes to increasing central and local expenses (including social benefits, labor offices and other institutions dealing with this problem, vocational rehabilitation programs, social reintegration and, in the longer term, also payments to the pension system). Secondly, it does not contribute to the GDP. The costs incurred by EU countries for this (the lost benefits of young people due to unemployment and the increase in public finances due to NETTs) were estimated on average in 2011 at 1.2% of the GDP of the Community as a whole. The highest were in Bulgaria and Greece (over 3% of their GDP), and the lowest in Luxembourg, Sweden, Germany and Denmark (0.2% - 0.6% of GDP). In Poland it is estimated at 2.0% of GDP. Return to the labor market 10% of people in this group in the EU will be able to save about 10 billion euro a year (Europejska Fundacja na rzecz Poprawy Warunków Życia i Pracy 2012).

Therefore at the Community level are being taken actions to counteract this. One of them is the "European Job Mobility Bulletin", published since November 2010, which aim was bringing European citizens closer to the professional opportunities they face in different countries (about the impact of the EU on the labor market – Uramová 2007). The bulletin provides information on employers' needs for qualified workers and illustrates trends in labor demand and supply in individual EU countries. Further steps are based on the priorities set out in the 2020 Strategy. They involve the promotion of learning beyond the formal, which includes the development of entrepreneurial skills and the promotion of young entrepreneurship etc.

Efforts to reduce the size of the youth unemployment in Poland, already exist (MPiPS, MIiR 2014). However, there is no system in which the institutions of state and local government, as well as non-governmental organizations and responsible business within the framework, could operate together. Legal forms of cooperation exist, but they are limited to analysis and recommendations and do not create instruments. The pre-incubation – an instrument important for promoting entrepreneurship among young people, is marginalized. System allows with a small financial and organizational investment "to make" entrepreneurship. It was confirmed by surveys on entrepreneurship conducted among students of economic studies in Poland. They have shown that a large proportion of graduates do not have the appropriate qualifications and skills. Knowledge acquired during the studies does not match the requirements and expectations of the modern labor market. Low level problem and incompatibility with the needs of the market also applies to other levels of education. Education in the country does not shape entrepreneurial attitudes, despite - what should be highlighted - existing potential among young people and their needs in this area (Brdulak, Godlewska, Matłachowski 2004, p.27–34). Graduates often cannot "find" themselves after graduation and fall into passivity. It is also a result of lack of prospects, because young people are offered only free internships, so-called junk contracts and work below expectations, which is associated with low wages and lack of career prospects. On the other hand, this is a consequence of the young man's ambition and lack of self-reliance.

Basic Assumptions of Pre-Incubation Supporting Youth Entrepreneurship

In the classic approach, incubation supports companies that are already established, often with the launching of cooperation. However, it is often the case that a person perceives the opportunity to launch the products or services on the market, but he does not do it. It concerns also to technologically advanced or innovative products developed by academics. This is due to the lack of entrepreneurial skills and characteristics typical of entrepreneurial attitudes, also with little economic knowledge or lack of practical skills in this field and lack of knowledge of legal issues (e.g. how to obtain licenses or permits, protection of intellectual property issues, which are important for undertaking high-tech business activities).

Incubator is needed to help to "get" entrepreneurial characteristics before starting a business, preparing for market practice, and helping to refine business. Therefore, to distinguish this support organizations from the "traditional" incubation, the name pre-incubation was introduced.
The participation of young people in the pre-incubation program will allow for the addition of knowledge and will increase the number of established companies (mostly micro-enterprises) and the development of skills affecting entrepreneurship, e.g.:

- creative, analytical and synthetic thinking
- innovation,
- creativity,
- perseverance, responsibility and ability to make decisions,
- independence with the ability to cooperate in a group,
- negotiation capacity and effective communication,
- ability to draw conclusions from mistakes,
- resource management,
- planning and implementation of the project.

The pre-incubation system should provide support in identifying the market for the product or service through surveys, search for business partners and customers, and lead to the first sale of a service or product offered by a person acting in that institution. The "first sale test" is important in terms of knowing customer expectations and determining the demand for the offer. This is important for a future entrepreneur when deciding on the establishment of an enterprise. It should also prepare to have contact with people or institutions offering capital (e.g. venture capital) or even establish a permanent relationship with them in order to facilitate the raising of capital.

Another benefit which results from the operation of pre-incubation is the awareness of the advantages and disadvantages associated with running a business and obtaining professional care in the relevant fields (e.g. management, marketing, finance, etc.).

The most important factors influencing the success of the future company, and guaranteed by the functioning of the pre-incubation, are:

- The process of moving from ideas to business start-ups taking place in friendly environment,
- providing access to research facilities and highly qualified staff,
- help develop a product or service,
- providing access to research facilities and highly qualified staff,

- assistance in product or service development,
- opportunity to assess market potential
- improving the competence and knowledge through training, workshops and case studies,
- limitation of individual risk.

In general, it should create entrepreneurial behaviors in different sectors (the participants themselves decide on the type of activity). It is also possible to set up more specialized units (for example, universities may set up technology pre-integrators bringing together researchers or people who are thinking of running a modern technology or social company that brings together people who are socially excluded) (Aernoudt 2004).

Theoretical classes (lectures, etc.) should be conducted in a group of people with similar features (e.g. education, experience), because it makes it easy to prepare the participants properly. In the case of practical classes (cooperation with companies, problem solving, case study), it gains better results in terms of knowledge, competence and age. When pre-incubation activities are addressed to students, it is essential to focus on providing them with practical knowledge and good examples. At school they receive theoretical knowledge, but practical they must acquire themselves.

Because aid should be limited in time, it seems reasonable to adopt a time limit a person's activities in pre-incubation, just as is the case in the incubator. The co-operation of the person concerned with the pre-incubation, for students of one to two years, should be sufficient to raise the skill level to make the right decision. For people who already have professional experience this period can be shortened to 6 months.

For concept verification, tested pre-incubation systems were launched in 2006. First in one of the universities in Poland and the other in the institution which provides help to the long-term unemployed. Their activity was completed in 2010. The effects of pre-incubation system activity were very positive. Participants who had a business idea could evaluate its probability and refine this idea with the help of experts. People, who did not know how to precise what should be the subject of their business activity, could (with expert support) look for free markets niches and develop a business plan.

An example might be the plan to open an internet cafe by a student in a small town. In the case of noticing the existence of market demand, but lack of the own know how, the participants looked for similar companies in other countries and on a franchising basis they transferred them to Poland.

During the pre-incubation system functioning, participation in it allowed to set up an economic activity of 70% of participants aged up to 24 and 80% over the age of 50 years. The business that was undertaken was concerned to different industries. From the standard, e.g. already existing activities (e.g. the establishment and maintenance of greenery, ceramics, care for the elderly and children, or the manufacture of soaps or candles), to rarely found in Poland (e.g. electronic translation agency, social image, selling works of art).

The market evaluation and the first sale test, not just expert opinions, turned out to be very important. In a few cases, their evaluations were wrong. For example the idea of opening an electronic translation agency. The business was based on the fact that, after signing the framework contract, the company could send the translated text and receive the translated work the same way. Because of the number of translation agencies, experts rejected the project as unsuitable for implementation. Attempts by the participants led to the execution of questionnaires and consequently to creation of such activities with

positive effect (companies participating in the survey declared the signing of the contract with the company after its establishment).

Several dozen percent of the participants did not decide to start a business. This was not often due to the lack of ideas, but the risk aversion and little confidence in one's own skills.

Conclusions

The survey conducted by the author on institutions supporting SMEs, entrepreneurs and students as well as surveys of other institutions (among others NBP) showed that entrepreneurship is of great importance for employing young people. However, education in the country focuses on theory rather than on the transfer of practical skills. It does not create entrepreneurial behavior. Upper secondary schools (despite the entrepreneurship lessons) or universities do not provide knowledge about how to run their own businesses, they do not emphasize the value of individualism and innovation. The educational offer should therefore be enriched with actions that will promote the development of entrepreneurial attitudes. Helpful in this action can be pre-incubators. The 3-year-old test incubators (which were created by the author's concept) have shown that they are an effective instrument for promoting entrepreneurship.

For maximum effect, they should not take participants for a few months (as was the case during the test) and a longer period (1-2 years). It would be best if the participation of young people in the pre-incubator was guaranteed at the level of post-gymnasium. At this level of education attainment, or at this education level a subject entitled entrepreneurship was introduced in Poland. Its aim was to achieve the same goals as the pre-incubation (e.g. to increase youth entrepreneurship). It turned out that didn’t fulfil the requirements. Teachers treat entrepreneurship lessons like any other school subject (e.g. boring and theoretically). Learning definitions and rules does not affect the growth of the society's entrepreneurship and even discourages self-reliance.

The state rightly pointed out that there is a need to increase the entrepreneurial spirit of the society, but the lessons should be exchanged for youth participation in the pre-incubator. Such exchanges will bring both financial and social benefits.

The Energy Sector as a Barrier to Economic Development in Poland

Sławomir Jankiewicz, Wyższa Szkoła Bankowa w Poznaniu, Poznań, Poland,
slawomir.jankiewicz@wsb.poznan.pl
Mirosław Kowalik, ENEA S.A., Poznań, Poland, miroslaw.kowalik@enea.pl

Abstract

Poland has the ambition to maintain a high rate of economic growth over the next several years. However, to do this we must meet many conditions. One of them is to ensure that the supply and quality of electricity in relation to needs. Article synthetically analysis the basic barriers to energy development in Poland, which cause that the development of capacity and electricity transmission can be less than demand. As a result, it may cause a significant reduction in the pace of economic development.

Keywords: economic policy, energy policy, energy development barriers.

Introduction

The task facing Poland is to increase the dynamics of economic development, which will require the supply of electricity in a sufficient quantity and at a relatively low price to economy.

The aim of this article was to present of the basic barriers to energy development in Poland, which should be overcome if we want to ensure the proper supply of electricity to the economy, which is a prerequisite for increasing the pace of economic development.

Power Distribution Network as a Barrier to Economic Growth

One of the problems with national networks is age. The level of the transmission grid decapitalisation is above 70% (Including 110 kV lines of about 75% and 220 kV lines of up to 80%) (AZ-SYSTEM 2009). This causes us to have frequent failures (the SAIDI indicator is even several hundred minutes long) (URE 2016) and significant transmission losses (it is estimated that in 2011 they amounted to 7.3% of total energy introduced into the system and cost PLN 2.1 billion) (Rudźko 2012). In addition, the density of electricity networks in Poland is twice lower than in our western neighbors. Modernization and construction of power grids is limited due to the lack of adequate financial means for the sector to engage or lend, as well as bad legal regulations that causes the investment process to be extended even to several years.

Supply of Electricity as a Barrier to Economic Development

Many experts (Jankiewicz 2014a, p . 341-351) and institutions (Bil et al. 2010, p. 23) warn that Poland needs to prepare for possible energy supply disruptions. This is because the power plants have a heavily exploited estate. More than 60% of installed power is in units that are over 30 years old (of which 1/3 is nearly 40 years old) and only 20% is younger than 20 years. Old units will have to be excluded from exploitation (estimated to be over 16,000 MW by 2030) (Ministerstwo Gospodarki 2009; Pricewaterhouse Coopers, ING Bank Śląski 2011). Investments accepted for implementation have less power (about 8.5

thousand MW) (ARE 2016), rather we will expect increase in demand for electricity in the future. It is forecasted that by 2030 there will be an increase in electricity consumption per capita of about 3000 kWh and thus will be about 7500 kWh (ie the current average for EU countries) (Jankiewicz 2013, p. 27-38). More demand is also expected by economic operators, which will be connected with the increase in production and services and the increase in the innovativeness of the economy. It is estimated that by 2030 the installed capacity in national production units should increase to minimum 46500 MW from the current 38000 MW (MAiC 2013).

The lack of coherent and consistently implemented government policy in the energy sector is not conducive to Increasing supply of production sources. Increasing investment, apart from the technical aspect, require seek new sources of financing, which is very difficult. In the case of the largest electricity producers, the majority owner is state that has serious problems with the sustainability of public finances. So the state is trying to maximize revenue to the budget, and for this reason the priority is to make dividends from companies in which it has shares, but not their development. Banks, on the other hand, will not lend more than acceptable risk (ie up to 4-5 times EBITDA).

Human Factor as a Barrier to the Development of the Energy Industry

Currently, in Poland, on the energy market there is a situation of dominance of large state-owned corporations, which have a privileged position. This stops the process of introducing market mechanisms and restructuring in the sector. When we analyze the costs and effectiveness of operations in the Polish power industry, we note that there is potential to reduce employment. Production companies employ up to four times as many employees (in conversion on 1 MWh) as compared to the West European level. In production companies there are not only over-employment, but also extensive so-called social packages. Industry growth requires an increase in labor productivity, which in turn forces a change in personnel management. The development of the energy sector will be determined by changes in the structure of energy production, causing reducing employment in large enterprises based energy coal, for small RES. It will also affect the labor market. There will be an increase in demand for distributed energy specialists and infrastructure security (Matusiak et al. 2009; Jankiewicz 2014b, p.113-116). Currently in Poland there is a deficit in terms of personnel for the modern economy, including for the modern energy industry. This is reflected in numerous reports, discussions and studies undertaken by both government agencies (Poland 2030 - Development challenges. Report of Strategic Advisors to the Prime Minister), scientific bodies (National Foresight Program Poland 2020), as well as the business community and employers' organizations (including project the Qualifications for employers, carried out by the Labor Market Council PKPP Lewiatan). Utilizing the opportunity that the energy industry can develop for the economy, requires a proper education policy. It is necessary to create appropriate courses and specializations in vocational and technical schools and also in universities. Bearing in mind that the education of an employee and the acquisition of his competence takes time.

Conclusions

The above-described synthesis of basic problems in the energy sector shows that we have difficulties in achieving the efficiency (including cost) and innovation of the Polish power industry and ensuring a stable investment and regulatory environment. Legal considerations have a negative impact on the development of the energy market in Poland, inter alia by increasing the risk of the industry, causing preference for selected fuels from which electricity is generated, and reducing the company's creditworthiness and thus

the ability to finance new investments. Thus, they create significant restrictions on the supply of electricity in Poland.

The alignment of distribution entities, resulting from the separation, caused transmission companies to focus on legal and organizational changes rather than on development.

As a result, despite the decapitalised transmission network, there are no adequate modernization programs implemented, and due to the lack of restructuring, there is also lack of funds for the necessary investments. A positive development scenario requires a stable legal framework and predictable conditions for investment in the power industry. The regulations governing the operation of renewable energy must be modified. It is necessary to develop and consistently implement development plans for energy sector. The education system needs to be adapted so that the industry receives the employees needed.

Marketing in Higher Education in the Czech Republic with a Focus on the Utilization of Websites and Social Media

Ing. Karolína Ptáčková, University of West Bohemia, Pilsen, Czech Republic, ptackovk@kmo.zcu.cz

Abstract

This research study focuses on a comparison of selected universities in terms of their communication with the public through the Internet. The research subjects include 23 Czech higher education institutions offering economics-related majors. The comparison was carried out from the point of view of the use of websites and social media outlets (YouTube and Facebook) for the purpose of marketing communication. The objective of the research is to define, using the Spearman correlation coefficient, the rank-order of individual subjects in the two areas and to determine whether there is a correlation between the level of website utilization and that of social media utilization by the subjects of the research. The theoretical part of this research study deals with the development of tertiary education in the Czech Republic and emphasizes the reasons why marketing is so important for Czech colleges and universities. Furthermore, it contains a detailed description of marketing communication and its possible implementation through the Internet, i.e., the most commonly used hypermedium among the young generation.

Keywords: marketing in education, websites, social media sites, the Spearman coefficient

Introduction

In recent years, there has been a decline in the number of university students in the Czech Republic. The reasons behind this include the population decline as well as pressure on funding higher education institution (HEIs), where in 2009 there was a dramatic decrease in the appropriations per student, which was nominally leveled only in 2016. This led to increased interest in marketing among universities. The main target group of HEIs are young people between the ages of roughly 18 and 23. This group is closely associated with communication over the Internet, including using mobile devices. That is why marketing that targets this group significantly utilizes online communication. The presented study starts with a theoretical introduction, which on the one hand deals with the development of marketing in the area of Czech tertiary education, and utilization of the Internet by HEIs for the purpose of communication with the target group on the other. The empirical part of the study deals with the research conducted, the goal of which is to compare selected universities in terms of website and social media utilization and to determine whether there is a correlation between the level of utilization of these two media types for the purpose of communication.

1 Theoretical introduction to the development of marketing in the area of education in the Czech Republic The main body of the paper

The tradition of Czech higher education dates backmore than 600 years ago, to when Charles University was established by Emperor Charles IV (ICEF Monitor, 2014). The past 25 years have been a period of reforms for theschool system in Czech Republic. The educational reform has been influenced not only by democratization in this country after the collapse of communism, but also by a more open approach to the world, globalization and the need for competitiveness (Eger, Egerová, 2016).

Universities now refer to Higher Education as a market, because there is considerable competition for students. This is the reason why they are aware of the importance of their reputations (Rutter, Roper,

Lettice, 2016). More and more universities apply common marketing techniques to compete effectively. It is necessary to understand, manage, and leverage a strong brand position, because a university's brand represents the totality of perceptions and feelings that stakeholders associate with that particular university (Luque-Martínez, Del Barrio-García, 2009, Rauschnabel, Krey, Babin, Ivens, 2015). It means that universities are no longer just institutions of higher learning but also a business. They spend a lot of money burnishing their image (Azoury, Daou, Khoury, 2014).

After 1989, university education was in high demand in the Czech Republic, as its capacity was limited during socialism. The democratization of higher education went hand in hand with the establishment of new regional universities, which replaced the higher education institutions in the regions. Marketing in the area of tertiary education did not seem to be necessary, as there was a much greaterdemand for education compared to its supply, and the institutions were only just learning to communicate with the public and handle public relations. Major changes in higher education came with Act No. 111/1998 Coll. on Higher Education. Very important was the accession of the Czech Republic to the European Union in 2004 andthe more intensive involvement of HEIs in EU programs. Important was also the gradual establishment of private institutions of higher education after 1999. As has already been said, higher education in the Czech Republic has seen a decrease in the number of young people. The statistics fromthe Ministry of Education indicate that while in 2009 there were 110 thousand newly enrolled students at Czech colleges and universities, in 2016 it was only 82 thousand. The biggest decrease instudents occurred at private HEIs, where in 2009 there were 18,597 new students, while seven years later there were only 8,592 newly enrolled students. Colleges and universities struggle to attract new students and thushave no other choice but to use effective marketing. The times when schools presented themselves only in specialized periodicals dedicated to education and at fairs organized by universities are long gone.

Although most colleges and universities handle their marketing themselves, there is an increasing number of cases where these activities are consulted with experts. Sometimes,we encounterthe problem that commonly used marketing principles are not applied to the area of education. For example, little attention is devoted to the school's mission and shared values. Extensive marketing is mainly the domain of private colleges and universities, which depend on tuition fees and thus must build up their brand and prestige.

The established schools (public ones with a long history) have the advantage of being well-known by people; however, that is only the first step. Another important step is to communicate issues related to the study program and target the right students. As a result of the lack of college applicants, universities also focus on attracting students from abroad – marketing of universities thus takes on an international dimension (Kartous, 2014, Křížová, 2017).

The absence of each student means the lossof a substantial amount of money for schools (according to the Ministry of Education, it is about CZK 36,000 per student/year), so there is an effort to accept as many applicants as possible and let them study as long as possible. This obviously can have a negative effect on the schools' output in terms of the quality of academic results (Kartous, 2014).

Experts agree that there is no reason for universities not to use marketing, quitethe opposite. At present, the primary goal of marketing is to communicate the portfolio of study programs to applicants in an attractive way and convince them that studyingthe majors taught at the school makes sense and there is a future in it (Kartous, 2014, Mocková, 2016). A significant topic for universities is brand building (Jurášková, Juříková& Kocourek, 2015).

The development of higher education in the Czech Republic, described above, the increase in competition and the demographic decline in the category of 18-to-23-year-olds, combined with the advancement of ICT, has resulted in university marketing significantly focusing on utilizing the Internet.

2 Use Of The Internet By Universities To Communicate With Their Target Group

Utilizing the Internet to communicate with the appropriate target group, i.e., young people between the ages of 18 and 25, makes perfect sense. Online communication is natural for young people – this group has very high computer literacy. Moreover, the importance of the Internet continues to grow in the Czech Republic. At the end of 2015, Internet penetration in the +10 age category was 76%, and for the generation of people aged 10-24 it was 96% (NetMonitor, 2016). This target group falls into a demographic group often referred to as generation Y, also known as the Millennials, which includes people born between 1976 and 1995 (some sources, e.g., Šimáková, 2017, define its range as 1985–2000) and it needs to be said that this generation has brought a number of changes to marketing and marketing communication. One of the basic characteristics of this group is their almost constant online presence, which is reflected in interpersonal communication as well as consumer behavior and expectations. Young people share information and experiences (both private and consumer-related) and they are also better equipped for this than the older generation (they are more likely to have a mobile Internet connection, etc.) (Flodrová, Šilerová, 2011).

The results of the adMeter project conducted by the MEDIAN Company indicate that when it comes to websites, the young generation spends most of their time on YouTube and Facebook. According to the survey, young people aged 15–24 spend more than 19 minutes a day using mobile apps and more than 110 minutes browsingwebsites. When consuming website content, young people at the age of 15–24 spend most of their time watching YouTube videos, which on average takes up more than 32 minutes a day, and using the social media site Facebook, where the young generation spends an average of 31 minutes a day. These two social media outlets are followed by other websites and mobile apps, among which social media sites like Instagram, Twitter and LinkedIn are gaining traction (Mediaguru, 2017).

Another communication channel covered by this research study is websites. This channel was selected primarily based on qualitative research conducted at the Faculty of Economics of the University of West Bohemia in the spring of 2017. The research was carried out in the form of four discussion groups, and the research results clearly indicate that websites are the primary channel where students look for information about colleges and universities.

3 Evaluating selected universities in terms of their use of websites, Facebook and YouTube

The deductive approach according to Punch (2008) was used in defining the research problem and setting the research goals. Also defined were the research area, research topic and the general as well as specific research questions. The research area was defined as marketing in the education sector in the Czech Republic. The research topic is the utilization of websites and social media sites by universities for the purpose of communication with the public. The research focused on 23 subjects – HEIs, which included faculties at public universities (16 = A), independent public colleges (2 = B) and private university and colleges (5 = C), all operating in the Czech Republic:

- A - Masaryk University – Faculty of Economics and Administration,
- A - Czech University of Life Sciences Prague - Faculty of Economics and Management,
- A - Faculty of Economics - University of West Bohemia,
- A - Faculty of Business and Management - Brno University of Technology,
- A - Faculty of Economics - University of South Bohemia,
- A - University of Hradec Králové - Faculty of Informatics and Management,
- A - Faculty of International Relations - University of Economics in Prague,

- A - Faculty of Business Administration - University of Economics in Prague,
- A - Faculty of Management - University of Economics in Prague in Jindřichův Hradec,
- A - Tomas Bata University in Zlín - Faculty of Management and Economics,
- A - Faculty of Economics and Administration - University of Pardubice,
- A - Faculty of Social and Economics Studies - University of J. E. Purkyně,
- A - Faculty of Economics - University of Ostrava,
- A - Faculty of Business and Economics, Mendel University in Brno,
- A - Technical University of Liberec - Faculty of Economics,
- A - School of Business Administration in Karviná,
- B - College of Polytechnics Jihlava,
- B - The Institute of Technology and Business in České Budějovice,
- C - University of Business in Prague,
- C -The Institute of Hospitality Management in Prague,
- C -Karel Engliš College in Brno,
- C -Unicorn College in Prague,
- C -Moravian University College Olomouc.

The following general research questions were formulated:

- What is the level of utilization of websites by individual subjects?
- What is the level of utilization of social media sites, specifically Facebook and YouTube, by individual subjects?
- What is the correlation between the level of utilization of websites and the level of utilization of social media sites in the selected subjects?

The specific research questions are defined by the individual criteria that were chosen for the evaluation of each of the selected communication channels.

The specific questions aimed atassessing the level of utilization of websites were defined as follows:

- Is the design of the particular website responsive?
- Is there a direct link from the homepage to the section for applicants?
- Does the homepage also address other relevant groups (students, graduates, employees and partners)?
- Is there a direct link from the homepage to the selection and admission policy?
- Does the homepage provide information about the major fields of study?
- Does the news section on the homepage provide information about the school's cooperation with industry, international cooperation or lectures given by experts?
- Does the design of the website reflect the specific target group (evaluated using the five criteria listed below)?

The specific questions aimed at assessing the level of utilization of the social media sites Facebook and YouTube were formulated as follows:

- Can the school's videos posted to YouTube be accessed directly from the website's homepage?
- Does the institution have its own YouTube channel?
- How many videos does the university channel contain?
- What is the average number of views of the videos in 1 year?
- What is the average number of "likes" in 1 year?

- Can the institution's Facebook page be accessed directly from the website's homepage?
- How many posts does each Facebook page contain?
- How many fans does each Facebook page have?

The specific question related to assessing the correlation between the level of utilization of websites and the level of utilization of social media sites (YouTube and Facebook) is identical to the third general research question. The association was assessedbased on selected features and evaluated using the Spearman coefficient (Chráska, 2016). Based on a theoretical input, we defined the following hypothesis:

We suppose that if a university utilizes its website at a high level (according to the selected criteria), it will most likely also utilize social media sites at a high level.

The following subchapters present in detail the methodology of the evaluation of individual criteria.

3.1 The Characteristics of the Criteria for the Evaluation of Websites

The first criterion for the evaluation of websites is their responsive design. A responsive design is based on several rules, the most important of which is the width and layout of elements on the particular website, the size of images and the use of the website (Responzivní design, 2016).

The responsiveness of the design was evaluated according to the Google Search Console. If the website of the selected university had a responsive design, it received 1 point, otherwise, it received 0 points.

Other criteria for the evaluation of the selected universities' websites relate to the accessibility of important information primarily with regard to the choice of the given university. The said criteria were evaluated as follows:

- the homepage contains a link to the admissions office = 1 point (otherwise, 0 points),
- it is possible to access information about the selection and admission process on the website's homepage = 1 point (otherwise, 0 points),
- the news section contains information about a lecture by an expert, cooperation with companies for the purpose of gaining practical experience, and international cooperation = 3 points (for each criterion which is not met, subtract one point; the absence of all three criteria = 0 points),
- and lastly, are there links to all of the aforementioned stakeholders = 1 point (if at least three of them = 0.5 point, none of them = 0 points).

These criteria were selected based on the opinion of experts on the heuristic evaluation of websites (Strauss, Frost, 2012) for the particular purpose and also based on the output of four discussion sessions with university students, which among other things showed the students' deep interest in information regarding the possibility of studying abroad and gaining practical experience during their studies. These criteria were evaluated by two Internet marketing experts by way of heuristic analysis (E1 and E2). Table 1a and 1b contain the average values.

If the rating of the set criteria differed by more than 1 point, the evaluators consulted their results by way of a conciliation procedure.

The last criterion for the evaluation of websites was their design. The following criterionpresents specific principles of creating an attractive design forawebsite's homepage, according to HubSpot, Inc., which are further supplemented byother specific principles for the age group of young people aged 18 to 25,

according to the American company Nielsen Norman Group, which for a number of years has specialized in website evaluation from the users' point of view.For the last criterion, two students were chosen (and trained) as evaluators (Hubspot, 2017), (Nielsen Norman Group, 2016):

1. If the homepage was clearly organized, it received 1 point (otherwise, 0 points, though it was also possible to assign 0.5 points).
2. If the selected university appropriately addressed their target group, it received 1 point (otherwise, 0 points).
3. If the homepage reflected the specifics of the particular faculty and referred to the added value of studying at that particular school(mentioned specific advantages connected with their study programs, e.g., the possibility of studying abroad, cooperation with specific companies during the studies, etc.), it received 1 point, otherwise, 0 points.
4. If the homepage contained a call-to-action, e.g., "I want to study", "I want to learn more", etc., the university received 1 point (otherwise, 0 points).
5. If the homepage featured dynamic content, e.g., the option to watch a video directly on this page, it received 1 point (otherwise, 0 points).

The tables below (Table 1a and Table 1b) show the evaluation results of the individual universities' websites.

Table 1a: Evaluation of the level of utilization of websites by individual subjects according to the first five criteria

The university	Responsive design		Applicant		Relevant Groups		Admission		Field of Study

The data in the table above answer the individual specific questions connected with the general question "What is the level of utilization of websites by individual subjects?", and thus also answers this general question.

3.2 The Characteristics Of The Criteria For The Evaluation Of Social Networks (Youtube And Facebook)

YouTube

The first assessment criterion in terms of the level of utilization of YouTube by the particular university was the fact whether it was possible to watch some of the videos uploaded to YouTube directly on the school's website. Subject to evaluation was also the existence of the university's own YouTube channel. If these two criteria were met, the university could get 1 point for each criterion, otherwise, they received 0 points for each criterion.

Another set of criteria dealt with the number of uploaded videos, the average number of views of the university's videos on its YouTube channel, and the number of "likes" the university's videos receive in a year. The annual averages were used due to the factor of time (a video uploaded to YouTube five years ago obviously has a different potential to get "likes" than a video posted in the past year). The specific figures for the given criteria are shown in Table 2.

Table 2: The specific number of videos, average number of views and average number of "likes"

The university	Video on YouTube	Average of video viewed/year	Average of "Like"/year
Masaryk University – Faculty of Economics and Administration	4	318	0
Czech University of Life Sciences Prague - Faculty of economics and Management	19	534	1,3
Faculty of Economics - University of West Bohemia	43	207	0,8
Faculty of Business and Management - Brno University of Technology	3	1285	1,7
Faculty of Economics - University of South Bohemia	68	169	0,4
University of Hradec Králové - Faculty of Informatics and Management	23	1194	8,2
Faculty of International Relations - University of Economics in Prague	30	394	1,9
Faculty of Business Administration - University of Economics in Prague	3	48	1
Faculty of Management - University of Economics in Prague in Jindřichův Hradec	*3*	435	1,2
Tomas Bata university in Zlín - Faculty of Management and Economics	6	199	0,4
Faculty of Economics and Administration - University of Pardubice	4	319	0
Faculty of Social and Economics Studies - University of J. E. Purkyně	21	253	1,1
Faculty of Economics - University of Ostrava	18	219	0,2
Faculty of Business and Economics, Mendel University in Brno	15	18391	57,9
Technical university of Liberec - Faculty of Economics	6	177	1,3
School of Business Administration in Karviná	7	149	1,5
College of Polytechnics Jihlava	4	423	2,8
The Institute of Technology and Business in České Budějovice	36	238	1
University of Business in Prag	34	174	0,5
The Institute of Hospitality Management in Prague	7	1023	2
Karel Engliš College in Brno	16	200	1,3
Unicorn College in Prague	110	236	1,1
Moravian University College Olomouc	73	835,4	1,5

Source: Author's own elaboration, 2017

The evaluation of the criteria listed in Table 2 was carried out as follows. If a university did not have a single video on YouTube, it received 0 points (which was not the case in any of the research subjects). For 1-25 videos, the university received 0.5 points, for 26-50 videos it received 1 point, for 51-75 videos it was 1.5 points, for 76-100 videos it received 2 points, and for 101 or more videos it got 2.5 points.

The evaluation of the average number of views was carried out as follows. If the videos of the particular university had an average of 0 views, it received 0 points (again, this was not the case of any of the research subjects). For 1-250 views, the university received 0.5 points, for 251-500 views it was 1 point, for 501-750 views 1.5 points, for 751-1,000 views 2 points, and for 1,001 or more views 2.5 points.

In terms of the average number of "likes", again, the absence of any "likes" meant 0 points assigned (this was the case of two research subjects). For the average number of "likes" 0.1-2.5 the university received 0.5 points, for 2.6-5 "likes" 1 point, for 5.1-7.5 "likes" 1.5 points, for 7.6-10 "likes" 2 points, and for more than 10 "likes" it was 2.5 points. These criteria were evaluated using the MS Excel tool.

It's important to note the fact that one subject, specifically the Faculty of Management in Jindřichův Hradec, does not have its own YouTube channel. In this case, the subject of the evaluation was three random users' videos that were related to the Faculty.

Facebook

The first evaluation criterion in terms of Facebook utilization was also the fact whether the university's Facebook page was accessible directly from its website. If that was the case, the institution received 1 point (otherwise, it received 0 points).

Microsoft Power BI was used to quantify the other selected criteria, i.e., the number of Facebook posts and the number of fans of the university's Facebook page.The total number of posts consisted of the number of events, photographs, videos, links and statuses. The specific values are shown in Table 3.

Table 3: The number of posts and fans of selected universities' Facebook pages

The university	Events	Links	Photos	Status	Video	Total of contributions on FB	FB fans
Masaryk University – Faculty of Economics and Administration	137	977	431	92	31	**1668**	**4673**

Source: Author's own elaboration, 2017

The number of posts and fans were evaluated as follows:

- 0-500 posts = 0 points,
- 501-1,000 posts = 0.5 points,
- 1,001 – 1,500 posts = 1 point,
- 1,501 – 2,000 posts = 1.5 points,
- 2,001 and more posts = 2 points,
- 1-1,500 fans = 0.5 points,
- 1,501 – 3,000 fans = 1 point
- and 3,001 and more fans = 1.5 points.

The tables below (Table 4a and Table 4b) show the overall evaluation results for social media utilization (YouTube and Facebook).

Table 4a: The level of utilization of YouTube by individual subjects

The university	Link for YouTube on websides	YouTube channel	Video on YouTube	Average of video viewed/year	Average of "Like"/year

Source: Author's own elaboration, 2017

The table above answers the specific questions related to the second general question: "What is the level of utilization of social media sites, specifically Facebook and YouTube, by individual subjects?", and thus also answers the general question itself.

3.3 Assessment Of The Correlation Between The Level Of Utilization Of Websites And The Level Of Utilization Of Social Media Sites

The important objective of this research was to determine the correlation between the rank-order of the individual variants using the Spearman coefficient, with which one can determine the correlation, or agreement, between the rank-orders of individual variants, that is, the level of utilization of websites and the level of utilization of social media sites (YouTube and Facebook) by the selected subjects – see the third general question. We suppose that if an institution is engaged in promotion through its website, it will also promote its activities, at a similar level, using social media outlets. Therefore, if the university's promotion on its website is evaluated, using assessment criteria, as very effective, we assume its utilization of YouTube and Facebook will also be highly effective.

To calculate the Spearman coefficient, the order of individual subjects based on their overall evaluation needs to be determined(see Table 1b, Table 4b).

The table below (Table 5) shows the rank-order of individual subjects based on the evaluation in the selected criteria. As can be seen, the subject with the highest rating (i.e., that which received the most points) was assigned rank "1", etc. If more than one subject received the same evaluation, they were assigned average rank-order numbers (e.g., in terms of their evaluation of website use, two subjects received 10 points, which would have put them at 6th and 7th place – therefore, they were both assigned the value of 6.5) (cf. Šubrt, T. et al, 2015)

Table 5: The rank-order of individual variants based on their evaluation

Total Evaluation (websides)	Rank Order (websides) = pi	Total Evaluation (social networks)	Rank Order (social networks) = qi
10	6,5	6,5	11
10,25	5	9	3
7	20	5	20
7,5	17	6	14
11,5	1	7	9
11,25	2	9	3
6,75	22	8	5
7	20	4,5	22
8,25	15,5	3,5	23
5,5	23	6	14
9	12,5	5	20
10,75	4	5,5	17
8,75	14	5	20
11	3	9,5	1
9,25	10	5,5	17
9,5	8	6,5	11
8,25	15,5	6,5	11
7	20	6	14
9	12,5	7,5	7
9,25	10	9	3
10	6,5	5,5	17
9,25	10	7,5	7
7,25	18	7,5	7

Source: Author's own elaboration, 2017

The formula for the calculation of the Spearman coefficient is shown below (Figure No. 1). The value of the Spearman coefficient ranges within the interval <-1; 1>, where the value 1 means complete agreement of the rank-orders; the value 0 indicates zero correlation of the rank-orders, and the value -1 shows complete negative, that is indirect, correlation between the rank-orders.

$$\rho = 1 - \frac{6\sum_i (p_i - q_i)^2}{n(n^2 - 1)}$$

Fig. 1: Formula for the calculation of the Spearman coefficient

Source: Hendl 2009 and Synek et al. 2009

The values p_i and $q_i$are the rank-order indices in Table No. 5. The letter "n" indicates the number of subjects, of which, in our case, there were 23.

Table No. 6 shows the process of calculation of the Spearman correlation coefficient, including its result.

Table 6: The calculation of the Spearman correlation coefficient

The university	pi	qi	(pi-qi)	(pi-qi)2	∑ (pi-qi)2	n	Spearman's coefficient

Source: Author's own elaboration, 2017, based on the aforementioned sources

The table above clearly shows that the value of the Spearman correlation coefficient is 0.394. Therefore, it indicates a low correlation between the selected values. In this case, it means a low level of agreement between the degree to which subjects utilize websites and social media sites. Therefore, we cannot assume that the level of utilization of websites by universities correlates to the level of utilization of social media sites (as per the evaluation using the selected criteria), which answers the third and last general question: "What is the correlation between the level of utilization of websites and the level of utilization of social media sites in the selected subjects?" and the stated hypothesis. The level of correlation is low.

Conclusion

This research paper presents the output of asurvey research focusing on the comparison of Czech colleges and universities that offer their target group mainly economic majors. The aim of the research was to determine how the individual subjects fare in terms of marketing communication through websites and social media sites, and also to establish whether a correlation between the level of utilization of these two communication channels can be expected (i.e., whether it can be assumed that institutions that utilize their websites at a certain level will also engage, at a similar level, in promotion using social media sites). Following the calculation of the Spearman correlation coefficient, it was determined that the agreement between the level of utilization of websites and social media sites by the selected institutions is low.

This research study is part of the output of an empirical survey that contributes to the development of the application of marketing in the area of higher education, and is a specific follow-up to, for example, creating university brands.

The limitation of the study lies in the fact that it was conducted among economic universities. Another limitation can be using of heuristic evaluation - research results seem to be subjective, but it made instructed experts. The research may be further expanded to include other universities or their major

fields of study and their online communication with the target group.

Principles of Managerial Work in the Hotel Industry

Petr Cech, Institute of Hospitality Management in Prague, Prague, Czech Republic, chromy@vsh.cz
Jan Chromy, Institute of Hospitality Management in Prague, Prague, Czech Republic, chromy@vsh.cz
Marek Tomastik, Tomas Bata University in Zlin, Czech Republic, mtomastik@flkr.utb.cz

Abstract

Making use of quality human resources, including managers at all levels of management, is one way to gain a competitive advantage for a hotel or a hotel chain regarding its competitors. The authors of this article surveyed views on selected management principles that influence the quality of their work in meeting the organization's goals. The method of research was a questionnaire survey conducted between hotel and hotel chain managers. The research dealt with the assessment of their opinions on the importance of selected management principles. In the cases of key variables, statistical methods of dependency testing have been applied to allow validation or disproving of the established hypotheses.

The research results show that hotel and hotel chain managers in the Czech Republic determined "customer orientation" and "result orientation" as the most important managerial principles. The "fairness and commitment to ethical values" and the "commitment to a company " were considered as the least important principles. The research confirmed that good relationships and loyalty of customers, alternatively loyalty to a hotel or hotel chain, bring results indirectly. The "dependence of assessment the significance of managerial principles on management level, age, and expertise of managers" was confirmed. No dependence was proven in the "gender and attained education attainment of managers, as well as in the "classification and size" of the hotel or hotel chain in which the managers work.

Keywords: hotel, management, manager, managerial principles

Introduction

The success or failure of a particular hotel or hotel chain depends, among other things, on the quality of the people who manage them. We can assume that their role will be further enhanced in near future. The determination of strategic goals and objectives, the creation of an efficient organizational structure, the selection of quality staff, or the ways of managing co-workers, will depend on their quality. Therefore, it is necessary to deal with the issue of principles that managers of the hotel industry considered to be the most significant in their work. Adherence and application of selected principles should help managers to meet established goals of the entire organization or its organizational units. The evaluation of selected principles of managerial work (focus on performance, focus on results, customer orientation, team orientation, commitment to the company, honesty and commitment to ethical values) provides further insight into a comprehensive view of the issue of managerial work in the hotel industry.

Principles of Managerial Work

For the purposes of this article, the authors proceeded from understanding the principles of managerial work by Veber et al. (2014). Veber points out that the principles may vary to a certain extent depending on the level at which the manager works, the nature of the managerial position, the size of the organization, sphere of its activity etc. Although it is not possible to clearly define universal common principles and features of managerial work for all levels of management, it is possible to summarize them with a certain level of simplification. Managers should be able to use in their work the following principles: replenishing and developing their knowledge and skills, increasing the performance of managed staff, result orientation, customer orientation, ability work with people, including the ability to

manage teamwork, loyalty to the organization, adherence of ethical standards as a part of social responsibility, managing the classical managerial functions, emphasis on conceptual thinking, paying attention to prevention, proactively acting, managing quality changes and risks, setting priorities, ability to formulate visions, missions and business strategies, as well as applying new approaches, methods and techniques in management.

The research of this issue is based on previous research concerning the replenishment and development of knowledge and skills of managers in the hotel industry (Cech, Koklarova and Cechova, 2015). It has been found that the most beneficial methods to acquire the professional skills of managers are the following methods: "thinking about my work"; "learning from your own mistakes" "learning at the workplace". The least beneficial were the methods of "trying to imitate my professional model" and "extra-work life “.

The contemporary advanced world is representative of the increased interest in continuing professional education. The environment in which today’s specialists work and continue their education is ever more volatile, more demanding, and more critical of possible mistakes; therefore, specialists are constantly forced to expand their knowledge and improve their occupational skills.

The issue of acquiring the desirable skills of managers is being addressed by more and more authors in their research activities. For the purposes of this article, the authors focused primarily on the economic education of managers (Asztalos 2016, Krpalek, 2015) and on the principles of managerial work (Cech, Beranek, Koklarova, 2015). The authors of this article focused on six selected principles of managerial work in their research:

- performance orientation;
- result orientation;
- customer orientation;
- team orientation;
- commitment to a company;
- honesty and commitment to ethical values.

Within fulfilling the principle "performance orientation" managers should realize that the staff’s performance is a set of their characteristics and dispositions that determine how they perform their assigned tasks (Krpalkova Krelova, 2016). In the course of time, the performance of workers changes and is influenced, among other things, by assigning and organization their work, by work with people in a company, by the quality of managing people or quality of interpersonal relationships at work (Dolezal, 2012).

Result orientation is intended to focus on key objectives so that the results meet all stakeholders while adhering to ethical, legal and environmental issues. At the same time, it is necessary to realize that the manager is not paid for the hard work, nor for the plans or reports he produces, or the hard work of all his subordinates. He or she is paid for the results of the organization or a part of the organization (Pitaš, 2012). As the Sveiby's model of intellectual capital show, the following principles "good relationships" and "loyalty of customers" (customer orientation), or "loyalty to the hotel or hotel chain" can be included under the customer's capital of the hotel or hotel chain (Sveiby, 1988). Hammer (2012), out of the nine recommendations for the success of an enterprise in the 21st century, dedicates two customer-orientated recommendations, specifically to make it easier for customers to collaborate with the company and offer to the customer added value.

Fulfilling the "team orientation" principle corresponds to the current developmental tendencies in organizational architecture of companies (Berkova, 2016). As a team, we can consider both the grouping of people who are associated to fulfil certain tasks, as well as an ad hoc workgroup designed for the creative solution or the realization of a specific task. The purpose of promoting teamwork is to persuade

workers that each of them contributes to the final results of the group and that cooperation and assistance are the right way to achieve their goals. The modern corporate environment and the trends in its development in relation to the skills required by professional managers (Ambrožová Ullrich) significantly influence team work and help the "team orientation" principle.

For any company in every field, including the hotel industry, loyal employees are a benefit (the principle of commitment to the company). Those who do not feel any sense of belonging to the company can do a lot of harm to the company. The advantage if an employee accepts positive goals and identifies with them, is that he or she then solves problems actively and initiatively. From the company management point of view, such a worker is ideal. There are many ways in which the employee's relationship to society can be directly influenced. Managers should primarily fulfil their promises and measure each one by the same metric, take an interest in both occupational and personal problems of the subordinates and ask questions about their opinion (Kralova, 2016).

Observance of ethical values is understood as a part of the corporate responsibility of a managed organization. For example, Philip and Milton Kotler (2013) consider corporate social responsibility as one of the possible strategies that will enable the company to make long-term and profitable growth. Indirectly, it will affect the achievement of results, i.e. the management principle of "result orientation". The possibilities of achieving the outstanding reputation of the company in the field of its social responsibility in the hotel industry in the Czech Republic were described in the article by Cech and Dohnalova (2015). Hotels and hotel chains in the Czech Republic, concurrently with promoting their professional interests, aim at ensuring that all business activities comply with generally accepted ethical principles of business activity and interpersonal relationships in a democratic society. Emphasis is put on customer health protection. It is also necessary to strictly observe hygiene standards and regulations in both the catering and accommodation areas.

Methodology

The aim of the research was to find out which principles of managerial work are considered by managers in the hotel industry to be the most important in their work. The core set included top-level, middle and first-line managers working in independent hotels or hotel chains in the Czech Republic. The authors examined whether there is a dependency between the assessment of the significance of the chosen principles and managers´ gender, level of management, age, achieved education, expertise, and classification and size of the hotel in which the managers work. For this article, a questionnaire survey method was chosen. Out of 900 questionnaires, respondents completed 435 of them. A total of 228 women and 207 men participated in the questionnaire survey. The gender ratio testifies in favour of an adequate and random selection from a point of view of respondents´ gender. These respondents form a sample set of managers. The return rate of the questionnaires was 48.3 %. The obtained data was arranged to groups to distinguish the characteristics of the monitored phenomena. To test the key variables, the statistical methods of dependency testing have been applied to allow validation or disproving of the established hypotheses. Neubauer claims that: "Statistical data analysis without computers is hardly imaginable nowadays" (Neubauer, 2011), and the results of this work have enabled the authors to select a suitable program to evaluate the data obtained.

Research includes a large area of management, which is a reason why only a part of the outcomes was chosen for the purposes of the article. The research outcomes are described in the following chapter in graphs.

Research Outcomes: Questionnaire Survey Assessment

The research outcomes were evaluated according to the six previously mentioned principles of managerial work whose appellations were shortened in the figures in the following way: - performance,

result, customer, team, firm and ethics. The respondents in the questionnaire ordered the selected principles according to importance for their managerial work (1 - the most important, 6 - the least important).
In the article, there is graphically presented a part of outcomes that documents respondents' opinions, including their ranking according to established criteria. For the data graphical presentation, the weighted means of significance order were used.

Fig 1 presents an assessment of the importance that respondents have assigned to the individual principles of their managerial work.

Fig 1: Assessment of managerial principles significance

From the obtained data assessment, it is possible to generalize that respondents selected as the most important principle the following management principles: "customer orientation" and "result orientation". As the least important principles they considered: "honesty and commitment to ethical values", and "commitment to the company".

Fig 2 shows the importance of gender from a point of view of managerial principles.

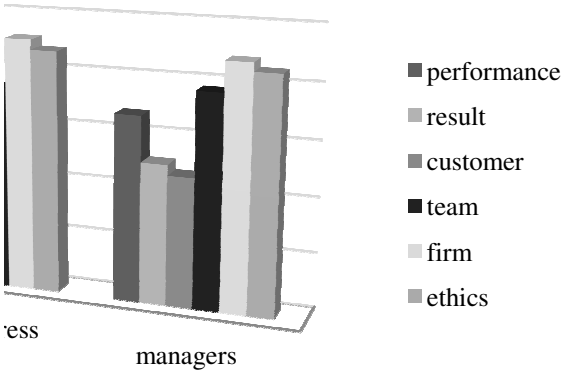

Fig 2: Assessment according to gender

The authors then examined whether there is a dependence between gender and the importance of selected principles of managerial work. The following hypotheses were formulated to assess the first principle of managerial work. H_0 hypothesis: "There is no statistically significant difference between gender of managers and their assessment of performance orientation" and H_1 hypothesis: "There is a statistically significant difference between gender and performance-oriented assessment." All other hypotheses dealing with managerial work were tested identically. Based on the Independence Test of 5 % significance level, the zero hypothesis (H_0) on the independence of individual characters was not rejected. This means that it has not been possible to prove that there is any dependence between gender and the assessment of selected principles.

Fig 3 gives an assessment of the importance of managers´ work principles with respect to the levels of management they are working on.

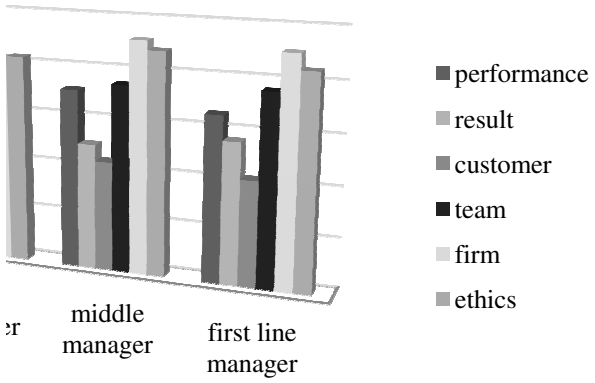

Fig 3: Assessment of importance according to a level of management

Respondents at all three levels of management assessed "customer orientation" as the most important managerial work principle. The test of 5 % significance level enabled to reject the zero hypothesis (H_0) dealing with the independence of individual characters and to accept an alternative hypothesis (H_1), which tested the "performance orientation" and the "team orientation" principles. This means that there is a certain dependence between assessment of these principles importance and levels of management on which managers work. All top managers attributed the greatest importance to the "performance orientation" principle, on the other hand, the principle of "team orientation" was the most important among managers at middle levels.

The Fig 4 shows the importance of selected managerial work principles in groups of respondents according to their age (15-24, 25-34, 35-44, 45-54, 55-64).

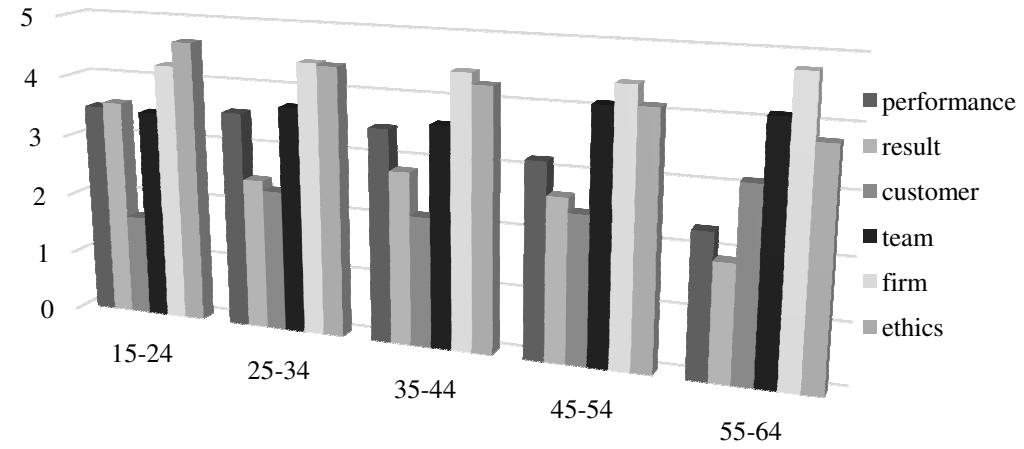

Fig. 4: Assessment according to managers´ age

The Test of Independence confirms at the level of 5 % significance that there is a certain dependence between the managers' age and their assessment of the following principles' importance: "result orientation" and "commitment to a company". The "result orientation" was assessed as the most important principle by respondents at the age of 55-64. The least emphasis on this principle was put by respondents at the age of 15-24. "Commitment to a company" was assessed as the least important managerial principle by all managers excluding the age category up to 24. The smallest importance was assigned to this principle by respondents at the age 55-64.

The Fig 5 demonstrates importance of selected principles of managerial work according to education of respondents. Legend to Fig 5: B-Apprenticeship with secondary school-leaving exam, C-secondary education with secondary school-leaving exam, D-higher technical, E-bachelor degree, F-master degree.

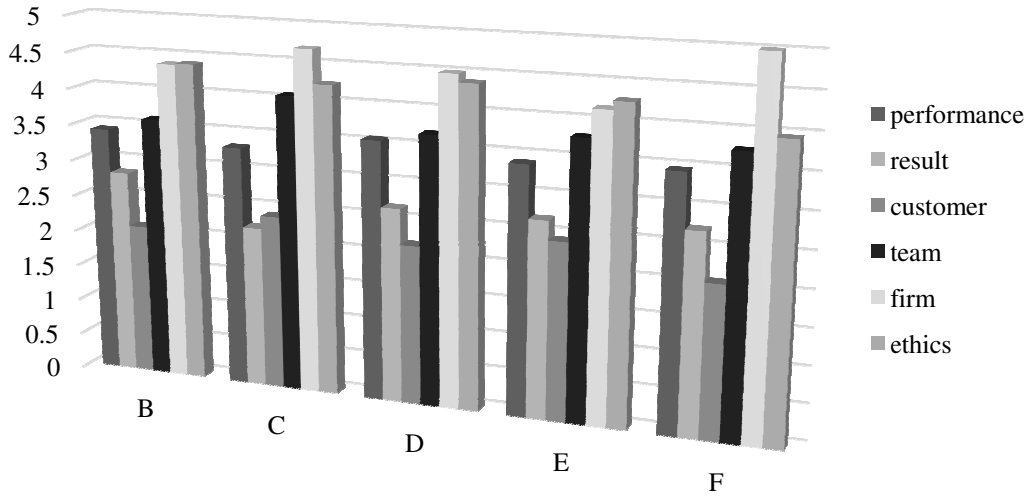

Fig. 5: Assessment of importance according to education

Based on the Test of Independence at the 5 % significance level, the zero hypothesis (H_0) dealing with the independence of individual characters was not rejected. This means that it has not been possible to prove that there is any dependence between the managers´ education and the assessment of selected principles of managerial work.

Fig 6 illustrates the importance of selected principles of managerial work according to their expertise and the related section in which the respondents work.

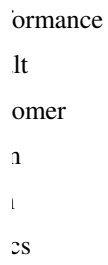

Fig. 6: Assessment of importance according to expertise (section)

The Test of Independence at the 5 % significance level enabled to reject the zero hypothesis (H_0) dealing with the independence of individual characteristics and to accept an alternative hypothesis (H_1) dealing with the principles of "performance orientation", "customer orientation", and "team orientation". This means that there is some dependence between the evaluation of the importance of these principles and the expertise (hotel section) of the respondents.

The work in a particular hotel section influenced the point of view at the importance of the individual managerial work principles. The "performance orientation" was assessed as more important by respondents from the economic section. The least importance was given to this principle by respondents from the catering section. "Customer orientation" was important for the respondents from the accommodation section, while on the contrary, workers in the technical department assessed it as the least important. It corresponds to the content of their work, as the duties of technicians are related to customer service indirectly only. "Team orientation" was significantly evaluated in the catering sector, but the least importance was given to this principle by respondents in the economic section. On the contrary, for the respondents working in the economic section, the "commitment to a company" was considered as more important than for the respondents from other hotel sections.

Fig 7 demonstrates the importance of selected managerial principles according to the hotel classification (number of stars) in which respondents' work.

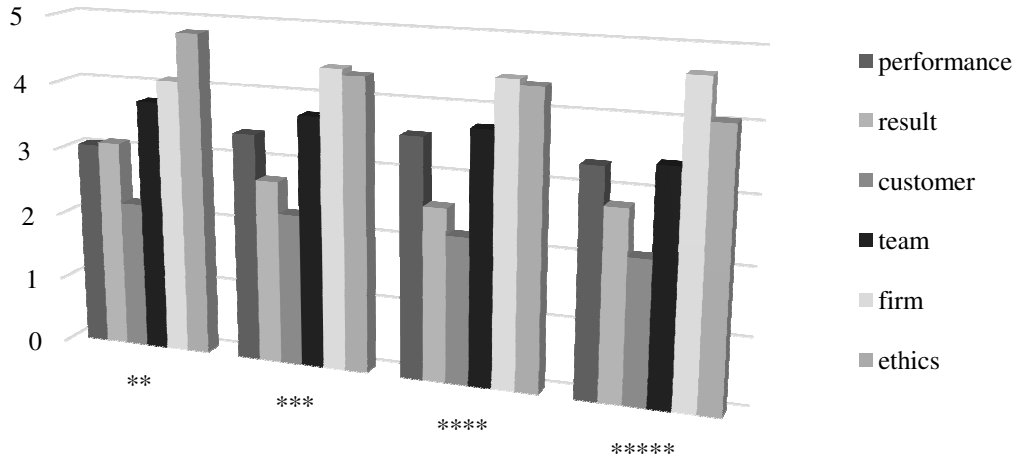

Fig.7: Assessment of importance according to a hotel classification

The Test of Independence at the 5 % significance level enabled the authors not to reject the zero hypothesis (H_0) dealing with the independence of individual characteristics. This means that it has not been possible to prove that there is dependence between the classification of the hotel and the assessment of selected principles of managerial work.

Fig 8 illustrates the importance of selected management principles according to the size of the hotel in which the respondents work.

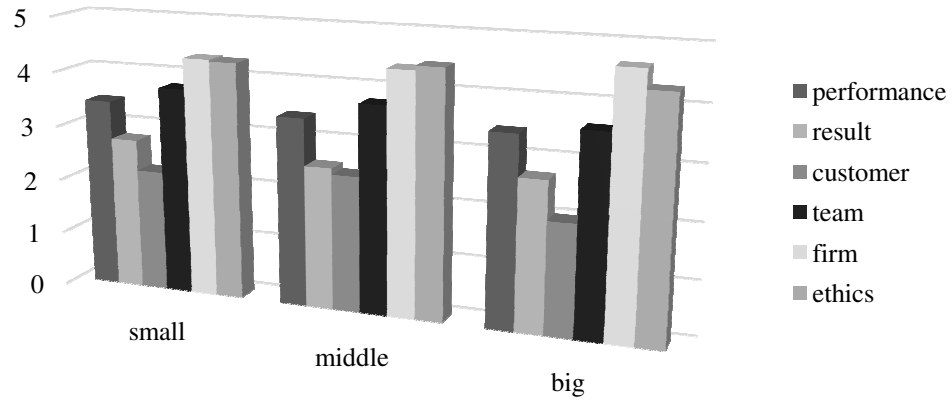

Fig. 8: Assessment of importance according to a hotel size

The Test of Independence at the 5 % significance level enabled the authors not to reject the zero hypothesis (H_0) dealing with the independence of individual characteristics. This means that it has not been possible to prove that there is dependence between the size of the hotel and the assessment of selected principles of managerial work.

Conclusion

The article deals with selected principles of the work of managers working in hotels and hotel chains. Within the framework of their research, the authors tested selected principles of managerial work according to the established criteria. From the assessment of the obtained data it is possible to generalize that respondents evaluated as the most important of the listed managerial principles the following: "customer orientation" and "result orientation". As the least important principle they chose "honesty and commitment to ethical values" and especially "commitment to the company".

The opinion of today's management that emphasizes the need to produce and deliver to customers a production that gives them a value have been confirmed. If managers in hotels and hotel chains can provide their customers with valuable services, it gives the business a competitive advantage. Good relationships and customers´ loyalty, alternatively loyalty to the hotel or hotel chain, brings indirectly appropriate results.

As the second most important managerial principle, the respondents chose “outcome orientation". Managers realize that all resources and efforts should be oriented towards achieving the objectives of the hotel or its part. This point of view requires an ability to set specific goals that ultimately lead to the fulfilment of the organization's mission and vision.

On the other hand, the respondents chose as the second least most important management principle “honesty and commitment to ethical values". Although the authors foresaw the possibility of this result, it gives us food for thought as to whether it should be evaluated in this way. Respect for ethical values should be understood by managers as a part of corporate responsibility.

The assessment of "commitment to the company" corresponds to the current situation in the hotel industry, where many workers at a particular job work only briefly, or after some time they leave the current employer and go to another one in the field.

The authors found that the assessment of the significance of management principles in the hotel industry does not depend on gender and the respondents´ education, nor does it depend on the classification and size of the hotel in which they work.

Certain dependency exists, if the managers´ responses were organized according to the respondent´s level of management, age and expertise. For example, respondents under the age of 24 put the slightest emphasis on "result orientation"; on the contrary, they set more emphasis than older respondents to the principle of "commitment to the company", which is a very interesting finding. "Output orientation" is related to channelling resources and to efforts to achieve the given goals. As respondents under the age of 24 work mainly at lower levels of management, it can be deduced that these positions do not put as much emphasis on planning and the associated goal setting.

The results were the opposite for the group of managers aged 55-64. It can be assumed that the respondents at this age group usually hold higher managerial positions, have a lot of experience from previous practice, and thus put greater emphasis on key objectives which satisfy all stakeholders. The least emphasis was put by these respondents on the principle of "commitment to the company". This may be related to the situation where these managers want to evaluate their knowledge and skills as much as possible and therefore are willing to change their job before retirement.

Selected Determinants of Educational Communication in a Multicultural Society

Jan Chromy, Institute of Hospitality Management in Prague, Prague, Czech Republic, chromy@vsh.cz

Dagmar Lanska, Institute of Hospitality Management in Prague, Prague, Czech Republic, lanska@vsh.cz

Petr Cech, Institute of Hospitality Management in Prague, Prague, Czech Republic, chromy@vsh.cz

Abstract

The paper focuses on determinants of educational communication in a multicultural society. For an overview, the paper analyzes the entire components of Laswell's communication model, putting the emphasis on the side of the recipient of the message. This area is fragmented and the most problematic in a multicultural society. It is also related to the recipients are equipped with tangible didactic tools differently in various parts of the world, and, logically, have consequent different skills at handling them.

Moreover, in some parts of the world, there is a digital divide, which not only restricts the use of modern forms of electronic communication, but even prevents directly their use in education. Some forms of education are, in fact, impracticable in those areas, e.g. E-learning.

Existent cultural differences can also cause problems in everyday communication and thereby hamper the optimal progress of educational processes. Together, these determinants impede the work of teachers, placing high demands not only on their expert knowledge, but especially on their orientation in a multicultural environment, their suitable communication and their best control of the latter.

Keywords: digital divide, education, communication, people, determinants

Introduction

Laswell´s communication model, which was originally intended for mass communication, can also be used for educational communication in a multicultural society. Basically, it is defined in one sentence "Who - Says What - To Whom - In Which Channel –- With what effect?", see Chromy, Semeniuk, Drtina (2011). Specialists in the field can study in a detailed and comprehensive way each of the separate parts of the sentence.

As far as the present article is concerned:

Who - is the message transmitter (source). Anything that relates to teachers, organizations, quality of schools, etc. is open to analysis.
Says What – represents the content and form of transmitted data, information and knowledge.
To Whom - is the recipient of the message that has certain personal individual characteristics, and cultural and social environment in which they live. In this article, the authors suggest a necessary content analysis of the communication recipient which should be done by the transmitter when planning the course content and development of educational processes.
In Which Channel - a means associated with the transmitted content and its form. In this article, we will deal exclusively with electronic environment, represented by the Internet. This can be understood as a specific analysis of the electronic environment planned to be used in education in a multicultural environment unrestricted by national borders.

With what effect? - represents the effect of the educational process, in this case it is the communication transmitter's impact on the recipient via communication channels; a specific form transmitting the required content.

In this article, the authors indicate a necessary analysis of the recipients at one hand, and they deal with the Internet as a communication channel between the recipients and the transmitters. The aim is to analyze the main determinants of educational communication in a multicultural society and to consider their possible removal, or uniqueness of a solution, and its time limits.

The preparation of modern education should be based on the assumptions which are analogous to normal operating communications in a multicultural society in a global environment, these being taken as a starting point. According to Charbonneau-Gowdy education is a social process in which communication is of crucial importance and she emphasizes that communication methods have dominated approaches to teaching and learning for over three decades, see Charbonneau, Gowdy, Cechova, Barry (2012).

Methodology

Based on Laswell's communication model, individual areas for future research were determined. Subsequently, all particular areas were analyzed. The article focuses primarily on the digital divide, i.e. communication recipient's area. In this case, the communication recipient's topic is very closely related to transmission channels (tools) that may not be available to communication recipients, or they are available in a limited extent.

The recipient group was geographically bounded according to the possibility of obtaining relevant data. Firstly, the recipient area with their particular specific properties that significantly differ according to the different areas in which they live, was analyzed. The need for a comparative analysis of cultural differences in these areas was stated.

Subsequently, based on a synthesis of several statistical researches, the ability (or, as the case may be, facility) of using the Internet use was investigated.

This is related to the subsequent analysis of the capability to maintain standards in terms of information and communication technologies. Google Analytics data were used, as they make possible to obtain geographically linked data about users and their use of information and communication technologies in different parts of the world. These data are associated to visits to specific Websites.

The research questions were set:
- Whether the communication and business negotiations are based on the culture of the monitored territories.
- Whether the use of the Internet is the same in different parts of the world.
- Whether a quick and relatively easy removal of determinants of communication in a multicultural society may be presupposed.

The synthesis of all the data collected resulted in determinants that, by analogy, are directly related to educational processes and their management in a multicultural society.

Results

It is globalization that accounts most for emergence and development of a multicultural society. Its biggest advantage is the growth of technological progress, the development of means of communication, dissemination of know-how or other knowledge and skills, job increase, investments and the overall

economy growth, and a better understanding of the different cultures by people from all over the world, etc, see Safe (2005).

Communication Recipients

At present, not everyone is in favour of the benefits of globalization. This is primarily caused by misunderstanding and fear of losing power on the side of individual governments, and fear of the growing power of international companies. With the ongoing globalization, traditional knowledge is not being transmitted and there is a fear of losing their own identity and uniqueness due to copying the behaviour which is common in Western countries. The disappearance of local products and their replacement by standardized products represent other threats. A major global problem is the spread of diseases and viruses, increased threat of terrorist attacks and the current civil war, especially in Africa.

Specific process of interaction and communication that takes place in different types of situations, when people from differing cultural backgrounds (with different languages, nationalities and religions) communicate in similar or different ways among themselves, and how they endeavour to communicate across cultures, is known as intercultural communication, see Prucha (2010). Every communication is based on a society´s culture.

Culture can be defined as an integrated pattern of human knowledge, belief, art, morals, law and any other capabilities and habits acquired by man as a member of society, see Tylor (2013). Humankind participate in the cultural development through their traditions, ways of communication, appearance, clothing, way of thinking, behaviour, beliefs, symbols and similarities or differences from other beings, see Berkova (2016).

Culture affects the daily lives of people. It is the basis for our living, getting dressed, eating, acting toward others. As a follow–up to these there are certain standards in human relationships in family life, social and labour spheres. Culture is closely linked with ethics - determines what behaviour is acceptable, and vice versa, in cultures known as universal, ethnic, racial, national, regional, industrial, professional and other entities, see Reisinger (2009).

Anthropologists divide culture into superficial and deep ones. Superficial culture includes anything that is visible at first glance. Deep culture is the one that is not directly visible, e.g. the language, habits, relationships, or other daily activities that make this group different from other, see Guirdham (1999).

Geert Hofstede identified four cultural dimensions that express the most basic level of cultural differences between societies and he highlights those that lead to a different conception of the basic parameters of people's lives and affect labour and management, see Simonova (2015):

Power Distance Index (PDI) - the extent to which the less powerful members of organizations and institutions (like the family) accept and expect that power is distributed unequally. For countries with a higher index is typical preference of formal relations. Employees are governed by the rules and instructions of their superiors and are fully dependent on authority (China and others). Low power index means that employees have limited dependence on their superiors and are asked for their feedback and suggestions (Australia etc.).

Uncertainty Avoidance Index (UAI) - expresses how members of different cultures deal with unfamiliar situations and risks. Societies that score a high degree in this index opt for stiff codes of behaviour, guidelines, laws, avoiding any innovations or new thinking (Greece, Japan etc.). Employees are loyal to their employer and do not like to change their jobs. In terms of communication these societies are supposed to show greater suspicion. Societies that have a low level of uncertainty avoidance, act calmly. A lower degree in this index shows more acceptances of differing thoughts/ideas. Society accepts threats,

is willing to trade without fear, and tends to impose fewer regulations and is more flexible (USA, Australia etc.).

Individualism vs. collectivism (IDV) - shows the degree to which people in a society are integrated into groups and the degree of an individual´s freedom to their own initiative. In individualistic society there is an emphasis on free expression and the independence of the individual. There is more decision-making freedom of the individuals in their jobs (USA, UK, etc.). Collective culture prefers overall cooperation within the group.

Masculinity vs. femininity (MAS) - determines the influence of sex within society. Masculine society is defined by assertiveness, competitiveness, the acquisition of material goods, self-esteem and high work enthusiasm. Emphasis is placed on success and job growth, consequently there is work stress and women are considered unequal (Japan, Venezuela and others.). Its counterpart represents a preference for cooperation, modesty, caring for the weak and quality of life, interpersonal relationships. Significant values are represented by solidarity, tolerance and respect, there is a greater focus on social relationships. Male and female roles are of equal value, so these values are expected from both sexes (Norway, the Netherlands etc.).

Promoting diverse elements in a group of two or more interconnected cultures leads to cultural conflicts. At the same time, there may be different motives: achieving one´ s own goals, confrontations, elimination of another culture members or of the whole culture, gaining power, etc. Differences between cultures and cultural conflicts arise primarily because of religious issues, see Reisinger (2009). Religion has an inherent impact on communication, as different cultural practices may be incomprehensible to Europeans and common behaviour may cause many misunderstandings and complications. A typical example is Islam, the followers of which pray under any circumstances, regardless of whether there is ongoing work meeting or alike. Huntington identified seven cultures - Western (USA, Europe, Australia), the Arab-Islamic (Arab countries etc.), Confucian (China, Thailand), Hindu (India), Japanese, Latin American and African. Each area and region has defined its own culture and religion. Therefore, each culture is viewed differently by the other culture. What may be civilized cultured and in accordance with the religion of the western culture may not apply to Islamic culture and vice versa, see Huntington (2001).

According to research carried out by an internationally active major bank, there are obvious shortcomings especially in African countries. Language barrier is one of the most serious causes of communication interference. When the participants of the educational projects have a problem to communicate and understand each other, problems arise on several fronts. When the trainer urges proper handling of communication technologies and the recipient pretends everything is fine, although they do not understand what this is about, this creates a large technical and communication barrier. Teaching single language (English) is unrealistic given the economic situation in most African states. Using the Internet, e.g. E-learning program, is also unrealistic.

The particular bank faced other problematic issues that are also important and, which by analogy, would impact education in a multicultural environment negatively. These include ignorance of ICT standards, disregard for ICT operation safety as well as the safety of the entire local bank. In addition to the absolutely fundamental security breach, e.g. during working with money, the report gives an example of a common electrical cabinet located outside the bank and accessible to anyone. ICT hardware, which banks received as a gift, was in many cases placed in storage without visible effort of putting it into use, see Brozova (2016). The above mentioned can be considered as significant determinants of educational communication in a multicultural environment.

Communication Channels

The process of globalization and its impact on the technical development of the areas that are more or less behind the times is also affected by the quality of used information and communication technologies. According to the above, cultural, social and other levels of a given area influence the dynamics of technological development.

Fig. 1 shows the dynamics of the growth of Internet users in comparison with the development of people in the world from 2000 to 2016. In 2016, approximately 46% of the population worldwide used the Internet.

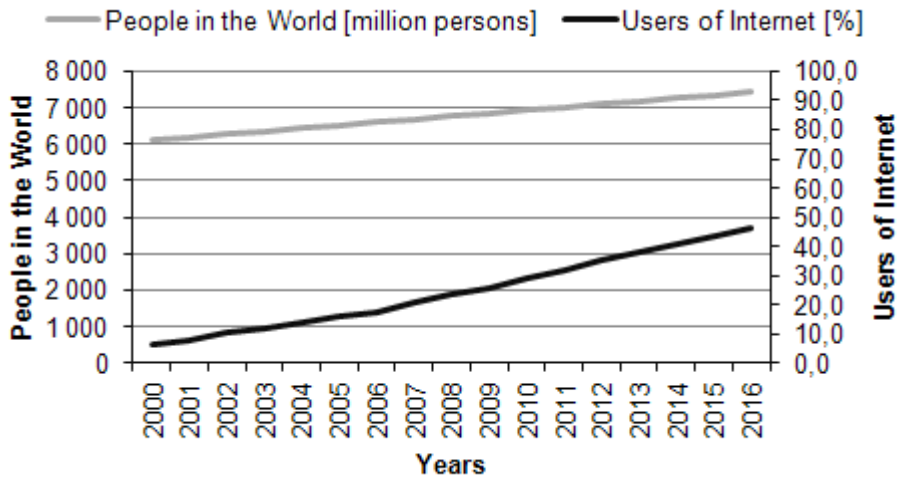

Fig. 1: Comparison of users of the Internet with people in the world, in accordance with IBRD-IDA (2016)

The number of Internet users varies in different regions and within them in individual states. Fig. 2. provides the number of Internet users by regions, valid for the year 2015.

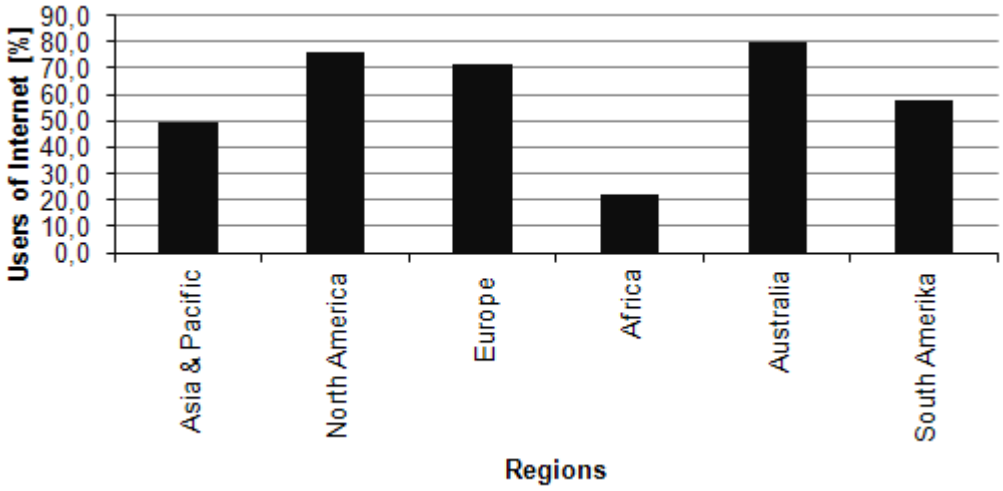

Fig. 2: Users of Internet [% of all people] - regions, in accordance with IBRD-IDA (2016)

The worst situation of all the regions is clearly in Africa, where only 22.39 % of the total population used the Internet in 2015. Comparing the growth rate of Internet users brings interesting information (Fig. 3). It provides charts comparing the growing percentage of Internet users of all residents in different regions.

Fig. 3 shows that Africa falls behind the most, there are almost 2x more users in Asia and the Pacific, which together with South America also rate among the weakest regions in the number of users. The growth dynamics of the number of users is highest in these regions.

In the remaining regions of Europe, North America and Australia the dynamic growth in the number of users is significantly smaller and it can be estimated that it is going to stagnate in the long term in the near future.

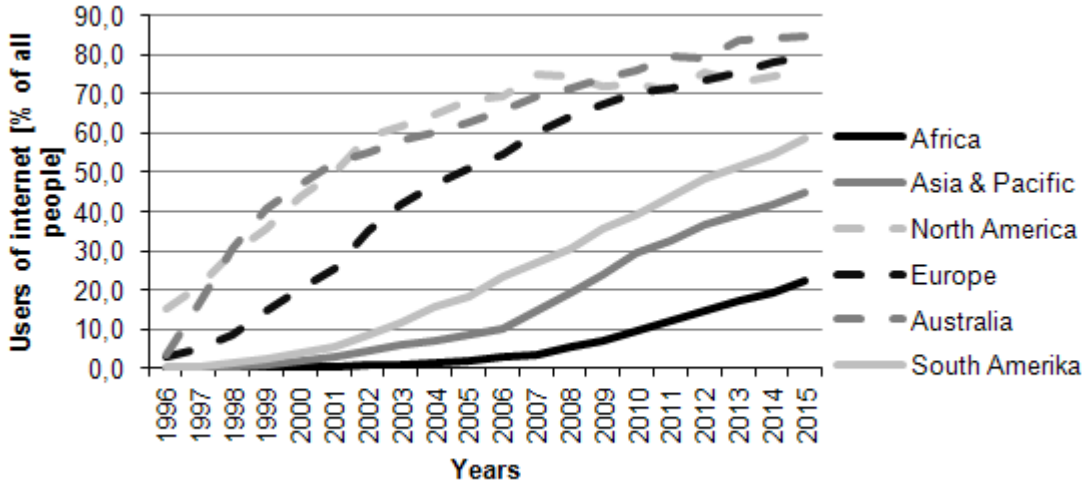

Fig. 3: Dynamics of growth users of Internet [% of all people] in years 1996 – 2015, in accordance with IBRD-IDA (2016, Internet live stats (2015).

In the world, there is quite a high number of people without access to the Internet. The reasons are various, e.g. social, demographic, etc., see OECD (2001). According to the statistics the situation in most African states is very bad. The average number of Internet users across Africa is 22.4% of the whole population. In Europe, Ukraine with 49.3% of users from the whole population ranks among the last, see Internet live stats (2014). It is comparable with the most developed countries in Africa. For example, Nigeria 47.4% of users, Tunisia 48.5%, South Africa 51.9%. The vast majority of other states rank below the African average, i.e. 22.4 %.

3.3. Quality of IT Equipment

The authors evaluated the quality of IT equipment according to the data obtained from website visits through Google Analytics. The source was a significant site for tourism where the total number of visits ranges in the millions per year and it includes data about visitors from all regions, as well. The data on the IT equipment gained through Google Analytics can be analyzed according to selected criteria. One of them is, e.g. the type of device. Other criteria can be, e.g., used CPUs, monitors (pixels, colours), operating system, etc. It is possible to obtain data not only for the region but also for individual states and even cities.

In this article, the authors chose monitor resolution as an indicator. This is an absolutely clear, unproblematic indicator which does not require more profound knowledge, as, e.g. that of processor types or operating systems, etc. Moreover, the latter can be comparable as far as the capacity is concerned, but labelled differently by their manufacturers, etc.

Monitor resolution is a manufacturer declared standard parameter, which determines the quality of the display unambiguously. Resolution is normally recorded as an aspect ratio (width x height of the monitor). There are different standards, which are based directly on the exact number of points of the sides, e.g. for full HD 1920 x 1080, for the low numbers then QVGA 320: 240. The total overall numbers characterize the grid display and the quality of the screen, respectively of the user´s needs. Furthermore, there are standards, which are based on the reduced number of points, e.g. 16: 9, 4: 3 etc. These reduced numbers only determine the proportions, and therefore aspect ratio.

To facilitate the research, the authors recalculated all points of the stated ratios of the monitors to obtain the product given by the sides.
This product represents the total number of screen points and it is an easily comparable parameter for display quality. Reduced aspect ratio does not play a role at all. It is possible to get Google Analytics number of visitors to specific websites for the sake of individual, completely individual aspect ratios in the point total numbers. Based on these numbers of visitors and their precise total number of points shown on monitors the authors calculated a weighted average, which represents the average of the given region. For greater clarity, it is stated by the authors in millions of displayed points, i.e. in megapixels. The same figure is cited as the main parameter of camcorders.

Google Analytics data include two different numbers of visitors. One number is given as a total one. That is not applicable for this research because it might contain the same information due to the repeated number of visits by individual persons. Therefore, the authors used the latter figure, which indicates the number of new visitors eliminating repeated visits of the same person. A little confounding may be the fact that the same person could visit the site once via PC, for the second time via tablet and again via smart Mobil. The authors did not exclude this possibility, because the research deals with quality of once connected equipment, not with numbers of persons. Similarly, the authors did not deal with the location of the internet access of the same person: e.g. at home and on other occasions at work, at an internet cafe, etc. They worked at the assumption that the total number of displayed points on an average monitor should be approximately the same for all regions. Given the fact the authors determined the number of points each month, it can be assumed that the number of displayed points will grow in relation to the use of more efficient equipment, or at least will not be lower. Fig. 4 demonstrates the average number of points displayed on a monitor for Africa in each month from January 2015 to August 2016.

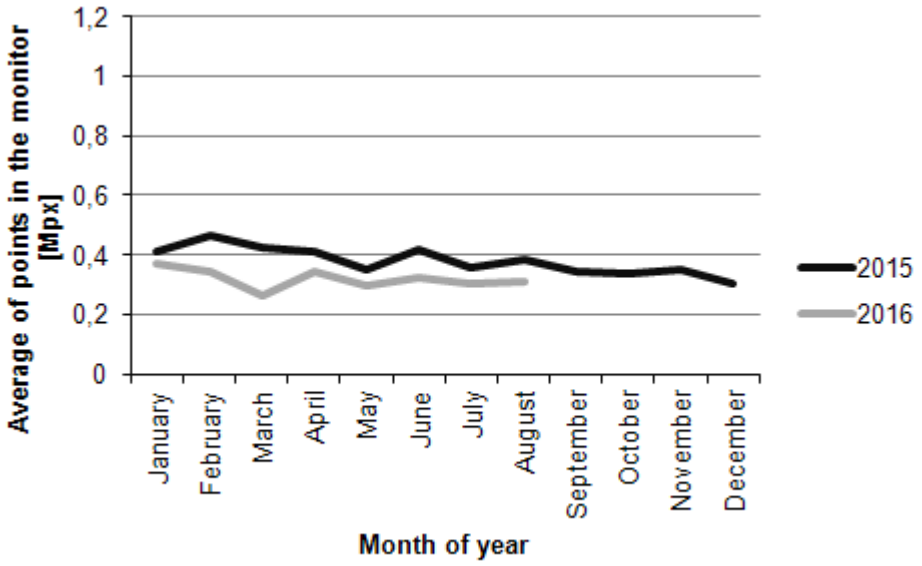

Fig. 4: Average number of points for Africa in each month from January 2015 to August 2016, in accordance with Soukup (2016)

From Fig. 4 it is evident that overall quality resolution of average used equipment decreased in 2016. If the average point resolution were shown continuously in individual years and conceived as a single time, the discovery would be very surprising. The authors´ surmise was not corroborated. On the contrary, the total number of points displayed on the average monitor is almost continuously decreasing in the entire region of Africa. This is can be seen in Fig. 5, showing the indicated trend line by 2016. Regression equation and the value of reliability R. are demonstrated, too.

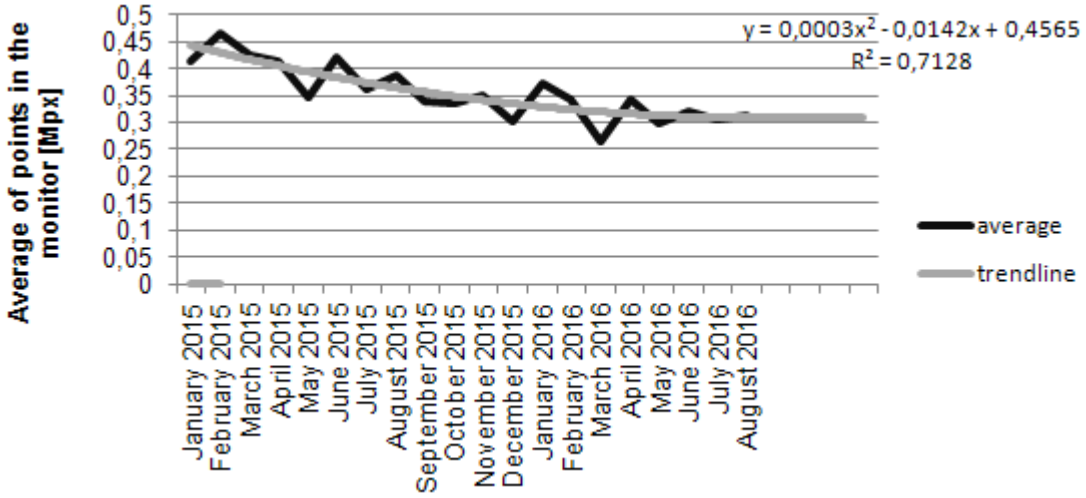

Fig. 5 : Average number of points in the monitor in each month time period January 2015 - August 2016, and the trend line by the end of 2016 for Africa, , in accordance with Soukup (2016)

Regression equation is y = 0,0003x2 - 0,0142x + 0.4565. The value of reliability equals R 2 = 0.7128, suggesting that the regression equation is not very reliable. Trend average of points in the monitor is definitely downward, as well as a trend line.

Using Fig. 6, we can assess the accuracy of the authors´ research presumption provided that the total number of points displayed on an average monitor should be about the same for all regions, and the number of displayed points will grow in relation to the use of more efficient equipment.

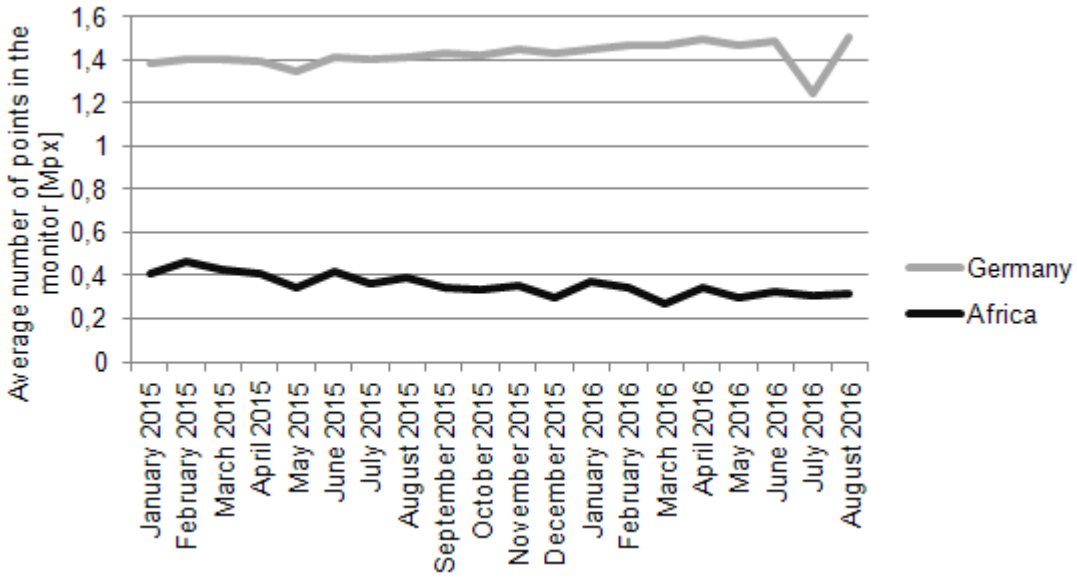

Fig. 6 Comparison of average number of pixels in the monitor in each month from January 2015 to August 2016 for Africa and Germany, in accordance with Soukup (2016)

It is absolutely obvious that in generally advanced Germany equipment with an average score of about 1 megapixel higher than in Africa is used. That is quite a huge difference. Additionally, the trend line in Germany, according to the chart, is basically growing, the only exception being July 2016, when the average score dropped. Nevertheless, the decline is very low, about 0.2 megapixels. To some extent it can be explained by website visitors enjoying vacation and holidays or giving preference to mobile devices with a smaller resolution on their journeys. Conversely, the trend line in Arica is downward in the long term, which is very surprising.

Conclusion

Cultural differences and the status of compliance with standards for information and communication technologies significantly affect the level of education in a multicultural society and affect the quality and efficiency of educational processes. Nowadays people are very afraid of Islamic culture. This fear is accelerated by a huge influx of immigrants from Muslim countries. Mosques and minarets are being built in European cities, Muslim communities residents gather in "their" neighbourhoods and protest against the ban on wearing Muslim headscarves in schools. They promote their culture and religion in Europe, which has a completely different values, customs and religion.

This is confirmed, too, by studies of a major bank carried out in various countries in Africa and Eastern Europe. Due to fear, mistrust and xenophobia, Europe today has to deal with terrorist attacks and unrest in many European capitals. The islamization of Europe results in tendencies to build barricades, to tighten immigration policy and eliminate the terrorist threat. Willingness to tolerate other groups´ points of view and interests is disappearing and thus almost all communities act accordingly.

European civilization is rapidly aging and the influence of Western civilization weakens, while Asian civilizations are expanding due to their economic, political or military capabilities. Islamic civilization demography is increasing. Europe is heading for a period when several different civilizations are adapting and competing with each other.

These phenomena can, unfortunately, be classified as significant determinants of educational communication in a multicultural society. They cannot simply be ignored or regarded as being clear, simple and quick The Internet Live Stats processes the data of the International Telecommunication Union (ITU) and the UN Population Division. The data can be regarded as credible. Internet user is defined as a natural person who has access to the Internet through a computer or mobile device in the house where they live at any time without restriction. Age, computer or mobile device ownership is not integral to the statistics. Therefore, it is strictly a person who can connect anytime at home without any further restrictions. The results of other organizations may vary, depending on the used method. For example, the United Nations Statistics Division recommends to enlarge data collection including the access to the Internet outside the home, as well, see Internet live stats (2013, 2014, 2015). The World Bank (IBRD-IDA) states data in Internet users (per 100 people), which are collected for several income groups. These are e.g. high income, upper middle income, lower middle income, euro area aggregate, low income. High income regions have an income greater than $ 12,476. Low income regions have less than $ 1,025, lower middle-income regions have between $ 1,026- $ 4,035, upper middle income regions have incomes of $ 4,035- $ 12,475, middle income countries have incomes between $ 1,026- $ 12,475, see IBRD-IDA (2016).

The synthesis of these different data is rather difficult, recalculations are necessary, in particular through various weighted averages, taking in account, as well, the total population of the regions, etc. In some cases, the authors could use the data of all residents directly regardless of their income. In some cases, the data of The World Bank (IBRD-IDA) vary very little considering different income groups in the same regions. We assume that the authors did not commit significant statistical errors basing on the total population figures data. Above all, they intended to determine the development trends and to predict future development. All this makes possible to identify the determinants of educational communication in a multicultural society, which are evident from the carried-out research.
Research questions were answered:

- Whether the communication and business negotiations are based on the culture of the monitored territories: all used sources answered the research question positively. Significant problems arise in a multicultural environment communication.

- Whether the use of the Internet is the same in different parts of the world: the research question was answered in the negative on the basis of the statistics listed in the text. The results are evident on all the graphs. Existing differences are abysmal.

- Whether a quick and relatively easy removal of determinants of communication in a multicultural society may be presupposed: the research question was answered in the negative. Removing determinants of communication in education in a multicultural environment requires high costs and long time in terms of communication channels and standards, willingness and ability to work with them. Determinants of common multicultural communications are a long-term issue that is difficult to solve even in states that had long been trying to solve it, and devote considerable funds to it, etc., see Kmecova (2016).

Standards of information and communication technologies are observed in all the areas - this presumption was rebutted. Fig. 6 shows a comparison of the quality of the average number of points in the monitor in individual months from January 2015 to August 2016 for Africa and Germany. There is a very distinct difference in the shown average number of points amounting more than triple. Unfortunately, Fig. 5 disproves the expectation that the situation will get better. It shows a declining average number of points in the monitor in each month from January 2015 to August 2016, and the trend line by the end of 2016 for Africa. The authors obtained the data of the research using Google Analytics. The source was a significant site for tourism, the total number of visits ranging in the millions per year and including data about visitors from all regions, see Soukup (2016).

Unfortunately, based on the research, we cannot expect significant improvements in the coming periods. There are truly abysmal barriers in education in a global multicultural environment with the use of electronic means, e.g. through e-learning, see Krpalkova Krelova (2016). The situation, however, may be different in a local multicultural environment where there may not be huge differences, mainly in hardware, but more in quality of human resources.

The authors would like to thank Petr Soukup for providing statistical data from a significant site for tourism, the total number of visits of which ranging in the millions annually.

Economical Evolution of Additive Laser Manufacturing (ALM) Technologies in Romanian Dental Industry

Băilă Diana-Irinel[1], University Politechnica of Bucharest, 313, Splaiul Independenței Street, Bucharest 060042, Romania, baila_d@yahoo.com

Lazăr Livia-Veronica[2], University Politechnica of Bucharest, 313, Splaiul Independenței Street, Bucharest 060042, Romania, livia_veronica_lazar@yahoo.com

Abstract

Additive Laser Manufacturing (ALM) is a set of processes which enable the manufacture of layer by layer by adding a metal powder, achieving a physical 3D model from a numerical model, using the sintering by laser power. Today, in the dental field had an industrial revolution concerning the manufacture of personalized dental implants and crowns, reducing process time, product weight and use of raw materials. This technology permits to obtain the products, using less energy, less landfill waste.
Additive Laser Manufacturing processes of metallic powder are achieved by SLS, DMLS, SLM, EBM, DMD, LM, Lens, DLF and used pure metal powders, yielding pieces which can be functional immediately, not always being necessary a sintering post-treatment. [1-5]
Each Additive Laser Manufacturing method has advantages and disadvantages because of appearance of residual stresses in the material after sintering / melting process.
The ALM technology for dental industry arrive to a great maturity degree TRL 9- TRL 10, because can be used in large series production. ALM technologies are used in different domains like dental, tooling, aerospace fields.
The SLM and DMLS processes are frequently used in Romanian medical industry for realized dental implants using Ti alloys (35%) and for dental crowns using Co-Cr alloys (65%).
The Additive Laser Manufacturing systems sold for Romanian stomatology field are Phenix Systems-PXS & PXM dental and EOSINT M270. The ALM systems are very performing and can creating up 450 dental units per day.
Concerning the Additive Laser Manufacturing (ALM) systems remarked that only 8% of sell of Romanian 3D printing companies are intended for dental field.

Keywords: Economical evolution, Additive Laser Manufacturing, metallic powder, innovation

Introduction

Additive Laser Manufacturing is a rapid prototyping technology using a laser power for sintered the metallic powders, layer by layer. Using this technology can realize dental crowns, bridges, dental implants, chapels and surgical instruments.

The metallic powders used in the Additive Laser Manufacturing technologies depending on the industrial domains (medical, aerospace, tooling, jewelry, automotive, etc.), where are used and classified as: tool and maraging steels (304L-ST2709B), stainless steels (316L-ST4404D), aluminum alloys (AlSi10Mg), cobalt-chromium superalloys (ST2724G, F75, F90), Ni based superalloys (Ni-Cr), commercially pure titanium (TiCP grade2), titanium alloys (Ti6Al4V, TiAl6Nb7), copper alloys (Cu10Sn) and precious metals (gold, platinum, palladium, silver).

The ALM systems manufacturers (Phenix Systems, EOS, ARCAM, Concept Laser, etc) realize and approve the material powders, but exist some clients who want used personalized metallic powders with special composition and different percentage of chemical elements and for these metallic powders, the cost is greater than if is buy the traditional powders of manufacturers. [1-5]

In figure 1 is presented the graph of metallic powders percentages used in Additive Laser Manufacturing technology in Romanian dentistry.

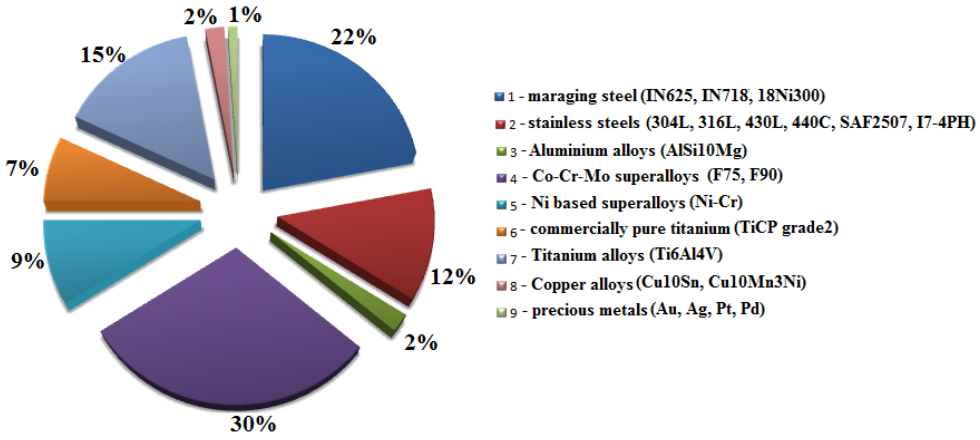

Fig 1: Metallic powders percentages used in Additive Laser Manufacturing in Romanian dentistry

Economical Evolution of ALM Systems in Romanian Dentistry

Companies selling ALM systems in Romania are frequently found in cities like Bucharest, Cluj-Napoca, Timisoara. In the last five years, some companies buy ALM systems in Brasov and Sibiu to be used in dentistry domain.
In figure 2 is presented the percentage of the dental companies that bought ALM systems in Romania distributed by cities.

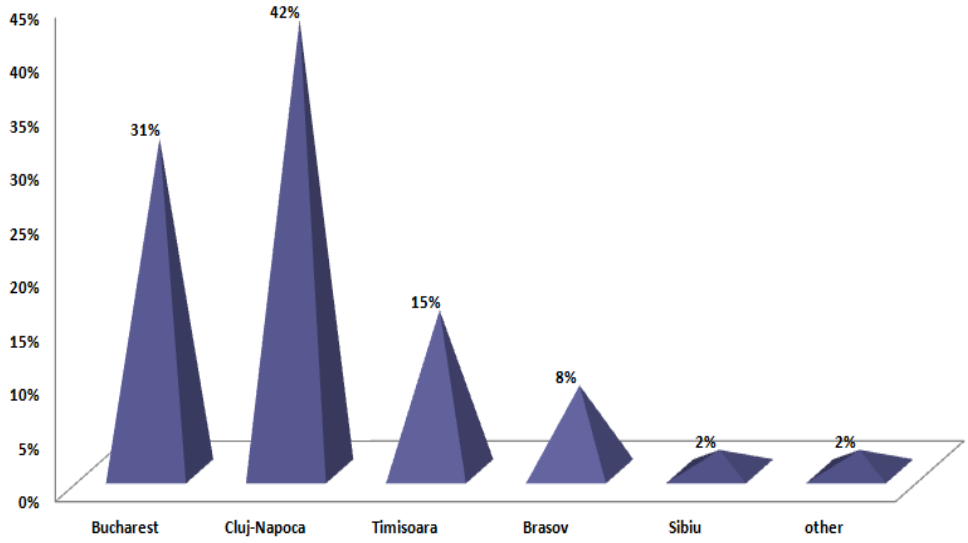

Fig. 2: Percentage of the dental companies that bought ALM systems in Romania distributed by cities

The marketing of additive manufacturing systems in the world notice that 10% of sales are for additive laser manufacturing systems – ALM, approximate 1.7 euros billions.

The powder costs vary, for stainless steel is 90 euros/kg and in the case of the titanium alloy is 200 euros/kg. Costs parts manufactured by ALM does not depend on the complexity of forms parts, unlike other manufacturing methods.
The cost of ALM sintered parts takes into account the cost per kg of metallic powder, the depreciation cost of the machine, the laser scanning speed, etc.
Cheapest ALM systems are using SLS method by indirect sintering of metal powder, but always, the pieces will must supported a post-sintering treatment.
In dentistry, the ALM systems are sold from the company EOS, Phenix Systems, ARCAM, etc. In general, a dental SLM (Selective Laser Melting) system cost around 200 000 – 500 000 euros.
Concerning SLM manufacturing of a cm^3 stainless steel 316L (90 euros/kg), 26% represent direct costs (metallic powder) and 74% represent indirect costs (3% energy, 22% labor, 42% machining, 7% overhead). The price of a cm^3 stainless steel can arrive to 3.20 euros/cm^3.
In figure 3 are presented the most sell SLM systems in Romania, SLM 250, Phenix Systems PXS & PXM dental, EOSINT M270 and other.
In Transylvania, the most sell SLM systems are SLM 250, SLM 280 in Cluj and in Brasov. In Bucharest, the most sell SLM systems are Phenix Systems PXS & PXM dental and EOSINT M270.
In Cluj, the SLM systems are used in general in automotive industry and in medicine. In Brasov, the SLM systems are used in medicine and in aerospace industry.
In the Romanian dental clinics, the cost of Co-Cr/Ti dental element SLM manufactured by a STL file varies from 6 euros to 45 euros.
The cost of Co-Cr/Ti dental element achieved by milling varies between 18 euros to 50 euros. So the cost using conventional technologies (milling process) is higher than SLM technology.

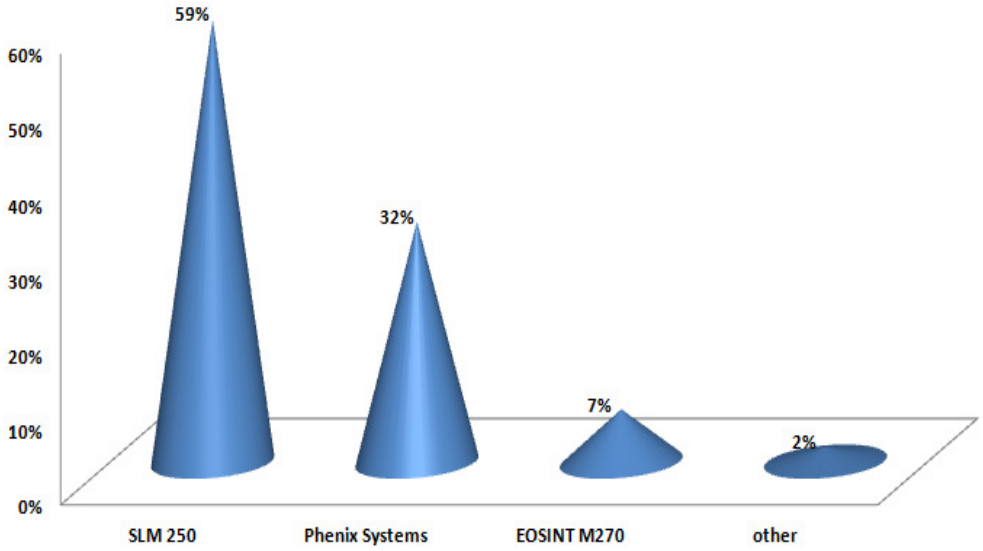

Fig. 3: Marketing of SLM systems in Romania

The SLM systems work with an accuracy of +/– 20 μm and can produce around 450 units at low cost within 24 hrs. This corresponds to an average construction time approximate of 3 minutes per unit.
The metallic prosthesis realized by SLM/DMLS manufacturing present a constantly high quality of crowns and bridges manufacturing. DMLS (Direct Metal Laser Sintering) process is similarly with SLM technology, differ the sintering temperature and power laser.

Actually, the Additive Laser Manufacturing of metallic prosthesis is an industrial production process, thanks of high productivity of the systems., the production cost fall whilst the quality of the final products result consistently high.

Conclusions

The advantages of ALM technologies are: cheaper than precision casting and milling processes; homogeneous metallic structure, high precision, good fit, constant quality, consistent tolerances, reproducible product properties, exact margin fit, good milling properties (particularly for crowns), flexible choice of veneer ceramics, permit a better adherence to ceramics (grace of porosity), production parameters are documented and can monitoring the parts production.

The dental parts realized by ALM methods present mechanical properties (density, elasticity and mechanical resistance) like the dental conventional technology.
Due to numerous advantages of ALM processes noted a sales increase of ALM systems in Romanian dentistry.

The price of SLM/DMLS systems is very important for dental clinic, but in the same times the quality and precision of dental works to satisfy the clients is a real reason to use these technologies.
In Romania, the dental industry has undergone a revolution in the ten last years, concerning the equipments performance and the materials used.

In the dental field in Romania 30% of the production of crowns are made by SLM/DMLS technologies and 70% by conventional technologies.
In Romania, in the future is expected an exponential sales growth of SLM systems in different industry like automotive, aerospace, aeronautic, medicine, mechanical, tooling and other.

Quality of Population Nutrition Reflected by Reference Budgets

Eva Abramuszkinová Pavlíková, Department of Law and Social Sciences, Faculty of Business and Economics, Mendel University in Brno, Brno 613 00, Czech Republic, email: eva.pavlikova@mendelu.cz

Abstract

This contribution deals with the economics of the population nutrition in relation to Reference budgets across EU. Current developments are analysed while combining a sociological interpretation to economic data and focus groups investigation. Reference budgets are perceived as guidelines which enable people to fulfil their differing social roles to be accepted by others. Various countries in Europe have different approaches to this concept, in the Czech Republic it is a new phenomenon. Authors present original comparative results for the Czech Republic based on focus groups discussions.

Keywords: reference budgets, nutrition, focus groups, Czech Republic

Introduction

The importance of active inclusion policies and adequate minimum income support for ensuring a decent life to all citizens have been emphasised by many official authorities including the Council, the European Commission and the European Parliament (e.g. Council of the European Communities, 1992a, 1992b; European Commission, 2008; European Parliament, 2009; European Council, 2010; European Parliament, 2010, 2011; European Commission, 2013; European Economic and Social Committee (2013). The European Commission (2013) proposed the development of comparable reference budgets as an instrument to help Member States design efficient and adequate income support and to facilitate the Commission's task of monitoring the adequacy of income support in Europe. Reference budgets are illustrative priced baskets of goods and services that represent a given living standard (Bradshaw, 1993). They can show the impact of publicly provided goods and services on the living conditions of households. Reference budgets are widely used in Europe, and serve many purposes (Storms et al., 2014, Goedemé, T., Storms, B., Van den Bosch, K., 2015).

Research Design and Methodology

This paper presents the Czech Food basket which was developed in the framework of the European pilot project on the development of a common methodology for the construction of cross-nationally comparable food baskets in the EU. The research activities which were conducted during 2 years consisted of the following steps. The first milestone was completed by detailed description of Czech food based dietary guidelines. The second step was to draw up a healthy food basket, based on typical Czech dietary guidelines, starting from a common base for comparative reasons. The third milestone included focus group discussions followed by the next step which allowed to draw up a total food basket fulfilling essential physical and social needs. The last milestone included pricing of the food basket.

Results and Discussion

Reference budgets propose a minimal financial resources which people need for adequate social participation in given society taking into account the specificity of respondents. This results which are presented are proposed for the target population which consists of children, persons of working age, in good health, without disabilities and living in the capital city, Prague. It is obvious that the social context as well as the price level of the capital city does not have to be the same as in other parts of the country. The reference budgets were developed for three model families: a single-person household (male/female), a single parent household with two children, a couple with two children. The adults are about 40 years old, children are about 10 years old in case of a boy who is at primary school and girl who is about 14 years old at secondary school. These households are hypothetical ones and representativeness in this case was not the main goal as it would be very difficult for cross-national comparison. We are aware of the fact that household structure vary widely across the European Union. The model families which we introduce in this study were chosen as a test case to see if the reference budgets methodology could be applicable on the level of European Union. They do not have represent the most typical situation and the household composition of the model families does not have to reflect the situation of the majority of the target population.

Eating habits and food guidelines

In the period 2000-2011, the total food consumption in Czech society consumption in Czech society increased by 6.7%, especially the consumption of plant products by 12%. Significant decrease in consumption occurred only in beef, bread and spirits. In contrast, the highest increase in consumption occurred in soft drinks (+39.3%), bread wheat (+33.6%), other dairy products (+30%), cheese (+23.8%), butter (+22%), wine (+20.5%), tropical fruit (+19.3%) and cereal products in total (+13.4%). There is notable demand to buy cheaper commodities (such as plant products, meat or dairy products) which results in a positive trend of increasing fruits and vegetables consumption as well as dairy products, and thus increase of Vitamin C intake and Calcium. On the other hand, the increasing consumption of butter, sugar and sugar products is a negative trend in Czech society. (Štiková, 2013)

Eating patterns are different for various European countries. In all EU member states, food has an important share in total household expenditures, often most important after housing, but situation varies a lot. As Goedemé, T., Storms, B., Van den Bosch, K. (2015b:67) explain, it confirms the findings already from the 19th century that poorer households spend proportionally a larger share of their income on food than richer households, later studies confirm that food expenditure is the highest in low income countries and poor countries spend generally more on low-valued staple foods such as cereals while richer countries spend more on diary and meat products. In the Netherlands, the third income quintile (with median income) spends about 10% of its total expenses on food, while the situation in Romania declares 33%. It can be observed that in most countries the first income quintiles spend more on food than the third income quintiles, except for Netherlands, Ireland, United Kingdom and France. Situation in Cyprus, Malta, Bulgaria and Romania shows quite large difference reaching almost 10 percentage points.

”Given that people in poorer countries and households lower down the income scale tent to spend relatively more on food, one might believe that in absolute terms differences in spending on food and non-alcoholic beverages are relatively limited. This, however, is not the case. In Europe, on average, households in the third income quintile spend about 70% more on food than households in the first income quintile, in absolute terms. Similarly, even though households in the third income quintile in the Netherland spend only 10 % of their expenditures on food, in Euros they spend 85% more than households in the third income quintile in Romania who spend 34% of their household expenditures on food. If we take account of price differences of food and non-alcoholic beverages (which were in 2010 43% higher in the Netherlands than in Romania), households in the Netherlands still consume 29% more food and non-alcoholic beverages than households in the third income quintile in Romania.” (Goedemé, T., Storms, B., Van den Bosch, K., 2015b:67) It is evident that food prices are

different in various European states but is not always true that the higher food prices are, the more households spend on food (in EUR or volumes). There is a positive correlation between the amount spent on food in PPS (purchasing power standards) in the third income quintile and average total household expenditures (in PPS), with some exceptions. It can be noted that Southern European countries are among top spenders on food, whereas the Czech Republic is in the opposite situation.

It is not only the amount of food and expenses but there are different eating habits across Europe which are explained in national dietary surveys. There is a general distinction between the North and the South of Europe. Southern European countries declare higher consumption of cereals, nuts, fish, seafood, fresh fruit and vegetables, legume and vegetable oils (mainly olive oil). Northern and Central European countries use more vegetable fats, animal lipids and soft drinks. The dietary studies in the Czech Republic show that "the eating habits in these countries are generally not meeting the recommendations. The high levels of saturated fats and sugar that are prevalent in overall dietary patterns in Eastern Europe are of great concern and are accompanied with insufficient intake of important vitamins, calcium and magnesium." (Goedemé, T., Storms, B., Van den Bosch, K., 2015b:70)

The first dietary recommendations for the Czech Republic were suggested by the Society for Nutrition in 1986, later updated form in 1989. In 1994, the Council for Nutrition of the Ministry of Health of the Czech Republic made recommendations on nutrition of healthy population, in 2004, the Society for Nutrition published a report "Nutrition recommendations for the Czech Republic" followed in 2005 by a report done by the Ministry of Health of the Czech Republic entitled "Nutrition recommendations for the population of the Czech Republic." In 2012, the Society for Nutrition presented an innovative nutrition recommendations for the population of the Czech Republic in a document for professionals who deal with the nutrition prevention of mass non-infectious diseases and promote good eating habits. These recommendations were done in relation to the children's age, nutrition of pregnant and lactating women and the elderly nutrition, based on the EU document: The Strategy for Europe related to health problems connected to nutrition, overweight and obesity (a white book) from 2007 and inspired by WHO. (Society for Nutrition, 2012) For the Czech Republic, it was decided to take as a reference framework the information provided by the Societies for Nutrition in countries, also known as "DACH" (Germany, Austria, Switzerland) which are based on professional and scientific studies and regarded as conclusive. (Society for Nutrition, 2014)

In 2013, the Czech "food pyramid" was suggested the Forum for Healthy Nutrition. It is a graphic simple explanation of recommended nutrition guidelines specifically set for the Czech population. It gives basic recommendations for the content of a food basket. The goal of these recommendations is the prevention of health risks which are rooted in the nutrition traditions of Czech population. (FZV, 2013)

The table 1 shows Food-based dietary guidelines for different age groups in the Czech Republic which were inspired by DACH guidelines and taken as official recommendations for the Czech Republic. We used this items to ask the nutrition specialist to suggest the menu for Czech population. The guidelines which she is using given by a software are related to DACH guidelines and allowed her to construct the menu which was discussed in focus groups.

Table 1: Food-based dietary guidelines for different age groups in the Czech Republic

	Age group							
Food group	Childre n 0-6	Children 7-9	Childre n 10-14	Student s 15-18	Women 19-64	Men 19-64	Men over 65 nonwor king	Women over 65 nonwor king

Source: ÚZEI, 2014

Focus groups have taken place in Prague, the group number 1 on Thursday 12.2.2015, group number 2 and 3 on Friday 13.2.2015. In total there were 23 respondents. This focus group took about 3 hours with one break. The group number 2 and 3 took place also in the Prague centre, the timing was 3.30 hours and 3.45 hours with 2 brakes. All documents were translated into Czech language and the process was done according to rules given by the team of reference budgets coordinated from Belgium. During the focus groups 3 experts were present: a moderator, an assistant and a reporter.

Social Participation and Social Needs

The first set of questions within focus groups was dedicated to the topic of Social participation and social position of respondents in Czech society. The opening question ask them which social positions as adults do they have and consider them as important. The most frequent answers were: a parent, a husband, a wife, an employee, an employer, a son, a daughter, a child in general - also in the case of adults which always stay children of their parents and have roles related to this social position. Furthermore, a consumer, a buyer, a member of a housing association, a member of community, a neighbour, a member of political party or church, a friend, a colleague at work, a receiver of social services, a member of church choir, parents as users of pre-school activities, a member of informal community where people live, a member of some collectives, movements, some positions which allows people to fulfil the capacity to earn money; a citizen; a student given the opportunity to learn, a long-life learner, a citizen as a person who is " not indifferent about the municipality, is in permanent participation, organiser of social and cultural event", an organiser of activities done at voluntary basis, interest groups.

The same question was repeated with the focus on social position of children. They consider as important to be for example a member of scouting organisation or any other organization which builds strong relations among children or in a community of the same minded people. An interesting comment occurred when we discussed a social position of parents explaining that nowadays a social position of employee sometimes substitutes to some extent the function of a parent as people are very busy and have lack of time for their own children.

The template which was given to stimulate the discussion about social positions included other items which were not preferred by Czech respondents. There were social roles of a voter or a member of

trade union. There were not fully recognised by our participants as important for social positions in Czech society. Trade union membership is not so common. There was one person who was member of trade union, but in general this position was found as not the most typical one. In another words, in a typical Czech family, in our case in the reference family, it is not probable that somebody would be a member of the trade union. As one respondent mentioned: "Trade unions are less important. Friends are more important. Neighbour and interaction with the environment is important".

The above mentioned social positions were suggested in a template based on Belgian experience. When we asked for other social positions specific for the experience of our respondents, the answers included the following: a member of community social position, such as people who create their own coffee shops, centres for kids, centres for mothers or fathers, community of parents where they do activities together like cooking, organizing Santa Claus evening or going with their families for trips. In villages, the social role of a citizen in the village becomes important which includes activities where interaction with society is needed and also citizenship related to voter position. It was interesting that other set of positions were connected with ownership of means which actually give a certain position to people in their surroundings such as an ownership of a smart phone, especially for kids and teenagers, of a tablet or a computer, eventually also access to internet depending on the age of children. Another ownership was mentioned in case of animals, especially a dog, as one respondent noted: "even if there is a new couple, they buy a new dog to take care of…dog is a mark of social status". Going with dog outside is important for social interaction, even more for singles or pensioners.

Human Needs and Satisfiers

Another set of question was related to human needs and satisfiers. Based on the answers from our respondents we can conclude that they found as very important the following: relationships with colleagues at work, friendly relationships outside of work, going out, as one respondent noted: "good relations are part of the job, it is important for good quality of life and regardless of advantages…". Followed by good relations with grandparents, primary relations in family, at home, security in general and security for the kids, economic security given by a job, good quality shoes for kids and cloth, shoes for sport, accessories, active live at community level, in the place where people live. It is important that cities have sport, social and cultural centres as well as freely accessible parks, playgrounds and drop-in centres. They mentioned also centres for handicapped people and accessible social services.

Having a bike or/and a car can be also important satisfier and a need which in some cases becomes a must. As one respondent noted noted: "when living in the periphery of the city, a small simple car should be a standard, car is a basic need for a family - depends on location in Prague". Bike is good to have for a free time activity in the city or outside, for everyday transport around the city the public transport is better option and the costs related to the monthly public transport should be calculated into the budget. Some respondents agreed that sharing economy is rising, bikes and cars can be used on rental basis as well as rental of sport equipment. Other standard activities are related to culture, going to theatre several times per year, going for skiing and children going to ski courses, schools in nature provided by school or going on summer and winter holiday should belong to a standard, does not have to be abroad.

For financial safety it is important to own a bank account. Large part of the budget is spent on housing which is in the capital city quite expensive. Good quality of schools and kinder gardens as well as public spaces was mentioned also. It was confirmed that secondary relations at work and outside of family relations are also very important, not only primary ones in a family. All basic needs for standard participation in society were confirmed including good food, health care, personal care, possibilities for relaxing and leisure, general security and security for kids, good primary relations, home, cloths and education. Although the respondents were of productive age, they realize that seniors in Prague make about 25% of population with special needs for services, communication or engagement in community. Based on the Czech dietary guidelines inspired by DACH countries, the

items for the healthy food basket were modified into categories which were inspired (for comparative reasons) by the Belgian example.

The Healthy Food Basket

Based on the Czech national food guidelines and the menu which was suggested by a nutritionist, we have discussed within the focus groups the acceptability of this healthy menu and healthy food basket. In general, comments given by focus group participants were minor. Majority of them was dedicated to the style of cooking and eating habit, not to ingredients. The comments and suggestions were more of individual nature than a general agreement of the focus group.

Other functions of food which respondents consider as important for adequate participation in society and keeping good relationships with friends include eating out, inviting friends for a meal, organising a birthday party or family celebrations. General agreement was on the fact that sometimes, such as during holidays or trips, it is needed to eat out. As one respondent mentioned: "I make sometimes a dinner to say thank you to somebody who helped me, for example when moving a furniture. Other functions of food are explained by its social meaning and relaxing function. We noted a trend among respondents of organising locally produced food events with friends or neighbours. Of course, there are people who have specific needs when food becomes a life style or the focus is on organic food or local food or ethnic food. Teenagers can be influences by preference in a peer group such as McDonalds or Hello Kitty Marks. The suggested conclusion for frequencies which we used for calculation of prices was based on Belgian example.

In the next step, the basket was a subject of pricing. The month of pricing was March 2015 and the procedure corresponds to guidelines given project partners with the aim to make it comparable across countries. The respondents in focused groups in Prague mentioned as the most common shop for their food shopping Tesco. This was the main reason for using Tesco for pricing the basket. We looked at the comparability of shops regarding the price and it can be stated that Tesco has more or less average price, it is not the top cheapest shop for all goods. The comparison is not easy, it depends on items which you compare. We did not face any particular difficulties in pricing while following the pricing procedure given in advance by Belgian coordinators. IKEA mainly was used as a reference point for pricing the kitchen equipment. It was mentioned by respondents as a shop which is widely used.

Table 2: The Czech food budget, monthly amounts in euro, March 2015

	WOMAN	MAN	COUPLE	SINGLE WOMAN + 2 CHILDREN (boy 10y-old & girl 14y-old)	SINGLE MAN + 2 CHILDREN (boy 10y-old & girl 14y-old)	COUPLE + 2 CHILDREN (boy 10y-old & girl 14y-old)

Total food budget	121,9	129,9	220,4	334,0	342,0	432,5

Source: own caluculations

As for purchasing patterns, there was an opinion mentioned in FG that when people have less money, they buy less quality food or they eat less vegetables. As a product which is not acceptable for choosing the lowest price they mentioned meat, salami and ham. Other comments were the following: our respondents shop mainly in supermarkets, namely Tesco, sometimes in small local shops or fruit/vegetable markets, some people shop on internet; Lidl is popular for cloths, Ikea and Kika for furniture, Tesco, Billa, Kaufland and big shopping malls are popular for combination of shopping and entertainment. For shopping in supermarkets it is good to have a car. Some people focus on the country of origin mark.

When we compare budgets for healthy eating, there are substantial variations between countries. The highest budget is in Denmark with 312 EUR and the lowest is in the Czech Republic with 82 EUR. This is result of a combination of differences in dietary guidelines and price differences. As the budget, according to different food groups, for a single woman shows, there are differences between countries in the share of the different food groups in the total budget. For example the Czech Republic has the smallest share of liquids. (Goedemé, T., Storms, B., Van den Bosch, K., 2015b:93) Comparable results show, that for vegetables, fruit, meat, fish and cheese the weighted pricing procedure declares the difference between member states in the number of low-priced items for each category. There are large variations across countries, ranging between 39 priced products in Sweden

up to 382 products in Belgium or 100 in the case of Czech Republic. The interpretation for Sweden explains that people choose seasonal products in the given time of the year and exclude expensive items. (Goedemé, T., Storms, B., Van den Bosch, K., 2015b:112) As the given explanation makes sense for Sweden, it also shows limitations to such comparative studies where clear instructions and detail methodological notes are urgently needed. The investigation in the Czech Republic makes a good basis for analysis how the reference households in comparison with other EU countries deal with healthy food guidelines and budget. It also stresses the variety of opinions, country guidelines, habits, amounts of food and expenses which were experienced by respondents in focus groups in different European countries.

Acknowledgment

This paper was supported by The Ministry of Education, Youth and Sports, Prague, Czech Republic: LD – COST CZ, project: LD15065 titled Gender dimension of active ageing implementation in the Czech private and public sector in comparison with western countries.

Regional Interbudgetary Relations: Problems and Solutions

Yuliya Viktorovna Karaulova, Postgraduate Student, Samara State University of Economics, Russia, spiel-fin@mail.ru

Abstract

The article examines theoretical aspects of public finance management. The author reveals some problems of interrelations among public-law entities in terms of budget process. The article analyses the issues of interbudgetary relations at the federal subject level in Russian Federation and, in particular, those of the financial dependence of most Russian regions and municipal entities; the redistribution relations among budgets at various levels; the issues regarding the lack of impetus for regions (municipal entities) to accelerate their local revenue potential. The author proposes some measures aimed at enhancing the interbudgetary regulation quality that, if taken, will boost the financial resources capacity of a federal subject of the Russian Federation, which, eventually, will affect the increase in the public finance efficiency.

Keywords: consolidated budget; interbudgetary relations; fiscal capacity; revenue potential; interbudgetary regulation instruments; public finance efficiency.

Introduction

Interbudgeraty relations are the most essential element of regulating the budgetary interrelations among various authority levels. This element assumes particular significance in a country like Russia that shows considerable difference in socio-economic development of not only federal subjects but also municipal entities within regions (Kostenkova, 2017).

There is a critical gap in the regional development of Russia deepened by gradual reduction in the reliance on local revenues. For example, in 1996, 59 federal subjects had positive balance of the interbudgetary relations with federal budget while, currently, the number is smaller and, by various estimates, ranges from 13 to 35. Besides, these regions produce about 52% of gross domestic product (GDP), with the other 10 federal subjects, which lag behind, accounting for less than 1% (Valentey, 2012).

Thus, substantial problems, which have their peculiar features in every region, are typical of Russian budgetary system. This fact determines the relevance of the research into the problems of interbudgetary relations at a regional level, the search for their most efficient solutions, as well as the development of directions for enhancing the instruments of interbudgetary relations.

The objective of the current study is to develop a theoretical framework for the interbudgetary relations at a regional level and a set of measures for enhancing the budget process efficiency in a federal subject of Russia.

The objective can be achieved through fulfilling the following tasks:

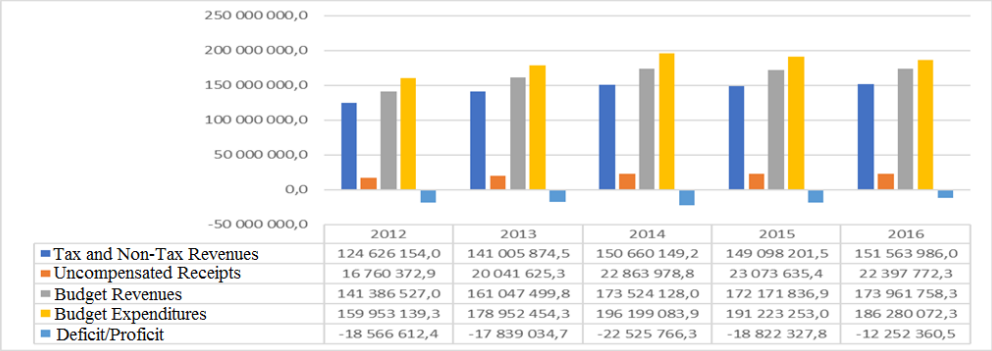
- to study the theoretical aspects of public finance management;
- to reveal the problems of the interbudgetary relations at a subfederal level;
- to propose measure that will allow to enhance the budget process quality, which, in its turn, will increase the financial resources capacity of local budgets of Russian federal subjects.

Material and Methods

The theoretical framework embraces the works by Russian and foreign economists specializing in public finance. The research is conducted based on the data obtained from The Ministry of Finance of Russian Federation, Samara Oblast Government and both Russian and foreign periodicals.

The system method is chosen as a leading approach to study the problem, with a range of general scientific methods applied. These methods are empirical, theoretical, logical and dialectic ones, analysis, synthesis, and that of visual presentation.

Results



It is fair to say that, currently, there is no single approach to the conceptual construct, evaluation and analysis of budget regulation in science. According to the majority of researchers, interbudgetary relations are a budget regulation of the redistribution among local budgets for ensuring the horizontal and vertical balance (Solomko, 2015; Shirobokova, 2014). This view does not seem comprehensive enough as it fails to take social processes and sector development proportions into consideration.

The author feels a need for more comprehensive consideration of the issue. In this regard, the author proposes a clarification of the essence definition of *interbudgetary relations*, which are one of the key elements of budget regulation for making the redistribution more even. The redistribution within the budget system is conducted through various mechanisms, with interbudgetary transfers, governmental grants, subsidies, grants-in-aid, public budget loans, revenue allocation standards being among the main ones. Thus, interbudgetary regulation is a basic element of budget process. This results from the fact that rational and equitable state budget distribution among local budgets can be referred to as one of the most crucial condition for balanced socio-economic development, economic efficiency and social justice, which let the population access the public goods equally and the economic entities get different kinds of state support, the right to which is guaranteed by law (Volokhina, Malysheva, 2015).

The drawbacks of the interbudgetary relations require effective measures to overcome or minimize their consequences. The balanced proportion of budget redistribution becomes possible due to interbudgetary regulation provided that an extensive analysis of current situation is conducted in order to ensure the correct process. “Consequently, finding justified, transparent, scientifically substantiated methods of interbudgetary relations regulation that contribute to the balance of the budget system is of primary importance” (Karaulova, 2017).

This article considers the case of the interbudgetary relations in Samara Oblast. It should be noted that this region takes top positions in Volga Federal District based on budget process indicators. This means that the region’s budget policy ensures certain balance and stability of the budget system, provides social support and stimulates investment activity. The cooperation among municipal entities and the government of Samara Oblast ensured the increase in tax and non-tax revenues of the regional consolidated budget (Figure 1).

For example, the budget revenues increased by 13% in 2016 compared to 2015 and now amount to 151.6 billion rubles. There is also an increase in uncompensated receipts. The Figure 2 presents the revenue structure from the perspective of the revenue types of the Samara Oblast consolidated budget in 2016.

	2012	2013	2014	2015	2016
Tax and Non-Tax Revenues	124 626 154,0	141 005 874,5	150 660 149,2	149 098 201,5	151 563 986,0
Uncompensated Receipts	16 760 372,9	20 041 625,3	22 863 978,8	23 073 635,4	22 397 772,3
Budget Revenues	141 386 527,0	161 047 499,8	173 524 128,0	172 171 836,9	173 961 758,3
Budget Expenditures	159 953 139,3	178 952 454,3	196 199 083,9	191 223 253,0	186 280 072,3
Deficit/Proficit	-18 566 612,4	-17 839 034,7	-22 525 766,3	-18 822 327,8	-12 252 360,5

Fig. 1: The consolidated budget execution in Samara Oblast (Kravchenko, Urman, 2015)

Source: http://samara.ifinmon.ru/analiticheskie-otcheti/analiz-ispolneniya-konsolidirovannogo-budgeta/ispolnenie-budgeta/

Based on the data analysis, it can be concluded that the two main sources for budget revenues are corporate income tax (31%) and personal income tax (31%) followed by excise duties (11%) and uncompensated receipts (6%). It should be highlighted that the structure of budget revenue part in Samara Oblast has been unchanged over the last 5 years.

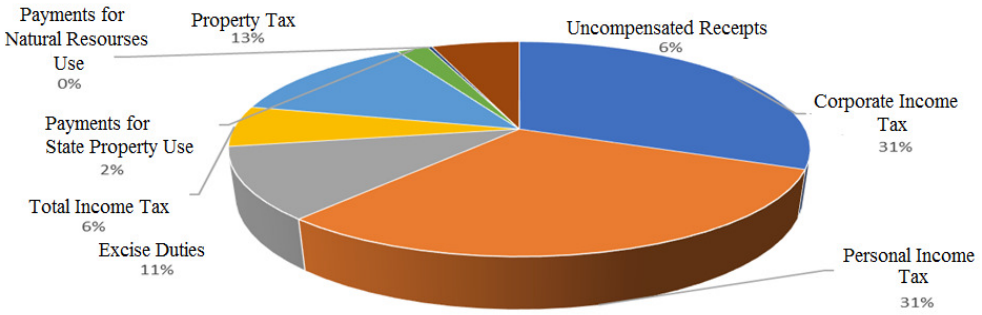


Fig. 2: The revenues structure from the perspective of the Samara Oblast consolidated budget revenues in 2016, % %

Source: http://samara.ifinmon.ru/analiticheskie-otcheti/analiz-ispolneniya-konsolidirovannogo-budgeta/ispolnenie-budgeta/

However, there is a slight reduction in the budget share of districts, settlements and municipalities concerning the revenues structure from the perspective of budget levels (Figure 3).

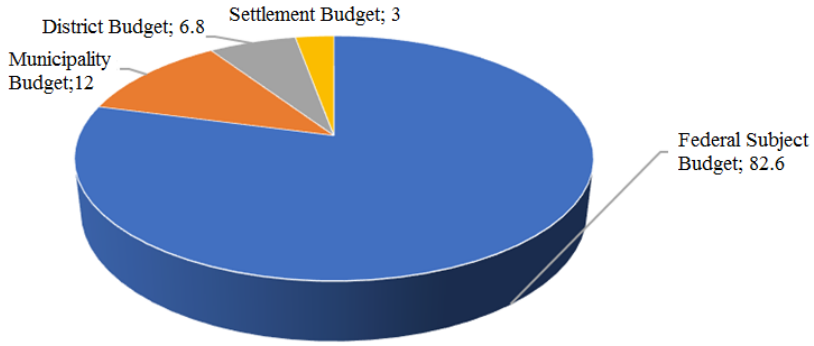

Fig. 3: The structure of the Samara Oblast consolidated budget revenues in 2016, % %

Source: http://samara.ifinmon.ru/analiticheskie-otcheti/analiz-ispolneniya-konsolidirovannogo-budgeta/strukturnaya-dinamika-fakt-postupleniya-dohodov-po-urovnyam-budgeta/

The analysis of receipts at various budget levels showed that the federal subject budget (82.6%) then municipality (12%) constitute its largest part and districts (6.8%) follow. The system dynamics seems negative as local income of municipalities goes down.

For example, while the federal subject budget increased by 3.6% in 2016 compared to 2012, the municipality budget decreased by 1.4%, the district budget – by 2.3% and the settlement budget – by 0.2%. In order to boost the receipts of non-tax and tax revenues, there were various measures based on the 2014-2016 regional state programme 'Public Finance Management and Interbudgetary Relations Development'. They aimed at enhancing the business process quality and the efficiency of budget expenditures as well as improving the interbudgetary relations and ensuring long-term balance and sustainability of the budget system of Samara Oblast.

The expenditures structure of the Samara Oblast consolidated Budget in 2016 is plotted on Figure 4.

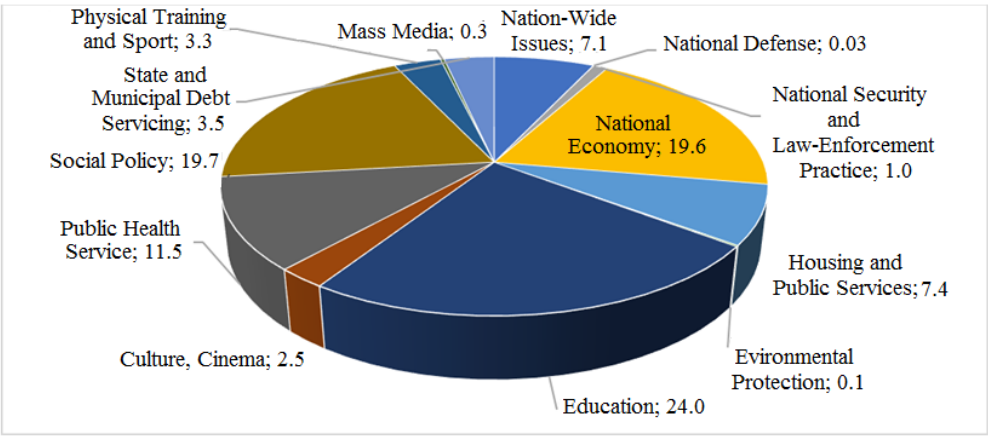

Fig. 4: The expenditures structure of the Samara Oblast consolidated Budget in 2016, % %

Source: http://samara.ifinmon.ru/analiticheskie-otcheti/analiz-ispolneniya-konsolidirovannogo-budgeta/ispolnenie-budgeta/

As seen, the expenditures were allocated to education (24%), social policy (19.7%), national economy (19.6%), housing and public services (7.4%), nation-wide issues (7.1%). It should be

stressed that no significant changes took place compared to the previous period, the order of expenditure categories remained the same, however, there is a decrease in social and education expenditures.

The statistics for 2015 show the interbudgetary relations efficiency in Samara Oblast is slight as there is a lack of balanced local budgets in the region while a number of deficit budgets is rather large (73% in municipal regions and 27% in municipality). The budget deficit accounts for 18.5% of total deficit for municipal districts and 81.4% of that for municipality.

The analysis shows that the main problem of interbudgetary relations at subfederal level is critical difference in fiscal capacities of municipal entities, which often show itself in unfair distribution of uncompensated receipts. It is rather common for wealthy municipal entities to shift to the category of less wealthy municipalities based on the budget revenues per capita upon the redistribution (Kravchenko, Urman, 2015).

The author believes that the prime thing that is necessary to do when approaching this task is to boost the regional and local tax revenues. Nowadays, the received revenues share in the budget structure of most municipal entities in Samara Oblast does not exceed 20%, which reveals the high dependence of local budgets on various interbudgetary transfers from the higher-level authority (Local branch of Federal Service for Statistics in Samara Oblast, 2017).

According to T. M. Kovaleva and I. A. Boyko (2017), an efficient measure to enhance interbudgetary relations would be to change governmental grants for leveling off fiscal capacities by additional standards of the revenue allocation of the personal income tax. However, the current standards of revenue allocation of personal income tax were set in 2005 and never changed since then.

The conducted study of the tendencies and peculiarities of Samara Oblast budget process makes it possible to conclude that, despite certain positive aspects related to rather high level of the regional development, the budgetary relations still suffer from a number of unsolved problems, among which one can mention:

- the efficiency indicators of budget leveling-off (a balance of local budgets) reveals rather considerable horizontal disbalance;
- the decrease in receipts of municipality, district and settlement budgets demonstrates the drawbacks of the approaches to subsidies granting and the public management quality ensuring in a region;
- insufficient increase in expenditure budget and its deficit shows low efficiency of the state financial support measures in recent years;
- large difference in the development of rural and urban territories in Samara Oblast.

The revealed problems of interbudgetary relations in Samara Oblast point at the insufficiency of monitoring, which highlights the need for enhancing the instruments of interbudgetary relations (hereinafter, IBR). The main directions of this process are presented on Figure 5.

It is possible to agree with many economists who think that the current methodology applied by The Ministry of Finance of the Russian Federation does not ensure certainty concerning the evaluation of interbudgetary relations as it has little indicators (Kadochnikov, 2016; Karaulova, 2017).

In this regard, there is a lack of sufficient analysis of particular spheres of regulating impact. Besides, particular indicators and ways of their interpretations are controversial, for example, those of the correlation between the subsidies for local budgets and transfers and the leveling off the fiscal capacity. Consequently, the existing technique requires enhancement.

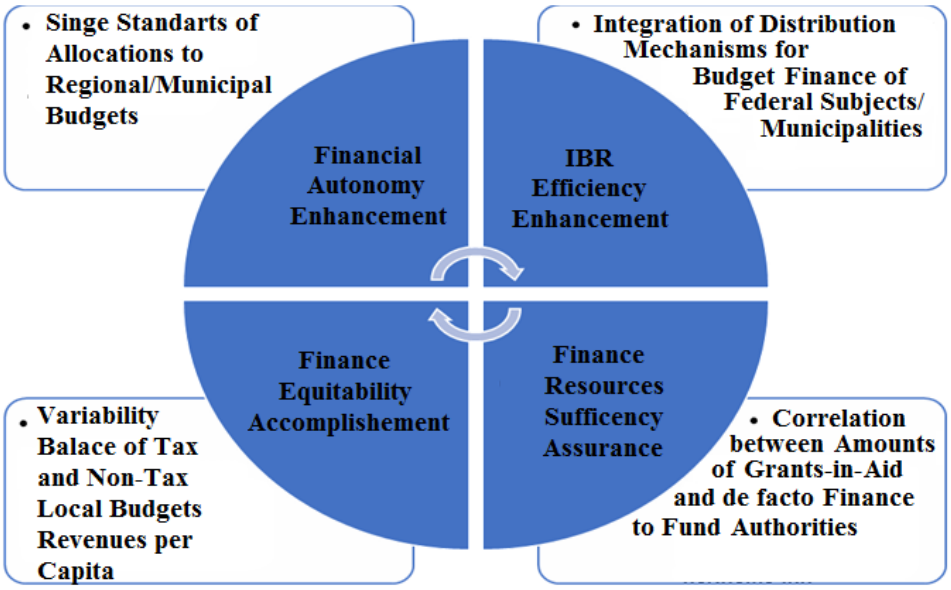

Fig. 5: The directions for enhancing the interbudgetary relations instruments
Source: Author

In addition, it is necessary to make a note of the considerable scale of redistributive relations determined by the amount of finance contributing to the federal budget from Samara Oblast that is almost equal to that of the interbudgetary transfers from the centre, i.e. one can see the finance flow from a regional to the federal budget and back. Such centralization of interbudgetary relations result in the largest part of regional budget system revenues going into to the federal budget first and finance in the form of interbudgetary transfers returning to the regions then (Syatchikhin, 2016). Along with this, the insufficient objectivity and explicability of these transfers distribution create the exposed environment that is also inclined to corruption. In other words, current state of affairs is characterized by the low dependence of regional fiscal capacity level in Russia on socio-economic environment, which, in its turn, prevent the development of impetus for regional authorities to enhance local revenues.

Discussion

Overall, the results allow to conclude that the most important task of efficient state governance and local self-governance is its adequate financial assurance and efficient interbudgetary relations (Solomko, 2015). Despite some positive shifts in interbudgetary relations conduct in Samara Oblast, the majority of municipalities does not practice the integration of result-oriented budgeting principles. The emphasis should also be laid on the insufficient level of the measurement system for interbudgetary relations efficiency.

In this regards, it seems relevant to consider the essence of an optimal structure for interbudgetary transfers. D. Bergvall, C. Charbit, D.-J. Kraan and O. Merk (2006) think that the transfers use efficiency is defined by the degree of their relevance to the social and economic regulation objectives. The explanation derives from the fact that the regulation based on purpose transfer allocation will be more efficient rather than non-purpose transfer in the conditions of the low quality of state and/or municipal finance management. It makes an interbudgetary transfers structure dominated by subsidies the most optimal (Sumskaya, 2017).

The author thinks that it is important to observe certain conditions. Above all, it is essential to set priorities for state financing with the account of certain aspects. The aspects under consideration are the socio-economic state of affairs in regions/municipalities, the competitive advantages peculiar to those territories that, if used, will ensure accumulation and intensive development of tax and economy potential. Besides, it is necessary to provide the transparency of the subsidies distribution techniques and ways that should be worked out based on the combination of competitive and non-competitive distribution mechanisms. The non-competitive mechanisms will bring the opportunities for regions with low economic development to receive additional finance. The competitive mechanisms will allow to heighten the authorities' economic interest in receiving subsidies. On this basis, it is possible to draw a conclusion that the integration of the budget redistribution mechanisms with municipal and state programmes should be obligatory.

The author thinks that the efficiency of interbudgetary relations should be evaluated based on, firstly, the quality and, secondly, the budget process effects. The quality evaluation of interbudgetary relations should derive from the grouping and systematizing of the indicators based on the tasks. As one of the basic objectives of interbudgetary regulation is to level off the territories (both vertical and horizontal) as well as economic stimulation, the following aspects are proposed to be considered as the indicators of interbudgetary relations quality assessment:

The first evaluation unit of horizontal leveling-off consists of:

1) the indicators of local fiscal capacities variability before and after governmental grants aimed at equitability and balance of budgets;

2) the alteration of the first indicator.

The second evaluation unit of vertical leveling-off consists of:

1) the level of sufficient budget revenues at all levels for fulfilling the expenditure obligations;

2) that caused by receiving an interbudgetary transfer;

3) the degree of revenue decentralization reached on the account of setting allocation standards by regional law.

The third evaluation unit of economic stimulation consists of:

1) the share of interbudgetary transfers distributed on the competitive basis;

2) the level of state financial support for one economic entity.

It can also be proposed to define a common indicator of interbudgetary relations efficiency using the score technique providing a preliminary calculation of standard figures and their compulsory legislative consolidation. However, the assessment based on the proposed scheme is complicated, above all, due to the currently existing time lag between the implementation of budget regulation measures and their effects.

The interbudgetary relation effects can be the following:

- budgetary effects related to the reduction in regional and/or municipal needs for interbudgetary transfers, to the increase in their fiscal capacity and balance.

- economic effects related to the positive dynamics of socio-economic regional and/or municipal development, to the decrease in interterritorial difference.

Thus, the proposed directions of interbudgetary relations enhancement based on their efficiency evaluation allow to assess these processes considering the existing drawback of budget process as well as the opportunity to detect actual regulation results. The permanent monitoring of the indicators will contribute to efficient managerial decisions and their timely correction.

Besides, the author proposes the following key directions for efficiency enhancement of the interbudgetary relations instruments. Regarding the governmental grants aimed at fiscal capacity equitability, it should be mentioned that the existing distribution system does not allow to solve the problems of the municipalities characterized by highly tense budget execution. Taking the financial insecurity of alike municipal entities in the contemporary crisis conditions into account, it seems relevant to use a Fund of Local Budgets Balance formed for a limited period and loaded by transferring a part of finance aimed at leveling off municipal fiscal capacity. It is necessary to define a precise goal of their use and introduce compulsory publication of the reports on these expenditures.

Since the share of special-purpose interbudgetary transfers has been increasing lately in Samara Oblast, the planned efficiency of granting subsidies to local budgets should be preliminary assessed and then one should control the set plan accomplishment.

The mentioned measures are relevant when subsidies are:

- connected with uneven distribution of municipal/states services consumers in municipal entities of Samara Oblast;
- oriented towards the reduction in a number of current differences among various municipal entities within the region in the process of providing municipal/state services;
- aimed at boosting the quantity and quality of municipal/state services in municipal entities of Samara Oblast (the quality and amount indicators of services per capita are compared).

Moreover, the emphasis should also be laid on consolidating the responsibility of the main holders of the Samara Oblast consolidated budget for taking decisions on the subsidies distribution among local budgets and controlling. In this regard, quite an efficient measure can be outlining the requirements for the rules and principles of subsidizing, which prohibit to provide several subsidies to one municipality on one direction, and monitoring and controlling the purpose accomplishment within the set period.

Nowadays, the existing practice of providing local budgets with grants-in-aid from regional budget seems to be an instrument of responsibility redistribution rather than optimization of administrative decisions. Therefore, it makes sense to boost the responsibility level of the main spending units of regional budgets that have power to vest local self-governance bodies of Samara Oblast with certain authorities.

In order to tackle the low efficiency of the measures controlling the performance quality of the transferred authorities, one should work out the rules that make it possible to coordinate the amount of grants-in-aid and the quality of exercising the state authorities. Besides, it seems necessary to make the results of these processes public in press, which will allow to enhance the efficiency of the transferred authorities as well as their relevance to the provided financial services due to publicity and transparency.

It is vital for the balanced interbudgetary regulation to ensure that regional and federal budgets give rational budget loans to local budgets. In the difficult current conditions, it is important to fulfill the obligations of returning credit means and prevent past-due debts. Besides, it seems relevant to strengthen control over the intended use of granted credits.

Conclusion

To sum up, it should be said that searching for efficient instruments and mechanisms of interbudgetary relations and developing the directions of interbudgetary relations enhancement are becoming rather topical in the contemporary conditions of large difference in regions and municipal entities within. A well-designed system of interbudgetary relations is of great economic, political and social significance for successful public development of Russia. Therefore, every region takes various measures aimed to ensuring the balance of budgets at different levels.

However, the efficiency of the undertaken measures remains slight. The conducted analysis revealed a number of interbudgetary regulation problems in Samara Oblast. The first problem is a lack of local budgets balance and the financial dependence of many municipalities that are characterized by budget deficit. Another problem is excessive redistribution relations among budgets. One more problem is a lack of impetus for building local revenue potential at regional and local level. Furthermore, the interbudgetary relations between Samara Oblast and the center and among the region and its municipal entities are unstable. Besides, this region as well as the majority of other federal subjects is characterized by the increasing tendency to centralize the local budgets revenues accompanied by the growing share of uncompensated transfers in the regional consolidated budget.

In order to solve these problems, it is primarily necessary to conduct the efficiency assessment of the undertaken budget policy measures to introduce the corrections timely. One should also understand that the main effort made by the state governance and local self-governance bodies shall be focused on accelerating the local tax basis at all level and searching for the reserves to form it. Additionally, the consolidation and balance of the interbudgetary relations depends on a more equitable finance distribution among budgets; an opportunity to transfer some tax revenues to municipalities; the taxation system enhancement; the restriction of finance centralization at the subfederal level.

Supply Side Competitiveness on the Polish Tomato Market Against The Rest of the Visegrad Group Countries

PhD Agnieszka Tarnowska, Wroclaw University of Economics, Wroclaw, Poland,
agnieszka.tarnowska@ue.wroc.pl
PhD Anna Kowalska, Wroclaw University of Economics, Wroclaw, Poland,
anna.kowalska@ue.wroc.pl

Abstract

This article deals with the competitiveness of the Polish vegetable industry, exactly the tomato producers and their competitiveness on the Visegrad Group market. The purpose of the study was to examine whether the supply side of the Polish tomato market was competitive with other Visegrad countries. The area and volume of tomato production was the subject of the study. The analysis was based on statistical data mainly from the FAOSTAT databases. The subject area was taken by 4 Visegrad Group countries (V-4), i.e. Czech Republic, Slovakia, Hungary and Poland as well as groups of countries belonging to EU-27, EU-12 and EU-15. The time span generally closes from 2004 to 2014. The calculated Gini and HHI coefficients have shown a strong concentration in the V-4 tomato market. They point out that Poland's position as a leader is still strengthening. The rest of the V-4 countries are hard to compete with Poland on this market. These countries are increasingly leaving the market and losing their customers. This makes the tomato producers in these countries often give up the production of tomatoes, which contributes to increasing the Polish market share in this market. The great challenge for Polish tomato producers is the need to invest in cultivation of tomato under cover, application of new cultivation technologies, search and production of new varieties of tomatoes.

Keywords: vegetables, tomatoes, supply competitiveness, production volume, productivity

Introduction

Competitiveness is the ability of entities to compete in open markets. Initially, these are usually native markets. It can be seen from supply and demand side. Supply competitiveness is encountered among the producers most often in the situation of abundance of offered goods, characteristic of developed market economies [Gorynia, Łaźniewska (ed.) 2009]. This abundance is often forced manufacturers to lower prices. According to Kowalska [2016] the quality criteria of products offered are increasingly important determinants of the competitiveness of entities than the price criteria themselves.

According to Porter [1990], building competitive advantage is based on the value of resources used, but maintaining it often requires going beyond the home market and taking strategic action internationally. The world economy is increasingly open and increasingly international. Poland belonging to the OECD, the European Union and the Visegrad Group is currently part of the market of countries that do not use barriers to the flow of goods, capital and labor. Free market is the foundation for building the international competitiveness of the participating countries.

A review of the competitiveness theory presented by Bednarz [2013] demonstrates the absence of one universally binding definition of "competitiveness". However, it emphasizes, for example, that in the definitions developed by the OECD or the World Economic Forum, the competitiveness of national economies is shaped by internal factors and that the right measure of competitiveness is productivity. In the 1980s and 1990s, a new trend of competitive advantage was developing. This trend referred to the so-called resource school. Its representatives, however, stressed that available capital, personal and financial resources, without appropriate opportunities, good management or communication system, would not guarantee market success [Juchniewicz (ed.) 2006]. In the economic literature more and more is said about the sustainable competitiveness of the national economy. However, there is a problem with its measurement [Popescu et al. 2017].

Market rivalry of entities takes place on three levels: enterprises (microscale), branches (mesoscale) and national economies (macroscale). Firlej et al. [2017] list other levels: enterprises and branches as well as regions and states. This paper focuses on the competitiveness of the Polish vegetable industry, and more precisely on tomato producers and their competitiveness on the Visegrad Group market. From an economic point of view, the branch is a sector of the economy (production, trade), which includes goods of the same kind, produced using the same technology [Gorynia, Łaźniewska (ed.) 2010].

It is believed that the vegetable market, regardless of socio-economic order, is one of the best suited to market rules. It is a highly autonomous, self-regulating and competitive market [Szwacka-Salmonowicz 1991]. The EU vegetable market has seen that tomatoes are one of the most important products in this market and at the same time are the least competitive. Their production is heavily concentrated in the south of Europe. The largest tomato producers in the European Union were in 2010-2012 respectively: Italy (35.5% of the EU market) and Spain (25.3%). These countries are export oriented [Valenciano, Perez Mesa 2004]. In Poland 4.2% of EU tomatoes were produced, which gave it 7th place. It is impossible for Poland to compete with Italian or Spanish producers of heat-loving tomatoes, because of the climate, which is very favorable to southern countries. In the top ten EU producers of this vegetable was also, from the Visegrad Group countries, Hungary (0.8% of production volume) [Tarnowska 2014b].

The main objective of the study was to investigate whether the supply side of the Polish tomato market, which has specific production resources, is competitive with other Visegrad countries operating in this branch in the common European market. The area and volume of tomato production was the subject of the study. The analysis was based on statistical data mainly from the FAOSTAT databases. The subject area was taken by 4 Visegrad Group countries (V-4), i.e. Czech Republic, Slovakia, Hungary and Poland as well as groups of states belonging to the EU-27, EU-12 and EU-15. The time span generally closes from 2004 to 2014.

Vegetables production in the European Union and in the Visegrad Group

Vegetables occupy an important position in the diet of Europeans and their market is changing. In 2015, the EU-27 produced 63.2 million tonnes of vegetables and compared to 2004 it was less about 5.9%. There is a downward trend in the European market for this crop, both in fifteen old union countries (UE-15) and in the new Member States (EU-12). The changing demand for vegetables means that more and more wealthy Europeans choose more quality vegetables to replace cheaper volumetric vegetables. This translates into lower total volume of vegetable production.

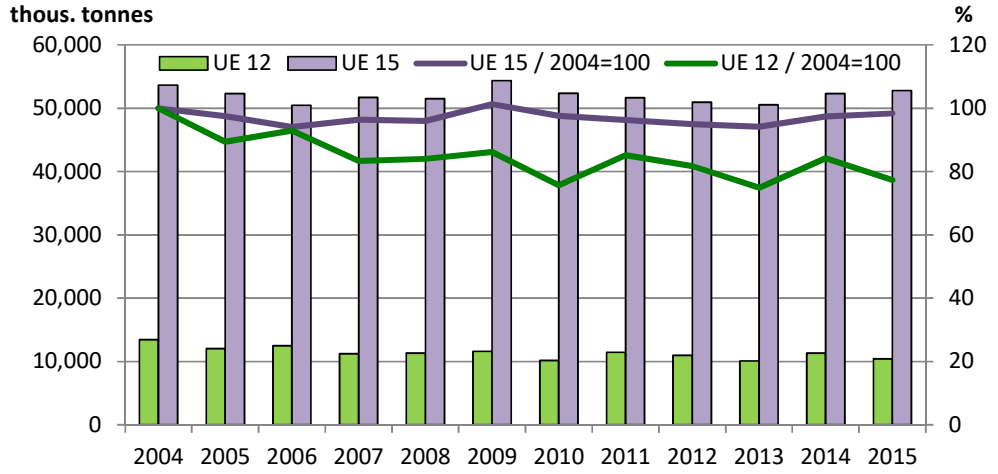

Fig. 1: Vegetable production (in thous. tonnes) and its change in constant basis (2004 = 100) in % in EU (EU-27), broken down by old and new Member States

Source: own study based on FAOSTAT

In Fig. 1, it can be seen that in the period 2004-2015 much more vegetables were produced in the EU-15 than in the EU-12. Average yearly production was accordingly: 52.1 million tonnes and 11.4 million tonnes. In the EU-15 countries this production was less volatile than in the EU-12. The standard deviation of the dynamics index was 2.1 vs. 6.9 in the EU-12. In both groups of countries, vegetable production remained below the baseline year (2004) during the period considered. The only exception for the EU-15 was the year 2009, in which it was produced 54.4 million tonnes of vegetables, i.e. 1.3% more than in 2004. In all other considered years, growth rates were below 100%. Higher supply fluctuations was observed in the new Member States of the Community. Compared with the EU-15, this indicates a greater instability of the vegetable market in EU-12. On the one hand the subsequent impact of the economic crisis on the vegetable market was noticeable in the EU-12 (2010) than in the EU-15 (2009). On the other hand, the crisis has rebounded stronger on the producers of these crops in the new Member States. This again shows greater instability on this market and uncertainty prevailing among producers of vegetables from the EU-12.

Preliminary research confirms that the EU-15 are unrivaled in the EU vegetable market. This is evidenced by the volume of production of these crops. Poland, however, has a chance to compete in the nearer markets, which are the Visegrad Group countries. These are states that have undergone a systemic transformation a quarter of a century ago. They rejected the centrally planned economy and geopolitical dependence. The market economy of these countries is not yet developed enough for them to compete on a par with countries of the rich west. This is mostly due to lack of capital. Visegrad Group countries are characterized by relatively low levels of [Bieńkowski, Stoykova 2016]:

- GDP per capita,
- technological advancement,
- innovation.

It was mentioned in the introduction to the study that the competitiveness of national economies depends on the abundance of the factors of production. The V-4 countries do not have as much capital as the EU-15 states. It is worth noting, however, that the Visegrad Group includes two countries with large agricultural production potential across the EU, i.e. Poland and Hungary. By the term 'potential' it should be understood here primarily big resources of land and labor in agriculture.

In 2012, Poland had 14.5 million hectares of agricultural land, which constituted 8.1% of UR in EU-27 and 28.8% of UR in EU-12. In turn in Hungary, there were 5.3 million hectares of UR, i.e. 3.0% of UR in EU-27 and 10.6% of UR in EU-12. In the same year the number of full-time agricultural workers was 2101 thous. AWU in Poland and in Hungary – 426 thous. AWU, which together accounted for 25.1% of employed in EU agriculture and 50.3% of labor force in agriculture of new member countries of the Community [Tarnowska 2014a].

Growing vegetables is labor intensive. Thus, this direction of agricultural production may be an opportunity to use excessive labor resources in agriculture. Such an excess is observed in the less developed new EU Member States, such as Poland and Hungary.

The total area of vegetable cultivation in V-4 was 284 thous. ha in 2014. The dominant crop area was in Poland (65.9%), followed by Hungary (28.1%), Czech Republic (3.5%) and Slovakia (2.5%). The area under vegetable cultivation in the countries concerned has decreased by 23% compared to 2004. However, thanks to the increasing productivity of their crops – the volume of production of these crops in V-4 decreased only by 9% in the analogous period. The increase in production was recorded in Poland (by 2.2%), the largest reduction – in Slovakia (by 68.4%) [FAOSTAT, 2017].

The share of tomatoes in vegetable production in the European Union (EU-27) and in the Visegrad Group (V-4)

Tomatoes, like peppers, belongs to nightshade vegetables. It is a thermophiles plant of great economic and culinary importance in Europe. Tomatoes came to this continent from South America

when it was discovered by Columbus. Tomatoes definitely dominate the vegetable market in terms of area, size and value of the crop. In 2010-2012, the share of tomatoes in total EU-27 grown vegetables was [Tarnowska 2014b]:

- 11.9% of the area,
- 26.5% of production volume,
- 25.8% of production value.

Tomatoes are therefore one quarter of all vegetables produced in the Community. FAOSTAT data show a large difference in this share in EU-27 and V-4 (Fig. 2). It follows from the above mentioned domination of the Mediterranean countries on this market.

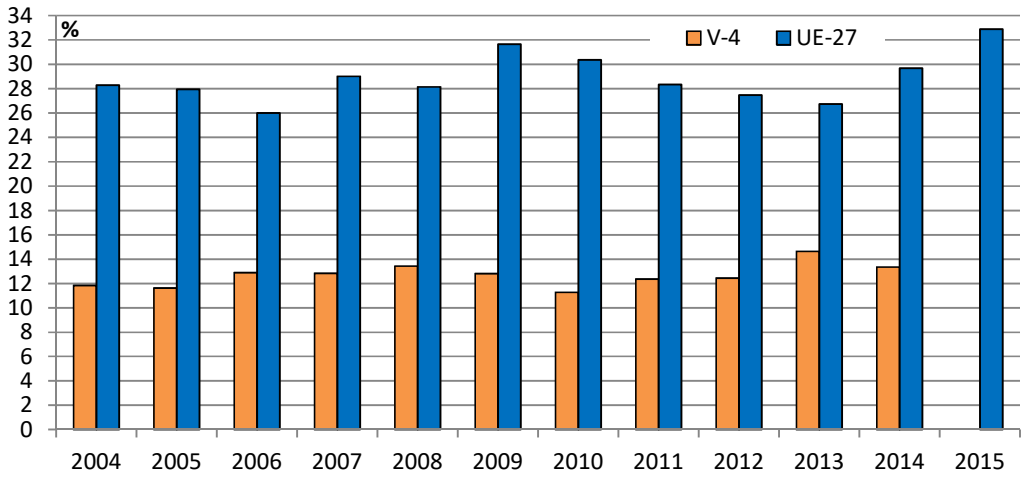

Fig. 2: Share of tomatoes in vegetable production in EU-27 and V-4 in 2004-2015 (%)
Source: own study based on FAOSTAT

In the Visegrad Group, tomatoes accounted for about 14% of all vegetable production in recent years. Differences in this share of individual countries from the group V-4 were relatively small. The exception was the Slovak vegetable market, which in 2007 was 85% dominated by tomato production and supply (fig. 3). This was a result of the drastic drop in total vegetable production in Slovakia due to the drought. This production amounted to only 65 thous. tonnes against 109 thous. tonnes of average annual production in 2004-2014. Tomatoes were more common than other vegetables grown under cover. Thanks to that most of their productions have been saved. From 2007 to 2013 there was seen in Slovakia a steady decrease in the share of tomatoes in the size of the vegetables harvest. The change in the unfavorable trend was brought only in 2014, when tomatoes accounted for nearly 20% of the country's vegetable production.

The fluctuations in the supply of vegetables in Slovakia have no significant impact on the market of these crops in the Visegrad Group. In 2014, their production in Slovakia accounted for only 1.5% of the total vegetable production in V-4. The biggest player of this market in the discussed group of countries is Poland. This country produced over 5.5 million tons of vegetables in the years 2004-2014. Poland's share in V-4 vegetable market was 77.1% in 2015 and increased by 9.2 pp in 2004. This demonstrates the growing position of Poland in the discussed market and the better use of the country's productive resources in agriculture.

In the Visegrad Group, Hungary is also an important vegetable producer. In the analyzed period, they produced an average of 1.5 million tons of these crops per year. That accounted for 20.3% of this market in the V-4. However, after the economic crisis, it was possible to observe the declining vegetable production in Hungary (fig. 3). This country is slowly getting out of the vegetable market. The attention of Hungarian farmers is increasingly focused on the production of, for example, wine or sunflower oil.

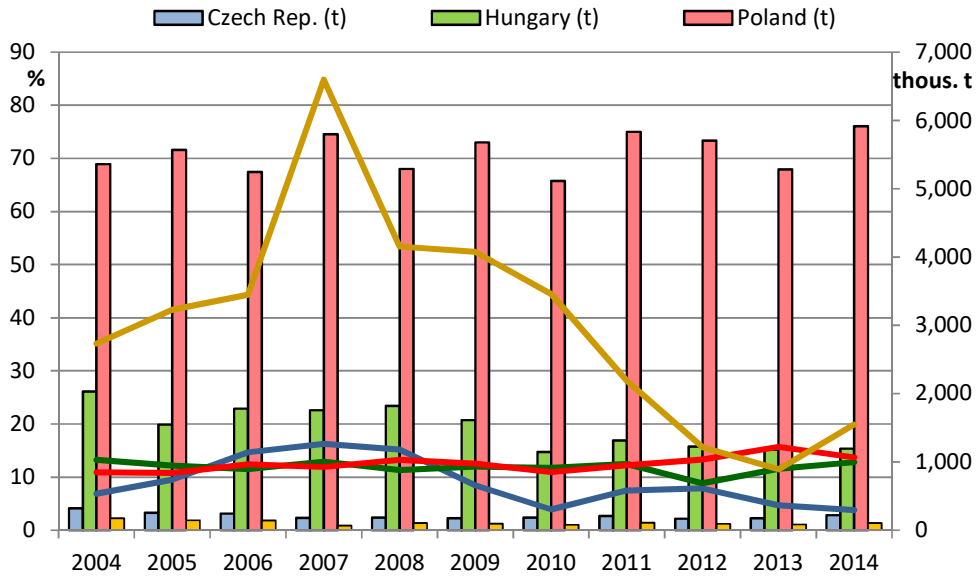

Fig. 3: Vegetable production volume (in thous. tonnes) and share of tomatoes in vegetable production (in%) in the individual countries of the Visegrad Group in years 2004-2014

Source: own study based on FAOSTAT

Poland as a significant producer of tomatoes in the Visegrad Group

Poland is the largest producer of tomatoes in the Visegrad Group. In 2004, the crops of these vegetables in Poland amounted to 14.5 thous. ha (fig 4). It was 2.5 times larger than in Hungary, more than 4 times bigger than in Slovakia and 18 times bigger than in Czech Rep. This year in Poland 582 thous. tonnes of tomato was collected, in Hungary by more than half less. The Czechs and Slovaks together produced only 14.3% of what Poles did.

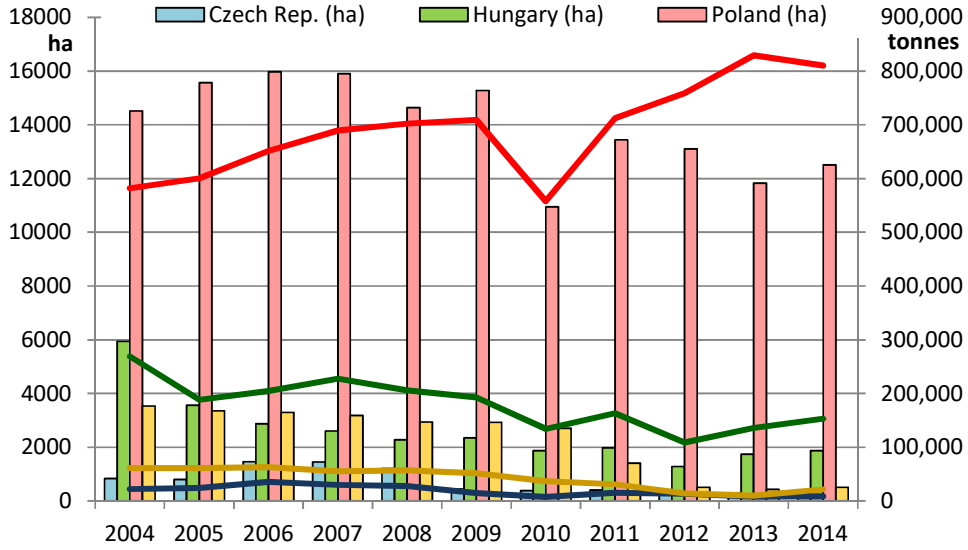

Fig. 4: Area of crops (in ha) and volume of production of tomatoes (in tonnes) in the Visegrad Group countries in 2004-2014

Source: own study based on FAOSTAT

The production of tomatoes in Poland was growing until 2009 at an average rate of 21 thous. tonnes per year. The world economic crisis, which appeared in Polish agriculture late, i.e. in 2010, caused a drastic drop in production. The crop area decreased by ¼ and the production volume fell by 4.1%. This year was significant for tomato producers. Survived the strongest, best organized. The crop area has not been reproduced yet, but production has continued to grow. Its braking occurred only in 2013.

In the remaining V-4 countries, since the time of their accession to the EU, there has been a tendency to reduce the area of tomato crops and the size of their production. These countries have failed to resist the competition of more developed southern producers. Poland as the only one of the V-4 countries handle the tomato market better and better.

It was mentioned in the introduction that the competitiveness of national markets, besides internal resources, determines the efficiency of production. The highest yields of tomatoes in the V-4 group distinguished Hungary (fig. 5). It is the southernmost country in this group of states. It has the most favorable climate for the cultivation of thermophilic tomatoes. The productivity of tomato production in Hungary increased most in the period 2004-2008, reaching over 90 tonnes per hectare in the last year of mentioned times. The results of Polish producers of this vegetable were almost half lower (48 t / ha). Czechs and Slovaks in 2008 achieved a yield of no more than 24 t / ha.

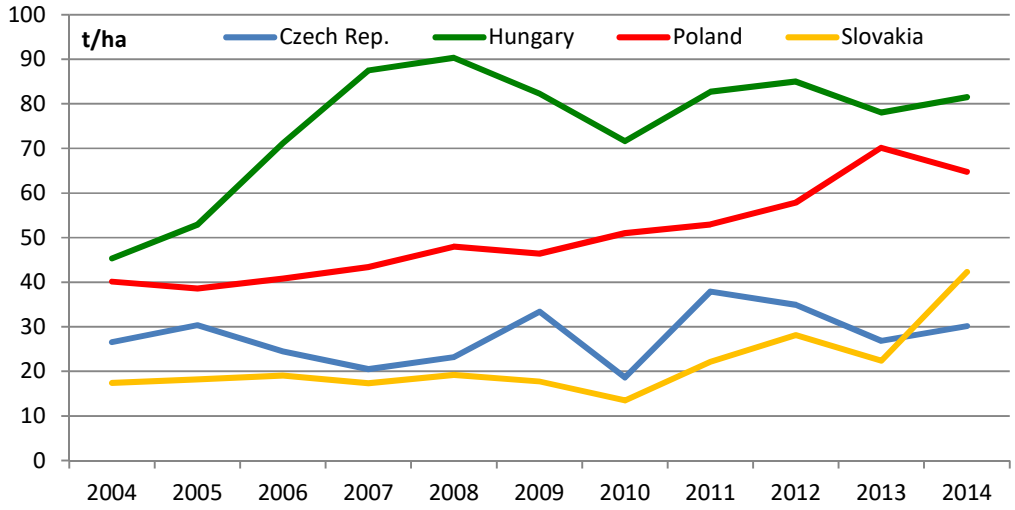

Fig. 5: Yield of tomato production (in tonnes of ha) in each Visegrad Group countrie in 2004-2014

Source: own study based on FAOSTAT

The next period of efficiency analysis close the years 2009-2014. In Poland, constant growth of tomato yields was observed at that time. Although these yields have not yet reached the value recorded in Hungary, but it can be expected in a few years. What is more, the Polish production efficiency was more stable than in the other smaller V-4 countries. The graphs in fig. 5 show much more fluctuations in yields in the Hungarian, Czech and Slovakian crops.

In Poland, after the economic crisis, the largest and most modern manufacturers remained. They mostly grow tomatoes in greenhouses. This, in spite of the cost of production, alleviates the risk of loss of crops caused by natural disasters and the impact of unfavorable weather conditions.

The paper focuses on the tomato market, which is attended by four Visegrad Group countries. For the defined market, the Gini-K [Pułaska-Turin 2011] concentration factor was calculated and, alternatively, the Herfindahl-Hirschman Index - HHI [Czarny, Rapacki 2002] determining the degree of monopolisation of this market (tab. 1).

Tab. 1: Gini coefficient (K) and Herfindahl-Hirschman Index (HHI) for tomatoes in the Visegrad Group (V-4)

Index	2004-2006	2012-2014
K	0,769	0,899
HHI	5832,8	7171,3

Source: FAOSTAT, own calculation.

The calculations in Table 1 show a strong concentration on the tomato market in the V-4 group (values above 0.75). In the years 2012-2014 this concentration increased to 0.899. It is easy to imagine that the country, in which is located the largest part of tomato production in the V-4 group, is Poland. This country dominated the tomato market in the Visegrad Group. What is more, Poland's position on this market is constantly strengthening and for the rest of the V-4 countries it becomes a state with which it is difficult to compete. Poland has undoubtedly the largest resource of land and labor in agriculture. This country can therefore use the effects of scale. In addition, Polish farmers make great use of the available production resources thus increasing the productivity of the crop. This makes it the most important producer of tomatoes on the V-4 and EU-12 markets. Its share in the production volume of tomatoes in V-4 increased in the three-year studied period from 66.4% to 83.5%.

Increased concentration of production in one country makes the tomato market in group V-4 is becoming less competitive. This is evidenced by the large increase in HHI's competitiveness index. Here again, it is noted that Poland's position as a leader is strengthening. The rest of the V-4 countries are hard to compete with Poland on tomatoes market. These countries have increasingly barriers to entry to this market and they gradually lose their customers. This makes the tomato producers in these countries often give up their cultivation. So they give the field of activity to the largest player on the market, which is Poland.

Conclusion

Poland has large production resources in agriculture in Europe's scale. In addition to the huge areas of agricultural land, it has above average and unused labor resources in agriculture. Vegetable farming is a branch of agricultural production that requires many hands to work. Poland should use this potential. This country is a significant producer of vegetables in the European market. Analyzes show the country's growing role in the tomato market as well. It would seem that the climate of Poland is not very favorable for growing these thermophilic vegetables. The European tomato market dominated southern countries (Italy, Spain, Portugal, Greece). In the European Union, these countries are essentially unrivaled in the tomato market.

Poland as an agricultural country should not abandon cultivation of these vegetables. It has huge production potential and it is itself a big market for vegetables, including tomatoes. Research has shown that Poland should look for markets for tomatoes in Europe particularly in the nearer and smaller countries. It will be easier for Poland to compete with them. This is mainly the other countries in the group V-4. After analyses it is clear that these countries are gradually abandoning the industrial cultivation of tomatoes. This is a great opportunity for Poland. It can successfully master these markets. Geographic proximity has the additional advantage of lower transport costs.

The great challenge for Polish tomato producers is the need to invest in crops under cover, in new crop technologies, in the cultivation of new varieties of tomatoes. Polish agricultural producers are characterized by lower farming culture than partners from richer western countries. The failure of a large part of the Polish vegetable sector is the lack of modern vaults and warehouses equipped with devices for making tomatoes for sale. There is also no modern tomato marketing.

Data-Driven Decision Making Matters: Preparing HBCU Students for Life after Graduation

Wang, C. P., Albany State University, Albany, Georgia, United States, cpwang@asurams.edu

Simmons, T., Albany State University, Albany, Georgia, United States, tsimmo13@Studentsasuramsedu77864.onmicrosoft.com

Abstract

The Higher Education Act of 1965 defined Historically Black College and University (HBCUs) as "a school of higher learning that was accredited and established before 1964, and whose principal mission was the education of African Americans." (Congressional Record Service, 2014) It is the responsibility for HBCUs to honor the fulfillment of its principal mission by not only "offering culture, a rich history and rigorous academic programs but also prepare students for leadership and life after graduation." There are 100 HBCUs enlisted in the most recent Digest of Education Statistics 2015. (NCES, 2016) The percentage of African-American college students educated at HBCUs dropped dramatically from 17.3% in 1980 to the 8.5% in 2015. (PEW, 2017) However, according to PEW, in 2015 HBCUs conferred 15% of bachelor's degrees to the blacks. Beside the percentage decline of degrees conferred by HBCUs to black minorities, HBCUs are still recognized to have successfully educated black Americans, especially low-income and the underprepared. (Gasman 2010) HBCUs' contribution in educating blacks does not stop questions regarding the educational quality and value of HBCUs since the 1992 U.S. Supreme Court Case of United States v. Fordice. Earning a college degree for blacks is not only an indicator of academic success but also a vehicle to fulfill their career life after graduation. (Kim and Conrad, 2006) The reality indicates the unemployment rate for age 22-27 recent college graduates was less than half compared to the same age range of black college graduates. (Janelle Jones and John Schemitt, 2014) Such a big unemployment gap fails many HBCUs graduates for a successful career life after graduation. How do HBCUs prepare students differently to have a successful and productive career life after graduation? Research has studied graduates' majors and careers. However, these research studies do not tell us if HBCU students choose their majors based on data of employability. From the researchers' perspective, a student's choice of major can affect his/her employability; good entry-level employment normally is an indicator of a job of satisfactory earnings. The aforementioned gap in employment of HBCU graduates versus all graduates could likely be the result of choosing majors of low employability. Thus, the goal of this pilot study is to prepare students for a productive career life after graduation by making data-driven decisions. In spring 2017, we assessed how the data of employability was used by students at ASU in choosing their majors by conducting a pre- and post-survey and a data-driven decision-making workshop for both ASU1201 and MGMT 4205 classes. This study found: All the surveyed 2010 and 2015 College of Business Alumni and undergraduate students did not use the employability data to choose their majors; Eighty-two percent of the surveyed undergraduate students highly valued the training they received from data-driven decision-making workshop. These two major findings support our two hypotheses of this research: 1) Most students at ASU do not make their decisions on choosing a major based on widely available data. And 2) a majority of students at ASU value the practice of the data-driven decision-making process once they have been taught to practice such kind of decision making. In this study, we also found that among those surveyed, students who changed their major at least once, fifty percent are

influenced by potential job characteristics in making this decision.

Keywords: data-driven decision making, HBCUs, higher education, life after graduation, choosing major.

Dealing with Consent and Privacy Trade-Offs In Health and Fitness Apps: Balancing the Conflicting Perspectives of Users and App Developers.

Kanwar Adeel Waheed Khan, University of Bradford, Bradford, UK adeelwaheed@gmail.com

Bushra Waheed, Institute of Management Sciences, Peshawar, Pakistan durranibushra@gmail.com

Abstract

Health and fitness app proliferation has been increasingly significantly over the last five years. Previous research suggests that privacy of the app user is often violated as users do not understand the consequences of agreeing to privacy policies when adopting and using health and fitness apps. This research uses a mixed methods approach, focusing on survey from 153 health and fitness users, followed by in-depth interviews with 12 app users, and 6 interviews with app developers. This study suggests that the level of experience of user has a direct influence on their ability to understand the privacy risks when using health and fitness apps. Users who are more experienced in the use of health apps are also more likely to have less privacy and consent concerns. This research also suggest that in order to undertake a fair trade-off between privacy and app facilitation, developers need to increase their interaction with users facilitating the design of health and fitness apps. The developers also need to undertake self-regulation in order to facilitate a simple way of gaining consent from user to ensure that app development is not hindered by future restrictive government regulation.

Keywords: *privacy, health, fitness, apps*

Introduction

The advent of information technologies has revolutionized the way services are provided to the health and fitness users. Increasingly mobile phone based apps are used to facilitate the user to collect routine data about themselves, which they can use for self-help and fitness improvements. Research has established many of the benefits of the more traditional Electronic Health Records, which include ease of use, as well as easy access to patient records in order to facilitate treatment. This has now transcended to the use of smart phone apps facilitating users. The shift in direction is also critically important, as the users are often looking a better trade-off between the options that they are provided by the app and to safeguard privacy. The safeguarding of privacy of the user is an important issue, but for most designers the urgency to get the app out there in the market is often seems to be more important. This often leads to a lack of understanding of privacy concerns for the user when new apps are designed and implemented by app developers. The literature has continually highlighted that by having a better concern of privacy issues for users, app developers can alleviate privacy concerns as well as facilities a higher uptake of health and fitness apps. This research aims to understand ways in which trade-offs between privacy and the use of health apps can be established.

Moreover, one of the issues which are present is the gap between the user needs and ways in which app development takes place. Increasingly, app development is undertaken at rapid speeds in order to stay competitive in the market. This leads to privacy polices being used as an instrument to shift the burden of privacy to the user. Long and winding privacy policies are often not even read by the user, leading to

blanket consent by the user without even reading the lengthy privacy and consent policy. On the other hand, research has shown that privacy trade-offs are often possible between user and app developers, as some users are often willing to share their personal information against use of free apps. This research aims to understand the ways in which this balance is and can be achieved in future, while focusing on ways in which health and fitness app developers can improve this process.

Literature Review

Rapid Proliferation of Health and Fitness App and Privacy Concerns

The rapid proliferation of health and fitness apps has been astounding, and this has continued to bring in new challenges for users and designers when dealing with ways in which privacy is handled by these apps. The use of mHelath apps is often associated with trade-offs that consumers are willing to undertake in relation to their privacy and security concerns (Kotz et al. 2016). Research suggests that the perceived benefits of an app is that it allows a better management of the control over personal data, but in reality this is often not possible due to lack of clarity of privacy policies of these apps (Nicholas et al. 2015). The desire to 'control' who receives and views the personal health information can in practice be often futile (Atienza et al. 2015). The trade-off between the privacy concerns and the potential benefits of health and fitness apps are based on the sensitivity of the information which is being communicated by the participant (Atienza et al. 2015). The concern of participants is often that while they had little concern when receiving general health tips or reminders over a mobile device, however they often show more concern when stigmatized diagnosis or 'bad news' (Atienza et al. 2015) is given over a mobile device or app. It appears that the more personal the data, the less likely a patient is willing to share it over a mobile device (Martinez-Perez et al. 2015; Paglialonga et al. 2015; Kotz et al. 2016; Kao and Liebovitz 2017). However, if the benefit of using a particular mobile based app or application are in the favor of a user, then they may give up on privacy protection policies to a large extent (Nicholas et al. 2015). In many cases, the privacy policies are neither read nor understood, and therefore as long as the patient has a meaningful benefit from the app, they could forgo many of their privacy concerns (Atienza et al. 2015).

Shifting the Privacy Burden towards the User

While the importance of privacy notices in the adoption of the mobile based mHelath apps has been seen as highly significant, they also have a number of issues (Liu 2014). Research has shown that if the privacy policies are too inconvenient to read, people are more likely to ignore them, and therefore this means most burdens is on users to safeguard their privacy in certain cases, when the patients feel that they have less benefit from reading the policies as compared to their perceived costs. A recent research undertaken by researchers at Carnegie Mellon has noted that the cost of reading the privacy policies could amount to $781 billion a year if there were read by every person (Liu 2014). The burden of giving informed consent is often also put on the user, as they must understand all the intricacies of the data sharing and use practice, which can often lead to significant changes in the way the user views consent and privacy policies. The main issue here is that a simple 'Yes I agree' button can have many different implications, and often the law assumes that the user will be able to understand the intricacies of sharing of data between a large number of stakeholders (Liu 2014). The increase in complexities and responsibilities which are assumed by the sharing of data through apps can also increase the burden of responsibility on the user. The same is often true in clinical organizations, which often do not have the capability or expertise to secure patient data in a sufficient manner (Kotz et al. 2016), and therefore this can further increase the burden on the patient.

Dealing With Regulation Of Health And Fitness Apps

Health and fitness apps often include reminder for pills as well as other fitness data that users may share, including location. The regulation of these health apps is often a grey area, as regulations are not clear. For example, in Canada the medical devices are subject to Medical Devices Regulation and the Food and Drugs Act (Grindrod et al. 2017). One of the main problems identified in the regulation of mobile health apps is the lack of regulatory control, which can ensure its reliability, accuracy and performance (Kao and Liebovitz 2017). Powell et al. (2014) are of the view that a bewildering variety of mobile health apps make it difficult to discern the good apps from the bad ones, especially when dealing with privacy requirements, making regulation difficult. The mobile health apps which are created by governmental agencies and third party developers have been working to come up with standards and evaluation techniques to certify the health apps (Stoyanov et al. 2016), but this is largely hindered due to fast changing app development environment. A number of online tools have been developed which provide users with ways to validate and use apps based on editorial reviews, such as the iMedicalApps (Kao and Liebovitz 2017), however there is no consensus within the literature on using a best approach (Martinez-Perez et al. 2015; Kao and Liebovitz 2017).

Within the United States, the Food and Drugs Administration (FDA) has over time shown a tailored and risk based approach to only apps which are intended to be used as an accessory to a regulated medical device. However, FDA has chosen to leave much of the regulation of health apps to the marketplace (Martinez-Perez et al. 2015; Kao and Liebovitz 2017). Attempts by companies such as Happtique to launch certified health apps have largely been unsuccessful due to a number of reasons. The pay per health app model only had 19 apps when it was launched in 2013, and the service was closed down only two weeks after its launch (Kao and Liebovitz 2017). Several of the apps were hacked, and consumer data was compromised, which also led to the sudden demise of the services. Similarly, in UK, the National Health Service (NHS) also launched its Health Apps library as an attempt to guide patients and health professionals towards safe and effective health apps. However, research on the NHS Health Apps Library has shown that none of the 79 NHS endorsed health apps stored encrypted personal data (Huckvale et al. 2015). Another study on the NHS health apps library shows that out of the 14 health apps listed in the NHS health apps library which were related to management of depression and anxiety, only 4 provided any patient reported outcomes of claims of effectiveness (Leigh and Flatt 2015). The NHS Health Apps Library was finally shut down in 2015. The main problem with the regulation of health apps remains the resource intensive process of vetting the apps (Huckvale et al. 2015). Researchers have suggested that one possible solution may be to use crown sourced app validation system, which is based on a set of standards (Kao and Liebovitz 2017). Validated health professionals may be able to use such a system in order to examine the clinical content, so that the usability of the systems could be examined.

Different Developer Concerns on Privacy and Consent

Another issue is that the developer's understanding of environment often has an impact on the privacy perception of the user. The more open Android platform, seems to have an image in the mind of the user as having less privacy protection polices (Gu et al. 2017), where developers are looking to turn out apps at a fast pace. The open nature of Android systems means that new app development has been highly robust, but often at the cost of privacy implications for users, as developers want to be competitive in the market place. On the other hand, the Apple based iOS is often perceived by users to be more reliable, and therefore allows users to have more confidence in the privacy settings. The permission to request is a demand form the app to access the control to a mobile app device, such as access to GPS settings, microphone and camera of the device as well as the ability to control the other access requirements of the device. The different stages (either at download or later use) of the mobile app can also change the privacy perceptions of the end users. During the download stage, android users are more likely to provide privacy invasive permissions, due to the nature of the operating systems. This can have a direct negative impact on the users with regards to the privacy invasion that may be taking place (Gu et al. 2017).

Despite a number of advantages of the health and fitness apps, many different issues of privacy and security have been established within the literature, which continue to be a problem due to lack of planning/clarity by developers (Martinez-Perez et al. 2015; Paglialonga et al. 2015; Kotz et al. 2016). Mobile apps are a new area of attack for hackers and attackers, and therefore increases the vulnerability of the personal data within the android environment (Gu et al. 2017) Keeping patient healthy and not just caring for them when they are ill, makes sense for the health care providers, and a more efficient way of dealing with patient needs (Kotz et al. 2016).

Research Questions

The following research questions have been generated based on the initial review of literature:

- How do users of health and fitness apps deal with the trade do-off between ease of use and privacy?
- What can app designers do to ensure that a balance between privacy and the need for a marketable health and fitness app be struck?

Research Design and Methodology

Philosophical approach

This research uses an inductive methodology to examine the issues of privacy and trade-offs by the users and developers (Creswell et al. 2004; Curry et al. 2009). Inductive methodology is often used to draw out theory, emerging from data (Patton 2002)

Research Approach
