In order to analyse different cloud-based tools and aspects of their application in companies as well as types of companies' behaviour in this context, the research was structured in the following way:

1. Choosing the companies based on the following criteria:
   - The companies run IT software development projects;
   - The companies are located in Saint Petersburg;
   - The companies are ready to share information about their operations.
2. Forming questionnaire for interviews. The interview questions were designed accordingly with the research questions and aimed to highlight the aspects of running software projects, connected with tools usage and project results in order to highlight the possible relation within these aspects. The design of the questions for the interview was organized in a spiral manner and the questions were revised several times after receiving feedback. The feedback was provided by an external reviewer with practical background and research experience. The initial approach towards the interview questions formation was based on the practical and research experience. The questions were formulated based on the listed aspects, and put in a chronological order, derived from the project activities sequence. Literature was studied mostly after the interviews and the results analysis in order to formulate scientifically-based research results and compare them with the existing knowledge of the topics. All the questions were formulated as open-ended questions. The key motivation for this choice was the interest towards getting a vast amount of information about the companies and provoking discussion if possible. Different companies have their own definitions in scopes of analysed topics, which also came out to be a factor for choosing the open-ended questions to avoid pushing the interviewee into the frames. It will help avoid restriction on their opinions about different aspects.
3. Holding interviews with the companies' representatives (Table 1).

Table 1: interviews overview

Interview number	Code	Representative title
1	C1P1	Developer
2	C3P1	Lead business analyst
3	C4P1	Process Orchestration, Process Integration analyst
4	C3P2	Business analyst
5	C5P1	Business analyst
6	C6P1	Technical product manager

4. Transcribing interviews' records.
5. Analysing the set of tools, utilized within each project.
6. Defining the 1st order concepts from original quotations out of the transcribed data from the six interviews.
7. Formulating the 2nd order themes based on Grounded theory-like approach (Strauss and Corbin, 1967).
8. Aggregating themes into dimensions to formulate the key findings. The steps above are presented on Figure 2.

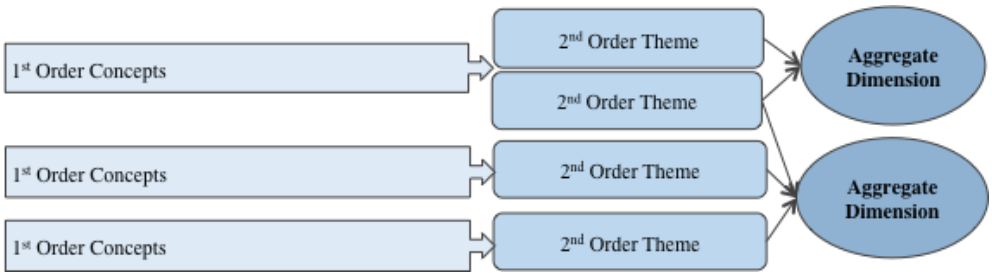

Fig. 2: Analysis process

The overall research process is presented in the Figure 3.

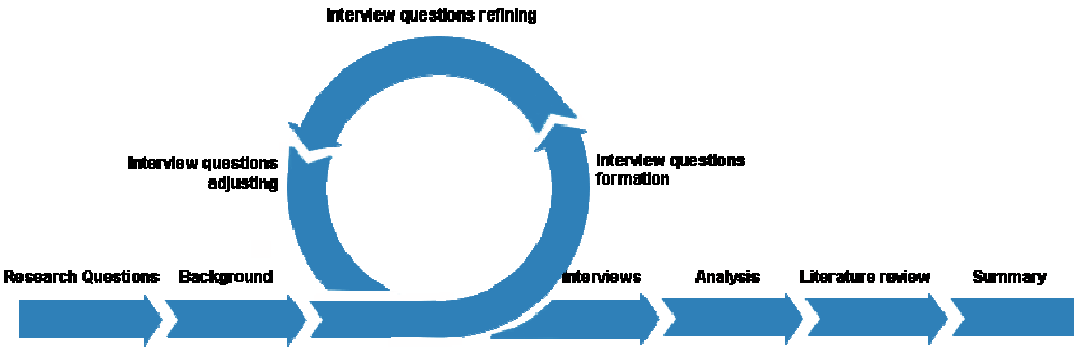

Fig. 3: Research process

Results

In order to understand the way how the companies use cloud-based tools in the software development project activities, the gathered empiric data was further analysed. Cloud-based tools distribution among the projects is represented in the **Error! Reference source not found.**4.

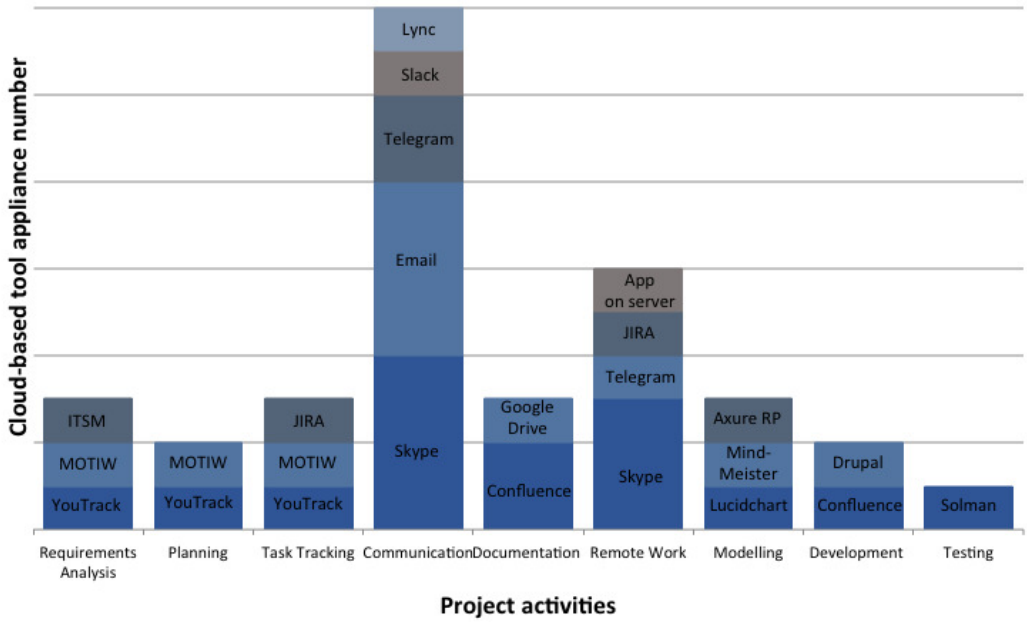

Fig. 4: Cloud-based tools distribution among the projects

This figure displays information in the context of project activities and represents which tools are used in the surveyed companies. Based on the gathered data, it can be seen, that for external and internal communication Skype was utilized almost in every project. Emailing services were probably as popular as Skype for communication process support.

Based on the gathered data, it can be noted that there are tools, which were used for several activities within the project. This might be potentially important aspect. The following tools were mentioned for several activities:

- YouTrack: task-tracking, planning and requirements analysis.
- Atlassian JIRA: managerial activities and remote work.
- MOTIW: planning, task-tracking and requirements analysis.

This phenomenon can be a potential indicator of the difference between the ways how the companies choose and use cloud-based tools, which aspects they are seeking for.

To reveal the potentially influential factors on the way how tools were adapted within each project, further analysis was conducted. Based on the interviews' transcription, the 1st order concepts and the 2nd order themes were formulated. Then they were grouped into the aggregate dimensions connected to cloud-based tools adaptation. These dimensions are presenting three different types of companies. The companies can be divided into 3 categories by the cloud-based tools adaptation influence: enhancing, disputable, intuitive refusal.

Enhancing Adaptation Type

The recognition indicators based on representative's quotations and 2nd order themes are the following:

- Willingness for processes improvement

  - "Company buys video tutorials for coding improvement and system optimization" (C1P1).
  - "We always have meeting to see how we can act better" (C5P1).
  - "We combine different approaches to act effectively" (C6P1).
- Clear tasks' management
  - "Tasks management was done by Architect and Project Manager" (C4P1).
  - "Tasks were shared according to competency of each team member" (C4P1).
  - "We do not have the hours, but the value of the task S, M, L, XL" (C5P1).
- Willingness for high-quality delivery
  - "Code review is done by developers, technical leader, internal testers from agency, external team review functionality, managers test final interfaces" (C1P1).
  - "Philosophy says that the documentation is not the first, the main thing is the collaboration and working high quality product" (C6P1).
- Focus on fast delivery
  - "We had several deployments per day" (C4P1).
  - "On Fridays, customers have the news instead of the desktop that we changed something, attached there are links to the instructions" (C5P1).
- Taking advantage of tools
  - "With JIRA risks to make mistakes are much less, everything is clearly defined" (C4P1).
  - "For tasks, we use the YouTrack task-tracker, which is sharpened to work in Agile" (C6P1).
- Right methodology in the right place
  - "We used Kanban to easily manage tasks to simplify the process" (C4P1).
  - "Conditionally, we can say that we work on flexible methodologies, but the first iteration is waterfall, to get at least a minimal valuable product" (C6P1).

Disputable Adaptation Type

The recognition indicators based on representative's quotations and 2nd order themes are the following:

- No planning habit
  - "They had no planning. Only when I came I've created Excel with daily and weekly plans" (C3P1).
- Cheapest is the dearest
  - "The whole project was led by one programmer (not an analyst, not an architect). And I was there to help her. They did not want to invest" (C3P1).
- Initial understanding of the failure
  - "It was immediately clear that the project will fail" (C3P1).
- Overconfidence in processes
  - "The decided to take the processes as it is. They were just correct by default" (C3P1).

Intuitive Refusal Adaptation Type

The recognition indicators based on representative's quotations and 2nd order themes are the following:

- Round-the-clock team
  - "In the morning we got up and went to the factory. Then we came from the factory, gathered in one room and continue to work further" (C3P2).
  - "We just had a fairly cohesive team, and the responsibilities were clear" (C3P2).
- Full availability of the team
  - "We had our own office in the factory, we had our own phone, everyone knew it" (C3P2).

- Intuitive team decisions and processes
    - "We analysed the requirements only within the team, by brainstorming" (C3P2).
- Choosing appropriate tools and techniques
    - "We had a notebook with special notes, who does what. We planned only for a week ahead" (C3P2).

Taking everything mentioned above into account, each type of company behaviour can be shortly summarized and characterized:

- Enhancing adaptation type describes the companies, which are ready for changes and follow Agile principles. In this companies high management maturity and contextual intelligence of the team can be noticed. The companies of this type are potentially able to take advantages of cloud-based tools in order to improve their processes.
- Disputable adaptation type of company's behaviour indicates overall unwillingness for changes, management immaturity and as a consequence team low motivation. This type of companies is likely to have difficulties in running software projects, which are result of poor managerial skills. They have low chances to benefit from cloud technologies as the overall project surrounding is poorly established.
- Intuitive refusal adaptation type of companies can be considered as specific one, because it represents the companies, which are close to Enhancing type, but the key difference here is that the project teams are collocated with users. Another important aspect here is that the team has considerably high level of contextual intelligence, which lets them run the project based on their professional experience and intuition, banking on face-to-face communication.

The types of companies' behaviour are presented in framework (Figure 5).

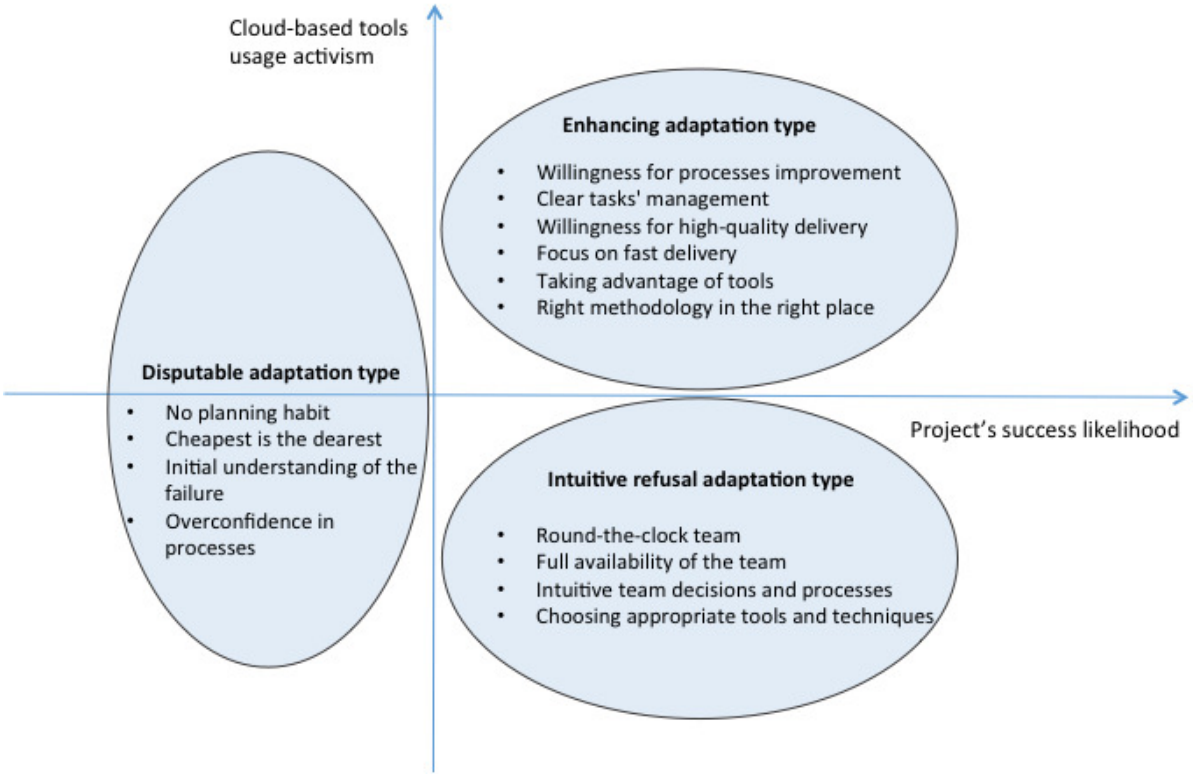

Fig. 5: Companies' behaviour framework

Conclusions and Discussions

In scopes of the current research different software project were analysed by the ways how the teams are adapting cloud-based tools. It was argued that there could be potentially 3 types of adaptation of "cloud" within the project: enhancing adaptation type, disputable and intuitive refusal. In the core of indicated types there were a number of concepts, which characterise them and appear to be the baseline for their difference: attitude to changes, team motivation, team collocation and contextual intelligence.

The topic of resistance and rebelling for changes was reflected by many researches. Based on previous research, the case of Total Quality Management (TQM) implementation was presented (Glenny, 1994). According to this research, such implementation has been successfully adopted by the vast number of companies. Nevertheless, author presents the projects, where process improvement was met by scepticism and rejection, what leaded to TQM realization and project's failures. Readiness or resistance for changes influence on any company's development and improvement. In current research resistance for changes and unwillingness of improvement also appeared to be influential on project outcomes.

According to the conducted research, low motivation of project team can result not only in unsuccessful cloud-based tools adaptation, but also in project failure. The influence of team motivation on project success was frequently mentioned in previous studies. The linkage between individual's motivation and project success can be reflected (Markus, 1983). In this study the case of management information systems was described. It was argued that low project team motivation leads to implementation project failure.

Previous researches emphasize that there are a number of aspect of team collocation, which potentially positively influence the process of running the project: informal contact; short communication lines; ability to receive opinions and feedback immediately; simplified Project Managers duties; usage of physical tools ("wall and paper") (Rafii, 1995). In scopes of the current research, it was proposed that such teams are likely to succeed if the members of the team are high experienced, ready to communicate, opened towards discussion.

It was assumed that successful cloud-based tool adaptation is inextricably linked with the CI of project team, managers and company (specifically, the ability to adjusting to circumstances, Agility, readiness for changes and management maturity). The CI is actually viewed as a wider phenomena in other researches, specifically its aspects are addressed as potentially important within complex tasks (Ilin et al., 2016). It encompasses the following skills: ability of influence on others; interpreting the changing environment and adjusting to it; critical thinking; understanding the future perspectives and opportunities and others (Kutz, 2017). Potentially, "Interpreting the changing environment and adjusting to it" can be viewed in prism of "Cloud-based tools adaptation" among the companies, as it was done in the current research, but the topic can be admitted as still poorly discovered.

The baseline limitation of the current research is the number of analyzed companies. It could be broadened in scopes of further researches in order to provide stronger judgements about the types of companies' behavior. In addition, the research raised new questions for the future researchers, which are linked to cloud-based tools usage for particular project types and discovering the potential difference between these types (product development, vendor's software implementation, continuous development projects and others).

Abstract

This study aimed to examine the effects of distributive and procedural justice, and Islamic work ethics on employee engagement. The study involved 171 employees of a private company under Islamic foundations. The analysis was performed using hierarchical multiple regression. The results showed that distributive and procedural justice plays a positive role in improving employee engagement while Islamic work ethics play a role to moderate the effects of distributive and procedural justice on employee engagement. The interaction of distributive justice and Islamic work ethics plays a role in explaining employee engagement. Similarly, the interaction of procedural justice and Islamic work ethics affects employee engagement. The contribution of the main effects in this study is 0.631 while the contribution of the interaction effect is 0.056.

Keywords: Employee engagement, Distributive justice, Procedural justice and Islamic work ethics

Background

In the last 10 years, the term 'employee engagement' has become crucial in the business world (Andrew & Sofian, 2012). Employee engagement is one of an organization's important outcomes and plays an important role in supporting sustainable competitive advantage. A study conducted by Saks (2006) shows that employee engagement can improve in accordance to the increment in employee's perception of justice. Studies on organizational behavior explain that employees are involved in building long-term prosperity with the organization so that they are concerned with justice (Tjahjono, 2011). Thus, distributive and procedural justice becomes significant determinants in explaining organizational outcomes such as employee engagement (Colquitt et al., 2001; Colquitt, 2001; Palupi et al. 2014; Swenney & McFarlin, 1993). This way, it is important to consider fair management in improving employee's positive attitudes and behavior in the organization (Tjahjono, 2010).

Another important issue is from the aspect of an employee's personality that are closely related to attitude and behavior in the organization. An employee's personality are shaped from internalized values in employee's long-term attitudes and behavior. In Islamic organizations, Islamic values are developed to build an employee's positive attitudes and behaviors. The Islamic values that are adapted into the work

environment then forms Islamic work ethics. This research was conducted to investigate any efforts to improve employee engagement of employees at Islamic universities through fair management and Islamic work ethics.

Employee Engagement in Islamic University of Riau

Due to the fact that many Islamic universities do not execute the rules of ethics of Islamic work in their work, we chose to apply the Islamic work ethics variable. In the Personnel Performance Report Quarter I (January-March) 2016 that was produced by the University itself described issues as below;

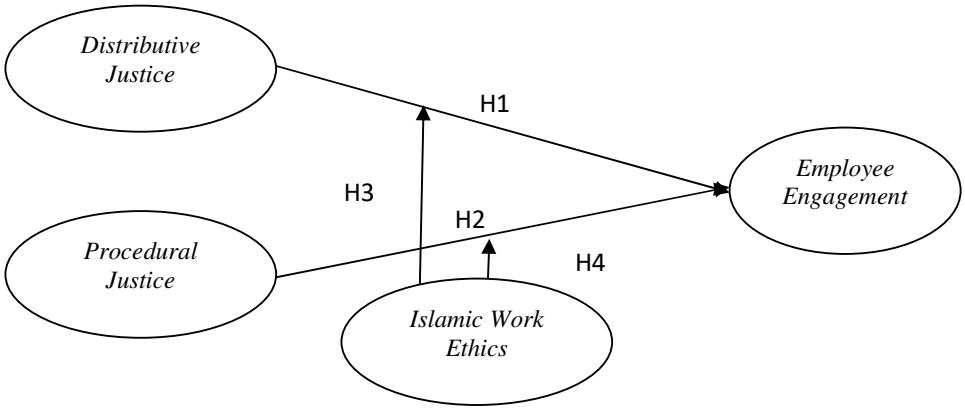
- Lack of communication between departments and parties related to it resulting in less harmonious relationships. If the relationship among these employees are not handled more seriously it can cause the deficiency of employee engagement which ultimately affects their declining performance.
- Organization and employment have no meaning for employees, rendering the employee-organization relationship unfavorable. The impact that arises from the lack of a sense of belonging of the employees in the organization makes their contribution less. Thus, the employee has not found the meaning of the work and the organization in which he/she works.
- Dishonesty of employees in carrying out their tasks and responsibilities.

Universities need to measure Employee Engagement as part of the HR planning and management system as an effort to increase employee productivity in order to contribute positively to universities. This needs to be done because the increased effectiveness and efficiency of an organization is highly dependent on the willingness of people in the organization to contribute positively in responding to change (Bogler and Somech in Widodo and Sami'an, 2013). Measurement of Employee Engagement in universities is conducted to determine the conditions that need to be the focus of improvement in an effort to improve the level of college performance.

Literature Review and Hypothesis

Employee engagement describes the forms of employee engagement towards his/her works so it could devote positive feelings towards their work (Brown et al*.,* 2016). Schaufeli (2002) and Saks (2006) emphasized the presence of three important dimensions namely vigor, dedication and absorption. Vigor is a form of employee's mental resilience in doing work. Dedication is a form of employee engagement in tasks that generates a sense of belonging to the organization and other positive emotional feelings towards the organization such as pride. Absorption is the level of concentration that employees are investing without interruptions or distractions so that they are not aware of the time passing by during their working hours. This way, organizations believe that employee engagement is an important outcome that encourages sustainability of organizational performance. A number of empirical studies indicate the importance of organizational justice effects on employee's positive responses such as employee engagement. At the beginning of the development of justice studies, distributive justice played a central role and became the focus of various researches on organizational justice. The perception of distributive justice was related to result allocation. On the other hand, the perception of procedural justice was related to the mechanism or procedure of generating allocations. The perception of procedural justice was complementary to the perception of distributive justice that could not be separated in assessing justice (Thibaut & Walker, 1978). In further developments, organizational justice that is believed to be dominant as a predictor of outcomes within an organization is distributive and procedural justice (Tjahjono, 2011). Empirically, the opinion that both distributive and procedural justice are an important reference for employees to show attitude and behavior has been proven in various studies (Folger & Konovsky, 1989; McFarlin & Sweeney, 1992; Tjahjono, 2010; Palupi, 2013; Palupi & Tjahjono, 2016).

H1: Distributive justice positively affects employee engagement



H2: Procedural justice positively affects employee engagement

Islamic work ethic encourages hard work and creativity as an element of personal achievement and happiness. Values in Islamic Work Ethics come from the initial intentions instead of only the results. The most interesting aspect of Islamic Work Ethics is the value that encourages people to be honest in their

work and forbidding them from conducting otherwise. Therefore, each member of the group begins to facilitate others to uphold the values and ethics; this then guarantees prosperity for individuals and organizations (Yousef, 2001; Ali, 1988; Khadijah et al., 2015). Employee's Islamic work ethics will distinguish an employee's attitude and behavior (Palupi & Tjahjono, 2016). Those with substantial Islamic work ethics have a tendency to have better employee engagement with their works. On the other hand, those who have low Islamic work ethics are closely related to being selfish and less sensitive towards any efforts to build social harmony in their environment.

H3: Islamic work ethics moderates the effects of distributive justice on employee engagement.

H4: Islamic work ethics moderates the effects of procedural justice on employee engagement.

Research Method

The study was carried out at a privately-owned organizations under Islamic foundation called the Islamic University of Riau. This study used an entire population of 171 employees of the selected location. The total response rate was 87.72%. The results of validity and reliability test showed valid and reliable results. The analysis used was hierarchical regression. The first step was to include the main effects namely distributive justice, procedural justice, and Islamic work ethics. The second step was to include the interaction between Islamic work ethics with distributive justice as well as Islamic work ethics with procedural justice. Lastly, to include the interaction among the three elements, namely distributive justice, procedural justice and Islamic work ethics in explaining employee engagement.

Findings and Discussion

Based on gender, the ratio of women and men is 32:68. Meanwhile, the working period and hierarchy of working rank are relatively equally distributed. The descriptive statistics shown in table 1 shows that the perceptions of distributive justice, procedural justice, and Islamic work ethics are in moderate category. Meanwhile, employee engagement falls in a relatively high category.

Table 1: Descriptive Analysis of Research Variables

Variables	Mean	Categories
Distributive Justice	3.32	Moderate
Procedural Justice	3.37	Moderate
Employee Engagement	3.55	High
Islamic Work Ethics	2.87	Moderate

Source: Analyzed Data, 2017

Table 2 illustrates the results of hierarchical multiple regression analysis, describing 3 steps of regression. The result of the regression analysis in the first step shows that distributive justice, procedural justice and Islamic work ethics have positive effect on employee engagement. The contribution of the main effect is 0.631, seen from adjusted R square. In the second step, the interaction between distributive justice and Islamic work ethics plays a role in explaining employee engagement. Similarly, the interaction between procedural justice and Islamic work ethics plays a role in employee engagement. The contribution in this second step shows that both interactions are significant by 0.687.

Table 2: Estimation Result of Regression

No	Model	Regression Coef.	t statistic	Sig	Sig. F	Adjusted R Square
1	Step 1 Distributive Justice (X1) Procedural Justice (X2) Islamic Work Ethics (Z)	 0.489 0.615 0.152	 8.866 9.842 2.901	 0.000 0.000 0.004	0.000	0.631
2	Step 2 Moderate 1 Distributive Justice x Islamic Work Ethics Moderate 2 (X1Z) Procedural Justice x Islamic Work Ethics (X2Z)	 0.080 0.168	 2.188 3.575	 0.030 0.000	0.000	0.687

Dependent Variable: Employee Engagement (Y)
Source: Analyzed Data, 2017

More specifically, distributive justice has a positive effect on employee engagement with a regression coefficient of 0.489. This way, an increase in distributive justice is followed by an increase in employee engagement. On the other hand, lower distributive justice is related to lower employee engagement. This result supports the first hypothesis.

In relation with the second hypothesis, the result shows a positive effect of procedural justice on employee engagement. The regression coefficient of 0.615 indicates that higher perception of procedural justice is associated with higher employee engagement. This result supports the second hypothesis.

In addition, the interaction between distributive justices with Islamic work ethics affects employee engagement. The regression coefficient of 0.08 indicates that variations in the interaction between distributive justice and Islamic work ethics are associated with a change in the variations in employee engagement. This result supports the third hypothesis.

Lastly, the interaction between procedural justices with Islamic work ethics affects employee engagement. The regression coefficient of 0.168 indicates that variations in the interaction between procedural justices with Islamic work ethics are related to a change in the variations in employee engagement. This result supports the fourth hypothesis.

The fact that the four hypotheses are supported shows that the research model can well describe the phenomenon of employee engagement in private companies in Indonesia. Adjusted R square of 0.687 indicates that the model can well explain the phenomenon of employee engagement of private company employees.

The results show that Islamic work ethics plays a significant role in explaining employee attitudes and behavior in private companies under Islamic foundation in responding to company policies. However, the results do not explain the specific impacts of the interaction among distributive justice and procedural justice with Islamic work ethics in explaining employee engagement.

Conclusion

Based on the results of the analysis, the conclusion are as follows. First, distributive and procedural justice have positive effects on employee engagement. Second, Islamic work ethics moderate the effects of distributive and procedural justice on employee engagement. However, the interaction among the three variables, namely distributive justice, procedural justice and Islamic work ethics, does not significantly influence employee engagement.

In the context of employees of private company under Islamic foundation, descriptive statistics explain that the perceptions of distributive and procedural justice fall into moderate category. Islamic work ethics are also in moderate category. On the other hand, the level of employee engagement of private company employees is relatively high.

Limitation of Study

This study has described that Islamic work ethics moderate the effects of distributive and procedural justice on employee engagement. However, the interaction among the three variables does not specifically explain its effect on employee engagement. Experimental studies are more appropriate to build the interaction among the three variables and their impacts on employee engagement. Such limitations allow chances for future studies in order to develop and improve the studies on the model of distributive justice, procedural justice, Islamic work ethics, and employee engagement.

Abstract

The purpose of this study is to investigate the interaction between social capital and organizational justice such as distributive justice and procedural justice in explaining employee engagement within higher education institution. The context of this study is the study of organizational behavior in private organization. The respondents were employees of private organizations amounting to 150 employees. The testing of variable and data analysis used hierarchical multiple regression analyses using SPSS. The result of regression to empirical data found that distributive justice has a positive effect on employee engagement. Likewise procedural justice positively affects employee engagement. Social capital in the model is able to explain the differences in employee attitudes and behaviors within the organizations. The results showed that social capital moderates the effects of distributive justice on employee engagement. Other result showed that social capital moderates the effect of procedural justice on employee engagement.

Keywords: employee engagement, distributive justice, procedural justice, social capital

Background

Studies on employee engagement are getting more important in understanding the phenomenon of the relationship between employees and organization. Employee engagement becomes one type of relationship that a company prefers as it plays an important role in supporting a sustainable competitive advantage. Employee engagement has a close relationship with employee's perception of justice (Saks, 2006). A study conducted by Tjahjono (2011) explains that organizational justice is the most important step in developing transactional patterns between employees and companies. The results of several studies on justice using meta-analysis technique by Tjahjono (2008a) shows that distributive justice and procedural justice play a dominant role in explaining employee attitudes and behavior. These study results are supported by many studies that distributive justice and procedural justice are important predictors - organizational outcomes such as employee engagement (Swenney & McFarlin, 1993; Colquitt et al., 2001; Colquitt, 2001; Palupi et al., 2014). Thus, studies on organizational justice are increasingly meaningful to improve employees' positive attitudes and behavior in organizations (Palupi & Tjahjono, 2016).

Social capital is an important concept that describes individual property. The concept of social capital plays a role in explaining employee attitudes and behavior in responding to organizational justice (Tjahjono, 2011). Social capital is present in this model as employees' social capital can distinguish

them when perceiving a policy and regulation as well as influence how they respond to justice and injustice (Tjahjono, 2011). Social capital can also influence employees in their involvement in a job, if an organization has justice then the social capital of employees will increase which causes employee involvement in a job also increases. Individual social capital differences will differentiate how they perceive justice.

Literature Review and Hypothesis

In general, employee engagement describes the forms of employee engagement to his works so he could devote positive feelings to his works (Brown et al*.,* 2016). Further, Schaufeli (2002) and Saks (2006) explain the presence of three important dimensions namely vigor, dedication and absorption. Vigor is a form of employee's mental resilience in doing a work. Dedication is a form of employee engagement in work that generates a sense of belonging to the organization and other positive emotional feelings towards the organization. Absorption is the level of concentration on work so that employees are not aware of the time used for the work. Based on these three dimensions, employee engagement is an important outcome that encourages positive dynamics and promotes sustainability of organizational performance.

The results of empirical studies have revealed that organizational justice positively affects employee's positive attitudes and behaviors such as employee engagement. In the studies on organizational justice, two types of justice that develop rapidly are distributive justice and procedural justice (Lind & Tyler, 1988). These two types of justice still play a more dominant role compared to the others (Tjahjono, 2011). In its development, procedural justice is complementary to distributive justice (Thibaut & Walker, 1978). Many empirical studies reported that distributive justice and procedural justice are important reference for employees in showing attitude and behavior in regard to a number of managerial policies within an organization (Folger & Konovsky, 1989; Tjahjono, 2010; Palupi, 2013; Palupi & Tjahjono, 2016; Badawi et al., 2017). When employees have high perceptions of justice in their organization, they are also more likely to feel obliged to be fair in how they perform their roles by giving more of themselves through greater levels of engagement (Ghost *et al., 2014;* Cropanzano and Mitchell, 2005; Biswas *et al.,* 2013)

H1: Distributive justice positively affects employee engagement

H2: Procedural justice positively affects employee engagement

The concept of social capital is a broad and abstract concept (Adler & Kwon, 2002). This concept can be observed from various analysis levels including national, organizational, group and individual level (Akdere, 2005). Social capital can be observed as an individual property which contains values that are oriented towards building social harmony from structural, cognitive and relational dimensions (Tjahjono, 2011). Such explanation is in line with the structural, cognitive and relational dimensions stated by Nahapiet & Ghosal (1998). Social capital strengthens social relations in its environment (Cendani & Tjahjaningsih, 2015). In addition, the first reason for the presence of social capital into the model of organizational justice is the limited information that leads employees to use subjective judgments (Tjahjono, 2011). The second reason is that social capital can distinguish between attitudes and behaviors in responding to managerial policies (Tjahjono, 2011). The third reason, social capital refers to the relationships between employees and social networks, norms and beliefs within an organization that can affect individual and group productivity (Carina and Harjanti, 2017)

H3: Social capital moderates the effect of distributive justice on employee engagement.

H4: Social capital moderates the effect of procedural justice on employee engagement.

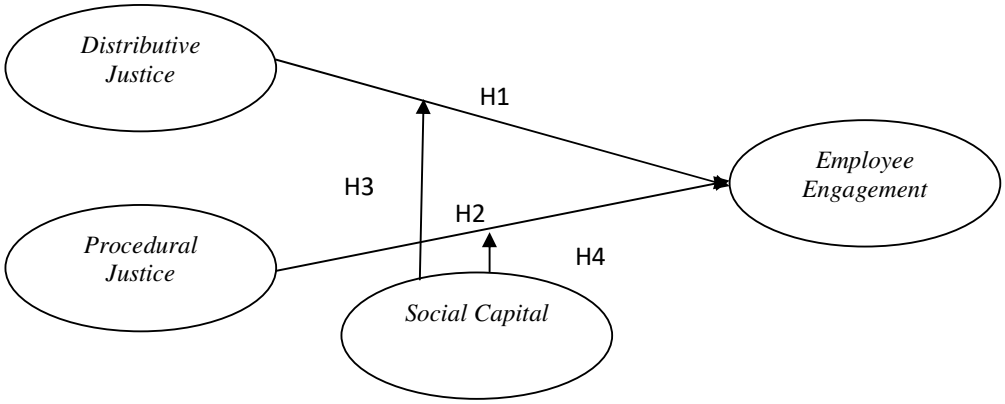

Figure 1 : Model of Interaction Between Social Capital And Organizational Justice In Explaining Employee Engagement

Research Method

The study was conducted to a population of employees of private organizations in Yogyakarta Special Region. The data were obtained from 150 employees. The results of validity and reliability tests of the research instrument showed valid and reliable results. Then it was followed by hierarchical regression analysis. The first step was to include the main effects namely distributive justice, procedural justice, and social capital. The second step was to include the interaction between social capital with distributive justice as well as social capital with procedural justice. The third step was to include the interaction among the three elements, namely distributive justice, procedural justice and social capital in explaining employee engagement.

Findings And Discussion

The descriptive data indicate that the comparison of gender-based employees is relatively balanced 60:40. The descriptive data also indicate that the working period and hierarchy of working rank are also equally distributed. Such relatively balanced comparison is beneficial in reducing bias associated with the prominence of certain aspects, for example when employees are dominated by those who are preparing for retirement, it may disrupt the analysis if the respondents were dominated by employees under 30 years old. Given the balance of each segment, the researchers found it unnecessary to use control variables in the initial step in the hierarchical multiple regression test.

Table 1: Descriptive Analysis of Research Variables

Variables	Mean	Categories
Distributive Justice	3.32	Moderate
Procedural Justice	3.37	Moderate
Employee Engagement	3.55	High
Social Capital	2.86	Moderate

Source: Analyzed Data, 2017

Table 1 shows the mean of each variable, i.e. distributive justice, procedural justice, social capital and employee engagement. These descriptive statistics indicate that the perceptions of distributive justice,

procedural justice and employee's social capital are at a moderate level. Meanwhile, employee engagement is at a high level.

Table 2: Estimation Results of Regression

No	Model	Regression Coef.	t statistic	Sig	Sig. F	Adjusted R Square
1	Step 1 Distributive Justice (X1) Procedural Justice (X2) Social Capital (Z)	 0.477 0.621 0.129	 8.649 9.889 2.519	 0.000 0.000 0.013	0.000	0.626
2	Step 2 Moderate 1 Distributive Justice x Social Capital Moderate 2 (X1Z) Procedural Justice x Social Capital (X2Z)	 0.076 0.155	 2.178 3.324	 0.031 0.001	0.000	0.674

Dependent Variable : Employee Engagement (Y)
Source: Analyzed Data, 2017

The result of hierarchical multiple regression analysis in the first step shows that the main effects including perception of distributive justice, perception of procedural justice and social capital have positive effect on employee engagement. The contribution of the main effects is 0.626, seen from adjusted R square. The second step in the form of the interaction between distributive justice and social capital plays a role in explaining employee engagement. Similarly, the interaction between the perception of procedural justice and social capital plays a role in explaining employee engagement. The contribution in this second step shows that the interaction between the two is significant, amounting to 0.674. On the other hand, the contribution in the third step shows that the interaction among the perception of distributive justice, procedural justice and social capital does not have any significant effect on justice model and employee engagement.

More specifically, distributive justice has a positive effect on employee engagement with a regression coefficient of 0.477. In other words, an increase in distributive equity is followed by an increase in employee engagement. In contrast, lower distributive justice is associated with lower employee engagement. This result supports the first hypothesis.

In relation with the second hypothesis, the result shows a positive effect of procedural justice on employee engagement. The regression coefficient of 0.621 indicates that higher perception of procedural justice is associated with higher employee engagement. This result supports the second hypothesis.

On the other hand, the interaction between distributive justice with social capital affects employee engagement. The regression coefficient of 0.076 indicates that variations in the interaction between distributive justice and social capital are associated with a change in the variations in employee engagement. This result supports the third hypothesis.

Lastly, the interaction between procedural justice with social capital affects employee engagement. The regression coefficient of 0.155 indicates that variations in the interaction between procedural justice with social capital are related to a change in the variations in employee engagement. This result supports the fourth hypothesis.

The fact that the four hypotheses are supported shows that the research model can well describe the phenomenon of employee engagement in private companies in Indonesia. Adusted R square of 0.674 indicates that the model can well explain the phenomenon of employee engagement of private company employees.

The results show that social capital plays a significant role in explaining employee attitudes and behavior in private companies in responding to company policies. (Folger & Konovsky, 1989; Tjahjono, 2010; Palupi, 2013; Palupi & Tjahjono, 2016; Badawi et al., 2017) In general company policies are appercieved as moderate (see table 1). This show that from Distributive and Procedural justice as still important to be inproved. According to study by (Tjahjono 2011, 2014) Social capital has stronger role during in Justice organization environment. Nevertheless, the results do not explain the specific impact of the interaction among distributive justice and procedural justice with social capital in explaining employee engagement.

Conclusions

Some key points to conclude this study are, first, in general, organizational justice is an important predictor of engagement. In particular, distributive justice and procedural justice have a positive effect on employee engagement. Second, social capital has a role as a moderating variable in the research model. Social capital moderates the effects of distributive justice and procedural justice on employee engagement. However, the interaction among the three variables, namely distributive justice, procedural justice and social capital, does not significantly explain employee engagement.

In regard with these private company employees, descriptive statistics report that the perception of organizational justice both the perception of distributive justice and procedural justice falls into moderate category. Similarly, social capital is also in moderate category. On the other hand, the level of employee engagement of private company employees is relatively high.

Limitation Of Study

The results of this study report that social capital moderates the effects of distributive justice and procedural justice on employee engagement. The interaction among the three variables does not specifically explain its effect on employee engagement. Future research is expected to accommodate the objectives to gain specific interaction between organizational justice and social capital. Approach using experimental studies is more appropriate for building the interaction among the three variables and their impacts on employee engagement.

Evaluating Marginal Excess Burden of Taxation in Russia and the USA

Chernogorskiy S., SPbPU, St. Petersburg, Russia, chernog_sa@spbstu.ru

Kuporov Ju., SPbPU, St. Petersburg, Russia, kuporov_yuyu@spbstu.ru

Shvetsov K., SPbPU, St. Petersburg, Russia, shvetsov@inbox.ru

Abstract

Any public expenditures include not only cash costs, but also an additional excess burden of the higher taxes that are used to finance the necessary expenses. As a result, the society not only pays for public expenditures financed due to tax collection, but also incurs additional losses. The assessment of these losses, called excess burden of taxation, must be taken into account when defining the tax burden and analyzing the options for improvement of the tax system. The general equilibrium model with taxes is considered in the paper. In the proposed model, the economy is described using a general equilibrium model in which one product is produced and one type of labor is used. This model includes three types of economic agents: producer, household and state. This problem is widely discussed in scientific literature. We assume that the rate of one of the taxes varies and each household receives additional income from outside, which allows maintaining the initial level of utility in equilibrium. Excessive tax burden is the difference between additional compensating income and increase in tax collections. The ratio of excessive tax burden to the increase of tax revenues is called the marginal excess burden of taxation for this tax (if its rate change is small).

Keywords: marginal excess burden of taxation, profit tax, value added tax, personal income tax, contributions to extra-budgetary funds.

Introduction

At present, increase of taxation is being discussed in Russia. Although this increase is planned only in 2018, after the election of the President, now it is necessary to understand what consequences for society can be expected and whether the government will achieve the desired results. Knowing the marginal excess burden of taxation of various taxes is necessary for the economic justification of tax reforms, i.e. the effects of reducing one tax against raising another tax, considering the total tax revenue as constant. Of the tax system also plays a role in determining an economically efficient tax system. This paper assesses the marginal excess of taxation burden in the Russian Federation and in the United States.

The work by Hicks (1941) is the main one in the theory of excess burden of taxation. Consider the equilibrium state in the general equilibrium model with taxes. In the work by Diamond and McFadden (1974) assumed to be that the rate of one of the taxes changes and each household receives an additional income from outside, which maintains the initial level of utility in equilibrium, i.e. it compensates change in utility caused by additional tax charges. Further on the English abbreviation (Additional Compensating Income) is used in the text instead of the term "additional compensating income". The difference between the value and increase in tax collections is an excess burden of taxation. The work Ballard et al (1985) is dedicated to the study ratio to the increase of tax revenues is called the of this tax, if the rate change is small. The essence of the proposed definition is that households are considered to be consistently rational: when assessing their losses and value, they take into account the potential impact on the equilibrium state. Precisely this would be necessary to maintain an unchanged level of utility.

The calculation method of marginal excess burden of taxation[1]

The method used has the following steps:
1. Definition of the economic-mathematical model for describing the economic system.
2. Definition of the marginal excess burden of taxation concept.
3. Definition of the economic system equilibrium after taxes are changed and obtaining an expression to calculate the n (in case the revenues received by the state are spent on its own consumption).
4. Bogdanova et al (1999) obtaining an expression for the in case tax revenues are redistributed.
5. Calculation of in the RF and the USA economies.

Hereinafter, the following notation will be used to denote basic taxes: PT - profit tax; VAT - value added tax; IT - income tax; PRT (Payroll Tax) – contributions to extra-budgetary funds. In the book by Debreu (1982) considered a competitive economy model. Works by Rodionov et al (2014), Kalinina (2016), Churkin and Kalinina (2016) are dedicated to the study Arrow-Debreu model. Model includes three participants: a representative household, a producer and the state. All products are aggregated into one. All types of labor are also aggregated. This means that there are two markets in the model: product market and labor market. We assume the price of the product is equal to one.

The household chooses its consumption C and working time L so as to maximize its utility, i.e. it solves the following problem:

$$U(C, L) \to \max ,$$

where U - utility function; C - household consumption; L - labor time (labor).

It is assumed that the utility function does not depend on public goods, it grows with increasing C and goes down with increasing L. Consumption C (or a budget limitation) is expressed by the following formula:

$$C = (1 - \tau)(wL + D) + n + e^0 , \quad (1)$$

where C – household consumption; τ - income tax rate; w - wages for a unit of labor time (wage rate); L - labor time; D - dividends paid to the household; n - net transfers; e^0 - any types of property.

It is assumed that any type of property is not taxed, and the labor time L is positive with any wages and any tax rate. The producer maximizes net profit, i.e. profit remaining after all taxes are paid. Profit is defined as the difference between revenue without VAT, excises and similar payments and prime cost, i.e. production costs, including the unified social tax PRT.

In this paper we analyze only a one-period model. Since the capital in this model is fixed, the producer plans to obtain maximum profit in the form of solution to the following task:

$$\Pr(L) = (1 - \alpha)\left[(1 - \beta)F(L) - (1 + \gamma)wL\right] \to \max , \quad (2)$$

where $\Pr(L)$ - after-tax profit; α - PT rate; β - VAT rate; γ - PRT rate; $F(L)$ - productive function that determines the volume of a net product, or the added value; w - wages for a unit of labor time (wage rate); L - labor time.

[1] This section is stated in accordance with Chernogorskiy S. Mathematical models of optimization of parameters of the state tax system: Ph.D thesis in economics: 08.00.13, 08.00.14 : SPb., 2002 158 p. RGB OD, 61:03-8/1690-X

The productive function $F(L)$ increases with a growth of L. The producer can reinvest the obtained profit and use it to develop production, or can pay out dividends to shareholders. We confine ourselves to the case when all disposable income is paid to the household in the form of dividends, then

$$D = \Pr(L^{\Pr}), \tag{3}$$

where D - dividends; $\Pr(L^{\Pr})$ - after-tax profit; $L^{\Pr}$ - solution of the profit maximization problem by the producer (2).

The process of tax rates adjustment requires legislative decisions and, therefore, takes a long time. Hence, we will consider tax rates as fixed, and government expenditures G will be equal to tax charges (at least in the short term prospects). If the state budget is balanced (it is assumed so), then government expenditures can be found from the following expression:

$$G + n = \tau_w w L^C + \gamma_w w L^{\Pr} + \beta F(L^{\Pr}) + \tau_D D + \frac{\alpha \Pr(L^{\Pr})}{1-\alpha}. \tag{4}$$

On the right side of the equation, the state budget revenues from the collected taxes are shown: IT, PRT, VAT, PT. Net transfers n are considered as fixed.

The equilibrium state in this taxation system $t = (\alpha, \beta, \gamma, \tau)$ is defined by vector $E(t) = (w^0, C^0, L^C, L^{\Pr}, G^0)$, where (C^0, L^C) is a solution (1), $L^{\Pr}$ is a solution (2), G^0 satisfies (4) and labor and product markets are balanced. This means that relations (1) and (2) are satisfied for the same amount of labor time. Mathematically, this is expressed by the relation $L^C = L^{\Pr} = L^0$. Also, the relation $C^0 + G^0 = F(L^0) + e^0$ is satisfied, i.e. the total expenditures of the household and the state are equal to the income from the production of the goods in the system and income on any types of property. We call an additional compensating income ACI such a change in any type of household property e^0 that ensures the invariability of its utility level before and after the change in tax rates. Let the tax rates at first be defined by a vector t^0, then they change to a value t. Denote the utility function in the equilibrium state with tax rates t^0 as $U(C^0, L^0) = U^0$ and add the requirement of invariability of utility, i.e. mathematically $U(C, L) = U^0$. Additional compensating income is defined by relation $ACI = e - e^0$. The government expenditures G also change when the tax rates change, where difference $G - G^0$ determines the increase in tax collection. The value $(e - e^0) - (G - G^0)$ is called an excess burden of tax changes $t - t^0$ for a given taxation system t^0.

The marginal excess burden MEB is a ratio of excess burden to the increase in tax collections, when the change in tax rates is small. More precisely, it is written as follows

$$MEB = \lim \frac{(e - e^0) - (G - G^0)}{G - G^0}, \text{ when } t \to t^0.$$

We should note that excess burden is associated with the given taxation system. In the theory of optimal taxation, on the contrary, government expenditures are set and taxes are chosen so as to maximize utility. Based on the obtained MEB expressions for the four considered taxes, we can write the following inequalities:

$$MEB(PT) < MEB(VAT) = MEB(IT) < MEB(PRT).$$

This expression allows you to determine ways to improve the taxation system by changing the rates of various taxes, reducing excess burdens. The MEB value does not depend on the use of tax revenues. Bogdanova et al (1999) mentioned regardless of whether these revenues are used for government

expenditures or are transferred to households, economic agents lose an amount equal to the value from changed tax rates per each ruble of additional tax revenue. The model has to be transformed to use statistical data and make calculations. A household income consists of wages in production, net transfers, including pension payments, and income from any type of property. The household uses its income to consume and save. In a research study by Chernogorskiy (2007) is considered that the pension fund and extra-budgetary funds are consolidated with the state budget.

The actual MEB value can be quantified using the statistical data and the following formula:

$$MEB = \frac{dn}{de} = -\frac{\theta\omega r}{L}\left[1+\frac{\theta\omega r}{L}\right]^{-1},$$

where $\frac{\theta\omega r}{L} = -T\frac{L_0 - L}{L(1+h)(C+S-n-e)}$, T - tax revenues from four taxes: PT, VAT, IT, PRT; h - an average of the values for different time periods; C – household consumption; L - labor time; L_0 - time for work and rest; S - savings; n - net transfers; e - any types of property.

Statistical data contains information on the parameters C, S, n, components T, as well as information on the size of economically active population and the number of unemployed. The labor time L can be calculated from these data.

Actual values of marginal excess burden in Russia and the USA

We should note the following assumptions and limitations of the model.
1. We consider a one-period model with fixed capital. The model includes three participants: the household, the producer and the state, all products and all types of labor are aggregated into one, the product price is equal to one.
2. The following taxes are considered: *PT; VAT; IT; PRT*. Extra-budgetary funds are consolidated with the state budget.

3. Any types of property are not taxed.
4. All profits received by the producer are paid to the household in the form of dividends.
5. The state budget is considered balanced, and taxes are the only source of state revenue.
6. Formula for the *MEB* is obtained based on a assumption that production function *F(L)* is linear.
7. When the model is transformed to use statistical data, it is considered that the economy is in equilibrium in each period of time.

In the paper by Goulder and Williams (2003) stated that ignoring general equilibrium effects leads to biases in estimating the excess burden. However, on the basis of this model it is possible to obtain a numeric expression for the marginal excess burdens, having rather scarce statistical data on minimal time and labor costs. Table 1 shows the actual *MEB* values, calculated for Russia and the USA for the period from 2010 to 2015.

Table 1 : the actual MEB value, calculated by an indirect method (by statistical data) on four taxes: *VAT*, *IT*, *PT*, *PRT*

State	2010	2011	2012	2013	2014	2015
USA	0.19	0.20	0.20	0.21	0.21	0.20
Russia	0.28	0.22	0.22	0.21	0.20	0.17

The *MEB* calculations in Table 1 show that the real *MEB* value in 2015 in Russia is 0.17, which means that the Russian economy in addition loses 17 kopecks per every ruble of tax collections. The Russian *MEB* value is almost equal to the *MEB* value for the United States.

Conclusion

The greatest distortions, as shown in the mathematical model, are caused by the *PRT* which is paid by employer and/or employee. Russia must continue reformation of contributions to non-budgetary funds, included in the *PRT*. These are the most difficult Russian problems.

To achieve this goal, we recommend the following set of measures.
1. It is necessary to lower the *PRT* rate down to 20-25%. In the paper by Myasnikov et al (2010) mentioned this will reduce the cost of manufactured products, increase the real demand of the population and reduce the excess burden, and the utility of households will increase more than the amount of contributions will decrease.

2. It is necessary to lower the *VAT* rate down to 15-16% (not to raise to 20% as planned). This will revive the demand by reducing both prices and excess burdens.

3. A slight increase in the income tax rate is possible, but at the same time, it is necessary to free from taxation the profits invested in innovation, expansion and modernization of production, and to exclude from the tax base all documented and substantiated expenses related to doing business.
According to the authors, the proposed set of measures will contribute to a growth of real incomes of the population, thereby reviving production and demand.

Abstract

Fighting corruption and enhancing integrity is a major challenge facing developing countries today. The adoption of ICT mainly in the procurement process in the public sector seems to be one of the ways used by some countries to fight corruption and enhance clean business. This research in progress examines the role of transparency, trust and risk perception in the adoption of e-procurement systems within the Moroccan healthcare sector.

Keywords: TAM, Transparency, Trust, Risk.

Introduction

Corruption has been one of the main factors hindering economic and social development in Morocco. According to the Corruption Perception Index (CPI) of 2015, Morocco's position has slightly worsened as it ranked 88 out of 168 countries compared to 2014 where it ranked 80 out of 175 countries. In an attempt to reduce corruption, the Moroccan government has initiated several reforms in law and launched several awareness campaigns. In fact, in March 2016, the government revealed an ambitious country-wide strategy to fight corruption. This strategy adopts a sectorial approach which, based on previous similar experiences, has proven to be more effective. One of the sectors targeted by this strategy is the healthcare sector.

The healthcare sector is often cited as one of the sectors affected most by corruption. One of the mostly affected functions in this sector is the procurement process. Fraud and corruption happens most at the acquisition of medical equipment and medication especially during the tendering process. Given the fact that corruption in the public sector is often linked to procurement, several countries have adopted e-Procurement systems as a way to improve transparency in the process and hence fight corruption.

Many developed and developing countries have adopted new information technology initiatives in order to improve their procurement process especially within the health sector (Al-Jaghoub, Al Yaseen, & Al-Hourani, 2010). E-procurement systems have proved to be an effective tool in enhancing transparency in the procurement process. Accordingly, the main objective of this research is to identify the main factors that affect the adoption of e-procurement systems within public hospitals in Morocco. Of interest to us is the role transparency, trust and risk perception play with the TAM theoretical model.

Research Model and Hypotheses

The purpose of this study is to identify factors affecting the adoption of ICT in the procurement process of the Moroccan Health sector. There are several theories that have been used to study the adoption of IT. The most widely used ones are Technology acceptance model (TAM) (Davis, 1986), Diffusion of Innovation (DOI) (Rogers, 1995), and Theory of Planned Behavior (TPB) (Ajzen, 1991). In this study

we will be using TAM as it is both a parsimonious and strong model which assesses the user's acceptance behavior toward the use of information technology (Gefen et al., 2003). TAM provides an attitudinal explanation of how individuals adopt or reject an information system (Horst, Kuttschreuter, and Gutteling, 2007).

In this research the TAM model is augmented by three constructs namely transparency, trust and risk perception that have been proven as important factors affecting adoption in different studies (Gefen, Karahana, and Straub, 2003; Al-Jabri and Roztocki, 2015). Our objective is to see the impact of these constructs on the TAM model within the e-procurement in the healthcare sector in Morocco. Figure 1 presents the research model.

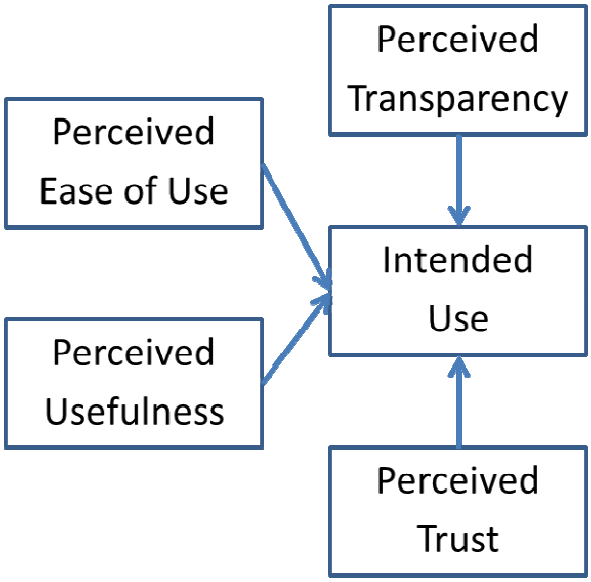

Fig. 1: Research Model

TAM and E-Procurement

Public procurement plays a paramount role in the evolvement of countries accounting for somewhere between 10 to 15% of GDP. In Morocco, this ratio is estimated to be even higher than 20% (La logistique du commerce et la compétitivité du Maroc, 2016). Thus, the flow of this process should be done in the most efficient way in order to maximize the value generated from it. Indeed, a proper functioning of the public procurement process goes hand in hand with a flow based on transparency, accountability, and integrity (Public procurement in Zambia, n.d). Therefore, many governments are nowadays trying to enhance their business processes by adopting new information communication systems that ensure the efficiency, openness, accountability, and transparency of their services (Al-Jaghoub, Al Yaseen, & Al-Hourani, 2010).

E-procurement is the use of ICT typically over the internet to conduct procurement transactions between organizations and their suppliers. It streamlines and integrates all the steps in the procurement process from the tendering to the payment process and beyond. Similar to other countries, the adoption of e-procurement within the Moroccan health sector would be a paramount step toward a more transparent, accountable, and efficient process flow.

E-procurement is an information technology innovation and therefore the user adoption of it can be explained by TAM. Several empirical research studies have demonstrated that TAM is a robust and parsimonious model compared to other innovation adoption and use models (Taylor and Todd, 1995; Geffen and Straub, 2000). The two main constructs in TAM are perceived ease of use (PEOU) and perceived usefulness (PU). According to Davis (1989), PEOU is defined as "the extent to which an individual believes that the use of a specific system will not require a lot of efforts" whereas PU refers to the degree to which a person is willing to use a specific system in order to enhance his or her performance. Though TAM is often used at the individual level, several studies have used it in organizational setting (Davis et al., 1989; Matheison, 1991; Gefen et al. 2000). Hence we hypothesize the following:

H1: PEOU will positively affect intention to use e-procurement systems

H2: PU will positively affect intention to use e-procurement systems

Perceived Transparency and E-Procurement Intended Use

Transparency refers to the ability to have access to the information anytime and anywhere, and the integration of all the data through the whole process flow (McManus, 2006). According to Sturges (2004), a transparency environment must be open, protects the public interest, has a clear transparent auditing process as well as free journalism investigation that detects and reveals all misconducts that could affect the public interest.

Today, with the advancement of information technology, transparency is becoming easier to implement. As a matter of fact ICT has been often cited as an effective tool in improving transparency and reducing corruption. Transparency is improved through transaction traceability, information availability and accessibility. Transparency has been shown to have a negative effect on corruption. By making processes more transparent and clear, accountability becomes easier and information becomes readily available.

Information systems such as E-procurement systems help streamline processes, enhance information transparency through information availability and hence improve decision making. Street and Meister (2004) posits that information transparency has two main dimensions within an organization. The first dimension is the internal transparency that refers to degree to which information is streamlined and can be easily accessed by employees. The second dimension is the external transparency which is defined as the exchange of information between parties outside the organization. Additionally, transparency tends to become an extremely regarded subject since it contributes in the enhancement of a fair participation, empowered decision making, and integration of information with the public (Cullier and Piotrowski, 2009; Mulgan, 2007; Quinn, 2003; Reylea, 2009; Shuler et al., 2010). Al-Jabri and Roztocki (2015) empirically showed that perceived information transparency has an effect on adoption of ERPs. Their findings suggest that ERP users appreciate the information made available by the systems in terms of tracking activities, accessibility and sharing of information about the organization performance. Hence we hypothesize the following:

H3: Perceived transparency is positively related to the intention to use e-procurement system

Perceived Trust and E-Procurement Intended Use

Trust is a pre-requisite to any business or economic transaction. It is a complex multidimensional construct. The concept of trust does not deal only with the personal interaction but also with the electronic environment. Perceived trust is based on the integrity, and trustworthiness of the whole information system including people, procedure, and the system (Gefen et al., 2003). From this standpoint we can point out that perceived trust is another critical factor which determines the customers' intention

to adopt information system. Zuboff (1988) suggests that the adoption and usage of information technology are both affected by customers' trust. Therefore, trust is a drastic predictor of IT adoption which has a strong influence on the consumer's behavior. Additionally, customers' trust determines whether the adoption of an information will be successful or not. Furthermore, Rea (2001) claimed that enhancing the awareness and the understanding of electronic processes is a way to promote trust. Likewise, there are several factors which have substantial impact on the customer's trust toward adopting information communication technology (Al-Ghaith, Sanzogni, & Sandhu, 2010). These factors appear in terms "the functionality of the system, the security standards, and the structural aspects" (Al-Ghaith, Sanzogni, & Sandhu, 2010). The latters have a significant impact on the customers' intention and adoption of ICT.

In the same stream of research, Gefen et al. (2003) in their influential study reveal that trust depends on some specific factors. End users build trust when they believe that the system has strong security tools that will enable them to use it in a safe way. Moreover, trust is enhanced when the system has an easy to use interface (Gefen et al., 2003). Given the above, we trust that perceived trust will have an important impact on the adoption of information communication technology within the procurement process of the health sector in Morocco. Thus we hypothesize the following:

H4: Perceived trust towards the e-procurement system positively affects its adoption.

Methodology

To examine the relationships between the different variable and to test the hypotheses, the survey method will be used. We will use the standard TAM instrument to measure PU and PEOU from Davis (1989). These items were previously validated in different contexts. To measure transparency we will adopt Bertot et al (2010) instrument. The items will be adapted to the e-procurement context of the healthcare sector. Data will be collected from public hospitals' procurement managers and employees. We are in the data collection stage and hope to have some preliminary results to share at the conference.

Conclusion

This study will attempt to extend our understanding of the role of information transparency, trust and risk perception in the context of e-procurement systems intention to use. As the Moroccan government is trying to fight against corruption, e-procurement seems to be an effective tool to enhance transparency. This research will help shed light on the factors that affect the adoption of e-procurement systems among procurement employees within the healthcare public sector.

University Attitude to the Applicability and Solution of the Society-wide Problem of Water Management

Martina Juříková, Tomas Bata University, Zlín, Czech Republic, jurikova@utb.cz

Abstract

Management of each university is currently dealing with qualitative parameters to withstand high national or international competition. Various university evaluation metrics – such as international ranking (QS World University Rankings, U – Multirank, etc.), as well as national indicators – often linked to the financing of individual universities – have been developed to monitor it. Significant indicators include, among other things, image of the university perceived by its stakeholders, built on communication of the educational process quality, scientific and creative activities, as well as the readiness of the graduates to practice. At present, qualitative indicators are more often related with society-wide overlap of activities where universities build image on the basis of activities resembling CSR in companies. Universities become places for discussion, prevention, but also for conceptual or realizable solutions to social problems and issues. Therefore the presented paper deals not only with the analysis of secondary data, but particularly with the results of primary surveys analyzing the impact of graduates' applicability on the perceived image in two periods and in a subsequent project "Water for All" of the Faculty of Multimedia Communications. The project reflected needs of practice and the whole society and at the same time analyzed the perception of university students of the problem of water management in a pilot survey at Tomas Bata University. The focus of interest was to find out whether young people are aware of the problem of water management rather in a local or global context.

Keywords: water management, students, water for all, CSR.

Introduction

In the existing global and competitive environment that universities are exposed to nowadays, universities must present themselves as service (products) providers to their customers. According to the marketing approach, it should identify, analyze, but also predict and meet the requirements of its customers. Hutyra ranks amongst university customers not only students and employers, but also society for which universities should look for new solutions, innovations, but also to analyze impacts and look for solutions to various societal problems or opportunities.

Table 1: University target groups and their needs, Source: (ČESKÁ SPOLEČNOST PRO JAKOST, Z.S., © 2009–2017)

Product	Characteristics	Customer	Customer requirements
Bachelor, Master, Doctoral Education	Acquired qualification	Students	Readiness for practice, prerequisites for gaining profitable jobs
		Employers	Eligibility for work classification performance
		Society	Compliance with development plans

Lifelong Learning	Deepening or changing qualification	Attenders	Possibility of growth and career change
		Employers	Employee development
Research and Scientific Activity	Looking for new principles and solutions	Society	New principle, implementability of solutions
Cooperation with Practice	Solutions to particular assignments	Companies	Usable solutions, efficiency of solutions

The quality of universities is then described by so called **outputs**, not only by a number of graduates, statistical criteria, but also by their knowledge, skills, which should represent one of the benefits of the studying, and at the same time of the goals. These outputs are then compared in the field, within the state and internationally. (Witzany, 2002). The quality of implementation processes is to a decisive extent given by **management quality**. Implementation of the customer approach and social context in university management seems necessary. In the Czech Republic (but also in many European countries) current systems of university management are based on the principles of "customary law", which over the years of operation does not always correlate with the current requirements of a dynamically developing society. At the level of faculties, institutes or departments, the topic of quality improvement was and remains a standard topic and it is reflected in particular outputs, such as: updating the content of individual subjects, as well as whole study programs, preparation of new teaching aids, involvement in research activities, outputs of which will be used in teaching too, engaging in international projects results of which are again reflected in teaching.

The limitation of quality assurance and assessment is mainly the lack of personnel capacities and qualified human resources for relevant processes and their management. Enlargement of quality assurance and assessment systems into all tertiary education institutions is also inadequate. In terms of personnel and organization one of the challenging areas of quality is cooperation with practice during the studying and the subsequent applicability of the graduates, which can be the decisive factor in choosing a university. In the Czech Republic The Higher Education Act does not strictly command cooperation of universities with practice, and in several of its provisions it creates the conditions for its implementation. However, a number of regulations lay down requirements for interconnection with practice (in particular, preparation for the exercise of regulated professions). With the increase in the number of students who have gone through Czech universities over the past twenty years, most of them has removed a mandatory requirement for operational (diploma) practice from its curriculum. According to the Framework for Higher Education Development by 2020 (MŠMT, © 2013 – 2017), "a number of schools was aware that they were unable to provide practice to all their students (from the side of practice, opinions that they were burdened by practitioners, that there is a threat of information leak etc., appeared and are appearing). In the cases that faculties or individual workplaces tended to a mandatory requirement of practice application, they are aware that this process is administratively demanding (contract terms, work safety, insurance, etc.). "

Other forms which can be considered a cooperation of university with practice:

- the inclusion of various professional excursions as part of study programs,
- involving professionals from practice in teaching,
- to a limited extent, the realization of professional experience abroad,
- awarding various analyzes, studies, research projects by the people from practice, e.g. in a form of competitions,
- education programs (lifelong learning) offered for practice, which can take several forms: short-term professional courses, various educational programs according to the specific directions of the contracting authority (effectuated at schools or at the premises of the contracting authority), long-term educational programs such as MBA etc.

In recent years the process of differentiation among subjects of practice can be seen. Successful businesses (regardless of ownership – both domestic and foreign) actively seek cooperation and they often come with offers of various forms and long-term collaboration with universities – e.g. in a form of involvement of top managers in scientific councils, councils of doctoral degree programs, etc., in a form of presentations of interesting topics in lectures, offering topics for bachelor or diploma theses or by providing financial means for equipment, student professional activities, by sponsorship of professional conferences, seminars, workshops, recently also by support of start-ups emerging at faculties or innovation centers, etc.

The second group includes various businesses and institutions that are aware of the potential of universities to solve their problems. These assign university departments various analytical or research studies or offer students different collaborative programs, common denominator of which is selection of suitable student candidates for their jobs. According to results of the PWC study (PricewaterhouseCoopers PwC. PwC, © 2017.), in the Czech Republic more than half (59 %) of companies plan to increase the number of employees this year and another more than quarter of them (27 %) at least maintains the current state, the unemployment rate belongs to the lowest in Europe. Managers of Czech companies are worried about not having people with necessary knowledge and skills. Lack of people is perceived even as the greatest threat to business. 95 % of 114 CEOs is worried about it. Companies are looking for a way to differentiate, engage attention and be a wanted employer. A total of 98 % of respondents stated that for this year their investment priorities are investments in the company's reputation, whether it would be marketing or social responsibility, last year it was 75 % of companies. Many companies (97 %) plan to get new employees via cooperation with schools, and here we see an increase in the comparison with last year (69 %).

A good reputation must be taken care of by universities too. The reputation with all target groups of a university is created by a number of factors: the quality of teaching, the applicability of graduates, the scientific performance of university educators and others. These parameters form not only quality but also added value. It is a value that gives the universities prestige recognition, which can be one of the decisive factors for potential applicants. There are currently 44 private, 26 public and 2 state universities in the Czech Republic. It is a total of 72 organizations trying to win study of Czech and foreign university applicants (MŠMT, © 2008-2010). In this highly competitive environment, for example, the social responsibility of universities, preventing or solving a community problem, or using potential opportunities for innovation, the sustainability of the country, etc., can be an added value. But do young people think that it is important to get a post-graduate job, or to ensure that schools (and universities in particular) take care of social responsibility of their students? This paper is looking for these answers.

Methodology of study

The Faculty of Multimedia Communications at Tomas Bata University in Zlín is a faculty where you can study Multimedia and Design or Marketing Communications. This unique combination is also a competitive advantage of the school, which still has relatively high number of applicants compared to the accepted students. The management of the faculty is still interested in the factors that create the positive image of the faculty, whether the young people perceive the applicability of the graduates as an important factor, the extent to which they want to solve the social themes within the individual subjects etc. Therefore a research team lead by the author of this article has been carrying out questionnaire surveys of the applicants for several years, in which perceived image and the development of the individual factors that create the image is measured. As part of the third role of universities, FMC management also decided to solve a society-wide topic across study fields and specializations, which proved to be a very effective way of linking ateliers (Glass Design, Shoe Design, Fashion Design, Graphic Design, Product and Spatial Design, Audiovisual Arts) and future marketers in creation of innovations, communication campaigns for water management prevention, as well as a pilot research on water management among young Czechs.

Findings

The research of secondary studies shows that the applicability of the graduates in practice is one of the basic indicators of the image of the university and therefore its perception by the applicants has become a basic premise for determining the hypothesis of the survey of the applicants, which has been implemented at FMC for the third year. Currently we have results from three periods: 2015/16, 2016/17 and 2017/18 applicants. Therefore it is possible to observe trends and to test the development of the image parameters of the university, respectively of the faculty. For example, a zero hypothesis was determined for the survey.

H_o: There is no dependence between a variable "The importance of graduate applicability" and the variable "FMC is an elite school".

Note: These variables were measured on a scale from 1 to 5 where 1 = low importance of applicability, respectively the perception of FMC as a school "for everyone", and 5 = the high importance of applicability, perception of FMC as an elite school.

Table 2: Statistical indicators to the variable "Importance of graduates applicability" in different years

Applicability	15-16	16-17	17-18
Modus (the most frequent)	5	5	5
OR (ordinal median – the middle)	4,682	4,643	4,658
Dorvar (discrete ordinal variance = dispersion)	1,267	1,224	1,134
Number of respondents	411	236	334

Table 3: Statistical indicators to the variable "FMC is an elite school/for everyone" in different years

Elite/ for all	15-16	16-17	17-18
Modus (the most frequent)	3	3	3
OR (ordinal median – the middle)	2,998	3,035	3,032
Dorvar (discrete ordinal variance = dispersion)	1,034	1,094	1,046

The table shows that applicants perceive post-study applicability as crucial to their decision-making, but they are not entirely sure whether FMC is an elite school that is the market leader. This may be due to the fact that the applicants do not have enough materials to assess the image of the school and / or are interested in "only" a rational argument on applicability.

A Chi-quadrate test was used for testing to assess whether the assumptions about equal distribution had been contravened.

Year 2015: X-squared = 12.7672, df = NA, p-value = 0.6931

Year 2016: X-squared = 24.788, df = NA, p-value = 0.07479

In all years it turns out that the question of elite status is for most applicants "insoluble". Applicants do not seem to know how or according to which factors they should judge the elite status of the school; therefore they opt for neutral value – 3. On the other hand, in terms of applicability, they perceive its importance to the maximum; most often they evaluate it with the mark 5. The data found are dispersed minimally in both cases. The dependence analyzed via chi-quadrate test is probably contravened by the "controversy" of the question "For whom is FMC intended," whether it is for everyone or whether it is an elite, unique school.

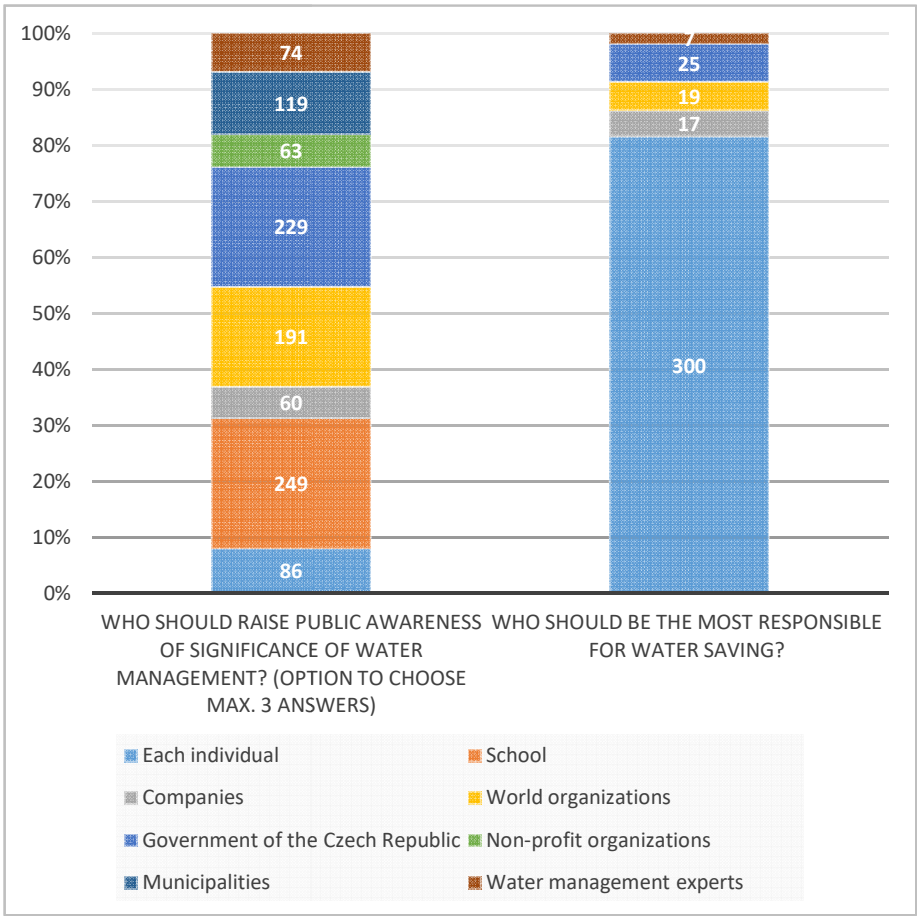

Figure 1: Responsibility and respondents attitude to water management (N = 370)

The p-value > 0.05, therefore H0 is not rejected, which means that the variables "importance of applicability" and "perception of school prestige" are independent of each other, and therefore the applicability as a rational reason for choosing a given school to study is more intelligible. Nevertheless, the university management should find a way to strengthen the image and perception of elite status of the university.

The increase in prestige of the school and creation of a positive image can be caused, for example, by the "society-wide projects" of the university, where it is possible to initiate a public discussion, to communicate with external entities during the analysis or solving a society-wide problem.

FMC TBU in Zlín, as was mentioned above, was also devoted to such activities, in academic year 2016/17 students worked on the topic "Water for All". Students of design have invented prototypes of water management products; marketing communications students have created water campaign communication concepts, among others with the headline: "Hold Water!" and have conducted a pre-

test of survey among university students to find out how they manage water in households, what do they think about this issue, who should deal with it, etc.

Besides other things, the results of the survey show that while more than 80% of 370 respondents declare that they feel personal responsibility for the water saving; in their opinion the public awareness should be mainly the focus of schools (from kindergarten to university), government and world organizations. More detailed results are shown in the following graphs.

Young people perceive the issue of water management very actively and independently of gender. Their perception is slightly more sensitive to the prevention of water spill from nature in the Czech Republic. 5 % of respondents mentioned companies and corporations as organizations responsible for water management, 5% mentioned the world's organizations, 7 % government of the Czech Republic and the appropriate ministries. Most of them, however, determined themselves being responsible, or more precisely each individual, in 81 % of cases. A key factor in our adaptation to changing environments will therefore be the ability to change people's thinking. History is known for civilizations that have had to cope with the change of their environment during two generations. Thilo Lehmann from the Vienna City Hall talked about change of mindset at the "Water Conference". According to him, the change of mindset, took place mainly at the municipality itself. In 2011 and 2014, Vienna suffered heavy rain that caused great damage. "Certainly, more capacity for sewerage could be built. But it is very expensive and people are annoyed when the city is dug up," says Lehmann. And so the municipality decided to simply not let the rainwater into the sewer, except for the historic center, where the spatial possibilities simply do not allow for another solution. (Martin Mach Ondřej, © 2017). A survey of people on a representative sample could bring inspirational ideas not only for organizations and cities that deal with management but the results will be used to educate and motivate these people to take interest in this society-wide problem and for proposals for its prevention or solution.

Conclusion

The key factors in the selection of university included employability of graduates, quality of teachers, space for personal development and success of students and graduates, confirming that it is not important to report "hard" data but also "soft" data, emotional stories on the real achievements of students, graduates and educators, who are not only a source of competitive advantage but also a reference to a given university. A possible solution is also fulfillment of the third role of the universities, i.e. the principles of social responsibility of the school by engaging in prevention and solving society-wide problems. One such project is The Water for All project which took place at the Faculty of Multimedia Communications at TBU under the patronage of the Ministry of the Environment and which had two main objectives. The first was to increase the awareness of the need for water management and to raise a debate on the subject with the general public. The second objective, which is also reflected in the name of the project, was cooperation, not only between the students themselves, but also between the Faculty and the city of Zlín, the production and non-profit sectors and the general public. The project involved 450 faculty students and created 360 unique outputs: a collection of clothes with print inspired by satellite images of drying Aral Lake, mobile applications that show users the source of drinking water in nature; a series of posters that highlight the necessity of water management, as well as architectural modifications of the river Dřevnice and Kudlov dam. Students of the department of Marketing Communications worked on a pilot survey, the partial results of which are the essence of this paper. The selected outputs of the project can be viewed at www.vodaprovsechny.cz.

From the above mentioned results of the surveys carried out at the FMC, it is clear that it is possible to build a positive image of the university based on the communication of "hard data", among others about the applicability of the graduates, which is very important for the applicants, but also by engaging in social projects where the young people think that the school should be the initiator of a discussion of all stakeholders, a place for innovation, as well as the analysis and creation of communication channels and tools to prevent or even solve this problem.

Theoretical Approach Regarding Corporate Entrepreneurship

Sebastian- Ion Ceptureanu, The Bucharest University of Economic Studies, Bucharest, Romania,
sebastian.ceptureanu@man.ase.ro

Abstract

Over the past several decades corporate entrepreneurship has been widely touted by executives and researchers alike as an effective means for revitalizing companies and improving their performance. But what do we really know about corporate entrepreneurs? Most of the evidence regarding corporate entrepreneurs is based on studies that focus on psychological behaviours. In an attempt to improve our understanding of this issue, this article present main types of corporate entrepreneurs, based on relevant academic literature.

Keywords: corporate entrepreneurship, entrepreneur, classical manager

Introduction

Sharma and Chrisman (1999) define corporate entrepreneurship as the process whereby an individual or a group of individuals, in association with an existing organization, create a new organization or instigate renewal or innovation within that organization.Zahra and Covin's (1995) depict some possible determinants and effects of the corporate entrepreneurship phenomena of corporate venturing and strategic renewal. Their approach is very general in that it does not distinguish between the causes and effects of these two entrepreneurial phenomena that, they argue, constitute corporate entrepreneurship's domain. Importantly, Burgelman (1983) consider corporate entrepreneurship as a set of phenomena that exist separate from organizational strategy.

The specific corporate entrepreneurship phenomena of internal corporate venturing and strategic renewal are Burgelman's (1983) and Floyd and Wooldridge's (1999) approach, respectively. Both are process-focused. That is, they depict how the venturing and renewal processes manifest themselves within organizations, with a particular focus on the roles and behaviors of various levels of management within the entrepreneurial phenomena of interest. Why the entrepreneurial phenomena of venturing or renewal come about as well as their ultimate effects are not of particular concern in these conceptualizations.

An alternative representation of the domain of corporate entrepreneurship is adopted by Dess & Beard (1984) who focused on how knowledge is created through four types of corporate entrepreneurship activity. Specifically, rather than adopting Hansen and Wernerfelt (1990) categorization scheme of corporate venturing and strategic renewal for describing the phenomena of corporate entrepreneurship, Kuratko *et al.* (2001). base their corporate entrepreneurship approach on the four forms of corporate entrepreneurship proposed by Covin & Slevin (1989)- namely, sustained regeneration, organizational rejuvenation, strategic renewal, and domain redefinition. The Churchill (2003) approach outlines how acquisitive and experimental learning processes mediate the relationships between the aforementioned corporate entrepreneurship forms and the emergence of specific types of knowledge (i.e., technical, integrative, and exploitive) and is tightly focused on exploring the causal interrelationships between specific corporate entrepreneurship forms and organizational learning.

Types of Corporate Entrepreneurs

To better explain the concept of corporate entrepreneurship, Kuratko *et al.* (2001) developed a typology of managerial characteristics of a corporate entrepreneur, as follows:

Initiater: is the individual or individuals who trigger the entrepreneurial activity. This is accomplished either through the analysis of the driving forces which help to change the external business environment, or by pursuing the innovative initiatives.

Sponsor/Facilitator: is the individual or group of individuals who support the activities of the initiator by managerial and financial aid. The sponsor/facilitator can be an entity within or outside an organization, such as a government agency, an association or a private financier.

Champion/manager: is the individual or individuals who help facilitate the project and take the initiative in all stages of the project.

Supporter of the team: plays a role in providing expertise, intelligence, marketing, and/or other management functions in order to support the concept or initiative.

Reactor: Has the role of "devil's advocate" in indicating weaknesses and threats to the concept or initiative. Provides information and managerial support in strengthening in consolidating the power of initiative.

Kuratko (2001) believe that the champion/manager and sponsor/facilitator play a crucial role in the entrepreneurial development within an organization. The authors argue that the champion/manager plays a key role in developing, facilitating and monitoring the entire entrepreneurial process within an organization.

Further, in order to highlight the best characteristics of a corporate entrepreneur, Pinchot highlights a clear difference between classical manager and a corporate entrepreneur:

Table 1: The difference between classical manager and corporate entrepreneur

	Classical manager	Corporate entrepreneur
Primary reasons	He wants promotion and reward from the organization. It is motivated by power.	He wants access to power and resources of the organization. He is goal-oriented and motivated, but also enjoys the rewards and recognition from the organization.
Decision	He agrees with those who hold power. He delays a decision until he understands what the superiors exactly want.	Try to persuade others to agree with their vision.
Orientation in time	Reply to quotas and budgets; weekly, monthly, quarterly, annual planning and follows the next promotion or transfer.	Achieve their goals within 3-15 years, depending on the business and the risks it entails. He is motivated to respect the timetable imposed by him and the organization.
Action	Delegates action. Supervision and delegation of tasks require more energy.	He likes to take part in the action. He knows how to delegate tasks but he involves when needed.

Courage and destiny	Considers others responsible for his fate. He can be strong and ambitious, but fears the ability of others to do harm to him.	He is confident in his capabilities and he is brave. Many corporate entrepreneurs have a cynical approach regarding the system, but are optimistic and confident in their abilities to deceive the system.
Attention	He focuses on events occurring within the organization.	He focuses on the events taking place inside and outside the organization.
Risk	Pays attention to risk.	Assumes a moderate risk. He is not afraid to be fired.
Market research	He did market research to discover customer needs and to guide product design.	Performs market studies and then evaluates them based on intuition.
Status	Takes into account the status other people have.	Considers the traditional hierarchies a joke - appreciates the symbol of freedom and equality.
Failure and surprises	Tries to avoid mistakes and surprises. Defers recognition of failure.	He does his best to look tidy, organized in the organization, so tries not to disclose risky projects, thus learning from mistakes without exhibiting failure in public.
Who serves whom	Pleasing others.	He is pleasing himself, customers and sponsors.
The attitude towards the system	He sees a prosperous system and seeks his position within it.	He is against the system, but learns to manipulate it.
Abilities	Professional management. Often he has an economic education. He holds analytical, political and human resources management abilities.	He has more economic skills than political or managerial. Often, he has a technical education and needs help to flourish.
Style to solve problems	Solves problems that occur , according to the system.	Solves problems that occur according to the system or bypasses it.
Family history	Family members have worked in large organizations.	Family members have entrepreneurial initiative, developing a business.
The relationship with parents	Independent from mother, in good relations with father - slightly addicted.	Pretty good relations with the father dad, but stormy.
Socio-economic background	He comes from the middle class.	He comes from the middle class.
Educational level	Very educated.	Often highly educated, especially in the technical field.
Relationship with others	Basic relationship - hierarchy	Transactions with hierarchy.

Source: Pinchot, 1985

Pinchot (1985) has also composed in his work a list of ten rules corporate entrepreneurs should follow to assess their ideas by the company where they work. He believes that if employees follow these tips, they will experience success within the organization.

Pinchot's rules can be called "the ten commandments on the path to success":

- Works everything to achieve your project regardless of the job description.
- Make your merit recognized in a wise manner.
- Remember, it's much easier to ask forgiveness than permission to someone.
- Go to work every day prepared to be fired.
- Seek advice from someone before asking for resources.
- Follow your intuition about people; create a team from the best.
- Create your ideas in an intimate environment, premature advertising leads to the failure of many ideas.
- Never bet on a race unless you participate in it.
- Be honest with your ideals, but realistic in terms of their achievement.
- Honour your sponsors.

Entrepreneurship and corporate entrepreneurship: advantages and disadvantages, similarities and differences

The importance of innovation in developing new products, processes and services to the market is widely recognized. Amo & Kolvereid (2005), Jennings & Lumpkin (1989), Ceptureanu SI *et al.* (2017) noted the link between innovation and entrepreneurship (Antoncic, 2001). According to Davis (1999), when the economy stagnates, entrepreneurs motivated by profit will innovate to increase productivity and thus increase profits.

Despite the increased interest in the concept of entrepreneurship there is no universally accepted definition, as we have seen in the first chapter of this work (Antoncic& Hisrich, 2003; Ceptureanu EG *et al.,* 2017). The concept of entrepreneurship has taken different meanings over time. Various writers consider the concept of entrepreneurship from slightly different perspectives (Jennings & Seaman, 1990; Zahra & Garvis, 2000).

To include all types of entrepreneurial behaviour, there is a rather broad definition according to which entrepreneurship is the process through which it is created something different, with value by dedicating time and effort and by taking financial, psychological and social risks. The reward of this process lies in the monetary and personal satisfaction. (Zahra & George, 2000; Molina & Callahan, 2009).

For people starting a business on their own, the experience is full of excitement, frustration, anxiety and hard work. There is a high failure rate due to low sales, intense competition and lack of capital (Miller, 1983).

Due to risks and increased costs arose a new form of entrepreneurship called corporate entrepreneurship (Pinchot, 1985). Corporate entrepreneurship is nothing but entrepreneurship, which happens this time in an existing organization.

So, we remark that it is not always necessary to set up a company to implement new ideas. Great potential also lies in applying the principles of entrepreneurship within existing organizations. In the conditions of a dynamic, this thing requires each company structure to be subject to constant changes that start, but this time, from within the firm.

Corporate entrepreneurs have new ideas and develop them in solid, functional and profitable businesses (Lehn & Makhija, 1996; Dixit & Pindyck, 1994). They have the same entrepreneurial spirit as entrepreneurs, but unlike them, they act in an existing organization. Thus, the corporate entrepreneur is the revolutionary in the organization, he fights for change and renewal of the system from the

organization. This may generate some conflicts within the organization, so it needs respect in order to constructively channel these conflicts (Jones & Butler, 1992).

Why are corporate entrepreneurs suddenly more important nowadays than before? The world is changing more rapidly under the influence of new technologies (Ghoshal & Bartlett, 1994; Ceptureanu *et al.*, 2017). Competition which takes place globally hinders our work. It is not sufficient to impose yourself over competitors simply by competition, but you must always come with something new on the market (Hitt & Ireland, 2002). Here comes into play corporate entrepreneurs, which help the firm (existing or newly created) to engage in new businesses and enter new markets (Hambrick, 1981).

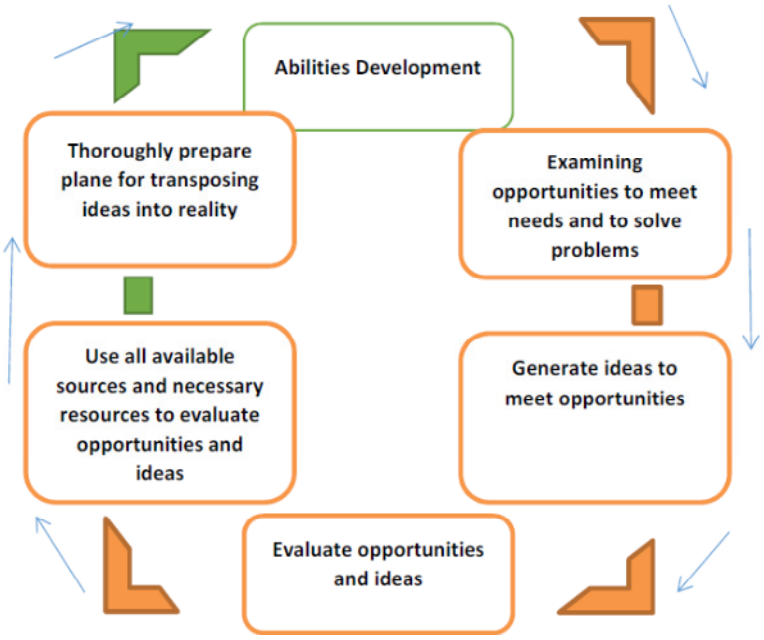

Fig.1: Cycle followed by corporate entrepreneur

To give an answer to this question, it is necessary to analyse the advantages and disadvantages of the two concepts. The table below is meant to help us to decide what type of business best suits us.

Table 2: Advantages and disadvantages of entrepreneurship and corporate entrepreneurship

ENTREPRENEURSHIP	
Advantages	**Disadvantages**
• You are your own boss – Independence • Revenues grow - financial reward • Freedom to choose - you can establish working hours, choose employees etc. • Opportunity to freely use imagination - originality • Have some adventure	• Pressure on money - giving up on the safety of a secure wage • Fewer benefits because of the novelty of business • Bankruptcy risk • Long working hours • Mistakes are magnified

• Less routine • There are plenty of opportunities to show what you can do • Advantage of salary - decide alone on the salary you deserve • Job security - do not live with the of being fired • Respect for your own person - personal satisfaction	• Stress • Financial risk • All decisions must be made by yourself - great responsibility
CORPORATE ENTREPENEURSHIP	
• Possibility to stay in a friendly and well known environment. • The chance to practice your skills in an organization - lower risk • Using the resources of the company, its reputation and knowledge • Access to clients and infrastructure	• Often the reward does not meet expectations • Innovation is not properly appreciated • Can be innovative, but to a certain limit – you are not your boss.

Among advantages that corporate entrepreneurship has over entrepreneurship, we include: access to customers and infrastructure; benefit from the knowledge of organization and lower risks than in the case of entrepreneurship (Merrifield, 1993; Lumpkin & Dess (1996)).

Among the disadvantages that the corporate entrepreneurship has over entrepreneurship, we include: short-term mentality; bureaucracy within the organization; lack of passion and way of reward for innovation (Levesque & Minniti, 2006).

Entrepreneurship involves innovation, ability to assume risk and creativity so that an entrepreneur will always be able to look at things in different ways. He sees risk-taking and failure acceptance as some incentives that help him learn and understand things. A corporate entrepreneur thinks like an entrepreneur and he is looking for opportunities that will bring profit to the organization. Corporate entrepreneurship is a new way to increase the competitiveness of organizations by giving employees freedom of imagination and entrepreneurial thinking. We conclude that the stimulation of corporate entrepreneurs is beneficial for any organization. Corporate entrepreneurship is an important method that helps organizations to reinvent themselves and improve their performance.

Morris *et al.* (1988) points out that in the literature it is often made the confusion between the similarities and differences between entrepreneurship and corporate entrepreneurship. Regarding the similarities between entrepreneurship and corporate entrepreneurship, the authors focus on:

- Both involve recognizing and defining opportunities
- Both require a unique business concept that takes the form of a product, process, or service.
- Both are led by a person working with a team to meet the proposed concept.
- Both involve concepts that are very vulnerable during training, and require adaptation in time.
- Both involve certain opportunities in which the concept can be successfully exploited.
- Both are based on value creation and responsibilities towards customers.
- Both involve risks and require risk management strategies.
- Both require the entrepreneur to develop creative strategies for resource mobilization.
- Both involve ambiguity.
- Both require strategies for collection and capitalization of ideas.

Regarding the differences between entrepreneurship and corporate entrepreneurship, Kazanjian et al. (2001) highlighted the following:

- In the case of entrepreneurship, the entrepreneur is the one who assumes the risk while in the case of corporate entrepreneurship, the company.
- In the case of entrepreneurship, entrepreneur masters the concept and the business, while at corporate entrepreneurship, company is holding the concept and has all the intellectual property rights, the corporate entrepreneur having little or no rights.
- The rewards received by entrepreneur are theoretically unlimited in the case of entrepreneurship, while in the case of corporate entrepreneurship, the rewards that corporate entrepreneur employees receive are limited.
- An hesitation, a mistake could mean instant failure in the case of entrepreneurship, while corporate entrepreneurship offers greater flexibility in terms of management errors.
- In the case of entrepreneurship, the entrepreneur is subject or susceptible to external influences, while for corporate entrepreneurship, the organization is protected from these external influences.

Besides the aforementioned differences, the biggest is constituted, in the opinion of Zahra & Garvis (2000), by the following: problems of flexibility in terms of planning; prioritization of innovative ideas; speed of the decision-making process; risk and safety issues; organizational behaviour practices (individuals and corporate culture); strategic planning and resource allocation (size and scope).

Also, other well-known authors have highlighted some differences between corporate entrepreneurship and entrepreneurship, namely:

- Corporate entrepreneurs take risky decisions using the resources of the company, whereas entrepreneurs take risky decisions using their own resources (Grant, 1996).
- Corporate entrepreneurship manifests itself among employees within organizations, while entrepreneurship primarily focuses externally (Dyer & Singh, 1998).
- Entrepreneurs prefer to develop tacit knowledge, in new organizations, instead of using procedures or mechanisms from other companies. On the other hand, corporate entrepreneurs are working in organizations that have policies, procedures and their own bureaucracy (Gulati, 1995).

Corporate entrepreneurship and entrepreneurship can be distinguished from each other as shown in the following table (Istocescu, 2006):

Table 3: Comparison between Entrepreneurs and Corporate Entrepreneurs

Criteria	Entrepreneur	Corporate entrepreneurs
Motivations for action	Profit, independence, ability to create, design and innovate.	Independence and the opportunity to benefit from the rewards of large companies (prestige, recognition, trade relations etc.)
Orientation in time	Survival of the company and its development over a period of 5-10 years.	Orientation mainly on long term (3-5 years), depending more or less on the imperative character of the fixed group obligations or of themselves.
Participation in the production processes	Strong direct involvement.	Average direct involvement.
Risk taking	High risk.	Moderate risk.
Failures and errors	Accept failures and possible errors.	Avoid projects that may cause failures before their launch.
Relations with third parties	The main relationships are determined by transactions and agreements.	The main relations take place within the company.

Conclusions

In conclusion we can say that both entrepreneurship and corporate entrepreneurship represent means to achieve a goal and not the goal itself. Corporate entrepreneurs through their innovations are trying to help an organization to compete, whereas entrepreneurs try through the businesses they develop to change their lives and satisfy the market needs. It doesn't always happen to find profitable opportunities but to own the gift of turning problems into profitable opportunities is extremely important for society.

Both entrepreneurs and corporate entrepreneurs do not easily accept failure being characterized and motivated all time by the fact that anything is possible and there is a solution for everything. When they feel they cannot cope with a situation, both prefer to withdraw because for them to fail when trying to do something is ridiculous and represents a failure. This does not mean, however, that both are always successful, but they have an optimistic thinking and they are very determined to transform their dreams into reality.

Unlike entrepreneurs, corporate entrepreneurs operate within an existing organization. Due to organizational culture, corporate entrepreneur does not have total liberty to implement his ideas and must comply with the rules set by management. In practice, corporate entrepreneurs often act before asking for permission or they are trying through an autocratic manner to make their ideas known. Entrepreneurship, on the other hand, thrives because the entrepreneur has the freedom to take all measures necessary to achieve success because he does not have to report to anybody and his decisions are not constrained by any organizational culture.

The entrepreneur is seen as the revolutionary in an organization that pushes the organization to change that is to change its system or culture. If a consensus is not reached on solving these problems, it can lead to misunderstandings within the organization. Entrepreneurs on the other hand, affect external organizations. They attempt to find alternative ways to create greater value for existing products that no longer meet consumer needs or they are trying to make a difference by creating new products.

One advantage of corporate entrepreneurs lies in the fact that he benefits from the resources of the organization. This is very important if we consider that in order to be effective a project should be tested several times, which means additional consumption of resources, resources that are made available by the organization. With the resources, funding and necessary human resources, the results will occur.

We can summarize the following: an entrepreneur takes important risks being an owner and operator of a new business because he does not have the safety of profit generated by his business. Conversely, an corporate entrepreneur is an individual employed by an organization so he has a certain remuneration. This remuneration may vary depending on the success the unit he is responsible for has. Corporate entrepreneurs share the same traits as entrepreneurs such as belief, enthusiasm for what they do and understanding. However, an corporate entrepreneur is successful only if the organization motivates him and support him in realizing his ideas. If he does not receive the necessary support from the organization, he is likely to leave the organization and to start his own business.

Whenever we find innovation in firms, we find behind them corporate entrepreneurs enabling the emergence of these innovations. According to Covins & Slevin (1986), innovation, large or small, requires certain courage, a vision, a desire to maintain control and to get things moving. Continuous persistence and practical imagination of the intrapreneur are essential for the success of any new idea. Therefore, the key of corporate entrepreneurship is hiring and keeping the right people, developing a results-based reward system that encourages and supports individual initiative, generation and development of new ideas. Companies need a corporate entrepreneurship culture if they want to grow and prosper. This suggests that firms do not have these skills automatically, but they require people who are willing to be exposed to situations with uncertain outcomes, who enjoy new and interesting activities, but

at the same time risky, who do not get tired easily towards challenges and have the ability to persuade others to help them to achieve their goal (Coff, 2002; Ceptureanu *et al*., 2017). This does not mean, however, that firms which have one corporate entrepreneurship leader are more oriented to entrepreneurial activities. It is needed for the leader to be innovative and charismatic, but perhaps more importantly is to instil a corporate entrepreneurship philosophy to all employees irrespective of the position they hold in the organization.

Therefore, within a corporate entrepreneurship organization, innovative persons should be considered examples, and their efforts should be rewarded accordingly so that the need to be innovative and to explore new approaches in the future to be part of the organizational culture. In other words, all employees should embrace new ideas and to be extremely active in generating new approaches and new ways of solving problems, willing to take the risk and to experience new things (Bartlett & Ghoshal, 1989; Ceptureanu *et al.,* 2012) . Typically, firms have a lot of ideas, but they are worthless if they are not used properly. The corporate entrepreneur is the one who is exploiting those ideas, who rejects bureaucracy and takes full responsibility for processing ideas within the organization and putting them on the market (Popa *et al*., 2009; Radu *et al*., 2017). Corporate entrepreneurs can be creative or innovative, but they are always dreamers who turn an idea into a profitable reality and therefore, it is extremely important to recognize their efforts.

How employees are rewarded have a strong influence on their motivation and it can be of various kinds, namely financial incentives, social incentives, incentives linked to work or incentives arising from the organizational culture.

Despite the lack of conclusive evidence on the motivational impact that monetary reward has on employee performance, many managers see the money as their main motivational factor (Lieberman & Montgomery, 1988). Although financial rewards play a decisive role in attracting talented, motivated and creative employees in the firm, Lengnick-Hall (1992) believe that these rewards have only a short term motivational impact on employees. Employees feel more motivated if the merits of their work are recognized, so (Leana & Van Buren, 1998) believes that recognizing and rewarding employees' work, which is a social incentive motivates employees more than financial incentives.

Social incentives are very important for employees as one of the most common needs expressed by them is the desire to be accepted (Morris, 1998). Social incentives may include verbal recognition of their merits, as well as encouragement and appreciation of their efforts. Although many managers proclaim that employees are key to the firm's success, many of them fail to offer their employees the necessary recognition, which is extremely important because employees who find their work challenging and rewarding might feel motivated by the simple nature of the work they perform (Ceptureanu EG *et al*., 2017).

Incentives related to the work are according to Honig (2001) those reward methods which include autonomy at work, career development and growth by recognizing individual performance. Shenkar & Zeira (1992) believe that these incentives are as important as the financial and social ones, because managers often use rewards such as offering an attractive position in the company to increase efficiency and employees' performance. More autonomy and assumption of a greater responsibility increase employees' motivation.

Employees can also find incentives in other aspects of internal organizational environment, such as firm size, organizational structure and management style. For example, the organizational structure of a company can influence motivation and employees' satisfaction in the sense that employees who prefer to work in a dynamic environment would be very frustrated if they were put to work in a bureaucratic environment, while employees who like structure and rules would find difficult to work in companies with a flexible organizational structure (Birkinshaw & Hood, 1998; Ceptureanu *et al*., 2017).

All these incentives can be seen as part of the reward system of a company, although Ceptureanu *et al.* (2016) believes that companies which decide to stimulate the corporate entrepreneurship behaviour have difficulties in finding the right mix between the financial and non-financial rewards.

The desire of employees and their ability to engage in corporate entrepreneurship activities are primarily influenced by how they are rewarded. Therefore, rewarding plays an important role in creating a favourable climate for these types of activities.

Models of Corporate Entrepreneurship

eduard.ceptureanu@man.ase.ro

Abstract

Our knowledge of corporate entrepreneurship continues to expand. However, this knowledge remains quite fragmented and non-cumulative. Herein, we try to develop theory by presenting concepts regarding corporate entrepreneurship factors and models. We discuss how these models contribute to the corporate entrepreneurship literature and distinguish between models, and identify challenges future corporate entrepreneurship research should address.

Keywords: entrepreneurship, corporate entrepreneurship, models

Introduction

The concept of corporate entrepreneurship, consisting of intra-corporate and entrepreneurship arose due to Gifford Pinchot and Elizabeth S. Pinchot, when they were studying at the "School of Entrepreneurs" in New York ("I will call this class of entrepreneurs intra-corporate, intrapreneurs", Elizabeth S. Pinchot).

After Pinchot (1985), there were other authors who have expressed their opinion on this concept, so that the variety of scientists' opinions as well as the complexity of this concept led us to study in detail the importance of corporate entrepreneurship for the economy.

The global economy undoubtedly creates profound and significant changes for organizations around the world, so that the role that the entrepreneur plays in each country's economic growth should not be ignored. Technological progress leads to continuous development of existing businesses and at the same time generates new businesses, constituting a decisive factor in acquiring new knowledge and thus in increasing productivity.

Entrepreneurship continues to thrive in nearly every corner of the world so that globally, one person from eleven decides to start a business. Entrepreneurs are reshaping the business environment, creating a world in which their companies play an important role in the vitality of the global economy. Their businesses have introduced innovative products and services, have removed technological barriers, have created new jobs, have opened the doors to foreign markets and have offered to the founders the freedom to do what they love most.

Defining the concept

Despite the increased interest in the concept of corporate entrepreneurship, academics have not reached a consensus on this concept. Scientists use terms like corporate entrepreneurship (Kuratko *et al.*, 1990), internal organizational entrepreneurship (Schollhammer, 1982; Sharma, 1999), corporate societies (Birkinshaw, 1999; Floyd and Lane, 2000), and new businesses (Myers, 1977; Cheney *et al.*, 1991) to refer to different aspects of organizational entrepreneurship.

Some researchers believe that corporate entrepreneurship is a concept that should be limited to creating new businesses within an existing organization (Floyd & Wooldridge, 1999; Ceptureanu E.G. *et al*. 2017). But others argue that the corporate entrepreneurship should include the fight for renewal, which is carried by big firms, through new methods of combining the resources it holds (Chung & Gibbons, 1997; Hitt & Ireland, 2000).

Sharma & Chrisman (1999) considers organizational entrepreneurship as a process by which firms commit to diversification through internal development. Such diversification requires new combinations of resources for expanding business activities in areas not related to the current field of competence.

Zahra *et al.(*1999) presents corporate affairs as marketing of a product or service that the parent company did not previously commercialize and requiring the use of new equipment, people and knowledge. Although both definitions describe the process of corporate entrepreneurship, the authors use different terms to describe it. On the other hand, Lumpkin & Dess (1996) considers corporate entrepreneurship as the term used to describe entrepreneurial behaviour in an existing large organization.

Corporate Entrepreneurship Factors

Corporate entrepreneurship has been a research subject for a period longer than two decades. Research in the renewal fields of the company, innovation, risk taking and creating of new businesses fall under the umbrella of the spirit of corporate entrepreneurship (Birkinshaw & Hood, 1998; Lumpkin & Dess, 2001; Ceptureanu *et al.*, 2016). Interest in this topic has increasingly grown because companies have to deal with a turbulent and competitive environment. Due to this complex and turbulent business environment, managers have been in constant search of new ways of managing the company. This has fuelled corporate entrepreneurship studies on the subject (Zahra *et al*., 2000; Popa *et al*., 2009). The studies in this field focused mainly on organizational factors that influence the spirit of corporate entrepreneurship, such as freedom, organizational limits and support from management (Nadler & Tushman, 1989; Shenkar & Zeira, 1992).

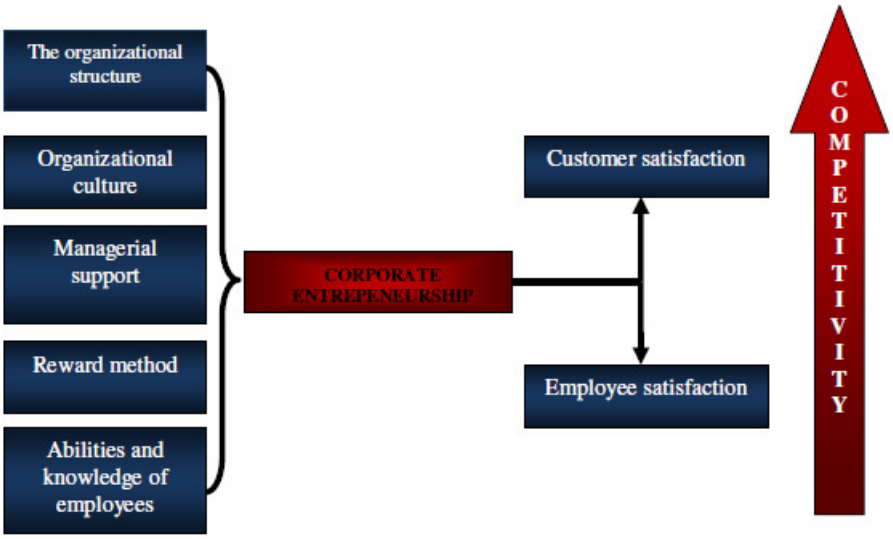

Fig. 1: Premises and the corporate entrepreneurship result

Corporate entrepreneurship has the potential to renew the existing firms (Covin & Miles, 1999; Kuratko *et al*., 1990; Pinchot, 1985). This process of renewal occurs through innovative activities that offers the company access to skills, capacities and new resources (Ceptureanu et al., 2017). In this case, innovation consists of the creation, development and implementation of ideas and a new behaviour.

Previous studies in corporate entrepreneurship have focused on several key organization areas that influence the intrapreneurial spirit. First, the level of decentralization in an organization impacts on corporate entrepreneurship (Geletkanycz & Hambrick, 1997; Pinchot, 1985). Researchers generally agree that a decentralized organization has the power to use effective intrapreneurial behaviour, while in a centralized organization employees are not given the freedom to behave like entrepreneurs.

Fierce competition between employees tends to block the implementation of new ideas that arise. This competition can also prevent employees to help colleagues who come up with new ideas, due to the envy on their future success.

Cooperation between departments of a company is an essential element when new and innovative products need to be developed. Quite often, the lack of communication leads to delayed development of new products. In order not to reach to this problem and the new product development to arise as naturally as possible, the company's departments must work in a climate of cooperation.

Also, the freedom of intrapreneurs to act is extremely essential. The intrapreneur should be responsible for his ideas and be able to develop and implement them in the organization (Pinchot, 1985). Therefore, a firm with too many rules and regulations have a negative effect on corporate entrepeneurship.

As it can be seen from literature, corporate entrepreneurship is characterized by a set of organizational attitudes and behaviors (Covin and Miles, 1999). Intrapreneurial organizations demonstrate skills such as recognizing of opportunities, organizational flexibility and the ability to measure, encourage and reward innovative behavior (Zahra *et al*., 2000).

Several researchers have tried to understand the factors that stimulate or affect corporate entrepreneurship so that during investigations, they have identified a number of organizational and external factors (Guth and Ginsberg, 1990; Kuratko *et al*., 1990).

Reviewing the literature on the concept of corporate entrepreneurship, we noticed that a group of researchers have highlighted the importance that the organizational factors have on corporate entrepeneurship. Based on previous research, variables such as support from management and its behavior (vision, commitment), organizational culture, structure and mode of action may affect corporate entrepreneurship (Hitt & Ireland, 2000).

Corporate entrepeneurship is seen as a strategy for economic growth and an effective way to gain competitive advantage (Pinchot, 1985). Kuratko *et al.* (1990) defines corporate entrepreneurship as a process of organizational renewal. Zahra *et al*., (2000) states that corporate entrepreneurship includes activities designed to create new businesses in existing firms through innovations of products and processes.

Intrapreneur is according to Pinchot (1985) the key actor in corporate entrepreneurship. The intrapreneur is the one who recognizes an opportunity, seeks and exploits it and hopes that the exploitation of new opportunities in a way, that deviates from previous practice, will be successful and will help to achieve the organization's objectives.

The individual decision to act intrapreneurially is based on organizational and individual experiences, when an event pushing a person to behave intrapreneurially (Zahra *et al*., 2000). The external

environment (technological opportunities, industry growth, competitiveness etc.), is also considered an important determinant of corporate entrepreneurship (Zahra *et al*., 2000).

As organizations become more complex and competitive, they embrace increasingly more corporate entrepeneurship in order to remain profitable (Zahra *et al*., 2000), to reinvent themselves from a strategic point of view (Guth and Ginsberg, 1990), to develop their innovative spirit and acquire knowledge to achieve future revenue flows.

Researches in the field of corporate entrepreneurship indicate that mainly individual, organizational environmental factors influence the entrepreneurial behavior within an organization (Covin and Slevin, 1991):

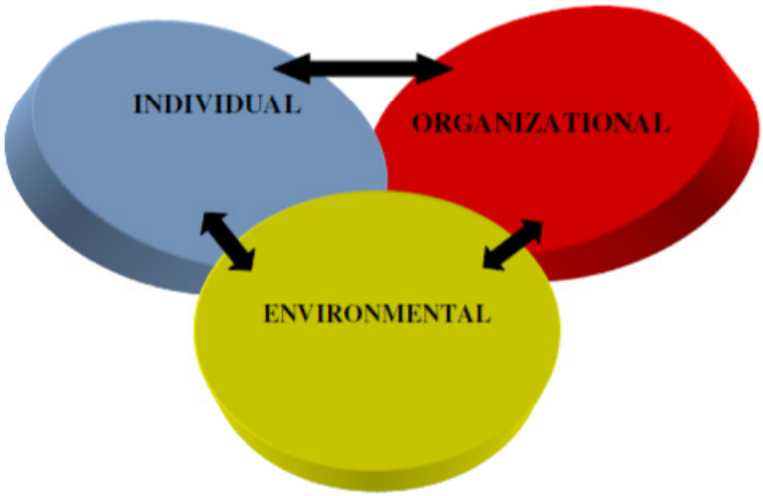

Fig. 2: The relationship between the individual, the organizational and environmental factors

- The tendency to act intrapreneurially is a function of motivation (Shenkar & Zeira., 1992) which in turn is a function of the individual's innate personality (Birkinshaw, 1999; Ireland *et al*., 2001; Ceptureanu SI *et al*., 2017). The individual levels focus on the individual characteristics of the intrapreneur (Kuratko *et al*., 1990). The recognition and support of intrapreneurs is also within this area of interest. Some research in this area emphasizes the vital role of managers in creating an environment that encourages innovation and entrepreneurial spirit (Kuratko *et al*., 2001; Ceptureanu *et al*., 2017). Intrapreneurs are seen as people who take responsibility for innovation within the firm (Pinchot, 1985).
- Different authors believe that entrepreneurial activity is a function that relates to the organizational framework (Birkinshaw, 1999; Morris, 1998). Birkinshaw (1999) defines the organizational framework as a set of administrative and social arrangements that shape the behaviour of individuals within the organization on whom top management has influence. The essence of the definition of Birkinshaw (1999) is that entrepreneurial initiative, as any behavioral trait is a function of the environment in which it is conducted, and that, in an organization many of the key factors of intrapreneurial success are under the influence and direct and indirect control of top management. Thus, corporate entrepeneurship is influenced by the characteristics and organizational values (Kuratko *et al*., 2001). A particular importance is granted to the intrapreneurial strategy and to its influence on the company (Kuratko *et al.*, 2001). Moreover, entrepreneurial strategy can be regarded as a potential source of competitive advantage for the company, being the way in which existing firms can develop skills essential for their success.

- Environmental factors refer to the argument brought by Birkinshaw (1999) that the behavior of employees in an organization is shaped not only by the administrative factor. Covin and Slevin (1991) saw the external environment as a determinant of entrepreneurial activity, both at the individual and organizational level. Researchers who are trying to build a model to explain corporate entrepeneurship and predict its results, are taking into account, in addition to a set of internal variables, also the external variables related to the environment. (Sharma & Chrisman., 1999). Kuratko et al. (2001) considers that in order to support the concept of corporate entrepreneurship there must be considered the following factors: reward, managerial support, resources, including availability towards time, organizational structure and risk acceptance.

Using **rewards** as a motivating factor is very common in the literature (Chung& Gibbons, 1997; Covin& Miles, 1999; Ceptureanu *et al.,* 2012). To be effective, a system of rewards that promote corporate entrepeneurship must take into account the objectives, individuality and performance-based rewards. Using an appropriate reward system can increase a person's willingness to take entrepreneurial risks associated with the company.

Managerial support, the desire of management to facilitate or promote entrepreneurial initiatives is also included in the literature (Ireland et al., 2001; Guth & Ginsberg., 1990; Ceptureanu *et al*., 2017). Managerial support can take many forms, including encouraging innovative ideas and institutionalizing entrepreneurship within the company.

Availability of resources and time is the third prerequisite for promoting corporate entrepeneurship. Employees must perceive the availability of resources for innovative activities (McGrath, 1999). Weak resources encourages experimentation and risk taking (Hitt *et al*., 1999).

The fourth condition is the **organizational structure** (Grenadier & Weiss, 1997). An organizational structure supporting corporate entrepreneurship provides certain administrative mechanisms that allow ideas to be evaluated, selected and implemented (Zahra & Covin, 1995; Radu *et al*., 2017).

Risk-taking is the final condition that occurs constantly as a necessary support for corporate entrepeneurship. Employees and managers must be willing to take the risk and have a tolerance for failure (Ghoshal & Moran, 1996).

Models of Corporate Entrepreneurship

As we could observe during the study of the concept of corporate entrepreneurship, we could figure out that many of the theories on this concept are rooted in the study of the concept of entrepreneurship (Oviatt & McDougall, 1999). Contemporary theories on entrepreneurial behaviour highlight the interaction between an individual's personality and environment (Morris, 1998). These theories include models of different authors whose fundamental idea underlies many subsequent publications. Among the most important models, we state: Guth and Ginsberg's model, Covin and Slevin's model, Zahra's model, Lupkin and Dess' model, which are presented below.

Guth and Ginsberg's model

Guth and Ginsberg (1990) developed a model based on the idea that they had done on the concept of corporate entrepreneurship. These authors consider corporate entrepreneurship as a combination of two phenomena:

- developing new business within an existing organization, or
- converting an existing organization through renewal.

Those authors substantiated their idea on corporate entrepreneurship through a model where the influential factors and their consequences are interconnected with corporate entrepreneurship. In their model, Guth and Ginsberg (1990) argue that: the environment, strategic leadership, organizational form / behaviour and organizational performance influence the intrapreneurial spirit and the latter in turn influence the company's performance.

- The environment influences corporate entrepreneurship. In this regard, Guth and Ginsberg (1990) related to the following:
  (a) the impact of major environmental changes - such as deregulation - can influence changes in business strategy;
  (b) the more dynamic and hostile the environment is, the more intrapreneurial the firms will be;
  (c) industry structure affects the opportunities to develop successful new products.

Clearly, changes in industry structure and the underlying technologies affect corporate entrepreneurship. Opportunities for new products and services result from development of new technologies and /or commercialization of technologies developed by others. In an industry that is trying to find new combinations of resources aimed at a competitive advantage, the potential of the company and of its competitors create both opportunities and problems.

- Strategic Leadership influence corporate entrepreneurship. Guth and Ginsberg (1990) included the following factors: (a) the management style of top managers affects the performance of new businesses; (b) the effectiveness of middle management in building coalitions among colleagues and senior managers to support their entrepreneurial ideas affect the degree of success in their implementation; (c) banks that are more innovative are managed by teams with deeper and higher education and which have some diversity on their areas of functional expertise. Many believe that entrepreneurial behaviour within an organization depends on the characteristics, values/beliefs, visions of the strategic leader.
- Type of organization/behaviour influence corporate entrepreneurship: Guth and Ginsberg (1990) refer here to two factors: (a) companies pursuing growth strategies through acquisitive procedures have lower levels of intensity in terms of research and development than companies pursuing internal growth strategies through innovation; (b) creating new business units within the firm does not affect the sales of new products. Many researchers in this field have observed a relationship between business strategy and innovative spirit.
- Organizational performance influences corporate entrepreneurship. In this category, Guth and Ginsberg (1990) included: (a) successful companies bring more frequent and radical innovations in terms of product or process than those who are not successful; (b) firms that are experiencing a decline in performance tend to develop new practices and change the strategic directions only after this prolonged decline led to the change of top management. Innovation and radical change can be triggered when firms have excess of resources that allow them to capitalize on the opportunities that arise.
- Corporate entrepreneurship influences the firm’s performance: Guth and Ginsberg (1990) considered three factors in this category: (a) the introduction of new products affects performance; (b) independent start-ups get to breakeven two times faster and end up twice more profitable than corporate start-ups; (C) early market entry does not affect the performance.

Fig. 3: Guth and Ginsberg's model on corporate entrepreneurship

Although the model of Guth and Ginsberg (1990) is meant to be generic, its drawback is its lack of mutual recognition between the component factors, except of the organization's performance. There is an unjustified presumption that environmental factors, strategic leadership and organizational culture influence corporate entrepreneurship, but without taking into account the influence that the latter has on them.

However, the model of Guth and Ginsberg (1990) is the starting point for many models which study the subject of corporate entrepreneurship, among the most important we recall the model of Covin and Slevin (1991) and the model of Zahra (2002), which are presented below.

Covin and Slevin's model

Covin and Slevin (1991) developed an integrative model that attempts to explain the association between entrepreneurial company and the environment, the strategy which it adopts, internal factors and organizational performance. According to them, corporate entrepreneurship involves increasing competitiveness and expanding opportunities generated through the combination of new resources within the firm.

Their model shows a less generic image on corporate entrepreneurship and focuses on behaviour at the firm level. The model seeks to improve the model of Guth and Ginsberg (1990) in at least two aspects:

- interpretation of the feedback loop between the intrapreneurial factors and corporate entrepreneurship;
- avoid clearly specifying the type of corporate entrepreneurship

Advantages of the model are:

- consider corporate entrepreneurship as behaviour of a firm;
- their model contains the company's success as the last dependent variable;
- external variables such as environmental factors are also included in the model;
- finally they take into account the direct and moderate effects within the model.

Key factors underlying this model are the external environment, strategy and internal factors. According to this model, the entrepreneurial orientation influences in a weaker manner the external environment, strategy and internal factors, but is closely related to firm performance. The three key factors have according to the model a moderate effect on the relationship between performance and entrepreneurial orientation.

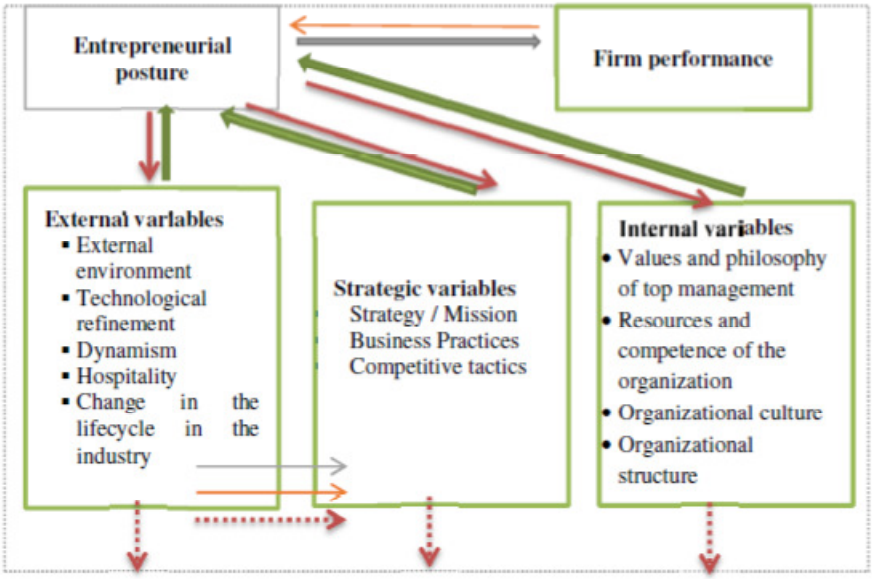

Fig. 4: Covin and Slevin's model on corporate entrepreneurship

Neither this model has got away with criticism. Zahra (2000) criticizes Covin and Slevin's model on the basis that they do not take into account the possibility that various entrepreneurial positions unevenly influence the various dimensions of performance and can even in different times.

Zahra's Model

Zahra (2002) presents a more compact model. He removes the technological complexity as a separate factor, including it in the dynamism of the environment.

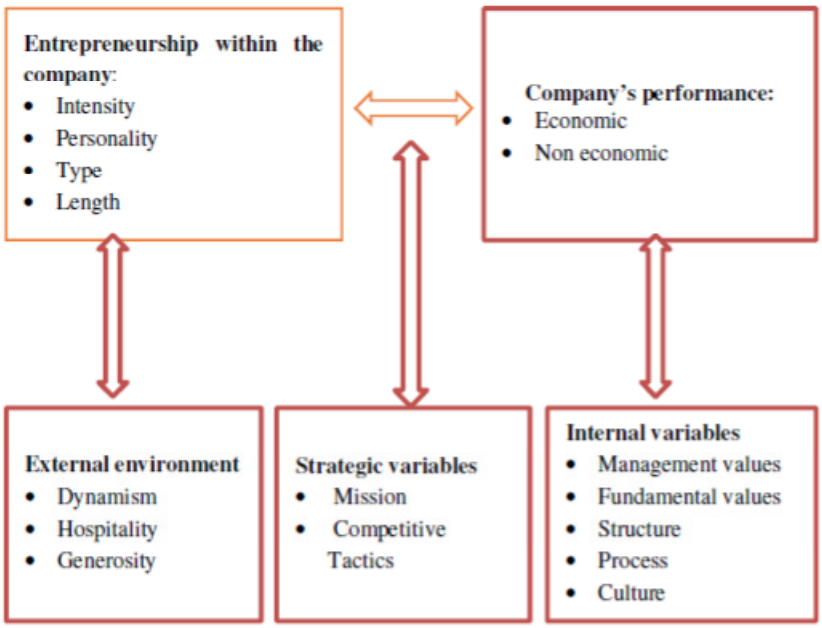

Fig. 5: The Zahra's model on corporate entrepreneurship

This author recommends using a concept encompassing aspects of the life cycle of the industry. In defining the entrepreneurial behaviour, Zahra (2002) emphasizes the need to consider entrepreneurial activities that are occurring domestically and internationally. Finally, Zahra (2002) argues that managerial values, organizational structure, management process and organizational culture should be considered in developing models on corporate entrepreneurship.

Lumpkin and Dess's Model

The authors describe the entrepreneurial orientation in terms of five dimensions: autonomy, innovation, risk taking, proactivity and aggressive competitiveness. According to Lumpkin & Dess (2001), entrepreneurial orientation refers to the processes, practices and decision-making activities designed to help a new entry on the market. The authors state that a new market entry is done by entering the market with new products and services. In this context, a new market entry is the idea behind this concept.

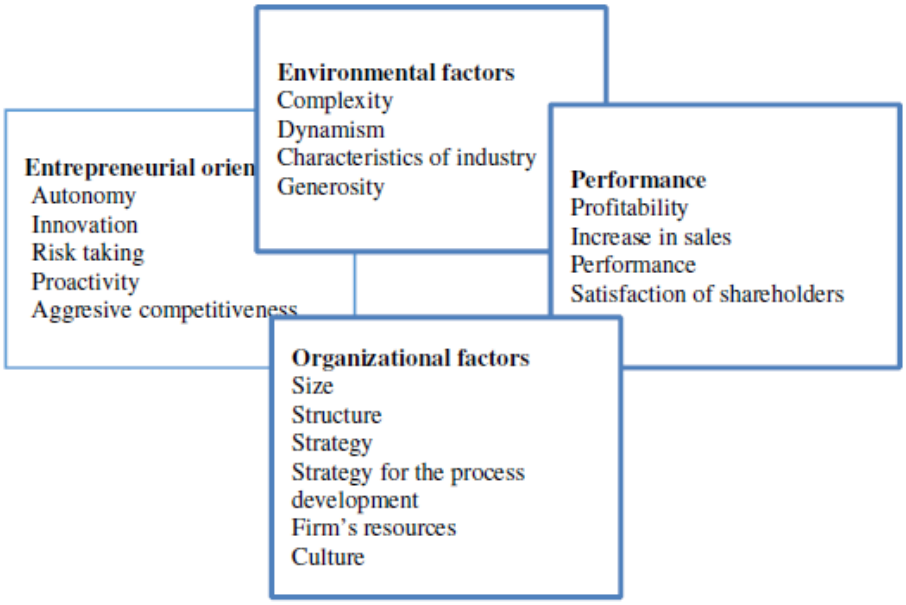

Fig. 6: Lumpkin and Dess Model

Lumpkin & Dess's model (2001) differs from the model of Covin and Slevin (1991), because it indicates that both environmental factors and organizational ones influence the relationship between entrepreneurial orientation and firm performance. The model does not provide whether the company's performance influences the entrepreneurial orientation.

Conclusions

We believe that our paper contributes to the growing literature on corporate entrepreneurship in several ways. First, it brings specificity to the concept of corporate entrepreneurship literature, a concept that is inconsistently depicted, ambiguously described, and quite often, simply undefined in the academic literature (Ceptureanu EG *et al*., 2017).

Second, our depiction of corporate entrepreneurship has two important implications for corporate entrepreneurship research and practice. Thus, the paper implies that fit between different pairs and collectively among all of the elements of a corporate entrepreneurship is a prerequisite to success. In this sense, the elements of entrepreneurial vision, pro-entrepreneurship organizational architecture, and entrepreneurial processes and behavior represent the core *work* associated with use of corporate entrepreneurship.

Also, greater understanding of corporate entrepreneurship will emerge as scholars complete empirical studies examining the phenomenon. The propositions associated with our article are possible sources for empirical studies. Effectively dealing with the sample and measurement challenges inherent to this topic will be critical to obtaining valid insights from empirical work.

To conclude, this paper offers a comprehensive analysis that depicts the "workings" of corporate entrepreneurship on international literature.

Abstract

In this paper we presented a model of the influence of motivational factors on the degree of motivation. The theme chosen for this papers is a highly topical issue at the moment because managers are increasingly concerned about employees' motivation. The paper contains the case study regarding the research conducted in 100 companies from Maramureș County in order to analyze the motivational factors and their influence on the degree of staff motivation. We have analyzed the motivational factors and their influence on the degree of motivation also we presented data processing and analysis comprising the analysis of the internal consistency of the questionnaire, the analysis of correlations between motivational factors.

Keywords: Analysis, factors, model, motivational, influence, degree, correlations

Introduction

Motivation, in a narrow sense, based on a classic vision regarding management and organization, takes into consideration only the employees of the organization.
Motivation in a narrow sense consists in developing a link between the needs, aspirations and interests of personnel with the fulfillment of goals and exercising the tasks, competencies and responsibilities assigned to them.

Motivation, in a broad sense**,** emphasizes a modern vision regarding management and organization, consisting in all decisions and activities which determine the stakeholders to directly and indirectly contribute to the achievement of functionalities and an increased performance, by correlating their interests in the approach and achievement of organizational objectives (Nicolescu, 2008, p.291).
Lefter et al. (2008, p.171) focus on two meanings of the concept of motivation:

- from the economic point of view, motivation represents the assembly of factors that determine the behavior of an economic agent;
- from the psychological point of view, motivation represents the action of conscious or unconscious forces that determine the behavior of the individual.

Motivation in the work context can be defined as the availability degree of the employee to get involved and to constantly put effort in order to achieve professional objectives, as they are defined at individual or organizational level (Constantin, 2004, p.170).

According to Pivovarov (2011, p.549), motivation of personnel represents one of the cornerstones that ensures the stability of the business as well as its efficiency.

According to Baldwin et al. (2014, p.829), motivation is the driving force that energizes, encourages and changes the behavior of employees in order to persist in pursuing their goals, leading to the fulfillment of their needs as well as to an improvement in the performance of the organization. Also, the efficiency of personnel is enhanced and they manifest positive feelings regarding the organization.

The main problem faced by the current economic environment is motivation.

The success of any company depends on the decisive extent of the performance of its employees. Thus, managers must develop creative methods to focus their attention in a productive way.

For Lage Monteiro de Castro et al. (2016, p.1140), motivation is considered beneficial for the organization, as it triggers human resources to act upon their work objectives, leading to the fulfillment of the organizational goals, workforce stability, employee commitment as well as improved performance and productivity.

Moreover, Baldwin et al. (2014, p.828) put emphasis on the fact that motivation provides support for employees in order to succeed, thus fostering innovation within a positively perceived work environment that attracts dynamic, creative and high-caliber personnel.

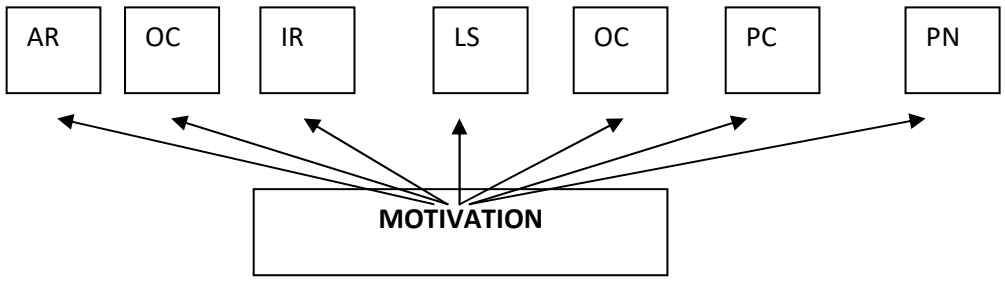
The performance of employees is directly proportional to the company's performance. Considering these things, the concern regarding employees must be as important as that for customers.

If there are dissatisfied employees, there will certainly be unhappy customers. Thus, motivation is a key and present issue. Crumpton (2013, p.145) focused on the active role of managers and supervisors in the motivation of personnel, who should provide positive feedback, publicly recognize the efforts of employees, active listen and show empathy, lead by example.

The authors considers that the provision of best motivation can be achieved by identifying the concerns that influence the employees within the work environment.

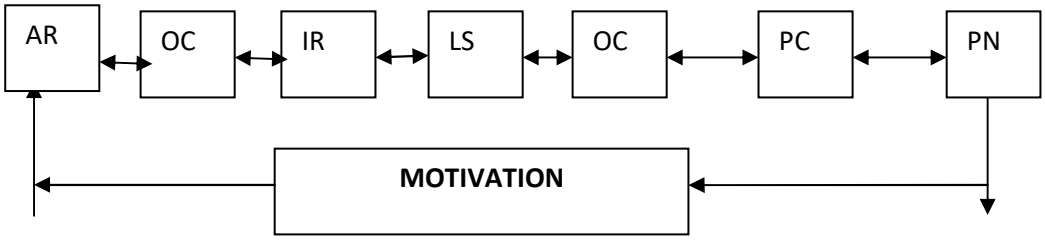
Case study

An Analysis of motivational factors



The general objectives of the research were the identification of motivational factors having an influence on the motivation degree of employees in companies from Maramureș County, Romania, and the proposal of improvement measures of the motivational system. The specific objectives were aimed at analyzing the motivational factors, testing the internal consistency, measurement accuracy and reliability of the 24 questions of the questionnaire, establishment of the correlations between the factors analyzed. The chosen motivational factors for the research are: organizational climate, industrial relationships, leadership style, financial rewards, promotion conditions and personal needs like in equation below where MD –represent the motivation degree (1):

$$\mathbf{MD\ (AR, OC, IR, LS, FR, PC, PN)} \qquad \mathbf{(1)}$$



The motivational factors chosen for investigation are: AR-age respondents (experience), OC – organizational climate; IR – industrial relationships; LS– leadership style; FR – financial rewards; PC – promotion conditions; PN – personal needs.

The hypotheses established in this research are:

Hypothesis 1: There is a significant relationship between the motivational factors: **AR**-age respondents, **OC** - organizational climate, **IR** - industrial relationships, **LS-** leadership style, **FR** – financial rewards, **PC** – promotion conditions, **PN** - personal needs and the motivation degree

Hypothesis 2: There is a correlation between motivational factors analyzed.

Given the research purpose and established objectives, a questionnaire was developed comprising 24 closed questions, requiring respondents to rank the answers according to their preference.

For each motivational factor OC organizational climate; IR – industrial relationships; LS– leadership style; FR – financial rewards; PC – promotion conditions; PN – personal needs were designed four questions.

The respondents choose on a Likert scale between 1 (very unsatisfied) to 5(strongly satisfy) the personal answer. The questionnaire was structure in the following items:
Item 1: personal characteristics (age, type of training, work experience);
Item 2: organization climate as a motivational factors (OC);
Item 3: motivation on market of production products as industrial relation (IR),
Item 4: leadership style and relation staff-manager (LS);
Item 5: motivation from manager to staff as a financial reward (FR);
Item 6: motivation on organization hierarchy a promotion condition (PC),
Item 7: identify the personal needs of managers (PN);

The content of questions it was focused on the influence of motivational factors, in order to analyze and improve the motivational system in companies from Maramureș County.

The investigated population consists of 100 managers with various types of training and age, in order to identify the influence of motivational factors on the degree of staff motivation.

Data processing and analysis was statistically carried out by using the software IBM SPSS Statistics. Descriptive statistical procedures were applied for organizing, summarizing and communicating numerical data in order to draw conclusions about the population investigated based on a data sample. In order to analyze the internal consistency of the whole sample Cronbach's coefficient alpha (α) was computed, while for the correlations between variables, Pearson correlation coefficient was calculated.

Results

Item 1: Personal characteristics

The sampling type is probabilistic stratified random sampling, the population being grouped in layers by age categories and for each layer of age category, a simple random sampling was made. The age groups of the investigated population are: 20-30 years old, 30-40 years old, 40-50 years old, 50-60 years old. Each investigated group will include 25 employees investigated.

Item 2: Assessment of the work motivation factors: OC= Organizational climate

The organizational climate was analyzed in the questionnaire through the questions OC1, OC2, OC3 and OC4, the possibilities of response being: 5-very satisfied, 4 satisfied, 3- neutral 2 unsatisfied, 1-very unsatisfied. For 46% percent respondents gives a score of 5 to the organization climate from satistaction work environmenr point of view (Figure 1).

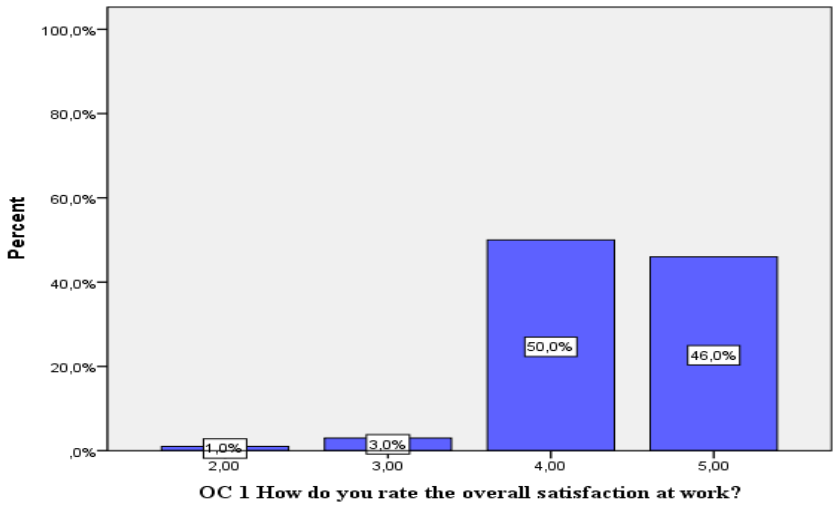


Fig. 1: Organizational climate and satisfaction at work. Source: By authors using SPSS processing

Another motivational factor taking in consideration was the atmosphere and environment work, which can infuence the employees attitut and behaviour(Figure 2).

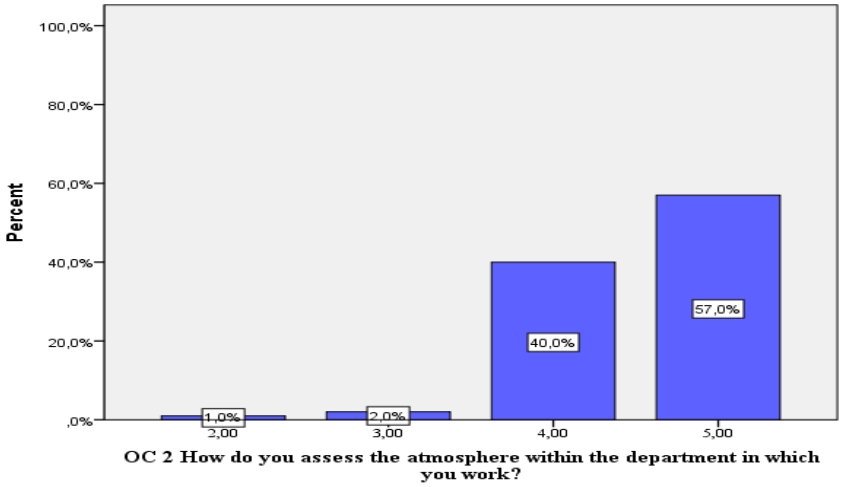

Fig. 2: Environment atmosphere at work . Source: By authors using SPSS processing

For 57% the atmosphere at work it is very important with a score of 5. Managers with 40 % percent give a score of 4.

In conclusion majority of managers consider that the internal environment in organization it is very important and it is a motivation factor for employees.

These results show that management in companies from Maramureș County succeed to provide very good working conditions to the employees of the companies, so that there was no discomfort for the employees which could have affected the production process.

Moreover, there are ensured ergonomic conditions of jobs within the company: proper lighting, suitable temperature and humidity conditions, cleaning and ventilation system.

Item 3. IR= Industrial relations

From the analysis of the four factors regarding the industrial relations , presented in the Figure 3.

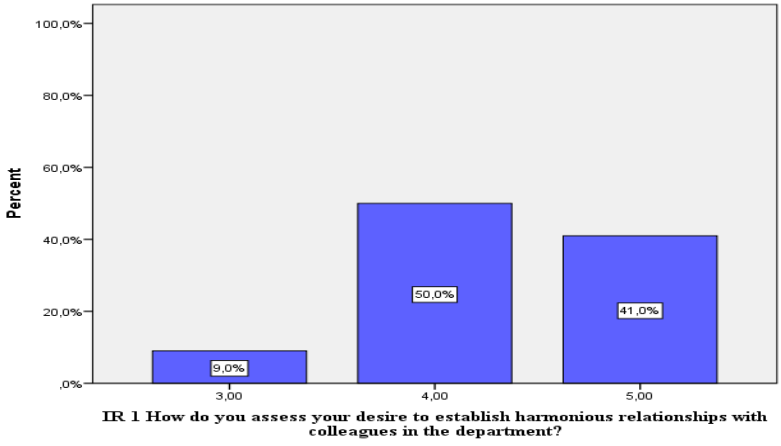

Fig. 3: Manager-employee relationship as motivation factor (IR). Source: By authors

We can conclude that the industrial relations are very good in companies from Maramureș County. For 91% percent the relationship between employees-superiors and superiors- employees, has a positive impact and show an aspect of the motivational process within the company.

Only for 9% the both relationship are not important and receive only a score of 3 from a 5 maximum value.

Another factor which can influence and motivate employees it is the financial rewards (Figure 4). The efficient resolution of conflicts within the company has a great influence in creating a harmonious working climate that encourages cooperation for 80% of respondents.

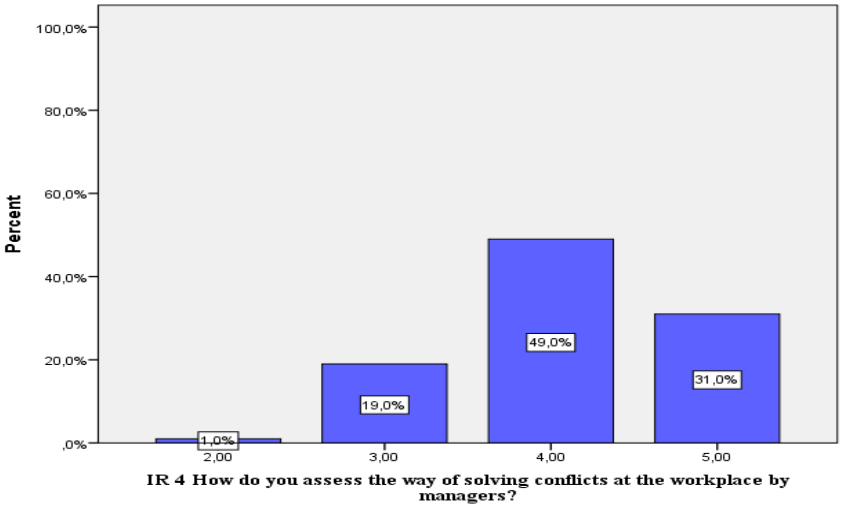

Fig. 4: Solving conflicts as motivation factor (IR).Source: By authors

Item 4. FR= Financial rewards.80 % percent from managers appreciate that the monthly salary of their employees covers their necessities (Figure 5).

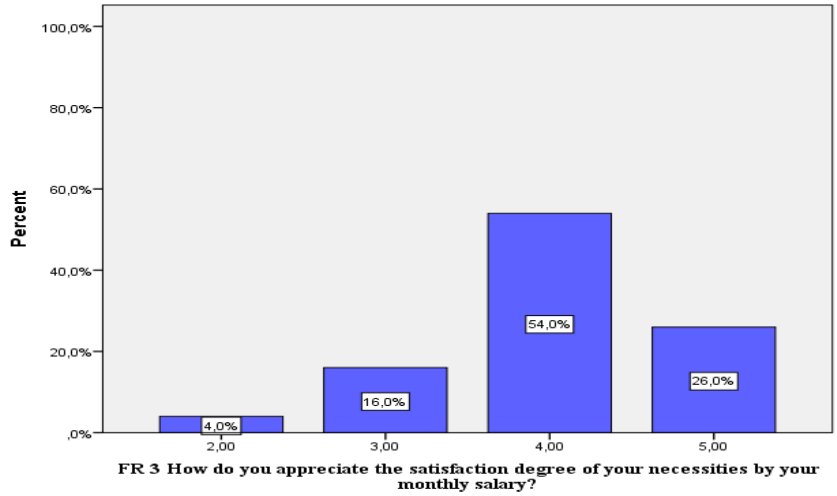

Fig.5: Financial rewards (FR). Source: By authors

The results of the respondents indicate that employees of companies from Maramureș County are very interested in financial rewards, thus management of the company should pay increased attention to the needs of employees regarding their salary, provision of private pensions and of private health insurances, which will be a positive aspect for the staff motivation and it will increase the interest of employees for achieving high quality standards and productive work.

The research apply Vroom's Expectancy Theory as a mean of providing evidence that reward will positively motivate employee.

MOTIVATION =

Item 5. PN=Personal needs. The answers of the respondents regarding their personal needs show that the company must focus on providing a safety environment that encourages and stimulates performance and recognizes employees' achievements, as well as on ensuring the assimilation of people at work to adapt them to the needs of the group to which they belong (Figure 6).

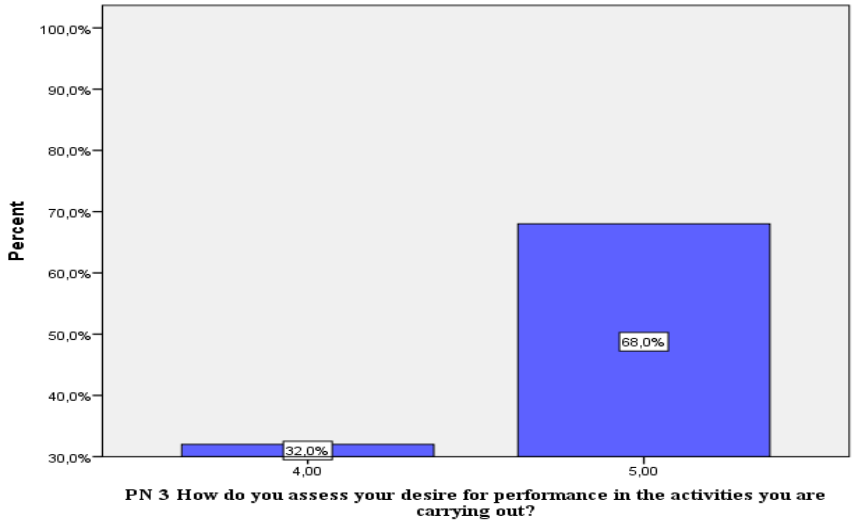

Fig. 6: Personal needs (PN)

This shows us that managers who receive employee benefits are involved 68% in their business and are responsible for their activities performance. Only 32 % select a score of 4 which present a large field of activities in their management act.

Professional integration (Figure 7) it is another factor which present the manager mentality with score 5 maximum value for 31% percent and 37% with score 4.

The results put in evidence that managers are involved in social environment of organizations and they are good specialists and en to the new market provocation.

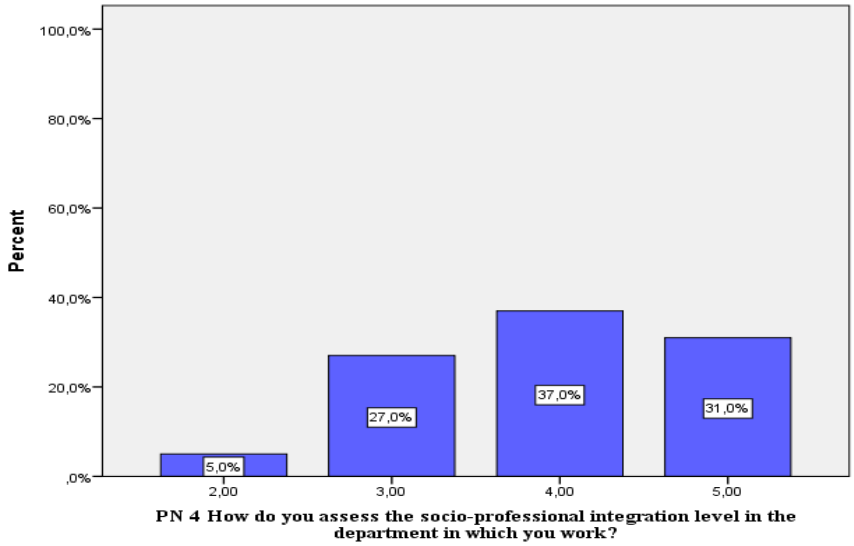

Fig. 7: Professional integration (PN)

Analysis of the internal consistency of the questionnaire

The internal consistency, measurement accuracy and reliability of the 24 questions based on Likert scale were tested using Cronbach alpha coefficient (α).

The test was performed for the whole set of questions which focus on the following motivational factors: OC-organizational climate; IR-industrial relationships; LS-leadership style; FR-financial rewards; PC-promotion conditions and PN-personal needs. Cronbach coefficient of the internal consistency can take values in the interval [0; 1].

The formula for computing this coefficient that is based on the number of items and inter-item correlation mean is presented below (Opariuc-Dan, 2011, p. 299):

$$\alpha = \frac{nx\,\bar{r}}{1+\bar{r}(n-1)} \quad (2)$$

where α – represent Cronbach alpha correlation coefficient, n – the number of items and $\bar{r}$ – the mean of inter-items correlation. In order to analyze the internal consistency of the scale "Motivation degree", out of 100 responses, none was excluded, thus Cronbach alpha coefficient was calculated based on a total of 100 valid responses, as it can be seen in Table 1.

Table 1: Cronbach Alpha coefficient for internal consistency
After calculating the coefficient for all 24 questions, the value of 0.917 sustain that the results can be taken in consideration.

Cronbach's Alpha	Cronbach's Alpha Based on Standardized Items	N of Items
0.917	0.914	24

The value is very close to one, which means that the instrument measures the actual score, the random errors being eliminated and shows that motivational factors are correlated with each other and the internal consistency of the instrument is excellent.

Based on the analysis performed up to this point, we have concluded that the scale is accurate, given the value of Cronbach alpha coefficient.

Table 2 shows that the scale consists of 24 items and has an average of 103.1700 points with a standard deviation of 9.27477 points.

Table 2: Scale statistics

Mean	Variance	Std. Deviation	Nr. of Items
103.1700	86.021	9.27477	24

Analysis of the correlation

Table presents the mean and standard deviation regarding the age of respondents and the 6 groups of motivational factors based on the answers of 100 managers questioned.

Table 3: Descriptive statistics

	Mean	**Std. Deviation**	**N**
Age of respondent	39.6200	11.63570	100
Mean Organizational climate	4.2575	.40116	100
Mean Industrial relations	4.2200	.49400	100
Mean Leadership style	4.1875	.47457	100
Mean Financial rewards	4.2700	.52426	100
Mean Promotion conditions	4.4725	.46723	100
Mean Personal needs	4.3850	.36136	100

Source: Processing in SPSS

Employees are essential to everyday good running of organizations and as we proven in our research when they are rewards for the attainment of organizational goals employees become motivated and increase the productivity and efficiency for the organization. As we can observed the hypothesis 2 was verify in conclusion the data and the proposal model can be take into consideration.

Table 4: Correlations between the means of motivational factors

		Age of respondent	Mean OC	Mean IR	Mean LS	Mean FR	Mean PC	Mean PN
Age of respondent	Pearson Correlation	1	.638**	.743**	.708**	.835**	.817**	.714**
Mean OC	Pearson Correlation	.638**	1	.571**	.523**	.693**	.732**	.637**
Mean IR	Pearson Correlation	.743**	.571**	1	.571**	.678**	.735**	.624**
Mean LS	Pearson Correlation	.708**	.523**	.571**	1	.756**	.715**	.506**
Mean FR	Pearson Correlation	.835**	.693**	.678**	.756**	1	.840**	.639**
Mean PC	Pearson Correlation	.817**	.732**	.735**	.715**	.840**	1	.725**
Mean PN	Pearson Correlation	.714**	.637**	.624**	.506**	.639**	.725**	1
**. *Correlation is significant at the 0.01 level (2-tailed).*								

Source: Processing in SPSS

From the analysis of table 4 we can observe that there is a good correlation between the motivational factors. The best correlation of * 840 (84%) is registered between the FR (financial rewards) and (PC) promotions conditions. Also the experience it is very important for the good understanding of staff and employee's and the knowledge assimilates in production and management, present that the correlation (FR) financial rewards and (AR) age respondents has the second value of * 835.

Conclusions

Motivation at workplace in companies from Maramureș County is very important both from individual point of view, reflecting the employee's attitude towards work, as well as collectively. From the conducted case study we concluded that the first hypothesis is confirmed.

Thus, there is a significant relationship between the degree of motivation and the motivational factors: OC - organizational climates, IR - industrial relationships, LS- leadership style, FR - financial rewards, PC – promotion conditions, PN – personal needs.

Through the analysis of Pearson coefficient, the second hypothesis is confirmed, regarding the existence of correlation between the motivational factors analyzed in the 6 clusters.

Motivation of employees within companies from Maramureș County will raise along with the increase in personal responsibility, recognition, respect of employees, which will increase their involvement.

A fair reward system based on performance will motivate staff to efficiently work and will have a positive impact on their morale.

The company is permanently concerned to improve the working conditions in order to increase employees' performance in obtaining products with higher quality and reduced costs.

This can be seen in the development of a Lean department, concerned with applying the lean manufacturing principles, regarding continuous improvement, elimination of waste, ensuring continuous operation of the machines, standardized work, programming of production based on actual demand, continuous flow, performance of operations that add value to the customers, reduction of dead times, prevention of errors.

Thus, the company had a low share of material sanctions for errors and deviations. The implementation of an efficient motivation model in companies from Maramureș County, Romania, will increase the performance of human resources.

Besides the frequent usage of formal motivations, companies from Maramureș County should capitalize on the motivational potential of informal motivations, especially moral and spiritual ones, which represent a sensitive issue for most employees, having a great influence in improving their job satisfaction.

Acknowledges

Factor Mapping and Modeling for Production Planning

Ing. Pavel Kábele, University of West Bohemia, Department of Industrial Engineering and Management, Univerzitní 22, 306 14, Pilsen, Czech Republic, pkabele@kpv.zcu.cz

Ing. Michal Bochinský, University of West Bohemia, Department of Industrial Engineering and Management, Univerzitní 22, 306 14, Pilsen, Czech Republic, bochinsk@kpv.zcu.cz

Abstract

Assuming continuous development and growing competition, high emphasis is placed on effective planning. Accurate planning makes timely claims and customer satisfaction is growing. In order for the planning to be based on optimal data, it is necessary to fully map the production processes and determine the exact value. This value is the basic tool for creating metrics for the evaluation of the production process. This idea is also engaged in practical study that analyzes the factors that affect time requirement of the operation. In the theoretical part of this study are presented the knowledge gained from technical literature from the field of industrial engineering. In the analytical part, precise operations´ time requirements were measured and these measured values were processed. A process map of the entire production process has been created. From these values, a calculator, which is verified in practice, has been compiled.

Keywords: Production parameter, time study, process, efficiency.

Introduction

Nowadays, it is increasingly important for the vast majority of companies to improve their production and make it more efficient. This is done by various older and modern methods of standardization and rationalization of work. Thanks to this knowledge, companies consolidate their place in the marketplace, acquire new customers and increase their competitiveness. It has been proven that production parameters have a significant impact on capacity planning and contract generation. If these parameters change due to optimization or rationalization, production control is faster and more accurate (JIE ZHANG, 2017).

According to (DASHCHENKO, 2006), time analyzes of operations are necessary for the creation of a precise planning system. The more accurate the time analysis, the better the date, which can be further processed in the planning system. This gives an absolutely accurate production planning.

In this publication, an analysis of influencing factors for the manufacturing process is made. Initial analysis and data collection were carried out in the form of time studies and the evaluation led to the design of the calculation model for production time requirements.

Factors Affecting Productivity

The main objective was to perform a production process mapping that led to the identification of all the key parameters that affect the time-consuming nature of operations in the production process. Thanks to analyzes of images of production operations it is possible to analyze the production processes. These

materials are designed to create a calculator that is able to calculate the resulting parts production times according to the specified parameters.

The cornerstone of production is production activity. This is the process of offering certain services or creating new products. This is the transformation of the material into the product and takes place from the insertion of the material into the machine until it is removed from the machine as a product. This also applies to products that are still being processed or modified in the company. The resulting product is one that the business can sell and get the desired revenue from it. (EDL, KUDRNA, 2013)

Production process means the transformation of the material and the semi-finished product into the final product. If the production process is properly and thoroughly processed it minimizes losses during production, which is most evident in mass and serial production. You can divide the manufacturing process individually into: (BOTEK, ADAMEC, 2004)

- Operation - a part of the manufacturing process that is performed by one worker on one machine, has a continuous duration and is properly terminated.

- Operations section - A part of the operation that is executed by one tool at a single clamp and in one place.

- Action - a simple work activity that is inseparable from the point of view of organization (turning on the machine, clamping the item, etc.)

- Movement - part of the act that is the smallest and measurable. This is the simplest move of a worker which has been finished.

Time analyzes

To achieve the highest possible work efficiency and lowest cost, the methods of continuous improvement of production processes are used. This improvement is called the rationalization of work. Standardization work is the activity that defines labor standards. For the continuous growth of production based on the growth of labor productivity, it is necessary to create conditions that can maintain a high level of production process. (MAŠÍN, VYTLAČIL, 2000)

In order to continue the project, it was necessary to map the current situation. These are the status of workplaces, operations, activities performed, types of material and other important parameters entering the production process. The greatest benefit of taking and analyzing images at individual workplaces is to get information and to map the current state of the company. This information can provide managers with enough space to improve production and increase profits. These results can be achieved by various rationalization methods. It is also possible to maximize the use of machines or increase employee productivity. (MAŠÍN, VYTLAČIL, 2000)

Objectives and Benefits of Mapping Factors in the Production Process

One of the goals of the project was to map individual processes and become familiar with its parts. Therefore, it was necessary to go through the entire production process, from saws to finish, and see how production takes place. Thanks to this activity, the parameters entering the production process and the factors that have influenced the production process were determined. For example, there is a description of the Cutti workplace analysis.

There are a lot of effects on the time consumption of the saw operations. First of all, it is a semi-finished material from which pieces are carved. There is a variety of types of material used, and a certain range of cutting speed is prescribed for each material. All these parameters must be set on the computer that controls the saw. The operator also adjusts the cutting program, depending on what shape the saw will cut. The workload of this worker before cutting, except for the program of the saw, is also to place the semi-finished products on the exact position for the material arrival. Additionally, the semi-finished product must be adjusted just before the cutting process. When the semi-finished product ready for cutting is received and serviced, the top plate of the saw is started up to the blank and the operator can start the cutting process on the computer.

In the first place, before the saw begins to cut pieces, it automatically cuts and aligns the front of the workpiece so that it can still be cut in exact dimensions. After that, the process of cutting individual pieces is already taking place. Additional parameters such as the shape of the individual pieces, whether they are to be cut straight after each other, or how many pieces can be cut out of the blank can be entered now. Specifically, the number of sharp edges, rounding of the walls and, in particular, contour length play a role in the shape demands of the work.

These parameters significantly affect the cutting time of one piece. The saw at each sharp edge must be correctly aligned and one sharp edge takes about 1 second at any cutting speed. Contour length is of course the most striking factor in cutting one piece. The cutting time can be roughly calculated from the total length of the cut contour circumference and the cutting speed that depends on the type of material.

Tab. 1: Workplace parameters

Parameters	Units
Material	-

Fig. 2: Manipulation inside Cutti

With the analysis of the operations images, it was possible to determine the exact times of the individual operations. Analyzes were progressively modified to the desired table formats that served to continue the project.

Method of imaging

The imaging was mostly done by camera-shooting. The movie snapshot method has been chosen because of a large number of parameters. Some operations were performed very quickly, and others took longer. Short operations were another reason to use film shots and to capture even the shortest operations. Some operations could be measured by moment observing method. As a result of all analyzes of the measured images, tables, where the times of individual operations in the workplaces are captured, were created. These partial times together give the total time value of one piece. The tables were created in Excel for each workplace separately.

Fig. 3: Process analyse CUTTI

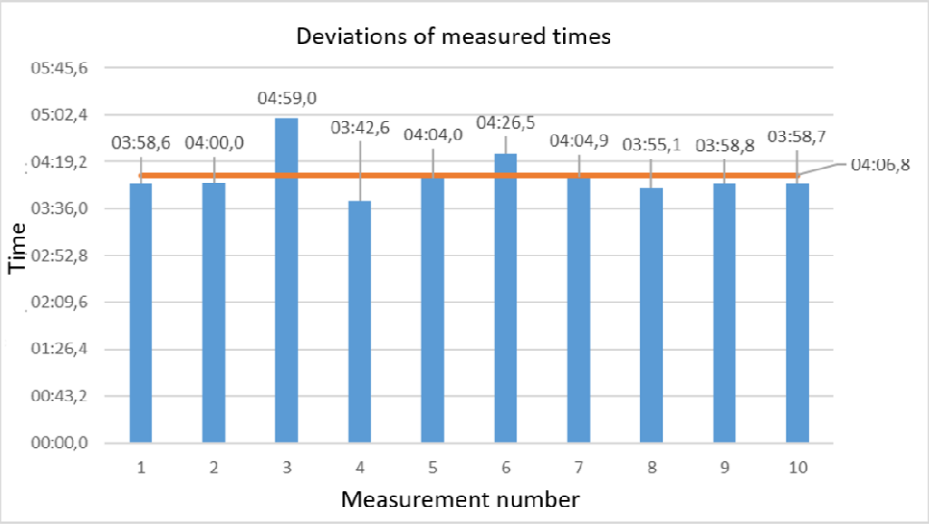

Fig. 4: Graph Cutti

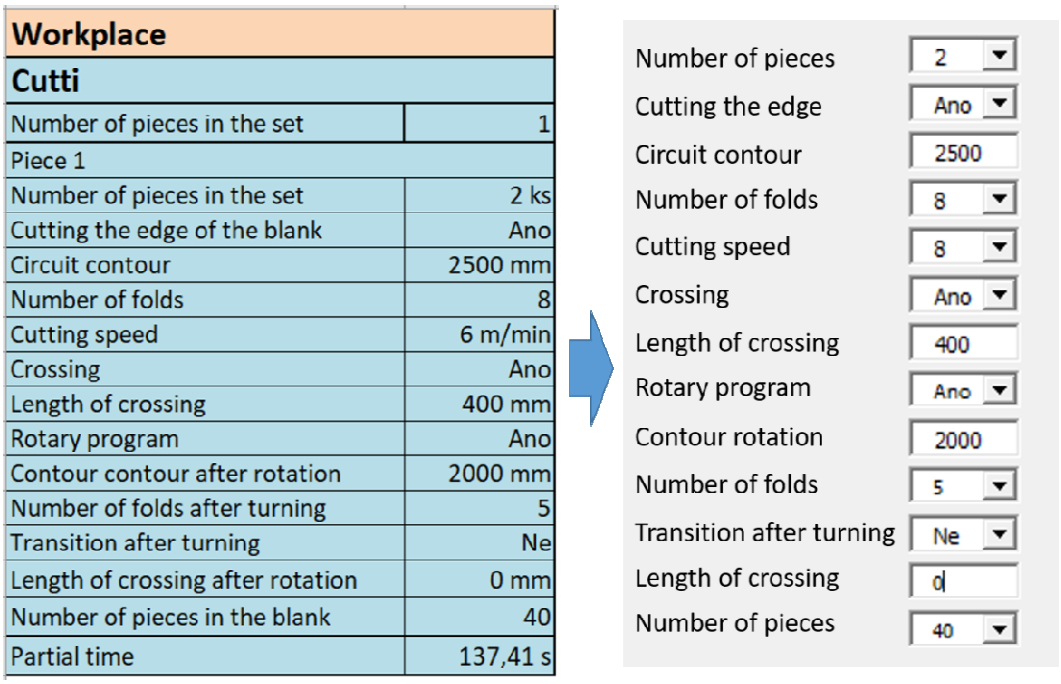
Material removal and cutting of sharp edges do not have significant differences between them because they are performed by the machine itself. Edge cutting depends on the size of the cut surface. Deviations from the graph show that in addition to the 3rd and 4th measurements there were not significant variations, but the biggest difference is higher by 52.2 seconds.

System Design

The MS Excel spreadsheet editor, which uses the data entered and drawn for the calculations, was chosen to implement the system. While making calculations, it was necessary to take into account all the tasks that are included in the operation. These operations have been analyzed to fit the formula for calculating the production time. As a data source for calculations, a sheet of values was created from the time analysis tables. At the Cutti site, this is the most complex operation, so it was necessary to define a really complex formula, see equation, which includes all the described factors and technological times determined by time analyzes.

$$t = \frac{t_m}{Q_p} + \frac{t_s}{Q_p} + Q_z * t_z + \frac{O_k}{v} + \frac{D_p}{v} + t_o + Q_{zo} * t_z + \frac{O_{ko}}{v} + \frac{D_{po}}{v}$$



tm .. Time of manipulation

All described workplaces and parameters are the basis of the submission form. The form was created in the Visual Basic for Applications programming language. The main function of the form is to insert data into the cells under which the calculations are performed. The goal in formulating the form was primarily factuality, uniqueness and user-friendly input of values and parameters. Label, textbox, combobox, and button were used to create the final form. Three other forms can be opened during the entry, in which you can define the parameters at the Cutti a workplace and formatting and cutting departments of workplace XI.

Fig. 6: User inrteface datatransmission

The study used techniques that aim to eliminate the most common mistakes, eliminate unnecessary movements, and assess the working position and the duration of individual operations. These incentives were based on time studies and production planning.

The biggest problem in the processing of the analysis were paradoxically the workers. Instead of working together to map the actual component production time to build an effective planning model that is a good helper against growing competition, they made the study more complicated by their negative reactions.

Most of the workers who were observed then worked above their average pace. Therefore, in the analysis it was difficult to determine 100% of the employee's workload. This was done using the basis and MTM and MOST analysis. The comparison of the acquired and analyzed procedures with the average employee productivity record in the company has created a sufficient springboard to successfully collect data for the compilation of the production calculator.

The assessment of the production plan is usually done on the basis of cost, capacity, quality, continuous production time and customer requirements, which are the basic common evaluation criteria. Quality is assessed as a limiting condition for this methodology and it is assumed that all proposed variants meet the quality requirements.

Conclusion

The basic and most significant part of the proposed methodology is the implementation part, in which, with the help of the given procedure, we create the calculator of the production plan in the processes of the company. Numerous measurements and analyzes of parameters influencing the production time have been carried out at all workplaces. After evaluation analyzes, calculations were made, including the observed values and dependencies. Subsequently form was created in Visual Basic for Applications,

which is perfectly connected to the calculation base. As a result of the calculations, the resulting table with partial times and the total production time of the entire production process was created. The calculator is able to ensure that the entire production process is nanomorphic by simply entering parameters that depend on the shape, purpose, and complexity of the product. Initial functional verification and training of the responsible employee has already taken place in the company. Input by a trained worker takes about two to five minutes depending on the complexity of the product, while standardization of the individual process segments by the standardizing worker would take up to a dozen hours for each axle product.

Click Activists of the New Era, Slacktivists: An Exploratory Research to Define Slacktivist Typologies

Hatice Ozbas, Anadolu University, Eskisehir, Turkey, ozbashatice@gmail.com

F. Zeynep Ozata, Anadolu University, Eskisehir, Turkey, fzozata@anadolu.edu.tr

Abstract

Most of the events which have taken place in the last decade prove that thinking independently of the 21st century activism apart from internet and social media isn't possible. This digital era provides people joining online signature campaigns, changing profile pictures to promote an idea or campaign and sharing content on social media. All these practices cause a rise of a concept called "slacktivism" which combines the words "slacker" (lazy) and "activism" has a meaning as to support a cause with minimum performance or without action.

Generally, concept of slacktivism takes part in the literature as a negative word which has no or little effect on social issues. In another respect, recent studies show that perhaps not a single slacktivist, but the collective power arisen by the combination of slacktivists have the potential to show a significant presence. Therefore, slacktivists play an important role in promoting awareness and support of campaigns which aim to raise social welfare or wellbeing of society. However, studies in the literature on slacktivism or slacktivists are still very limited although those have the main roles in the spread of social messages. From this point of view, this research aims to describe the main subject of slacktivism, who is slacktivist, and slacktivists' profiles. In addition to present typological features of the slacktivists in terms of differences and motivations, it will be tried to understand what the slacktivists think about impacts and effectiveness of their slacktivist behaviors.

In-depth interviews with 10 participants from 4 different generations (Baby Boomers, X,Y and Z generations) are conducted to collect data. Miles and Huberman model is used to analyze qualitative data to explore the main codes related to the typological features of slactivists. Different motivations and values are determined that differentiates various types of slacktivists. Participants are seperated from each others such as motivation of using social media platforms, their feelings after slacktivist behaviours or the effect of these behaviours on their activist practices. On the other hand, participants' point of view about slacktivist behaviours mostly resembles each other.

This study was supported by Anadolu University Scientific Research Projects Commission under the grant no: 1609E679

The Impact of Monetary Policy on Bank Lending Rate in Kenya

Wairimu Wanjaiya

phd jomo kenyatta university of agriculture and technology, nairobi, kenya
wwanjaiya@gmail.com

Abstract

Monetary policy is an activity of The Central bank that controls the availability of money and credit in a country's economy Cecchetti, (2009). Tight monetary policies raise the nominal interest rate and reduces long run output such as the supply of bank loans, leading to a rising lending rate, thus discouraging bank-dependent borrower's activities. In the condition of easing, more liquid money is available for banks, thus as the supply of money increases the interest rate decreases. The study centered on the impact of monetary policy on bank lending rate in Kenya. In terms of methodology, the study employed secondary data to study the relationship between monetary policies and bank lending interest rates in Kenya. Currently, Kenya has 43 commercial banks. This study used time series data averages for all the variables as provided by the Central Bank of Kenya (CBK) as a representation of all the 43 banks so as to avoid the sampling bias problem. Quarterly time series data for the period 2000 to 2014 was used. The study revealed that Central Bank Rate and Treasury Bill Rate were both positive and significant Monetary Policy instruments in explaining bank lending interest rates. Reserve Requirement was found to be a negative and insignificant Monetary Policy tool in impacting Bank's Lending Rates. The study recommends that the Central Bank of Kenya should adopt the TBR and CBR more in their efforts of implementing the Monetary Policy Committees decision.

Introduction

The general public views their respective Central Banks as the solution to economic downturns such as inflation, exchange rate fluctuations and depreciation of their currency or as the quickest way to stabilize the economy. The Central Bank's overall role is to stabilize the economy from macroeconomic shocks (i.e. Exchange rates fluctuations, Inflation pressures as well as excess liquidity in the market) through the use of both fiscal and monetary policies. Economists view monetary policy by Central Banks as the readiest of tools that can be used to arrest economic downturns.

The most prominent change in the management of the Kenyan economy after Kenya got her independence was the application of the structural adjustment programs (SAPs), which were introduced around the 1980/1981 financial year. The SAPs consisted of a set of economic policies designed to generate rapid and sustainable economic growth while eliminating fiscal and external imbalances with macroeconomic stability. In trying to stabilize the Economy in the earlier years the government used SAPs so as to liberalize prices and financial markets as well as the well instill changers in the financial sector, integrate international trade reforms, and make sense of the budgeting process (MPAC 2005). Several studies done in the 90's (Ikiara 1990, Mwega and Ndulu 1994, World Bank-UNOP1993, Swamy 1994) found that the structural adjustment programs have had some negative effects on the economy, such as inflationary pressures and increase of government debt.

Owing to the negative effects derived from the SAPs the government sought other ways of stabilizing the economy in terms of exchange rates volatility, the depreciation of the shilling, the runaway debt pressures of the government. The government through the CBK established the Monetary Policy Advisory

Committee (MPAC) which was mandated to stabilize the economy against macroeconomic shocks. The Monetary Policy Advisory Committee in 2008 through gazette notice 3771 on 30th April 2008 changed to the current Monetary Policy Committee (MPC).

The MPC in its objective of stabilizing the economy has also achieved other success such as Financial Inclusion by enabling credit access to majority of the Kenyans as well as transformation in terms of Mobile Money transfer.

Literature Review

The Central Bank of Kenya's (CBK's) Bank Supervision Annual Report (2014) showed a reduction in the Central Bank Rate (CBR) which impacted positively on short-term interest rates. A steady decline in the average 91-day Treasury bills rates was also witnessed. The reduction in interest rates was not replicated in commercial banks average lending rate during the period. There has been a systematic reduction of the CBR over the last three years, from 19.7% as at 1st December 2012, 17.9% in 2013, to an average of 15.3% - 16.8% in 2014. The pass through rate reduction in the CBR has only been reflected marginally in the lending interest rates by banks which in turn has heightened the cost of credit above the reach of many potential borrowers. The CBK issues monetary policy rates every two months meant to guide the direction commercial banks take in their lending rates.

In acknowledging the role played by the CBK, several studies have been conducted about the banking sector. The studies however, have mainly focused on the financial performance of Banks, Monetary Policy transmission mechanisms, how monetary policy affects the real economy and the impact of money supply on current account.

According to Misati et al, (2010) interest rates play a significant role as a link to other macroeconomic variables, mainly output that also forms one of the overall goals of any monetary authority. The theoretical basis of this study was embedded to the traditional Keynesian view which suggests that monetary policy influences the real cost of borrowing by setting a nominal short-term interest rate. Changes in nominal interest rate are expected to influence real rates and eventually have an impact on investment and consumption both of which are key components of economic output.

Kashyap and Stein, (2007) and Cecchetti, (2008) considered national concentration ratios in their analysis of the effectiveness of monetary policy in Europe. Both studies used three and five-firm absorption ratios respectively, as tools of bank size in their association between monetary transmission and competition in their overview of the subject. Empirical studies using European data confirmed the existence of the bank-lending channel and found that the operations were similar to those in the U.S.

Adams et al. (2005), studied the effect of local banking market structure on the bank lending channel of monetary policy. The study used Community Reinvestment Act (CRA) data that measured the volume of loans originated from 1996 to 2002, collected annually for six years. The study tested the theory of Structure-Conduct-Performance which posits that greater market concentration leads to less lending and higher loan rates. The dependent variable was the volume of loans originated in each market Kashyap and Stein (2007).

A study by Mohammad (2010) on the impact of money supply on current account based on the extent of Pakistan rupee evaluated the effects of money supply on current account, that is, the empirical association among money supply on current account, exchange rate, and industrial production .Time series data from 1975 to 2008 was collected and a multivariate model applied. The study found that the monetary policy

system has an important influence on the domestic variables, for instance, output and inflation; therefore central bank should target the domestic (producer) inflation when issuing the monetary policy.

Somoye and Ilo (2009), in their study spanning (1998 -2015) sought to undertake the impact of macroeconomic instability for the period on banking sector lending behavior in Nigeria using time series data the Central Bank of Nigeria of quoted commercial banks operating in Nigeria. Other data on bank lending activities and other bank characteristics were obtained from the annual published financial statements of the banks and the fact book published by the Nigerian Stock Exchange. The study hypothesized that bank's lending behavior was generally influenced by the environmental factors particularly the regulatory and macroeconomic.

Buigut (2010) assessed the importance of the bank lending channel in the transmission of monetary policy in Kenya. Annual time series data the period from 1979 to 2008 sourced from the International Financial Statistics was analyzed. The study suggested that a monetary tightening directly constrains the ability of banks to make new loans, therefore forcing dependent bank borrowers to reduce investment. It was also suggested that restrictive monetary policy works not only by raising interest rate but also by restricting bank credit directly. Five variables, namely the real GDP, inflation, real private sector credit, lending rate, and a short-term interest rate (Treasury bill rate) were tested. The results showed that a shock to the policy instrument only affects the prices and real output with a lag. The effect on the loan quantity is a permanent decline that settles about two years to a long term effect of around 8.2 basis points below the baseline. Taken together, the decrease in loan quantity and the increase in the lending rate suggest a dominance of the lending channel over the interest rate channel in Kenya.

Mature, et al (2006), conducted a study on how monetary policy shocks influence the level of macroeconomic performance in Kenya. Twelve-month percentage change in the Consumer Price Index (CPI) was analyzed focusing the analysis on variability of the data series over time beginning 1997.The study used the structural vector auto-regression model and proposed that monetary policy is transmitted through many channels including the money supply, credit channel, the interest rate channel represented by the 91-day Treasury bill interest rate, bank lending interest rate and the exchange rate channel.

There have been several studies done in Kenya in this and related areas. Some of these include: A study by Bett, (2010) which examined the financial performance of banks and non-banking institutions over a period of 5years (2004 - 2009), A study by Mutwiri (2007), which focused on factors affecting bank failure, such as liquidity and poor management. Mature, et al (2006), conducted a study on how monetary policy shocks influence the level of macroeconomic performance in Kenya for the period 1997 – 2010 and a study by Mohammad (2010) which examined the impact of money supply on current accounts for a time period 1975 – 2008.These studies and many more, however, do not address the influence that monetary policy has on bank lending rates.

Research Methodology

The study centered on the impact of monetary policy on bank lending rate in Kenya.

Research Design

The study employed secondary data to study the relationship between monetary policies and bank lending interest rates in Kenya.

Target Population

Currently, Kenya has 43 commercial banks. This study used time series data averages for all the variables as provided by the CBK as a representation of all the 43 banks so as to avoid the sampling bias problem. Quarterly time series data for the period 2000 to 2014 was used.

Model Specification

To examine the relationship of monetary policy on bank lending interest rates, the study used the ordinary least squares model (OLS). Under this approach, it needs to be considered that the OLS's main assumption is that the errors must be uncorrelated.

$y_t = \alpha + x'_t \beta + \varepsilon_i$

Consistent with, Brooks, (2008), the econometric model is specified;

Model Specification

$$LIR_t = \alpha + \beta_1 \Delta CBR_t + \beta_2 \Delta TBR_t + \beta_3 \Delta RR_t + \varepsilon_t$$

Where,

LIR_t = Lending interest rates at time, t

CBR_t = Central Bank rate at time, t

TBR_t = Treasury Bill Rate at time, t

RR_t = Reserve requirement at time, t

t = time

ε_t = Error term is presumed to be normally and independently distributed with mean zero and constant variance, t

α_t = captures all other explanatory variables that affect monetary policy, but were not captured in the model.

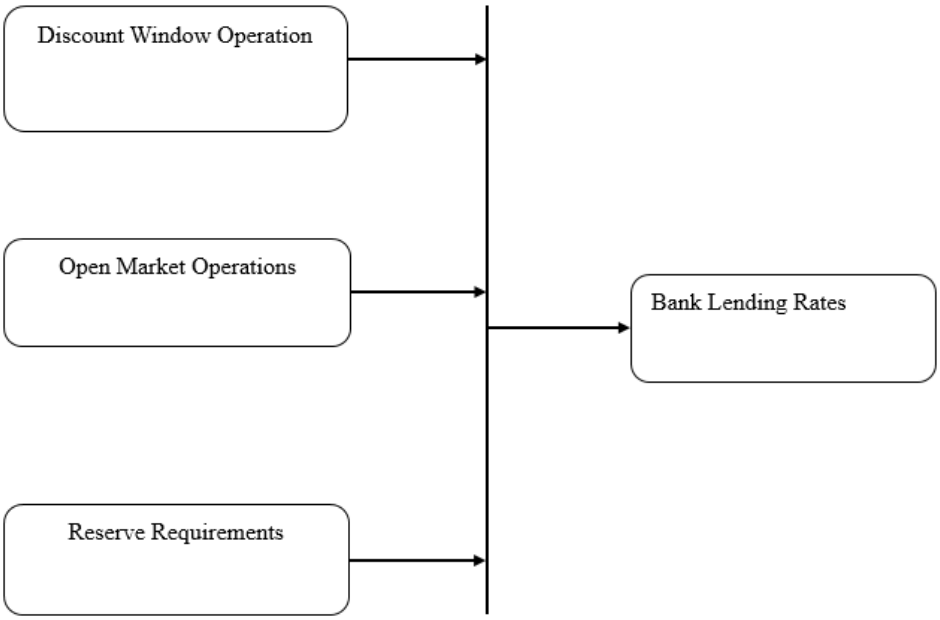
$\beta_1, \beta_2, \beta_3$, are the coefficients of monetary policy, measured with respect to CBR, TBR, and RR, respectively. Previous studies have shown that OLS is a suitable model to quantify the relationship between monetary policy and lending interest rates Espinoza & Prasad, (2010).

Conceptual Framework

The study adopted a conceptual framework to examine the relationship between monetary policy and bank lending rates in Kenya. The study utilized the following independent variables as a measure of monetary policy: the Discount Window Operations, Open Market Operations and Reserve Requirements; and the dependent variable as bank lending rates in Kenya.

Discount Window Operations

The CBK may provide short-term secured loans to commercial banks on overnight basis at the Central Bank Rate (CBR) in its capacity as a lender of last resort, thus restricting banks to seek funding in the market resorting to Central Bank only as a last resort. This arrangement is known as discount window operations of the Central Bank. The CBR is reviewed every two months, and its movements are a signal of the intended direction of change of money market interest rates.



Open Market Operations

According to Akhtar (2007), Open Market Operations objectives are that the government sells government-backed securities to the economy to mop up excess liquidity. The Central Bank alters the Central Bank Rate, which impacts the short term interest rates as witnessed by a steady decline in the average 91-day Treasury bills rates CBK, (2012).

The government in instances of excess liquidity in the markets, high inflation rates and or a spiraling depreciation of the Kenyan shilling, employs open market operations which are a tightening monetary policy. The object of OMO is to mop up excess liquidity, therefore the government will sell off government backed treasury bills at the risk free rate in the economy to mop up the excess liquidity and achieve the desired level of reserves Bogdan and Bilken, (2009).

Reserve Requirements

Central Banks are empowered to demand a certain proportion of commercial bank's deposits held as non-interest bearing deposits. This is used to influence some of the loans that banks can advance the public and thus affecting the supply of money. According to CBK (2013), the volume of liquidity in circulation influences the levels of interest, as well as the value of the Kenyan shilling against other currencies. Bank reserves are kept very close to the required levels since banks generally do not earn a return on reserve assets. The cash ratio is a direct credit control instrument, which works by enhancing or reducing the ability to create credit out of a given deposit base.

Fig. 1: Monetary Policy Instruments

Effects of Monetary Policy

Introduction

This section covers the empirical analysis of the sampled secondary data regarding the variables under consideration in the study. The data was tested for stationarity of the variables and the residual, correlations, and Cointegration. Regression analysis was done for the same sample covering the period 2000-2014. E-views, econometric software were used to analyze the data.

Diagnostic test for normality

The characteristics of the distribution of the variables are presented in table 4.1 below.

Table 5.2: Descriptive statistics

	LIR	CBR	TBR	RR
Mean	17.40527	11.34518	6.28987	9.44583
Median	15.25742	11.301	5.25754	10.89710
Maximum	24.08909	15.19075	21.09633	12.77380
Minimum	8.48497	5.26509	8.13243	8.49087
Std. Dev.	6.00547	1.76049	7.56981	5.67532
Skewness	0.04001	0.07810	0.09105	0.24661
Kurtosis	1.83000	1.78355	2.42820	1.32187
Jarque-Bera	2.46410	2.69492	0.64520	2.48139
Probability	0.29169	0.2599	0.72426	0.06453
Observations	60	60	60	60

From the test, the distribution probabilities for LIR is 0.292, CBR is 0.2599, TBR is 0.724, RR is 0.0645 (for a normal distribution, the probability should be greater than 0.1). Therefore, all variables are normally distributed. The statistic for Kurtosis (K) shows, LIR, CBR, TBR, and RR are platykurtic, suggesting that their distributions are flat about the normal. Skewness (S) for LIR is 0.04, CBR is 0.0781, TBR is 0.091, RR is -0.247 (for normal distribution, skewness: S=0). From the results LIR, CBR TBR and RR were all positively skewed. The Jarque-Bera test was used to determine whether monetary policy instruments and Bank lending rates follow the normal probability distribution. It utilizes the Skewness and kurtosis measures and uses the following formula;

$JB= n [S^2/6 + (K-3)^2/24]$

Where n= sample size;

S= skewness coefficient; and

K= Kurtosis coefficient.

The JB normality test is a joint hypothesis that of skewness (S) and kurtosis (K) (for a normal distributed variable, S=0 and K=3). Therefore we conclude that all the variables in our study are not normally distributed since there is no variable whose distribution has S=0 and K=3.

The standard deviation is a measure of variability from the mean. From the test, we find that LIR has the greatest variability (6.0075) while CBR has the smallest variability (1.7605) from the mean. The minimum, maximum, median and the mean, shows the smallest growth rate, the maximum growth rate, the middle growth rate and the average growth rate for each variable respectively.

Test for Stationarity

When estimating a model that includes time series variables, it is necessary to ensure that all time series variables in the model are stationary, which means that they were integrated of the same order. This was done by conducting a unit root test on each variable to find the order of integration. A stationary variable has a time-invariant mean and covariance. Estimation based on non-stationary variables may lead to

spurious results with high R^2 and t-statistics, but without any coherent economic meaning and inconsistent parameter estimator. This is called spurious regression.

An I (0) series is a time series that is stationary at level. An I (1) series contains one unit root and is a time series that is stationary at first difference. If the time series data is non-stationary, and y_t is differenced d times before it became stationary, then it is said to be integrated of order d. We write $y_t \sim I(d)$. So if $y_t \sim I(0)$ then $\Delta dyt \sim I(0)$. If the variables in the regression model are non-stationary, that is, not integrated of the same order and then, the analysis will call for the error correction model to be run. However, if stationary, that is, integrated of the same order, then, we go ahead with our analysis using the OLS.

In this study, Augmented Dickey- Fuller (ADF) test was used to test for unit roots. The results are as shown in the table below. The decision criterion involves comparing the computed ADF statistic values with the Mackinnon critical values for the rejection of a hypothesis of unit root. If the computed ADF Statistic is smaller compared to the critical values, the null hypothesis of non-stationarity in time series variables is rejected and vice versa. In our case (Table 4.3), the computed ADF test-statistics are smaller than the critical values at 1%, 5%, 10% significant levels, therefore, we can reject Ho. It means the time series does not have unit root problem, and the series is stationary at 1%, 5% and 10% significant level. In our case (Table 4.3), the results show that LIR is stationary at level i.e. I (0) at 5% significance. CBR is stationary at level i.e. I (0) at 10% significance while TBR and RRR are stationary at level; I (0) at 1% significance.

Table 5.3 ADF Unit-Root Test (at zero difference) Results

Variable	t-Statistic	Test critical values			Remark	Order of Integration
		1% level	5% level	10% level		
LIR	-3.899718	-4.186481	-3.51809	-3.189732	Stationary	I(0)**
CBR	-3.428392	-4.205004	-3.526609	-3.194611	Stationary	I(0)*
TBR	-4.081079	-3.596616	-2.933158	-2.604867	Stationary	I(0)***
RR	-4.761063	-4.205004	-3.526609	-3.194611	Stationary	I(0)***

*Notes:*Significant at 10 percent ** Significant at 5 percent, *** Significant at 1 percent; H_0: there is a unit root*

Cointegration Test

If all variables are integrated of the same order, the second step is to estimate the model, also called a "Cointegration equation," and test whether the residual of the model is stationary, in which case the model defines a long run equilibrium relationship among the co-integrated variables. This was done by generating the residual series using Eviews 7 Software, and the residuals were subjected to an ADF Test.

The computed values were compared with the critical values as shown in Table 4.4. The results show that there is the existence of co-integration. It shows that there is a linear combination between the dependent variable Lending Interest Rate (LIR) and the independent variables Central Bank Rate, Treasury Bank Rate and Reserve Ratio requirements.

Table 5.4 Unit Root Test for residual results

Variable	t-Statistic	Test critical values			Remark	Order of Integration
		1% level	5% level	10% level		
Residual	-6.390081	-3.596616	-2.933158	-2.604867	Stationary	I(0)***

*Notes: ** Significant at 5 percent, *** Significant at 1 percent; H_0: there is a unit root*

The results indicate that these residuals are stationary, at 1% significance (i.e. I (0)). The linear combination of the variables of the model is stationary, and they are co-integrated which shows the presence of a long-run relationship between the dependent and independent variables.

Correlation Analysis

Correlation analysis is a statistical technique employed to analyze the relationship between the variables used in the study. Column 2 shows the relationship between the dependent and independent variables. From the results CBR and TBR, are directly correlated to LIR (note the positive) while RR is inversely correlated to the same (note the negative sign). Columns 3, 4, 5 show the relationship among the explanatory variables. The correlation matrix shows that all the variables are not highly correlated (for high correlation, the coefficients are above 0.8). As a result, the problem of multicollinearity brought about by a high correlation between the variables was avoided. This outcome gave the researcher the green light to run the OLS, model.

Table 5.5 Correlation Matrix

	LIR	CBR	TBR	RR
LIR	1.00000	0.17925	-0.31476	0.28948
CBR	0.17925	1.00000	0.11386	0.17806
TBR	0.31476	0.11386	1.00000	-0.31356
RR	-0.28948	0.17806	-0.31356	1.00000

Testing the OLS Model

The tests determine the impact of independent variables on the dependent variable by comparing the results of the model. In this study, the test was to govern the impact of MPC i.e Central Bank Rate (CBR), Treasury Bank Rate (TBR) and Reserve Requirements (RR) on Bank Lending Rates (LIR).

Table 5.6 OLS analysis

Variable	Coefficient	Std. Error	t-Statistic	Prob.
C	-25.08526	4.20929	-5.95950	0.00000
CBR	0.23530	0.13026	1.80642	0.07880
TBR	0.35839	0.04146	8.64362	0.00153
RR	-0.00492	0.07049	0.06981	0.94470
LIR (-1)	-0.00556	0.15004	-0.03708	0.06735

R-squared	0.741075	Mean dependent var	14.40527
Adjusted R-squared	0.704086	S.D. dependent var	6.00547
S.E. of regression	3.298606	Akaike info criterion	5.21680

Log likelihood	-103.16110	Hannan-Quinn criter.	5.29232
F-statistic	20.03487	Durbin-Watson stat	1.87511
Prob(F-statistic)	0.00000		

Discussion of results and Comparison with other Findings

An examination of the econometric results shows that the overall fit is satisfactory with an R-squared (R^2) of 0.741075 or 74%. It implies that LIR, CBR, TBR and RR explained about 74% systematic variations of Bank Lending rates (LIR) over the observed years in the Kenyan economy while the remaining 26% variation was explained by other determinant variables outside the model. The value of Durbin-Watson is 1.88 for the model. This fell within the determinate region and implies that there is a positive first order serial autocorrelation among the explanatory variables in the model.

The potency of CBR in explaining LIR in the country is positive and is statistically significant at 10 percent significance level (p-value < 0.1). Which can be interpreted to mean that one percent (1%) increase in CBR will cause LIR to increase by 0.23530 percent, ceteris paribus. The result is consistent with the works of Misati et al, (2010), Kashyap and Stein, (2007) and Cecchetti, (2008) who found that the Central Bank rate was the greatest determinant of bank lending rates. A plausible interpretation of these results is that an increase in the CBR will automatically lead to an increase in the LIR through the increase in KBRR + bank specific margins.

TBR was also found to be an important determinant of Bank Lending rates at 1% significant level (p-value < 0.01). This implied that a one unit increase in TBR would lead to increase in LIR by 0.35839 units. It can be inferred TBR ratio has a positive impact on LIR in Kenya. The result is consistent with the works of to Somoye et al. (2009), Akhtar, (2007), Adams, et al. (2005) and Kashyap and Stein (2007). A probable interpretation of these results is that an increase in the TBR, which guides the economic environment in terms of the approximate prevailing risk-free rate of return for the next three months. An increase in the TBR rates will lead to a significant increase in the LIR since banks will view this as a sign of increase investment. Borrowers will borrow more, and there will be excess money supply to counter this the govt will use monetary policy instruments to mop up the excess liquidity and hence an increase in LIR.

Reserve Requirement ratio was not an important determinant of Bank lending rates at 1% significance level (P-values > 0.1). This implied that a one unit increase in reserve requirements will lead to a decrease in GDS by 0.00492 units. It was inferred to mean that Reserve Requirements have a negative and

insignificant impact on LIR in Kenya. The result is consistent with the works of Mohammad (2010), Somoye and Ilo (2009), Hancock and Passmore, (2006) and Buigut (2010).

A probable interpretation of these results is that Reserve Requirements are used as a means of the last result by the CBK in trying to arrest excess liquidity. The Reserve requirements makes the commercial banks have less liquid money for lending /loan purposes and as such will lead to an increase in the LIR. Further to this, the study found a negative relationship to this which was consistent with other works. A plausible explanation would be that the CBK hardly uses it as an MPC tool unless in instances of spiraling shilling depression and high bank lending rates and hence the negative and insignificant relationship to LIR.

Comparison of Findings with other Local Studies

This study sought to investigate the impact of Monetary Policy Instruments as drawn up by the Monetary Policy Committee of the Central Bank on Commercial Bank's Lending Interest Rates in Kenya. The study found that the Central Bank Rate (CBR) and Treasury Bill Rate (TBR) were both positive and significant monetary policy instruments that influenced bank lending interest rate (LIR) in a manner that advances the Monetary Policy Committee stance. The study however, found Reserve Requirements to be negative and insignificant as a monetary policy tool in helping the Monetary Policy Committee's cause.

The results from this study are supported by a study titled *"Bank Rate and the Transmission Mechanisms of Monetary Policy in Kenya"* done by (Mwega 2013), who was a member of the Monetary Policy Committee at the time. The study found that CBR and TBR as instruments frequently used by the CBK for monetary policy were effective but often with a lag of several months as opposed to immediate. The study found that an increase in the CBR, TBR and lending rates does not reduce private sector credit amounts until from the third month after the change.

This study results were also further supported by a study titled *"The choice of Optimal Monetary Policy Instruments for Kenya"* done by (Gichuki, Odour and Kosimbei 2012). Using time series data sets for the period 1994 to 2010 and an Error Correction Model the study established that both TBR and CBR rates resulted in minimal losses in output compared to Reserve Requirements/ Money when used as monetary policy instruments. The study was also seeking to see which among the two instruments; (TBR, CBR i.e. interest rates) and Reserve Requirements/Money when used individually or simultaneously were most effective. The study established that a combination of the instruments minimizes losses from equilibrium output better than the other two instruments taken independently. The study recommended that the CBK should adopt a pure interest rate instrument policy i.e. (CBR and TBR). It went further to suggest that there was need for the CBK to construct a monetary policy conditions index which would help in the implementation of a combination instrument policy.

Conclusion

The first objective of the study was to establish the extent to which discount window operations increase bank lending rates of commercial banks in Kenya. The variable was operationalized by use of CBR as a variable most suited to represent the discount window operations. The findings indicated that CBR rate has a positive and significant effect on Bank's Lending Interest rate. This implied an upward increase of the CBR will see the banks revise their Lending interest rates upwards, *ceterius paribus*.

The second objective of the study was to establish the influence of open market operations on commercial bank's lending rates in Kenya. The variable was operationalized by use of TBR as a variable most suited to represent the open market operations. The findings indicate that TBR had a positive and significant

effect on Bank's Lending Interest Rates. This implies that an increase in the TBR would signal an increase in the banks will further push holders of loans to default hence an increase in the non-performing loans.

The third objective of the study was to establish the effect of Reserve Requirements on Banks' Lending Interest Rates of commercial banks in Kenya. The objective was operationalized by use of RR ratio as a variable most suited to represent the discount window operation. The findings indicate that reserve requirement ratio was negative and insignificant in explaining the Lending Interest Rate in commercial banks. This implied that fluctuations in the ratio required by the CBK regarding commercial banks did not affect bank's LIR, this was elucidated by the fact that the CBK tends to use Reserve Requirement ratio as a measure of last resort in trying to arrest macroeconomic shocks as well as runaway depreciation of the shilling

Recommendation

The study sought to provide more information to the Central Bank, and Managers of commercial banks on the impact of the different monetary policy instruments/ tools as used by the Central Bank of Kenya. Following the conclusions drawn from the study findings, it is recommended that the Central Bank of Kenya should play a more active role in ensuring that they use the CBR and TBR as a first measure for trying to communicate its desired stance on Bank Lending Interest Rates (LIR) and maintain economic stability. The CBK through the monetary policy committee should also implement measures that act in concert such as reserve requirements coupled with the introduction of the CBR liquidity measures as it tries to arrest the liquidity risk in the market since the banking system is less sensitive to changes in CBR rates that are supposed to reflect the lending interest rates.

Suggestions for Further Research

The Impact of Monetary Policy Instruments on Bank Lending Interest rates is a research area where not much research has been carried out and also varying results have been published on the same in Kenya. As such, it would be a great area of research for scholars and other stakeholders alike.

Abstract

Article presents an executive summary of primary and secondary data on the situation of the economically active population, the unemployed in Slovakia, with an emphasis on educational structure. Consumer behavior affect the different personal characteristics such as sex, education, income, lifestyle, personal attitude of consumers. The high prices of goods and services, high prices for housing, low income and unemployment represent significant restrictions for the purchasing decisions the population of the Slovakia. All these and many other factors have an impact on economic growth and its impact on social well-being and quality of life. The article offers an analysis of the factors affecting the consumer decision making with regard to the educational structure of the population. The present text allows you to understand the importance of human resources in terms of the nature and importance of education and the need for support from the State in the field of employment.

Keywords: educational structure, economic activity of population, Slovak republic, unemployment.

Introduction

Human resources have traditionally been considered primarily with regard to the educational structure. Well-educated people able to work with information and knowledge are less threatened by unemployment and have higher wage ratings (Ježek, 2007). Mitríková (2008) defines the general concept of retail trade as a summary of all the activities related to the sale of products or the provision of services directly to end consumers. Retailers expressed some form of distribution, in which the consumer acquires a range of (goods) as a final consumer in order to meet the needs of retailers. When customers have to choose not only catalogue of goods and services, but also to the place of purchase, or sales. Consumers shop at those places where their purchase reaches a maximum efficiency with minimum effort (Lajčin, Frankovský, Štefko 2012; Mudrík, Fedorko, 2010). Localization is the process of site selection (of the region) for the particular socio-economic activity. Every region has certain resources and each activity is characterized by the same needs. The best location is where the resources are optimal for a given socio-economic activities. I tis therefore possible to agree with the view that the location is the most important topic of the examination with a focus on the use of space (Ježek et al., 2007). Similar themes are explored by the authors: Batistova (2013); Vavrek et al. (2014); Coad, Nielsen, Timmermans (2017); Fedorko, Kakalejčík (2015); Storey, David J. (2016).

Literature Review

Consumers make a substantial number of purchase decisions every day. These decision are being examined by companies to see consumers' behavior – what to buy, in what amounts and how often, when and why (Bartáková et al., 2007; Gburová, Bačík, 2014). Anyone who buys any goods or services is a consumer. A consumer is a unique entity with its own opinion which should be respected by any entity that wants to sell its product or maintain its customers (Hes et al., 2008). Consumer in making the

purchasing decision is influenced by a number of elements. External factors, respectively external have link to the environment in which the consumers live and the way they live. This group includes such determinants as culture in which an individual is born, the income, age and social status. Other important variables among consumers are their internal specifics that result from the different psychological characteristics such as personality traits, motivation or degree in consumer learning. These internal characteristics are called internal factors, respectively. They are psychological impact. External and internal factors of consumer behavior to interact and collectively shape the decision-making process on the consumption of goods and services (Richterová et al., 2015).

The primary factors in the decision making process of consumers are purchasing (awareness of the needs, evaluation of alternatives, product selection, after-shopping review usefulness) and consumption, which are mostly obvious and observable acts (Kita et al., 2005). The shopping behavior of consumers represents a vibrant interaction between people and the environment because it is containing emotions, cognition, action, through which people carry out exchanges, in order to satisfy your benefit (Richterová et al., 2005). Highly satisfied customers generally remain loyal, buy more goods, talk about the brand and its products in front of others, are less receptive to the brand's competitors and their prices, provide their ideas. Moreover, selling goods and providing services to loyal customers is cheaper since the whole purchasing process has become a routine for both sides (Kotler and Keller, 2013).

„The economic situation in the sectors and industries in Slovakia is not the same. Similarly, the economic situation is not identical in different regions and there are recorded the regional disparities, while the other EU countries compared with the Slovak Republic have also different economic results. In the current dynamic period is not possible to assess the economic level of countries and propose measures to improve the situation without taking account of these disparities. In general, we can define several factors that contribute to the quality of economic life and competitiveness of the country and have a decisive impact on them. The three most significant changes that have affected the nature, strength and performance of the national economy might include: the transformation from a centrally planned economy to a market economy, the integration of the Slovak Republic to the European Union and the implementation of structural reforms"(Kotulič et al., 2015). The Slovak Republic, at the time a candidate state for EU membership, participated in the meeting and received guidance for implementing economic policies promoting the inclusion of disadvantaged groups. Slovakia's response was to develop a set of policies and guidelines that addressed poverty by promoting employment, called the *2004-2006 National Action Plan on Social Inclusion* (NAPS). The NAPS seeks to address poverty by promoting independence in an attempt to reduce government expenditure on welfare. The central strategy is to assist individuals to become economically self-sufficient via engagement in the paid labor market. Following the perceived success of welfare-to-work programs in reducing expenditure on welfare in countries like the United States, Slovakia. Similarly sought to reduce its spending on welfare by requiring an individual to participate in the labor market in order to receive welfare benefits. (Gould & Parker Harris, 2017).

Methods and Methodology

The social expression of individual processes, i.e., economic activity of the population or unemployment in individual regions has led to significant differences and social inequalities, which in the previous homogeneous society are accepted inconsistently. Economically active inhabitants are a source of labor in the Slovak Republic, resulting in an increase in household consumption, a higher living standard of the population and, ultimately, a reduction in social inequalities in society. The following (Table 1) represents the sum of the economically active population from the point of view of the educational structure in Slovakia.

Table 1: Economically active population by education and sex in thous Persons (2012–2016)

The most frequent group of economically active population was represented by persons with secondary education with graduation, 54% (2016) of the total number of economically active, followed by University - Master graduates, 31.4% (2016). The share of University - PhD. degree was 1% of the total number of economically active.

Unemployed by education

Education is a priority in terms of securing positions in the market, the higher the income, the lower the possibility of job loss, or lower the degree of threat against long-term unemployment.

Table 2: Unemployed by education and sex in thous Persons (2012 - 2016)

Unemployment in education is the largest group of population with Secondary education with graduation, 43.40% (2016) of the total number of unemployed. Followed by basic education 33.15% (2016) and education on the University - Master degree, 28.6% (2016). As can be seen from the perspective of unemployment with Secondary education with graduation is critical and there are several reasons. Ignorance of foreign languages, no practice in the field, inability to present themselves on the labor market, unwillingness to travel for work, etc. From the point of view of Higher – Mater degree, there may be an inappropriate selection of study departments, which are in the market enough. Every year,

education at universities in Slovakia successfully completes more than 45,000 students and more than a quarter of them find themselves in employment offices.

The aim of the presented article was to fulfil the established goal, it means, an analysis of the differences in preferences, shopping habits within the purchasing process. The basic set is formed by the respondents divided according to the basic characteristics-from the education of the respondents. The object of research are consumers living in Eastern Slovakia (Prešov region). The significant sample-resource of the primary information-is formed by 418 respondents. The research was realized in November 2015 - January 2016. Respondent´s (consumers) answered in the form of closed questions in the questionnaire.

Primary data obtained were then processed in a statistical program Statistica. On the confirming or rejecting the established hypotheses were used methods Pearson Chí-square test and Pearson pivot coefficient. To achieve the objective we set out to research the following hypotheses:

H_1: Assume that the purchase of the consumers in the Presov region limits largely the amount of income (earnings) for consumers with lower levels of education.

Survey Results

Hypothesis 1 predicts that the consumer buying in the Presov region limits largely the amount of income (earnings) off consumers with lower levels of education. The survey results have shown that low income is one of the most obvious reasons for restrictions when buying consumers in supermarkets. Carried out a survey focused on educational inequality, which points out the differences in levels of education and study of the factors influencing purchases respondents to the limitations of the goods and services in supermarkets.

Hypothesis 1 predicts that the consumer buying in the Presov region limits largely the amount of income (earnings) off consumers with lower levels of education. The survey results have shown that low income is one of the most obvious reasons for restrictions when buying consumers in supermarkets. Carried out a survey focused on educational inequality, which points out the differences in levels of education and study of the factors influencing purchases respondents to the limitations of the goods and services in supermarkets.

Table 3: Factors of consumer decision making according to the educational inequality

	Please indicate which of the above mentioned factors are limiting you in your purchase in retail network							
education		a)	b)	c)	d)	e)	f)	
		No answer	The high prices of goods and services	Low income	High prices for housing	Unemploy-ment	Other	∑
	basic education	0,00%	28,57%	38,10%	4,76%	23,81%	4,76%	100,00%
	secondary education without maturity	6,12%	16,33%	36,73%	12,24%	28,57%	0,00%	100,00%

Source: SU SR (2016), own processing

From the survey we can assess that educational inequality refers to the differences in the levels of education achieved and factors affecting the purchase behavior of the respondents to the limitations. The resulting inequalities in education affect the employment and income of the people. The unemployment rate for respondents is concerned with lower levels of education than among respondents with a university degree.

H1: The level of significance ($\alpha = 0.05$), is less than what is that hypothesis (H0) may be rejected. The test revealed a statistically significant relationship.

Table 4: Chi-squared

	the value	df	p- the value
Pearson chi-squared	122,606	20	0

Source: own processing

Hypothesis 2 anticipates that the purchase of the consumers in the Presov region limits largely the amount of income (earnings) multiple consumers with higher age.

The results of the survey showed that respondents in all tested age structures for the most important reason the restrictions when buying in supermarkets are considered low income. Unemployment in shopping behavior restricts in particular 36.73% of respondents aged 18-30 years old, which may stem from the inability to work due to insufficient qualifications, professional experience and expertise. In the case of 32.98% of respondents aged 51-60 years reported as the most common factor in purchasing restrictions, high prices for housing (rent, energy, transport and other). The survey showed that 20% of respondents at the age of 61 years or more troubled by the high prices of goods and services in comparison with other age structures. At the same age as limiting factor when buying in supermarkets 30% of respondents said high prices for medication.

Conclusion

The high prices of goods and services, high housing prices, low income and unemployment are important indicators for the population and has a major impact on quality of life. A key indicator - employment in the examination of standards of living of the population is employed, which allows an individual to provide a higher standard of living. The results of the present article shows that in spite of the higher education it is not clear that an individual receives the coveted job, which will ensure him a better life. People should not hesitate to invest themselves, whether linguistic, or disciplining professional skills. The shopping decision making in supermarkets, affects a lot of other factors, such as: high prices of goods and services, housing, the lack of jobs in individual regions of Slovakia. That's why I need to be aware of the

importance of promoting the creation of new jobs with regard to Secondary education students with graduation and University-Master degree.

Effectiveness of Investment on the Example of Selected Woodworking Plant

Kornelia Polek-Duraj, Opole University of Techmology, Opole, Poland, k.polek-duraj@po.opole.pl

Abstract

Sawmilling industry in both the wood sector and Polish economy plays a special role. This is mainly due to the fact that it functions mainly due to natural and renewable domestic raw material base. This does not require relatively high energy requirements for wood processing. At the same time it has the opportunity to recover and dispose of wood waste. These elements largely represent the ecological nature of wood products, which is important in terms of achieving sustainable and sustainable development. Therefore, the need to invest in this industry is great. The article describes the reconstruction and expansion of a large sawmill located in the south-western part of Poland. An attempt was also made to show the effectiveness of the changes.

Keywords: sawmill industry, investment, efficiency

Introduction

Polish woodworking industry in the national economy occupies an important place being one of its pillars. Its share of national production is approximately 10% on average. Much of this is influenced by its production based on rich and renewable domestic raw material base, an export volume and positive balance in foreign wood products trade. In addition, about 40% of wood material from Polish forests in various forms (especially construction timber) is sent abroad. Export of Polish wood ranging from furniture, sawn wood, veneer, plywood, windows and doors, round wood and unprocessed wood in the structure of Polish exports accounts for almost 10% and 2% of domestic gross domestic product (GDP)[1]. Currently the best results are achieved on the sale of woodwork to the European Union countries. In 2016, second year in a row, Poland was the leader of woodwork exports, outstripping Germany by over 2%[2].

Sawmilling industry is an area of generally low involvement of foreign companies in Poland. Low interest of foreign investors in that particular industry has a number of reasons, among the most serious is mentioned the process of privatization of the industry. Woodworking plants belonging to the State Treasury were subjected to direct privatization in which participated employees of these entities. In many cases, this method of ownership transformation was not effective (among others due to the lack of sufficient funds of new owners and lack of organizational and marketing skills), therefore many of them failed to find themselves in new economic conditions.

The paper presents the role of sawmill industry in the woodworking industry and the importance of acquisition of a plant by a foreign investor in terms of improving its efficiency.

Polish Sawmilling Industry as a Particular Branch of the Woodworking Industry

The woodworking industry[3] despite its unusual characteristics resulting from both internal and external factors (e.g. poor working conditions, obsolete machines, lack of major foreign investment) plays an important role in the national economy. Its particular role stems mainly from the fact that it operates on natural, yet renewable domestic raw material base (according to the Central Statistical Office, the forest area in Poland was 9196.9 thousand hectares at the end of 2015, corresponding to the forest cover of 29.4% of the country, which allows to obtain approximately 25-26 million m^3 of wood per year, while retaining other non-production functions of forest4). Therefore, this branch of industry does not require relatively large demand for the energy needed to process the wood. At the same time, it has the opportunity to recover and recycle wood waste. These elements fundamentally determine the ecological character of the woodworking industry, being important in terms of sustainable development**.**

Every year, Polish forests supply large quantities of wood in the form of round wood to the domestic market. Raw material is divided into several main assortment groups, purchased by separate branches of the wood industry, among them the sawmill industry[5] dominates, it has the largest share in these purchases (about 38% of total harvest), the value of which is majority of wood sales in Poland realized by the State Forests National Forest Holding (more than 50%). After 2009, the dynamics of marketed production is also significant, despite many unfavorable factors in sawmill industry (Table 1). The dynamics of average employment in sawmill industry (Table 2), which does not differ significantly from the dynamics of total industry and industrial processing, remains important.

Table 1: Dynamics of marketed production in the woodworking industry on the background of the industry in total in the years 2008-2015

[1] sawmill industry as sawmill products (according to PKD section C 16.1)

Sawmilling industry is a peculiar market. There are a number of problems, ranging from financial ones (usually lack of financial liquidity allowing for necessary investments and upgrades, including improvements in work mainly it involves unpopular material work environment, lack of full mechanization of machining operations and obsolete machine park) to non-compliance with OSH regulations of employers and employees (employers do not always attach due importance to occupational safety training, workplace hazards and awareness of the need to use personal protective equipment, but employees often do not see the need for e.g. usage of personal protective equipment).

Economic changes introduced in the 1990s, affected the entire woodworking industry, triggered complete reorganization of the sawmill industry in Poland. Until then, the market was dominated by approximately thirty powerful enterprises, grouping a dozen of wood processing plants located in one voivodeship, and their centralized management did not allow for rational economy since the funds earned by profitable plants, instead of increasing their production and investment capacity and introducing required modernization, were directed to plants less profitable or even unprofitable, which did not bring visible benefits to either party. After closure of the centrally planned economy, enterprise from woodworking industry were left unaided and failed to introduce reforms and lift the burden of restructuring (most of them were on the verge of bankruptcy or collapsed) (Polek 2004:339). Currently operating sawmills are plants with limited production volume (200-300 m^3 per month). Most of them were based on plants previously run by wood industry or other rural production sites (e.g. old brickworks). These are generally small and medium-sized establishments, mainly located in villages and small towns. According to the National Business Registry Number (REGON), the number of entities operating in this sector following the privatization period (late 1990s) first fell sharply and then increased more than 12% and has remained relatively stable for a couple of years (about 8600-8700). At present, the actual number of sawmills operating in the market is steadily stable, oscillating within 1200-1400, while the basic core is about 700 companies (Polek-Duraj 2016:59). They are mainly small entities, only 3% of them employ more than 49 people. A small percentage are large corporations. The majority of sawmills are located in the northern and western part of Poland. The Opole region has relatively weak position in terms of the number of operators from this particular branch of industry, and the number of companies is the lowest in the country. This situation of Polish sawmills, is caused, inter alia, by the economic difficulties of plants, high costs generated by the purchase of wood (the cost of raw materials in the structure of generic costs is about 55%), the specificity of the product, the level of export, low possibility of self-financing of investments and pursuing required modernization and low interest of foreign capital in this sector.

The main supplier of wood in the Polish market is the State Forests National Forest Holding, under the control of which is the 90% of harvested in the country timber[6], so that it has a significant effect on the structure of the wood market primarily by shaping the supply of material. The final price, since 2006, is set on the E - drewno portal, where the wood from forest districts across Poland is being sold. In this form, sale consists of three stages. In the first two stages, forest districts offer a particular type of wood with fixed minimum price below which it cannot be sold, and the entities place orders giving their price offer. Here, while dividing the timber, the history of the purchase of raw material is taken into consideration, which means that the best chance for the purchase have plants operating for some time on the market, already benefiting from this form of purchase. The situation is different in the third stage of the electronic auction, where one can buy timber that have not been sold yet. Here, the price fixed during the auction determines who would be the buyer. Consequently, the price at the third stage is much higher than in the first and second stage, but anyone who wants to purchase timber, and has adequate resources, can do it. The accepted form of sale significantly differs from the current practice, which is characterized by a specific allocation, at prices set by the State Forests National Forest Holding. Is it better? It is difficult to say, it can only be inferred that it is not a factor encouraging new entrants to this market.

The sawmilling industry in the wood processing chain occupies a special place. This is due to the fact that the first and basic raw material unit is wood. The product of sawmill industry is an indispensable base for the production of other industries (e.g. construction business, furniture industry). It is also worth noting that by-products of sawmills are of great importance in the country's energy balance as they are a source of renewable energy (e.g. in the combination of electricity or heat in the power industry). This industry does not require high-skilled workers. The main characteristic of sawmilling is its location mainly in small towns or villages near forests. Most of them are small and medium-sized businesses (often family businesses) with low timber processing potential. It is worth noting, however, that the sawmill industry is functioning quite steadily, yet relatively intensively.

In Poland, as in other European countries, woodworking workers and furniture carpenters are listed among the occupations with highest risk of work accidents. The greatest number of accidents is recorded while operating the circular saw, planer and milling machines. Major injuries resulting from accidents at these posts are: hand and abdominal injuries.

Characteristics of the wood industry plant in Murow in the aspect of foreign investment

The wood industry plant in Murow was a part of a joint-stock company of the Opole Wood Industry OPDREW S.A until December 2006. The company was established on the basis of an entity that had been established on January 1, 1950 by the then Minister of Forestry and Wood Industry by separating wood processing plants from the economic organization of the State Forests. From the very beginning the plant was one of the largest sawmills in Poland. Its annual processing reached 150,000 m^3 of wood in the best years. It was the second largest factory in Poland.

Throughout its operation, the plant was focused on modernizing production processes, increasing labor productivity and economic efficiency to the extent adequate to capital and organizational capacity of its owners and on improving working conditions.

The period of economic transformation forced the company to take measures to adapt its business to market economy rules. These actions were completed with legal liquidation of the enterprise. In April 1997, its assets, i.e. 14 plants (one of the most modern and largest sawmills in Poland - in Murow) were taken over from the state treasury by the Opole Wood Industry Joint Stock Company "OPDREW" for lease. Unfortunately, this was not a successful transaction, because less than four years later the company declared bankruptcy. This largely contributed to the strategic investor who used the company for its own purposes, rarely coinciding with the business interest. After the

[6] Lasy Państwowe http://www.lasy.gov.pl/pl/drewno/skad-sie-bierze-drewno [19.08.20017]

bankruptcy announcement, all sawmills were put up for sale. The sawmill in Murow was in the best situation as it was bought from the receiver by Zakład Przemysłu Drzewnego Sp. z o.o in 2002. Thanks to that it functioned without unnecessary downtime caused by the bankruptcy of the previous company. The purpose of economic activity was production of sawn timber (i.e. floors, soffits, construction timber, paneling, balcony boards, garden system components, etc.). Annually, approximately 45,000m^3 of sawmill wood was processed there. The contractors of the plant, apart from individual customers, were also foreign companies (German, Belgian, Dutch). Unfortunately, the following years showed that it did not function well enough to be able to develop properly and bring expected profits. This was due to the lack of adequate financial liquidity enabling necessary modernization of the plant and new investments. Consequently, the company's management decided to take an offer of Stora Enso, a Swedish-Finnish company, which decided to invest in the plant's modernization and thus promote the development of the regional industry.

Foreign investments in the sawmill industry (case study)

The first and so far the only foreign investment in the Opole region (in this region, it mainly invests in the production of construction materials, food products, chemicals and plastic products (Bernat 2016:47) in the sawmill industry took place in December 2006. At that time Stora Enso finalized the purchase of the wood industry plant in Murow (it acquired 100% of shares). Thus the Murow plant became part of the Stora Enso Timber Central European Production Group, including sawmills in Austria, the Czech Republic, Germany and Poland. The unit consists of 27 wood processing plants and is one of the leaders in the world market of wood processing.

Stora Enso Corporation is an integrated wood processing company that produces paper, industrial packaging and wood products. Its products are of the highest quality produced in accordance with international standards. Currently it is the second largest producer of lumber and timber products in the world. Stora Enso group employs approx. 29.000 people in more than 35 countries on five continents[7]. The company's annual production capacity is 13.1 million tons of paper and 7.5 million cubic meters of sawed wooden products.

The choice to invest in sawmill in Poland was not accidental, as the area of our country is characterized by very good wood material and high quality sawmill wood. The experience of the Swedish-Finnish consortium on many markets and the capital base provide great opportunities for the development of the company.

The new investor has committed to carry out modernization of the plant and its further development. It is especially important for the local community of the municipality of Murów where unemployment reaches 19% and is higher than average in the region, with a low level of industrialization of the municipality.

Characteristics of the Project and Its Benefits

The purpose of the company's management is to create a modern wood processing facility in Murow, which will significantly improve the economic situation not only in the district but also throughout the region. Professionally functioning sawmill will not only provide jobs, but will also be a chance of development for a number of transport companies involved in logging and service. In addition, activities designed to improve working conditions are planned. For this purpose, the plant was redeveloped in autumn 2014. The investment costed 27 million Euro and was the largest sawmilling industry in Poland. The official opening after the modernization took place in September 2016.

As part of undertaken measures, new technology halls, social rooms and machines were designed. The sawmill site has been hardened with new bitumen and concrete slabs. All the actions have been

[7]http://www.grupalokalna.pl/wiadomosci/tartak-w-murowie-na-swiatowym-poziomie [20.08.2017]

carried out using the latest technical solutions, taking into account both high quality requirements as well as OSH and environmental protection rules. Among the most serious changes are the following:

1. Instalment of the new line woodworking with sorting function with a length of 400.
2. Creation of a new line for the processing of soft wood.
3. Construction of a new workshop, boiler room and transformer station.
4. Liquidation of re-sorting hall and building new sorting hall.
5. Setting modern planer hall, further processing hall and warehouse.
6. Introducing a modern system of transport and storage of sawdust.
7. Transfer of administrative work to a modern office.
8. Change of land infrastructure – i.e. from the remaining material of the site's equalization, the embankment was docked at the border with neighboring plots acting as a limitation of visibility for outsiders.
9. Building of a car park in the vicinity of a new office for customers and employees, and entry to the premises equipped with a toll booth.
10. Focus on periodic training of workers in the field of health and safety regulations, which were previously not carried out regularly and often in an incomprehensible way, which did not fulfill its task. The company attaches great importance also to the use of protective equipment necessary for the various positions and compliance with working time.
11. The possibility for the employees to participate in various job trainings and free courses of German or English (foremen and administrative staff of all departments) in order to improve communication with the management from Austrian and foreign clients.
12. The annual family festival at the end of the vacation, a so-called Family Day.

All production facilities are equipped with automated lines imported among other from Austria. Most of the work is done by a device that is supervised by a person.

It is also worth emphasizing that all implemented solutions are environmentally neutral, which means that they do not adversely affect both protected and endangered habitats and species of plants and animals, and at the same they do not impact on functioning of refuge under Natura 2000 in the Opole Voivodeship[8].

In coming years the sawmill in Murow is to be responsible for the accounting of Stora Enso Timber Central European Production Group.

The company's head of management, when deciding to modernize the plant, assumed primarily a significant improvement in its functioning, both in production, sales and working conditions. The official opening of the plant after implementation of changes was held in September 2016.

In 2016, in a reference plant a number of surveys were conducted and company's statistics on occupational hazards, accidents, number of finished goods, employee productivity and efficiency were analyzed. The purpose of the survey was to acquire the respondents' opinions on the working conditions, their motivation, their involvement and their perception of the organizational culture of the company. 85 people participated in the survey, which accounted for 50.3% of the total crew. Respondents were randomly selected.

Based on the analysis of surveys and statistical data it can be concluded that since beginning of 2007 when the implementation of the new rules of operation and modernization works were carried, significant changes have been noted both for the organization and its crew. Among the favorable changes are the following:

1. Employment growth of 146% in relation to the number of employees at the time of purchase.
2. Improvement of working conditions (modernization of machines and tools, systematic training on occupational hazards, observance of working time, provision of personal protective equipment and awareness of their use).

[8] On the basis of the document of the company Information Card of the project "Reconstruction and expansion of sawmill in Murów" Murów 2016, p. 11

3. Decrease in the number of accidents at work (in 2007 - 10 accidents, 2008 - 6, 2009 - 8, 2010 - 5, 2011 - 4, 2012-2013 - 0, 2014 - 1, 2015 - 2, 2016-1)
4. Increased efficiency of business activity (increase of raw material purchase by 190%, which increased the abrasion by 150% - compared to 2007).
5. Improvement of the company's image (social activities for the local community e.g. financing construction of a sports hall - PLN 100.000, modernization of roads or repairs of municipal facilities).
6. Better competitiveness on both domestic and foreign markets (increase of sales of sawn timber by 129% - compared to 2007).
7. Workers' training trips to foreign institutions (Austria and Czech Republic).
8. Acquiring new customers (e.g. Chinese buyers - export of wood in containers) and deepening loyalty (preferential terms of sale for permanent, long-standing customers).
9. Daily, short information training, before start of work for the employees in the scope of basic principles of occupational health and safety.
10. Introduction of the so - called Observation Card, every employee can record noticed both proper and improper activities/actions from particular departments they work in.
11. Increase of motivation and employee engagement (opinion of 81% of respondents).
12. Higher level of organizational culture (opinion of 79% of respondents).
13. Improvement of interpersonal relations on the line employee- superior (opinion of 85% of respondents).
14. Resignation from work on a chord, while raising basic salaries, which according to employees (opinion of 80% of respondents) turned out to be more beneficial.
15. Decrease of municipality unemployment by 50%[9].
16. Increase in municipality tax revenues (estimated at 1 million).

It should also be noted that most of the employees of the sawmill are residents of the municipality and surrounding districts. The exception is a few people from Austria and the Czech Republic, who have been temporarily outsourced from their wood processing plants to streamline their work organization, for example in the area of modern wood shredding. Unlike many companies in the Opole region, the company has no problem with acquiring new employees (Kubiciel-Lodzinska 2017: 486) (last year it was 100 people). This may be due to relatively good working conditions (eg fixed and full-time jobs) and a high unemployment rate in the municipality (about 15%[10] at the regional average of 10.1% (Statistical Yearbook Opolskie Voivodship 2016) at the time of the sawmill expansion.

In general, 78% of the respondents expressed a positive opinion.to the question "How do you assess actions taken by the new owner in terms of production growth, employment, wage increases and improvement in working conditions?

In addition, the change of the owner directly influenced the change of the recipient to whom company's offer is addressed. Previously, they were mostly individual customers, now they are construction, development and service companies. This change is primarily a result of the strategy implemented in all countries where the plants are located and as a consequence of the scale of production carried out in the concern plants, the alignment of the machinery park to the customer. The resignation of individual customers creates opportunities for other small sawmills both in Murow and in the region.

The capital of the Murow plant exceeds PLN 8.5 million. It is the largest sawmill in Poland. The plant is equipped with modern, highly advanced production line. At present, it is capable of processing over 800,000 m^3 of wood per year. The foreign investor successively pursues the goal,

[9] On the basis of data obtained at the Municipality Office in Murow in April 2017

[10] On the basis of data obtained at the Municipality Office in Murow in April 2017

currently approx. 40 000 m^3 of wood per month is rubbed there. Compared to the pre-acquisition period (45 000 m^3 per year) it is a major step forward.

The fact that the investor is not a financial institution focused on further sales of shares, i.e. speculative goals, but a well-established company, with a long tradition and firm position on the European and global markets, is also a positive aspect of the acquisition.

Summary

The actions undertaken by Stora Enso so far, indicate that the objectives adopted by the new investor are progressively implemented (e.g. increase in employment rate, increased production, education and training, improvement of working conditions). The plant develops dynamically and is becoming increasingly competitive in the wood processing market.

The investment of the company, with years of experience in the wood processing industry, having a solid capital base, creates the conditions for a sawmill in Murow to become a viable link, thereby benefiting both the investor and the community (and not just local), leading to a decline in unemployment rate, an income growth and raise of living standards. These are significant premises since the plant is a particularly important place of work not only for the inhabitants of the municipality but also for the region of Opole, Kluczbork and Namysłów.

Expansion of the company, growth of employment and income are crucial factors in socio-economic development. The investment also provides prospects for decent work for young people, which in the near future may be reflected in the decline of intensive foreign labor migration of municipality inhabitants.

Foreign investments in the sawmill industry both at district and voivodship level are necessary, as due to an influx of capital the desired changes in the industry can be achieved (including an increase in economic efficiency, increase in use of modern techniques and technologies, protection and improvement of the natural environment and working conditions), which may be an incentive to increase its domestic and international competitiveness.

LAGs as a Way to Rural Area Development in the Region of South Bohemia

Ing. Petra Pártlová, Ph.D., Institute of Technology and Business Department of Management, České Budějovice, Czech Republic, e-mail: partlova@mail.vstecb.cz

Abstract

Local Action Groups are important for participating of the citizens, entrepreneurs and municipalities in the process of support for regional development. In the long term, they have proved that people living in Czech rural areas have never been indifferent to both the tradition and the future. That is why the local action groups are sometimes called “local action groups as a way of rural development”. The paper focuses on a closer look at the period of the past (2007-2013) in the region of South Bohemia. The author focused on the extent of support from South Bohemian LAGs from public funds through the Leader program to the development of rural municipalities. An evaluation of the functioning of the LAGs was carried out taking into account the period 2007-2013 and the prediction of the new programming period of 2014-2020. The research used several methods, including content analysis of important documents (especially different community-based strategies) followed by an analysis of the distribution of implemented projects within the scope of the LAG. In addition, a questionnaire survey was carried out. All the chief executives of LAGs in the region of South Bohemia were asked. The last method used interviews with experts and representatives of the South Bohemian Region and all sample LAGs.

Keywords: LAG, rural regions, local, LEADER, rural development

Introduction

The paper discusses common issues that are met by a majority of rural municipalities in the Czech Republic. In connection with this, it deals with the possibilities that these municipalities have encountered after the accession of our republic to the European Union. It is primarily focused on a possible solution of the problems of rural municipalities through using the financial support of the European funds and the national funds. The most important topic of the paper is a phenomenon called a "local action group", which is also included in the program document of the "Rural Development Program" (RDP), which is funded by the European Agricultural Fund for Rural Development (within the EU Common Policy). A Local Action Group is a kind of group of rural actors from different sectors (public, civil and private), whose aim is the joint development of the territory supported by the EU funds. The aim of this paper is to assess whether the local action group can really be important in dealing with the problems of rural municipalities on the example of a detailed analysis of the development of South Bohemian LAGs.

Literature Review

Rural areas generally involve a really diversified structure of interest groups with different importance and potential influence on the policy making process. It includes the rural population, municipalities, micro-regions and local action groups, agricultural and non-agricultural businesses, academic sphere, NGOs, etc... (Falkowski, 2013), (Pělucha, 2015). In the case of rural development, there are various forms of cooperation and different organizations that are supposed to deal with the problems of municipalities. These organizations include: Association for Rural Reconstruction, Union of Towns and Municipalities of the Czech Republic, Healthy Cities of the Czech Republic, The Czech National Rural

Observatory, National Network of Local Action Groups in the Czech Republic (Woods 2003; in Gorlach, Lošťák, Money 2008, Binek, Gavlasová, et al., 2012). The local action groups are in the EU within the LEADER method (see also Woods, 2011). By Larsson (2002; in Dargan, Shucksmith 2008), the original purpose of this Community initiative was to develop innovative ideas for a rural development model that would be useful in other areas, too. Ray (2000; in Marsden, Sonnino 2008) describes the LEADER as a programme that helps the socio-economic viability of the site and promotes innovative approaches to rural development at local level through the use of local resources, both physical and human.

A properly working local action group, which wants to fully exploit the potential of its territory, applies mainly the features of networking and cooperation (Faludi 2006), (Putnam, 1995) (Bosworth, 2015). It also uses new approaches and practices to guide the local development of the territory (Coleman, 1988). The aim of the local action groups is not making a profit as it is in case of the private sector, to but to create a synergy effect. It is therefore more difficult to assess the efficiency of LAGs compared to the private sector.

Material and Methods

The research was carried out in a sample of 17 active LAGs in the region of South Bohemia. The data were surveyed mainly from questionnaire surveys and managed interviews, data from the National Network of Local Action Groups of the Czech Republic (referred to as NN LAGS of the Czech Republic), individual LAGs and ministries of Agriculture and Local Development, data from questionnaire surveys, managed interviews and also from the author's archive.

In the paper, the sample included only such LAGs and projects meeting the binding criteria. The Local Action Group can only receive EU funding if it fulfils the criteria set out in the Development Program document. The most important criteria include:

(1) The LAG must establish appropriate partnerships between the private and the public sectors, where at least 50% of the participants must be from the private sphere (farmers, people from rural municipalities).

(2) The LAG must have mandatory bodies that are able to manage public funds, ensuring the implementation of the partnership for the implementation of the LEADER Strategic Plan.

(3) The area covered by the LEADER Strategic Plan must be coherent, offering sufficient critical mass of human, financial and economic resources to support a sustainable development strategy.

(4) LAG members must have either their permanent or legal address or business premises in the area of the LAG or be territorially competent in the territory.

(5) The LAG must present a quality LEADER Strategic Plan for a given programming period according to the binding outline, including the definition of the areas of support under the Rural Development Program.

(6) The LAG may use only one source of European Union funding for its eligible (acceptable) expenditure.

LAGs started in the Czech Republic in 2003. In the region of South Bohemia, the first LAGS were founded a year later, in 2004.

During this year, twelve local action groups were officially founded, a full 70 % of all LAGs that have been active so far in the region.

The following year, two local action groups were established and in 2006 a single LAG was founded. The next two years meant a difficult journey to win support for their operations from the Rural Development

Programme 2007–2013. However, even after this period, the efforts were made to expand the LEADER method in Czech Republic. The result of these efforts was the creation of a stimulating environment for the emergence of other local action groups. In the case of South Bohemia's, it meant a helping hand meant for establishing two other LAGs. In total, the number of ranged to 17.

The seventeen LAGs take a considerable part of the area of the region of South Bohemia. Similar situation applies for number of residents living in the area of LAGs in the region of South Bohemia. A total of 601 municipalities of the region are incorporated into LAGs. Due to the fact that there are 623 municipalities in the region of South Bohemia, it is obvious that LAGS comprise the vast majority of the region (see figure 1).

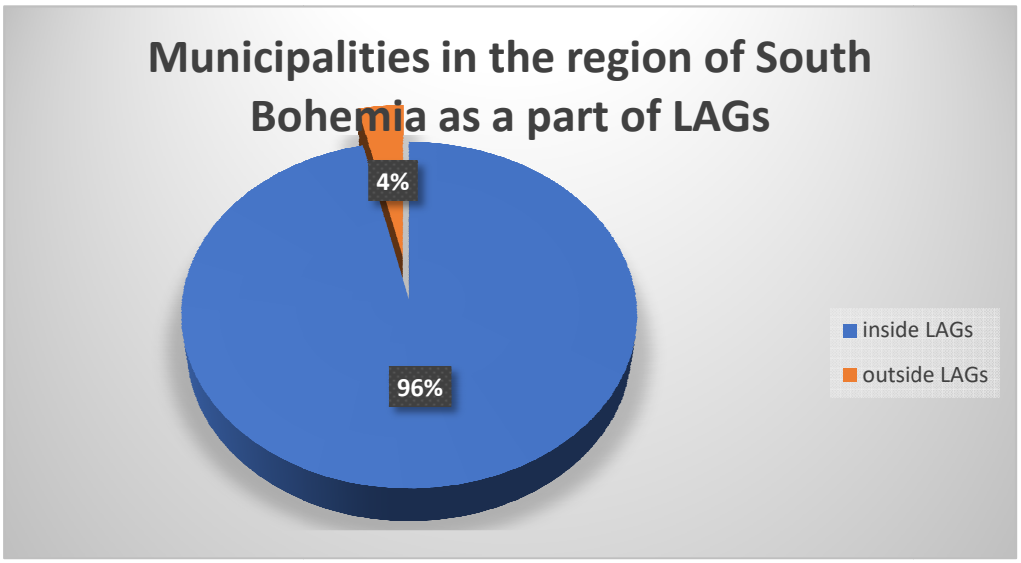

Fig. 1: Municipalities in the region of South Bohemia as a part of LAGs

The area of the above mentioned 601 municipalities is 9 402km2 (as of 1. 1. 2014). This is a major part of the South Bohemian region, as its total area was 10,057 km2 (CSO 2014).

Based on the data verification, it is possible to say that there was a total population of 455,626 inside the area of LAGs on January, 1st 2014. This was 71.6% of the total population of the region of South Bohemia. Moreover, after deduction of the 3 towns with the populations over 25,000 inhabitants, the LAGs cover 96.3% of the population. This means that local action groups occupy more than 90% of the region regarding its size, number of municipalities and the number of inhabitants (with respect to the limits of the RDP).

Results and Discussion

The beginnings of the LEADER method and its application

The majority of Czech LAGs started in 2004. In 2004, the first support programme of the LEADER method was designed. LEADER CR was approved by the Minister of Agriculture on December, 16th 2004 on the basis of the law on state budget of the Czech Republic for 2004. LEADER CR was created under the Ministry of Agriculture. The total of 294 098 000 CZK was allocated from its budget between 2004 and 2008. This represents the support of almost 59 million CZK for each year that could have been used by the LAGs. The programme was set up to support the local economy, service jobs, but also the cultural and social life, and thus helped alleviate the depopulation trends. It gave the opportunity to

support local action groups´ projects by consensus of the public, business and non-profit sectors considered important for the development of its territory.

During the programme period, the programme administered 201 applications for support to LAGS, including 31 in 2004, 41 in 2005, 64 in 2006 and 57 in 2007 and 8 in 2008. It meant support to 451 projects and 98.5% of the allocated budget. For LAGs, this meant the first experience with the distribution of funds in their regions. Based on the developmental strategies for the LAGs and after the conclusion of the implementation of delegated activities each local action group started to perform its administrative activities that set the transparent distribution of funds. It was necessary to ensure the receipt of applications from the area they controlled and to select those that would be supported. They were also included in the ex-ante, interim and ex post control of projects on the spot. It was the Leader Czech Republic, programme which was completely covered from national sources and the LAGs gained experience so essential to their future activities.

In the region of South Bohemia, there were nine active local action groups within the Leader CR Programme; thanks to whose activities a total of 70 projects could be supported. As can be seen, when counting the total number of 13 regions in the Czech Republic (Region Prague could not be supported due to the limits of the LEADER programme in the Czech Republic), such number of supported projects in the region of South Bohemia is undoubtedly an important success, also regarding the fact that this area is the second largest region.

Number Of Projects Implemented By Lags

Local Action Groups administered, implemented or participated in implementation of a large number of projects in the previous years (2007-2015, following the rule of N+2). The total of 1,313 as reported by the NN LAGs of the Czech Republic is not necessarily the total amount. The number of projects implemented under the measures of IV.1.2. and IV.2.1 (Local action group, Implementing local development strategy), can be exactly reported. The total number of other projects is more or less indicative. Based on data from National Network of Local Action Groups in the Czech Republic, it is highly likely that some LAGS did not report all the projects which they participated in. An example might be a large number micro-project annually organized by the National Rural Network together with the LAGs. As already mentioned, this difference would not be crucial for documenting the benefits of LAGs, because we focus primarily on the RDP 2007 - 2013. The complete list is presented in the figure below.

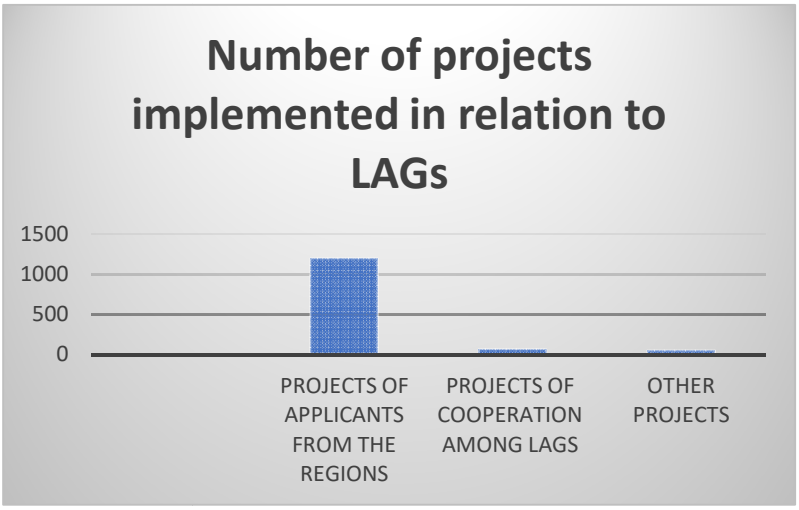

Fig. 2: Number of projects implemented in relation to LAGs

In the strategic plans of the LEADER, Local Action Groups supported 1,196 projects in total as submitted by regional applicants.

On this basis, it is necessary to calculate what amount of support to these projects and the average allocation for each project. In the case of IV.1.2 (Implementing local development strategy) measure under which LAGs´ calls were supported, an allocation of 413,719,892 CZK was used through the South Bohemian LAGs under the RDP 2007-2013. The average grant per a project amounted to more than 345,919 CZK. This means that most common support was granted to projects supported by less than a half a million CZK.

The total allocation only represents the expenditure on each project of the final applicant in the sum of all applicants in the South Bohemia's LAGs. However, if considering the overall benefit, therefore, in layman's terms how much money came into the region in general, we should add two amounts to this; at least. The first is the sum of the allocations to individual projects implemented in cooperation of the LAGs. It is a wide range of projects, whose aim was to establish ties not only to promote cooperation in South Bohemia but in the whole country, and sometimes internationally. In any case, you can legitimately claim that allocation used by the LAGs for these projects meant further support of the area, as the results of the projects might have been the costs for suppliers or directly the purchase of less expensive assets. Similarly, it is also possible to consider the case of expenditure on measures IV.1.1 (IV.1.1. Local action group). Within this measure, the Local Action Groups were reimbursed for expenses on their activities. In the period 2007 - 2013 100% of eligible expenditure of LAGs was bailed out under the RDP. As the name suggests, they were also some of the ineligible expenses that were not bailed out. These expenditures to the benefit of South Bohemia are also included. The only thing omitted are the resources used by the LAGs for Other projects and it is precisely for this reason that it is impossible to determine exactly how many of these allocations were actually brought by LAGs, not only involved in the effort to obtain them. Ultimately, the total amount of funds was 547,230,158 CZK.

Discussion

In average, more than 91 million CZK were added to the budget of South Bohemia due to the Lags´ activities in 2007-2013. The financial support was used to many issues within the RDP 2007-2013, axes I-III. It was possible to support agricultural and forestry enterprises, but also the development of

communities and improving their civic amenities, education, tourism and, ultimately, to draw funds for rescuing the cultural heritage of the country. As revealed, it is evident that very important areas of rural life were supported. The LAGs have contributed to the improvement of villages and small towns, but also to the development of business, in agriculture, forestry, tourism and elsewhere.

The contribution of South Bohemian LAGs to their region and is basically a higher sum than what the region used to ensure the allocation of the Rural Renewal Programme (hereinafter RRP of South Bohemia). This grant program was created in the South Bohemian region following previous village renewal program as approved by the Government of the Czech Republic on 29th May 1991 and by the Czech Government Resolution dated November 11th, 1998, no. 730.) The above-mentioned statement is based on comparison with the published costs of the RRP of South Bohemia. See the table for details.

Table 1: Real expenditures in RRP of South Bohemia (CZK)

Real expenditures in RRP of South Bohemia (CZK)							
2008	2009	2010	2011	2012	2013	2014	2015
67 740 833	70 732 744	77 770 245	84 759 706	83 935 700	89 339 605	91 774 136	90 157 294

Source: Czech Statistical Office, own processing

To make it complete, we should say, that the RRP of South Bohemia is not is the only form of support used for the development of the South Bohemian countryside.

Conclusion

Local action groups have shown a direct connection with the development of the South Bohemian rural area in the implementation of all their projects. All these projects amounting to about CZK 0.5 billion have played an important role in rural development, but also in other areas such as the development of SMEs in the rural area, but also the development of tourism, significantly influencing the whole region.

As reported by the research, it is primarily clear that the successful implementation of the community-led local development strategies is particularly crucial for the LAGs. Such activity should bring the greatest amount of financial resources (up to CZK 1.5 billion) for the development of the region of South Bohemia in the next few years.

As the new programming period means a significant increase of the complexity of the process of distribution of resources to the regions, it is very useful to maintain and deepen the cooperation of all active LAGs both in region of South Bohemia, and nationally.

Working together and sharing the experience is a possible prerequisite for smooth functioning of the LAGs. Otherwise, the LAG would experience a significant reduction of resources for rural development and the threat to their very existence. LAG cooperation is also a guarantee of a stronger negotiating position for the LEADER method and LAGs in general. The negotiating position is absolutely crucial for the future of the LEADER in the Czech Republic.

Cooperation with the South Bohemian Region is proved to be truly crucial regarding the South Bohemian LAGs, being a very important synergic element for the development of the region of South Bohemia.

In addition to its core mission of intermediary agencies, the LAGs have shown that they also have the ability of a broad creative cooperation and the effort to maximize support for the development of the

whole South Bohemia. This cooperation needs to be further developed, including a possible extension of LAGs´ activities (small subsidy title to local and regional cultural events and community development, conceptual support for education, etc.). The LAGs can also provide the region with a much-needed information service on the state of their territory free of charge because they have fairly accurate statistics on their territory. The results show that LAGs are a very important element of rural development and it is the most desirable to keep them in operation.

Abstract

The article substantiates that development of forest complex of the Russian economy is not possible without implementation of its structural reform and emphasizes diversification of forestry as the most important sectoral segment. An assessment of the level of diversification of the most important areas of forest complex made it possible to draw a conclusion about low level of its diversification. It has been established that woodworking and deep wood processing sectors are characterized by high diversification, logging is distinguished by specialization with delayed diversification, and forestry is a low diversified branch. The prerequisites for diversification of forest complex are developed, including: disproportions in the development of technological chain - forestry-logging - woodworking; technological, territorial and economic disconnection of forestry, logging and processing enterprises and industries; infrastructure and economic barriers; low level of development of science and industrial innovation at all stages of technologically related industries. The specific nature of diversification in forestry complex is in incompleteness of the processes of horizontal integration in forestry. It is determined that diversification in forestry reduces the time of cultivation of target timber and reduces costs of growing forest. Positive direction of diversification in the country's forestry complex is creation of industrial forest plantations on forest lands.

Keywords: diversification, forest complex, diversification index, priority strategies

Introduction

Diversification is an important part of the structure of modern market economy, which has a significant impact on the division of labor, competition and even the efficiency of production in the industry segments. In the most general sense, diversification is associated with expansion of variety and modifications of products for the most complete satisfaction of the needs of consumers [1].

The issues of diversification of enterprises and industries have a long history. Kenneth Andrews was one of the first in 1951 who formulated the concept of diversification as an extension of nomenclature of goods produced by individual enterprises and associations [2]. A number of studies have being conducted in developed countries to explain the relationship between diversification strategies and organization effectiveness [3, 4].

Questions about the need and benefits of diversification for sectors and economies remain not fully understood [5]. The researchers are unequal in the assessment of diversification and its effectiveness [6, 7].
At the same time, statements about the need for diversification in industries and complexes are not always justified, primarily because of the lack of theoretical and practical research base of the process of diversification itself [8]. Considering diversification as a development mechanism, Pablo de Andrés (2017) notes that not only the increase in assets, but also new growth opportunities are positive ones [9].
Understanding the fact that development of sectors and complexes of the Russian economy is not possible without implementation of their structural reform in the interests of improving social and

economic indicators of the development of society as a whole, allows us to consider diversification as one of the factors contributing to the achievement of this goal.

Moreover, scientific community has a unity of opinions on diversification as a strategic alternative to the development of an economic entity having its own purpose and objectives [10, 11]. If, for the enterprise, the strategic goal of diversification can be connected with increase in incomes, then, for sectors and complexes of the economy, it is aimed at ensuring their competitiveness in the regions and even countries, and its achievement is possible by coordinated implementation of a set of tasks, interrelated in terms, resources and results.

The type of diversification strategy depends on specific nature of the activity and involved resources. At the same time, most of the problems of industries and complexes of the national economy in the context of their diversification are reflected in the state of enterprises. Russian forest complex, which is included in the list of eight major industrial complexes of the country, is not an exception.

Methods

In the theory of economic analysis, there is a system of quantitative and qualitative indicators that allow one to assess the level of economic concentration: market share, concentration ratio, Herfindahl-Hirschman index, Lind coefficient, Lerner's index and others. Each of these indicators has certain advantages and disadvantages, which are described in the economic literature. To estimate the level of diversification, value, which is converse to the concentration coefficient, Herfindahl-Hirschman index was used.

Herfindahl-Hirschman index was defined as the sum of the squares of the sales shares of each enterprise in the industry:

$$HHI = S^2_1 + S^2_2 \ldots + \ldots S^2_n \quad (1)$$

S_1, S_2 — company's sales in the industry expressed as percentage, defined as the ratio of sales to the volume of all sales in the industry.

$$C_{div} = \frac{1}{HHI} \quad (2)$$

The values of determination coefficient may be within the limits:

$$0 < C_{div} < 1 \quad (3)$$

At the same time, the higher its value, the higher the level of diversification in forest sector, the more uniform development can be seen in the different sectors of forest complex. Indices of sectoral diversification were calculated by us for 260 production enterprises of Russian forest complex.

Results and Discussion

Forest complex is an integrated system of forestry, woodworking, pulp and paper and wood chemical industry, machine building and other industries.

The activities of branches of forest complex of the Russian Federation are based on the use of renewable natural resource - forest, and all other industries, linked by an unbroken technological chain, use related technologies, materials and wood raw materials. At the same time, due to low degree of development of production facilities for deep processing of timber, the activities of forest complex do not currently meet economic interests of the state as the owner of forest fund. The share of forestry enterprises accounts for 1.7% of the gross output of the Russian economy, less than 3% of industrial output, and 2.1% of foreign currency earnings from Russian exports.

Diversification leads to better use of material and intangible resources of the enterprise, including better use through synergy. At the same time, diversification, although it reduces the risk by eliminating dependence of enterprise on any single product or market, it increases it, since there is a risk which is typical only for diversification.

Then, considering diversification within forest complex, understanding of the necessity of restructuring all the industries entering into it should become the starting point. Horizontal diversification is widely represented in forest complex and implies growth in existing market due to new products requiring new technology different from that is used now and based on the integrated use of wood raw materials and recycling. Vertical diversification, involving expansion and branching of components, consists in building a complete production chain of already existing "product" (Fig.1).

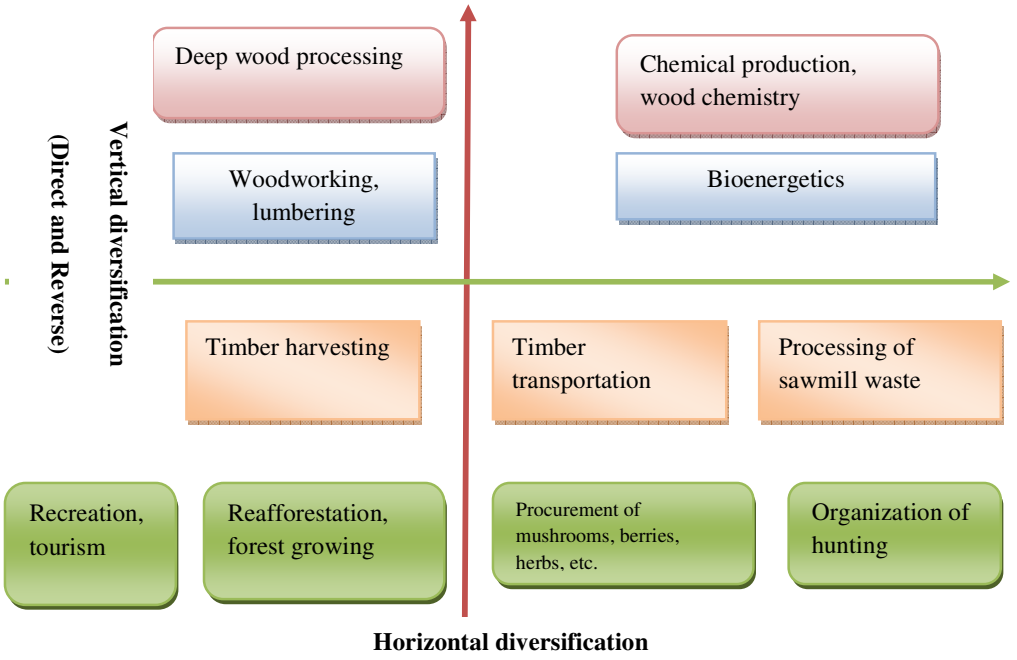

Fig. 1: Types and forms of diversification in forest complex

In total, there are 165 pulp and paper mills in Russia, 10-15 of them can be considered large - and 15 forestry concerns. The pulp and paper industry in Russia has a pronounced export orientation. More than 80% of the produced market pulp and about 50% of paper and cardboard are supplied to the foreign market. The production of pulp, paper and paperboard is limited to low volumes of logging. It should be noted that their specialization played a huge role in the crisis of the Russian pulp and paper industry in the mid-1990s. In the light of the shrinking demand for paper, greater use of diversification strategies is needed.

Using the coefficient of diversification, it is possible to estimate the retrospective dynamics of the change in the specific structure of production in forest complex of the country, by calculating it for each considered year. An assessment of the level of diversification of the most important areas of forest complex made it possible to draw a conclusion about the low level of diversification of forest complex in Russia (Fig.2).

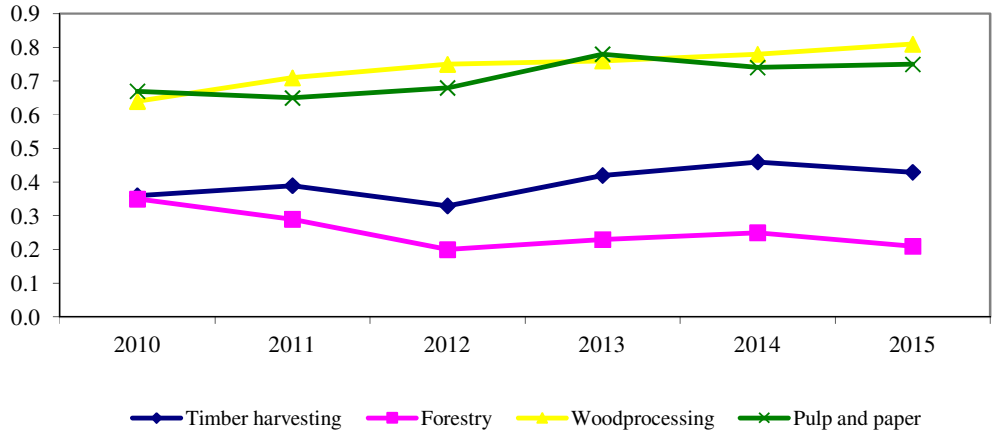

Fig. 2 : Level of diversification in forest sector

It can be seen from the diagram that for the period from 2010 to 2015, the majority of enterprises in forest sector have increased the level of diversification of production structure. In this case, we can distinguish two main trends of sectoral diversification:

1) High degree of diversification is characteristic for the sphere of wood processing and deep processing of wood. First of all, this is deepening of territorial division of labor, increase in assortment groups, and creation of new industries and diversification of existing activities. Such a mechanism of diversification has less impact on risks, profitability and financial stability of enterprises. Creation of effective structure of enterprises of deep processing of wood in the form of vertically integrated structures is one of the measures for removing forest sector from crisis, mobilizing resource potential of enterprises.

2) Harvesting sector is distinguished by specialization and concentration of industries. The analysis of indicators characterizing the work of logging enterprises, presented in Table 1, let us to make a conclusion.

Table 1: The main performance indicators of harvesting enterprises

	2010	**2011**	**2012**	**2013**	**2014**	**2015**
Number of organizations (at the end of the year) [1)], thousand.	15.6	13.6	12.2	11.4	10.6	10.2
Average annual number of employees [2)], thousand people	156.6	144.4	134.3	119.2	107.1	103.4
Balanced financial result (profit less loss)[3)], million rubles.	-5420	-3769	-3818	-8465	-17652	-6591
Profitability of products (work, services) [3)], percent	-0.9	-0.6	-2.8	-3.6	-0.8	4.2
Production of untreated wood, million dense m^3	117.3	122.7	121.8	119.8	123.4	126.7

Firstly, this type of activity is characterized by a constant decline in the number of enterprises. Secondly, there is a decline in the production of forest resources. If growth took place until 2011, on average by 4% annually, then from 2012 there is a decrease in this indicator. Third, there is a decrease in the number of people employed in the forest business. Moreover, since 2005, by 2014, this figure has decreased in 5 times. Fourth, the share of unprofitable enterprises in harvesting (logging) industry makes up more than 50% of the total. In our opinion, the typical reasons of lag behind of Russian forest complex in terms of diversification are:

Firstly, disproportion in the development of technological chain - forestry-logging - woodworking;
Secondly, technological, territorial and economic disconnection of forestry, logging and processing enterprises and industries;

Thirdly, infrastructure and economic barriers, in the absence of support for basic production;
A significant part of the timber stock is located in remote, inaccessible areas, with undeveloped or absent transport infrastructure. For one thousand km^2 forests in Russia there are only 1.2 km of forest roads [15]. Weakly developed production and road transport infrastructure limits the possibilities for integrated and complete development of operational forests.

Fourthly, low level of development of science and innovation at all stages of technologically related industries.

In relation to other branches, logging industry lags behind in terms of diversification, in spite of the fact that 35% of logging enterprises are vertically integrated holdings integrated under the principle of vertical diversification. Vertical diversification was typical for forestry enterprises, in 1990-2000.Logging companies proved to be objects of accession and takeover by the producers of final products - pulp and paper mills and woodworking enterprises, which act as initiators and leaders of integration.

3) Diversification of forestry is characterized by low level of development. The total forest area in Russia is 1073.4 million hectares, while 20.7% are leased to enterprises. The main type of forest use is logging, with 31 to 135 thousand hectares of forest land annually without reforestation, which creates an imbalance in the forestry of the country [12]. The development of multipurpose forest management, the transition to the reproduction of forests on the basis of plantation afforestation is the main directions of diversification in forestry.

In recent years, diversification has become a strategy of competition among forestry enterprises primarily with foreign producers in the direction of reducing dependence on purchased raw materials and equipment. [13] The specific nature of diversification in forest complex lies in the incompleteness of horizontal integration processes in forestry.

The low level of diversification in forestry is associated with features of forestry production, its high labor intensity, riskiness due to the length of forest growing processes. In this regard, the goal of diversification is transition to technologies that allow shortening the period of growing timber as a whole, or its target assortments.

Diversification reduces the time of target wood growing and reduces the costs of forest growing and therefore makes sense for enterprises. Positive direction of diversification in the country's forest complex is creation of industrial forest plantations on forest lands [14].

Conclusion

Forest complex of Russia has trends of lagging behind and disproportions in the development of industries and interprises. Considering forest complex, it is possible to single out a number of targets for diversification:

1) Elimination of disproportions in the development of forest complex areas on the basis of balance of disposal and reproduction of forests;
2) Increase of capacity utilization at the enterprises of deep processing of wood;
3) Increase of efficiency of use of forest fund plots;
4) Access to new commodity markets, without making harm to ecosystems;
5) Increase in the number of enterprises engaged in forestry;
6) Growth of investment attractiveness of forest business with industry risks reduction;
7) Decrease in the cost price of production due to effective logistics;

8) Transition to new resource-saving technologies and integrated use of raw materials in conditions of increasing wood deficit.
Key directions of diversification of activities in forest complex:
- Horizontal diversification (logging - integrated waste treatment);
- Vertical diversification - logging and woodworking, or logging and forestry.

Dividend Policy of Russian Companies at the Present Stage

Lukasevich Igor, Doctor of Economics, Professor, Financial University under the Government of the Russian Federation, Russian Federation, Moscow, e-mail: lukas1963@yandex.ru

Sukhorukova Daria, Lecturer, Financial University under the Government of the Russian Federation, Moscow, Russian Federation, e-mail: DVSuhorukova@fa.ru

Abstract

The article considers main theoretical and practical aspects of the dividend policy in Russian companies in the post-crisis period as well as the peculiarities of its implementation in modern conditions. The research contains the results of analysis of more than 1000 Russian companies for the period 2009-2015, whose shares are traded on the MICEX. We have singled out the key factors that influence the dividend policy in Russia and given a description of the main stages of its development.

Keywords: dividend policy, dividend analysis, post-crisis period

Introduction

The maximization of business value and its value to owners is the main goal of management. Therefore, it is not surprising that financial relationships with owners, whether it is a sole proprietor or millions of shareholders of a large corporation, have a significant impact on the development strategy of any firm. In economic practice the adoption of management decisions in this area is carried out within the framework of the dividend policy.

Theoretical aspects of dividend policy are quite various and complex, however, the following questions are considered to be the main ones: do the decisions on payments to owners affect the firm's value and what should their optimal value be? Despite numerous studies in this field abroad these issues remain the subject of debate among scientists and practitioners: Lintner (1956), Miller et al (1961, 1985), Fama et al (1968), Ofer et al (1987), Boeheme et al (2002).

This article will consider the main theoretical and practical aspects of the dividend policy of Russian companies, as well as the features of its implementation in modern conditions.

Less than three decades ago, the absence of dividend policy was quite typical for Russian enterprises. A few cases of dividends payment did not play a special role because of the insignificance of the announced amounts. Since 2001, the situation has begun to change dramatically, when many large corporations that were interested in raising capital from financial markets, increasing their reputation and quality of management and forming a positive image in the eyes of foreign investors began to pay dividends on a regular basis. Later in the charters and corporate codes of the leading domestic companies, a paragraph or a separate document appeared that was revealing the content of their dividend policy.

Studies have shown that during the evolution of the dividend policy of domestic companies we can distinguish three periods (stages): "birth" (1994-1998); "formation" (2001 - 2007); "maturity" (2009 - up to the present).

It is not difficult to see that the given periods coincide with the financial crises of recent decades.

The peculiarities of the dividend policy of Russian companies in the first two stages were reflected in a number of publications and were considered in a research study by Lukasevich (2007).

That is why below we will present the results of the study of dividend policy in modern conditions, i.e. during the post-crisis and "sanctions" period of the development of the Russian economy.

Results

The analysis shows that the specific features that are characteristic of the dividend policy of domestic companies can be grouped according to two directions that are closely interrelated:

1) exogenous, conditioned by macroeconomic and foreign policy conditions as well as institutional factors;
2) endogenous, caused by internal factors and the microenvironment of the activities of the companies themselves.

The most significant factors of the first group include:

⇒ uneven growth and disproportions in the development of separate sectors of the economy;
⇒ the composition of owners that is based on the specifics of the mechanism of privatization of the Russian enterprises, as a result of which a significant proportion of their shares belongs to the state, a small number of people or management;
⇒ economic sanctions of Western countries, which significantly restricted the access of the Russian companies to the world capital markets;
⇒ transparency and clarity of legislation in this sphere.

The current stage of the development of the Russian economy is characterized by considerable sectorial disparities. In addition, the most intensive development in recent years has occurred in the oil and gas sector, metallurgy and telecommunications. The uneven development of various industries and sectors affects both the revenues received by enterprises and their distribution. The table below shows the dividend yield of the MICEX sectorial stock indices in 2015-2016.

Table 1: dividend yield of the sectorial indices of the Russian Federation[1]

Stock	Stock payment (rub)	Payment yield	Capitalization (mln $, US)
MICEX index	142.94	5.71%	522855.12
MICEX index Telecoms	23.91	9.49%	18626.08
MICEX index Metals	270.84	6.47%	99864.48
MICEX index Consumer sector	74.21	5.13%	27820.95
MICEX index Oil and Gas	327.32	4.98%	247349.55
MICEX index Chemicals	89.98	4.86%	20080.08
MICEX index Utilities	0.0852	3.73%	31136.25
MICEX index Finances	3.08	2.79%	76512.48
MICEX index Machine industry	0	0%	2477.04

As we can see from the table above, the largest dividend yield is demonstrated by the companies of the telecommunications sector. The payments of high and stable dividends by telecom companies are connected with both the intensive growth of the industry in recent years and the level of corporate governance that practically meets world standards. This dividend policy is also explained by the composition of the shareholders of the companies in this sector, including many institutional foreign investors and by the circulation of a number of shares in the form of depositary receipts on international stock exchanges - NYSE, LSE, etc.

In terms of payments oil and gas and metallurgical companies are traditionally the leaders, as together they account for more than 65% in the Russian stock indices. A significant share of dividend payments (60.9% and 14% respectively) in these sectors is based on both high incomes and significant need for additional investments. The desire to attract external investors, including somebody from abroad, forces the companies of these sectors to implement a transparent dividend policy.

At the same time machine-building enterprises practically do not pay any dividends because of the low profitability and unsustainable financial position that has been rapidly deteriorating in recent years.

A significant, if not the main, impact on the dividend policy of domestic companies is provided by the composition of shareholders. The structure of the composition of shareholders of Russian enterprises is presented in Table 2.

Despite several stages of privatization, the state still remains one of the largest owners. In Russia there are even special stock indices of companies with public ownership and regulated activities, which include shares of 34 leading Russian companies, a large part of which are monopolists or main players in their markets.

Being a majority or controlling shareholder the state directly affects the dividend policy of these companies, in fact determining its parameters. At the same time, the goals of such a shareholder may be very far from economic.

Table 2: structure of shareholders in the Russian federation[2]

Type of owner	Share
Authorities (incl. regional)	20.6%
Insiders (owners, management and people connected with them)	37.6%
Strategic investors	13.5%
Share of negotiable stocks (free float)	28.3%
Stock market as a whole	100%

It should be noted that at the initial stages of dividend policy development in the Russian Federation the owner in the person of the state received an extremely low level of dividend income. According to statistics the share of dividends in the total amount of non-tax revenues at the beginning of 2005 was no more than 7%, the number of joint-stock companies with a stake in the charter capital of the Russian Federation, which accrued certain dividends, has not exceeded 17% of the total number since 2001, more than 80% of the dividend income of which was provided by only 15 joint-stock companies.

In order to overcome these negative trends in 2005 the Ministry of Economic Development and Trade developed a draft resolution of the Government of the Russian Federation on the dividend policy of state companies. The draft presupposed annual payments of dividends equal to 10 – 20% of net profit. Since 2012, joint-stock companies with public ownership were supposed to allocate at least 25% of net profit for dividends without taking into account the income from revaluation of financial investments. Starting from 2015 the bar was raised to 50% because of the problems of financing the state budget.

Despite rather ambiguous results (in practice, the dividend yield of state companies in 2015-2016 ranged from 0 to 100%), the directive intervention of the state in the dividend policy of the controlled companies will have a serious impact on the general situation in this sphere in the near future.

The dividend policy of private Russian companies and the amount of payments allocated for these purposes also significantly depends on the composition and motives of majority shareholders that are often represented by a narrow circle of interrelated persons or by management.

Depending on the need the owners of such companies can significantly limit dividend payments or not implement them at all. Through various manipulations (for example, through transfer prices or

withdrawal of profits to subsidiaries) their official profit is understated, and the income of controlling shareholders settles on the accounts of affiliated intermediaries or in offshores. At the same time, enterprises can work on the verge of balance sheet losses, while their main owners are flourishing. Russian enterprises can also pay record-high dividends, if majority shareholders are interested in it.

For example, in the context of the financial crisis of 2008-2009 and in the post-crisis period, majority shareholders of well-off companies actively applied the practice of calculating interim dividends that were used to repay loans or for other projects. Thus, in 2009 two large companies – "TNK-BP" and "VimpelCom", which are co-owned by Alfa Group, decided to pay interim dividends. The group needed the funds to pay off VEB loan that was taken for refinancing of the loan of Deutsche Bank. At the same time, TNK-BP allocated almost 100% of net profit received for 9 months to the interim dividends.

Dividend payments are also often used by majority shareholders for financing of other businesses that are not related to the main activity of the controlled entity.

The economic sanctions imposed by Western countries in 2014 had a significant impact on the dividend policy of Russian companies. At the same time, studies show that the results of their impact are quite controversial.

Deteriorating financial conditions, a sharp increase of the exchange rate, the interest rates and the inflation led to a decrease or a halt in dividend payments in many sectors. We are going to give a number of examples of companies that were forced to make adjustments to their dividend policy taking into account the tightening of creditors' claims.

On the other hand, successful companies that have adapted to the new conditions not only increased dividends, but also began to actively introduce the practice of intermediate payments (once a quarter or half a year). The main reason for this phenomenon – the presence of majority shareholders who are actively withdrawing funds from business to finance other needs or companies – has already been analyzed. We would only like to note that as a result in the Russian Federation in 2015 – 2016 there was a record for dividend payments, which amounted to 1.3084 and 1.224 trillion rubles respectively. Given the increased demand for dividends from the state, we can expect that this record will be beaten in the nearest future.

The most important institutional factor affecting the dividend policy of domestic enterprises is legislation. It should be noted that the legal framework in this area is constantly being improved, gradually approaching the world standards and practices of developed countries. In 2014-2016, significant amendments were made to the Russian legislation aimed at protecting the rights of shareholders, clearly defining the basis, the terms of announcing and paying dividends and the basic rights of holders of ordinary and preferred shares.

Summarizing the intermediate results we should note that the considered endogenous factors have a direct effect and largely determine the content and consequences of the effects of factors of the other group, i.e. endogenous.

The most significant factors of this group are:

- ⇒ an increase in the number and volume of operations for buy back;
- ⇒ growth of the aggregate dividend yield of the Russian stock indices;
- ⇒ mass companies transfer to payments of interim dividends;
- ⇒ significant debt burden of a number of companies and individual industries, consideration of creditors' interests in dividend policy;
- ⇒ complexity and intricacy of the calculation base methods, which hinders the forecast of dividends;
- ⇒ dividend payments on the residual principle, the lack of a clear dividend policy for many Russian companies and as a result, the unpredictability of decisions on dividend payments and their volumes for many Russian companies

It is known that the payment of dividends can be carried out in various forms, each of which has its own advantages and disadvantages. The most common forms include:

- ⇒ payments in cash (cash dividends);
- ⇒ automatic dividend reinvestment plans;
- ⇒ payment of shares (stock dividends);
- ⇒ stock split;
- ⇒ repurchase of treasury shares (stock repurchase / buy back), etc.

The main form of dividend payments that is widely used in practice throughout the world is the monetary one. Scoter et al (1996) and Chan et al (2007) mentioned that in developed countries the repurchase of shares has been widely used. As an illustration, below there are the results of a comparative analysis of the forms of dividend payments considered for US companies that are part of the well-known stock exchange index S&P500.

Table 3: shares purchase and dividends of American companies for 2011-2015 (US $ bln)[3]

Determinant	2015	2014	2013	2012	2011
Aggregate volume of redemption	587.07	579.56	503.53	399.25	449.30
Yield of redemption	3.09%	3.13%	3.16%	2.98%	3.72%
Total amount of dividends	417.23	381.60	333.44	305.23	255.90
Dividend yield	2.19%	2.06%	2.09%	2.28%	2.12%

Because of such operations, the number of shares in circulation decreases, and earnings per share (EPS) increase. This gives an opportunity to automatically increase the amount of profit for the remaining shares and increase the dividend payout ratio in the forthcoming period. In addition, the purchase of treasury shares usually leads to an increase in their rate, which brings additional income to shareholders in the form of capital gains.

Bought out shares are called treasure stock and can be realized once again among existing or new owners, used for motivation programs of managers, reserved for the issue of convertible bonds or placement in foreign markets (for example, as part of ADR and GDR programs), or redeemed.[4]

The redemption of shares reduces excess cash and also increases financial leverage and can lead to a more efficient capital structure. Finally, it is one of the ways of protection against unfriendly takeovers.

In general, the repurchase of shares is a positive signal for the market. Analysis shows that such a policy is becoming increasingly common among domestic companies.

Large-scale programmers for redemption of treasury shares were sold by “Lukoil”, “Surgutneftegaz”, “MTS”, “Polus Gold”, “Severstal”, “LSR”, “Norilsk Nickel”, “Uralkali” and other companies. The aggregate indicators of shares redemption and dividend payments for Russian companies included in the RTSI index for the period from 2011 to 2015 are presented below.

Table 4: shares redemption and dividends of Russia companies for 2011-2015. (US $ bln)[5]

Determinant	2015	2014	2013	2012	2011
Aggregate volume of redemption	0.92	3.08	10.55	8.21	11.38
Yield of redemption	0.25%	0.77%	1.62%	1.21%	1.68%
Total amount of dividends	62.90	32.42	25.80	27.46	15.08
Dividend yield	17.25%	8.08%	3.95%	4.05%	2.22%

Despite the growth in the popularity of such transactions, in terms of their number and volumes the Russian market is significantly inferior to the markets of developed countries. At the same time as the macroeconomic and political situation improves, the number of such transactions will increase.

As we can see from the table, in the post-crisis period there has been a rapid growth in the dividend yield of domestic indices, which significantly exceeds this figure in developed countries.

A similar trend is being observed with respect to the dividend payout ratio (PR). If in 2011 companies, whose shares are included in the MICEX index, sent only 14.3% of net profit for dividends, then in 2013 this figure amounted to 38.3%.

Along with the growth in overall dividend payments, another reason for this situation, in our opinion, is the devaluation of the ruble. Indirect confirmation of this opinion is the reduction in 2016 of the dividend payout ratio to 31.2% due to the companies' lack of surplus profits from the devaluation of the ruble.

We have already discussed the main reason for the transition of many companies to intermediate dividend payments. Other motives that should also be indicated include the desire of companies to attract additional investors, especially institutional investors, for whom such a policy is very attractive.

The main consequences of the global financial crisis of 2008 and the introduction of international sanctions are the growth of indebtedness of Russian companies and the problems of its refinancing. Together with the aggressive borrowing policy pursued by many Russian companies in the pre-crisis and post-crisis period, this led to the need for changes in the dividend policy, in order to take into account the covenants of creditors and control the level of the debt burden. This trend is most pronounced in the metallurgical industry.

Below you can see examples of key parameters of dividend policy (calculation base and allocation coefficient) of a number of Russian companies after the revision of the policy.

Table 5: parameters of the dividend policy of Russian companies[6]

Company	Calculation base for the dividend payments / Payment ratio
'Norilsk Nikel'	It is recommended to allocate for dividends 60% EBITDA, if the ratio Net debt/EBITDA for the end will be less than 1.8 and 30% EBITDA – if it is more than 2.2.
'Severstal'	There is the payment of quarter dividends of not less than 50% of net profit, which is calculated according to IFRS in case the ratio Net debt/EBITDA is less or equal to 1. If the ratio Net debt/EBITDA is more than 1, the company will pay dividends of 25% of net profit.
'NMLK'	There is the payment of dividends on the quarter base in the following range: 1) if the ratio Net debt / EBITDA is less or equal to 1.0: the level of dividends will be in the range of the borders - 50% of net profit and 50% of free cash flow; 2) if the ratio Net debt / EBITDA is more than 1,0: the level of dividends is in the range of the borders - 30% of net profit and 30% of free cash flow.
'Megafon'	The company pays to shareholders the bigger sum out of two: either 50% of net profit, or 70% of free cash flow. At the same time the debt burden after the payment of dividends should be between 1.2 and 1.5 OIBDA.

The desire of many companies to increase the flexibility of the decisions made in this sphere and to limit dividend payments led to the development of "smart" methods for calculating the dividend base,

as well as to vague formulations of the possible payout ratio values, which is often specified as a range of values, or with the wording "no less".

For example, a well-known Russian company Gazprom publishes three types of reporting: RAS (Russians Account Standard) consolidated under RAS and consolidated under IFRS. At the same time, in accordance with the law, RAS accounts are used when calculating dividends. The dividend policy of Gazprom implies payments of 17.5% to 35% of net profit. At the same time the calculation of the base is made according to the following scheme: part of the net profit of 10% is directed to payment of dividends; part of the net profit of up to 75%, but not less than 40% is reserved for use for investment purposes of the company; the remaining part of the net profit is channeled equally for the payment of dividends and reservation for use for investment purposes.

The dividend policy of a number of companies allows the use of both the RAS standard and IFRS for calculating the base. For example, in 2013, 'Rostelecom' directed 25% of RAS profit for dividends, and by the end of 2014 – 25% of profits under IFRS.

It is also known that the financial result of the company's activities can significantly differ, even be the absolute opposite one, depending on the use of one or another standard. For example, the dividend base can be significantly influenced by the results of revaluation of foreign currency assets and liabilities, etc.

Finally, many Russian companies do not have a clearly formulated dividend policy at all. It might seem like a paradox but the best examples here are representatives of retail trade.

For example, the board of directors of "M.Video" while determining the dividend recommended to the general meeting of shareholders is guided by the group's net profit under IFRS. The decision on the distribution of profits is made based on such factors as: the amount of net profit, indicators of financial and economic plans, the structure of working capital, debt burden.

Conclusion

The study also showed that currently about 40% of domestic enterprises, whose shares are listed on the MICEX and RTS, do not pay dividends at all. Many of them still remain closed in terms of information and are not ready to share their income with shareholders.

Summing up the results it should be noted that many problems in the field of dividend policy center on corporate ethics and are not always subject to legislative or economic regulation.

Modern features of the dividend policy of domestic companies should be taken into account in the process of making both investment and financial decisions by all the concerned parties.

Abstract

The history shows, that the world is subject to constant technical changes, starting with the 1st industrial revolution to the point of the actual ongoing 4th industrial revolution. It also is unarguable that the world changes faster and innovation cycles decrease with the time as the technical development advances. The digitalization is one of the key drivers of our century and has a conspicuous influence on society and economy. A lot of researches on this topic focus mainly on the technological side and disregard the effects on organizational behavior. Therefore, and based on the actuality of the topic the authors decided to analyze the effects of the digitalization on Organizational Behavior whilst focusing on the impact it has on employees as well as leadership. The article is based on a vast literature review and structured in three parts: first of all the definition of Organizational Behavior and digitalization were reviewed to establish a theoretical framework, followed by the analysis of the effects of the digitalization on leadership and employees. Finally the findings are summarized in a structured scheme clustered by technologies.

Keywords: Organizational Behavior, Digitalization, Leadership, Employee

Introduction

Against the backdrop of digitalization, globalization, demographic changes and shortage of resources it is important for companies to understand the impacts and effects associated with these mega trends and to prepare their self for the future. Due to new technologies, algorithms, interconnectedness and big data storage the world is becoming more and more digitalized and transparent for all stakeholders. It is no longer only about a marketing strategy to influence consumers, company branding to retain employees or to identify ways to improve processes or automate the manufacturing. Nowadays not only the integration and utilization of innovative technologies and business models matters, it is essential to understand the interdependencies and impacts on the fundamentals of organizational behavior namely the interaction between the two determinants technology and people. Therefore and because of the actuality of the topics the authors decided to study and summarize the impacts of digitalization on leadership and employee workforce to proactively manage the necessary change to ensure the companies sustainability and to maintain or extend their position on the market. By means of an explorative literature review the goal of this research was to study the main technology drivers of digitalization and their effects on leadership and employees' behavior. Starting by understanding the fundamentals of the Organizational Behavior theory, followed by summarizing the technology brought up by digitalization and combining this with the impact on leadership and workforce the following research questions should be answered:

- What are the main technologies drivers related to digitalization?

- What are their effects on leadership and employees?

In literature, extensive definitions of the study of Organizational Behavior can be found, however for the purpose of this paper the authors´ will use the definition of DuBrin (2002, pp.3-6) who describes Organizational Behavior as the systematic approach to understand the behavior of individuals within organizations – starting from individuals as smallest entity of study to big organizations and their interaction with the environment. In addition, it is important to understand the interrelations of human behavior with other variables such as technology which together cover the whole organization (Mullins, 1990). In literature, three major factors can be found that affect Organizational Behavior. These are people, structure and technology, which constantly interact with the environment that surrounds them within and outside an organization (Richards, 2017). Figure 1 describes the factors and the interaction within an organization.

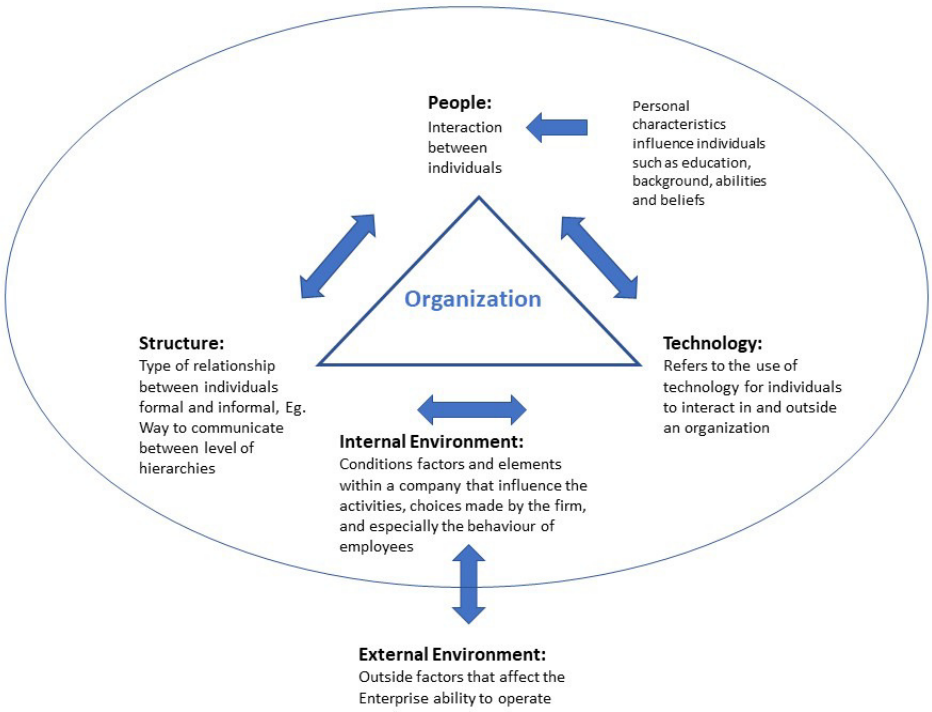

Figure 1: Factors affecting Organizational Behavior
Source: Authors' own contribution based on Richards (2017)

The influence of technology on work environments and workflows is an important determinant of Organizational Behavior science as changes in technology may not only affect the individual characteristics of the workforce but as well the organizational structure of enterprises. The way technology is implemented or used within a company may affect the company's inner culture as well as their behavior towards stakeholders. Furthermore, the implementation of modern technology may bring along a gradual change in the composition of the workforce. For example, younger, better educated, more mobile as well as more technologically versed generations will enter companies in greater numbers as in the past resulting in a changeover within organizations that may as well bring along a new set of values, attitudes and concerns that affect the Organizational Behavior within companies (DuBrin, 2002).

Understanding the meaning of Digitalization

Over the last decades the digitalization and interconnectedness has shifted the economy from a mainly physical to software controlled economy and the information technology has become a fundamental part of our industry and society. In this context buzzwords like digitalization, Internet of Things (IoT), big data, robotics, automation, mobility and others are ubiquitous, they are discussed in social media, by politics and economy. But what do these terms mean, how are they interlinked with each other and in which ways do they change our whole work and life environment?

The omnipresence of the words digitalization and digital transformation and their obvious interconnection to all the other terms induced the authors to have a closer look to their definitions, characteristics and impact on leadership and employee workforce. According to Ernst & Young (2011) digitization means the conversion of analogue information to digital (computer-readable) information. From the middle of the 20th century onwards, after the invention of the transistor and microprocessor the technologies of digitization enabled the conversion of traditional media such as picture, paper, sound, video or signal into bits and bytes (ones and zeros) of computer storage (Press, 2015). Since the beginning of the 21st century, with the emergence of social media, social networks and by the improvement of the sensor technology, additional information is being recorded, digitalized and shared such as social life activities and physical data of life like location, temperature, force, weight, blood pressure and stress. Today, non-digitalized products are more and more digitalized as they receive for example tracking sensors to locate them or network connections to deliver status information. The numbers published by BMWi (2016) show that the amount of digital information has increased dramatically, in 1993 it was just 3% and in 2007 it reached already 94% of the worldwide information (see also figure no 2).

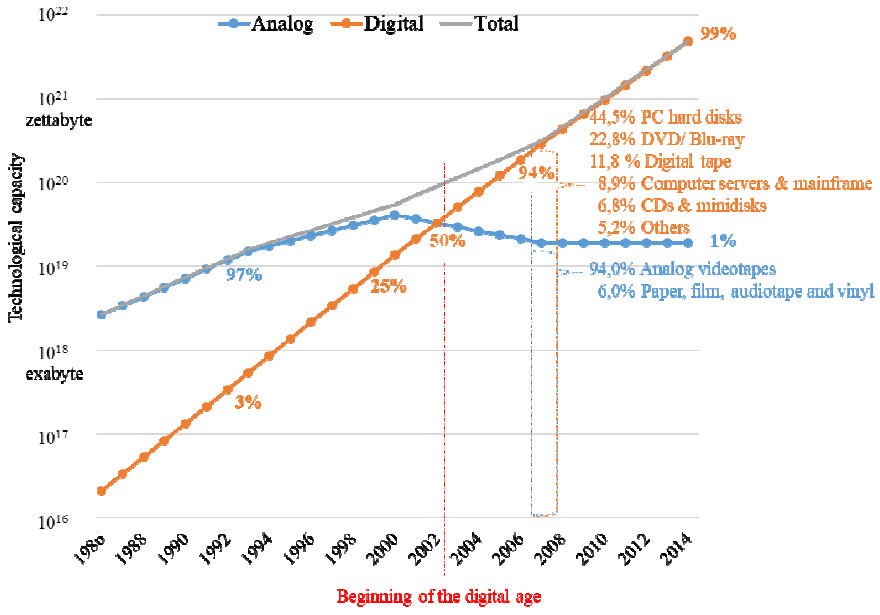

Figure 2: Development of the global information storage capacity
Source: Authors' design based on Hilbert (2015)

The last years have shown that the digital transformation of economic processes and transactions and human interactions became an inescapable megatrend in ways never been anticipated years ago and it is

still the beginning. This growing dependence on the ubiquitous technologies and solutions combined with the demographic changes, declining availability of resources, globalization of the markets and growing international competition, and the increasing customer demands request innovative ways of thinking and acting to identify and deal with the related opportunities and challenges (Marquardt, 2017).

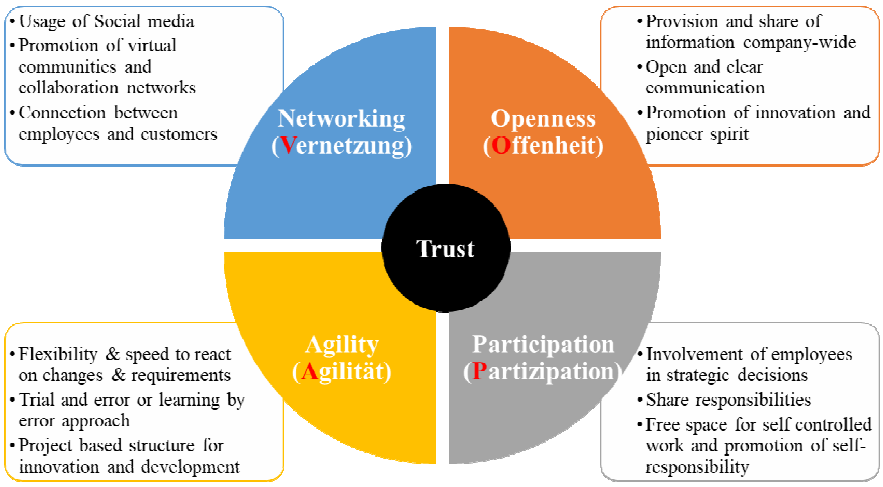
To provide an overview and to gain a common understanding, the authors have summarized and grouped in table number 1 the most significant digital technologies and solutions based on their main purpose and included examples.

Table 1: Overview digital technologies

TECHNOLOGY	**EXPLANATION /** ***EXAMPLES***
INTERCONNECTEDNESS & AVAILABILITY	
MOBILE & IOT & CLOUD (COMPUTING)	**Mobile** is the generic term for cellular communication and mobile computing with wireless networking / *Smartphone, tablet, laptop* **IoT** is the connection from on and off switchable devices to the internet. They get a virtual presence and can connect to other objects and database data (Morgan, 2016) **Cloud** is the provisioning of IT infrastructure (e.g., networks, servers, storage, applications, services) over the internet on demand / *Software-as-a-Service (SaaS), Platform-as-a-Service (PaaS), Infrastructure-as-a-Service (IaaS)*
INFORMATION & INTELLIGENCE	
BIG DATA & ANALYTICS	**Big Data** is the synonym for vast and complex data volumes which differs by their size, diversity and rapid pace of change (Plattner, 2016) **Analytics** is the process of examining Big data to uncover patterns, correlations, market trends, customer preferences and other useful information (Rouse, 2017a)
AUTOMATION & EFFICIENCY	
ROBOTICS & AUTOMATION & ROBOT PROCESS AUTOMATION (RPA) & INTELLIGENT AUTOMATION (IA) & ARTIFICIAL INTELLIGENCE (AI)	**Robotics** is the interdisciplinary branch of engineering and science that deals with the design, construction, operation, and use of robots (Rouse, 2017b) **Automation** is the technique of making a machine, a process, or a system to be operated automatically with no or reduced human intervention. It can be done by various means like mechanical, hydraulic, pneumatic, electrical, electronic devices and computers (ISA, n.d.) **Robot Process Automation** is the fully automated processing of structured business processes (repeatable and predictable interactions) by software robots or by using artificial intelligence (AI) **Intelligent Automation** is a nascent and high cost technology which enables automating non-routine tasks such as those involving intuition, judgement, creativity, problem solving, etc. based on dynamic information (Deloitte, 2017) **Artificial Intelligence** is part of computer science bringing human capabilities and characteristics to machines like understanding language, learning, reasoning, solving problems, etc. (McKinsey, 2017)

	/ *Digital assistant Siri, Alexa, Cortana or Echo*
COMMUNICATION & COLLABORATION	
SOCIAL (MEDIA)	is the collective of online communications channels dedicated to community-based input, interaction, content-sharing and collaboration (Rouse, 2016a) / *Facebook, Twitter, Instagram, Pinterest, Snapchat, YouTube*
PRIVACY & SECURITY	
NEXT-GENERATION SECURITY	is a new generation of intelligent, highly scalable security products and platforms which includes both cybersecurity and physical security and with a more proactive and adaptive approach (Rouse, 2016b)

All the above listed technologies and solutions have and will have a growing and powerful effect on economy, environment and society. They provide new functionalities, increase productivity and efficiency, give higher flexibility and diversity and allow more reusability, parallelism and duplication. Additional they will change the business models and production processes, the way of working and collaborating, permit more mobility, enable faster decision making and delivery, support higher standardization, customization and prosperity. On the other side, they can also be related to negative impacts as for example unemployment, immiseration, pressure, always-on mentality, ever-increasing exhaustion, despair, higher complexity and social isolation. Therefore, it is important to be aware of these impacts, either positive or negative, and to deal with them from the very first beginning. In this connection and interlinked with the digital transformation terms like work 4.0, management 2.0, and leadership 4.0 came up, and their meaning will be reviewed in this article.



Modern Leadership and the effects of Digitalization

Understanding how digitalization is affecting and changing leadership practices in organizations is essential because today digitization is taking place in almost all sectors of the economy at a very fast pace and in a very deep manner. Manufacturing, financial services, customer service, health, agriculture, retail and logistics, all of these sectors are using big data, new technologies and solutions to drive their business forward and to survive on the highly competitive market. This not only implies changes in the economy and work system, it also implies changes in leadership management, thinking and acting. To support this digital transformation the companies, need to shift from their traditional, hierarchical structure to a flexible, decentralized organization with a team/project-oriented leadership to keep pace with the complex and fast changing environment (digital-centric business) and the increasing customer requirements (customer-led market). Additionally, the generation change from the baby boomer and generation X to the digital natives (Generation Y and Z), which have unique characteristics and capabilities in comparison to past generations, will require new working structures and leadership.

The new leadership, digital leadership or leadership 4.0 means not only usage of the new digital media for collaboration and communication, it also requires the adaption of the leadership strategies and methods to the digital reality. The future leader should be able to utilize the new technologies and solutions, to adapt himself fast to changes and manage them, to have a pioneer spirit, be able to learn quickly, be contextual and emotionally intelligent and trustworthy, lead democratically and share responsibilities, decide situational and participative, control and promote networks, trust and motivate employees, and give them regular feedback (Sattler, 2016). From the authors' viewpoint, the so-called VOPA leadership model (see figure no. 3) designed by Buhse (2014) combines all those characteristics and can be used as the basic model for the digital leadership by covering all the central elements for a

successful corporate and management culture in the digital age, also reflecting the demands from the new generations.

The core of the digital leadership built on trust is not new because "trust" is one of the significant emotions in human relationships. The leader needs to trust in the management and the employees need to trust in the leader and vice versa, only then the right decisions can be made and the required actions can be taken within the time of increasing complexity, insecurity and speed. All the other four points support the establishment and maintenance of trust. Openness and transparency take away fear and uncertainty, give a clear view and gain understanding. Participation and involvement give the possibility to actively engage, modify and assume accountability. Agility allows to react faster and context based and networking enables and support the sharing, collaborating and improving. Leaders need to have a direct and personal engagement with all employees and especially to the new talents from the next generations, because they are the

incubators of change in the digitalized world (Ernst and Young, 2011).

Figure 3: VOPA plus model for digital leadership

Source: Authors' design based on Buhse (2014)

The new digital technologies and solutions are not just stimulating the need for change, they also enable and support the change itself. Here are some examples: big data in combination with learning algorithms enable organizations and leaders to better predict and control their processes and applications, allow to optimize the work such as material flows, targeted marketing activities, decide on employee's performance or tasks. Likewise, the integration of social media platforms can support the engagement with many more employees in distributed organization as it was possible before with standard meeting structures. Here the leaders can share information, give regular updates, foster understanding and create conviction to the spread workforce at the same time. Furthermore, the usage of data-enabled talent-management systems (based on algorithmic data analysis) can rise the number of employees meaningfully evaluated against their knowledge and competencies, increase the precision of these evaluations and free up the leadership to concentrate on the personal relationship (Feser et al., 2017). But it must be kept in mind that the way technology takes over or interferes in some of the managerial activities. It also bares the risk that the creative adaption to a problem might decrease, the historical background gets lost and the organizations will be increasingly dependent on the providers of these new technologies as they most likely lack internal resources with the capability to program and run this system. Hence it is important for the managers and leaders to analyze their business and market situation first, decide which will be the right strategy and structure and to involve their employees in the digital transformation.

Impact of Digitalization on Employees

The continuous change that the digitalization of things is bringing along is having major impact on the workforce at various levels such as rationalization, knowledge, performance, efficiency, skill set, etc. Hereafter the authors summarized the impact based on an extended literature review.

Digital learning platforms can improve the company's internal education by hosting tailored trainings and development programs for employees and leaders, where they can attend the training in alignment with their work schedules, matched with their self-pacing and choice of topic. This new training methods support the acquisition of skills based on the strategies organizations follow and where educational systems fail to deliver. However, this on the contrary demands from employees to be able to continuously learn to be able to keep up with the advancements of technology and avoid rationalization in the long run (Gow and MacDonald, 2006).

Until now the rationalization of workforce due to digitization has majorly affected those employees with low qualifications due to the automation of production processes. However, the advancements in intelligent automation and artificial intelligence start to cast a shadow over higher qualified resources. Having a formal qualification is no longer a guarantee for a lifelong secured career. This is due to the fast changes in technology that can no longer be secured by the educational system. Nowadays, specially endangered are those professions in which precision and routine make a high portion of the daily job activity as these can easily be automated and replaced by computer algorithms such as sales agents in call centers, clerical workers, packers, pilots and even judges. It is argued that these fight an unequal competition against autopilots and algorithms which can navigate flawlessly and are sly decision takers. On the other hand, jobs that require a higher amount of creativity, social intelligence as well as entrepreneurship seem to be more sustainable (Rinne and Zimmermann, 2016). This said, the future of work based on a digitalized economy also requires a new skill set which will enforce a sustainable working future. For example, the outsourcing industry has started to demand specific hard and soft skills related to the advancements in technology to be able to deliver added value services which will allow to win the competition against artificial intelligence and algorithms (Foerster-Metz & Golowko, 2017).

Within higher qualified jobs in the digitized world a new working space is created that allows new collaborative working models due to cloud computing platforms. The software industry is one of the trendsetters regarding this working model which is based on agile development such as Scrum with principles of Lean Production. This new type of collaborative working on clouds permits quick development sprints which constantly and in real time allow to test the performance of each delivered work package. Furthermore, it enables to take decisions and work direction at a higher speed as well as to make the work performance of each team member transparent. Consequently, each team gains more empowerment however it shows also the tendency of simple execution as in an "assembly line" (Boes et. al., 2016).

Due to the digitalized world employees are no longer limited to work only from the office and for only one employer. This has brought changes in how workforce is being contracted. Many individuals today chose to work as digital freelancers, so called "crowd worker", who can work from everywhere through mechanisms like clouds, skype, teleconferences, etc.[i] They offer their work and skills through virtual crowdsourcing platforms in which organizations can outsource and post specific work packages. Because of this flexible work organization flexible work time models, home office and variable time schedules will continue to increase due to the limited availability of qualified workforce. Through this trend entrepreneurial risks are shifted from employer to employee. Instead of strict work instructions new civil arrangements come to place. Flat hierarchies as well as performance based remuneration gain more significance. Employees turn into entrepreneurs which consequently demands entrepreneurial thinking as a key competence for the future work market place. In addition, work compensation is reduced to work

packages so that costs last for the time of an assignment and hidden cost reserves of permanent employees can be reduced. Through these virtual platforms also the workforce turns global and is exposed to higher competition. On the downturn, these "employees" have no sense of affiliation to companies requiring higher effort to motivate and engage them towards the values, vision and mission of companies. At the same time contractors are not protected by syndicates or similar and do not have codetermination rights. They fall out of the labor law agreements as they are independent entrepreneurs. Furthermore, freelancers are often not integrated by law to the social security systems if the government has not foreseen any protection (Rinne and Zimmermann, 2016; Staab and Nachtwey, 2016).

Performance surveillance has taken a new shape through the digitization of work steps as for example the logistics industry in which pickers hold a hand scanner enabled with cameras and microphones which are able to transfer movement data of the workforce. Companies can use this information to define performance profiles, measure and compare the performance of diverse workforce. In addition to having a performance surveillance also a high technical process control is enabled through this hand scanners as these provide the employees with consecutive work steps to maximize workflow efficiency. Resulting in an almost gapless system automation reducing the workforce autonomy to structure their work place and creativity for innovative solutions. This trend can also be found in higher qualified jobs such as developers, sales agents and analysts within the tertiary sector. This is possible through individualized performance review based on analysis of big data and control related software. For example, through the analysis of big data it is possible to determine if a sales man ordered enough products for a specific selling period as well as to analyze how many client contacts have been realized and which was the duration and outcome of the meeting (Staab and Nachtwey, 2016; Boes et al, 2016). Performance measure through target setting also takes on a new dimension as companies start to use mobile apps with which their employees can document their target accomplishments on daily basis. These apps create an elevated level of transparency as they allow to make the individual performance transparent to everyone in the company. Platforms like Twitter allow to "follow" colleagues and inform about alterations in their work activities. As a result, communities can be used to track, measure and influence the social behavior of employees.

Dissolution of boundaries regarding time and work place started in the 80s with telework possibilities. In course of the years due to the increased digitalization of work through the possibility of taking work everywhere with smartphones, tablets and laptops, work has become a constant companion in many countries and especially for higher qualified jobs. It has become a normality to work on weekends, vacations, trains and airplanes, etc. However, still not all companies allow their employees to make use of this possibilities as despite advance possibilities of performance surveillance they fear not to have enough control over their employees and the expected work results. On the other hand, those employees that are enabled with this work technologies started complaining about higher expectations of constant reachability. In this case some EU countries are struggling to find the right labor law mix that will cope with this new work environments. At the same time, flexible and boundary free work requires a high level of self-organization and time management from the individuals (Carstensen, 2016).

Company information which in the past was only accessible to higher leadership - as it often implied higher printing and informational costs - can now be shared with employees through diverse digital technology like sharing platforms, chatting rooms, intranets, etc. This allows employees to have a higher awareness about the company and its activities permitting organizations to become more transparent and open towards employees. Because of greater transparency improvements in decision-making, employee confidence and internal networking have been achieved (Francis and Scheers, 2013). However, increased transparency implies new code of conducts to protect information from leaking (Schildt, 2017).

In addition, companies need to deal with the fact that the increased digitization of information generates informed employees, consumers and partners that have real time access to competitive pricing and

product information which increases pricing transparency. Digital platforms allow peer recommendations by consumers which can be on the one hand frightening as these put major pressure on the control of the branding message and on the other hand it gives the opportunity of employees to engage with consumers as ambassadors for the brand. Latter ones are called "prosumers". In this sense, a new two-way communication has been enabled between consumer and brand which bares opportunities and risks. New collaborative approaches towards stakeholders are required to keep the engagement up. Companies have started to use this new digital communication to test in communities' innovations, receive and provide feedback on issues of problems with products, etc. However, this active communication with the stakeholders also requires a new way of thinking and culture within organizations that is more than ever service oriented (Ernst and Young, 2011).

Conclusion

Cloud computing, advanced algorithms, artificial intelligence are all interrelated and have a major effect on how individuals are changing their way of acting within and outside organizations. The digitalization has shown that it has majorly changed the workforce population, the skill set needed, the way to interact and collaborate as well as to communicate within an organization, not only from employee side but also from the leadership side. Table 2 provides a summary of how the analyzed technologies are having an impact on the factor people within an organization.

Table 2: Summary of Findings

TECHNOLOGY	IMPACT ON WORKFORCE	IMPACT ON LEADERSHIP
INTERCONNECTEDNESS & AVAILABILITY		
MOBILE / IOT / CLOUD	Changes in contracting form of Workforce: Crowd sourcing Flexible work models in time and space Free space of self-controlled work Entrepreneurship and empowerment at the risk of simple execution Exposure to higher global workforce competition Reduction of sense of affiliation of the workforce Lose of social security protection	Flat Hierarchies Implies agility and speed in decision taking Enforces collaborative approach Requires higher motivation of employees due to the externalization of work packages and personal distance to the contractor Middle Management loses importance as managers can cover larger departments and locations
INFORMATION & INTELLIGENCE		
BIG DATA & ANALYTICS	Higher performance surveillance Lose of creativity due to higher and detailed process structure Higher amount of performance based remuneration	Optimization of processes Increased evaluation of employees, frees up management from their surveillance role as analytics start to take over the decision Dependency of providers due to lack of programming knowledge
AUTOMATION & EFFICIENCY		

ROBOTICS / AUTOMATION / ROBOT PROCESS AUTOMATION / INTELLIGENT AUTOMATION / ARTIFICAL INTELLIGENCE	Rationalization of workforce for higher qualified and lower qualified jobs Reduction of workforce autonomy, creativity and innovation	Level of hierarchies becomes flat Loss of creative adaption to problems and historical background
COMMUNICATION & COLLABORATION		
SOCIAL MEDIA	Transparency Knowledgeable workforce Increased need for service orientation toward client Enforces collaboration and knowledge sharing	Demand for collaborative and transparent leadership Open and clear communication Provision and share of information company wide at low cost Enforcement of engagement Influence social behavior of employees
PRIVACY & SECURITY		
NEXT-GENERATION SECURITY	Risk of leakage of personal employee data	Development of new codes of conduct

Through the authors' analysis it has become clear that the workforce of tomorrow will have to think and act interconnected and will need to focus on innovation and creativity to be able to cope with structural changes the technological development has brought along. Still questions are open such as at what pace further rationalization will take place or which efforts are being undertaken by the environment to get along with the skill need of rationalized workforce.

Abstract

In this paper, the authors analyze the influence of some factors on the economic growth at the level of the European Union. The factors selected for the evaluation are indicators corresponding to the group of countries that recorded the most significant amounts of Gross Domestic Product since 2007Q1, and of Romania. We consider two types of analysis, as detailed in the main body of the paper, and we use a dedicated econometric analysis to substantiate the estimation of our parameters, meant to help measure the impact of factors on the main variable selected.

Keywords: Gross Domestic Product, final consumption, foreign trade, influence, regression

Introduction

The impact of two growth factors, the final consumption (as final consumption expenditure of households) and the foreign trade, on the economic evolution, measured by the most significant indicator used in the quantification of macroeconomic outputs and growth, which is the Gross Domestic Product, makes the subject of this article.

Our study includes a presentation of the research methodology and datasets subjected to processing, analysis and interpretation. Then, we present the results and comment the value achieved for the processed parameters. The conclusions outline the most important findings in the scope of our paper.

We consider that the final consumption and foreign trade influence both the values of GDP, but also its evolution, thus our analysis pursues these two coordinates: a size-based analysis, together with an econometric study on the relationship between factors and GDP, including an evaluation of its intensity.

Research Methodology and Data

Our methodology is based on the principles that govern the accumulation of the Gross Domestic Product according to the expense method. According to this method, the relationships between these macroeconomic indicators follow the balance pattern. We shall pursue the treatment proper to this method, which requires the study of evolutionary trends in a comparative approach, between the main indicator and the factors, and then we will resort to the econometric (regression) techniques, to identify the factual impact over time posed by the factors considered.

The datasets are extracted from official statistical sources, EUROSTAT, and cover the following dimensions:

a) Time: from 2007, Quarter 1, to 2017, Quarter 1;
b) Space: three members, namely the EU28, the five main contributors to the EU28 total GDP (they were selected according to hierarchy for total contributions across the time: Germany, France, United Kingdom, Spain, Italy, grouped under the acronym SIG5) and Romania;
c) Indicators: Gross Domestic Product (market prices, unadjusted data), which is the main indicator and final consumption expenditure of households (current prices, unadjusted data), export and import (also, current prices, unadjusted data), which assume the role of factors.

Data Analysis, Results and Discussions

As stated in the previous section, the analysis of data pursued the following stages:

- The comparative analysis between the evolution of the main indicator and the factorial variables, grouped according to the space (geographical) dimension;
- The regression analysis, which synthesizes the influence of the factors on the main indicator, across the entire period considered. We shall use both simple and multiple regressions, as we have three factors in our dataset.

For the Gross Domestic Product analysis, we apply the balance method, knowing that the values for Romania and the group of five countries will be considered factors for the GDP at EU28 level.
The graphic below describes the comparative evolutions of the three indicators:

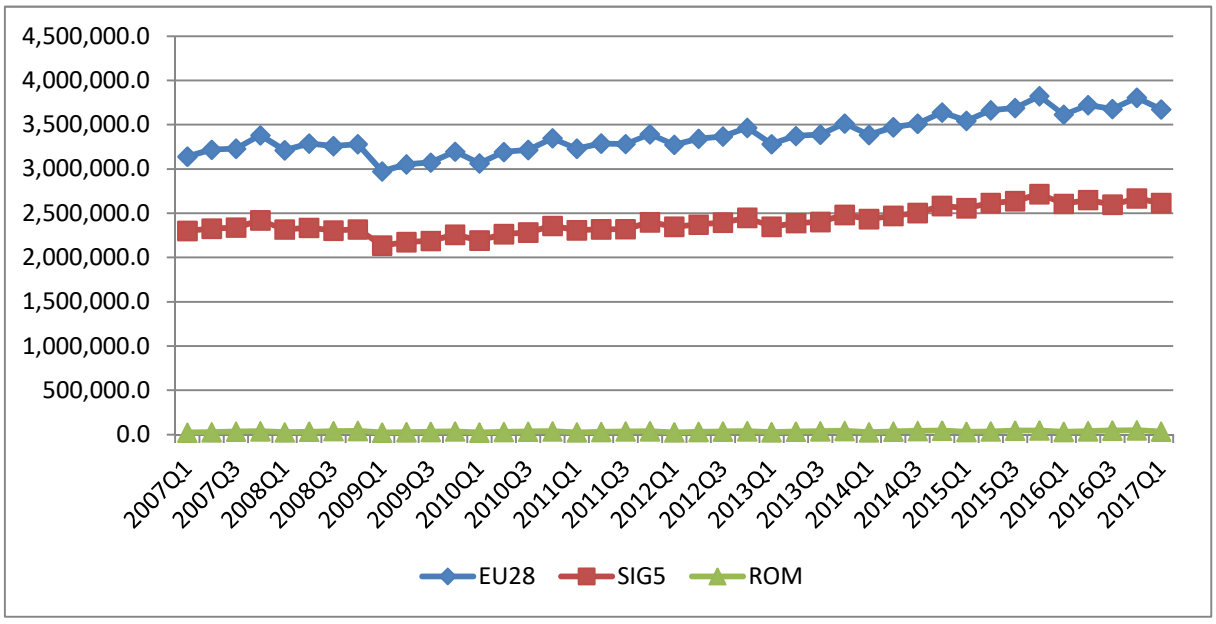

Fig. 1: Comparative evolution of Gross Domestic Product for selected geographic dimensions

Data source: Eurostat Database, *GDP and main components (output, expenditure and income) [namq_10_gdp]* **,** item *Gross domestic product at market prices,* retrieved 03.08.17, measurement unit *Current prices, million euro*, Unadjusted data (i.e. neither seasonally adjusted nor calendar adjusted data), graphical representation by the authors.

It can be easily observed that the evolution of the EU28 Gross Domestic Product is largely influenced by the movement of the SIG5 level, while Romania poses a less visible evolution. For the entire interval subjected to analysis, the overall amount of SIG5's GDP covers more than 71.25% of the entire EU28 group, while the quota of Romania is slightly above 0.10%.

To collect additional information on the correlation between the evolutions of Gross Domestic Product grouped by geography, we selected the multiple regression model, which would allow us to measure the impact of SIG5 and Romania's GDP modification on the EU28's GDP.

The expected equation should have the following form:

$$EUG = \alpha + \beta 1 * SIGG + \beta 2 * ROMG \qquad (1)$$

where:

α = the free term of the model;
EUG = EU28's Gross Domestic Product;
SIGG = Gross Domestic Product cumulated for the SIG5 countries;
ROMG = Gross Domestic Product of Romania.

We have imported the datasets for the three variables within dedicated econometric software, which provided the following estimations for our regression model:

Dependent variable: EUG

	coeficient	eroarea std.	t-ratio	p-value	
const	116504	57746,2	2,018	0,0507	*
SIGG	1,28904	0,0293019	43,99	3,32e-034	***
ROMG	4,52235	0,640757	7,058	2,05e-08	***

Mean dependent var	3378797
S.D. dependent var	214640,3
Suma pătratelor reziduurilor	1,55e+10
Eroarea standard a regresiei	20218,00
R-pătrat neajustat	0,991571
Adjusted R-squared	0,991127
F(2, 38)	2235,115
P-value(F)	3,89e-40
Log-likelihood	-463,1062
Akaike criterion	932,2125
Schwarz criterion	937,3532
Hannan-Quinn	934,0844
rho	0,534291
Durbin-Watson	0,793711

Fig. 2: Estimation for the multiple regression model

Therefore, the equation of the model can be written as follows:

$$EUG = 116504 + 1.28904 * SIGG + ROMG * 4.52235$$

The values of the parameters display favorable influences for the EU28's Gross Domestic Product on behalf of both factors, SIGG and ROMG. However, it can be seen that Romania exerts a stronger influence on the main indicator, meaning that for a unit increase (1 Euro) of Romania's GDP, the Gross Domestic Product for the European Union tends to increase by more than 4.5 Euro. Regarding the SIG5 countries, when their total GDP (counted as a single, cumulated variable in the scope of our analysis) increases by 1 Euro, the results is likely to indicate the increase of the main indicator by more than 1.28 Euro.

The tests associated with the model offer relevant information for the significance of the parameters estimated. Therefore, as both *R-squared* and *Adjusted R-Squared* are higher than 0.991, we consider that the model describes in accurate manner the correlation between the three variables. The free term, expression of the evolution of the main indicator when all regression factors are null, is significant (some 25 times higher than the β2 parameter), indicates also a favorable influence of factors that are not yet included in our model.

Next, our research will focus on the impact of the GDP accumulation factors on the Gross Domestic Product itself, for two geographical dimensions selected (SIG5 countries and Romania).

For Romania, we have defined the appropriate dataset, covering the specified time period, and the variables that are to fulfill the following econometric model:

$$ROMG = \alpha + \beta1 * RCF + \beta2 * REX + \beta3 * RIM \qquad (2)$$

where
ROMG = Gross Domestic Product;
RCF = final consumption expenditure of households;
REX = export;
RIM = import.

The graphical representation of the indicators' evolution is drawn in the figure below:

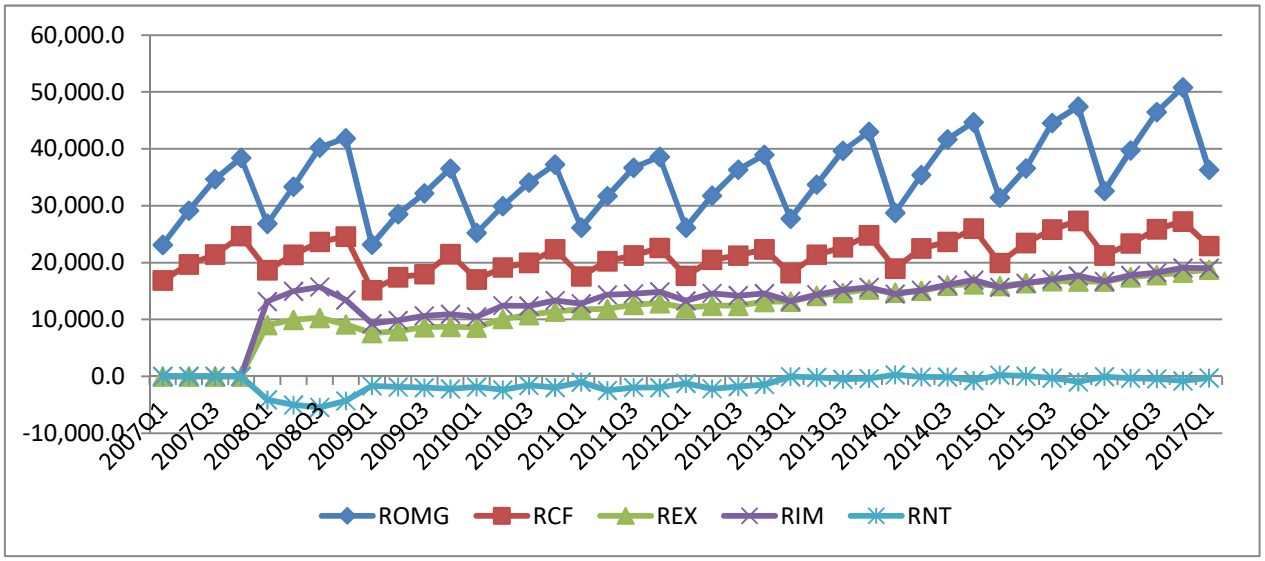

Fig. 3: Evolution of Romania's GDP and its influence factors

Data source: Eurostat Database, *GDP and main components (output, expenditure and income) [namq_10_gdp]* **,** item *Gross domestic product at market prices,* retrieved 03.08.17, measurement unit *Current prices, million euro*, Unadjusted data (i.e. neither seasonally adjusted nor calendar adjusted data), graphical representation by the authors.

The above figure presents a symmetrical evolutionary trend for all indicators considered by our analysis. It can be seen that the less significant values belong to the export factor, with the final consumption having the highest values in the set of factorial indicators. To be noted, the net value of the foreign trade,

the RNT parameter in figure 3 is most of the time negative, which clearly outlines a less than favorable situation that is the predominance of imports over exports.

Next, we shall apply an econometric regression model based on the three factors, with the Gross Domestic Product as the main indicator. We have used the same econometric analysis software for all the estimations in this paper, to ensure a higher level of cohesion for our results. Therefore, after preparing the four datasets and uploading them, the estimation generated the results presented in the figure below:

Dependent variable: ROMG

	coeficient	eroarea std.	t-ratio	p-value	
const	−11823,7	2068,73	−5,715	1,53e−06	***
RCF	2,12244	0,104563	20,30	1,20e−021	***
REX	−0,137751	0,198435	−0,6942	0,4919	
RIM	0,231451	0,197721	1,171	0,2492	

Mean dependent var	35154,03
S.D. dependent var	6799,006
Suma pătratelor reziduurilor	1,15e+08
Eroarea standard a regresiei	1760,400
R-pătrat neajustat	0,937988
Adjusted R-squared	0,932960
F(3, 37)	186,5539
P-value(F)	2,20e−22
Log-likelihood	−362,4772
Akaike criterion	732,9544
Schwarz criterion	739,8087
Hannan-Quinn	735,4504
rho	0,251818
Durbin-Watson	1,466370

Fig. 4: Model estimation for the case of the Romanian economy

The equation of the Romanian model can be written as such:

$$ROMG = -11823.7 + 2.12244 * RCF + (-0.137751) * REX + 0.231451 * RIM$$

The β coefficients for the three factors reveal their influence on the Gross Domestic Product's evolution in the case of Romania. The final consumption expenditure of households and the import have favorable influences, while the export has a negative impact, and its coefficient is smaller, in absolute value, than the other two βs. If the financial consumption expenditure of households records an increase by 1 Euro, the Gross Domestic Product of Romania shall increase by 2.12244 Euros. A unit modification of the imports is susceptible to lead to a GDP growth of 0.231451 Euros. The model estimation produced a value of the free term which is significantly higher than the three βs, and is negative, which means that there are other factors, not considered in our model, whose influence on the GDP evolution is both major and not favorable.

Considering the tests associated with the estimation, as seen in fig. 3, the *R-squared* and *Adjusted R-squared* are higher than 0.932, which provides confidence in the reliability of the model and the possibility to use it in further studies on similar topic.

The evolutionary trends of the indicators that characterize the SIG5 group are detailed in figure 5:

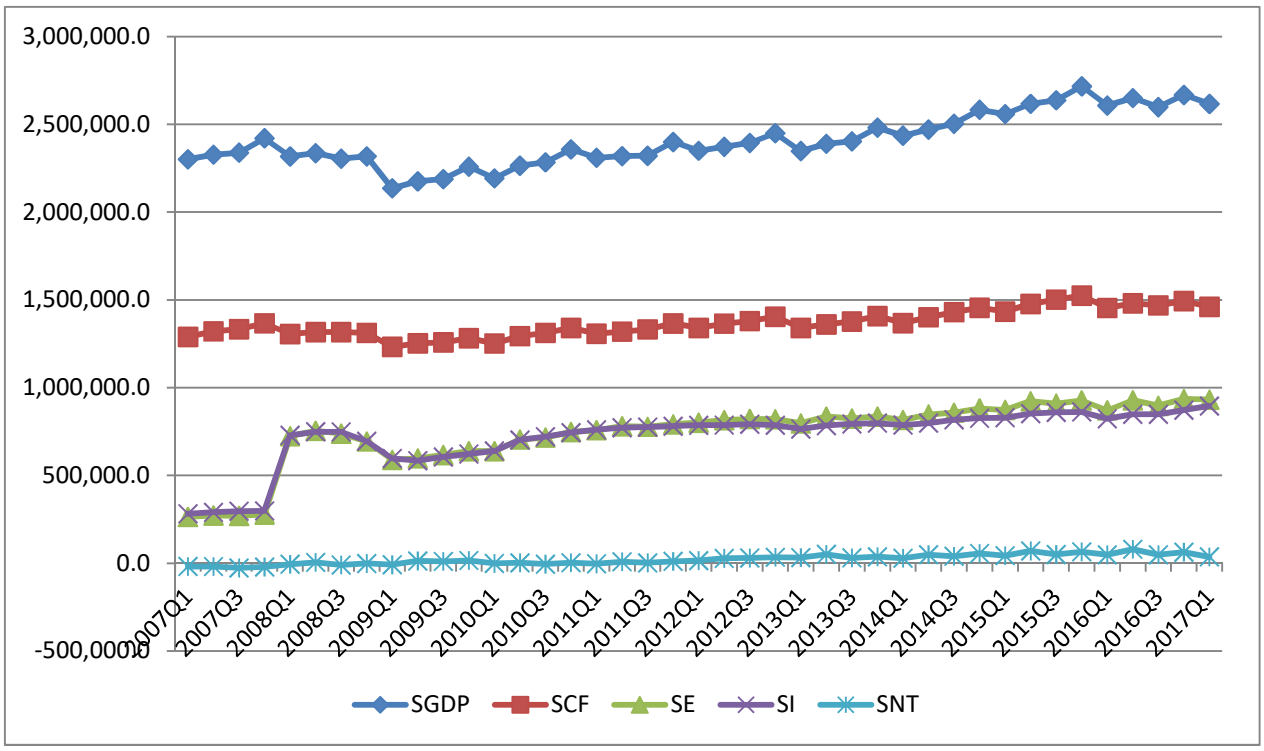

Fig. 5: Evolution of GDP and its influence factors for SIG5 economies

Data source: Eurostat Database, *GDP and main components (output, expenditure and income) [namq_10_gdp]* **,** item *Gross domestic product at market prices,* retrieved 03.08.17, measurement unit *Current prices, million euro*, Unadjusted data (i.e. neither seasonally adjusted nor calendar adjusted data), graphical representation by the authors.

Also, in the above figure, the major influence of the final consumption is visible, then the export, followed by import. We conclude that the net value of foreign trade, the net export presents a more favorable situation than in Romania

In the case of the most significant states in the European Union, the model estimation is based on the following core equation:

$$SGDP = \alpha + \beta 1 * SCF + \beta 2 * SE + \beta 3 * SI \quad (3)$$

where
SGDP = Gross Domestic Product;
SCF = final consumption expenditure of households;
SE = export;
SI = import.

The results of the estimation are presented in the figure below:

Dependent variable: SGDP

	coeficient	eroarea std.	t-ratio	p-value	
const	-264764	98780,7	-2,680	0,0109	**
SCF	1,97225	0,0720732	27,36	3,74e-026	***
SE	-0,0175274	0,246323	-0,07116	0,9437	
SI	-0,0140170	0,264568	-0,05298	0,9580	

Mean dependent var	2407461
S.D. dependent var	148676,7
Suma pătratelor reziduurilor	1,44e+10
Eroarea standard a regresiei	19742,94
R-pătrat neajustat	0,983689
Adjusted R-squared	0,982367
F(3, 37)	743,8045
P-value(F)	4,19e-33
Log-likelihood	-461,5847
Akaike criterion	931,1694
Schwarz criterion	938,0236
Hannan-Quinn	933,6653
rho	0,314290
Durbin-Watson	1,280138

Fig. 6: Model estimation for the case of the SIG5 group of economies

The regression model can be transcribed in the following form:

$$SGDP = -264764 + 1.197225 * SCF + (-0.0175274) * SE + (-0.0140170) * SI$$

The interpretation of the regression parameters reveals a single factor with positive influence, that is the final consumption expenditure of households, whose modification by one unit leads to a likewise modification by more than 1.19 units of the Gross Domestic Product. The other two factors are characterized by non-favorable influences, even if the β quotients are slightly below 2%. To be noted, the *R-squared* and *Adjusted R-squared* coefficients associated with the model have significant values, giving evidence on the reliability of the model. Like in the case of Romania, the free term indicates a major influence of factors that are not specified in this scenario, with an overall unfavorable impact.

Conclusions

Econometric methodology is an useful tool for the measurement of correlations between the evolutions of macroeconomic variables. The analyses we have performed within this article revealed the major influences on macroeconomic growth at the level of geographic regions. Thus, even if in absolute value the Romanian GDP poses a small contribution to the EU28 amount, the regression model displayed a stronger influence, characterized by a parameter greater than 4.5. Another set of useful results characterize the influence factors of GDP growth in Romania and within the group of five countries. The estimated models outlined the positive influences of final consumption expenditures made by households, and mixed situations in the case of foreign-trade related factors. The final consumption proved to be the most significant factor (as absolute value) in the evolution of Gross Domestic Product indicators studied. The models presented can be extended across the dimensions that govern the grouping of values for various indicators, which is the possibility to analyze data for an extended interval, for a larger set of measures, and more countries. The results are useful for analysts and decision makers, as they outline the impact of important factors on the economic situation and evolution of the country. The final consumption is a key factor of GDP analysis, as it refers the inclination of people towards consumption, while the performance of the foreign trade affects the position of the country in the international commerce system.

A New Classification of the Risks of the Quality Processes

Daniel S. Demidenko, Department of Finance, Institute of Industrial Economics and Management, Peter the Great St. Petersburg Polytechnic University, Russian Federation, demidenko11@rambler.ru

Alexander M. Malinin, Department of Regional Economics and Nature Management, The St. Petersburg State University of Economics, Russian Federation, Department of Regional Economics and Nature Management**,** Department of World Economics and Management, International Banking Institute, Saint-Petersburg, Russian Federation, alexmalinin46@mail.ru

Alexander N. Litvinenko, Department of economic security and management of socio-economic processes, Saint-Petersburg University of the Ministry of Internal Affairs of Russia, Lanfk@mail.ru.

Abstract

The factor of the quality process is the general economic situation, which can be conditionally expressed by two states of the economy: growth or decline. In the case of growth, the quality process develops, in the event of a recession, it brakes and damps. If quality improvement is viewed as one of the most important areas of socially significant process aimed at meeting social needs, then changing demand, supply and corresponding changes in market prices for products are risk factors for this process.
There are many approaches to analyzing and determining risks, but, in accordance with the approach developed by the authors, the risk can be considered as "insufficiency" for all factors of the quality process. Insufficiency means the deviation of the actual factor value of the quality process from the required or expected value. For example, inadequate supply and demand for products of improved quality, inadequate production factors, inadequate investment in projects or income from investments, or both. Having determined, therefore, the quality process, we further assume that all factors of the process are risk factors at the same time. The article presents a new classification of the risks of quality processes.

Keywords: Quality process. Risk classification. New risk's factors.

Introduction

Let us consider that the possibility of realizing each process is determined by the inherented factors, and the effectiveness of implementation is the effectiveness of applying these factors. So, the production process can be successfully implemented only if all the factors of this process are realized - the factors of production, which are determined as (materials, labor, production technology, equipment process control system, other factors can be allocated). This is true fact of any process, and therefore we can talk about the factors of any process. From this point of view, the process of creating quality (Hackman & Wageman, 1995, Biazzo & Bernardi, 2003), (let's call the "quality process"), if it is fair to consider it separately from the process of creating or producing products, is also determined by the action and effectiveness of the application of the factors of this process, which we henceforth call "quality factors".

The innovative component always plays a central role in the processes of quality (Crosby, 1980, Nikolova & Rodionov, 2015). The improvement in quality leads to an improvement / change in the properties of the product, and as a result it is possible to talk about a new product with new properties. Commercialization plays an important role in the process of improvement the quality of the products (Flynn et al., 1995); ensuring the effective demand for products of improved quality. Improving the quality of the product cannot be ensured without it, it will slow down the process of quality and it may finally stop, the quality improvement will not be achieved, the quality of the

product will return to the previous level (Stevenson & Hojati, 2007, Sokolitsyn, Ivanov & Sokolitsyna, 2016).

The economic model of the described process is as follows: with an increase in the quality of the demand curve in terms of the quantity of product / product price shifts to the right parallel to itself. The process of improving quality is represented by a set of parallel functions of demand for a product. But the increase in effective demand for foodstuffs encounters a decline in effective demand in the conditions of economic recession. This can be graphically represented as a price increase due to quality improvement with a fixed amount of product. In a broad sense, the increase in the price of a product with the growth of quality is the mechanism of inhibition of the quality process, since an increase in price reduces demand. In the conditions of economic recession the slowdown effect of the quality process is exacerbated by the likely possibility of reducing the supply on the market due to the slowdown in production rates.

This situation is equivalent to a shift in the supply curve to the left parallel to itself. At the same time, the increase price will be even more intensive.

Problem Statement and Research Objective

There are many approaches to the analysis and identification of risks, but, in accordance with the approach developed by us, the risk can be considered as "insufficiency" in all factors of the quality process. Insufficiency means the deviation of the actual value of the factor of the quality process from the required or expected value. For example, the lack of demand and supply for products of improved quality, inadequate production factors, inadequate investment in projects or income from investments, or both. (Nikolova & Rodionov, 2017, Sweeney et al., 1999)

In the economic literature, there are different points of view regarding the numerical definition of the magnitude of the risk. It is normally to consider the value of the parameter which characterizes the risk factor (in this case the quality factor), the random and normally distributed quantity, whether to evaluate as the risk factor the "second half" of the distribution, because the excess of the actual yield over the expected or planned is not a risk of loss but the additional effect. The author's point of view is that this deviation should still be viewed as a risk and not as a "gift of fate", since in this case the overall financial balance in the economic system is violated, there are disproportions of financial plans, which requires their correction and the implementation of additional corrective measures, possibly requiring additional resources, and can also lead to a change in the timing of the implementation of plans and obtaining the required results. From the point of view of risk management processes, including the quality process, two main tasks can be distinguished:

1. To determine the composition and classification of risks, i.e. identify them, as well as know their quantitative value. Here the main thing is the definition of the composition of risks, their description and classification.

2. According to the authors, any types of risks can be quantified. The simplest method for quantifying process risks is an "expert evaluation" of the magnitude of the risk, which is the most accessible in practice, but also the least justified because of subjectivity assessments.

Key Results

Let us outline the author's approaches to solving these problems. Let's consider a conditional economy- an economic system in which, within the quality process, we will allocate "n" directions of investment investments, the implementation of which corresponds to the corresponding needs existing in the economic system or in society. Let us consider that the satisfaction of any social needs, other than the current consumption of goods, requires "long" investments or costs from a financial point of view.

As part of the quality process, "open" investment projects are considered in certain areas that meet public needs, but with unlimited (or limited in a wide range) investment / capital investments in each direction.

To optimize investment activity in the economic system, "linear" optimization tasks can be used. As it is known, the duality property is inherent in linear optimization problems: the direct problem (as a rule, the problem of optimization of the production plan in the wide sense) always corresponds to the dual problem (as a rule, to determine estimates, parameters of the optimal production plan). Hereinafter, the term "production plan" is considered by us within the framework of the quality process, although it can be used for any process.

If the dual optimization task formulated in accordance with the established mathematical rules and it is difficult to find a meaningful economic interpretation, this may be an indication of the erroneousness or incorrectness of the formulation of the direct optimization problem. In the author's opinion the existing notion that a dual task does not need to have a meaningful interpretation could be considered erroneous.

Let's formulate the direct problem of optimization of the production plan (for the quality process):

$$\widehat{I_1} \times x_1 + \widehat{I_2} \times x_2 + \cdots + \widehat{I_n} \times x_n \to max$$

$$\begin{array}{ll} x_1 + x_2 + \cdots + x_n \le \lim & (y_1) \\ x_1 \le \overline{x_1} & (y_2) \\ \ldots & \\ x_n \le \overline{x_1} & (y_3) \end{array}$$

Where: $\hat{I}$- the expected or "normative", projected return on investments in the areas: $(x_1, \ldots, x_n)$- the size of investments in the economic system in the directions; lim - the available limit of the amount of investments, capital investments in the system for all directions, $\overline{x}$ - - the amount of investment in areas reflecting public needs; $(y_1, \ldots, y_n)$– - variables of the dual problem.

The discussed optimization problem is linear, a solution can be obtained by a simplex method of linear programming. Variable values of the problem are the size of investment in socially significant areas (($x_1 \ldots x_n$).).

The economic meaning of the task is to determine the size of the investment (investment plan) for the economic system in areas reflecting social needs, which ensures maximum return on investment with appropriate restrictions. In a wide sense, one could also talk about the usefulness of investments in these areas.

Let us formulate the dual problem. By definition, the dual task is always the task of determining the estimates or prices of the optimal plan obtained as a result of solving a direct problem. It is always the maximizing of the objective function for the direct task and minimizing of the objective function for the dual problem.

$$y_1 \times lim + y_2 \times \overline{x_1} + \cdots + y_{n+1} \times \overline{x_n} \to min$$

$$\begin{cases} y_1 + y_2 \ge \widehat{I_1} \\ \ldots \\ y_1 + y_{n+1} \ge \widehat{I_n} \end{cases}$$

The economic meaning of the dual task is to determine the estimates of the parameters of the investment plan, under which the costs of attracting financial resources are minimized for the implementation of the investment plan:

• The price of capital in the discussed economic system (% rate on the financial market- y_1);

• the price of capital investments risk in socially significant investment directions ($y_2 \dots y_{n+1}$), considers the risk of non-fulfillment or failure to ensure the required effectiveness of investment.

In general, it is required to minimize the costs of attracting financial resources for the implementation of the social needs at the available risks It will be equal to the price of investment resources and payment for the risk of dissatisfaction with public needs.

We will explain the last component. In the left-part of all inequalities, there is a "payment for the investing risk " and since the risk of investing in areas reflecting the public needs is singled out as a separate component, it is logical to assume that the price of capital in the economic system (the interest rate in the financial market-) reflects the risk-free interest rate (otherwise there could be a double risk accounting). In the left part - the market price of investments in the directions taking into account the risk (risk-free interest rate and risk premium). According to the principle of "duality", the market price of attracting investments in all directions simultaneously reflects the amount of required return on investment. Thus, the constraints of the dual problem express the necessary condition: "the actual return on investments in risk-oriented areas should be greater than the" normative "yield"". This excess can be used to compensate for losses from investment risks in the directions. If the condition is not fulfilled, the required return on investment will be more practically achievable and the optimization condition will not be met - the costs of attracting financial resources to the system will not be minimal, and the quality plan will be optimal. However, additional costs may be required to implement the plan.

If we transfer the risk-free interest rate to the right side of the inequality, we get the value of "added value" per unit of each direction of investment - the normative return on investments in the direction minus the interest rate: $y_{n+1} \geq \hat{I}_n - y_1$.

At the same time, for each direction of investment, the added value should not be more than the "risk price".

The described new type of systemic risk can be defined as "the risk of a suboptimal financial solution" - , the risk of making a decision to attract financial resources to the economic system for the quality process.

The risk caused by investment activity in the economic system can still be described as a "temporary risk", because investment processes always develop in time. This risk is also present in the quality processes, since these processes are unrealizable without attracting investments. It can also be attributed to financial risks, since the use of the time factor is an important point of financial analysis (as opposite to economic analysis). Let us show what is behind the definition of the numerical value of the "risk of a suboptimal financial solution".

Consider the simplest scheme of investment analysis: first, one-time investment costs are realized, after which an equal cash flow "CF" income can be obtained from the investment during a certain period of time "n". The invariable amount of income is used to exclude the influence of the income factor in the numerical analysis of risks. In accordance with the rules of investment analysis, we determine the current value of the total income from investments for the whole period - PV: $V = CF_1 \times DF_1 + CF_2 \times DF_2 + \cdots + CF_n \times DF_n$, , where $DF_{1\dots n}$denoted discount factor for the corresponding year at the risk-free rate r.

Here we will consider a specific type of investment risk: a decrease in the return on investment (CF) over time - the further away the income from the moment of one-time investment, the lower the amount of expected income. It is assumed that in each subsequent period of time the forecasted revenue decreases by a relative amount $0 \leq \alpha \leq 1$. Under such conditions the current income PV after period "n" is equal $PV = CF_1 \times (1-\alpha)^0 \times DF_1 + CF_2 \times (1-\alpha)^1 \times DF_2 + \cdots + CF_n \times (1-\alpha)^{n-1} \times DF_n$.

Let us see the following:

$$PV = \frac{CF}{1+r} \times \left(\frac{(1-\alpha)^0}{(1+r)^0} + \frac{(1-\alpha)^1}{(1+r)^1} + \cdots + \frac{(1-\alpha)^{n-1}}{(1+r)^{n-1}} \right)$$

Let' $1-\alpha/1+r = \beta$, then $PV = CF/1+r \times (1+\beta+\beta^2+\beta^3+\dots+\beta^{n-1})$.

According to the rules of arithmetic, the sum of such a series will be equal to $^{1}/_{1-\beta}$.. Taking into account these conditions, the current income of PV is equal to after the algebraic transformation: $PV = {}^{CF}/_{1+r} \times \left(\frac{1}{1-\left(\frac{1-\alpha}{1+r}\right)}\right) = {}^{CF}/_{r+\alpha}$.

As you know, the current market value of the final cash flow of income of any configuration can be equivalent to the current market value of the capitalized cash flow in the form of an infinite annuity. Refer to the above analysis we can see that the rate of capitalization of the stream of expected returns from investments under these conditions is a risk-free interest rate plus a risk premium equal, in this case, to a probable increase in the uncertainty of future revenues, which increases with distance from the current time. We designated this value as "temporary risk", here it is the rate of decline in the expected income "α". Since the time factor is an indispensable element of financial analysis, temporary risk can be viewed as a form of financial risk. This is a complementary, but at the same time complicating moment for classifying risks.

Conclusion

All considered risks fully relate to the management of the quality process, as well as to other processes that can be identified as an independent object of management. All risks that correspond to the proposed classification are complex and can be estimated quantitatively from the positions offered by us. In some cases, preconditions are necessary to apply the proposed quantitative methods for assessing the risks associated with the process. Thus, in order to quantify the systemic "risk of making a suboptimal decision" about attracting additional financial resources for the quality process, it is necessary to ensure the optimality of the quality process itself, and therefore to have practically acceptable criteria for its optimality. "First, optimize the quality process, and then ensure that the optimality of the process management solutions is appropriate." Since this is a complex task, perhaps this explains the underdevelopment methodologically and in practice of the new types of risk of the quality process we have considered.

Abstract

In the scientific field, characterized in general as "research of innovative problems", a clarification of terminology and basic concepts pertaining to the studied problems is of great importance (perhaps more important than in other issues of the science of economic management). The article presents the author's definition of a number of key concepts of this scientific field, besides the peculiarities of the methodology of quality management which are applied specifically to the innovative activity of industrial enterprises are formulated.

The issues discussed in the article, in spite of the rich scientific background, are particularly relevant and still controversial. The authors justify the meaning of a "new / innovative product" not only as a "proper" product, but also as a process, a technology that, in turn, can be used both for the production of new products only and for the production of traditional "old products" with use of new methods / technologies, providing more economic use of resources.

The article presents a schematic diagram of an innovative mechanism that reflects the typology of managing the innovation process of an industrial enterprise as a single process of production and consumption of innovative products. Within the innovation system of the enterprise, quality management issues are considered separately, namely, its economic component as an innovation process. The article also shows how innovation processes are managed within the framework of the innovation system based on the example of quality management

Keywords: Innovative mechanism, innovation process, product, new / innovative product, proper, quality management.

Introduction

The concept of an "innovation system" combines such key components as the creation / production and consumption / use of innovative / new products. In our opinion, these are products that first appear in the relevant market (labor, factors of production, capital). The formation of an innovative system ensures the unity of the processes of creating and using new products within the framework of a single "innovation process". Based on this, new products can be:

- ✓ "actual" products,
- ✓ Processes, technologies that can be used to produce only new products, or also for the production of traditional "old products" using new production methods / technologies that ensure more cost-effective use of production factors in the production process (higher labor productivity, lower resource intensity of production).

Problem Statement and Research Objective

The company strives to maximize the useful result of its activities, while usually there are financial and budgetary constraints, so we can talk about optimizing activities under the specified conditions. (Asheim et al.,2003, Chesbrough, 2004, Hobday, 1998) When introducing system innovations - innovations such as management automation tools, switching to new products, technologies, etc., the object of research should be not only the innovation itself, as a tool that determines the main factors for the formation of the economic effect, but also the forms of interaction of systemic innovations with the organizational and production system, within which it is being implemented. (Freeman & Soete, 1997, Demidenko, Gorovoy & Malevskaya-Malevich, 2017)

Thus, in the actively developing risky external environment, the development of modern, effective management mechanisms is required, which primarily includes planning mechanisms in the broad sense, in particular, innovative mechanisms for the formation and economic justification of innovation programs. (Nikolova, Kuporov, & Rodionov, 2015, Rodionov, Rudskaia & Degtereva, 2017)

Key Results

In principle, the scheme of the innovative mechanism, reflecting the typology of management of the innovation process, as a single process of production and consumption of innovative products, is presented in Fig. 1

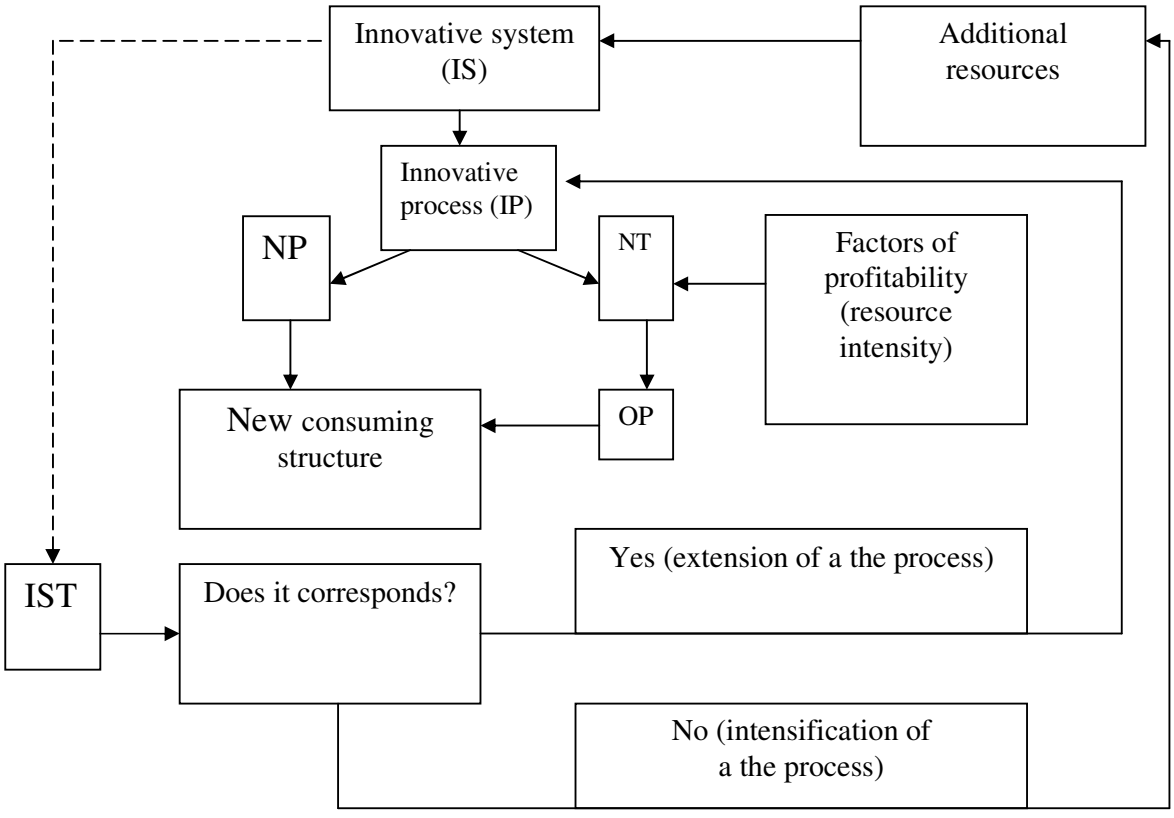

Fig. 1: Scheme of the innovative mechanism.

IS is an innovative system; IP is an innovative process; NP - "new" products; NT - new technologies (production technologies of products, in which the factors of economy (resource intensity) are

intensified); OP - "old" products produced using NT; NSC - a new structure of consumption; IST is an innovative standard.

An innovation system does not necessarily represent any organizational structure. It is a mechanism of economic management that generates new structure of consumption products, both "new" in their consumer properties, and "old", with the former consumer properties of economy or, in a broad sense, resource intensity. The new structure of consumption is "checked" in the innovative system for compliance with its innovative standard, which can be developed in the most innovative system, or is externally specified in relation to it (the diagram shows the dotted line). An essential element of the innovation system is an innovative process that includes "new" and "old" products and processes / technologies for their production. If the standard is complied with, the innovation process continues, if there is a discrepancy, its "intensification" is necessary, if necessary - by attracting additional resources.

We can talk about the cycle of the innovation process in the innovation system, it can be defined as a period from the beginning of the innovation process to the formation of the new structure of consumption. In this sense, the diagram (Fig. 1) depicts one cycle of the innovation process, which recurs during the innovative process.

As part of the mechanism of the innovation system, the innovative standard should ensure the timely promotion of both strategic and actual goals and objectives for managing the innovative process within the framework of the innovation system.

New production technologies in the framework of the innovation process can be used both for the production of new products and for traditional products, and when used by the consumer the utility, is higher due to improved performance indicators for their production (less resource intensity). The result of the innovation process is a new structure of consumption of products, which is either preserved if it meets the current consumption standard (old products may also be preserved if they become more economical in use due to improved production technologies) or changes in the direction of strengthening the influence of innovative factors to ensure compliance with the current, ever-changing consumption standard

The peculiarity of managing the innovation process, as the process of economic management, is the need for a certain resource base for the continuation or intensification of the innovation process. The existence and, if necessary, the replenishment of the resource base is an important function of the innovation system. The resource support of the innovation process should be considered separately, in particular, the question of whether resource provision should be considered as part of the Innovation process.

Quality management could be considered as one element of the Innovation process within the innovation system and its economic component. Quality, as it is known, is defined as a set of product properties that determine its consumer value when used. Using the example of quality management, it is possible to see how the IP is managed within the framework of the innovation system. As the properties of the product, you can consider the consumer characteristics of the product itself (purpose, speed, power, composition and accuracy of operations / works, etc.), as well as indicators that are more relevant to the process of product manufacturing (economy of use, resource intensity). At the same time, innovative functions in the quality management process are improving the quality of products and ensuring their quality.

The improvement of consumer characteristics of the product leads to the improvement the quality of products, and to ensure the quality of the product - the preservation of the consumer characteristics achieved in the production, as well as the cost reduction of products, reducing their resource-intensive use (production costs in terms of the methods used to evaluate the quality of the production process, metrology, reducing the level of rejects and technological losses, using economical and reliable quality control methods).
It can be seen that part of the quality management system related to products is not the task of economic management: improving the properties of products is an engineering task, often requiring

capital investment and a long time for implementation. Consequently, in a short period of time, in which IP is usually considered within the framework of an innovation system, improving the quality of products by improving their properties should not be considered at all in the production sphere, only in the sphere of consumption. You cannot improve the properties of the products produced, but you can improve the structure of their consumption. This is justified with regard to the quality of products, which is determined by the composition of consumer properties. (Figure 1)

Conclusion

When introducing innovation system - innovations such as management automation tools, switching to new products, technologies, etc., the object of research should be not only the innovation itself, as a tool that determines the main factors for the formation of the economic effect, but also the forms of where it is being implemented.

Thus, in an actively developing risky external environment, the development of modern, effective management mechanisms is required, which primarily includes planning mechanisms in the broad sense, in particular, the mechanisms for the formation and economic justification of innovation programs

Abstract

As is known from economic theory, the market is a socio-economic institution that gives sellers and buyers the opportunity to come into contact for the exchange (mutually beneficial trade transactions). Taking into account the transactions difference in terms of the objects and conditions of implementation, different types of markets are allocated depending on the degree of competition (that is, the number of sellers, buyers and the number of exchanged products). The mechanism of free competition is not comprehensive in a market economy. There are industries in which one firm is a supplier of a product that does not have close substitutes or competitors on the market, thus such industry or enterprise are monopolies in the market place.

Keywords: Natural monopoly. Criteria of economic efficiency. Balance

Introduction

Unlike free competition, the monopolist sets not only the quantity of the products offered, but also the price, choosing a point on the curve of the sectoral demand. (Sharkey, 1982)

The market of a homogeneous goods is fully monopolized and there is only one seller and other sellers do not have permit to enter this market One of the reasons for the emergence and existence of a monopoly is the possibility of obtaining significant economies of production scale (saving on fixed production costs). The economy is the greater, the fewer suppliers (producers) are presented on the market. The presence of only one supplier on the market could be considered the ideal situation, who receives all the economies of production scale in the form of profits. (Baumol, 1977)

The market is the most monopolized under absolute or pure monopoly conditions. In practice, the so-called natural monopolies are closest to the pure monopoly market model. (Berg & Tschirhart, 1988) (Laffont & Tirole, 1994)

A natural monopoly exists when economies of production scale allow one enterprise to satisfy the entire market demand before the returns to production scale begin to decline. In addition, this type of monopoly is called natural because in this case the entry barriers are built on features of technology that reflect the natural laws of nature, and not on property rights or government licenses. Forced dispersal of production at several enterprises in this case is inexpedient, it would lead to an increase in costs.

Thus, a natural monopoly is a state of the market for services (goods, works), in which the creation of competitive conditions to meet the demand for a certain type of services is impossible or economically impractical due to technological production features and type of services it offers.

Features of the status of natural monopolies are manifested in various aspects: from the stage of creation to bankruptcy (insolvency).

For example, to recognize a person's legal status as a natural monopolist, the following requirements must be fulfilled: the existence of an objective economic situation in which a certain type of activity is characterized as natural monopoly; actual performance of such activity; legality (competence) of carrying out such activities. Legality can be confirmed by the constituent documents of the organization, the availability of necessary licenses, certificates, etc.

For example, the following features can characterize a natural monopoly:

1) most often, these are industries and infrastructures, which have a unique technology that requires significant initial investment;

2) there is a steady inelastic demand for the their products;

3) there is no competition in connection with economies of production scale and high conventional costs;

4) parties of natural monopoly produce a public (collective) nature products. The main purpose of their functioning is the implementation of any type of activity (mission) aimed at solving social and economic problems determined by the needs of society and the state.

5) A main feature of many parties of natural monopoly is a high share of equity in the overall structure of liabilities.

6) The activity of enterprises in the field of natural monopolies is regulated by the state with the help of antimonopoly legislation, and the tariff method takes the central place in this legislation system.

Based on the foregoing, we can conclude that the production of electricity, including production using alternative energy sources, has characteristic features of natural monopoly entities. Produced products are certainly a product of a collective nature, production technology is expensive, requiring significant initial investment, the demand for electricity is inelastic.

The majority of enterprises - subjects of natural monopolies - are in state ownership, subject to state regulation. Such organizations are forced to work in the interests of all participants in the sphere of natural monopolies (enterprises, consumers, the state themselves), therefore the main purpose of their functioning is the implementation of some kind of activity (mission) aimed at solving social and economic tasks determined by the needs of society and the state. The purpose of the enterprise's activity is reflected in its charter and approved by the authorized state body.

In addition to the obvious economic function, enterprises and electricity producers with the help of alternative sources solve the very urgent task of ecological efficiency

Problem Statement and Research Objective

For entities of natural monopoly, the task of a formation a sufficient amount of financial resources is closely linked to the tariff policy pursued at the enterprise, since the tariff value directly affects the profit received by the enterprise - the main source of its own financial resources. Formation of financial resources of enterprises - subjects of natural monopoly can be carried out at the expense of attraction of credits. The return of borrowed funds is carried out at the expense of net income and the funds of the depreciation fund. (Laffont & Tirole, 1986, Baumol, Bailey & Willig, 1977)

A feature of many subjects of natural monopoly is a high share of equity in the overall structure of liabilities.

Most natural monopoly entities have a number of features that determine the asset management policy: high capital intensity of production, the availability of obsolete equipment necessitates the renovation of fixed production assets, the search for financial resources for their renewal; growth of accounts receivable, etc., which also determine the specific structure of liabilities. (Sokolitsyn, Ivanov & Sokolitsyna, 2017, Rodionov, Rudskaia & Degtereva, 2017)

The main direction of investment policy, characteristic for natural monopoly entities are real investments. (Korol'kova, 2000, Borisova & Konoplyanova) They are characterized by a long

payback period, a high volume of capital investment, a long period of amortization of elements of fixed capital. Real investments can be carried out both at the expense of own funds (net income, depreciation charges), and at the expense of borrowed funds. The implementation of financial investments by entities of a natural monopoly and other participation in the activities of other commercial organizations is possible only upon agreement with the authorized body, at the expense of net income (actual profit). When assessing investments, it is necessary to take into account their social significance along with the financial effect.

Key Results

It is legally prohibited for the parties of a natural monopoly to invest free cash in securities, so the task of optimizing the money turnover is solved by effectively managing the company's cash flows during the circulation of its cash, ensuring the synchronization of volumes of receipt and spending of money for certain periods, maintaining the necessary liquidity of current assets. One of the results of such optimization is the minimization of the average balance of free monetary assets, which ensures a reduction in losses from their inefficient use and inflation.

The most favorable environment for the effective operation of any enterprise is the general economic equilibrium, which ensures the balance of all macroeconomic parameters: the volume of output produced by enterprises, final and intermediate (internal production) consumption, inter-production relations between enterprises, employee wages, products market prices

The most substantiated and successfully applied economic equilibrium model in the economic system is the balance-sheet "input-output" or the model of inter-branch balance of V. Leontiev (Novozhilov, 1972). Let consider a static, so-called "open" model of "input-output", which establishes equilibrium in the manufacturing sector. The products of "intermediate consumption" in this sector are the needs of technological processes, and the final demand is realized in the consumer sector. At the same time, it is possible that the same products refer to both final and intermediate consumption. It is assumed that the number of branches in the economic system corresponds to the number of products (one industry is one product). In the framework of this study, a model of production planning in the economic system is considered, ensuring a balanced and, under certain conditions, an optimal production plan and a model providing balanced estimates (hereinafter-the price) of an optimal balanced plan.

The balance of the production plan determines the quantity of each type of product that must be produced in a certain period to meet the production (intermediate) demand and the final (consumer) demand for products.

The parameters of the model are the coefficients of direct costs of resources for the production of products, due to the technologies used.

Mathematically, the problem can be represented in the following form (here and below - in the matrix form): $A \times X + C = X$, where A is a technological matrix with the elements of non-negative "technological" coefficients of "direct costs", indicating how many physical units of one product (one production sector) must be used to produce one unit of another product, X-vector- the column of the physical volume of output of products of each type in a certain period / planning period (Physical unit); C-vector- the column of final consumption of products in the planning period, (Physical unit).

It is also possible to isolate the column vector "$A \times X$", which is usually characterized as a vector of "material costs in the production sphere".

Matrix "A" provides information on the existing structure of intersectoral relations with the existing production technology and under these assumptions can be used for current or long-term planning. An additional condition for the application of the model is, in addition to the unchanged production technology, the linearity of the production cost model. The described model represents a direct task to make a balanced plan of manufacture in natural indicators.

The inverse / dual problem can be represented as follows: $P \times A + Y = P$, where P - vector- the row of product prices, (rubles / units); Y-vector of wage costs for production of a unit of production, rubles / unit.

These tasks are not optimized, because they do not have objective function and optimization criteria, and they contain strict equalities as constraints. From the relationship between the conditions of a direct and dual task (a balanced plan and its estimates), we can derive important equilibrium conditions in the economic system.

1. (***the balance condition***). All wages in the economic system must be spent in the consumer sector (final consumption).

The balance conditions are transformed to the following form:$X \times (I - A) = Y, P \times (I - A) = Y$, where I is the unit matrix, then the final consumption / demand in value form can be determined taking into account the given conditions:

$$P \times C = \frac{Y}{I - A} \times C = \frac{Y}{I - A} \times X \times (I - A) = Y \times X$$

From the above relations follows the condition of intersectorial equilibrium: to ensure a balance in the economic system, the value of the final consumption / demand should be equal to the amount of wages, which means that all wages must be "spent" in the consumer sector

Let us consider a conditional numerical example. Given

$X = \begin{pmatrix} 12 \\ 8 \end{pmatrix}$, $C = \begin{pmatrix} 4 \\ 5 \end{pmatrix}$, Y=(5 6), A= $\begin{pmatrix} \frac{1}{3} & \frac{1}{2} \\ \frac{1}{12} & \frac{1}{4} \end{pmatrix}$.

It is necessary to confirm the fairness of the conditions for ensuring a balance in the economic system.

Solution:

P*(1-A)=Y, $(P_1 P_2) * \begin{pmatrix} \frac{2}{3} & -\frac{1}{2} \\ -\frac{1}{12} & \frac{3}{4} \end{pmatrix}$ =(5 6)

$(\frac{2}{3} * P_1 - \frac{1}{12} * P_2 \quad -\frac{1}{2} * P_1 + \frac{3}{4} * P_2)$=(5 6)

$\frac{2}{3} * P_1 - \frac{1}{12} * P_2 = 5$

$\frac{1}{2} * P_1 + \frac{3}{4} * P_2 = 6$

$P = (P_1 P_2) = (\frac{102}{11} \frac{468}{33})$

P*C=Y*X $(\frac{102}{11} \frac{468}{33}) * \begin{pmatrix} 4 \\ 5 \end{pmatrix}$ =(5 6)* $\begin{pmatrix} 12 \\ 8 \end{pmatrix}$

107,91 ≈ 108. Condition fulfilled

If it is possible to avoid strict equality in the restrictions on the production and consumption of products, the task of determining the optimal interindustry balance and the corresponding optimal balanced prices becomes economically viable.

Optimization condition. The optimal balance in the economic system in planning is provided by determining the optimal balanced production plan (direct optimization problem) and the prices of the optimal production plan (dual task). Optimization of the production plan can be formulated as follows:

$$Y \times X \rightarrow min$$
$$X \times (I - A) \geq C$$

The economic meaning of the direct task of optimizing the production plan is to get an answer at what minimum level / standard of wages in the production sector of the economy "$Y \times X$" can be achieved the volume of production "X", allowing to provide the required level / standard of final consumption "C".

The economic meaning of the dual task of determining the prices of the optimal production plan is to get an answer at what maximum level of food prices, the required standard of final consumption in the economic system can be provided, while observing the available salary standards. The vector of the unknown variables of the dual problem "P" represents the prices of all the titles of products produced according to the optimal plan. The optimization of consumer prices can be formulated as follows:

$$C \times P \rightarrow max$$
$$P \times (I - A) \leq Y$$

Due to "linear" assumptions, the direct and dual optimization problems refer to linear programming problems and their solutions could be found using the appropriate methods

Conclusion

Profit maximization is achieved due to effective management of the company's assets, attraction of borrowed funds to the economic circulation, selection of the most effective areas of operational and financial activity. At the same time, in order to achieve the goals of economic development, the company should strive to maximize the net profit remaining at its disposal, which requires the implementation of an effective tax, amortization, and in the case of enterprises - natural monopolies and tariff policy. The volume of profit in the parties of natural monopoly is limited by the level of profitability, which is included in the calculated tariffs, as a mark-up to costs. Therefore, for enterprises -parties of natural monopoly - it is important to determine such an allowable level of profit that would allow them to function effectively and improve the quality of services provided.

The activity of enterprises belonging to the sphere of natural monopolies is regulated by the state with the help of antimonopoly legislation, the central place in which is given to tariff methods. In the world practice, the regulation of the activity of enterprises in the sphere of natural monopolies in the field of pricing takes place in accordance with models: based on regulation of the rate of profit, or regulation of tariffs.

Acknowledgment

This research was supported/ partially supported by Peter the Great Saint-Petersburg Polytechnic University. We thank our colleagues from the Department of Finance, Institute of Industrial Economics and Management who provided insight and expertise that greatly assisted the research, although they may not agree with all of the conclusions of this paper. We thank Alexander E. Karlik for assistance with methodology and for comments that greatly improved the manuscript.

Abstract

Fraud is a global issue overwhelming all aspects of human economic and business activities as it poses potential threat of financial losses. Many detection and prevention mechanisms such as internal control systems, operational audits, codes of conduct and forensic accounting have been applied in organizations aiming at effectively mitigate internal fraud activities with questionable outcomes. Instead of putting much attentions studying the effectiveness of existing fraud prevention mechanisms in mitigating the fraud but less promising outcomes, this doctoral-level research proposal explores the determinants of the effectiveness of organizational fraud prevention programs. In doing so, the proposed study would base the exploration on the theory of planned behaviour (TPB). The central part of this study is to investigate the behavioral intentions as determinants following the variables of TPB. By this exploration, the potential determinants of the effectiveness of the prevention programs and how those determinants influence current practice related to the fraud prevention mechanisms could be learnt. This proposed study would be a quantitative study in which local authorities in Peninsula Malaysia will be solicited for data collection.

Keywords: Fraud, Fraud Prevention Mechanism, Malaysia's Local Authorities, Theory of Planned Behaviour (TPB), Determinants.

Introduction

Fraud is a global issue overwhelms all aspects of human economic activities and business-related matters. Conceptually, fraud includes all acts of misappropriation, unethical and unlawful conducts involving financial and assets are fraud in its essence. Fraud as unethical and unlawful conducts on financial and assets has a severe effect on organizations. A vast literature (Levi et al. 2007; Levi & Burrows 2008, Isa 2011; Kennedy & Xu 2012; Tuan Mat et al. 2013) espoused the effect of fraudulent on the massive organizational financial losses. The Association of Certified Fraud Examiners' (ACFE 2014) estimated that approximately 5 percent of a business' annual revenue is lost to fraud. The Kroll Global Fraud Report (2015) states that "the number of businesses suffering a financial loss as a result of fraud has also increased, from 64% in the previous survey period to 69% this year (pp. 7)". The LexisNexis (2016) reports that "there are indications of increasing fraud challenges for US retailers based on rising fraud costs and volume" (pp. 7). As a global problematic issue, fraudulent in all types (e.g. asset

misappropriation, corruption and fraudulent financial statements) lead to tremendous severe effects to both public and public organizations.

Aligned with global initiatives in mitigating the fraud, the fraud prevention mechanisms have also been widely used in Malaysia. The prevention mechanisms namely internal control systems and operational audits (Bierstaker, Brody & Pacini 2006), reference checks on employees (Bierstaker, Burnaby & Hass 2004; Bierstaker, Brody & Pacini 2006), whistle blowing system (Deloitte 2014), corporate security (Campbell 2011) and forensic accounting (Golden & Dyer 2006) are common mechanisms used by both local authorities and consulting firms (KPMG, Ernst & Young and others) in auditing the fraud cases.

However, generally, the application of prevention mechanisms was unsuccessful in mitigating the fraud. In a fraud survey, KPMG (2004) showed that 83 percent of respondents admitted as having experienced fraud in their organisations. The survey had also found that kickbacks, hit and kiting and false invoices were the three most common types of fraud faced by businesses in Malaysia. The high percentage of respondents' acknowledgement on the reality of fraud in their organizations indicates that the effectiveness of organizational fraud programs is low. In Malaysia context, despite the long run of fraud prevention programs over the years, the fraud cases continue to grow with no sign of deterioration.

The ineffectiveness of the current fraud prevention mechanisms in mitigating the fraud activities as indicated by the growing figures of fraud cases leads to an attempt of "understanding the conditions" (Ramos 2003) conducive for and maintain the fraud activities. While the triangle explains the factors, or causes of fraud occurrences, the conditions that associated with the effectiveness of preventive efforts remain questionable. This proposed study therefore takes the challenges in identifying the conditions that possibly influence the effectiveness of such mechanism as an academic effort.

Studying the effectiveness of detection and prevention mechanisms is endless and seems less fruitful in mitigating the fraud as the number of fraud cases increased yearly as Ernst & Young Global Limited (2016) acknowledged that *"while many businesses have made significant progress in tackling these issues, there remains a persistent level of unethical conduct"*. This acknowledgement indicated that detection and prevention mechanisms does not effective nor satisfactorily solved the fraud issue as it keeps increased over year. Earlier, Ramos (2003) suggested that the "investigations into the mechanisms of fraud prevention and detection must seek to understand the conditions that are generally present when fraud occurs. Therefore. instead of solely considering the effectiveness of prevention mechanisms, "understanding the conditions" in Ramos' suggestion may include exploration into the determinant of effectiveness of those mechanisms.

Getting triggered by this suggestion, the proposed study highlighted in this paper would explore the determinant of the effectiveness of fraud prevention initiative. In mechanizing the exploration, the proposed study looks at the potential of theory of planned behaviour (TPB) as determinant for measuring the effectiveness of organizational fraud prevention initiatives. This movement is due to the believe that fraud is caused by intention of fraudster as initially explained through the pressure, opportunity and rationalisation of Cressey's (1973) Fraud Triangle. Extending the intention trait, the proposed study would explore the factors determining the effectiveness of fraud prevention initiatives in Malaysian local authorities, and examine the relationship between the planned behaviour variables and the effectiveness of fraud prevention framework. The proposed study thus would explore the psychological process that *"put up a behavior that is stimulated by intention which is also influenced by some underlying beliefs"* (Ajzen, 1985; 1988; 1991). In this way, the internal behaviour such as ihsan, personal integrity, self-efficacy, idealism-ethical ideology, organizational commitment and intrinsic motivation are the determinants presumably influence the effectiveness of fraud prevention initiatives.

The rest of the paper is arranged to include the necessary components justifying the proposed doctoral-level of study. Next section justifies the issue, gap and objective of the proposed study. The following section briefly presents the related initial literature on the fraud issue followed by the potential determinants factors of the proposed study in Section 4. Section 5 presents the research model with its respective hypotheses. Section 6 follows to outline the potential method in mechanizing the study.

Section 7 discusses the significant and the potential outcome of the study while section 8 concludes the proposal.

Fraud Prevention Mechanisms

One of the practical way to minimize losses - mainly the financial - due to fraud is to prevent their occurrence. Identifying the fraud occurrence can be made through fraud risk assessments that attempt at recognizing the potential factors and threats that make organizations vulnerable to the fraud. The literature reports numerous organizational fraud detection and prevention mechanisms in detecting and preventing the fraud before or after its occurrences, respectively. Among the well-known fraud preventive mechanism are internal control systems, operational audits, code of conduct (Efiong 2013; Bierstaker, Brody & Pacini 2006), reference checks on employees (Bierstaker, Burnaby & Hass 2004; Bierstaker, Brody & Pacini 2006), whistle blowing system (OECD 2012; Deloitte 2014), corporate security (Campbell 2011) and forensic accounting (Ranallo 2006; Golden & Dyer 2006) are widely practiced as a continuous attempt in mitigating the fraud. The procedural methods and the success level in implementing these detection and prevention mechanisms globally and locally were widely reported and easily retrieved and therefore do not briefed out in this paper.

Despite the numerous mechanisms applied in detecting and preventing fraud, the number of fraud cases grow every year. Kummer, Singh & Best (2014) reveal that *"a review of several fraud surveys conducted by large accounting and consulting firms [including Association of Certified Fraud Examiners (ACFE), Binder Dijker Ottec (BDO), Ernst & Young (EY), Klynveld Peat Marwick Goerdeler (KPMG) and PricewaterhouseCoopers (PwC)] reveals that fraud is a growing crisis that is being faced by organizations*. This acknowledgement implies that the effectiveness of fraud detection and prevention mechanisms is an issue and questionable.

The Determinants of the Effectiveness of Fraud Prevention

There are many factors that can inhibit the control of desired behaviour including abilities, planning, skills, and knowledge. Ajzen and Madden (1986, p. 457) argued that there is a possibility to measure perceived behavioural control. The Theory of Planned Behaviour (Ajzen 1991) centralizes on the individual's intention to perform a given behavior. This theory posited that greater perceived control over behaviour may occur with more resources and opportunities available for individuals. TPB outlines three variables that effectively measure individual intention. Detailing out TPB, Ajzen (1991) stated that *"Intentions are assumed to capture the motivational factors that influence a behavior; they are indications of how hard people are willing to try, of how much of an effort they are planning to exert, in order to perform the behavior. As a general rule, the stronger the intention to engage in a behavior, the more likely should be its performance"*.

With respect to fraud issue where the fraudsters are generally involved internal employees, this proposed study assumes that the fraudster's intention is the motivational factor that lead to conduct of fraud. Therefore, this paper argues that in investigating the effectiveness of the prevention mechanisms, the employees' intention should be the focus as perceiving the planned (intention) behaviour of fraudster (employees) would enable the "safeguard" planning in mitigating the fraud. The following section discusses the proposed theoretical framework guiding the proposed study.

The Framework of Determinants for Fraud Prevention Effectiveness

As indicated earlier, the TPB outlines three variables (attitude toward the behavior, subjective norms and perceived behavioral control) as general guidelines for examining intentional behaviour in an individual leading to physical behavioural conducts. This proposed study devises the elements of intentional behaviours to include ihsan, personal integrity, self-efficacy, idealism-ethical ideology, organization commitment and intrinsic motivation.

Ihsan

Ihsan or kindness is the first element considered as inclined toward the behavioural intention. This element is under the attitude toward the behaviour variable. Ihsan can be defined as "*The actions that benefit others than those of the action without any obligation*" (Umar-ud-din, 1991, p. 241). In Islamic point of view, kindness is highly encouraged and the Prophet (P) was reported to have said that among the people of Paradise are the "*People who hold power and the fair and equitable; truthful and has been endowed with the power to do good deeds; and he who is merciful and kind to his brothers and to every Muslim who works and who does not lend his hand even had a large family to support" (Iyad Ibn himar, Sahih Muslim, hadith no. 6853).* The inclusion of this element as a determinant for measuring effectiveness of the fraud prevention is justified in the following paragraph.

The Ihsan is the core concept in Islamic ethics as it focuses on behaviour for the love of God. The idea of worship in Islam includes any constructive effort or work. This shows that a Muslim employee who is committed at any level of the organization should be doing his/her work for the love of God and with an awareness that God watches his/her behaviour all the times, even if his/her superordinate and mates do not know his/her doing.

The concept of Ihsan also includes excellence. Islam emphasises not only the productivity but also excellence in workplace. Al-Quran emphasised that remuneration shall be commensurated with the effort made (3: 136, 99: 7, 48: 19). This rule applies to immediate reward in this life and deferred reward in the hereafter. Performance appraisal and reward to an individual is not only judged by humans but also by God (Qur'an, 18: 30). Prophet Muhammad (P) taught: ''God has ordained excellence in everything…'' 5 and ''God loves, when one of you is doing something, that he [or she] does it in the most excellent manner'' (Al-Qaradawi, 1995).

Personal integrity

Personal integrity is the second element considered under the TPB's attitude toward the behaviour. Personal integrity has many conceptual definitions. It can be defined as individual "coherence" (Selznick 1992), "personal commitment to principles" (Becker 1998; Maccoby 1988; Mayer et al., 1995) and "honesty" (Yulk & Van Fleet, 1992), and/or "private modal codes" (Barnard, 1968, p. 263). In the field of ethics however, personal integrity relates to the principle of self-imposed ethics, values and moral autonomy (Solomon, 1993; DeGeorge, 1993; Kolb, 1988). For philosophical reasons, scholars (McFall, 1987; Williams, 1973; Taylor, 1985) had considerably advanced to increase their understanding of individual integrity by developing elaborate descriptions of this concept. The following reasons justify the personal integrity as a critical element regarding the subject of the study.

Calhoun (1995) describes personal integrity with three philosophies: (1) integrated-self (2) identity and (3) clean-hands. On integrated-self, integrity involves an integration of internal determinants of self's desires, evaluation, also commitment to the whole community. As for identity, integrity means loyalty to projects and principles that represent the core of one's identity. Integrity in the clean-hands view means maintaining transparency, morality, and honesty of one's actions.

The personal integrity can be explained in three picture following McFall (1987). The first picture is an integrated self-picture where the integrated self-picture of integrity outlines several conditions that require integrity. An individual will not just become a follower of the crowd, but he/she will stand for something and had his/her own reason to take that stance. A person of integrity is willing to suffer consequences for his beliefs, despite facing undesirable consequences. Therefore, there is an unconditional commitment towards something that determines what we think is important, which defines largely to private moral identity (second picture of personal integrity). In the third picture, personal integrity, clean-hands picture, integrity is a matter of support. Should the occasion arise, an individual will stand on main principles that determine what the individual could have done through the agency and within the limits which he/she will not go beyond (here lies embedded and professional integrity).

A person who has integrity will not do unethical things, even if he can gain good results from the unethical things (Calhoun, 1995). This view captures the "action" part of the identity of the picture portrayed, for which individuals would stand for something that is not just a matter of personal identification with a set of values or principles, but also a commitment to overcome a defect of values (which means action).

Organisational commitment

The organisational commitment is the last element considered under attitude toward the behaviour. Elizur & Koslowsky (2001, p.594) defined organisational commitment as the attachment of an individual, emotionally and functionally, to his/her place of work. Organisational commitment can also be referred to as the relative strength of individual's identification with involvement in a particular organisation (Mowday et al., 1979, p.226). O'Reilly and Chatman (1986, p.493) refers organisational commitment as the psychology attachment felt by a person for an organisation. It reflects the degree to which an individual internalises or adopts characteristics or perspectives of the organisation.

Allen and Meyer (1990; 1991) identified three general themes in attitudinal conceptualisations of organisational commitment: affective attachment, perceived costs, and obligation. The three components of commitment are regarded as a psychological trait where employees experience at various degrees. Each component of the commitment gain experience in various strengths (Stallworth, 2003). As for the first component, workers with higher affective commitment would stay in the organisation because they want to. Secondly, a worker with high continuance commitment would stay because they need to. Lastly, workers with high normative commitment would remain because they must. All components may depend on different backgrounds, for example personal characteristics, work characteristics, duration of work, and others.

Intrinsic motivation

The intrinsic motivation is the sole element belong to the variable of subjective norms of TPB. Intrinsic motivation can be described as conducting an activity for its inherent satisfaction, rather than for some separable consequence (Ryan & Deci, 2000, pp. 56). Generally, intrinsically motivated person does an action for the fun of it or to be involved with challenging activities. It is not driven by reward, external products or pressures. Referring to White (1959), the phenomenon of intrinsic motivation was first recognized within experimental studies of animal behaviour. White (1959) found that many organisms engage in exploratory, playful, and curiosity-driven behaviours without elements of reinforcement or reward. This spontaneous behaviour apparently bestows adaptive benefits on the organism, which do not look for any reason to play that role. The positive experience is subsequently related to exercise and expansion of moral capacity to a person.

In humans, intrinsic motivation is one of form from the forms of human desires or motivation. Humans in their healthiest states are active, inquisitive, curious, and playful creatures, displaying ubiquitous readiness to learn and explore. They do not require extraneous incentives to do things. This natural motivational tendency is very important, especially during the development stage of cognitive, social and physical abilities. By acting on self-interest, a person will grow their knowledge and skills on their own. The tendencies to have interest in something new, to assimilate actively and creatively make use of developed skills are not limited to childhood. This tendency is an important feature of human nature that affects performance, persistence, and prosperity throughout life (Ryan & LaGuardia, in press).

Self-efficacy

The self-efficacy and idealism-ethical ideology are two elements placed under perceived behavioural control. Self-efficacy refers as individuals' beliefs about their capability to mobilise cognitive resources and courses of actions needed to perform a specific task successfully within a given context (Bandura, 1982, 1997). Individuals with high self-efficacy beliefs that they can achieve their goals by three leading factors, which are to put more effort on it, pursue career strategies, as well as setting higher career goals.

By referring to King (2004), it is learnt that people's self-efficacy and their intention to exert control over career outcomes would enable them to exhibit career self-management behaviours. Moreover, those behaviours can also lead to the achievement of desired career goals and ultimately career success.

Stucliffe and Vogus (2003) stated that individuals create an overall sense of efficacy and competence which enables them to gain control and mastery over task-related behaviours. The results have shown positive correlation between career decision-making as they are being made with self-efficacy and personal characteristics, thus supporting the argument that individuals with self-efficacy gain greater control in the events of their lives and successfully master tasks decided for them and influencing their behaviour in career decision-making (Taylor & Popma, 1990; Abdalla, 1995). Noe and Wilk (1993) and Bell & Staw (1989) noted that the evidence obtained from their empirical study supported that the self-efficacy beliefs can influence career development and growth.

Bandura (1997) had conceptualised self-efficacy in three-layered dimension, which are level, strength, and generality. Level refers to an individual's feeling regarding their ability to perform a task based on the degree of difficulty of the behaviour or task. Strength refers to individual performance that can be achieved based on that individual performance. Weak self-efficacy expectations are easily modified by disconfirming experiences, while strong self-efficacy is robust and promotes persistence in the face of obstacles. Generality refers to self-efficacy concerning the range of situations, in which an individual considers him or herself to be efficacious (Lent & Hackett, 1987). The self-efficacy theory states that determination of self-efficacy is based on the strength of self-efficacy and the level of self-efficacy. That determination consists of several factors, such as how much effort will result to good results, how long the effort can be sustained in the face of obstacles, also whether behaviour will be initiated. Self-efficacy provides individuals with the ability to influence their one course of action and alter their environments (Bandura, 1997).

Idealism-ethical ideology

The idealism-ethical ideology is the last element considered for inclusion under TPB's perceived behavioural control variable. Forsyth (1980) stated that moral judgment consisted of two orthogonal dimensions, which are idealism and relativism. Individuals with high idealism, believe that "desirable consequences can, with the 'right' action, always can be obtained" (p. 176). Idealism can be described as the level of individual's concern and the individual show it for the welfare of others. The relativism can be described as the extent to which someone accepts or rejects universal moral rules.

When there are some who are more preferred to choose moral in absolutes when deciding on which action is the ''right'' one, there are also others who takes contextual information into account before making any conclusions. It means that people who are affected by contextual information are relativists. Relativists feel that the right decision depends on the complexity of situation and the people involved in it. Relativists also tend to be more dependent on circumstances and personal attitudes rather than ethical principles when judging the actions of others (Forsyth, 1992). On the other hand, low relativists tend to believe that the right thing is always the one that is in harmony with universal moral principles, norms, or law, depending on the context.

The Research Model

The six elements of intentional behaviours belong to the three TPB variables discussed in prior section are diagrammatically illustrated as the research framework in Fig. 1. These six elements are the variables for the proposed study. Following these variables, the study progresses to formulate the hypotheses necessary for testing and measurement as shown immediately after the model illustration.

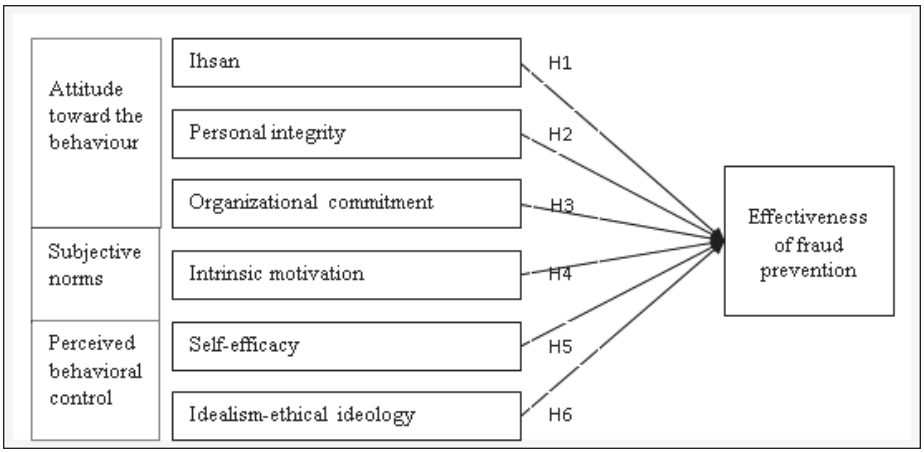

Fig 1: Conceptual Model for Exploring the Determinants of Fraud Prevention

The model depicted in Fig. 1 can be represented as;

$FP = ß_0 + ß_1 IH + ß_2 PI + ß_3 SE + ß_4 ID + + ß_5 OC + ß_6 IM$

Where:

FP : The Effectiveness of Fraud Prevention

IH : Ihsan

PI : Personal Integrity

SE : Self-efficacy

ID : Idealism-ethical ideology

OC : Organizational Commitment

IM : Intrinsic motivation

$ß_0, ß_1, ß_2, ß_3, ß_4, ß_5, ß_6$: Parameters

Based on the Figure 2, the potential hypotheses for testing are;

H1: Is there any significant relationship between ihsan and fraud prevention framework.

H2: Is there any significant relationship between personal integrity and fraud prevention framework.

H3: Is there any significant relationship between self-efficacy and fraud prevention framework.

H4: Is there any significant relationship between idealism-ethical ideology organizational commitment and fraud prevention framework.

H5: Is there any significant relationship between ideology organizational commitment and fraud prevention framework.

H6: Is there any significant relationship between intrinsic motivation and fraud prevention framework.

Research Methodology

This proposed study would adopt quantitative approach. The population of this study consists of 149 authorities in Peninsula Malaysia (Kuala Lumpur City Hall, 13 City Halls/Councils, 38 Municipal

Councils and 98 District Council). The questionnaires administered through mail will be used as the instruments for data collection. The data analysis would be using latest SPSS package but AMOS is another potential option for statistical examination. The statistical analysis techniques would be reliability and factor analyses, descriptive, correlation and regression among others.

Discussion: The Potential Outcome of the Study

The academic studies on the effectiveness of fraud detection and prevention are very common in the literature. The commercial and institutional reports on such issue are also easily retrieved. The study on the fraud issue looked at multiple dimensions of fraud such as the causes, the practices and the effectiveness of the mechanisms used in mitigating the fraud. With respect to the mechanism, different study produced different claims on the effectiveness of the mechanism adopted. Isa (2011) for example, claimed that "the literature on fraud consistently claims that an effective internal control system (ICS) is the primary means of preventing, detecting, and correcting fraud and errors". In contrast, Efiong, Inyang & Joshua (2016) posited that "forensic accounting techniques appears to be the most effective and are currently used in most developed countries of the world". Many other studies stated the claims that seem inconsistent with others in the subject of the effectiveness of fraud prevention mechanisms.

Deviating from this track – that does not effectively contribute to the decrement of the fraud cases – the proposed study seeks to explore the psychological aspects that triggers the occurrence of fraud. In other words, this study attempts at exploring the determinants or factors that associated with and leads to ineffectiveness of the fraud prevention mechanisms. By this, the proposed study explores the root instead of the shoot of the cause as embarking at the root is deemed to be more beneficial rather than justifying the outcome. Understanding the internal behavioral factors that possibly lead to fraud physical or behavioral commitment would help in devising and formulating a more comprehensive and effective prevention programs. While the existing fraud mechanisms concentrate more on "post" fraud conducts, the intentional determinants would help in tackling the "pre" fraud conduct that is internal to potential fraudster. The blend of both "pre" and "post" mechanisms complement each other in battling this universal organizational issue.

Conclusion

In Malaysia's context, this proposed research mainly aimed at driving the country's transition to a high value added and high-income economy with adequate preservation of financial sustainability. The National Key Result Area (NKRA) target to reduce crime and fight corruption and fraud in Malaysia is a key focus of the Government Transformation Program (GTP). Aligned with this aim, the issue of effectiveness of the fraud prevention mechanism should be properly addressed. It is expected that by knowing the cause of ineffectiveness of such programs, the appropriate solution may be formulated. This proposed study provides the basis for the formulation of the potential solutions that effectively addressed the fraud by first understanding the intentional behaviours of fraudster.

Acknowledgement

The proposed doctoral degree research described in this paper is supported and made possible by Malaysian Ministry of Higher Education's (MOHE) grants (600-RMI/FRGS 5/3(114/2015) under the administration of Institute of Research Management & Innovation (IRMI), Universiti Teknologi MARA (UiTM), Shah Alam, Selangor, Malaysia.

Abstract

Library has massively developed from traditional services to digital services in recent years. The demand from library patrons, institutions, colleges, and private organization needs and technology evolution, has changed the library setting either in budget allocation or in decision making approach. This study analyzes the borrowing transactions at private university's Digital Library users through application of bibliomining process. The objectives of this study are to identify decisions that can be predicted made from the bibliomining process and to discover the trends of popular subjects searched by library users. In answering the research questions, data from the university's Digital Library database was used to examine the process where unsupervised clustering method was employed for segmentation of subject searched into homogenous groups. Bibliomining process that are similar with data mining fields are tools used to visualize the results. Unsupervised learning method was applied where an optimal number of cluster generated is eight. The profiles fed to the model are related to bibliographic, circulation and patron attributes. Findings of the study indicates that borrowers profiles related to subjects of social science, history, finance and language composed the largest portion of the cluster with size of 51.7% . Library authority may use this finding to assist them in decision making, to craft library budget planning and as well to recommend to the top management for new topics/subjects/materials that could be offered.

Keywords: Segmentation, Data mining, Bibliomining, Digital Library

Introduction

Library has massively developed from traditional services to digital services in recent years. The demand from library patrons, institutions, colleges, and private organization needs and technology evolution, has changed the library setting either in budget allocation or in decision making approach. The fast growing development of information technology, communication technology and computer technology itself has changed the landscape of traditional libraries. Therefore, new digital libraries need to reinforce their capability of information processing and their resource organization. In view of that, data mining technology could help libraries through their library administrators to develop massive amounts of information in depth, extract the inherent link of the diverse information to promote and increase the capability of the library. Data mining technology and it is application techniques is the answer to deep dive and drill down structured or unstructured data. It has been applied in many industries which usually illustrate its positive aspect and advantages as well as its

potential for operationalization. As stressed by Zhang (2011), data mining could discover and extract hidden information from huge databases and it's a vast network information space in digital library. Since many decades ago, library, information services centres and knowledge centres in universities, colleges, schools and private organizations as well as government bodies and communities have had the capability to capture information about their library users, circulation history, resources or library collection and search patterns (Nicholson & Stanton, 2003).

This study discussed the role of data mining through bibliomining process and techniques in predictive decision-making for improvement of digital library services. The importance of predicting decision making in digital libraries will assist library administrators to make good evaluations and decisions in ensuring library services meet user needs. Against this background, a study was conducted with the following objectives: (i) to identify decisions that can be predicted made from the bibliomining process, and (ii) to discover the trends of popular subjects searched by library users.

In this paper, the case study is focused on Digital Library of private university in Malaysia. Every year the library needs to prepare their annual yearly budget. This budget encompasses all costs including purchasing new library resources and for library operations. Library administrators need to well plan, strategize and make decisions on allocating the budget amount with respect to its library needs. Most academic libraries act as none profit centres where it relies solely on the amount given and approved by the management of university.

The rest of this paper is structured as follows. Firstly this study presents the literature review in data mining and bibliomining, focusing on concepts, related theories, and model or framework used by researchers for studying data mining and bibliomining adoption. Secondly, it describes the research method, giving details on population and data collection. Thirdly, it presents the results based on data analysis. Fourthly, it elaborates on the research findings. Finally, it draws the conclusion of the study.

Literature Review

The use of data mining application techniques and methods has increased over the years in organization. With the use of this technique, the main advantages that the organization receive is organizations be able to know the hidden valued information in their data warehouse. A review of the previous literature has been made further to explore the determinant on how much this method has been successful to apply in organizations especially in this context of digital library. Booth and Brice (2004) claimed, studying the library's bibliographic data using bibliomining process is related with 'Evidence Based Research'.

Karno et al. (2013) mentioned that, it is an approach to information practice which promotes the collection, interpretation and integration of valid, important and applicable users – reported, librarian observed and research derived evidence. Their study involves the bibliomining process in order to assist the authority management of UTM library in decision-making. They adopted the 5 steps research framework introduced by Chen, Lin and Wu (2004), as exhibited in Fig. 1. Chan and Chen (2006) conducted a study on using data mining approaches to solve classification problem in a campus digital library.

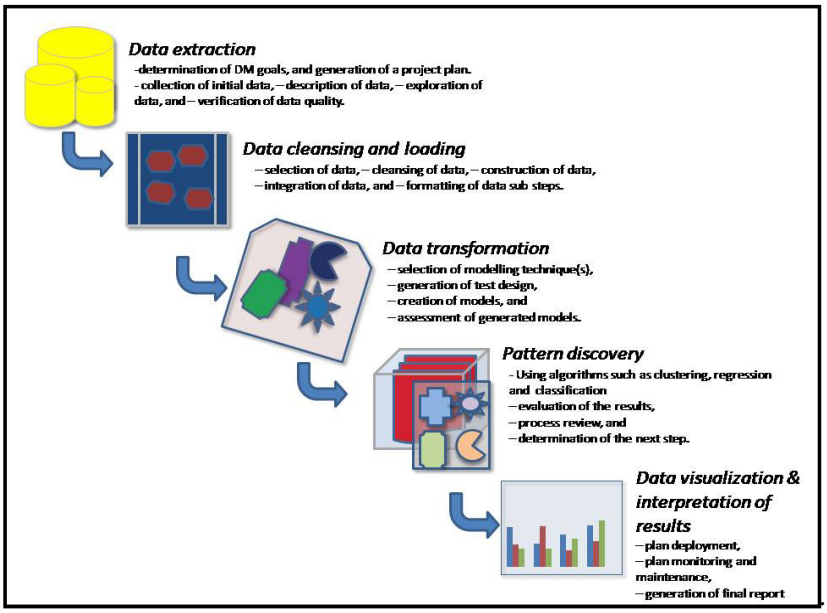

Fig. 1: Five Steps for research framework

Source: Karno et al. (2013) cited from Chen, Lin & Wu (2004)

The researchers examine the library catalogues that have become inefficient and inconvenient in assisting library users. They used data mining technology to elicit the knowledge from databases and established various kinds of data cubes. Chen and Chen (2007) employed data mining as a tool to explore the process. According to their findings, the flooding information often renders users unable to look for information they need. Therefore authors attempt to rectify the situation by proposing personalized smart user interface by developing personalized book recommender system through using existing historical record files in databases via data mining approaches.

Nicholson (2005) has developed a study on the basis for bibliomining framework for bringing together usage based data mining and bibliometrics. As mentioned by Karno et al. (2013) based on issues cited from Shieh (2009), the detailed behavioral data on existing customers from operational systems, enterprises hope to turn these myriad into some coherent profile of their customer in order to improve the quality of services.

Theoretical Framework

Fig. 2 shows user information records collected from the library source. The data carefully collected and picked in relating the prediction on how these variables could affect the digital library service through organization. Nicholson (2003) claimed that when a library authority wished to understand their user population better, they performed a frequency analyses to explore the demographic of their user base. Decision making tools one of the independent variables (IV) is an application methods that the library could apply as techniques to identify the behavior and interest of users. As suggested by Han and Kamber (2006) bibliomining process can apply five steps; data extraction, data cleaning, data transformation, pattern discovery and data visualization. Through the process it then would determine the result, finding or pattern produced which will be used as decision making tools level.

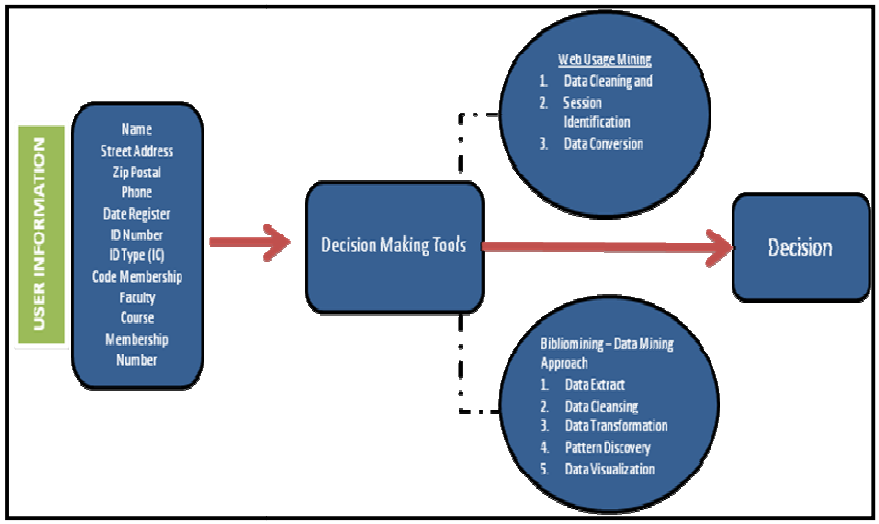

Fig. 2: Contextual Theoretical framework (extension)

Methodology

In this section, the methodology developed for the research is elucidated. This methodology provides instruments to answer the research questions and to fulfill the objectives of the research.

3.1 Data

The research used quantitative data from the library management system (LMS) KOHA, and qualitative approach (interview) to validate the research findings. This study is based on 11,517 borrowing transactions of the selected university's Digital Library from year 2008 – (April) 2015. The transactions were recorded and detected from the system. After the cleaning process, only 9,897 data were used and examined. In total, 9,129 registered users were detected in the system and the library was found to have about 5,493 titles.

The circulation data table was the main external data record that stores all circulation history process. User / patron data ID, gender, location and address were located in patron table and loaded in the circulation history when the borrowing process occurs. Data related to the book's details were kept in bibliographic table and it was designed for identifying volumes, series, format, dates, item number, call numbers and materials location. In Fig. 3, the relationships between table entities, as referred to Karno et al. (2013), are exhibited. However, for the purpose on this study, **three** main entities to feed the cluster model are used i.e. bibliographic (data on volumes, series, format, dates, item number, call numbers and materials location), circulation (external data record that stores all circulation history process) and patron (data related to user / patron, gender, location and address).

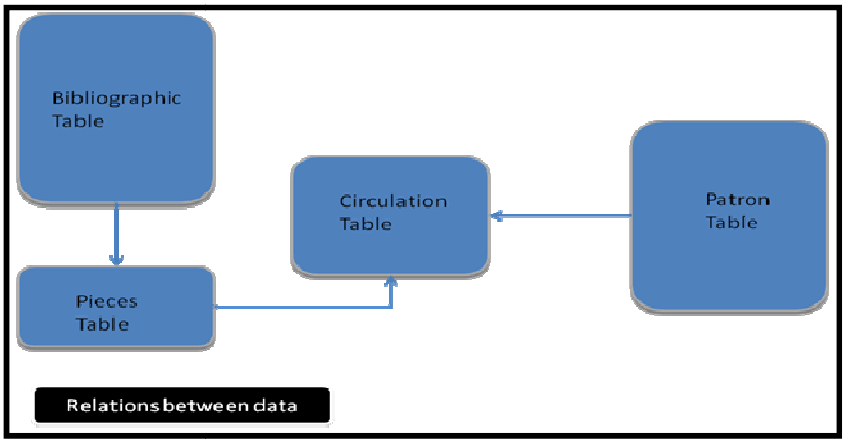

Fig. 3: Relation of entities

Source: Karno et al. (2013)

Framework of mining analysis

This study analyzes the bibliographic data as an example of circulation of data records in the university's Digital Library (as presented in Fig. 3). In extracting of the homogenous characteristics within groups, the typical five steps in the data mining process for library data applied are as follows:

- **Steps 1**: *Data Extraction* - the research method is to investigate numerous patron users based on the circulation of history of a 6 year period from 2008 to (April) 2015, via data mining approach.
- **Step 2**: *Data Cleansing* – process of cleaning readers' borrowing records by selecting the appropriate data from databases, performing data reduction, constructing multi-dimensional data tables and formatting them with accordance to analytical form and research needs.
- **Step 3**: *Data Transformation* - using Orange Data Mining tool, a free tool that available on-line. The tool is capable of analyzing big data mart of the library bibliographic records.
- **Step 4**: *Pattern Discovery* - performs appropriate data mining technique and unsupervised learning algorithms according to mining goals. Unsupervised learning deals with unlabeled data as opposed to supervised learning.
- **Step 5**: *Data Visualization* - performs various operations such as knowledge filtering from the output, analyzing the usefulness of extracted knowledge, and presenting the results to the users for feedback.

Tools

Data mining tools used for segmentation analysis is an open source machine learning and data visualization for novice and expert called *Orange*. *Orange* (Fig.4) is a component-based data mining software encompasses range of data visualization, exploration, preprocessing and modeling techniques. It can be used through an intuitive user interface or, for more advanced users, as a module for the Python programming language (Biolab, 2017).

Fig. 4: Official toolbar icon for *Orange* data mining tool

Below screenshots (Fig.5 and Fig.6) are taken from the main GUI of *Orange*.

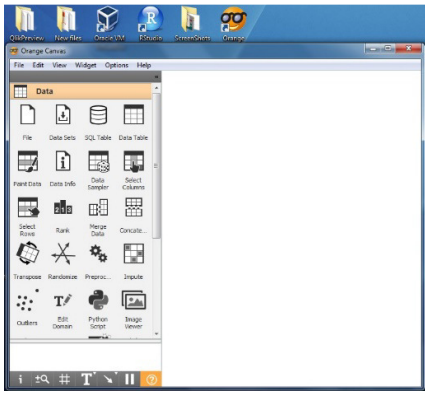

Fig. 5: *Orange* canvas

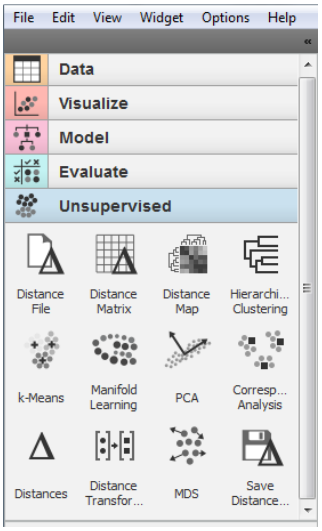

Fig. 6: Methods available in *Orange* for unsupervised clustering method

Findings

Findings with accordance to the research objectives stated are presented in this section. Table 1 shows the users' demographic profiles. Majority of them are Postgraduate students (71.29%) and followed by Undergraduate students (15.6%) whereas the minority were the External members (0.23%). Table 2 presents the frequency of transaction made by the library users in the analytical time window mentioned earlier. The highest transaction was made in a year 2012 with 29% followed by 2013 (26.9%) and 2014 (21.5%).

Table 1: Category of Users

Category of User	Frequency	Percent
AF (Academic Facilitator)	22	2.58
IM (External Member)	2	0.23
Undergraduates	133	15.6
Postgraduates	606	71.29
SPEED (Partner students)	5	0.58
Academic	44	5.17
Non Academic	38	4.47

Table 2: Total of borrowing transactions, by year

Year of Transaction	Frequency	Percent
2015	706	6.13
2014	2479	21.5
2013	3100	26.9
2012	3349	29
2011	263	2.28
2008 - 2010	1620	14.06

Segmentation results

The highest frequency of popular subjects and classification were determined by analyzing user / patron ID with the Call Number data. Through the data mining process and requirements, an unsupervised clustering method was applied and illustrate all borrowers can be clustered into 8 groups. There are different factors for each cluster and these are shown below:

i. **In Cluster 1**, borrowers are Academic Facilitators (AF). They are interested in Commerce (HF), Industries, land use and labor (HD), books on Theory and Practice of Education (LB) and Languages and Literatures (PL)

ii. **In Cluster 2**, borrowers are Individual Members (IM). They are interested books in Industries, land use and labor (HD) and Commerce (HF).

iii. **In Cluster 3**, borrowers are postgraduate's (PG) students (Master and PhD). They are most interested in Industries, land use and labor (HD), Theory and Practice of Education (LB), Commerce (HF), Social Sciences – General (H), Mathematics (QA), Statistics (HA), Finance (HG), English Language (PE), Sciences – General (Q) and History of Education (LA).

iv. **In Cluster 4**, borrowers are non – academic staff members (SN) of Asia e University. They are interested in Industries, land use and labor (HD), Commerce (HF), Theory and Practice of Education (LB) and Mathematics (QA).

v. **In Cluster 5**, borrowers are SPEED (SP06 & SP12) students (Executive Master & Executive Diploma programme). They are interested in Mathematics (QA) and Psychology (BF).

vi. **In Cluster 6**, borrowers are the Academic Staff (ST) of Asia e University. AeU academicians are more interested in Industries, land use and labor (HD), Commerce (HF), World History – Asia (DS), Mathematics (QA) and Social Sciences – General (H).

vii. **In Cluster 7**, borrowers are Librarians (SYS). AeU Librarian are more interested to borrow books in land use and labor (HD), Theory and Practice of Education (LB), Finance (HG) and Mathematics (QA).

viii. **In Cluster 8**, borrowers are Undergraduate students (Diploma and Degree). This category of students are more interested books in Commerce (HF), land use and labor (HD), Mathematics (QA), Theory and Practice of Education (LB), English Language (PE), Economic Theory and Demography (HB), Psychology (BF) and World History – Asia (DS).

Table 3: Cluster profiles

Cluster Group	Subject Interest	Number of borrowers	Percentage
Cluster 1	HF, HD, LB, PL	59	0.59%
Cluster 2	HD, HF	40	0.4%
Cluster 3	HD, LB, HF, H, QA, HA, HG, PE, Q, LA	5120	51.7%
Cluster 4	HD, HF, LB, QA	90	0.9%
Cluster 5	QA, BF	10	0.1%
Cluster 6	HD, HF, DS, QA, H	210	2.12%
Cluster 7	HD,LB,HG, QA	67	0.67%
Cluster 8	HF, HD,QA, LB, PE,HB,BF,DS	539	5.44%

The findings of clustering method are as exhibited in Table 3. An optimal number of segments generated using three main data entities is eight. Out of the total of eight clusters, Cluster 3 contributes the majority of segment size with 51.7% of borrowers followed by Cluster 8 with 5.44%. Other clusters with minimal size such as from cluster 1 (0.59%), cluster 2 (0.4%) and cluster 4 (0.9%) can be further studied with library experts in terms of combining them, if appropriate, into one or two segments by considering the suitability or other relevant factors. The main idea is to gain more suitable profile to personalize their needs that can be used to craft the future library planning.

Borrowing Trend

Postgraduate students borrowed significantly more than undergraduate students or any library borrowers group in the university's Digital Library population. In cluster 3, Master Degree and PhD or DBA level holders borrowed 7499 books on average or 75.9% compared with Undergraduates students from cluster 8 who studied in Degree and Diploma level holders, who borrowed 875 books only. The borrowing trend can be extended from the angle of usage of such digital library. Razilan, Diljit and Fatimah Almah (2013) pioneered the study in the context of electronic libraries, as well as digital libraries, where they examined the relationships between usage of students of higher institution and its impact using formative measurement model via partial least squares (PLS) model. Embarking on the relationships may reveal predictive elements of the behavior of borrowers using additional borrower's profiles.

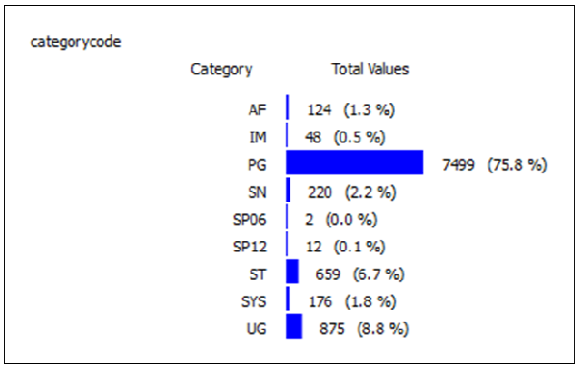

Fig. 7: Distribution of borrowings

Popular Subject and Classification

Land use and labor subjects from class number HD was described for the most popular subjects borrowed, that have the highest frequency with a huge margin. It is interesting to reveal that it is the most popular subject being used and read by the users which showed more than 2000 cumulative frequent usage. Secondly, *theory and practice of education* from LB classification showed that it was also among the top subjects borrowed. It contributes 1364 times or 13.8% of the total transaction. *Commerce* subject from HF class number also played a major role. It managed to attract library users to borrow from the collection. Chart as shown in Fig. 7 stated that on average, a total of 1,152 times books have been checked out within the modelling window selected for the study.

Discussion

This section includes a discussion of this study's contribution to research and practitioners, limitation of the study and agenda for further research.

Contributions to Research

This study contributes to research two main valuable insights. Firstly it provides researchers the visibility of what type of benefits can be received by libraries from data mining approaches. Secondly, it provides one framework to be used when examining library data bibliographic in order to assist Library authority in decision making and to craft strategic planning ahead to accommodate the current and future needs of the library users. Thirdly, the effectiveness of such plan can be assessed, as proposed by Razilan (2014), Noor'Aini, Saiful Farik and Razilan (2014), on any related systems once deployment of the digital library commenced in a period of time (to obtain enough data for modelling needs).

Contribution to Practice

Researchers may use the results of this study to assist them in decision making in library budget preparations. Moreover, the research provides researchers with a few options and guiding them where to focus in library expenses and what new services are suitable for the target group. Apart from that, it may add value to the performance of digital library perspective (Razilan 2014) i.e. by considering the profiles generated from the bibliographic, circulation (borrowing) and patron entities as used in the study.

Limitations of the Research

There are a few limitations in this study, which could hinder generalizing the results. Firstly, data mining needs special tools and applications to generate the desired objectives and results. Secondly, open source tools like Oranges as used in this study, provides high level functions of analytical data mining where beginners need a great deal of time for tools exploration. Finally, data preparation is very tedious and may consume more than one third of the research duration.

Further Research

This study provides a number of important themes for further research. It recommends the study can be extended on ezproxy login captured into digital library or electronic library. The digital library has become one of the major resources of knowledge acquisition where it is not limited to the academia but as well as to government and private sectors. Online database subscriptions (e-book, e-journal & etc.) may spark high costs. Having data mining to analytically explore the library borrowings data may lead to some important insights that can apply to reduce some costs. Moreover, injecting more attributes like demographic profiles of library users may add new insights of usage (Razilan, Diljit, Fatimah Almah, 2013; Razilan, Saiful Farik, Muhammad Khairulnizam and Wan Ab Kadir, 2015; Razilan, Safawi, Mohd Yusof, Fadhilnor & Zahari, 2014) indicated that ethnic and age play dominant role in the different of use of academic digital libraries of postgraduate students.

Conclusion

The segmentation of borrowing usage of one of private university's Digital Library is presented. Moreover, all of the research questions are answered accordingly, supported by statistical and visualization analysis. This study revealed that, effective library resource usage relies on borrowers' interest, programme offered at the university, subjects taken and the number of students. Results showed that subject on land, use and labor (HD) are the most popular subjects used and searched by library borrowers and the largest size of segment comprise of this subject. Thus, this may produce useful lead to library or library experts to craft their plan ahead in terms of subject allocation, budget, re-stock based on popular versus non-popular subjects and so forth. Based on the techniques applied, library administrators may regulate their library budgets accordingly based on the suggestions made by using the bibliomining process. This technique can be applied in any library as long as they have historical records on circulation transaction. It is a useful approach to justify estimation of certain monetary amount when preparing the library budget allocation. It may also set the priority on venturing money on hot or popular topics.

The Relationship of the Social and Economic Progress: A Case of European Cohesion Regions

Abstract

With increased attention of society to issues of income inequality, we decided to explore how the Social Progress Index relates to the overall distribution of GDP and when the Social Progress Index ceased to follow this behaviour. This paper describes the Social Progress Index for a holistic assessment of both social and economic progresses. The work analyses the main trends influencing the wellbeing of society in Europe. At the same time provides analyses of the relationship between economic development (measured by region GDP per capita) and social development of society (measured by Social Progress Index). In frames of significant difference between GDP and SPI, we tried to find a deeper understanding of the relationship.

Keywords: Social progress, Income, Wellbeing, Social Progress Index (SPI)

Introduction

Economic growth in many countries has made it possible to improve the lives of hundreds of millions of people in many countries. But authors of SPI claim that (Social Progress Imperative, 2017): "*a model of development based solely on economic progress is incomplete*". Economic growth alone is not enough. A society is not succeeding when it fails to address basic human needs, equip citizens to improve their quality of life, protect the environment, and provide opportunity for its citizens. Inclusive growth requires achieving both economic and social progress.

The Social Progress Index aims to meet this urgent need through a robust and holistic measurement framework for social and environmental performance that can be used by leaders in government, business, and civil society to benchmark success and accelerate progress. The Social Progress Index is the first comprehensive framework for measuring social progress that is independent of GDP, but complementary to it. It was first implemented at the national level in 2014, and has been enhanced each year and expanded to regions, cities, and individual communities (Porter, 2015, Porter M., Stern S., Green M., 2016). The index is published by the non-profit organization The Social Progress Imperative, and is based on the writings of Amartya Sen, Douglass North, and Joseph Stiglitz (Pristine Journal, 2011).

The European Union Social Progress Index, which is measured across the 272 regions of the 28 European Union member states, is an aggregate index of 50 social and environmental indicators that capture three dimensions of social progress: Basic Human Needs, Foundations of Wellbeing, and

Opportunity. The Fig.1 shows the three dimensions each including four components and sub-components of every of them.

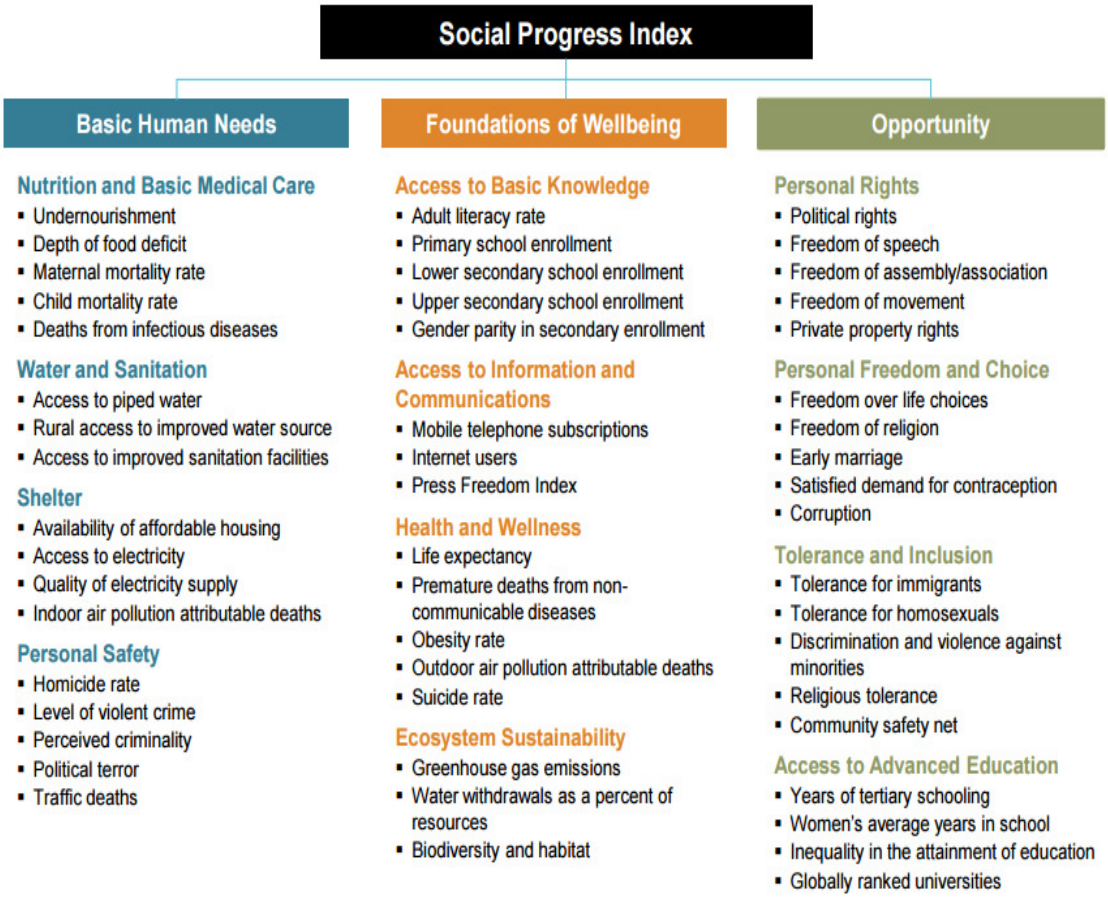

Fig. 1: The components of the Social Progress Index

Source: (Porter, 2015)

This regional version of SPI may help regions to identify similar regions. This is possible at any level of economic development and thus regions could learn about each other, solve and prioritise issues they want to address with their Cohesion Policy Programme. SPI is useful because it can serve as an indicator for the European Commission to evaluate whether the 2014-2020 programmes address the right issues. It is a composite index based on the aggregation of information from indicators derived from different sources (Annoni P., Dijkstra L., 2016).

One of the key differences with other wellbeing indexes is that the Social Progress includes social and environmental indicators and excludes GDP or any other income-based indicator. The main idea behind the index is to measure social progress directly, rather than utilize economic proxies.

The essence of this paper is analysis of SPI and GDP relationship to understand the relationship between economic and social development. The advantage of SPI is the possibility to separate the cause and consequences (this is perceived as a drawback, for example, in the Human Development Index used by the United Nations). The Social Progress Index has been designed to describe social and environmental aspects of regions, thus it is a complement of GDP. The authors of SPI designed this index to be (Annoni P., Dijkstra L., 2016): „*a robust, comprehensive and practical measure of inclusive growth*".

Several indexes already try to go beyond GDP, such as the Human Development Index and the Happiness Index (Bubbico B., Dijkstra L., 2011, Annoni P., Dijkstra L.,2016, European Commission, 2017), but none specifically tracks social and environmental outcomes. These outcomes include access to schools, healthcare, a clean environment, sanitation and nutrition.

While there might be (for someone) a clear correlation between the level of economic development and social progress, the relationship varies significantly. A country classification by income level often does not correspond to its level of social progress, especially in middle and lower income countries. All but one country in the high and very high-social progress tiers are also high-income countries, but not all high- or upper middle-income countries rank in the top half of social progress countries. For example, Russia, Saudi Arabia, and Venezuela are all relatively high-income countries but lower ranked on social progress (Ramos, Royuela, 2014).

Methods and Data

In this paper were used data regarding SPI (The Social Progress Imperative - Dataset, 2017) and GDP (Eurostat statistical data, 2016) for 2016 across the 272 regions of the 28 European Union member states. The data consists of NUTS 2 of 9 states of EU. As a method for our research was used correlation and regression analysis. The correlation analysis is aimed at determining the intensity of potential dependencies between random variables of the statistical set. The result of the analysis is determination of the degree of dependence, which is realized by calculating the values of the different types of correlation coefficients. The higher the value of the correlation coefficient, the higher the dependence (in the causal relationship) or the relationship (in association) between the variables X and Y.

Regression analysis is used to determine the statistical dependencies between dependant variable and one (or more) independent variables. The most common goal of regression analysis is to quantify the best estimates of unknown regression model parameters. A simple linear regression model is called a model where the graph of the regression function is a straight line and we can formally express it:

$$Yi = \alpha + \beta xi + \varepsilon i,$$

where εi are independent random variables for which $E\varepsilon i = 0$, $D\varepsilon i = \sigma 2$, $i = 1,2, \dots , n$.

εi is called a random folder in a linear model. A random component involves the effect of random influences or the effect of quantities not included in the model. We used the least squares method to estimate the regression parameters. The least squares method provides sufficient parameter estimates only when all assumptions about the data and regression model are met (Meloun, Militký, 2006).

In order to build a regression model, the proper variables have to be selected. The choice of variables focuses on those independent variables that explain a significant volume of variability depending on the variable (Hendl, 2004). This phase of research requires the breakdown of variables into dependent and independent variables. A meaningful use of regression analysis requires that the choice of dependent and independent variables is based on the hypothesis of the causal dependence. The causal dependence arises either from the previous implementation of the correlation analysis or is evident from the nature of the phenomena investigated.

In our research, GDP (economic progress) is a prerequisite for achieving high SPI (social progress). For this reason, the SPI index was chosen for the dependent variable and GDP was chosen as the explanatory variable. It must be stated that this view is a simplification of the actual relationship between social and economic progress, since social progress is likely to be linked to the economic progression.

As the results of the regression analysis are susceptible to the violation of OLS assumptions, normal distribution and other assumptions have been tested. Rejection of the existence of normal distribution

is often due to the existence of outliers. However, it can be partially removed by application of appropriate procedures (Meloun, Militký, 2006).

Results

How was mentioned before, economic development alone is not sufficient to explain social progress outcomes. That is why we try to find optimal way how to assess quality of life by comparison of two approaches - economic and social.

Fig. 2 shows that there is a subtle dependence between European Social Progress Index scores and GDP per capita.

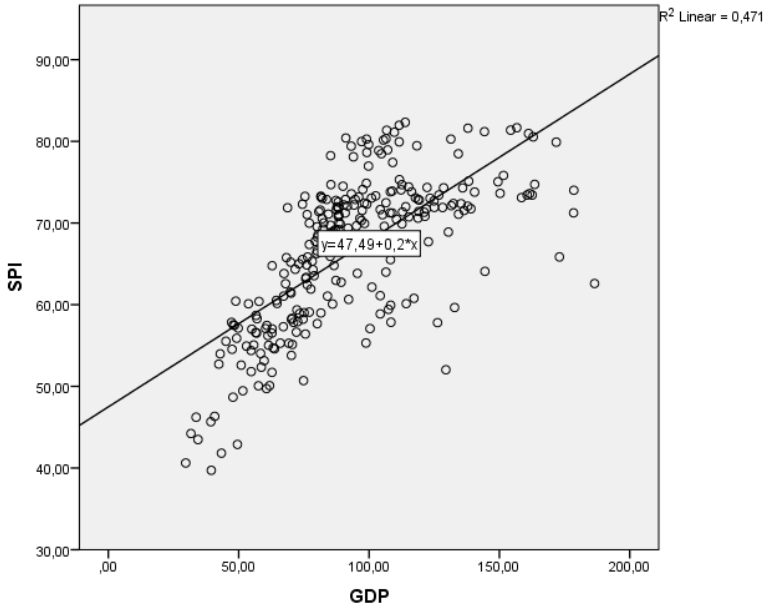

Fig. 1: Relation between the EU regional SPI and GDP per capita (2016)

Four values were classified as outliers and therefore were excluded from analyses, namely Inner London (now known Inner London – West and Inner London – East), Luxembourg, Brussels and Hamburg.

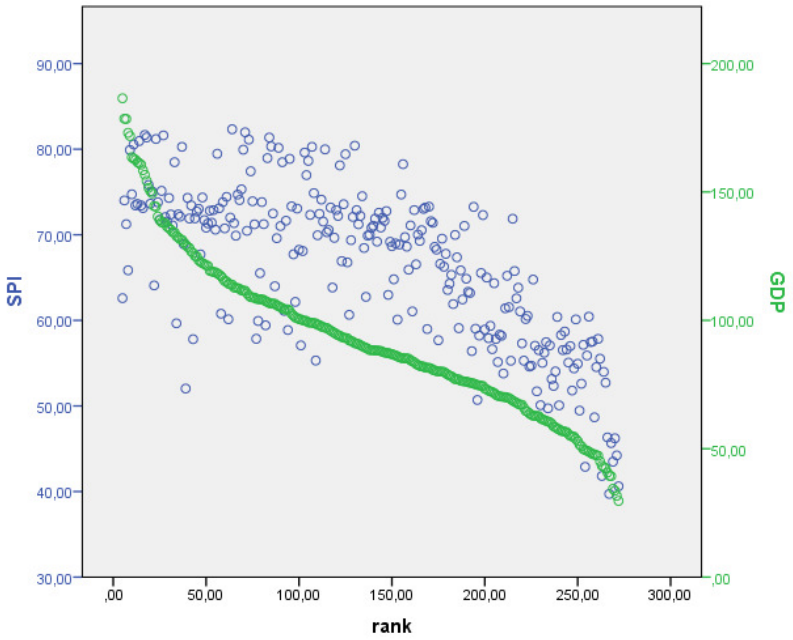

Fig. 2: Regional GDP per capita and Social Progress Index (sorted by decreasing sequence GDP)

The figure 3 indicates that there is a visible dependence between SPI and GDP mostly among regions on the lower end of GDP. This can be interpreted as a situation where a certain amount of GDP ceases to increase SPI. The figure 4 shows the distribution of cumulative correlation between GDP and SPI. It can be seen from the figure that there is a maximum point, i.e. the correlation between GDP and SPI takes the highest values for regions with GPD per capita lower than 98.22 in PPS (Purchasing Power Standard).

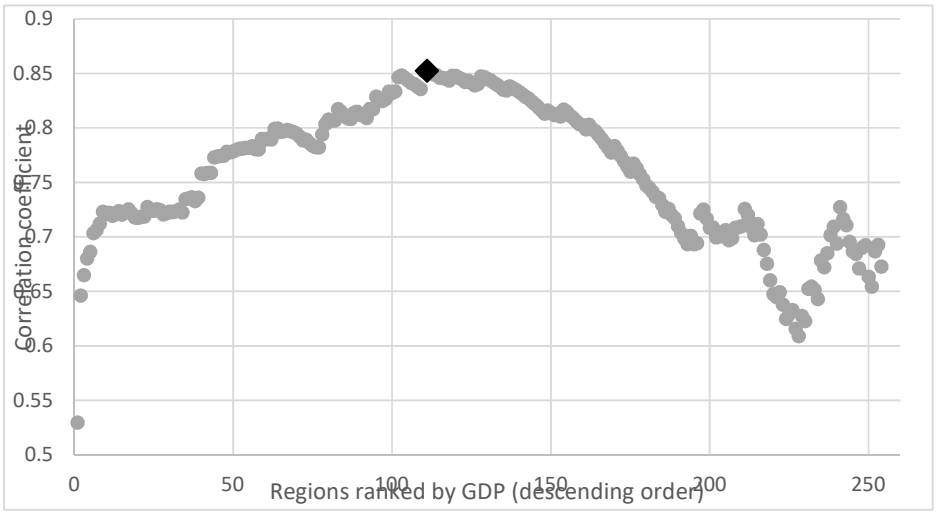

Fig. 3: Cumulative correlation coefficient between SPI and GDP (descending order)

Provided analyse show that economic growth translates into social improvement, but after some threshold this dependence ceased to exist. Fig. 5 represents the strong dependence between the SPI and the GDP lower than 98.22.

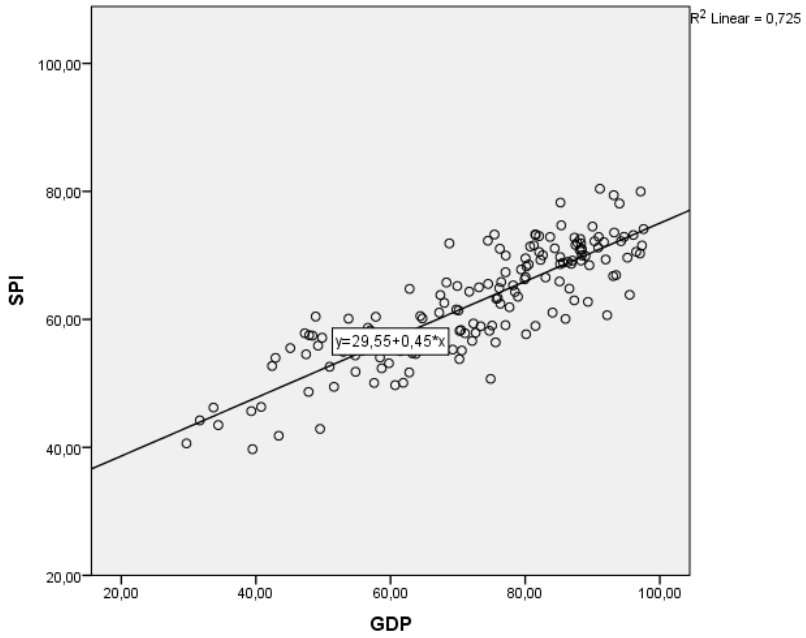

Fig. 4: Regression between SPI and GDP for reagion with GDP < 98.

Fig. 6 shows that the residuals does not show any significant signs of heteroscedasticity.

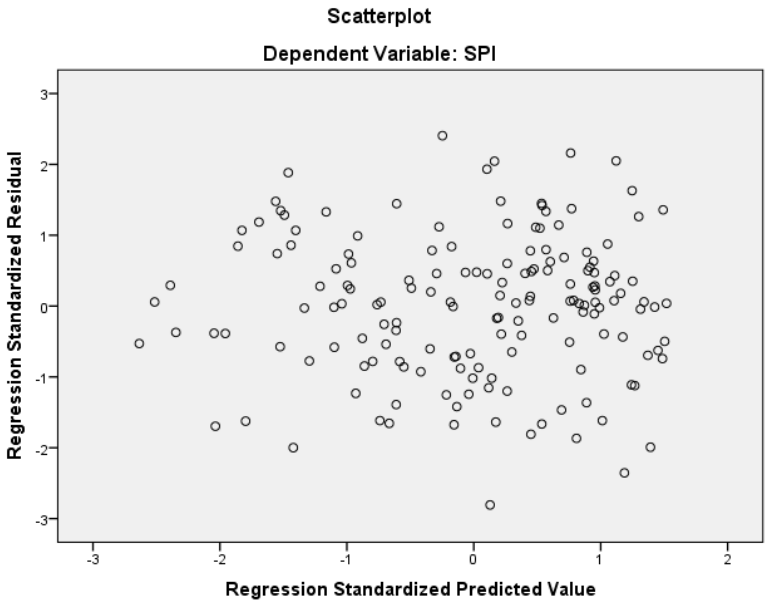

Fig.5: Residual analyses

Discussion and Conclusion

The results of the regression analysis have demonstrated the existence of a stochastic dependence between economic and social progress. This result leads to the conclusion that regional SPIs are growing with GDP growth. This relationship is not equivalent - when GDP grows by 1 PPS per

capita, SPI grows only by 0.45 units (which is apparent at least for regions with GDP below 98.22 PPS per capita).

The results of the regression analysis have clearly demonstrated the effect of the variability of the SPI index in the case of regions with a GDP per capita higher than 98.22 purchasing power standards. This limit was found by means of a correlation analysis, the results of which are shown in the curve in Figure 4. The concave course of the curve demonstrates the existence of a limit point in which the dependence between the variables studied increases. From this value (GDP = 98.22), the already found relationship fades. This can be explained by the hypothesis of the marginal declining benefit of economic progress in the direction of social progress, but it should be thoroughly examined in further research.

Limitations of our research stem mainly from the data base that was based solely on data for 2016 due to the recent creation of the SPI index. In the subsequent research, our focus will be on deeper exploration of this concave dependence and the context of income inequality. One possible explanation for the variability of the SPI index, even at very similar levels of GDP, can be explained by the existence of strong income inequality, which leads to the fact that even high GDP values do not lead to demonstrable social progress.

At the end it could be stated that thanks to rigorous and holistic measure of inclusiveness that is independent of GDP and other economic measures, the Social Progress Index provides a powerful tool for evaluating effectiveness of economic to social progress transformation. Thanks to that it can be used for leaders in government and broad society to benchmark performance, identify priorities for action, and to track the impact of interventions.

Peculiarities in Convergence of Slovak Capital Stock to Western Countries

Karol Morvay, Department of Economic Policy, Faculty of National Economy, University of Economics in Bratislava, Slovakia; Institute of Economic Research, Slovak Academy of Sciences, Bratislava, Slovakia. karol.morvay@euba.sk

Martin Hudcovský, Department of Economic Policy, Faculty of National Economy, University of Economics in Bratislava, Slovakia; Institute of Economic Research, Slovak Academy of Sciences, Bratislava, Slovakia. martin.hudcovsky@euba.sk

Abstract

The Slovak economy is for a long time dealing with the problem of capital intensity. It is lagging behind other developed countries with significant improvement since 2014. However, the spread of undercapitalization is selective to industries which are present in the economy since the era of socialism. New established industries are not dealing with this issue. Despite the lag behind other developed countries, the situation is relatively favourable when compared with other CEE countries. The difference in the structure of the fixed assets between Slovakia and other developed countries lies in lack of intellectual assets on expense of machines and other non-intellectual assets.

Keywords: Undercapitalization, Capital Stock, Intellectual Assets,

JEL Classification: E22, E24, O34

Introduction and Motivation

Lagging in the capital intensity (i.e. undercapitalization) was perceived as a barrier to greater performance of the former transition economies of Central and Eastern Europe. The economic theory perceives changes in the capital to labor ratio as an explanatory factor for the economic growth and convergence of their level (see Solow growth theory). This paper examines how the Slovak economy overcame this undercapitalization problem. We assume that during the economy transformation, the level of capital intensity improved significantly, however, very differently within the sectors. It is also possible that there were significant differences within the group of former socialist economies of Central and Eastern Europe. We seek the answers to following questions:

To what extent the problem of the low capital to labor ratio has already been removed (alleviated)? Are there any sectors in which this process has progressed very significantly or on the other hand lagged?

Was the elimination of the undercapitalization associated with the formation of a similar fixed capital structure as we see in the most advanced economies? Has the convergence to the level of capital intensity of advanced economies been accompanied by imitation of their structure of fixed capital?

The Issue of Undercapitalization Overcoming in Literature

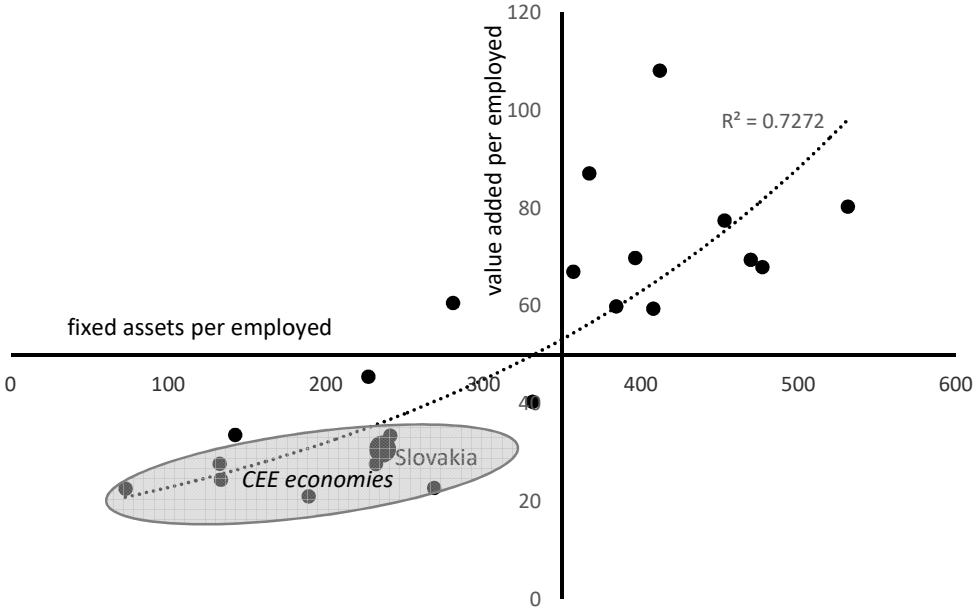
In the well-known simple production function is the amount of production defined by labor (L) and capital (K), therefore Q = f(K, L). The ratio K/L is used to express the capital intensity. Many remarkable papers focus on topic how changes in capital volume and capital intensity affected economic growth and the convergence of CEE countries. For example, Dombi (2013) proved with the use of growth accounting that the main driver of economic growth in CEE countries was the capital accumulation in the period after the year 1995, while the impact of the labor and multifactor

productivity was only marginal. That means the CEE countries followed the model of extensive and investment-oriented growth with a significant increase in K/L ratio. The results of so-called "development accounting" suggests that lower levels of GDP per hour worked in CEE countries (particularly compared to Germany) can be primarily attributed to their less capital intensity and secondary to their lower multifactor productivity (while the job quality is about the same as in Germany). The very low initial level of capital intensity, coupled with the higher level of investments rate (share of capital formation in GDP) than in developed economies had resulted in the significant potential for capital accumulation and thus, rapid economic growth.

Doyle, Kuijs and Jiang (2001) conducted an analysis for the period from 1991 to 1999 and stated that in the case of Slovakia, the benefit of fixed capital formation growth to GDP growth was the dominant driver (six times stronger than the contribution of multifactor productivity). However, the group of CEE countries achieved relatively heterogeneous results with the various contribution of capital in different countries. They also pointed out to difficulties in estimation of capital stock and capital intensity at the beginning of a transformation in these countries. A significant part of the capital had to be discarded as ineligible for further production. In Slovakia, the estimated capital intensity was relatively high even before the transformation process began (what was caused by the historically significant investments in the sectors of heavy machinery, arms production, and other capital intensive productions).

The importance of capital (more precisely its contribution to economic growth) varies greatly depending on the selected period of analysis: Borys, Polgár and Zlate (2008) in their analysis of the period 1997 – 2006 came to little different conclusions than papers mentioned above. They attributed in the CEE countries higher contribution to multifactor productivity and less contribution of capital changes. However, what these analyses have in common is the relatively high contribution of changes in capital and significantly lower (sometimes negative) contribution of changes in the labor force. Okáli (2008) revealed the contribution of production factors for different time periods. The contribution of changes in the capital is always dominant.

As well as in the already mentioned paper by Doyle, Kuijs and Jiang (2001), the paper by Němec and Prachár (2000) addresses the topic of the specific barrier for greater growth in the capital intensity – a slow depreciation of assets. Němec and Prachár (2000) elaborate the issue of blocked funds for capital renewal. Due to the increase in prices of capital goods (with the slow depreciation of capital), there was no room to cumulate sufficient amount of funds for replacement of worn-out capital. Consequently, other resources of funding must be used (loans and other "temporary solutions alleviating the pressure on resources").



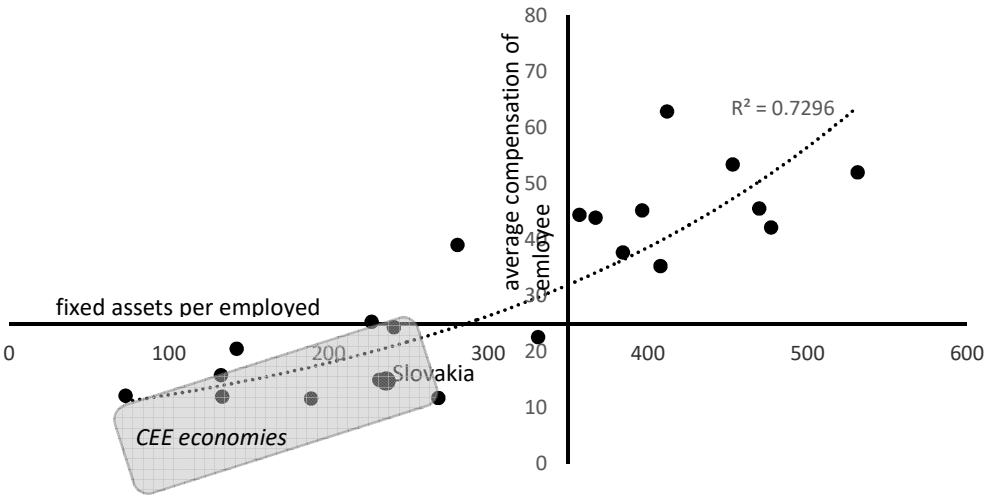
In summary, the increase in capital intensity in the Slovak Republic and CEE countries is in the literature considered to be a decisive factor in economic growth (although differently seen in various periods). The capital formation was mainly in the earlier stages of transformation complicated and distorted by slow depreciation (depreciation did not create a sufficient supply of capital reproduction).

The Problem of Low Capital Intensity Moderated. However, This Process Lagged Behind In Some Areas.

The literature demonstrates the importance of capital expansion and increase in capital intensity for the growth of the Slovak economy. Therefore, the undercapitalization explains the economy underperformance, yet gives the opportunity for higher economic growth and quicker catching-up. Here we focus on the assessment of the undercapitalization and changes in capital to labour ratio. In order to reflect the status of undercapitalization, we utilize the stock of fixed assets per employed, an approach based on national accounts methodology (Box 1). The volume of gross fixed assets is divided by the employment (based on ESA 2010 methodology). Thus, we obtain the ratio capable of international comparison. Its values describe what was the fixed assets (fixed capital) per worker.

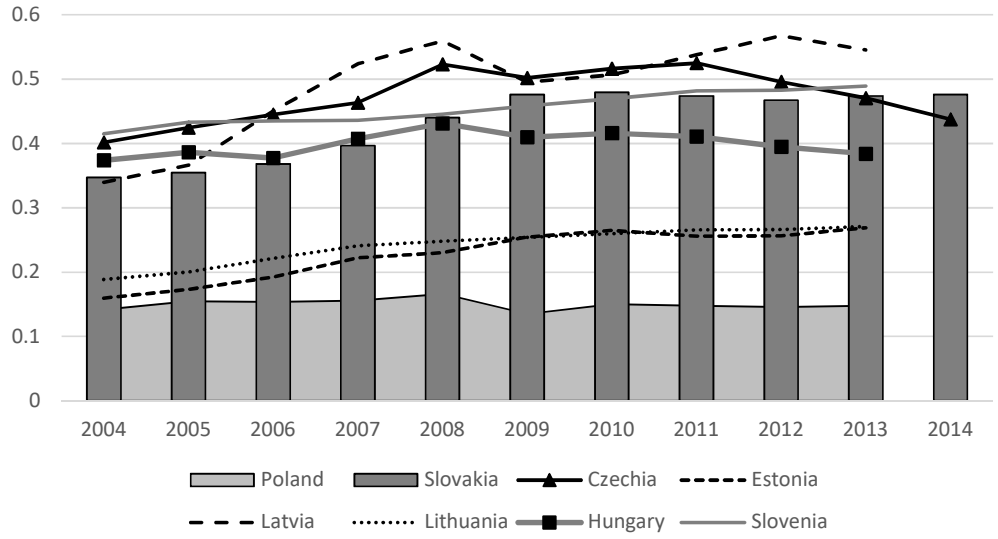
the following

The higher levels of fixed assets per employed are linked with higher labor productivity (Figure 1). The CEE economies are concentrated in the lower-left quadrant of the figure where low levels of capital to labor ratio is combined with low labor productivity (labor productivity is expressed as value added per worker).



F i g u r e 1:Combinations of fixed assets per employed and value added per employed (thous. EUR, 2013)

Note: CEE- Central and Eastern Europe
Productivity calculated as value added divided by a volume of employed.
Source: Own calculations based on Eurostat- data.



Approximately the same level of determination can be identified in the relationship between fixed assets per employed and compensation of employees level. We deal with the compensations of employees volume divided by the number of employees (by categories of national accounts). The

trend has an exponential character in both cases (Figure 1 and 2). When the fixed assets per employed reach level 350 thousand EUR, there is a significant increase in the labor productivity as well as in average employees' compensation. However, this is only a steady approach. Thus, it is not possible to gain the information on development in fixed assets per employed ratio and recognize if the phenomenon of undercapitalization is diminishing. The development trend is shown using ratios to the group of TOP3 countries. TOP3 group consists of three EU countries with the highest level of fixed assets per employed ratio. Thus, the figure 3 deals with the values of CEE countries in comparison to the three EU countries with the highest ratio of fixed assets per employed by the end of analyzed period.

F i g u r e 3: Relative level of fixed assets per employed ratio (TOP3 = 1)

Note:
TOP3- average level of three countries with the highest level of total fixed assets – labor ratio (these countries are Denmark, Austria, and Finland).
Source: Own calculations based on Eurostat- data.

Up to 2009, there was visible a significant catching-up process in the case of SR to the level of TOP3. However, since then, the relative level of Slovakia to TOP3 did not change dramatically. Moreover, the catching-up process in fixed assets per employed ratio was also hampered in some other CEE countries. This might be associated with the general fall in investments during the "troubled" period after the recession.

Now we focus on the relative level of fixed assets to employed ratio – by asset type and by sectors. We follow the typology of fixed assets according to the methodology of national accounts (see Box 1). We utilize from this typology the top three categories: total construction, machinery and equipment and intellectual property products – for the sake of simplicity we refer to them further as "intellectual assets". "Intellectual assets" consist of software, databases, research and development products etc.

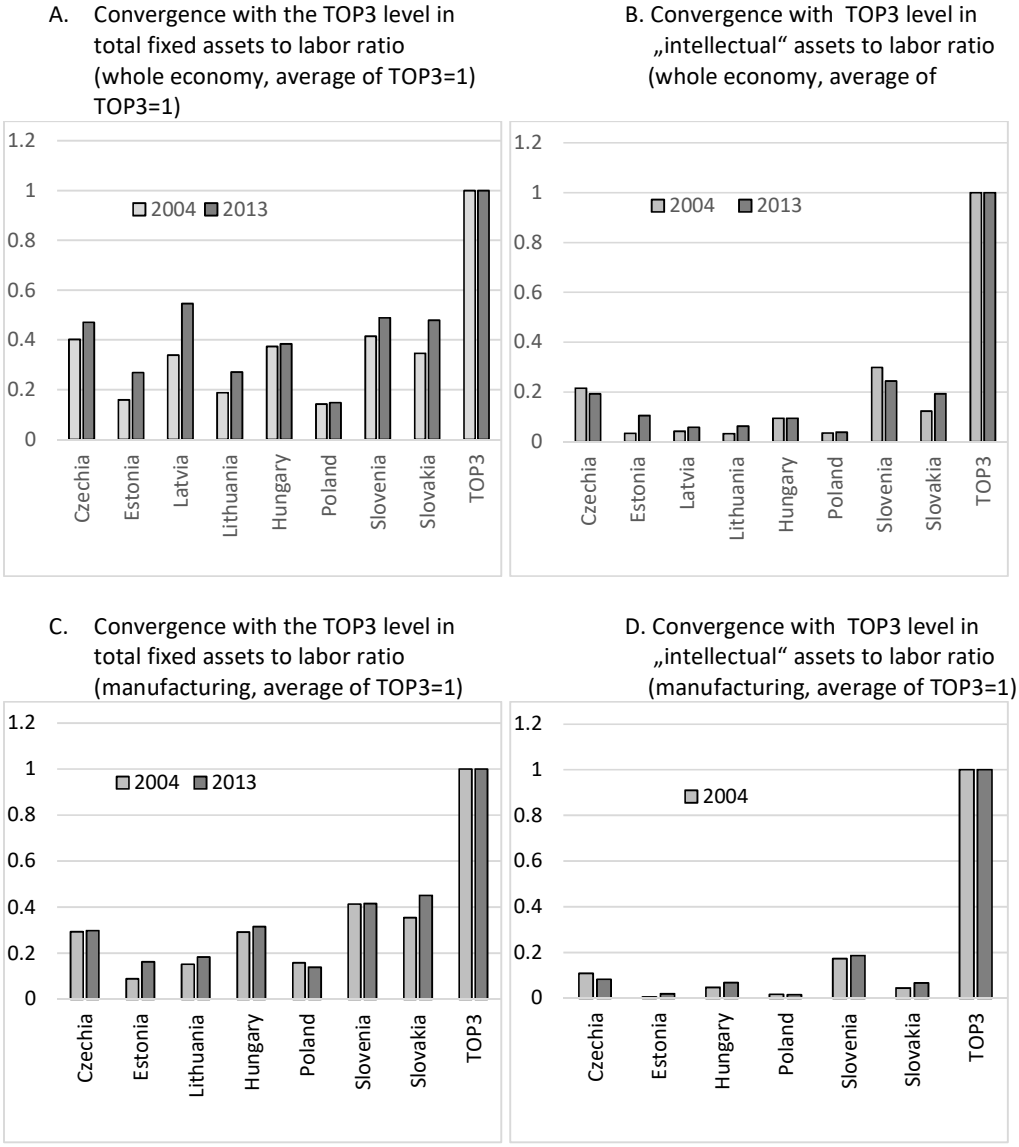
In the gross perspective, we observe that the Slovak economy improved its relative fixed assets per employed ratio to TOP3 from 34.7 % in 2004 to 47.3 % in 2013 (Table 1). It implies a substantial convergence. However, this process took place mainly in period 2004 – 2009. Since 2009, the ratio is for SR rather stable at the same relative level with no significant change.

The undercapitalization does not apply to the sectors, which can be described as the newly emerging ones in the former transforming economy. Those are the IT sector, as well as the sector of financial and insurance activities. The level of fixed assets per employed is in these sectors in Slovakia almost at the same level as in TOP3 countries (in 2013). The much less favorable situation is in the "traditional" sectors such as agriculture, manufacturing, trade, transportation, accommodation or food services. The relative position of the Slovak Republic has been better than the average of CEE countries and V4 (V4 average is lowered by very low levels in Poland).

The disaggregation of fixed assets to individual types (see Box 1) has some remarks worthy of mention:

The relative level of machinery and equipment per employed ratio is higher than in other types of fixed assets.

The Slovak economy most significantly lags behind the level of TOP3 countries in the intellectual assets per employed ratio.



The extreme cases are the intellectual assets per employed ratios in manufacturing and sophisticated services (professional, scientific and technical activities). The Slovak position in these areas is particularly adverse.

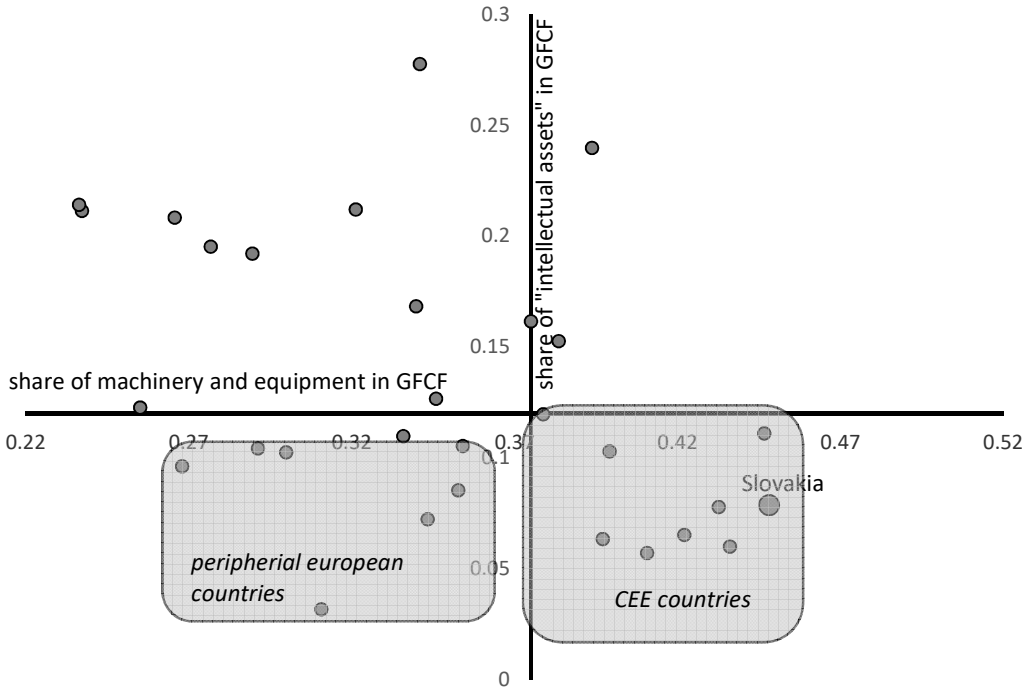
In the overall picture of the state of undercapitalization in Slovakia, the weakest element is the level of intellectual assets per employed. The overcoming of the lag in the intellectual assets per employed has been proved to be far less successful than the overall overcoming of the deficit in the total assets per labor. Particularly significant is the lagging in the manufacturing sector – however, the Slovak manufacturing is achieving the best results among the CEE countries with available data. (Figure 4C and 4D). Moreover, the fact that this problem emerged in manufacturing represents an additional problem: the manufacturing performance is considered to be crucial for the competitiveness of the economy.

F i g u r e 4: Catching-up with the most developed economies in assets to labor ratio



Note:

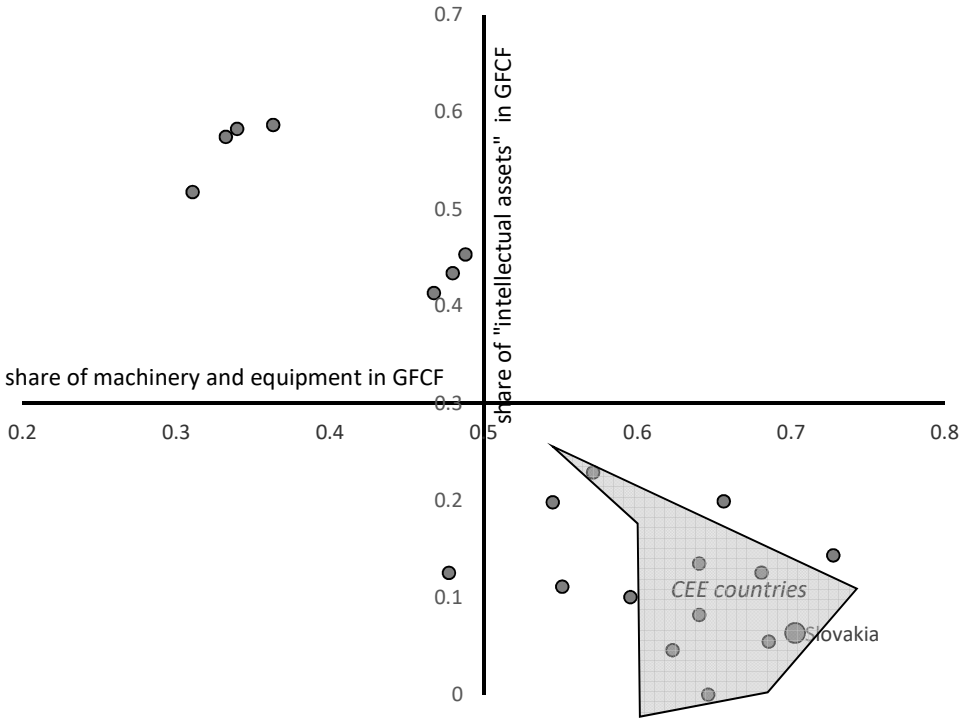
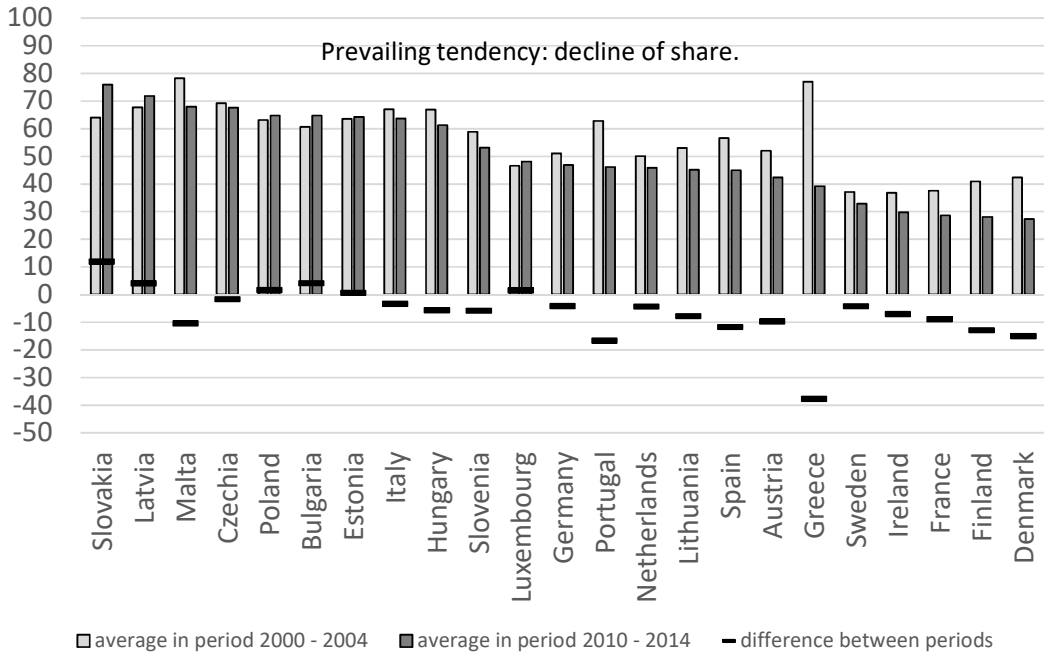
Particularities of Capital Formation Structure in the Slovak Economy



In the following, we deal with the category Gross Fixed Capital Formation (GFCF is a flow variable, while up to this point we analyzed the stock variable). The CEE countries are characteristic by their extremely high share of machinery and equipment in the GFCF and extremely low share of intellectual assets. In Figure 5 (combining the share of machinery and equipment with a share of intellectual assets), the group of CEE countries is located in the lower right quadrant. A notable case is also the group of "peripheral" EU countries (e.g. Greece, Portugal, Spain) where the low share of machinery and equipment in GFCF is combined with a low share of intellectual assets (therefore, the share of constructions is necessarily very high).

If we narrow down our focus just on the manufacturing sector (previously labeled as a specific case in the undercapitalization of the Slovak economy), we find a similar situation, however, with even more "extreme" values (further away from the values in the most developed economies – they are located in upper left quadrant of Figure 6).

F i g u r e 5: Shares of machinery and equipment and „intellectual assets" in gross fixed capital formation



Note: GFCF- gross fixed capital formation
Calculated from indicators in current prices.

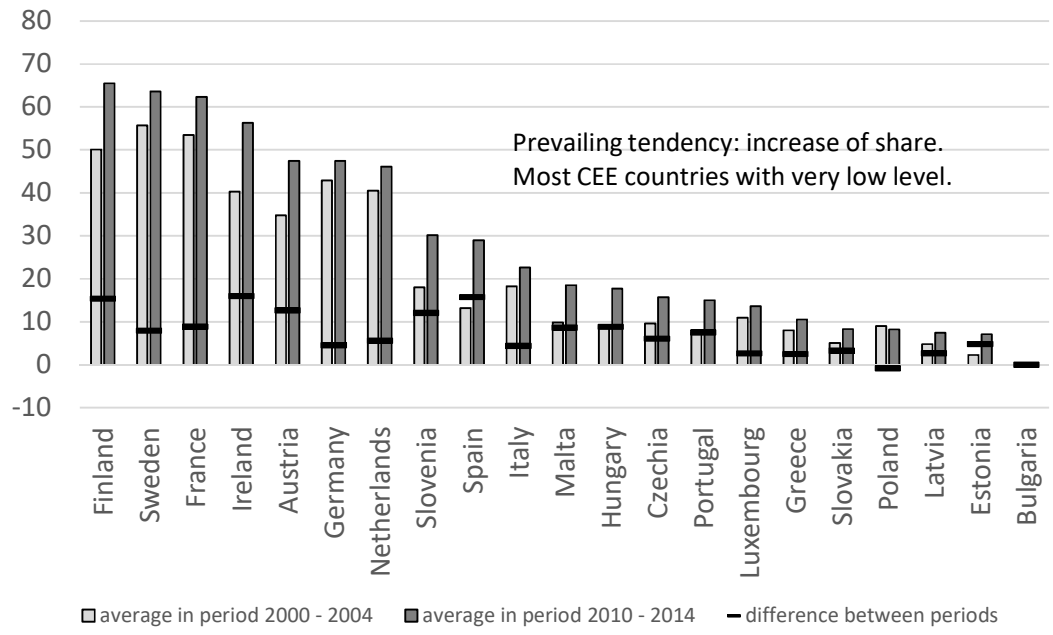
F i g u r e 6:Shares of machinery and equipment and „intellectual assets“ in gross fixed capital formation- in manufacturing

Note: GFCF- gross fixed capital formation
Calculated from indicators in current prices.
Source: Own calculations based on Eurostat- data.



There is an extremely high proportion of machinery and equipment in GFCF in Slovakia. However, the international comparison suggests that there is an overall tendency of decline in the share of machinery and equipment (Figure 7). On the other hand, the share of intellectual assets has increased in majority of countries. The increase of this share was also recorded in the case of Slovakia and other CEE countries, but only with almost insignificant values. Therefore, it is clearly visible that the structural change is taking place in the advanced economies: the investments in machinery and equipment are substituted by investments to intellectual assets (this is in accordance with generally known facts about the investment process). More interesting is rather the fact how the CEE countries strongly deviate from these tendencies. The increase of fixed investments (in CEE) is mainly driven by machines and equipment with the only little contribution of intellectual assets. However, this could be at least partially explained by the fact that optimal conditions for convergence in intellectual assets can be created only after a certain level of machines and equipment is reached.

F i g u r e 7: Structural change of fixed investment in manufacturing: share of machinery and equipment on GFCF.

Note: percentage of total gross fixed capital formation, differences in percentage points
Source: Own calculations based on Eurostat- data.

Also, the investment structure was influenced by the typical fragmentation of production during which the less intellectual demanding activities of mass production developed in the CEE countries (see Garielová, 2008 or Morvay et al., 2015). It is the middle part of production chain, which is characterized by a lower rate of value-added; it has assembly nature or high intensity of physical capital in the form of machinery and equipment. This fragmentation contributed in a certain phase of former transition economies development to expansion of investments in machinery and equipment. The evolving nature of production is necessarily related to the nature of fixed investments.

F i g u r e 8:**Structural change of fixed investment in manufacturing: share of „intellectual capital“ on the gross fixed capital formation.**

Conclusion

The undercapitalization of the Slovak economy has eased during the recent decades. However, it was a very uneven process: the massive increase in labor to capital ratio lasted till the period of 2009 recession, and then it froze. The undercapitalization used as the general characteristics of the economy in the previous period was deeply sectorally differentiated: It was absent in the sectors formed during the post-socialist period. The sectors such as information and communication or financial and insurance services were formed with similar capital intensity as they did in advanced economies. However, the undercapitalization was significantly present in sectors, which have been traditional present in the former socialist economy (agriculture, manufacturing, trade, transportation, accommodation, etc.).

Although the Slovak economy lagged in capital to labor ratio behind the most advanced economies, the position of Slovakia in the CEE countries has been relatively favorable. The total fixed assets per employed ratio increased in Slovakia substantially, however, the level of intellectual assets per employed remained at very low levels. The Slovak economy has particularly improved in one segment of capital intensity: in the machinery and equipment per employed ratio. It appears to be related to the nature of the production which is especially intensive for this component of fixed assets.

In the process of undercapitalization overcoming, the similar structure of fixed capital as may be observed in advanced countries has not been formed yet. The dynamics of machinery and equipment accumulation was particularly high, however, the accumulation of intellectual assets almost negligible.

The “weak spot” in the process of capital to labor ratio convergence is the development of intellectual assets per employed in manufacturing and sophisticated services (professional, scientific and technical activities). The position of the Slovak economy is particularly poor here.

Abstract

The article is devoted to the analysis of factors of the inflationary process in Russia. It shows the influence of internal factors on the consumer price index, such as price expectations, the amount of money supply, per capita incomes of the population, as well as external factors: exchange rate, foreign trade openness. It is substantiated that in the conditions of heterogeneity of economic space, differentiation of territorial involvement in trade and economic relations in large federal states, there are differences in the price reaction of the regional economies. The depreciation of the ruble, as a macroeconomic factor, in regions with a high and low level of foreign trade dependence has spatial differences in price manifestations. The principles of coordination of actions of the federal center and regions in the implementation of the stabilization policy are formulated, allowing taking into account the external economic differences and the reaction of regions to changes in macroeconomic indicators.

Keywords: inflation; monetary policy; currency crisis; macroeconomic instability; territorial differentiation.

Introduction

The development of a theoretical model of inflation processes is the subject of many scientific papers. In the theory of inflation, the main problems are focused on the identification of factors and the driving forces of inflation in the country, which facilitates the choice of instruments and methods for conducting monetary policy to ensure price stability. Theoretical and practical questions of modeling and regulation of inflation processes are devoted to the works of R.J. Barro and D.B. Gordon (1983), C.A. Sims (1992), M. Woodford (1994), K. Aoki (2003), B.S. Bernanke (2005), J. Boivin, P. Eliasz and others. In publications J.B. Taylor (1999), J. Galí (2014) and R. Gupta (2017), attention is paid to the evaluation of factors and the mechanism for implementing anti-inflationary policies. The specific features of inflation processes in Russia, the impact of external economic factors and structural changes on the money sector of the economy are devoted to: A.O. Baranov (2015), E. Deryugina (2016), S. Tabata (2016), A.V. Ramazanov (2016), E.S. Alpatova (2016), etc. At the same time, insufficient attention has been paid to the problems of inflation and ensuring price stability in the conditions of spatially heterogeneous economic systems, the specifics of the factors determining the level of prices and the reaction of the regional economies to foreign economic factors and changing institutional conditions. In our opinion, the study of inflation processes in Russia requires the inclusion of both macroeconomic factors affecting the overall price level and the meso level factors associated with territorial socioeconomic characteristics, which together determine the variability of regional susceptibilities and differences in the level of price stability.

External and internal factors of inflation processes in Russia

Inflation is traditionally understood as a sustained, steady decline in the purchasing power of a monetary unit, manifested in the growth of the general price level. Influence of inflation is ambiguous: insignificant inflation promotes increase in economic activity, stimulates growth of GNP and promotes economic development. A high level of inflation has negative consequences for the standard of living of the population, the structure and magnitude of real incomes, and the activity of business processes. Because of this, inflation is an object of monitoring and one of the goals of economic policy with its significant manifestations.

The development of stabilization measures and the mechanism of active actions depends on an understanding of the factors that induce inflation. Depending on the key factors generating a rise in prices, there are: a) inflation, inspired by the monetary or real sector (a wide range of determinants, such as monetary, demand inflation, cost inflation); b) inflation, determined by internal, endogenous factors and external, exogenous for the country; c) inflation associated with objective events (for example, within the political cycle, economic shocks, etc.) or subjective, such as household expectations; d) system factors (macroeconomic nature) that determine the average, aggregated price level in the country and regional inflation, which is caused by meso level factors that generate a lot of price variations. Identification of the type of inflation is essential for the choice of stabilization policy instruments, as well as regional strategies for maintaining stability in the face of increasing external economic instability.

To assess the impact of inflation factors on the general price level in Russia, we will conduct a study of the statistical dependence of the consumer price index adjusted for seasonality (CPI) with the following internal and external indicators reflecting the effect of the relevant factors:

a) expected (previous) value of the consumer price index adjusted for seasonality;
b) growth rate of the money supply (M2 aggregate in the national definition), adjusted for seasonality;
c) growth rate of per capita income of the population, adjusted for seasonality;
d) growth rate of the weighted average US dollar rate adjusted for seasonality.

The alignment of the series of data was carried out using the Hodrick-Prescott filter, the statistical dependence was determined based on the correlation coefficients of the monthly statistics of the indicators for the period from January 2006 to January 2016 with a lag of 1 to 36 months, the source of which was data from the Statistical Bulletin of the Bank of Russia. The results of the analysis are shown in Figure 1.

According to the results of the analysis, a strong statistical dependence (the absolute value of the autocorrelation coefficient exceeds 0.7) between the consumer price index in the current period and the consumer price indices taken with a shift persists for 12 months, which indicates a high value of inflationary expectations and a significant inertia of changes in System of prices.

The change in the volume of money supply is accompanied by moderate changes in the consumer price index only after 12-18 months, which indicates the high extent of the transmission mechanism of monetary policy in Russia.

The change in the per capita income of the population is also accompanied by changes in consumer prices with a lag of at least 6 months, the closest relationship between these indicators is observed with a lag of 14 months, this indicates that Russian households form their consumer decisions on expenditures based on the possibilities of permanent or Long-term consumption, rather than from the level of current income.

The high statistical dependence between consumer prices and the weighted average US dollar rate for the first 6 months indicates that foreign economic shocks and changes in the value of imported goods are

instantly reflected in the dynamics of consumer prices. This is an objective factor of the external nature from which any developing country that has a monopoly in both exports and imports is poorly protected.

In our opinion, the weighty influence of the dollar rate can be explained by three effects:
1) change in the exchange rate has a direct effect on the value of the consumer basket, due to the high dependence on imports in the consumption of the population of Russia;
2) increase in prices for imported goods leads to a shift in the share of demand for consumption of domestic products, which in the absence of a corresponding increase in supply in the short term provokes an increase in the price level;
3) increase in the exchange rate forms expectations of price increases among consumers and producers, which stimulates the expansion of demand, the reduction of supply and increases the overall level of prices in the country.

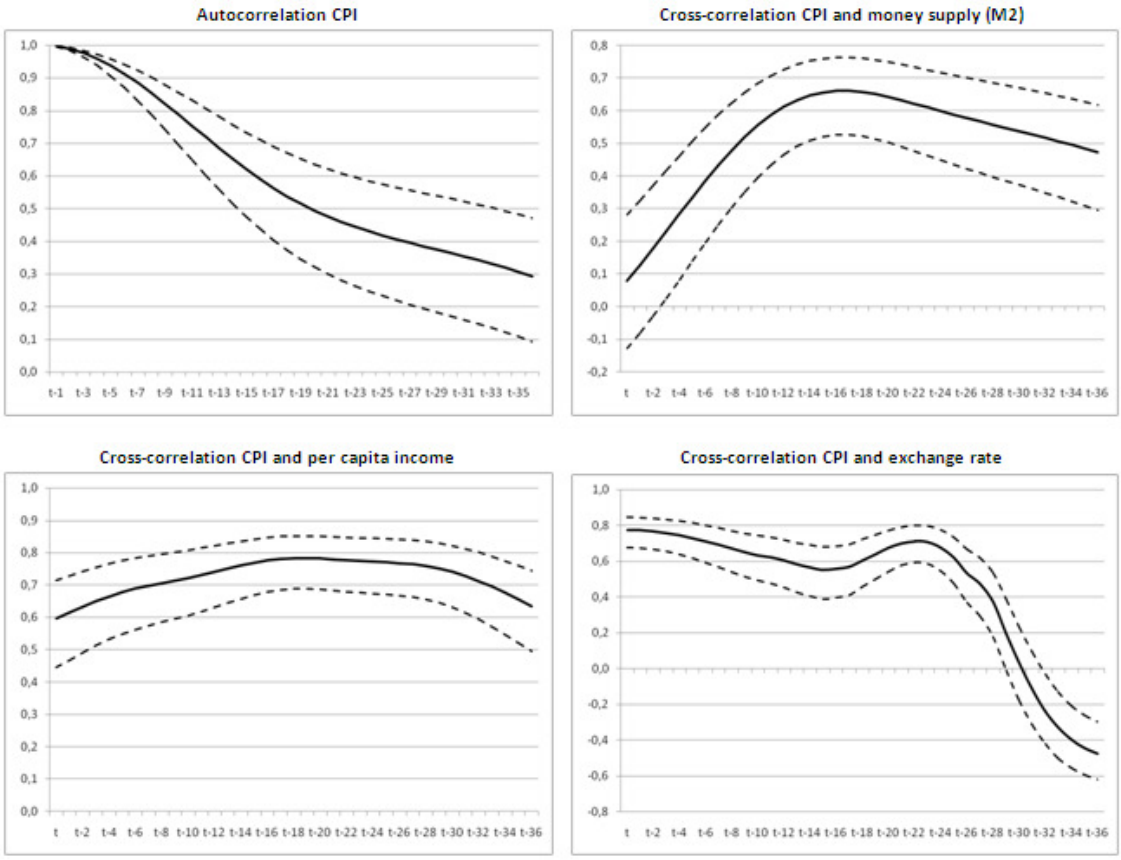

Fig. 1: Analysis of CPI and inflation factors interdependence.

Based on the information on time lags providing the closest relationship between the dynamics of consumer prices and the dynamics of the indices of the components of the inflationary process, a multiple regression model has been created that makes it possible to determine the contribution of individual factors to the formation of a common price level in each of the periods of inflationary processes in Russia under consideration. In our opinion, the inertial component of inflation should be excluded from the factorial distribution, since inflation expectations are formed under the influence of changes in per capita income, money supply and exchange rate dynamics and the preservation of this component is likely to

lead to a shift in the estimates of the significance of other factors. The results of the factor analysis are shown in Figure 2.

In each of the periods under review, the factors have different significance, so the reduction in the growth rates of consumer prices in 2009-2011 in many respects was determined by the decrease in the growth rates of the money supply (as confirmed by the relevant studies of Russian authors (Tabata, 2016; Akalin, 2015; Golovnin, 2016; Grigoryev, 2015), and the impact of the exchange rate turned out to be the maximum in the periods of the 2008 and 2014 crises. Currently, foreign economic factors and the dynamics of the currency rate have a significant impact on the state of the price system in. During the period 2015-2016 there was an unprecedented volatility of the US dollar rate in the Russian foreign exchange market, which generated differently directed impulses to change the general price level. The problem of achieving macroeconomic stability and exit from crisis processes is complicated by the fact that the economy of large federal states typically has high socio-economic differentiation in the regional context. This means that aggregated indicators like "average hospital temperature" do not give an idea of the actual processes, respectively, of the required changes, a combination of the center's tools and regions necessary to accelerate the yield to the price stability of the country as a whole. Individual regions show different reactions to changes in the parameters of the functioning of the national economy.

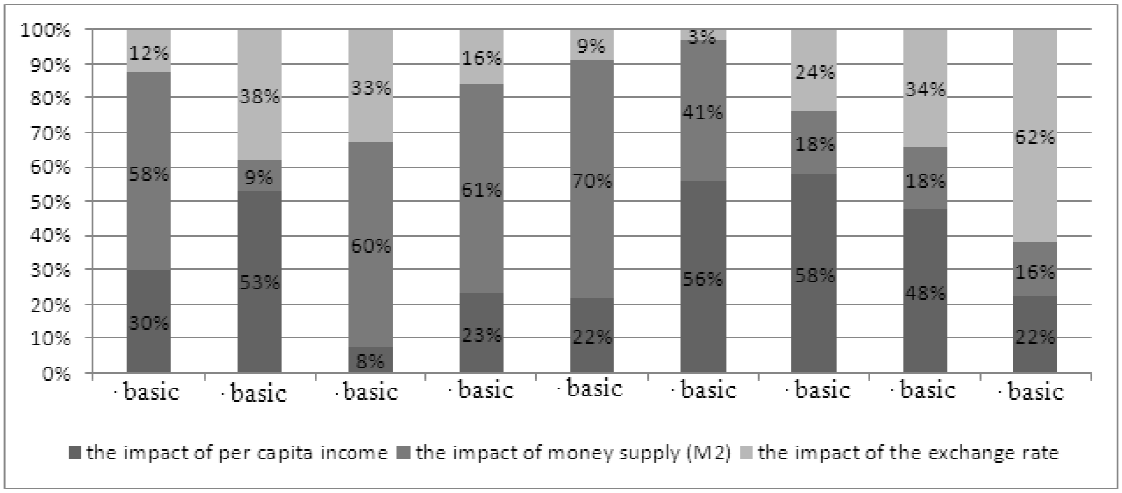

Fig. 2: Analysis of the impact of factors on inflation in Russia.

Regional factors of inflation processes in the Russian Federation

As it is known, the Russian Federation is a large and spatially heterogeneous economic system, so macroeconomic factors have a specific manifestation at the level of the territories. The authors formulated the hypothesis that the most important external factor for the dynamics of the level of consumer prices (it is revealed that it is the exchange rate determined by the system of external economic relations of the country) in different ways affects the price stability in the regions, which is largely determined by their foreign trade dependence.

To test this hypothesis, the subjects of the Russian Federation were typologized according to the level of external economic openness (dependence). To separate the sample into clusters, the Ward's method of clustering was used, the metric was the square of the Euclidean distance, the cluster analysis was based on the external economic indicators of 85 constituent entities of the Russian Federation for 2015. As parameters of the difference in the level of external economic dependence of regional economies, the following were determined: 1) foreign trade quota (the ratio of the arithmetic mean value of the value of

exports and imports to GRP in percent); 2) import quota (the ratio of the value of imports to the value of GRP in percent); 3) the share of imports from non-CIS countries in total imports in percentage terms.

Based on the results of the analysis, it is justified to identify four groups of RF subjects from the "low" (cluster 1 - the Altai Republic, Voronezh, Kursk, Omsk regions, etc.), "below average" (cluster 2 - Ivanovskaya, Kurgan, Tula, Chelyabinsk regions, etc. .), "Above the average" (cluster 3 - Krasnodar and Krasnoyarsk Territories, Novosibirsk, Sverdlovsk regions, etc.) and "high" (cluster 4 - Tyumen Region, Moscow, St. Petersburg, etc.) foreign economic openness (Dependence). The average values of clustering parameters and consumer price indices are presented in Table.

Table1: average values of indicators for clusters of subjects of the Russian Federation, divided by the level of external economic dependence

Cluster	Index	Foreign trade quota, %	Import quota, %	The share of imports from non-CIS countries in total imports, %	Consumer price index, %
Cluster1 (13 regions)	Average value	9,02	7,79	39,11	111,46
	Means quare deviation	7,65	8,98	15,58	1,87
Cluster2 (21 regions)	Average value	10,92	8,35	68,27	111,58
	Means quare deviation	9,56	7,18	8,52	2,03
Cluster3 (38 regions)	Average value	12,39	9,27	89,47	112,88
	Means quare deviation	61,35	8,47	6,51	1,84
Cluster4 (13 regions)	Average value	46,01	43,15	91,53	113,98
	Means quare deviation	8,25	26,28	8,57	1,98
RussianFederation (85 regions)	Average value	15,54	12,89	76,46	112,87[1]
	Means quare deviation	14,27	19,99	20,66	2,29

Analysis of consumer price indices for clusters showed that in 2015 the appreciation of the US dollar was affected in different ways in regional consumer price indices: the largest average consumer price index corresponds to cluster 4, which includes regions with "high" external economic openness (dependence); The smallest average value corresponds to cluster 1, which includes regions with a "low" openness (dependence). Thus, the external economic openness of territorial entities affects the projection of changes in the exchange rate on regional consumer prices. It is logical to expect differences in the reaction of regional economies to external economic shocks experienced by the Russian economy. This necessitates the development of conceptual approaches to the coordination of federal and regional stabilization policy measures with respect to the principles of regulation (Blanchard, 2001; Danilova, 2014).

Conclusion

The principles of the stabilization policy in federal states require a combination of regional regulation and the actions of the center, namely: 1) the principle of diagonal coordination of actions of federal and regional government structures, which implies the compatibility of actions of regulating bodies at different levels in the subject areas of stabilization, which allows adapting the center's measures to specific spatial conditions of their implementation; 2) the principle of effective market classification, the implementation of which supposes the addition of federal measures by the regional to reduce the negative

[1]Average value of the consumer price index for goods and services in the Russian Federation in 2015 - 112.9%.

consequences, which in the case of a price stabilization policy is manifested in the braking of the gross regional product; 3) the principle of combining the Strategy for Social and Economic Development of the Russian Federation with the Regional Development Strategies, taking into account the level of external economic openness and differences in susceptibility to shock impacts.

In our opinion, the application of these principles will allow to take into account the heterogeneity of the economic space of Russia and build a system for coordinating the interaction of the federal center and regions that ensures the effectiveness of the stabilization policy and non-inflationary and sustainable development of the economy of the regions and the Russian Federation as a whole.

Abstract

Efficient project-type order management is of an increasing importance in manufacturing and service enterprises work. It is a result of the fact that market competitive advantage depends of efficient order execution. Enterprises managers seek therefore new solutions in project type orders management. One of the methods may involve an application of methodological approach to projects management, in particular in the application of module methodology of large projects management based on critical chain concept. The methodology has been implemented in project planning and execution of electrical installation execution project in a water treatment station. Module type of methodology has facilitated selection of appropriate project planning modules. Selected elements from tactical and operational modules group have been applied, which brought significant advantages for the company. The project was successful and the project efficiency was higher than initially planned.

Keywords: projects management, large projects, module methodology, critical chain concept

Introduction

Efficient large projects planning and execution requires application of appropriate project management methodologies. Methodological approach to project management constitutes an ordered method of project planning, execution and inspection, characterized by certain formalization, discipline and structural activity. Such approach to projects management is based on: a specific project management methodology, gradually collected experience, and minimum intuition (Wirkus, 2014).

Projects management methodology can therefore be defined as a logical and coherent set of instructions for projects management measures taking method, which facilitate obtaining certain projects aims within a time and cost planned (Trocki, 2009). Projects management methods include: (1) basic project planning, execution and inspection principles, (2) methodology modes governed by ordered processes and procedures, (3) organization solutions, ordering principles of work, scope of duties and authorizations of persons involved in the project execution and (4) methods and techniques of project management support. The most popular methodologies of project management include: PRINCE2, TenStep. PMBOK is also applied in practice, being a guide for a Project Manager. It includes knowledge and the best commonly acknowledged solutions for project management, collected and published by the Project Management Institute (Strojny, Szmigiel, 2015, PMI, 2013, Rehacek 2016).

Project maturity is under extensive focus, which is also reflected in methodologies, as the higher the enterprise project maturity the higher is the importance of methods and methodologies of project management in project execution. Similarly as enterprises project maturity evolved, the project management methodologies developed as well (Łapuńka, Pisz 2014, Spałek 2014, 2016). We also currently speak about projects management methodologies maturity. The level of methodology

maturity is dependent upon the company's needs, and knowledge, experience and abilities of project team members.

There are more and more attempts in literature to find methodologies which facilitate flexible selection of elements for project planning and execution. The methodologies have been named component methodologies (Gasik, 2015). The component methodologies are constructed so that the Project Manager could select elements he needs (components), e.g. scope and time management procedure, and reject the rest of procedures. This type of methodologies shall provide the Project Manager a set of components, including a procedure, knowledge and other components, necessary for project planning and execution. A well-constructed component methodology must take into consideration all components of lower maturity level components, i.e. elements of methodologies focused on function, process and knowledge (Gasik, 2015).

The module methodology of large projects management described in the paper, based on critical chain concept is a kind of component methodology, which has been constructed for the needs of planning and execution of large production and service projects. The article presents a general structure and premises of individual methodology with a practical example of its application in industry. Module methodology has been applied in planning and execution of electrical installation execution project in a water treatment plant.

Guidelines for Large Projects Management Module Methodology Based On a Critical Chain Concept

Large projects management module methodology based on a critical chain concept has been constructed for the purpose of execution of complex, unique, strategic production and service projects. It facilitates selection of appropriate elements for planning and execution of large projects, therefore it can be assigned to component methodologies. It includes elements of methodology open to functions, as it is based on a critical chain concept. It presents a method of activity time estimating, using accumulated opposite of normal disintegration and allows calculating time buffers size, using fuzzy sets. The methodology includes also elements of process methodologies, as the individual modules include all project management processes. Additionally, the methodology has been developed on the basis of research conducted among manufacturing-service enterprises involved in large projects, which enhances it with values assigned to knowledge oriented methodologies. The project management process has moreover been extended by a working stage, which frequently occurs in large projects, as indicated by UNIDO methodology (Behrens, Hawranek, 1993). The methodology described can be applied both as complex support, using all modules, or may implement only selected modules of large projects management accordingly. This facilitates flexible selection of modules for planning and execution of a large project by the Project Manager (Marek-Kolodziej, Lapunka, Paszek, 2016). The method consists in total of 48 modules, divided into three groups: strategic, tactical and operational. Each of the modules has been marked by two letters and a number, which mean:

- the first letter describes a method of management in a project: S – strategic management, T-tactical management, O – operational management,
- the second letter determines a parameter of an iron project triangle: Z – scope of project, C – project time, K – project cost
- a number determines project execution stage: 1 – initiation stage, 2 – planning stage, 3 – execution stage, 4 – closing stage, 5 – exploitation stage.

The methodology described includes all project management stages. Pre-project, planning, execution, completion and exploitation stages have been included in it. The levels of project management have been extended by tactical level, which in large projects management occurs most frequently, when the project is executed separately, and tasks are performed by subcontractors at individual project stages. It moreover includes a process of inspection management at each of management stages. The method also suggests new solutions in large projects management, which refer to the processes of:

1. *Project team forming* – project team constitutes the most important body in projects planning and execution, as according to The Standish Group (2013), 13% of a project success depends on the competencies of project team members and following 15 % on the Project Manager. Module methodology focuses in particular on the roles performed by the members during team works. Research shows, that efficiency and effectiveness of a project team depends not only on knowledge, competencies, clearly determined relations, conformity of interests, but also on roles incorporated by the team members themselves (Chomicz, 2015; Gellert, Nowak, 2008; Kołodziejczyk-Olczak, 2013; Rutka, Wróbel, 2012; Scheurer, Ribeuro, 2009). Therefore, during team forming process and at the turn of forming and adjustment stages, it is advised to do the Belbin test, to check of team members represent adequate variability of roles, as only such a team is able to work efficiently (Belbin, 2010; Marek-Kołodziej, Łapuńka 2015).

2. *Estimated tasks duration times* - to estimate tasks duration times in the methodology described, the accumulated opposite of normal disintegration has been applied, with maintaining of 0,5 probability of timely execution of the project. This is the way of determining task aggressive times.

3. *Project programme* – project programme is established pursuant to the guidelines of critical chain method. The process includes: (1) determining relations between tasks, (2) determining of critical chain, (3) location of time buffers in programme, (4) determining of time buffers size, (5) introduction of time buffers into programme, (6) verification of critical chain location and (7) determining of time tolerances for individual stages of a project or sub-project. The methodology presented shows step by step how to build a project programme pursuant to the assumptions of critical chain concept. Method of time buffers location determining has also been presented (Goldratt, 2009; Marek-Kołodziej, Skomudek, 2015).

4. *Determining of time buffers size* – triangular fuzzy numbers have been applied for determining of time buffers (of a project and supporting one), (Marek-Kołodziej, Łapuńka, 2014). Buffers size calculated on the basis of triangular fuzzy numbers guarantees probability of 0,9 for project execution on time, which is not guaranteed by other calculation methods determined in literature (Marcini, Ruggeri, Caron, 2008; Patrick, 2014; Tenera, 2008).

5. *Project inspection and monitoring* – project inspection involves inspection and monitoring of the scope, programme and budget of a venture. Project programme inspection is performed according to time buffers use (project and supporting ones). Project Manager monitors at least once a week the progress of programme execution, dividing buffer into three zones: (1) green (monitoring), (2) yellow (planning), (3) red (performance). Project budget inspection takes place at least once in two weeks. Project budged inspection according to module methodology applies a method of EVM (Earned Value Method).

6. *Evaluation of project efficiency* – NPV (Net Project Value) or ROI (Return on Investment) shall be applied for project efficiency evaluation. The evaluation shall be conducted at the stage of the project finishing, when the company is the project contractor, but will not use the project product, or at the stage of project exploitation, when the enterprise is a contractor and recipient of the project product.

Apart from the new solutions listed above, the module large projects management methodology includes a description of processes which refer to risk, quality, communication and project interest parties management. Tools supporting selected processes have been elaborated additionally. Seven spreadsheets have been attached to the methodology, supporting planning and execution of large projects, according to module methodology, which are designed for: (1) project chart establishing, with specifying of the project risk, (2) NPV index size determining, (3) estimating the tasks time, (4) project budget establishing, (5) determining of time buffers size, (6) monitoring of buffers and (7) calculating the project value.

Large projects management module methodology based on critical chain concept is established so that the Project Managers and enterprise managers using it could choose proper modules for large project planning and execution. There are several options of modules selection, as presented in table 1.

Table 1: Possibility of application of large projects management module methodology based on the critical chain concept

No.	Project type	Name of modules/ group of modules
1.	A project as a whole is executed by one enterprise. At the same time the product of the project will be used by a given enterprise.	Application of all modules of the methodology.
2.	Project is executed as a whole by one enterprise, but its product will be used by another organization.	Application of all modules of the methodology except for part of modules which refer to the project use.
3.	Project is partly executed by a company and partly subcontracted.	Depending on the part ordered to the contractor: 1. If the enterprise supervises the project – a group of strategic modules is to be applied. 2. If the enterprise supervises and manages the project tactically, i.e. supervises and manages execution of project stages or subprojects, and the rest is subcontracted – groups of strategic and tactical modules are applied.
4.	Organization is a subcontractor and executes a group of works or specific tasks.	Application of operational modules group.
5.	Organization is a subcontractor and performs a specified stage of a project or sub project.	Application of tactical and operational modules.
6.	Organization has its own project management system and needs support in a specific part.	Any module may be applied separately, without implementing the whole methodology.

Source: own elaboration

The module methodology established can be applied as a whole, or selected modules can be implemented, e.g. if a project is executed partially be an enterprise and partly by its subcontractors, a group of strategic and tactic modules can be applied. Project Manager has a possibility to select proper tools for large projects management in the enterprise.

Characteristics of an Enterprise and a Project Under Execution

The enterprise described works in Opole District, and performs industry automatics projects since 1997. The company provides services in design and implementing of automation and industry systems of electrical installations for: technological installations, production halls and office buildings, machinery and machinery and processing devices, power supply objects, water treatment plants and environment protection installations.

The company executes automation systems using modern controllers of SIEMENS, GE Fanuc or other companies indicated by a client. The company also executes apparatuses and tools based on products of renowned manufacturers and suppliers. Additionally, the automation systems include execution of drive control, power supply distribution cabinets and in company workshops, and systems of objects pneumatics. The electrical installations are designed and executed by the company using modern technology and tools of the most renowned manufacturers.

The core of the company are several engineering and technical employees, with several years of experience in technological processes automation and control systems, with branch staff with licences for designing and execution of electrical installations.

The orders performed by the company constitute projects, because they must be completed within time set, at cost determined and give a product according to the customer's requirements. The orders are moreover unique and require individual approach in their planning and execution.

The company most frequently performs several orders simultaneously, which causes that persons responsible for the orders execution planning meet problems in duration time estimating, using the same resource in several orders at the same time. Planning of an order for electrical installation in a water treatment plant involved selecting of module methodology for large projects management, based on the critical chain concept. It results from the fact that the method uses an innovative approach for estimating the tasks duration times and use of resources in the project.

The project (order) for the electrical installation execution in the water treatment plant involved execution of ten main tasks: (1) internal power supply, control and measurement installations in the building, (2) assembly of power supply-control distribution station for the technological system, (3) assembly of power supply-control distribution station (RTOO), (4) internal power supply, control and measurement installations outside, (5)internal power supply, control and measurement installations in the filters building, (6) lighting system in ozone room, (7) assembly of power supply-control distribution station in ozone station, (8) internal installation of electrical power supply and control, (9) levelling installations.

Implementing of module methodology based on the concept of critical chain concept in practice

According to the client's programme the project was due to start no sooner than on 7.11.2016 and be completed no later than on 28.04.2017. The project value was about PLN 1 million, and expected return on the project is of 14,60%. The value has been determined by the company manager, at the assumption, that the project planned cost increases at most by 11 %.

The company performing the project has got a Quality Management System implemented, including a procedure named: "Services execution" adjusted to planning and execution of orders in a company. Modules of the methodology, indicated a need for implementing its following elements, included in the group of tactical management: (1) „T.Z.2", (2) „T.C.2", (3) „T.K.2", (4) „T.C.3", (5) „T.K.3", (6) „T.Z.4", (7) „T.C.4", (8) „T.K.4", (9) „T.K.5" – only for project efficiency, (10) „Tactical management of the project inspection". Only these modules have been selected as the project operational management (i.e. at the level of works manager) is performed pursuant to procedure named: "Services execution", which is included in the Quality Management System implemented in the company.

Project planning was commenced from project team appointment, pursuant to "T.Z.2" module. Structure of the project team has been presented in fig. 1, where project team members were selected, responsible for:

- project strategic planning and execution – company management,
- tactical planning and execution of the project – Project Manager, constructor, supplies specialist, financial specialist, and H&S specialist.
- operational planning and project execution – two working teams with foremen as managers, installations electricians and mechanics are team members.

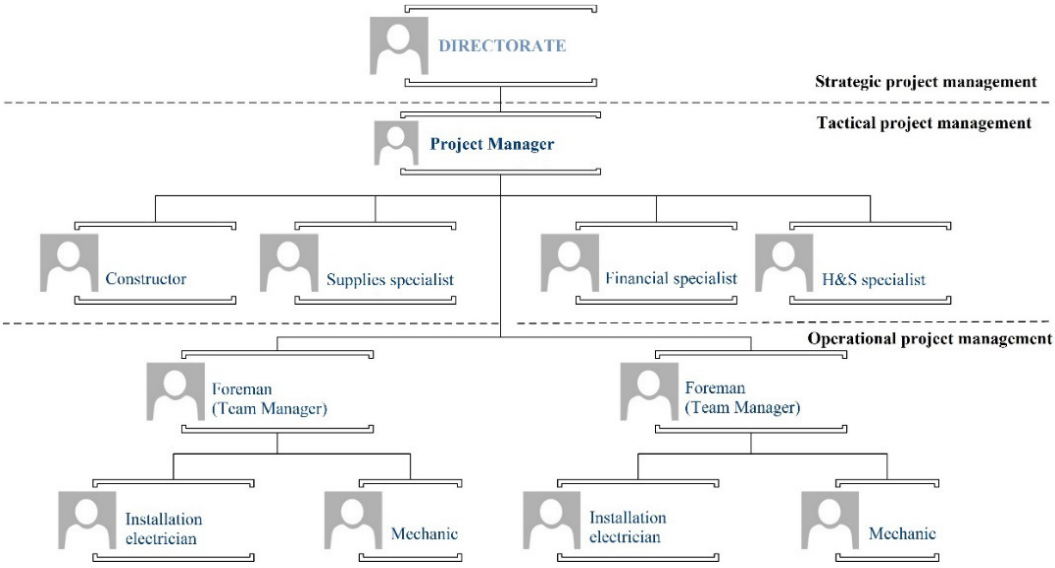

Fig. 1: Project team structure

Source: own elaboration

Pursuant to modules "T.C.2" and "T.K.2", duration times have then been estimated for the project stages, project programme was elaborated and cost of the stages determined. Spreadsheet used for the time duration was applied: "Tasks time duration estimating", including determining of aggressive execution times, pursuant to the critical chain concept. As the company is experienced and has got data collected from execution of similar projects, the following overlap has been applied for the times estimating: "According to statistical data". Times estimated in this way, had 0,5 of timely execution probability.

The project programme has been established in Microsoft Project, according to module "T.C.2". After all data and duration times have been introduced, the project critical chain was determined, and time buffers introduced. 8 time buffers were introduced in total, including 1 project buffer and 7 support buffers. Project buffer has been placed at the end of the critical chain, and support buffers at the ends of non-critical paths. The size of the time buffers introduced (project and support ones) was determined on the basis of fuzzy sets theory, according to module "T.C.2". Module methodology support spreadsheet was used for this purpose: "Buffers size determining". Project buffer size was calculated on its basis, including 46 days. Hence, the project had probability of 0,9 for timely execution. Table 2 presents sizes of the remaining time buffers.

Table 2: Size of the time buffers in the electrical installation execution project

Buffer type	Tasks path	Length of path [days]	Buffer size [days]
Project Buffer (PB)	1.1. – 1.3. – 1.5. – 1.6. – 2.2. – 2.4. – 2.5. – 3.1. – 3.3. – 3.4. – 4.1. – 4.2. – 5.2. – 5.4. – 5.5. – 6.1. – 6.5. – 6.6. – 7.1. – 7.2. – 8.2. – 8.3. – 9.1. – 9.2. – 9.4. – 10.1. – 10.2.	63	46
Feeding Buffer 1 (FB 1)	1.2. – 1.4.	4	1,5
Feeding Buffer 2 (FB 2)	2.1. – 2.3.	5	3
Feeding Buffer 3 (FB 3)	3.2.	2	0,5
Feeding Buffer 4 (FB 4)	5.1. – 5.2.	2	1

Feeding Buffer 5 (FB 5)	6.1. 6.2. 6.3.	3	1,5
Feeding Buffer 6 (FB 6)	8.1.	1	0,5
Feeding Buffer 7 (FB 7)	9.3.	1	0,5

Source: own elaboration

Project programme with buffers introduced and resources assigned, has been established in Microsoft Project. Installation electricians constituted key resources for the project execution, their number was limited depending on the working day. Programme established included also efficiency of installation electricians. The project aggressive programme has been presented in fig. 2. Critical chain has been marked in red in the programme, non-critical paths in blue, support buffers in green, and the project buffer in purple. Pursuant to programme established, the project should start on 7.11.2016, and be completed on 6 of April 2017. This means that the project should be completed by about 10 days earlier than previously planned. According to the initial programme the project was planned to commence on 7.11.2016 and be finished by 20.04.2017.

Fig. 2: Project programme established in Microsoft Project
Source: own elaboration

Project execution was performed pursuant to modules “T.Z.4", "T.C.4” and “T.K.4”. Project Manager supervised project scope execution, the programme itself and the project cost. Every two weeks, on the basis of daily reports from the team managers (foreman), and project inspection, he prepared reports on: (1) project scope execution, (2) budget stage execution and (3) programme timely execution Project inspection was performed pursuant to module: “Project inspection tactical management”. Project Manager monitored the programme by means of spreadsheet: “Time buffers monitoring”, checking the time buffers use. Project buffer was used in 67%, i.e. about 31 days. Electrical installation execution project in water treatment plant was completed on 16.03.2017, i.e. 40 days earlier than expected by the client.

Electrical installation execution in the water treatment plant was inspected according to time buffers use (project and support ones). Project buffer use during its execution has been presented in fig. 3. Although the project buffer use during project execution time appeared (see fig. 3, item A and B) twice in the red zone, it had no impact on the completion of the project in time. It was caused by a delay in materials and prefabricated item supply to the project execution site.

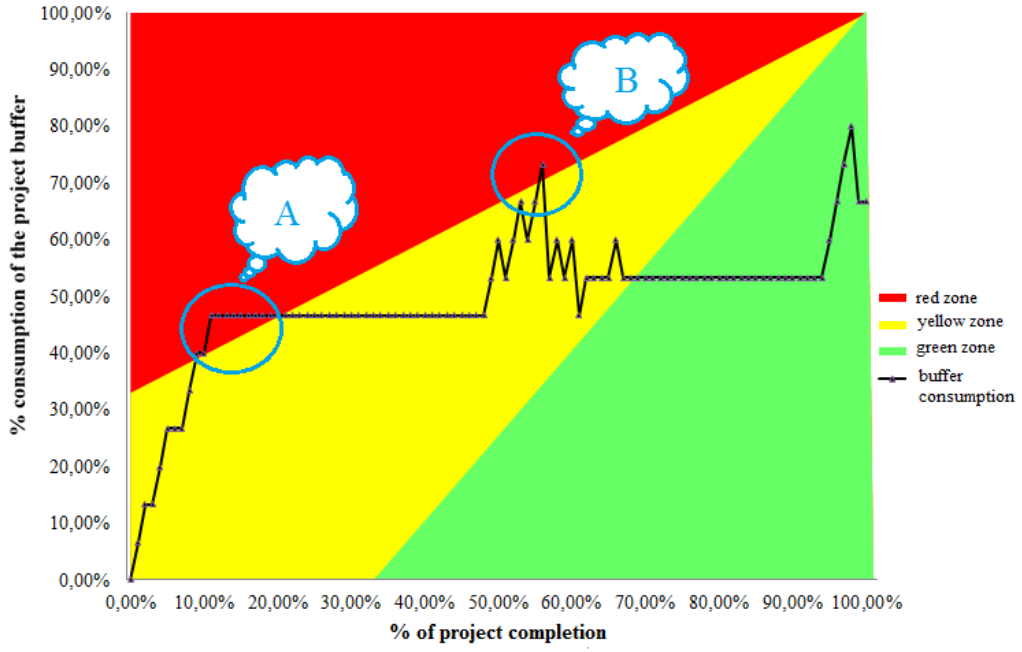

Fig. 3: Project buffer use in the electrical installation execution of a water treatment plant
Source: own elaboration

Except for programme inspection, an inspection of the project cost was performed, on the basis of the project value obtained. The cost of the project increased during its execution by PLN 28000, due to the tasks time extension in critical chain. The cost however has not exceeded the assumed budget tolerances.

Project execution was completed on 16.03.2017, and project completion process commenced. Project Manager prepared final report and project product handing over report. The project product with all documentation was handed over to the client.

After the project completion, a closing meeting was held, where all positive and negative project effects have been discussed. Efficiency and effectiveness of the project have been presented. The project efficiency has been analysed for the scope, programme and budget of the project execution,

by comparing the planned and actual values. Project effectiveness has been determined on the basis of Net Present Value and the Return on Investment, and compared with the values planned by the Project Manager.

The analysis indicates, that the electrical installation execution project in the water treatment plant was performed successfully, as the client received a project product 100% compliant with the client's requirements. The project has been moreover completed 15 days earlier than planned. Only the project cost was higher than planned (by 2%), but not higher than tolerances assumed. The cause of the project cost increase was the extension of several tasks in critical chain, which was caused by longer working time of the fitters.

Project effectiveness indicates, that module methodology brings higher financial profit for the company, as the project return increased by about 9,5%. NPV index was 25% higher than planned. To calculate the NPV, it was assumed that the annual return on assets involved in the projects execution is 22%.

Conclusions

The module methodology of large projects management based on the critical chain concept connects features of function, process and knowledge oriented methodology, i.e. it is a kind of component methodology. Large projects module management method based on critical chain concept, has been established so as to provide to the Project Managers, and company managers a possibility of selecting appropriate modules for planning and execution of a large project. It may be applied as a whole or involve implementing of selected modules only, i.e. when a project is partially performed by a company and partially by its subcontractors, a group of strategic and tactical modules is used. It provides possible selection of tools for large projects management in a company for a Project Manager.

Module methodology application in planning and execution of electrical installation execution project in water treatment plant caused increase of the project efficiency and effectiveness. Project execution time was by over 21% shorter than initially planned. Project efficiency increased at the same time, as the ROI index was higher by 9,5% than initially assumed.

Abstract

The authors suggest a system of financial and economic calculations for efficient management of complex IT projects. It consists of the following calculations regularly and consistently performed at four project phases: commercial evaluation of projects and business planning; financial diagnostics of the companies which implement projects; business valuation at different project phases. The features of economic methods of project management are considered.

Keywords: economic methods, project management, commercial evaluation, company value, financial and economic calculations.

Introduction

Revolutionary development of information technologies has caused constant growth of investments into this sphere. The majority of developing companies make significant part of their capital investments in IT projects. Therefore, it is necessary to improve IT project management and to promote economic methods for enhancement of operating efficiency.

Project management means management of project implementation process. Project implementation, in its turn, means a package of measures to be taken to achieve project goals. Yield increase and company value maximization are the priority goals of IT projects implemented by trading companies. Economic results included in the original plan may be significantly altered during project implementation process depending on evolving circumstances and obtained interim results. Therefore, project implementation should be regarded as a continuous process which requires regular analysis of the current situation and trends. Such analysis may result in necessary adjustments.

Recent Research and Publications Analysis

A significant number of scientists have been published on the subject of project economic evaluation of IT project management (Adamenko et al, 2017; Focacci, 2017; Moran, 2016; Pelin Gurgun et al, 2017; Silkina, 2017).

A lot of works which study this problem are devoted to different economic and financial aspects of IT project evaluation (Ampatzoglou et al, 2015; Glukhov et al (2016); Laine et al, 2016; Matvienko, 2009; Marhasin, 2000; Nyuhin, 2010; San et al, 2017; Yuryev, 2008; Zalaeva, 2009; Zozulya et al, 2017; Ilin et al, 2016; Glukhov et al, 2015).

Projects are classified using various criteria, such as application area, subject field, scope, length, types of participants, complexity, impact of results on social sphere etc. (Akoff, 1985; Ivasenko et al, 2009; Golov et al, 2015).

Depending on the scope and structure projects are divided into mono-projects, multi-projects and mega-projects. Multi-projects are complex programmes and projects implemented within big companies. Such projects include both establishment of new companies and development of existing ones, as well as corporate management modernization.

This paper is dedicated to economic and financial calculations for IT multi-projects, i.e. projects aimed at establishment of new IT companies or branches of existing IT companies. The suggested calculation system provides for their effective development and creates conditions for operational management and decision-making at different phases. It should be noted that there are quite a lot of classifications of large-scale project phases (Bril et al, 2012; Ivasenko et al, 2009; Golov et al, 2015).

Problem Formulation

The authors use classification which divides a project into four phases:

- Pre-opening arrangements, initial financing and organizational development (start-up);
- Fast sales growth, significant investments in production, optional negative cash flow;
- Substantial economic results, return on investments, positive cash flow;
- Loss of income due to escalating competition, search for new ideas and development scenarios, optional negative cash flow.

Specific financial and economic calculations will ensure successful project implementation at each phase. Feasibility study comprising commercial evaluation of projects and business planning is applicable at the first stage. Regular assessment of a company's financial position and control over achievement of financial and economic goals set in its business plan is expected at the second stage. Control over a company's financial position and business valuation are performed at the third stage in order to prepare for the fourth stage. Another business valuation, development of new ideas and business planning are done at the fourth stage.

Calculation methods should be based on decision-making criteria at each phase in order to achieve successful project management and rational decision-making (Table 1).

Table 1: Project phases and financial and economic calculation methods

Multi-project phases	Financial and economic calculation methods	Decision-making criteria
1 Pre-opening arrangements, initial financing	Feasibility study and business planning	Net present value, profitability and operating leverage
2 Fast sales growth, optional negative cash flow	Regular assessment of a company's financial position and control over achievement of goals set in its business plan	Special system of financial indicators
3 Return on investments, positive cash flow	Control over a company's financial position and business valuation	System of financial indicators, company value
4 Escalating competition, search for new ideas and development scenarios	Another business valuation, development of new ideas and business planning	Company value, profitability and operating leverage

Initial decisions are made based on the project feasibility study and business planning. A business plan is a list of works and activities structured by sections which are required for project implementation. In this context a project is an investment plan aimed at achievement of intended benefits.

A business plan is prepared in order to provide rationale for project costs and, consequently, for its financing sources. The business plan is one of the principal documents to be submitted to investors and creditors. Business plans were originally prepared only for investment projects. That is why costs and resulting income should be calculated and justified for all works and activities included in the document. Based on these calculations investors and creditors make a decision on whether to finance the project or not. The financing decision is made based on such characteristics as payback period and simple rate of return, as well as such discounted indicators as net present value (NPV) and internal rate of return (IRR).

As multi-projects started to evolve, this calculation system turned out to be flawed due to the fact that above mentioned decision-making criteria were not applicable to describe business efficiency (Goremykin, 2013; Strekalova, 2013; Vilensky et al, 2015).

Financial position of a company and its development effectiveness are characterized by efficiency and solvency indicators. Among the most important indicators there are return on sales, return on assets and return on equity, as well as such solvency indicators as equity-to-asset ratio, financial leverage, current ratio, quick ratio and solvency ratio. In order to ensure efficient multi-project management, it is necessary to combine these indicators which are different for projects and businesses in one business planning system.

Problem Solution

Having performed multiple studies and calculations, the authors recommend the following two approaches to economic assessment of IT multi-projects:

- Two-step financial and economic calculations for investment projects;
- One-step calculations for operational projects.

The methodology suggested by the authors to evaluate investment projects using the first approach is based on the UNIDO method (Berens and Havranek, 1995) and provides for two-step calculation (Bril et al, 2012, 2015, 2016):

- Step 1: efficiency evaluation based on calculation of profitability and discounted indicators;
- Step 2: assessment of project implementation impact on the increase in profit, labour efficiency, profitability and operational risks.

In such a way business planning performed at the first phase of an IT multi-project is naturally incorporated in the general planning system of a company due to the fact that development project business plans and company business plans are elaborated according to accepted company strategies. While current (annual, quarterly) plans for trading and manufacturing activities are based on approved business plans. A company's planning system may be thus presented as follows (Figure 1).

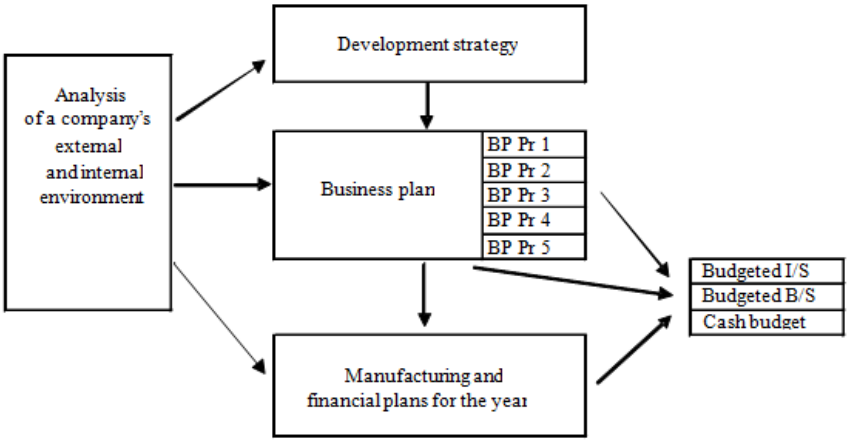

Fig 1: General planning system at an IT company

Business planning is a part of the general planning system of a company. It is based on a strategy development and used for current annual and quarterly planning. In order to evaluate specific projects such approach requires preparation of three documents which are usually disregarded when a usual project business plan is prepared. These documents include a budgeted income statement prepared using a standard income statement template, a budgeted balance sheet prepared using a standard balance sheet template and a cash budget prepared using a standard cash flow statement template which could be consolidated with respective statements.

These documents make it possible to evaluate how implementation of each project will affect financial position of the company under consideration, its profitability and solvency, as well as manufacturing and commercial risks. The main financial and economic indicators used to characterize budgeted results at both steps of multi-project evaluation are listed below.

Step 1. Efficiency evaluation based on calculation of profitability and discounted indicators.

	Indicators:
• Payback period	r
• Simple rate of return	i
• Net present value	NPV
• Internal rate of return	IRR

Step 2. Assessment of project implementation impact on the increase in profit, labour efficiency, profitability and operational risks.

	Indicators:
• Increase in sales profit	Inc
• Performance improvement (sales per one employee per month)	PI
• Return on sales	ROS
• Operating leverage	OL

It should be noted that the list of indicators for the second step may be significantly extended depending on the specific nature of each company which implements a multi-project. Additional indicators are selected using the financial diagnostics method developed by the authors within economic and financial calculations for IT multi-projects (Bril et al, 2012).

Calculation results based on a business plan of a big telecommunications company of the Siberian Federal Okrug are presented in Table 2. Only payback period is included in the table from resulting (criterial) indicators of the first step. Initial decisions are made based on the project feasibility study and business planning.

Table 2: Economic evaluation using the two-step calculation system

Project types	Special mobile Internet 1	Special mobile Internet 5
Number of users, thousand people	50	75
Number of employees, people	12	8
Investments, million rubles	157.0	120.0
Sales, million rubles / year	120.000	58.00
Current expenses (cost), million rubles / year, including :	69.0	36.0
Variable expenses	48.3	26.5
Fixed expenses	20.7	9.5
Payback period, years	3.08	3.75
Sales profit (budgeted increase for a company on the whole), million rubles / year	51.0	32.0
Performance improvement (number of sales per person per month), %%	11.3	5.1
Increase in return on sales, %%	5.6	3.2
Operating leverage for a company on the whole	2.79	3.20

As for the control over changes in financial positions of companies which implement multi-projects, a special financial diagnostics is performed at the second and third phases in order to ensure successful implementation of IT investment projects. It has been developed by the authors and described in Bril et al, 2012. Its purpose is to trace changes in sales profit, net profit, profitability and return on assets, as well as risk level and solvency at the second and third project phases.

Equipment upgrade, automation or start-up of new production projects in existing company can significantly affect the structure and the cost of capital, shares of fixed and variable expenses in total expenses and cash flows. Regular control over financial position of a company makes it possible to take timely reasonable measures for successful implementation of multi-projects.

Financial diagnostics is based on:

- Quarterly calculations;
- List of financial and economic indicators in line with those set in business planning methodology;
- Comparison of actual figures of the quarter with established standards, figures of the previous quarters and business plan figures;
- Decision-making methods (strategies) in case of significant variance between actual figures and figures for comparison.

Business valuation methodology to be used at the third and fourth phases of IT multi-projects is described below.

Company value maximization has been one of the most common goals of financial management and, therefore, business efficiency criteria for the last 20 – 25 years. It makes it possible for owners to make more sound decisions on company sale according to the early exit strategy or on multi-project investment at the third and fourth phases in order to compensate for losses from evolving competition and decrease in sales according to the leadership strategy. In view of this, the main purpose of regular business valuation during multi-project management is to identify a moment when the value starts to decrease, to understand the reasons for that and to make timely decisions on further project implementation.

The value of listed companies which have gone through IPO is determined on a daily basis, which forms a good statistics for decision-making. Valuation of small and medium enterprises may be performed by professional valuation experts. Usually this is an expensive single-use procedure. An easier alternative is required to reduce costs and provide regular results. The authors thus suggest a set of rather simple valuation methods based on financial diagnostics methodology which are easily incorporated in the overall system of financial and economic calculations for multi-projects.

Business valuation theory suggests three approaches achieve project goals, namely cost, income and comparison approaches. Quite a lot of methods are actually used within these approaches (Friedman and Ordway, 1997; Ilin et al, 2014). For IT multi-projects the authors suggest business valuation based on various development scenarios and financial diagnostics results at the second and third project phases.

In order to determine initial company value at the third phase of multi-project implementation, it is necessary to consider at least two development scenarios:

- The first scenario is *the lack of additional investments*. The project is implemented according to the goals set forth in the business plan.
- The second scenario is *fund-raising using the leadership strategy*. The rise in competition, commercial and financial risks, price reduction for company services are projected for the nearest period.

In both scenarios the company value as of the valuation date is determined using the cost approach after audit and financial diagnostics of the company. In order to have more information about the company value as of the valuation date it is also necessary to use such income approach methods as profit capitalization, 50% of sales and fivefold sales profit. Information about the company value may be also supplemented by the information about sales of similar enterprises. Actual value is determined based on obtained results. This figure is the base for further calculation of the company value in the planning period.

Valuation of a company which implements a multi-project on production of IT equipment elements and components is presented in Table 3.

Table 3: Initial business valuation at the third phase of multi-project implementation

Valuation method	Amount, million rubles
Cost approach	142
Profit capitalization	120
50% of sales	165
Fivefold sales profit	175
Approved actual value	145
Company value after investments into assets taking into account appreciation rate	190

When actual value of the company as of the valuation date is determined, it is necessary to set a planning period for calculation of changes in the company value. Its length depends on the type of project but cannot exceed three years.

In *the first development scenario* calculation of changes in the company value is made based on the above mentioned income approach methods, such as profit capitalization, 50% of sales and fivefold sales profit. Calculation is based on budgeted amounts of sales and profit for the planning period.

Net profit for the reporting period and statistics on average return on equity of the IT group of companies under consideration are used for profit capitalization method.

In *the second development scenario* it is necessary to obtain the company value as of the date of additional investments. It is important to take into account appreciation of the company due to

attraction of additional capital. Assets turnover (turnover during the year) and return on assets are used to obtain appreciation rate.

When the company value as of the date of additional investments is calculated, it is necessary to calculate the company value for the planning period. Several valuation methods may be applied here. The authors recommend using venture approach and future value method.

The venture approach is easier in terms of calculations but it requires construction of a cash flow diagram for determination of the future company value. Its implementation is possible with statistics of average profitability of the IT group of companies under consideration and its budgeted profitability rate. Then the company value as of the planning moment of time will be calculated as follows:

Value as of the planning moment of time = value as of the time of additional investments $\times (1+i)^n$
where:
i is the comparison rate accepted at the budgeted profit level taking into account average statistical data (10-12% per year);
n is the planning period in years.

The planning period may be set in months. In this case the comparison rate should be set on a monthly basis. The comparison rate determination is a key moment of the calculation which needs special justification.

The future value method provides for more detailed and difficult calculation. It is based on tables and diagrams of budgeted cash flows and takes into account provision of loans, revenues and payments of the enterprise under consideration during the planning period. Weighted average cost of capital (WACC) or actual return on assets (ROA) are used as a comparison rate here.
This calculation system makes it possible to obtain information base for specification and determination of actual and budgeted company value, adjustment of project implementation process and finding solutions for organizational, production and financial issues.

Conclusion

1. IT project management is a complex multiple-option process consisting of four main phases. Each phase requires adjustments based on economic analysis and calculations which include:
- Two-step commercial evaluation and business planning;
- Special financial diagnostics;
- Regular business valuation.

2. Financial diagnostics and business valuation at the second and third multi-project phases provide a wide base of financial and economic indicators used to approve and adjust operational plans for further multi-project implementation.

3. Rather simple calculation algorithms suggested by the authors and available software will make it possible to pay more attention to reliability of benchmark data for project development monitoring.

Social Supermarkets in the Czech Republic – an empirical study

Alexandr Asmalovskij, University of Economics, Prague, Czech Republic, alexandr.asmalovskij@vse.cz

Tomáš Sadílek, University of Economics, Prague, Czech Republic, tomas.sadilek@vse.cz

Abstract

The paper focuses on the so-called social supermarkets and their presence in the Czech Republic. The authors aim to give an overview of the status and form of social supermarkets on the Czech retail market. The analysis is based on data obtained from an empirical study conducted by the authors. The theoretical part consists of literature review on social enterprises in general and definition of social supermarkets. The criteria for selection of the research sample for observation were chosen based on the research conducted in Austria by researchers from University of Economics in Wien. The research sample consists of 40 retail stores belonging 5 retailers. The particular variables of the study are number of stores, store size, range of categories and products, discount rates, location, and number of employees in the selected stores in the Czech Republic.

Keywords: social supermarkets, social enterprise, retail, food waste, sustainability, Czech Republic

Introduction

Social enterprises (SEs) are a phenomenon in modern economy that emerged from lack of solutions to various social issues which are neither addressed by the private sector nor the public sector. Inspired by non-profit organisations, SEs focus on a particular social issue and build a business model brings a solution or helps resolve the issue, which is their main purpose. At the same time while benefiting the society, SEs try to make enough profit to ensure self-sustainability.

SEs fall within the so-called third sector. Literature also names it as social economy, the social sector, non-profit sector, voluntary sector, community sector, or civic sector (Dohnalová, 2006). A social enterprise is a socially oriented, implemented, innovative intent achieved through economic activity in the presence of real economic risks (Schumpeter, 1961). Entities like social enterprises operate under a wide range of legal forms and often represent the new or renewed expression of civil society against a background of economic crisis, the weakening of social bonds and difficulties of the welfare state (Borzaga and Defourny, 2004).

Food waste in relation to food surplus found mostly in developed countries is one of the issues addressed by the third sector and non-profit organisations. According to Abzug (1999), a large number of academic studies on non-profit organisations are related to topics like health, human service or education, while non-profit or social retailing was barely found in the academic sphere. But in the recent years, cross-sectoral cooperation has emerged in retailing (Gupta and Pirsch, 2008), including cooperation with non-profits and SEs. One of the initiatives of such cross-organisational partnership between retailers, manufacturers and government are the so-called social supermarkets (SSMs) (Holweg et al., 2010a).

Literature Review

In literature, various retail models with certain types of cross-organisational relationships related to food retailing and food waste can be found, for instance: Food Banks in countries all over the world including Czech Republic (Filipová et al., 2014; Robinson, 2016); Charity Shops in the United Kingdom (Broadbridge and Parsons, 2003; Horne, 2000); Super Discount Stores (Caroli and Gautie, 2008; Oh and

Kim, 2003); and Social Supermarkets (De Renobales et al., 2015; Holweg et al., 2010a, 2010b; Maric and Knezevic, 2014).

Due to orientation on Czech Republic and Austria, as a similar and comparable county, this paper focuses on two types of the aforementioned models – social supermarkets, and super discount stores. SSMs in Austria were first defined by Holweg et al. (2010a) based on their models in six European countries – France, Austria, Belgium, Switzerland, Luxembourg, and Romania:

"*Social supermarkets receive surplus food and consumer goods from partnership companies (e.g. manufacturers, retailers) for free and sell it at symbolic prices to a restricted group of people living in or at risk of poverty*".

Another definition is based on an SSM model in Croatia:

"*Social supermarkets are a social innovation that comprises social responsibility of associated individuals with the aim of showing social solidarity toward socially vulnerable persons or families, by collecting and distributing goods gathered from individual donors, large retail chains and/or other companies*". (Klindzic et al., 2016)

In the Czech Republic, the term "social economy" is usually poorly recognised within the general public. One of the reasons for this might be the absence of legislation concerning SEs defining their form or status. Despite this fact, academic research along with practice confirm that SEs are present in the Czech Republic (Dohnalová and Průša, 2011). Also, it is necessary to mention that the term "social" tends to arouse negative connotation in the context of Czech language, therefore this linguistic oddity as well as negative perception of people rather prevents the development of social entrepreneurship in the Czech Republic (Policar, 2010). This might be given not only by the language, but also the period of socialist political regime in the second half of 20th century.

Given the circumstances, the authors of this paper have decided to focus on research of social economy, retailing, and their relation in the Czech Republic by zooming in on the issues of citizens with low income and food waste, as well as the initiatives addressing them. Therefore, the aim of this observation was to map the current situation in social retailing and find out whether social supermarkets or other forms of social retailers are present on the Czech market, and analyse them using the variables presented in the research by Holweg and Lienbacher (2011) in order to make a comparative study. The outcomes will serve further research in order to select the best practices in retailing dealing with food waste and people living in or at risk of poverty.

Observation and Methodology

Due to lack of legislation defining SEs, it is currently not possible to determine the amount of SEs in the Czech economy, nor their specialisation in retailing (Asmalovskij and Sadílek, 2016a). Therefore the authors have chosen to conduct field research by looking for enterprises based on models similar to those defined in the literature review and carry out an empirical research.

In the first phase, the authors have done literature review to identify and choose the most appropriate criteria for the research sample in the context of Czech retail market. A set of variables has been chosen based on research by Holweg et al. (Holweg and Lienbacher, 2011) from University of Economics, Vienna with approval of the researchers. The aforementioned research has been selected due to its quality, geographical as well as demographical reasons, and retail market similarity as Czech Republic and Austria are well comparable neighbouring EU member countries.

Criteria for determining the observation sample have been set by the authors upon which a profile of a relevant entity was created as follows:
A retail company selling discounted food/non-food products with significant rate of discounts – 30% or higher discount rate compared to average retail market prices.

Applying the aforementioned profile, 5 retail companies with 40 stores (n = 40) were found on the Czech market using online sources and publicly available press. Further empirical field research in the form of observation was conducted. All of the selected stores were visited by the authors in August and September 2017 where variables derived from research by Holweg and Lienbacher (2011) were observed 7 of which are presented in the paper: assortment in food categories, non-food categories, discount rate, average spending per visit, store size, location within the country and district, number of employees.

Empirical Study Results

Overview

In total, 40 retail stores (n = 40) belonging to 5 retail companies were observed on the Czech retail market in Q3 2017, most of them located in smaller towns. With the exception of one company, which is run under a business licence of a physical entity, the form of the enterprises is Limited Liability Company (LLC). Two (2) of the retailers operate with central warehouses for their stores. As of their marketing activities and communication, all of the retailers are presented on their websites, some communicate via social networks, mainly Facebook, some distribute leaflets, and the largest retailer runs an e-shop with non-food goods. A more detailed overview is presented in profiles of the companies. All the information stated in the retailers' profiles was gathered from their websites.

- Levné potraviny s.r.o. (LLC) – the largest retailer, founded in 2007, owning 14 stores in 10 towns and cities including the capital city of Prague. The company runs a website (http://www.levnepotraviny.cz/) with an e-shop for non-food products, is a retailer and wholesaler, being an exclusive distributor of OKF brand products such as Aloe King. Its stores operate under a central warehouse. The discount rates reach up to 70% compared to average market prices. The company also communicates through social networks (Facebook, Twitter, Instagram) and distributes leaflets.

- DKS Morava s.r.o. (LLC) – the company was founded in 2008 and operates 10 stores in 7 towns. It runs a website with limited general information (http://www.dksmorava.cz/), and operates under a central warehouse. The discount rates reach up to 70% compared to average market prices.

- Nejlevnější potraviny Flaška (physical entity business licence) – runs 10 stores in 10 towns, communicates via website (http://www.nejlevnejsipotraviny.eu/), Facebook and leaflets. The discount rates reach up to 70% compared to average market prices.

- Václav Primus - ŘEZNICTVÍ, s.r.o. (LLC) – the company founded in 1999 runs 7 stores in 7 towns, communicates via website (http://www.potraviny-za-babku.cz/). The discount rates reach up to 70% compared to average market prices.

- Gridexel plus, s.r.o. (LLC) – the retailer founded in 2011 runs 2 stores, one largest, in the capital city of Prague. Its main activity is wholesale. The company communicates via website (http://vyplatise.cz) and Facebook. The discount rates reach up to 30% compared to average market prices.

Merchandise

The merchandise offered in the observed stores is similar to categories of products sold by conventional retailers on the Czech market. The categories are further divided into food and non-food goods. Nevertheless, the amounts and categories of products offered vary on the merchandise these retailers have been able to acquire from their suppliers – conventional retailers and manufacturers. All of the observed stores (100%) offer beverages, diary, tins and packets, and sweets, while none of them (0%) sell fresh fruit and vegetables. This might be given by difficulties of acquiring fresh produce from the suppliers but also demanding and complicated hygiene standards with which the retailers do not comply. On the other hand, frozen food is offered in 95% of the sample and often includes frozen vegetables, as well as frozen meat and poultry. Meat and poultry as a separate category are offered by 70% of the stores, while bread and bakery is present in 57% of the stores.

In general, less than a half of stores offer products in the non-food section. Only 40% of the stores offer products such as diapers and baby care, toilet paper, washing powders, cleaning products, and pet food. Body care and cosmetic products are offered by 22% of the stores and only 5% of the shops provide dental hygiene products. These products are mostly acquired by the retailers from manufacturers due to production changes, faults in labelling or returns by conventional retailers.

Prices

The discount rates in most of the observed stores (95%) reach the level of 50% up to 70% compared to average market prices in conventional retail stores. In only 2 stores (5%) the discount rates are at 30% level or lower. Discount rates are also dependent on the amount of goods retailers are offering and their expiration date or shelf life.

Average spending per shopper per visit on a regular basket of goods is up to 4 EUR in 57% of stores and more than 4 EUR in 43% of the stores in the sample.

Store layout

Average store size, meaning shopping area, in most stores varies from less than $50m^2$ up to $200m^2$ with an exception of the largest store in Prague counting more than $200m^2$. Most of the stores contain facilities such as storage and cooling storage and some of them even have freezer storage available in order to keep a larger amount of goods for longer period without the need for frequent restocking and order of goods.

Employees

In 93% of the stores, less than 5 staff members per store are employed. The maximum number of employees is up to 10 people. This is given by the small size of the stores and lower complexity of their management in comparison with conventional supermarkets and hypermarkets. Also, none of the stores recruit volunteers as it is often the case in social supermarkets or non-profit organisations. On their websites and on in-store displays, the companies present their job offers for positions of shop assistants and store managers for full-time and part-time employment contracts.

Location

An interesting factor is that locations of stores of the individual retailers do not overlap, with the exception of Prague where 7 stores of 2 retailers are located. Therefore, the retail chains do not represent direct competition to each other, at least from the geographical perspective which allows them to engage their position and gain return customers within their area of influence. As a matter of fact, in most cases these stores are not even located near conventional retail stores to avoid local competition. As for store

location within towns and cities, 60% of the stores are located in city centres allowing them to provide higher convenience and attract more shoppers.

Conclusion

Social enterprises as part of the so-called third sector address social issues and come up with innovative sustainable business models resolving various socio-economic issues to benefit the society. One of the major global issues such as food waste in relation to food surplus is also fertile ground for emergence of new innovative solutions where social enterprises play a role. So far, the academic sphere has rarely focused on social initiatives in retailing but in the recent years this trend has been changing. One of the initiatives addressing food waste and individuals in need is a concept of social supermarkets as defined by e.g. Holweg et al. (2010a).

Due to historical circumstances of socialist regime, without basis in legal environment and low level of public support, social entrepreneurship in the Czech Republic has to emerge from bottom-up and develop through prodigiously innovative approaches inspiring itself by initiatives from abroad. The main aim of this study was to analyse the up-to-date situation in social retailing and discover whether and in what form social retailers exist in the Czech Republic.

The outcomes of this empirical study show that a certain form of retail entities providing discounted food and non-food products to members of lower social class and thus helping reduce food waste and increase social status of citizens in need is present on the Czech retail market. It is represented by a specific type of small retail stores selling discounted food and other products nearing the end of expiration date or shelf life to all members of the public. As it has been proven by the authors in their previous research of identifying three factors that most affect consumers while shopping food, the most important factor for the vast majority of Czech consumers is price (Asmalovskij and Sadílek, 2016b). Therefore, even though such concept attracts mostly members of lower social class, the group of individuals shopping in these retail stores is rather large and not limited by any commercial, legal or other factor. Also, the observed retail chains are not non-profit or voluntary organisations. On the contrary they exist mostly in the form of for-profit entities such as limited liability companies. As for type of employment and labour, they provide common full-time and part-time employment to the wide public without narrowing down their interest to social minorities or groups of people in need like e.g. the long-term unemployed. Another factor is the way of acquiring goods from their suppliers – according to the information presented on retailers' websites, the selected stores do not receive goods for free like most concepts of social supermarkets, but they buy out products from conventional retailers and manufacturers which those would otherwise dispose of due to quality faults of the goods, labelling, or nearing expiration date. Therefore, these goods are bought by retailers for discounted prices and subsequently sold at significantly lower prices in comparison with the average market prices with discount rates reaching 70%.

Summarising the aforementioned information, the authors came to conclusion that these stores cannot be considered social supermarkets such as those in Austria or Croatia according to definitions of Holweg et al. (2010a) and Klindzic et al. (2016). Nevertheless, these stores can rather be considered the so-called super discount stores as described by Caroli (Caroli and Gautie, 2008) or Oh and Kim (Oh and Kim, 2003). One way or another, these super discount stores present on the Czech market, functioning on a different model than SSMs, play an important role in reducing food waste and aiding certain citizen groups to obtain goods of basic need.

In conclusion, it is possible to discuss the reasons of such development in the Czech Republic. The findings of this empirical study will serve as ground for further research in this field of the Czech retail market. The next step of the research will focus on comparison of such retail models in Austria and Czech Republic as well as other selected European countries. The outcomes will then be used in order to select

the best and most efficient practices in retailing dealing with food waste and people living in or at risk of poverty, which is meant to be the main contribution of the authors.

Abstract

The article deals with the problem of defining business model. The classification of various approaches to defining business model in terms of its sustainability management capability is given. The advantage of stakeholder approach is justified. The article also provides requirements of stability imposed on a business model in order to turn it into a management tool. Implied application of a business model is proved to be the key to sustainability management capacities of an organization. The matrix of possible implied applications of a sustainable business model has been developed. Various aspects of sustainability (including static, dynamic and structural sustainability) have been identified.

Keywords: business model, management system, sustainability of a business model, types of economic system, enterprise, stakeholders, strategy.

Foreword

Nowadays circumstances, which management is conducted in, are rapidly changing. Economic globalization, crisis phenomena, social and ecological problems demand reconsideration of management concepts. One of the directions management is now being developed in is strongly connected to various aspects of sustainable growth.

The problem of sustainable growth has recently become essential for the humanity itself. Solving it is the matter of saving our civilization, natural ecosystems, the stability of political and economic systems, preserving animal and plant species, preventing climate change etc. The problem of sustainable growth is the one of considerable interest to researchers in numerous scientific fields. Searching for models that ensure the sustainability of a system within predetermined time, space and other limits is aimed at reducing management expenses.

As far as the article is concerned, the advancement of the management system of an organization is regarded as choosing such a models that is more likely to ensure the organization's survival and development over the long period of time (Bezrukih, Medvedev, Ryabova, 2015, p. 123). It is essential for the goal of the research to look into conceptual basis of a business model and its significance for management system; identify the difference between a strategy and a business model; characterize the term "sustainability"; identify the approaches to estimating the sustainability of a business model.

The hypotheses of the research is that business model, not the economic entity serves as the object of strategic management. We believe it to be the case, for the sustainability of an organization itself will ultimately reduce it to stagnation and destruction, whereas sustainable business model guarantees its resistance to sinking within predetermined time and space limits.

Being an administrative and development management tool, business models are of interest, for the successful ones can be replicated and transferred into different fields of business (Bezrukih, Medvedev, Chuvayeva, 2015, p. 529). According to the view of some authors, "more than ninety per cent of all innovative business models are nothing but a combination of existing ideas and concepts borrowed from other spheres" (Gassmann, Frankenberger, Csik, 2014, c. 9). However, we are inclined to consider it impossible to adapt borrowed business models, integrate them into an existing

management system and, what is more, create a brand new business model without conducting an in-depth theoretical research on the matter.

Regarding the evaluation of successfulness of a business model, more emphasis is generally put on brand new business model, for "innovative business model tends to have more potential for becoming successful rather than innovative product or process" (Gassmann, Frankenberger, Csik, 2014, p. 17). Yet, how do we assess an existing business model? What criteria do we use? What is more, how can this tool be used so as to expand the development potential of traditional industries with buoyant demand? Searching for answers to these question ultimately leads to analyzing conceptual framework and especially how the terms "business model", "management system", "strategy" and the correspondence between them.

Modern organizations can no longer be considered in static. Management systems are constantly developing; so do its aims and strategies. Strategy is a long-term identified vector of development of an organization. That is to say, strategy is a vector of development that was chosen either freely, based on strategic targets and the vision of the responsible executives, or forcedly, based on competitive pressure, which is understood as influence of Porter's Five Forces, taking into account macroeconomic factors and stakeholders' interests (Medvedev, Bezrukih, 2015).

Business model is a business mechanism, which is less dynamic than a strategy, part of management system, and the base that the strategy is implemented on. According to one of the researches, "business model is a way that a company chooses to create value for its clients and to get profit from it" (Soolyatte, 2010, p 11). Other researchers (Morris, Schindehutte, Allen, 2005) put emphasis on the fact that business model is able to stimulate conceptualization of a company as an interdependent system of separate strategic choices and to search for interconnections between elements with the help of unique combinations. What is more, these strategic choices include both those that "made on purpose and on default" (Morris, Schindehutte, Allen, 2005, p. 733).

Unlike a strategy, business model is not necessarily unique; it is a miniature maquette of business that can be represented with different degree of formality and accuracy. Thus, there are process oriented models, sustainable management models, perfection models (Chugumbaev, 2016, p. 60), and their purpose varies accordingly. Coherence between management system, strategy and business model in terms of demand for sustainability can be defined the following way: any strategy, even the most risky one, the one that is able to unbalance the system should be counterbalanced by a business model so as to ensure organization's manageability.

On Methodology of Analysis of Business Model's Sustainability

According to basic classification of economic systems suggested by G. Kleyner, "the characteristics of a system should reflect particular qualities of its natural limits in space and time" (Kleiner, 2010, p. 9). Defining a manufacturing plant as a system of class S4 with clearly defined space limits while being unlimited in time, the author emphasizes that in absence of time limits those object systems tend to be economically passive (are willing to preserve a status quo in time), yet actively make use of space (Kleiner, 2010, p.11). We believe that business model reflects those particular elements of management system that remain stable over a long, not limited in advance period of time (until considerable environmental disturbance). Since "real economic systems generally tend to possess qualities of all four types S1, S2, S3, S4" (Kleiner, 2010, p. 13), the author admits that there are hybrid systems. Therefore, business model can be a maquette not only of an object system – of an organization – but of environmental, process, project systems, which can be corporate culture, manufacturing process, innovations.

It is the position of the designer of a business model that plays an important role. The founder world consider the organization a project, consultants and shareholders – an object, production managers – a process, top managers and specialist – an environmental system. That is why choosing the designer of a model is the key question in terms of ensuring its effectiveness as a tool. It is preferable to choose someone from the outside – business consultant or a consulting company – so as to design an

object business model, which is the basic type for manufacturing plant. If “an object is an object system, than subject should have characteristics of a project system” (Kleiner, 2010, p. 44). In actual practice, a process type system – manufacturing subsystem of an organization – generally becomes an object for design. In this case a specialist in the area or a department can be the designer.

Considering the sustainability of an organization, we think it is reasonable to consider “sustainability” as a “variable” product of an object system (Kleiner, 2010, p.20). Being at the same time dependent on perception, knowledge and time limits of the evaluation, sustainability makes us approach defining a subject and limits of a model more deliberately.

In our opinion, the understanding of a business model as the apprehended and conscious part of the control system serving as the instrument of achievement of goals of management is the most adequate regarding the research aims. Since the purpose is always limited “timed”, the substantial change in the next management cycle has to be followed by the change of a business model. The cause for additional interest towards the problem of sustainability of a business model is determined by the fact that the object system has to change smoothly, in dialectic opposition to flexibility and stability.

Thus, the appeal to classification of economic systems allows to draw a number of practical conclusions:

1) approaches to understanding of a business model differ both on a typology of the modelled systems and on the degree of involvement in development of various management subsystems;

2) the aspiration to stability is the "built-in" purpose of object systems;

3) the management system of an organization as an object is adequate to its goal if it supports the manufacturing of new products, reproduction of resources and conditions of activity;

4) smooth change of a business model is coordinated with the requirement of stability of an object system;

5) organization modeling as an object system demands involvement of an “outside onlooker”.

The problem of maintenance of raw materials base motivates the enterprises of the nature operating branches to consider an organization as environmental system, to introduce the concept of corporate social responsibility, etc. Lag from other competitors demands considering the organization in process aspect. Signals of the future essential change of the environment (macrofactors, structure of branch) have to initiate project management. Considering such organizations as systems of hybrid type increases the practical importance of development of business models and allows to expect direct recoil from their use in management.

Conceptual Approaches to Understanding a Business Model

The polysemy of understanding of the nature of a business model in Russian is most fully presented in the work of Strekalova (2009). Agreeing with the author regarding the six approaches to the interpretation of a concept of a business model, within this work, we considered it possible to point out two more approaches: the stakeholder approach and the information approach. The characteristics of approaches given below not only reflects the contents of each of them, but also represents the perception of the modelled system and the characteristics of its stability.

Economic approach represents a business model in terms of formation and use of profit, considering the organization in a process key. Assessment of stability is carried out in the form of the analysis of financial and/or economic stability, and its long-term aspect is implemented in the investment analysis. Market and macrofactors are not involved into the process of sustainability assessment.

Since this approach can easily be used as a tool, the majority of all assessment approaches correspond with it.

Operational approach is implemented in the form of the description of business processes. The coordinated among themselves, effective, not demanding further rationalization business processes form perception of a business model as stable in the current determined timescale (it is realized in Bezrukih, Medvedev, Alashkevich, Mohirev (2015)). This approach corresponds with the definition given by Harvard business school: "the business model is a set of the defining business solutions, and also concessions and compromises involved into generating profit" (Sahlman, Stevenson, Roberts, Bhide, 1999).

Strategic approach forms a business model in categories of market positioning with identification of interests of stakeholders, considering the organization as environmental and/or object system. The description of a business model does not give in to strict formalization, however there is time factor in the form of division briefly and long-term tendencies, interests. Sustainability of the model presented thus can be estimated in the expert way; significant elements of a business model act as units of assessment.

The integrating approach offered in Morris, Schindehutte, Allen (2005) and presented to Strekalova (2009, p. 98), defines a business model as the description of the mechanism of creation and maintenance of steady competitive advantage. Let's note that the requirement of sustainability is put in a concept of a business model, and in the description six components of model are allocated, each of which ideally can undergo sustainability monitoring. Morris, Schindehutte, Allen (2005, p. 730) distinguish from model components offer factors, market factors, internal opportunities, factors of competitive strategy, economic factors and factors of intentions. Authors represent the last component as follows "the integrated business model has to cover the businessman's time, scale and the size of ambitions" (Morris, Schindehutte, Allen, 2005, p. 730). The component is interpreted as investment model of firm and offered the list of variants: model of survival/existence (subsistence). income model, growth model, speculative model (Morris, Schindehutte, Allen, 2005, p. 730). As in model the owner's purposes are considered, system perception of the organization corresponds to both object type, and project type.

Structural approach considers business system elements in their interrelation and allows to estimate organizational and administrative sustainability of business if necessary. Prospects of this approach in line with this research are connected with the fact that such description of a business model allows to denote the replicated secret of sustainability of the enterprises of industry. The emphasis of attention on "design" of components (Mayo, Brown, 1999) allows to define perception of system as object, however also possible the environmental type of system. As in some works structural approach is treated in a broader sense is possible, the business model also includes network of interaction with stakeholders. In this work we allocate stakeholders approach as independent which along with communication aspect reflects also target aspect of interaction with stakeholders.

Imperfection of the structural approach (understood in narrow sense) is in the exception of consideration of interactions with the external environment. This restriction is overcome within the system approach, based on methodology of open systems.

Inclusion in investigation the external factors complicates a business model. At the same time dynamic sustainability is distinguished as a separate element of model, and continuous changes in the external environment predetermine adjustment and replacement of a business model. Sustainability is understood as ability "to keep the competitive advantage" (Afuah, Tucci, 2003, p. 70-71), the choice or a combination of three strategy is offered: "defend", "run away", "unite".

Other authors emphasize the cognitive importance of creation of a business model in commercialization of technologies and prove need of its change if "opportunities … technologies are not combined with the current business model of firm" (Chesbrough, Rosenbloom, 2002, p. 5). Thus, the steady business model is the model capable to the operated transformation after change of an external environment.

System approach combines environmental type and object type of the organization, allows to consider sustainability of the company in the environment. The matrix of system characteristics of a business model presented in (Strekalova, 2009, p. 101), allows to project system of indicators of assessment of a management system, including sustainability indicators, with emphasis on competitive sustainability. Indicators of competitiveness can be used to describe stability (Melnikova, 2010, p. 274), but do not exhaust its content.

Information approach considers a business model as set of information models of the company. It is offered (Melnikova, Hanagyan, 2012, p. 387) to allocate goal-setting model (includes a mission, the purposes, competitive advantages), organizational model (distribution of powers and responsibility), functional and technological model, resource model, process model and model of structure of data (the description of regulations of the company and objects of an external environment). The central place is allocated to a process model which reflects a chain of creation of value (Melnikova, Hanagyan, 2012, p. 387). Sustainability of a business model at high extent of formalization of its structure can be estimated by means of quality indicators of coherence of its separate components or indicators of stability of separate components of a business model. Can be projected of separate quantitative indicators, such as standard stock rate, a reserve of production capacities (Bezrukih, Medvedev, Alashkevich, Mohirev, 2015, p. 25). The central place is allocated to goal-setting model, estimated indicators are offered, allocation of three levels of management decisions (functional model) is proved (Aksenovskaya, Boos, Vaisman et al., 2010, p. 152).

Stakeholder approach to business simulation is directly connected with long-term sustainability of the company. The balance of interests of stakeholders, and subject of the analysis – features of interaction, efficiency and ways of communications with stakeholders can become a starting element of creation of a business model. The steady business model within stakeholder approach is such, in our opinion, way of business which minimizes contradictions of interests of stakeholders, and also the financial and non-financial purposes of the company. In case of the conflict the business model has to allow to make such choice which effectively would balance briefly and long-term goals of the company with interests of interested parties, minimized reputation risks and expanded the business horizons. Sustainability of a business model is provided thanks to creation of the divided value (M. Porter and M. Kreymer) that "increases competitiveness of the company, at the same time improving economic and social conditions of communities in which it conducts the activity" (Porter, Kramer, 2011, p. 66).

Generalizing told, we counted expedient to correlate approaches to definition of a business model and a typology of economic systems, having revealed the considered types of sustainability (Table 1).

Table 1: Comparative characteristic of approaches to determination of essence of a business model

Approach to definition of a business model	Type of the modelled economic system	The considered sustainability types
Economic	Process	Financial sustainability, economic sustainability
Operational	Process, design	Sustainability of technology, separate business processes, reliability of information systems, resource sustainability
Strategic	Environmental (external environment), object	Market sustainability; sustainability of interaction with stakeholders
Integrating	Object, design	Competitive stability
Structural	Environmental (internal environment), object	Organizational and administrative and communication sustainability

System	Environmental (in general), object	Sustainability of situation in the external environment, including competitive sustainability
Information	Object	Sustainability of each component of model as lack of a mismatch
Stakeholder	Environmental (in general)	Sustainable development

Conclusion, presented in the Table 1 can become a starting point of studying of sustainability of a business model. Depending on the revealed problem (or research objectives) the adequate approach to modeling is chosen. This allowes to bare relationships of cause and effect without excessive expenses and to carry out due administrative actions. Representation of approaches "from simple to difficult" to some extent explains attention of scientists and practicians to economic and operational models, a research of financial, economic, resource sustainability. However even more often there is a need for creation of more labor-intensive and difficult models, for a research of all aspects of sustainable development.

Despite limitation of use, prospects of stakeholder approach are connected, in our opinion, with the next moments:

1) approach assumes division into economic, social and ecological sustainability;

2) concordance with the concept of sustainable development (UN);

3) presence of adequate information of a research, including for carrying out the comparative analysis on the basis of reports of sustainable development;

4) management of sustainability is integrated into system of corporate social responsibility and a control system in general;

5) despite prevalence of not quantitative methods of the analysis, this approach allows to give a cost assessment of interaction with stakeholders.

The principle of assessment of benefits of stakeholders from interaction (Yefimova, 2013, p. 47) based on the analysys of added value distribution allows to gain primary impression about scale and structure of financial streams, about influence of the company on economic situation of stakeholders.

Non-financial reports as sources of information have considerable, in our opinion, advantage of comparability, are formed on the basis of the Guide to the reporting in the field of sustainable development of GRI, the Social charter of the Russian business, and also standards of interaction with interested parties of AA 1000SES and AA 1000AS. In our opinion, the choice of the standard of the reporting has to depend on branch of industry, problems of sustainability that are solved and extent of integration of management of sustainability into a business model of the company.

The review which showed the general growth of the companies forming reports of sustainable development, fix the termination of providing the report by the separate companies (Alenicheva et al., 2015, p. 92), included in a research. We see in this fact not only the strong-willed act of the management, but also signs of not inclusiveness of management of sustainability in a business model of the organizations, perhaps, decrease in efficiency of primary activity. The relation to the reporting of sustainable development as to the project, without inclusion in a business model – a striking example of pendular decisions.

Summing up the results, we will note that the business model as the instrument of management, irrespective of conceptual approach to its representation, has to meet the following requirements (Table 2):

1) possibility of the formalized description, including graphic;

2) existence of internal structure, orderliness of elements of model;

3) comparability with models of other organizations at least within branch, ideally – in intercountries and interindustry scale;

4) instrument of competitiveness , possibility of determination of advantages, obvious to managers, but unevident for competitors;

5) multifunctionality of model predetermining a possibility of its use in realization of each of functions of management (planning – organization – motivation – control - coordination);

6) measurability, presence of quantitative parameters of model that gives additional opportunities for comparison of models;

Table 2: Extent of realization of requirements to a business model

Approaches to definition of a business model	Requirements to a business model					
	Forma-lized	Structu-ring	Compa-rability	Instru-ment	Multi-functio-nality	Measura-bility
Economic	*	*	*		*	**
Operational	**	**	*		*	*
Strategic	*		*	**		*
Integrating	*	*	*	*		*
Structural	**	**			*	
System	*	*	*	*	*	*
Information	**	**	*	*	*	
Stakeholder	*	*	**	*	*	*

As shown in the table, only two approaches meet all requirements: system approach and stakeholder approach. The business models developed on their basis can be considered as instruments of effective management of the organization.

About Assessment of Sustainability of a Business Model

Logic of development of open social and economic systems such is: chaos and an order – two regularly replacing each other states. Chaos as stability loss inevitably leads to an order – its finding. It is impossible to resist development dialectics, however the steady business model in a bifurcation point (a decision-making point) will allow without additional managerial influences, in an operating mode to keep sustainability of system provided that deviations of conditions of the environment, or fluctuations, do not go beyond admissible significances. Successful numerous passing of such points of the choice allows to note that the company has an adequate business model, and the management managed to avoid notorious "manual control".

The organization cannot but be considered as the system having the following properties: openness, purposiveness, humanism. The organization as open system is more subject to influence of weak signals, and therefore in its model also has to be put sensitivity to weak signals for the purpose of the subsequent adaptation to essential indignations in the external environment . Weak signals by Ansoff's definition are "indistinct early indications of the forthcoming important events" (Ansoff, 1975).

Sustainability of the organization in the unstable external environment can be considered as attribute of system and as reaction to external instability (Melnikova, 2009, p. 195). Absolutely steady system has no attribute of adaptability, does not provide ability to development. The aspiration to sustainability can be realized at the level of perception of system, that is to say concerning a business model. The condition of insustainability of economic entity is inevitable, moreover, on the basis of the research of life cycle, it is possible to forecast not only an unsustainability position, but also its reasons, typical for this stage of life cycle. According to V. A. Lubkov, at different stages occur "an activation of various components of a business model" (Lubkov, 2013, p. 48). The applied research objective has to consist in search of the mechanism of creation of a steady business model and its regular updating.

According to I. Prigozhin, "during the initial period … instability is localized in a small part of system, then extends" (Prigozhin, 1991). The task which can be solved by means of a business model consists in timely recognition of a source of instability, decision-making for its elimination or inclusion in strategy. Diagnostics has to be performed by means of the indicators which are built in a business model and procedures of tracking of weak and strong signals as instability sources.

The choice in a point of bifurcation is more complex problem which is solved by means of subsystems of management of knowledge and innovations. Their allocation as a part of a business model and in the real organization allows to eliminate delay of process of accumulation of information and knowledge about fluctuations of the environment in comparison with real processes. This element of a business model is represented to us critical in preservation of long-term sustainability as only a learning organization is capable to distinguish systematically new opportunities in the revolting influences, to refuse the existing competitive advantages in favor of new, to redesign a business model, acting in the conditions of the lack of information. Thus the requirement of flexibility of a business model is implemented. Than the flexibility is higher, than the more simply and cheap to change this business model, than more changes go on the way of "thin tuning" – imperceptibly for competitors and ordinary employees.

So, the methodology of management of sustainable development of the company has to include assessment procedure of stability of a business model and its adjustment if necessary. The business model is steady if it allows with sufficient efficiency to react to changes of the environment, compensating negative consequences of these changes and keeping a condition of key parameters of model in the set range.

Depending on the used approach to the description of a business model, extent of its formalization, the available information base and type of the modelled economic system, significantly differ the directions and ways of assessment of its sustainability . In what measure each of approaches provides a capability of business model concerning management of long-term sustainability? In a descriptive key the answer to this question consists in assessment of compliance of the purposes, procedures and results of development of model within this or that concept to business model sustainability conditions. In a constructive key the decision is connected with differentiation of definitions "a steady business model" and "management of sustainability of the organization on the basis of a business model", and in the latter case is of importance the type of the reached sustainability of the organization.

The list of conditions with which the steady business model has to satisfy is created by logic of this research and includes:

1) Measurability, existence of quantitative indicators of sustainability;

2) Complexity, possibility of the accounting of all aspects of sustainability (economic, social, ecological);

3) Aiming at sustainable development, built-in need of the accounting of social and ecological aspects of sustainability;

4) Strategic, internal orientation on long-term development;

5) Comparability, including with the best practicians in branch and/or with the best practicians outside branch, in the country and the world;

6) Flexibility, ability to effectively change key parameters of a business model without decrease in volumes of activity;

7) Sensitivity in relation to "weak signals" of the external environment.

Assessment of degree of compliance to these requirements of various "models" of the organizations is given in Table 3.

Table 3: Compliance of approaches to sustainability conditions of a business model

Approaches to definition of a business model	Business model sustainability conditions							
	Measurability	Complexity	Aiming at sustainable development	Strategic	Comparability		Flexibility	Sensitivity
					in branch	in the country and the world		
Economic	+	–	–	–	±	±	–	-
Operational	–	–	–	–	+	–	±	-
Strategic	+	–	–	+	+	+	±	-
Integrating	+	+	±**	+	+	+	+	±
Structural	–	+	–	–	+	–	+	-
System	+	+	–	+	+	+	+	±
Information	+	+	-	-	+	-	±	-
Stakeholder	+	+	+	+	+	+	+	+

* in narrow sense
** compliance to the requirement only for the enterprises of those branches where the problem of negative outer effects in social and ecological spheres is particularly acute especially

Thus, it is possible to draw a conclusion about opportunities of the corresponding models in ensuring sustainability of the organization and to formulate a number of research problems: ensuring measurability and comparability of business models, formation of the built-in target orientation to sustainable development in the long-term period, coordination of the economic, social and ecological targets, at last, a problem of adaptability of model as instrument of management. Each of problems is cross-disciplinary and demands separate review.

On Target Reference Points of Sustainability Management

In works of a number of foreign researchers it is rather obviously possible to observe evolution of views from sustainability as the purposes (result) of a research of other problems prior to a research of management of sustainability. So, Peter Johansson (Johansson, 2007, p. 4) sets as the purpose to formulate the management model maintaining both sustainability of the organization, and global stability, realizing it by means of instruments of quality management. In later work, in a co-authorship, he considers the stakeholder theory of management of sustainability (Garvarea, Johansson, 2010), noting that organizational sustainability can be reached, meeting requirements of interested parties. The founder of the theory of stakeholders Edward Freeman, having offered

stakeholder's model of firm (Freeman, 1984), showed influence of management of interested parties on survival of the organization (Freeman, Harrison, Wicks, 2007). The idea of influence of stakeholders on sustainability, is developed in (Savage, Nix, Whitehead, Blair, 1991), including applied aspect.

Development of logic of the real research demands differentiation of the concepts "steady business model" and "management of sustainability of the organization on the basis of a business model", thereby we bring up a question of subjectivity and type of system again. Let's use classification of types of economic systems (Kleiner, 2010). The business model is the system of project type, replicated, limited in time and space. The organization, depending on the used approach can be considered as system of any of 4 types, or as system of hybrid type that extremely complicates its modeling.

The business model is created for the solution of a specific administrative problem, and if that is connected with sustainability, there is a natural question: about what sustainability there is a speech? The steady business model to some extent is "mirror" of the organization striving for sustainability. The model sustainability conditions given above are necessary for adequacy of this tool in order that "the mirror was not curve". For what sustainability the subject of management strives?

The fullest classification of types of sustainability of the enterprise is presented in (Grigoryan, 2015), however concerning a business model similar systematization is absent. The theoretical platform of the analysis of sustainability of system has, in our opinion, cross-disciplinary character and in the most general view assumes allocation of static and dynamic sustainability. Static sustainability assumes consideration of system as closed and reflects: a) a keeping of properties of system of rather certain ideal (sustainability of a state - SS1) and b) a keeping of the communications of system defining its uniqueness and viability (structural sustainability - SS2). Using the characteristic "by contradiction" (vice versa), we specify: statically unsustainability system has the current indicators of activity significantly better or worse planned (an unstable state) or uses other business model, there was its change control or not. Ability of a business model to adaptation will be coordinated with research objectives, and therefore the question of a measure of structural sustainability remains open.

The organizations as open systems, being in interaction with an environment, change the purposes, structure, communications, and therefore dynamically steady organization is the adaptive organization, viable in a long period. The dynamic sustainability (DS) of a business model reflects ability to keep integrity of the organization in the conditions of its constant evolution. The target reference points concerning sustainability realized within this or that approach to modeling taking into account type of the modelled system are presented in Table 4.

Table 4: Target reference points (intentions) concerning sustainability of a business model

Approaches to definition of a business model	**Type of the modelled economic system**			
	process	**project**	**object**	**environment**
Economic	SS1			
Operational	SS1, SS2	SS1		
Strategic		SS1, SS2	SS2	
Integrating		SS2, SS1	DS, SS2	
Information			SS2, DS, SS1	
Structural			SS2, DS	DS, SS1
System			SS2, DS	DS
Stakeholder				DS, SS2, SS1
SS1 - sustainability of a state (static sustainability), SS2 – structural sustainability, DS - dynamic sustainability				

Data of table reflect possibilities of this or that approach to modeling concerning achievement of the objectives of sustainability. The developer, based on its position relative to the object modelling and the objectives, can choose an adequate approach to creation of a business model, rather simple that the model was apprehended by performers, rather difficult, allowing to consider significant sources of fluctuations.

The sustainability type at which the control system is aimed introduces the accents in a business model. So, if "static approach to assessment of sustainability assumed accent on structural, technological and financial making models, then dynamic approach requires attention to a goal-setting, processes and functions" (Melnikova, Hanagyan, 2012).

Conclusions and suggestions

Theoretical and practical interest in a problem of ensuring sustainability presses for developments of the instruments of improvement of management integrating the economic, social and ecological targets of development of the organization. The problem is, of course, strategic, requiring study in statics and in dynamics.

The study used a systematic research methodology. Organization as primarily object-based, has a "built-in" commitment to sustainability, changes should have a smooth flow. The business model of the enterprise is understood as the accepted and recognized part of the control system, the prototype of the ideal. Finding a good business model allows the organization to maintain sustainability with minimal administrative intervention when fluctuations in the external environment within a certain range. It justifies the thesis that the pursuit of sustainability can be implemented at the level of the business model.

The appeal to a typology of economic systems allowed to systematize the content of eight approaches to understanding of a business model, to define their opportunities regarding management of sustainability. Requirements with which has to satisfy a business model as the instrument of management, and also business model sustainability conditions in relation to each of approaches are formulated.

Opportunities and mechanisms of management of sustainability at the level of a business model, are defined by target orientation of model. Seeking for maximizing profit in the short and medium term, the subject of management creates economic (financial) model of the company which is essentially unsuitable for the solution of problems of competitiveness, environmental problems. In the choice of the purpose and type of model it is impossible to rely only on strategic vision of the owner or head.

In work it is shown that achievement financial, technological, competitive, etc. sustainability as the purposes of development of the organization, so, and creation of a business model, is deprived of sense. In all-managerial context it is important to choose target orientation of business in temporary aspect, taking into account a phase of life cycle and a conditions of the environment. The target type of sustainability, eventually, depends on how the subject of management outlined environment borders. It is offered to consider static sustainability, structural sustainability and dynamic sustainability. Consideration of problems of sustainability in dynamics will influence not only contents and a way of calculation of indicators of sustainability, but also transforms requirements to structure of a business model, the importance of its elements, will change ability to adaptation, and also on a contour of feedback will affect features of a goal-setting and priority of development goals.

Along with a problem of formation of target orientation to sustainable development, further researches can be aimed at providing measurability, comparability and replicability of business models, coordination of the economic, social and ecological targets by the principle of "trinity", providing adaptation opportunities of a business model.

The practical importance of a research is connected with development of a matrix of target reference points of sustainability and systematization of approaches to creation of a business model.

Advantages of stakeholder approach are formulated. Further developments can be conducted in the direction of formation of indicators of sustainability of a business model.

Acknowledgements

The research has been completed with the support of RGNF (grant № 15-12-24003) and KGAU "Krasnoyarsk Regional Foundation of Science and Technology" (project "Developing a management system for enterprises of wood-processing industry in modern conditions").

Abstract

This paper outlines the economic perspective for MAESTRO as both an Ambient Assisting Living (AAL) research and innovation project and as a viable quality assurance service platform. It examines the process of building an effective and sustainable business model and business plan for MAESTRO to address the current and future economic context. The MAESTRO project's objective is to develop an on-line platform that can create and showcase 'confidence, trust and reliability' in the emerging marketplace for monitored and self-monitored devices, systems and services that promote health and wellbeing for older people. With the pace and quantity of new products, services and technologies emerging within the AAL marketplace, it is difficult to source reliable and trustworthy product and service quality information that can underpin selection and procurement decision making. The MAESTRO platform is being developed to address this identified gap and market weakness, and it is being co-designed with solution providers, service commissioners and end users across the value chain, within a set of pilot projects in 4 European territories.

Keywords: Ambient Assisted Living (AAL), Service Platform, Self-monitored devices, Economic model

Introduction

Nowadays, there is a big quantity of new products, services and technologies emerging within the Ambient Assisted Living domain, see the works of Aggoune-Mtalaa et al., (2014) and Aggoune-Mtalaa and Aggoune (2014). However the clues and control references for adequate orientation of the consumer are lacking and the result is a media-supported image of a fantastic potential for follow-up of one's activities and even some vital parameters, but with often no verified nor legitimised and verified less certified criteria (there are exceptions of course), regarding such key dimensions as performance, reliability, user-friendliness, acceptability, potential for delivering medically ascertained data, privacy issues, etc, see the papers of Park et al. (2017) and Mainetti et al. (2016). This confusing and probably in many cases misleading landscape, is problematic for the elderly, often non fully digitally literate and not always in the capacity to know, understand and distinguish the key elements of the underlying promises associated with these technologies. There is therefore at the same time a claim to give access to truly helpful devices for well-being and health-related monitoring capabilities, but most of the time as an emerging market not accompanied by the kind of references and metrics which could establish the basis for an effective user-centered affordance of these new means, see the work of Norgall and Wichert (2013) and the one of Knegel and Auinger (2015).

The aim of MAESTRO project is therefore to deliver a reference framework for a commercially viable platform in the domain of monitored devices to promote health and wellbeing for older people. In the frame of the European Ambient Assisted Living (AAL) programme, MAESTRO project partners who are

either associations helping seniors and their caregivers, enterprises or research and academic institutions are joining their efforts to develop an ICT platform which will address the gaps in the market identified through the consortium research. The final look and feel, functionality and purpose of the MAESTRO platform will be informed by the user requirement interviews, focus groups and particularly by the pilots being conducted in Switzerland, Ireland, Luxembourg and Italy during the project. Based on the analysis of initial programmatic goal, constraint and requirement data, the consortium decided on two inter-dependent and sequential 'go-to-market' value propositions for the MAESTRO platform. It will form as two overarching services into two complimentary 'spaces', a developmental and formal assessment process into the 'professional space' and a curated informal marketplace for the 'consumer space'. This work is presented as follows: the next section is dedicated to strategic considerations. Then the framework dimension and value proposition are presented. The market landscape is described in the next section. The strategic options are then discussed followed by the consideration for preferred scenarios and the options that have to be analyzed to fine tune the go to market strategy. The paper ends with a summary of the scenario analysis conducted so far.

Strategic Considerations

The AAL market is a relatively new one, see the work of Maciaszek et al. (2017), and the MAESTRO platform will be an early development in this space. There are therefore many unknowns at this stage in the process but some of the key strategic questions need to be answered if the consortium wants to reach a successful commercialization of the platform.

Probably the starting question will be what do we see as our core target market - where are the best opportunities for MAESTRO? Is it focused on the smart homes segment, the AAL device market, eHealth? It may be better to develop a sense of a specific market segment where we feel there is a good chance for early success - with a view to moving into differing segments later in the enterprises life-cycle.

What is the value proposition? Is it to build trust and confidence for the consumer in choosing AAL products and services? Is it a developmental process or is it both? At this stage of the process we can see that MAESTRO could be an interdependent platform where a MAESTRO development process develops products for the MAESTRO marketplace registry. This hypothesis requires further detailed analysis. Understanding the value proposition is fundamental and needs careful consideration if MAESTRO has to be commercially successful.

Who are MAESTRO customers i.e. who will use MAESTRO services? Is it buyers of the devices and/or services? Or sellers of systems? Or companies developing services and products? Understanding the customer profile and their motivations is crucial but this question will obviously be shaped depending on the value proposition.

What are the key resources or assets? Is it a hosting platform, an online marketplace, a quality benchmarking site or a process which enables the exchange of intelligence and expertise? This will again depend on the agreed value proposition. This will also have a knock-on effect on how the enterprise will generate revenues; is it through membership fees, transaction fees, hosting or advertising revenue?

Above all, when conducting detailed marketing analysis for the strategic considerations noted above it is vital that the goal is to come up with a value proposition that has a clear point of differentiation or a Unique Selling Proposition (USP) which is easily communicated in order to support the successful launch of MAESTRO. The early stage of market development needs also to be taken into account and should shape a 5-year plan of how the platform could be launched, supported and developed in its early life-cycle.

Framework Dimensions and Value Proposition

There are three key variables when we look at framing the MAESTRO go to market scenarios. These are:

- Those who are selling monitored products or services - push companies.
- Those who are buying monitored products and services - pull organisations.
- Market maturity and readiness - where along the technology and market readiness spectrum does the product/service/system sit?

These variables can be further broken down to their component characteristics.

Those selling monitored products or services (push companies)

We can analyse the sellers of monitored systems and services according to the complexity of the system they are selling - at one end of the axis we have simple or standalone systems e.g. smartwatch and blood pressure monitor, moving on to more complex scenarios e.g smart homes through to fully integrated monitored systems at the opposite end of the axis, see Fig 1.
Each of these types of seller (Push Company) will have specific requirements in order to get to market which will help to define the MAESTRO value proposition from simple benchmarking or marketplace placement through to professional sales consultation and systems integration design.
In terms of market segmentation - sellers (push companies) will also broadly fit into differing market segments i.e. for simple systems it will more than likely be a mass market, consumer segment but for more complex, integrated solutions it will more than likely be a smaller pool of potential customers however these customers will be higher in value.

Those Buying Monitored Products or Services (Pull Organisations)

Similarly we can analyse those buyers of monitored systems and services against the type of buyer/level of expertise required in the buying function. On one end of the axis we have the end user i.e. older person, family member or caregiver buying the system. This moves up the axis to professionals buying or advising a series of systems for different end users e.g. brokers through to the procurement manager of an organisation (either public or private) e.g. the health service at the other end of the axis.
Each type of buyer (pull organisation) will have specific requirements which will again help to define the value proposition. In a simple product/system/service the value proposition could be a trusted presentation of options from a benchmarking portal all the way through to a co-design function to allow for tailored services/devices and support systems.
In terms of market sizing, we can again look at the differing market segmentation - buyers (pull organisations) will also broadly fit into differing market segments i.e. for simple systems it will more than likely be a mass market, consumer segment but for more complex, integrated solutions it will more than likely be a smaller pool of potential buyers who will be higher in value.

Market and Technology Readiness

One of the key variables in this framework in terms of defining where both the sellers and buyers are within the market, is the technology and market readiness of the products, services and systems.

Overlaying technology readiness in terms of whether the products and services are new and emerging or whether they have been launched and possibly nearing maturity will offer another lens to determine what go to market scenarios are best to launch with. For sellers (push companies), there is a massive difference in their potential needs between developing new products to selling mature products and services in this space. For buyers (pull organisations), there is also a difference in their requirements based on the technology/market readiness primarily in terms of the guidance needed in purchasing.
It will be critical when choosing a winning go to market scenario that we fully map these variables to give an overview of what combination(s) offers the biggest commercial opportunity.

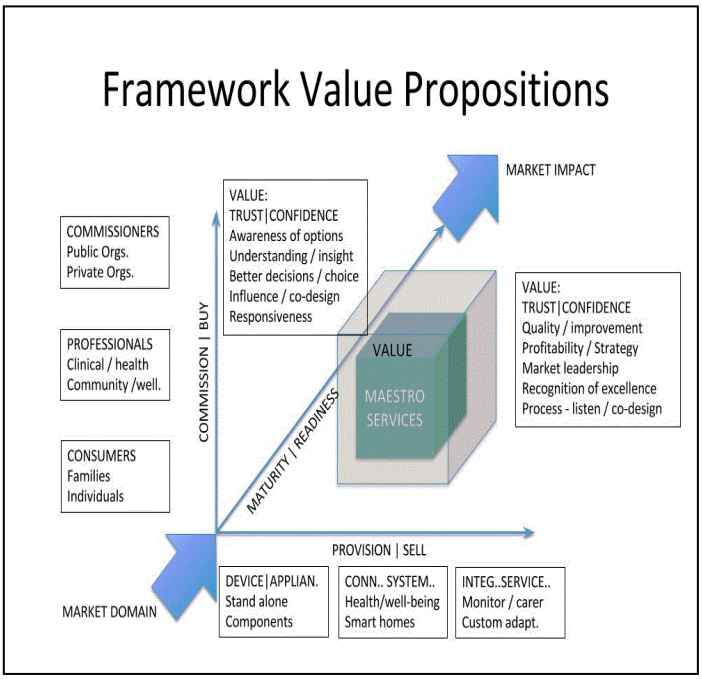

Fig. 1: Framework dimensions

Market landscape

Competitive Environment

There are many online sites offering information and comparisons on a range of smart monitored devices for instance just for fall detectors there is a wide selection of websites offering advice and guidance e.g. www.telecare.ie, www.assistireland.ie, www.medicalalertadvice.com, www.livingmadeeasy.org.uk. For cognitive support www.unforgettable.org and www.alzproducts.com are just two examples. For smart homes there is again many websites offering advice e.g www.pcmags.com, www.cnet.com, www.digitalhomes.ie, www.toptenreview/best home automation service 2017. There is also some consultancy styled websites for more complex systems e.g. www.medtronic.com and www.nhsbenchmarking.nhs.uk.

Even at this early stage, it is both a complex and confusing arena for caregivers and it is quite a competitive arena in which to launch a platform. A strong understanding of the target market, gaps in that market, value proposition and the USPs are all going to be critical when launching MAESTRO.

Gaps and Opportunities

Interviews with both push companies and pull organisations across Ireland, Switzerland, Luxembourg and Italy have all pointed several gaps and opportunities within this environment namely the need for guidance - both for push companies in developing their products and services and for pull organisations in procuring or advising the right solutions for the older people in their care. If we are to start to refine some of the possibilities that MAESTRO could provide commercially, investigating the gaps as perceived by end users will provide very valuable insight. The gaps identified by care providers (pull organisations) thus far are as follows:

- **Trust** - there's a lack of universally understood accreditation, standards or endorsements in websites offering monitored systems, products and services.
- **Online advice** i.e. benchmarking or marketplace with an initial assessment by a professional e.g. occupational therapist, which leads to a presentation of two/three options and their websites (This applies to professional 'pull' organisations as well as to end users).
- **Citizen's advice** element to the site - whereby you can have a tracker to only get options and you could receive financial assistance in procuring.
- **Links to global research** for pull organisations along with **links to feedback** from other users for families or end users in the area you are looking at e.g fall prevention.
-

Gaps identified by push companies looking at developing AAL products and services include:

- **Access to market research** reports initially e.g. specific Gartner styled reports to understand what the market potential is for their companies.
- **Networking** - access to other organisations who could help in the development cycle - particularly those in other jurisdictions.
- **Living Lab** - Access to end users for testing and evaluation
- **Advice on legal and ethical** issues particularly on data-sharing
- **Product monitoring and improvement**, or feedback during early post-launch phase.
- **A trusted route to market** - to give them a competitive edge.

Market structure and size

Global market size in dollars

The AAL market is a large and growing global market which is projected to be worth in the region of $60.14 billion by 2020 (this is split into $56.18 billion for smart homes and $3.96 billion for AAL products, systems and services). This represents a growth of 45% and 36% respectively in the five years from 2015, see Maclaszek (2016).

Though much of the growth in this area is anticipated to come from the US, particularly in the early adopter segment, Europe's ageing populations give rise to sizeable opportunities in this arena. Many technology companies who have developed products, services and applications in other arenas e.g. gaming

or fitness are looking at the possibilities offered by an emerging health and wellness enhancement market to support a global ageing population. There is massive potential to both target individuals and the national health systems, private healthcare and health insurance companies who are supporting them.

Stakeholder Analysis

We have already broken the AAL market from a MAESTRO perspective into both developers (push companies) and companies or individuals procuring AAL products and systems (pull organisations) who would find an information sharing site useful.

Using the detailed feedback from the field research carried out by the consortium we can start to look at some of the characteristics of the stakeholders in this market.

a) End users and caregiving 'pull' organisations:

Today, older end users have a tendency to be cautious in embracing technology, this however will change as the penetration of technology increases; it is worth noting that the penetration of smartphones is estimated to increase to 70% of the global population by 2020 as shown in Marketsandmarkets.com (2016).

Currently end users receive guidance from professionals in the area of wellness or health supports (particularly those with a technological aspect) or family who will also seek some assurance from a trusted source before choosing wellness or health supports. A simple benchmarking or marketplace site in this arena is not enough for them - they need guidance in making decisions.

Brokers or professional care-giving organisations see the value that technology offers in supporting older people, especially where there is a lack of government, community or family support - which is often the case. However, in our field research the overarching theme of risk came up. As a broker or professional caregiver they will not advise or recommend something they are not 100% sure of. Also, they need to know if the options are financially feasible i.e. the person can afford them.

Further detailed analysis of the care giving organisations and the end user profile will be required for the business case.

b) Developers or 'push' organisations

The analysis of stakeholders in the domain of developer or push company is complex and will depend on the type of product or service they are developing and the markets they wish to access. Some of the characteristics will be common to all developers however. These include the need to access a network of expertise and most importantly access to end users in testing their solutions. All developers wish to utilise a route to market which gives them a competitive advantage. Ultimately what developers need is the ability to plug a gap in the market with their solution, delivered in a manner which meets their target customers' needs. Our stakeholder analysis needs further development throughout the project in order to complete the business case.

Strategic options

The market framework described in the preceding section which overlays the key variables of product complexity against market and technology readiness, led us to come up with four market scenarios or strategic options for further investigation:

- A development process for new technology to support mass market products and services.
- An online curated/benchmarked marketplace for mass market product and services which will be purchased in a relatively simple transaction.
- A development process for new technology to support niche, high end and more complex products and services.
- An online consultative marketplace for niche high end and potentially more complex integrated systems, which require complex purchasing capability and sales support.

We have added a further layer to this model, shaped by the gaps in the market as identified by the detailed field research across the consortium. This layer addresses the expressed need for guidance and trust by both push companies and pull organisations.

The strategic options which we are now considering are built on those listed above and can be viewed as an interdependent, sequential platform which meets the needs of push companies both developing and selling the right, trusted products and services and pull organisations and end users who want to procure the right, trusted services and products.

This will be described further as MAESTRO development process which feeds the MAESTRO online registry.

Mass Market - Development process and curated marketplace registry

The characteristics of the mass market in this context are that it is driven by the consumer i.e. business to consumer sales [B2C] with a high volume of lower value units.

Mass Market early technology or early market scenario-emphasis on development (consultation, feedback forums, off the shelf research, advice on commercial partnerships, standards etc.) This scenario, as shown in Fig 2. focuses on push companies offering them access to a range of development and testing tools for mass market devices or services.

Mass Market mature technology or early market scenario-emphasis on availability (impartial curation/advice, benchmarking, branding). This scenario focuses on both the push companies and pull organisations, offering push companies a route to market and offering pull organisations or end users an impartial guide (curated comparative or benchmarking) platform where they can feedback user experiences.

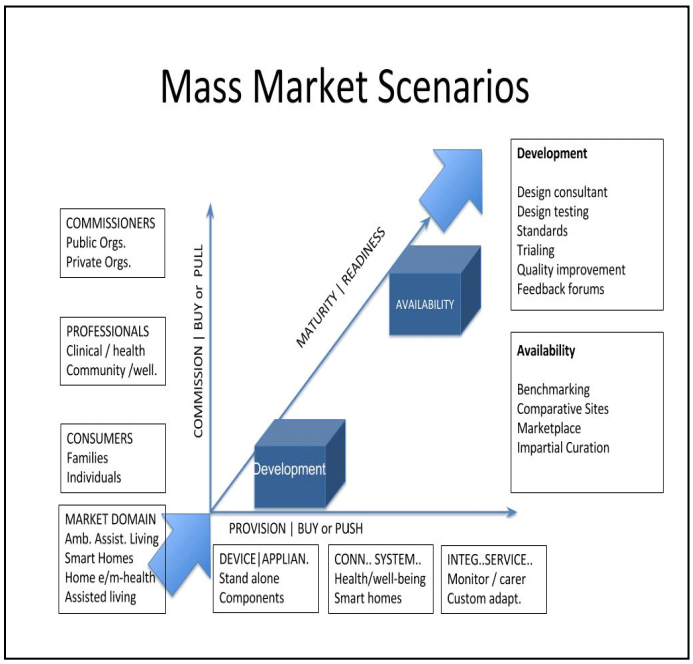

Fig. 2: Mass market scenarios

Niche market, Development process and consultative online sales channel

The niche market characteristics in this context are more business to business (B2B) in nature, developing and selling high value, complex solutions in lower volumes.

Niche high value, early technology or market scenario -emphasis on development (co-design, collaboration, consultation, integrated design and testing). This scenario, illustrated in Fig 3. focuses on push companies as they could use this platform to help develop their complex products and services by engaging expert pan European consultants to aid in design, interoperability, standards etc. Pull organisations may be interested in joining this type of forum to receive information/research analysis and to potentially participate in conferences, testing/trials**.**

Niche high value mature technology or market scenario - emphasis on market availability (complex consultative sales and procurement). This scenario focuses on both push companies and pull organisations as it facilitates a complex sales/purchasing transaction and could offer a range of consultative integration/training services to both**.**

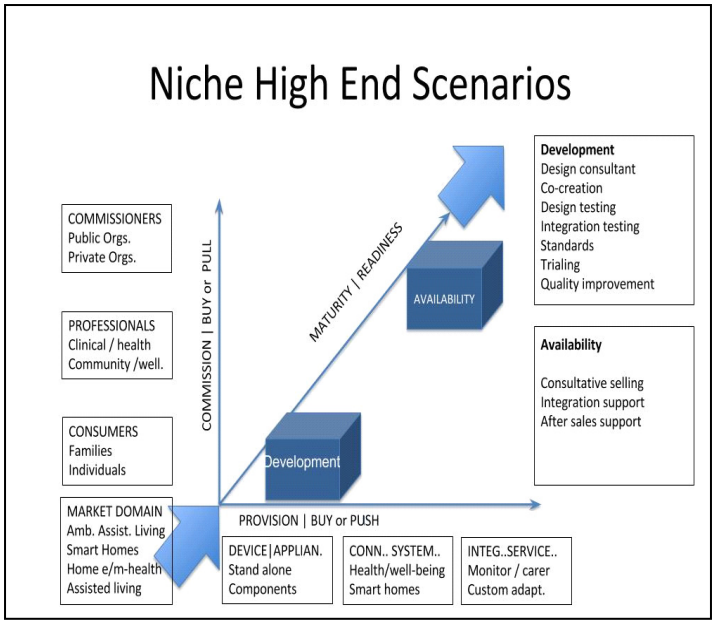

Fig. 3: Niche High End Scenarios

The MAESTRO Development and Formal Assessment Process (B2B)

The model highlighted above for both mass market and niche or high end developments can be further refined by inserting the need to build trust, confidence and reliability in both the mass market and niche product offerings which can be clearly demonstrated to consumers in the attached online registry.

This forum centres on the MAESTRO service delivery platform which is an eco-system for which push companies pay a membership to access. The platform will allow companies to access a network of companies which will help them to develop their products, systems and services to a recognised standard. These companies will encompass pull organisations, third party in various areas of expertise along with complementary companies. The platform will most importantly offer access to end users for testing and evaluation and refinement. The output will be a reliable, trusted product/service which has been tested with end users to deliver a truly useful and competitively superior offering to the customer.

The overview of the generic MAESTRO development and assessment process is set within the process model highlighted in Fig.4.

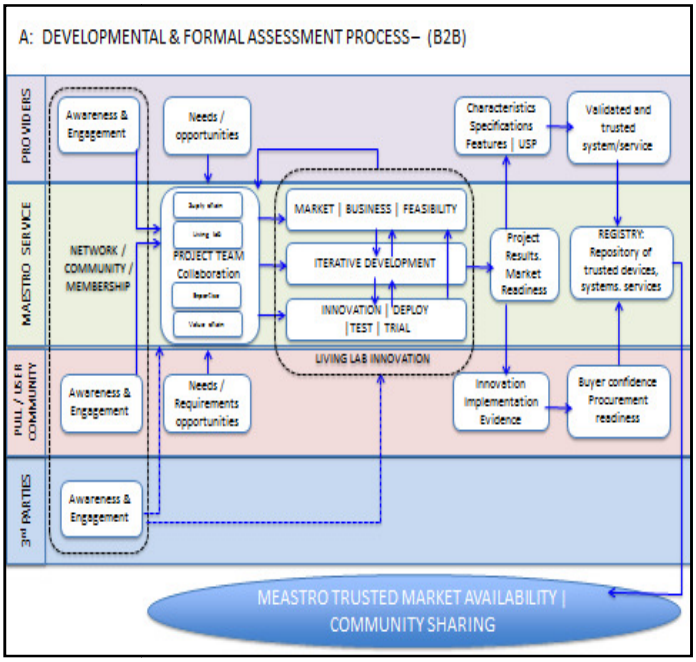

Fig. 4: Development and formal assessment process

The MAESTRO marketplace and informal assessment process (B2C)

The marketplace model as described earlier for both mass market and niche or high end products and services can also be refined based on the gaps or needs that our consortium research has outlined.

The MAESTRO marketplace centres on trust, confidence and guidance. This is achieved in the online registry's front end configuration. The insertion of both a search by condition which would prompt an online assessment questionnaire (which could be developed by healthcare professionals e.g physiotherapists) or a search by monitored system which would again prompt an online assessment questionnaire (again developed by a healthcare professional) was deemed to be very valuable and would install a sense of confidence.

Once completed, the prompt would be to either seek further assessment from a healthcare professional e.g. your doctor (if you fall into a risk category) or else you would be offered a selection of MAESTRO developed or tested products and services - this would satisfy the requirements for a trusted source of product/service.

Further online tools such as access to brokers ('broker' is an emerging role which act as a gateway to recommending and finding AAL technologies that meet a client's needs) in the area you have expressed an interest e.g. online dementia support forums, information on financial guidance to enable the person to access products and services along with an on-line feedback facility would all offer significant guidance, trust and therefore easily communicable USPs in the market.

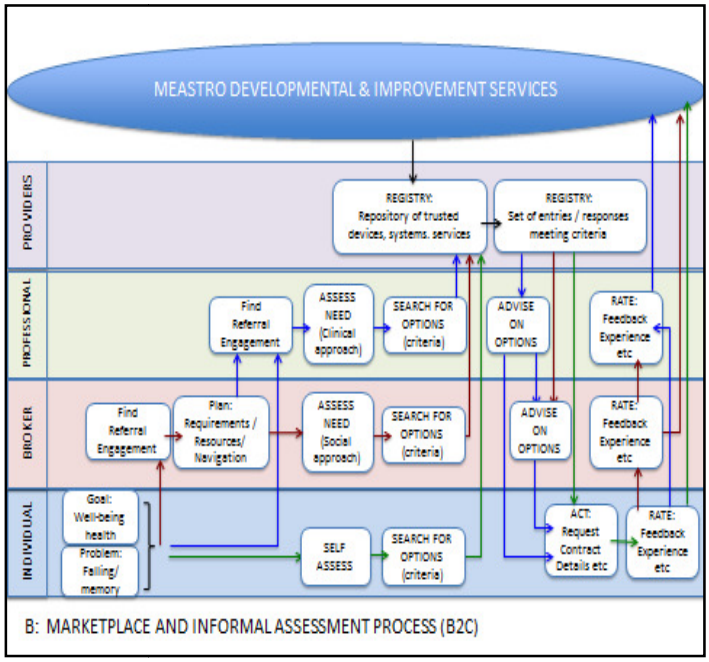

Fig. 5: Marketplace and informal assessment process

To fully evaluate this MAESTRO developmental and formal assessment process and associated marketplace and informal assessment process, we will separate them into their individual categories (mass market development, mass market maturity, high end development and high end maturity) and analyse each separately around opportunities, market entry strategy, development and potential revenue models to be further fully analysed.

Consideration for preferred scenarios

Consortium Readiness to Approach Market

One of the key considerations in deciding which scenario or scenarios is preferred is to see how these scenarios could be brought to market. Is the consortium in a position to launch either or both of the scenarios outlined in this work? Some of the detailed considerations can be investigated in the following sections.

Capacity

What resources are needed to support the launch and to maintain and grow the MAESTRO enterprise? The general organisational needs of the enterprise i.e. administrative staff, sales/marketing and commercial or accounting functions will need to be in place along with software developers and engineers.

The USP of the MAESTRO developmental and formal assessment process is access to a network of relevant, cutting edge companies and consultants and expertise in this field. This could, for the most part, be outsourced but would require a central function to maintain and grow this eco-system. The USP of the MAESTRO marketplace and informal assessment process would be the assessment tool, potentially access

to real healthcare or wellness professionals along with a database of services, products and special interest forums. These functions could again be outsourced but would require management within the MAESTRO enterprise. The capacity required to launch and support MAESTRO should be viewed in a 1-5 year plan as the model will need to be scalable.

Willingness to invest in enterprise

Are there any partners within the consortium who would be in a position to invest in the enterprise? Can the partners identify other commercial entities that may be willing to invest in the MAESTRO platform either as a Joint Venture or as a separate entity?

Market readiness

There is no doubt that the AAL market, particularly the smart homes segment represents huge growth opportunities for the companies developing products, systems and services in this space. This is a new market and as such exhibits all the characteristics of new market i.e. early adopter leads, niche player proliferation and confusion in the mass market. Some of the opportunities however lie in the fact this is an early market environment as developers see huge potential but need guidance, likewise, the companies procuring AAL devices need a lot of support in their decision making. Therefore, whilst the market is in its infancy, it represents the most potential for MAESTRO.

The suggested go to market scenario of a MAESTRO developmental process which feeds to a MAESTRO marketplace would fit with the general market development or readiness as the marketplace or registry, by its nature, would come later in the life-cycle of the enterprise.

Costs

A detailed analysis of potential costs associated with launching both or either go to market scenarios identified in this document will be provided in the business plan. Costs will broadly encompass internal organisational costs, third party expertise fees, advertising, and access to up to the minute medical or wellness assessment information along with on-going customer care costs.

Go to Market Strategy

In order to fine tune the go to market strategy, the MAESTRO consortium will need to address the critical considerations detailed in the table below. This can only be finalised following the feedback from the pilot phase of the project.

Considerations	Options
Commercialisation vehicle	Consortium Lead partner New Start-up Joint Venture Other

Considerations	Options
Business Model	What Development platform Benchmarking site Marketplace
	To whom: • Developers • Procurement officers • Consumers • Caregiving organisations
	Money Flows:
	Pricing Models: • Subscriptions • Transactional Fees • Hosting Fees • Advertising • Fellowship fees • Consultant fees
	Activities: • Core Activities • Outsourced activities
Go to market Strategy	Route to market • Direct • Joint Venture • Other
	Geography • Territories

Summary

Detailed field research has been undertaken by the consortium across Ireland, Switzerland, Luxembourg and Italy during months 1 - 18 of the project with both push companies and pull organisations. This research supports the project's overarching hypothesis, see Ouedrago et al. (2017); that there is a requirement for a collaborative ICT platform which would act as a central point for both the development of, and access to, AAL products and services to support wellness and wellbeing for older people.

This research has further refined the thinking on how this platform could look and what functions it could usefully and, most importantly, commercially provide in the AAL market.

Given the overwhelming need for guidance, trust, reliability and confidence in this area, we can see two value propositions emerging at this stage of the project:

- A central MAESTRO developmental assessment process which brings together developers, users/caregiving organisations along with third party expertise to develop services, systems and products with a level of accreditation or endorsement.
- These 'MAESTRO' developed or tested products and services could then populate a marketplace, which would have an element of online assessment and guidance for both end users and professional care giving organisations or brokers.

Further refinement of this scenario analysis will come from the additional detailed research currently being undertaken in the pilot phase of the project.

Conclusion

The global trend towards ageing populations, coupled with technological advancements in monitored wellness products all point to strong commercial opportunities in the Ambient Assisted Living market.

The go to market analysis conducted in this work gives some insight into the AAL market as it is today, one which is for the most part in its infancy, but one which promises much to the producers and procurers of technology to support older people.

Despite competition in this space, the gaps we have thus far identified i.e. the need for impartial guidance and trust, point to a potentially successful position for the MAESTRO platform which will need to be fully analyzed during the pilot phase of the project.

At this stage we believe, this position could be offering a sequential two staged value proposition of 1. An online development process, along the lines of a virtual living lab. In fact, the virtual living lab services could be our USP - the thing that plays to our unique strengths - access to a collaborative eco-system of research, networking and third party expertise to give guidance to developers. This would then feed 2. A MAESTRO marketplace of approved systems, services or products with online assessment, impartial advice, curated benchmarking and user feedback to give trust to caregivers and users.

We believe that both these 'market-spaces' and service concepts address clearly communicated gaps across the AAL value continuum, and can offer significant value to commissioning and supplying organisations and consumers within the AAL marketplace going forward.

There are many considerations which merit further investigation when deciding on our finalized preferred go to market scenario(s) - including how these services might look in the market, how will they be successfully brought to market, what pricing models could be attached to services, what are the projected revenue streams and the costs attached to the different models.

Further refinement of this scenario analysis will come from the additional detailed research currently being undertaken in the pilot phase of the project and will shape the business plan and ultimately the development of the MAESTRO platform.

Optimization of the Enterprise Value On The Basis of Value Added

Abstract

In this article, we investigate the relationship between the possibility of optimizing the company's market value with economic added value. It is shown that if we exclude from the production function of the enterprise the capital costs, in its classical sense, then only the added value will remain. At the same time, the result having scientific novelty is the proof that, under the assumptions made, the added value will have an extremum, thus one can find the maximum value of added value and optimize the market value of the company, which is the main objective of the enterprise according to the cost approach. The article presents the corresponding economic-mathematical model and a conditional numerical example

Keywords: Enterprise value. Economic value added. Production function.

Introduction

The innovation process is a vector of actual economic development for the Russian economy as a whole and every Russian enterprise. (Melnikov, Nadezhina, Rudskaya, 2016) An adequate criteria for the success of enterprise development is the known indicator of "added value" produced by an enterprise over a certain period of time that reflects the contribution of the enterprise and the production process to the creation of the product.

To assess the value of a product in economic research, the mathematical method of the "production function" is used, (Solow, 1957) which presents a model of the dependence of production results on the costs of production factors. The model in the form of the production function is usually based on reasonable assumptions about the interrelationships of the product parameters or the production process with the final result, established earlier, based on the provisions of economic theory, the results of scientific research, practical experience or logic and common sense.

The elasticity of substitution between capital and labor is a central parameter in economic theory, as it is shown by Pol Antras (Antras, 2004). The most common model is the Cobb-Douglas production function (Meeusen & van Den Broeck, 1977), which has the form $Y = L^{\alpha} \times C^{1-\alpha}$, $0 < \alpha < 1$, where L is labor for the production of a product in the quantity Y, C is the capital investment in the production process, α -is the output elasticity of Labor, 1-α – output elasticity of capital.
Creating a product in the amount of "Y" under the existing production process will require labor input of "L" and the creation of "value added" (McCaffrey et al., 2003) in amount $Y = \alpha\sqrt{L}$.
"Alpha" is a parameter of the connection between the units of quantity and the units of labor. A parabola of this type ($Y = \alpha\sqrt{L}$) corresponds to the neoclassical principle of "diminishing marginal

productivity of production costs," the most commonly used form of a growth model with a decreasing growth rate. The choice of the function form is based on the neoclassical idea of a diminishing marginal growth in the return on production costs-each subsequent unit of production costs has less effectiveness than the previous one. In the conditions of a perfect competitive market, the price of a product is a decreasing function of the quantity of the product, in the simplest case, a decreasing linear function of the quantity of product,

$P(Y) = P_0 \quad \beta \times Y = P_0 \quad \alpha \times \beta \times \sqrt{L}$, where P_0, β - are the constants.

After the necessary substitutions, we obtain an analytical expression for the added value:

$$Value\ added = P \times Y = \left(P_0 - \beta \times \sqrt{L}\right) \times \alpha \times \sqrt{L} = P_0 \times \alpha \times \sqrt{L} - \alpha \times \beta \times L$$

According to I.Fisher's (Fisher, 1930) principle, there exists an inverse relationship between the price of a product and its quantity in production with a fixed money supply, which by definition is curvilinear (hyperbola), it is replaced by a linear decreasing dependence. As a result of assumptions made, after the capital component has been removed from the production function, the only variable factor remains is - labor. We got production function as the dependence of the quantity of a product on labor. In order to turn this dependence into value, the quantity must be multiplied by the price. That shows that value added has an extremum and it can be determined, and it is clearly shown on a numerical example in the article.

Problem Statement and Research Objective

In the considered variant of the production function, its extreme / maximum value is at the edge of the range of possible value of production costs, the boundary of the range of possible values is determined only by the limit of production possibilities (production capacity). In fact, the growth of added value is accompanied by an increase in production risks (operational risks and financial risks), which sets a limit to the growth of value added. This economically known effect of the contradiction between "risk and return" can be clearly seen in the example of the definition of the "enterprise value" by the so-called "value-based method"(Young et al., 2000), when the market value is the current value of future earnings of the enterprise, while "revenues" are treated as net cash flows (the difference between incoming and outgoing cash flows for the review period). As "incoming" cash flows, income from the sale of products and services, as well as income from resale of the asset / enterprise at the end of the period, if the asset is resold to another owner. As "outgoing" cash flows, respectively, the costs of production in the review period, including investment costs.

The value added is created by labor (Rodionov, Nikolova et al., 2016) and, with no risk (constant in time) interest rate, the more labor will be expended. When using the Cobb-Douglas production function model as a value model, it already contains a division of cost factors (labor-creates added value, capital-does not create added value).

Key Results

Let us consider the proposed statement in details.

Let there be an asset / enterprise that brings a stable annual income from its activity in the amount of "Cash Flow" (CF) cu / period (henceforth, to exclude the influence of the income factor on the market value of the enterprise, we assume CF = 1). Let's also assume that the income stream is a regular cash flow with a discrete time scale, which means that the amount of the monetary amount of each period refers to the end of each period. Then, according to the principles of the "value approach", the market value of the enterprise as determined by the value-based method, is equal to the discounted interest rate "r" of the CF cash flow plus the terminal cash flow, that is, some residual value

The residual value V-this is the market value of the enterprise, since the enterprise is resold at this cost at the end of the hold period with the previous owner.

As is known from the theory of finance, the numerator of the formula is a finite ordinary income stream equal to "1", or a single "annuity", the sum of which is equal $\frac{1-(1+r)^{-n_1}}{i}$ and taking this into account, the market value of the enterprise, determined by the value-based method, (Ivashkovskaya, Kukina & Penkina, 2010), (Karlik, Kobelkov & Kolokoltseva, 2011) is equal to:

$$Value = \frac{1-(1+r)^{-n})}{(1-(1+r)^{-n}) \times r} = \frac{1}{r}$$

So we got the market value of the enterprise, determined by the value-based method, and it represents the current or reduced cost of an uninterrupted uniform annuity of the company's income, which confirms the fairness of the income approach. It could be added that in case the income stream of an enterprise before its resale does not represent a uniform annuity, the fairness of the conclusion is not lost, since any final annuity can always be equivalent to an infinite uninterrupted annuity.

Lets assume that "r" is risk -free rate (money price in a perfect financial market). In this case, the risks are not taken into account, or their magnitude can be taken into account indirectly in the form of corrective adjustments to the income in each period. It corresponds to the accepted rule - to take into account the risk by using a risk premium to a risk-free interest rate. The specific methods of the practical approach to risk taking are discussed below.

The market value formula of an enterprise can be specified taking into account the inevitable costs of an assessment of the market value that precede the resale of the property to the new owner. The need for the assessment always arises when using a value-based method for estimating market value, since there are no identical enterprises with the same income. The costs of assessing the market value of an enterprise can be significant and are usually determined as a percentage of market value. Let the share of expenses for an estimation makes "a" from value of market cost then the market cost of the enterprise defined by a value-based method, is equal:

$$Value = \frac{1-(1+r)^{-n})}{(1-(1-a)\times(1+r)^{-n})\times r} \quad (*)$$

$$Value(n) = \frac{(1+r_1)^{-1} + (1+r_1)^{-1}(1+r_2)^{-1} + \cdots + (1+r_1)^{-1}(1+r_2)^{-1}\ldots(1+r_n)^{-1}}{1-(1-a)(1+r_1)^{-1}(1+r_2)^{-1}\ldots(1+r_k)^{-1}}$$

Then shortly:

$$Value = \frac{\sum_{k=1}^{n}\prod_{k=1}^{n}(1+r_{kj})^{-1}}{1-(1-a)\prod_{k=1}^{n}(1+r_k)^{-1}}$$

Regarding interest rates that differ for each discrete period "n", it can reasonably be assumed that their value will increase as you move away from the current time at which the estimate is made. The reason is that at a constant value of a risk-free rate, the risk surcharge will grow as a consequence of the uncertain future. In the numerical example given below, an increasing number of risk surcharges is adopted experimentally. For practical purposes, no doubt, a more rigorous justification is required.

The obtained results of the numerical example are presented graphically. We consider "n" values from 1 to 21, substituting them in the formula to determine the market value of the enterprise, we obtain the market value values presented in the graph.

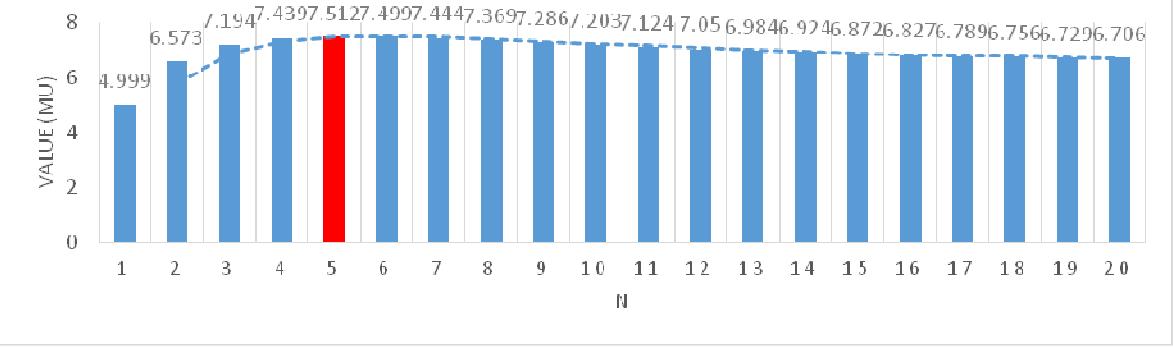

Fig. 1: Optimization of the enterprise value.

Obviously, for n = 6, the formula will reach a maximum, then it starts to decrease. The maximum of the function will correspond to the highest market value of the company / enterprise, which can be

considered optimal, there is no reason to keep the asset in the ownership when the market value of which falls.

For economic analysis, it is also interesting, at what ratio the combination of capital costs and value added (if we take into account that the type of production function that we have adopted reflects the amount of value added), we can expect the maximum value of the market value of the enterprise. Based on the results of the analysis, the owner can make a decision to run of enterprise until the market value of the enterprise starts to decline or sell it at a market value. For analysis a well known in economics "Tobin's coefficient" can also be used - the ratio of the market and accounting value of the enterprise.

Conclusion

The article shows that the optimization of value added can be achieved with the help of the proposed value model on the basis of risk taking by using the growth parameter of the interest rate in different periods.

Assuming an increase in the interest rate and a significant cost of valuation, the value added may have an optimum that can be determined by using a "modified parabola" in the model.

Cluster´S Internationalisation Platform as a Springboard for Internationalisation of Firms in the Age of Digitalisation

Professor Aihie Osarenkhoe (PhD) & Dr. Daniella Fjellström (PhD), University of Gävle, Department of Business & Economic Studies, Gävle, SWEDEN

Abstract

This study aims to answer the following question: What platform does cluster organisation create to enable its internationalisation process in order for its partner´s organisations to effectively manage the challenges brought about by the cataclysmic changes in business logic in the age of globalisation and digitalisation? **Theoretical lens** draws on combination of the experiential learning-commitment interplay, which is the driving mechanism of Uppsala´s internationalisation process model with a similar experiential learning-commitment mechanism focusing on business network relationships. **Data collection** through in-depth interviews with Process Manager – R&D, Cluster Market Manager, Communication and Information, Cluster coordinator took place in the Swedish cluster Future Position X (FPX) - a leading cluster organisation in Europe within geographical information. **Findings** show that FPX was building international links with similar clusters in the Nordic, Baltic, and European countries. FPX later learned that for it to be in forefront of innovation, it needs to mix its own core competences with very complementing technology areas of the biggest hotspots in the world in Geo Spatial technologies. **Conclusion remarks and implications:** A sustainable internationalisation platform created by cluster is of utmost importance these days because digitalisation is fundamentally disrupting traditional industries, labour markets and the global economy, and transforming various facets of exchange. To companies, this means opportunities for new or changed business models, spanning from marketing and sales channels to logistics. **Originality:** This study contributes to the literature examining location can help firms to increase their competitiveness and thus supporting them in getting access to global value chains and new markets, by focusing solely on exogenous activities which serve to improve cooperation with global markets, that are critical to cluster dynamics.

Keywords: Cluster´s internationalisation, Internationalisation process, formal and informal networks, Future Position X (FPX), Digitalisation, Small and Medium-sized Enterprises

Introduction

In today's networked world (LeMahieu et al., 2017), turbulence, unpredictable uncertainty, and ambiguity are more the norm than the exception. So, a pertinent form of strategising is called for, one that differs from strategic approaches developed for less turbulent and more stable contexts, where organisations of various forms are less tightly connected to each other than is the case today (Awa et al, 2011). This study explores and explains a form of strategising that is fit for purpose in such conditions.

The basic premise of this study is that the fundamental mechanisms used to explain the internationalisation process of firms, cluster organisations, educational institutions and other types of organisations are at parity or equivalent. Hence, we consider theories and models used to explain internationalisation process of for profit and non-for-profit organisations to be at *pari passu* or on equal footing. While extant literature focuses on the concept of internationalisation of clusters from the perspective of the tasks they perform, and their links with international partners (Xu and McNaughton, 2006; Prashantham, 2008; Pla-Barber and Puig, 2009; Carneiro Zen *et al.* 2011; and Richardson *et al.* 2012; Carneiro Zen et al., 2016; and Ślepko, 2012), this study illuminates how a cluster´s internationalisation platform is used as a catalyst to leverage its entire innovation system to an international level. Thus, integrating the cluster with global innovation networks and international matchmaking and capitalization so as to get more links to investment capital for the companies in its platform. This will invariably increase the international links for startup companies and the regional innovation system.

The gap in literature is attributed to the fact that the impact of clusters on the internationalisation of cluster firms (Caputo *et al.* 2016) and the degree to which cluster activities improve collaboration and interaction between Firm-to-Firm, Firm-to-Research, Firm-to-Education, Firm-to-Capital and Firm-to-Policy, has received tremendous coverage in extant literature (Sölvell, 2009; Lindqvist et al 2013; Xu and McNaughton, 2006; Prashantham, 2008; Pla-Barber and Puig, 2009; Carneiro Zen et al. 2011; Richardson et al. 2013; Lamotte, 2014; Jankowska and Główka, 2016; Valdaliso et al , 2016). In other words, previous studies have mostly addressed internal gaps hindering effective mobility and collaboration inside clusters, to the detriment of external gaps vis-à-vis collaboration and interaction with global markets. This perspective has gained prominence because digitalisation combined with globalisation enables internationalisation by firms and clusters on a global scale (Caputo *et al,* 2016). To Swedish firms, this means opportunities for sales to customers worldwide. Conversely, to foreign companies this facilitates sales in Sweden. Both international and domestic competition toughens, as Sweden becomes part of a global market.

The following research question is used to guide the exploratory nature of this study:

RQ: What platform does cluster organisation create to enable its internationalisation process in order for its partner´s organisations (SMEs) to effectively manage the challenges brought about by the cataclysmic changes in business logic in the age of globalisation and digitalisation?

This study aims to shed light on exogenous gaps that are critical to cluster dynamics (Morgulis-Yakushev and Sölvell, 2017). Thus responding to recent calls (Jankowska and Główka, 2016; Valdaliso, Elola and Franco , 2016) for more research on gaps that are alien to the cluster, consisting of cross-cluster gap barring collaboration and interaction with firms in other clusters, and, most especially, the global market gap barring collaboration and interaction with global markets.

Theoretical Lens

Extant literature makes distinction between formal and informal networks (Forsgren, 2002, Hill, McGowan & Drummond, 1999). Forsgren (2002) described the formal network as a business network comprising a number of actors, linked with one another through different kinds of relationships. Johanson and Vahlne (2009) believed that also the current market is a network where actors are linked with one another, and in which a company must be active in order to establish itself on a new market. Furthermore, becoming established in a relevant network might result in an increase in knowledge, opportunities, and trust, resulting in an increased profit in the companies. Hill et al (1999) defined informal networks as social networks, incorporating relationships and alliances with people in society, outside the work place. Informal networks can furthermore create opportunities to develop SMEs, and might be viewed as an invisible asset. It is thus of great importance to be part of a large network, since that creates more opportunities as compared to small networks (Granovetter, 1973). Adrichivili, Cardozo, and Ray (2003) argued that informal networks might yield advantages for the company when identifying new markets.

Research concerning the significance of networks in connection with companies' internationalisation is abundant, though with divergent conclusions. Coviello and Munro (1997), Zain and Ng (2006), and Ojala (2009) argued that more research on the subject is required. Furthermore, formal as well as informal networks are of importance to the internationalisation process of organisations. Ojala (2008), Eberhard and Craig (2013), and Jeong (2016) claim that more research nonetheless is required in order to establish in what manner these network forms affect the internationalisation. Zhou, Wei-ping, and Xueming (2007) called for research around the linkage between the two network forms. In addition, there is a gap in the literature in terms of research on whether formal and informal networks unite during internationalisation.

Although understanding innovation in the context of the current changing industrial landscape in the age of digitalization has become cumbersome, and necessitates serious challenges to traditional internationalisation models (Luostarinen, 1994; Cavusgil, 1980; Bilkey and Tesar, 1977; Leonidou and

Katsikeas, 1996; Johanson and Vahlne, 1977, 1990, 2003) our theoretical lens draws on Uppsala internationalization model (Johanson and Wiedersheim-Paul, 1975). The central tenets of the model are how organizations learn and how their learning affects their investment behavior (Forsgren, 2002). Another important aspect of the Uppsala model is that it describes the internationalization of a firm as a gradual process. However, it is pertinent to mention that the number of people with extensive experience of international trade has also grown, meaning that firms can easily hire the competence they require rather than creating it themselves (Hollensen, 2007; Hill, 2003; Wild et al., 2007). Osarenkhoe (2009) propounded that "in an evolving international economy dominated by growing global integration, emerging fragmentation of traditional markets into global niches, and the birth of new competitive spaces thanks to technological developments, the steps and modes of foreign markets entry could experience significant deviations compared to the internationalization patterns of firms characterized by a series of incremental decisions, experiential learning and risk aversion, as envisaged in the traditional sequential models" (p. 287)

Internationalisation of firms has attracted great attention over the past decades (e.g. Johanson and Vahlne, 1977, 1990, 1992, 2003, 2009; Johanson and Mattsson, 1988; Dunning, 2000; Sun, 2009). However, this is not the case with small and medium-sized enterprises (SMEs). Hammond and Groose (2003) stress that international business activities should be seen as a continued development of firms´ competitive capabilities, which in turn enable them to compete successfully against rivals from and within different countries. As a growing number of SMEs have started operating on an international level (Coviello and McAuley, 1999; Chetty and Campbell-Hunt, 2003; Arte and Barron, 2016), it is important to understand how SMEs handle this challenge with their limited resources. Hence, Ngoma, Abaho, Nangoli and Kusemererwa (2017) investigated entrepreneurial orientation (innovativeness, proactiveness and risk taking) as a predictor of internationalisation of small- and medium-sized enterprises (SMEs), and established a significant relationship between the dimensions of entrepreneurial orientation and internationalisation of small- and medium-sized enterprises.

Both economic research and current business policy debate stress innovation as a key requirement to economic growth. Innovation is described today as an interactive process that rarely occurs within the confines of a single company or organisation (Inauen et al., 2012; Windrum et al., 2016; Sergeev, 2017; Bolaji Ilori et al, 2017). Rather, innovation is often a result of combining the resources of a multitude of actors in new constellations, where the goal is to generate value for everyone involved. Against this backdrop, digitalisation is fundamentally disrupting traditional industries, labour markets and the global economy (Koren, 2008). We are experiencing a digital revolution that transforms the world as we know it (Plesner and Raviola, 2016; Pinho and Pinheiro, 2015; Preston and Rogers, 2012; Quinn, Dibb, Simkin, Canhoto and Analogbei, 2016). Traditional business models and value chains are challenged as digitally performed activities allows for increased availability, shorter lead times, faster time-to-market and lower transaction costs. This translates into opportunities for lower overall costs, allowing smaller companies to compete with well-established companies and brands (Holmlund, Strandvik and Lähteenmäki, 2017). Simultaneously, customer expectations mount with increased transparency, and competition increases across sectors.

As mentioned above, networks can be divided into formal and informal networks, and Jeong (2016) maintains that earlier research agree in terms of how the two forms may be defined. Formal relationships are described as company activities between actors within a network, while informal relationships can be defined as personal relationships (Ojala, 2008). Zhou, Wei-ping, and Xueming (2007) moreover argued that actors' informal networks generate extended knowledge about foreign market opportunities, counseling, and experience-based learning along with trust and loyalty. By being active in formal networks, companies are able to utilize each other's resources and competences with the purpose of performing tasks. Companies may however act on their own initiative, which results in increased costs and higher risks for the companies. Informal as well as formal networks both proffer various advantages (Fernhaber & Li, 2013).

Methodology

This study aims to shed light on exogenous gaps that are critical to cluster dynamics. Consequently, we describe the platform created by cluster organisation to enable its internationalisation process in order for its partner´s internationalisation to effectively manage the challenges brought about by the cataclysmic changes in business logic in the age of globalisation and digitalisation. Data collection took place in Future Position X (FPX). FPX initiates and supports research and innovation projects as well as helps companies and organisations to reach new markets. Primary and secondary data sources were used in this study. Secondary data entailed a review of various evaluation reports. Primary data were collected through in-depth interviews with Process Manager - R&D, Cluster Market Manager, Communication and Information, Cluster coordinator, outward internationalized firms and inward internationalised firms at Future Position X.

A roundtable talk that took place in conjunction with the visit of international expert evaluators, sent by Vinnova (Sweden´s Innovation Agency), to evaluate the first three years of FPX´s Geo Life Region. A co-author of this paper was among senior researchers in Sweden invited to represent research and academic institutions with focus on the competitive edge of research and knowledge development – strategy and results". The other co-author was invited to participate in workshops with FPX and SMEs to discuss internationalisation. In other words, invited researchers represented the collaboration and interaction between Cluster-to-Research and Cluster-to-Education.

After the conclusion of the roundtable meeting with external evaluators of FPX, another roundtable talks with process leader of cluster initiatives, regional and local networks was conducted. The duration was two hours during two separate occasions. Answers our questions facilitated an understanding of how cluster´s formal and informal networks amalgamate during establishment on an international market. In other words, to shed light on exogenous gaps that are critical to cluster dynamics (Morgulis-Yakushev and Sölvell, 2017).

Transcripts were created from the tape recorders from various interview sessions. Questions were asked in an interactive group setting where participants were free to talk with other group members. The discussion was loosely structured, and free flow of viewpoints was encouraged on the main theme for discussion, which were solely based on the research questions. Having key themes and sub-questions in advance lies in giving the moderator or researcher a sense of order from which to draw questions from unplanned encounters (David and Sutton, 2004).

Data analysis

Data collected was analysed in three steps: data reduction, data display, and conclusion drawing (Miles and Huberman, 1994). Data reduction entails selecting and excluding/filtering data in order to focus, discard and organize the data in such a way that conclusions can be drawn and verified (ibid.). As for the tape- and video-recorded interviews, this analysis process began while transcribing the interviews. The aim of data display is to organize the data into a compressed assembly of information to elucidate appropriate conclusions and action. Accordingly, main themes, in our case the focus, objectives, activities and organisation of the clusters and networks, were extracted so as to provide succinct insight on the salient features of the cluster initiatives, regional and local networks in the region studied. Conclusion drawing and verification focuses on reflecting and understanding the data chosen for display. Although the process began at the initial stage, this step became more dominant during the later stages of the research. Despite the fact that the three steps are viewed as separate processes of analysis, it is important to note that the processes were going on simultaneously in this study.

Presentation and Discussion of Findings

The prevailing reason for FPX to consider an international scope was to keep its lead in technological development, identify upcoming market needs, properly reacting to transformation processes and to strengthen its own position on markets worldwide. From the beginning, FPX was building the

international links with similar clusters in the same technology area in Nordic, Baltic and European countries. Nevertheless, later learned that for FPX to be in forefront of innovation, it needs to mix its own core competences with very different technology areas. FPX built relationships with a number of the biggest hotspots in the world in Geo Spatial technologies. Thereafter, it started to build new relationships with complementing knowledge and hot spot centers, like the mobile and new media industry in Malmö, the digital media and gaming industry in China, the health industry in Beijing and Australia, the sports industry in Åre and Barcelona and Melbourne. This is enabling FPX to work with cross cluster international innovation and importantly supports the strategy of 'innovation within the gaps'.

Findings show that FPX has, since 2005 had an internationalization strategy and since 2012 a 'Born Global' vision for the spin-off companies coming out of its innovation system. FPX has a focus on the largest economy in the world, the Chinese market - a market with great potential and with a high psychic distance. Thus, FPX internationalisation strategy is in sharp contrast to the core assumption of Uppsala model (Johanson and Wiedersheim-Paul, 1975) that an entity starts its foreign operations in countries with low psychic distance. In other words, organisations favour countries countries that share similar environment with their home country. FPX has encouraged Gävle city to set up sister city relations with Zhuhai City in south China – the region in the world with the highest growth rate and that is also known as the factory floor of the world, Guang-dong.

FPX´s "global mindset, which is in line with entrepreneurial orientation (innovativeness, proactiveness and risk taking), is epitomised in the study by Ngoma, Abaho, Nangoli and Kusemererwa (2017), resulted in several new agreements with partners to ensure that they have the resources and expertise available for their activities and channels to investment capital and platforms for companies' international expansion. The prevailing reason for FPX to consider an international scope was to keep its lead in technological development, identify upcoming market needs, properly reacting to transformation processes and to strengthen its own position on markets worldwide. Fernhaber and Li (2013), who suggested that by being active in formal networks, companies are able to utilize each other's resources and competences with the purpose of performing tasks, support this strategic decision by FPX.

Our findings show that in the beginning, FPX had an internationalisation strategy which concurs with Johanson and Vahlne (1977 & 1990), who studied the internationalisation behavior of Swedish firms and found that they follow a sequential process. FPX was building the international links with similar clusters in the same technology area in Nordic, Baltic and European countries. Hence, it first entered country markets with low psychic distance. Combined with the experiential learning-commitment interplay as the driving mechanism from their previous internationalisation process with a similar experiential learning-commitment mechanism focusing on business network relationships (Johanson and Vahlne, 2003), FPX entered markets with high psychic distance.

Having learned that to be in forefront of innovation, FPX decided on mixing its own core competences with very different technology areas. Furthermore, its realisation that being active in networks will facilitate identification of opportunities that further govern its choice of entry modes and entry nodes (Albaum and Duerr, 2008; Koren, 2008; Sandberg et al., 2015; Galkina and Chetty, 2015; Jeong, 2016) when undergoing internationalisation. In compliance with Zhou, Wei-ping and Xueming (2007) who argued that actors' informal networks generate extended knowledge about foreign market opportunities, counseling, and experience-based learning along with trust and loyalty, FPX built relationships with a number of the biggest hotspots in the world in Geo Spatial technologies. Thereafter, it started to build new relationships with complementing knowledge and hot spot centers, like the mobile and new media industry in Malmö, the digital media and gaming industry in China, the health industry in Beijing and Australia, the sports industry in Åre and Barcelona and Melbourne. This is enabling FPX to work with cross cluster international innovation and importantly supports the strategy of innovation within the gaps.

Concluding Remarks and Implications

This study aims to facilitate understanding of how cluster´s formal and informal networks amalgamate during its international establishment. It is recognised in this study that clusters act as real "springboards" for firms, especially small and medium enterprises (SMEs) to help them in increasing their competitiveness and thus supporting them in getting access to global value chains and new markets (Meier and Zombori, 2011). Cluster participants can benefit from specialised business support services of cluster organisations stimulating and organising these actions. In particular, if firms have to increasingly integrate their activities into global value chains in order to become and remain competitive, being part of a cluster is supportive (Pavelkova, *et al.,* 2015). Clusters in the emerging industries face the needs for internationalisation. Consequently, transformation processes within value chains, brought about by digitalization, urge clusters to think global and internationalise accordingly.

Clusters' internationalisation is essential to their activity or even their very existence. The level of those activities then has a decisive influence on the competitiveness of clusters' firms, and it is a showcase of cluster organisation managers' ability to coordinate and administer those activities. The journey from initial idea to market-ready product or commercialisation of innovation, which is key to entrepreneurial success, is uneven, indirect and has many twists and turns. The path is plagued with many obstacles and possible entry and exit points. The participants in clusters are mainly SMEs, and they are often devoid of time, resources, knowledge, and international market experience and networks required to singlehandedly embark on the journey to go international. This is the rationale why cluster organisations can provide customised supporting measures and tools to the cluster participants on their paths towards internationalisation, as they usually have more resources at their disposal and are more experienced in internationalisation matters. A common understanding within clusters (e.g. FPX), a sophisticated internationalisation strategy and a consequent implementation of related actions are the prevailing key success factors for internationalisation of clusters. This requires specific cluster manager internationalisation skills for building long-term transnational and cross-sectoral cluster partnerships.

A sustainable internationalisation platform created by cluster is of utmost importance these days because digitalisation is fundamentally disrupting traditional industries, labour markets and the global economy (Einsiedler, 2013; Lee & Kao, 2014), and transforming various facets of exchange (Hagberg *et al* 2016). To companies, this means opportunities for new or changed business models, spanning from marketing and sales channels to logistics (Ivang *et al*, 2009). Traditional business models and value chains are challenged as digitally performed activities allows for increased availability, shorter lead times, faster time-to-market and lower transaction costs (Holmlund *et al*. 2017). This translates into opportunities for lower overall costs, allowing smaller companies to compete with well-established companies and brands. Against this background, collaborative development environments (Mendikoa *et al.,* 2008; Lin et al., 2012), such as FPX internationalisation platform, gain importance especially for small and medium enterprises (SME) with limited resources. This reinforces a need for clusters and firms to develop their management of interactive innovation processes.

Implications of this study are that internationalisation of clusters gains a new dimension and quality, if the future transnational collaboration and interaction is driven by a deep understanding of ongoing transformation processes in respective value chains – a process which is a sequel to digitalisation and globalization (Hagberg *et al*. 2016). It is obvious that such transformation processes or digitalisation process may have different dynamics in different regions (Holmlund *et al*. 2017). Therefore, clusters should focus their international and global partnerships on those regions with the highest dynamic. This is one important pre-condition to successfully conquer related markets or initiate cooperation with sustainable impacts. Furthermore, this study demonstrates that cluster companies can leverage on internationalisation operations performed by cluster organisations.

FPX global network serves to help the small and medium sized companies reach new markets and commence international business. FPX also inspire international companies to establish themselves in Gävle and further strengthen the GIS-environment in the region. The prominent ends attained by FPX internationalisation include increased access to knowledge, market, and key infrastructure. Internationalisation also helps FPX to get access to new business partnerships and collaborative

research. In addition, internationalisation enlarges its knowledge base by sourcing knowledge, technology and skills from other locations than their traditional environment. Transformation processes within value chains urge clusters to think global and internationalise accordingly.

This study offers insight into internationalisation of cluster in a Sweden context. It bridges the approaches to firm internationalisation with the theory of clusters. This is the first study to incorporate discussions on digitalisation in cluster internationalisation. This is particularly important because to succeed in the global marketplace, SMEs must put digitalisation in the center of their international strategy. Furthermore, by focusing solely on exogenous activities which serve to improve cooperation with global markets, that are critical to cluster dynamics, this study contributes to the literature examining location can help firms to increasing their competitiveness and thus supporting them in getting access to global value chains and new markets.

Yields and Land Use for Wheat Production in Romanian Agriculture

Silvius Stanciu

„Dunarea de Jos" University of Galati, Romania, sstanciu@ugal.ro

Abstract

Wheat production represents an important factor in ensuring Romania's food security, independence and supremacy. During the interwar period, Romania was the main agricultural area producing cereals at a European level. Growing cereals, and especially wheat, is a very old practice on Romanian territory. Although wheat production suffered an important decrease after the change in the political regime from Romania, lately there has been a recovery in the sector, although the optimal use of Romania's natural potential hasn't been reached yet. The present paper proposes an assessment of the national wheat production, of the surfaces on which wheat is grown and of the average productivity per hectare by means of analysing the official data offered by the Romanian and local statistics. The conducted research showed that the record wheat yields obtained in the last few years by Romanian agriculture were not directly influenced by government investments in irrigation systems or by additional quantities of chemical fertilizers. Government and private measures to increase the invested capital or the irrigated areas, to modernize agricultural technologies or to improve wheat species may lead to an increase in the volume of wheat production and could place Romania among the most significant exporters in the world.

Keywords wheat, land, yields, Romania

Introduction

Wheat represents the most important crop in the world, covering the largest surface worldwide, estimated at over 220 million hectares. Wheat grains have a high carbohydrate and protein content. The foremost use of wheat is for human consumption, flour being the main ingredient in making bread and bakery products, the basic food for about 35-40% of the world's population. In industrial processing, wheat is used for the production of ethyl alcohol, of starch, of dextrin and of glucose, whereas in zootechnics, it is used as fodder for feeding animals. Virtually, nothing is wasted from the wheat yield. The bran, resulted after grinding the wheat, represents valuable fodder, rich in proteins, carbohydrates and mineral components, whereas straws are used in the pulp and paper industry or in feeding animals (Cristu, Cristu Scurtu and Stanciu, 2016). As far as agricultural technology is concerned, wheat growing is a good precursor for rapeseed and autumn fodder plants, because it improves the conditions for the administration of organic and mineral fertilizers.

During the interwar period, Romania was considered Europe's foremost wheat producer. Wheat growing has been practised since ancient times on the Romanian territory. The archaeological evidence from Cucuteni, Iași, shows that wheat was grown even from the Upper Neolithic and The Bronze Age. According to Troșan (2011), who quotes historical sources, the primitive species of wheat grown in our country were *T. monococcum* (such yields have been sporadically kept up to the present), *T. dicoccum, T. compactum* and, probably, *T. spelta*. Since the yields of *T. aestivum* were used even from the end of the third millennium BC, due to their technological advantages, this species of wheat may have been grown even from The Bronze Age on our territory, too. The Geto-Dacians used to practise a flourishing wheat trade with the Greek colonies from the shore of Pontus Euxinus and with the Thracians from the south of the Danube. The first information regarding the presence of bread in the north part of the Danube dates back to the 5th century BC at Xenofon, which reminds of unleavened bread. Also, in the 1st century AD, Pliny the Elder commented on the extraordinary taste of bread in this area. Wheat growing is also

mentioned by Darius, the king of the Persians, in his expedition against the Scythians (513 BC) from the Plains of Eastern Europe, Ukraine and the regions around the Caspian Sea. Wheat covered big surfaces, ranging from the Danube Plain towards the East and the South of Moldavia and the steppes of Ukraine, up to West in the Pannonian Plain. Mentions regarding wheat yields in the Danube Plain are also made by Alexander the Great in his expedition against Geto-Dacians (335 BC), whereas Teofrost (372 - 287 BC) speaks about a rich agriculture practised by the Geto-Dacians. Since 1850 and until WWII, local agriculture has continuously developed, largely due to wheat growing. During WWI, wheat growing declined a lot, in 1920, the surface on which wheat was grown reaching 2.03 million hectares. In 1925, the surfaces allotted to wheat growing were estimated at 2.3 million hectares, reaching 3.3 million ha. from 1926 to 1938. During the interwar period, the average productivity varied between 5.1 q/ha (1932) and 13.1 q/ha (1938) with an average of 9.4 q /ha. After WWII, wheat growing has continuously developed, due to an increase in the national technical equipment and material possibilities, to the introduction and expansion of improved wheat species and to the improvement in agricultural technologies (Răsfoiesc.com, 2017). The local lexical resources have kept numerous Latin-based terminology, which name the main operations performed when transforming wheat into bread, thus proving the continuity of a number of domestic operations on the territory of our country (Troșan, 2011).

Materials and Methods

The information regarding the farmland on which wheat is grown and regarding the yield obtained was taken from the National Institute of Statistics and Eurostat databases. The average productivity per hectare was calculated by comparing the yields to the cultivated lands. Other information, related to the characteristics of wheat species or the agricultural technologies employed in Romania were selected from the domain-specific literature. Some official information regarding the wheat yield was collected from the official media or from the press releases made by the Romanian officials. The data was statistically processed and graphically represented. The obtained results were interpreted and compared with data from the domain-specific literature for an adequate interpretation.

Wheat growing in Romania

Romania occupies an important position in European agriculture, being placed on the 6th position as far as the use of the farmland is concerned, with approximately 13.9 million ha in 2013, after France, Spain, Great Britain, Germany and Poland (PricewaterhouseCoopers Management Consultants SRL, 2017).

In Romania, the wheat-cultivated land represents almost 25% of the total arable land and 40% of the cereal-cultivated one (Dragomir, 2009). According to the data taken from the National Institute of Statistics (2017), the land allotted for wheat growing in Romania was between 1.46 million ha in 1992 and 2.54 million ha in 2001, with an annual average of 2.11 million ha from 1990 until 2016 (figure 1).

The main species of wheat in Romania is the common wheat (*Triticum aestivum ssp vulgare*). On smaller surfaces, which represent approximately 0.3% of the total land allotted to wheat, a variety of wheat with a higher grain hardness, the durum wheat, is grown (*Triticum durum* or *Triticum turgidum conv. Durum)*, which is intended for the manufacture of pasta.

As compared to France, Germany, Great Britain or Italy, the largest wheat producers in Europe, countries in which early (Apache, Autan) or semi-early (Renan, Reflection) varieties of wheat are grown, in Romania, the varieties used for high-performance agriculture are those semi-early or late, which can successfully cope with the more arid climate (BASF, 2017).

Although, lately, the durum wheat quantities harvested in Romania have recorded an upward trend, there is only one company specialised in the industrial processing of this wheat variety, the vast majority of the production being exported (Cristu, Cristu Scurtu and Stanciu, 2016).

At a European level, in 2016, Romania occupied the 5th place as far as the wheat-cultivated land is concerned, with 2.11 million ha, after France, Germany, Poland, Spain, the same place being held as far as the total wheat yield is concerned, after France, Germany, Great Britain and Poland, with 8.28 million tons (Agerpres, 2017).

In the international statistics, the first places are occupied by China, India, Russia and USA, countries that account together for more than half of the global wheat production (figure 1). The European Union, which is considered the biggest wheat producer, had a production level of 147.8 million metric tonnes in 2015 with a forecasted growth rate of 2% when comparing with previous year's performance. (Cristu, Cristu Scurtu and Stanciu, 2016).

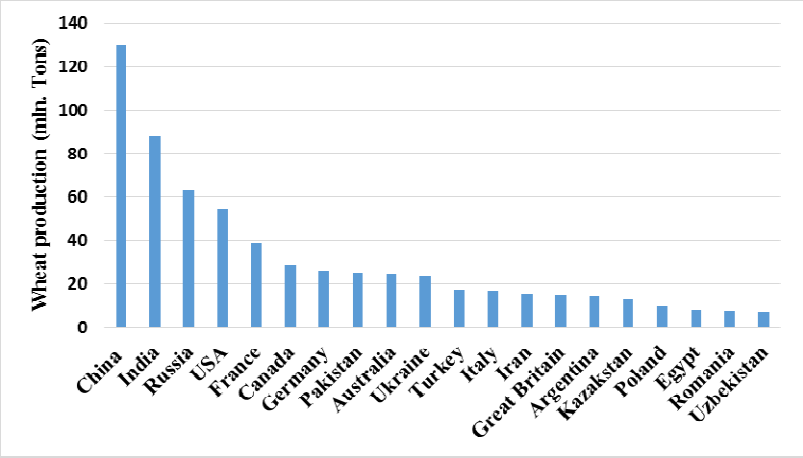

Figure 1:The worldwide wheat producers (2016)

Source: Author, using United States Department of Agriculture USDA data (2016),

The average productivity per has varied during the analysed period between a minimum of 1.429 tons/ha, recorded in 2012, and a maximum of 3.664 tons/ha in 2011, with an annual average of 2.77 tons/ha (figure 2). The general trend at a national level is to increase the average productivity per hectare, in the conditions in which farmland was reduced and agricultural technologies improved.

In May, experts estimated an average yield for 2017 of over 4 tons of wheat per ha, and significantly higher for farms with larger areas, given the climatic conditions of autumn-winter 2016 and the spring of 2017, respectively (Anghel, 2017).

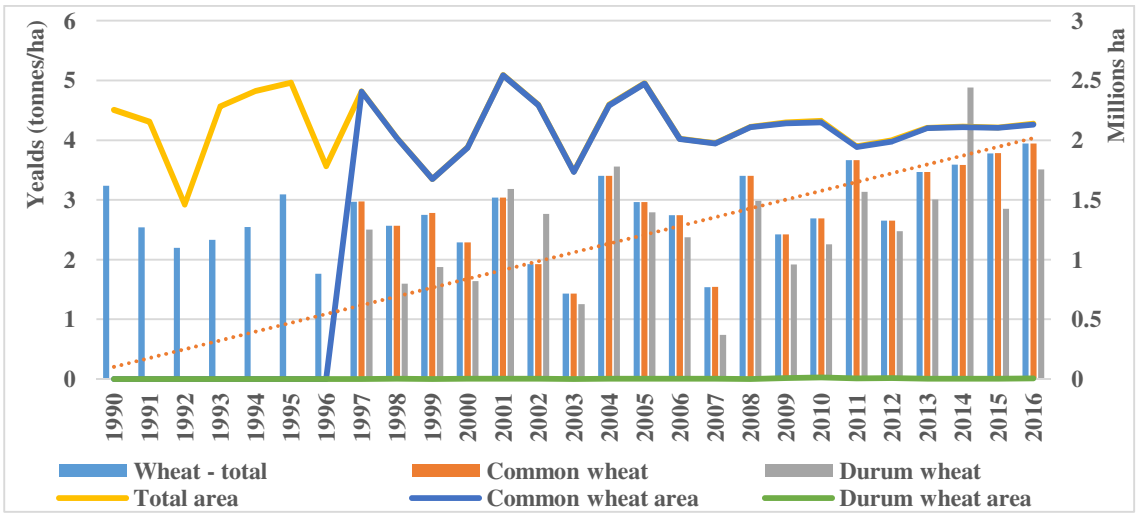

Figure 2: Wheat-cultivated land and average annual productivity in Romania
Source Author, by using NIS Data (2017)

The experts' forecast was confirmed by the Minister of Agriculture, who validated at the end of the harvesting campaign an average yield of de 4.836 kilograms per hectare, a record for Romania. According to the Eurostat data (2017), in 2016, Romania was on the 5th place in Europe regarding the average wheat productivity, surpassing countries such as Italy or Spain (figure 3).

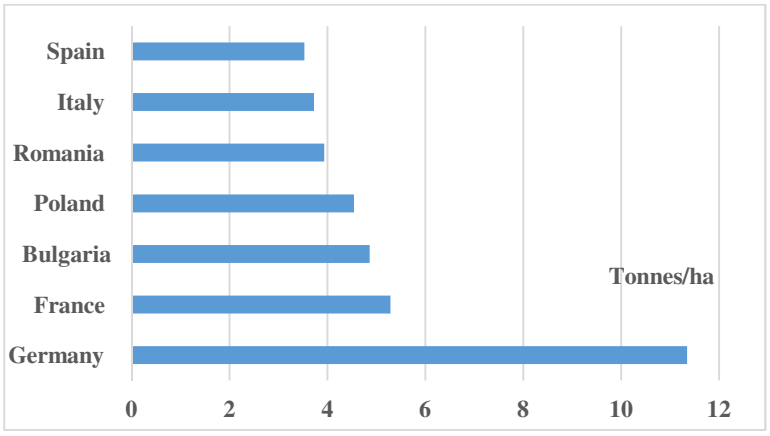

Figure 3: Average yield on wheat production by the main European producers (2017)
Source Author, by using EC Eurostat data (2017)

Romanian producers achieved in the recent years a growth of the average per ha production, more than 4 tons this year, and surpassing Ukraine, USA and India (figure 4). This agricultural productivity is a record of Romania for the last 10 years, with the highest average quantities obtained last year, respectively 3.84 tons per hectare, 2011-3.68 tonnes per hectare, in 2014 -3.58 tons per hectare, and finally, in 2008 - 3.40 tonnes per hectare (Ministry of Agriculture and Rural Development MARD, 2016).

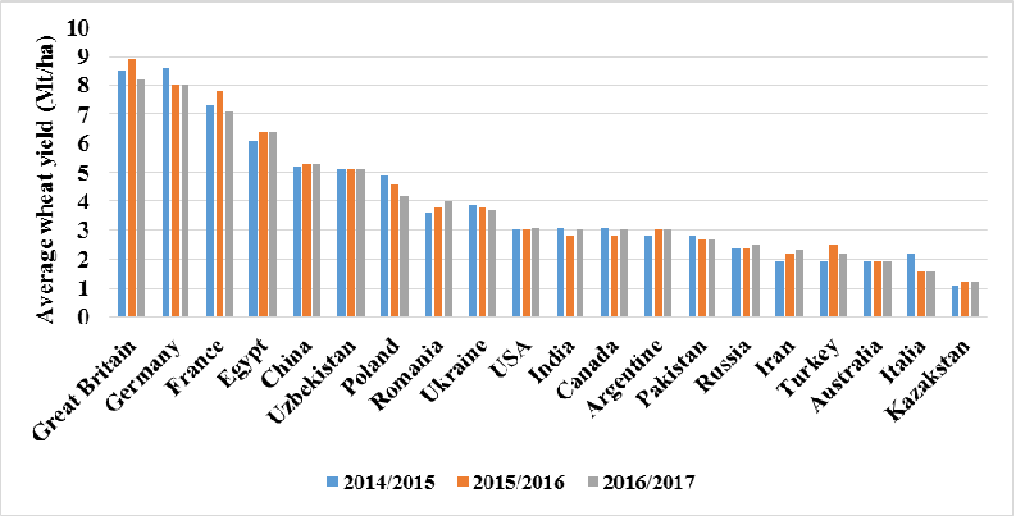

Figure 4: Woldwide average wheat productivity

Source Author, using Cristu, Cristu and Stanciu (2016)

The historic quantities of wheat obtained this year by Romania can be correlated with the national investments in the irrigation system, the Minister stating that other national irrigation systems are being implemented, and the cost of which exceeded 1 billion lei from the national budget and 431 million euro through the Rural Development National Programme 2014-2020 (Economica.net, 2017). The Minister's allegations are contradicted by official statistics, the NIS data (2017) showing that there weren't any substantial changes at a national level regarding the irrigation facilities. The evolution of the irrigated land at a national level is presented in figure 5.

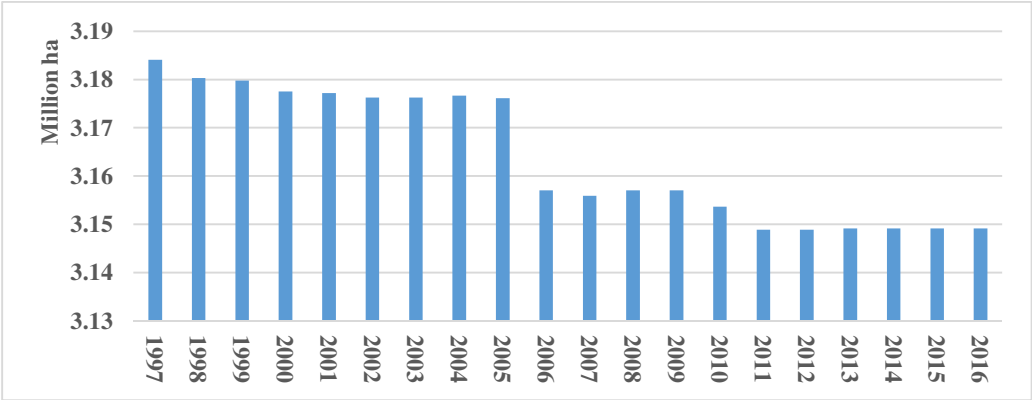

Figure 5: Irrigation facilities in Romania (ha)

Source NIS Data (2017)

According to the presented data, one cannot notice a significant evolution of the irrigated land at a national level from 2011 until 2016, which lately has remained at a relatively constant value of approximately 3.2 million ha.

There isn't any direct correlation between the quantities of fertilizers distributed in Romanian agriculture and the increase in wheat productivity, given the fact that there aren't any significant differences between the levels of fertilizers distributed on farmland in the last few years (figure 6).

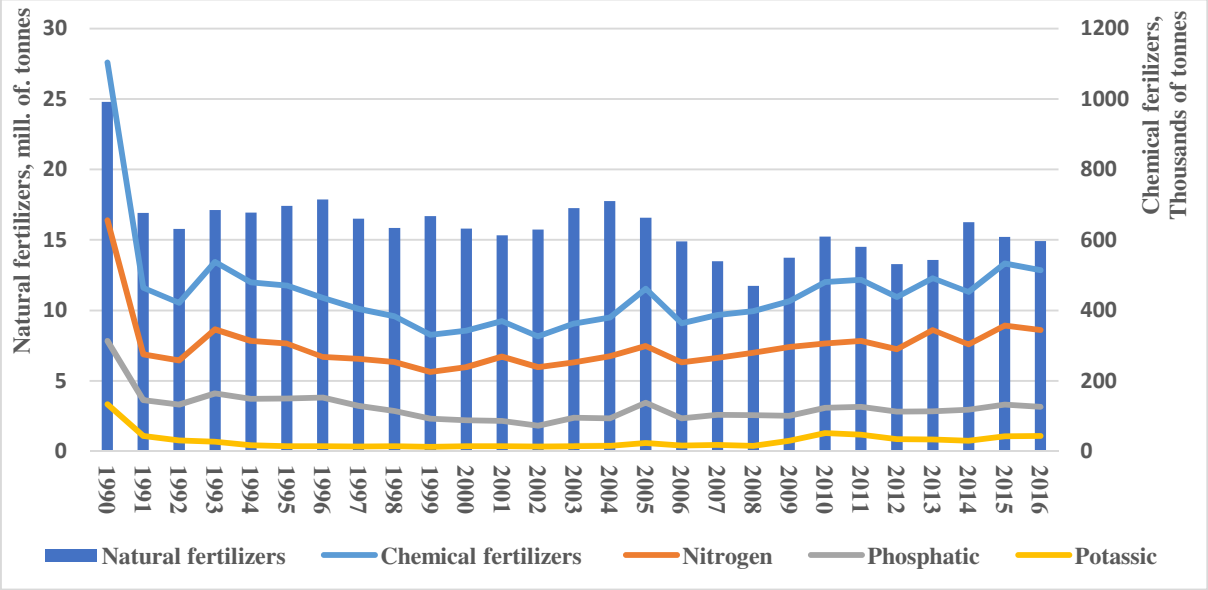

Figure 6: Chemical and natural fertilizers in Romanian agriculture (tonnes of active substance)
Source Authors, using NIS data (2017)

Since there weren't any significant evolutions in the development of irrigation facilities or in the usage of chemical fertilizers, it seems that the record yields obtained this year were mostly due to luck, represented by sufficient rainfall at the proper time, and not to irrigation or to fertilizers. An exhaustive analysis of the factors which led to an increase in wheat productivity must also take into account the climatic conditions, the agricultural machinery and the varieties of wheat used, the workforce, land merging etc.

Although it is characterised by a relatively low productivity as compared to other countries at an international level, Romania has constantly been, in the last few years, in the top 20 wheat-producing countries in the world, due to the large area of farmland dedicated to wheat growing, being a net exporter of cereals. In 2015, Romania occupied the 9th place as far as global wheat exporters are concerned (PricewaterhouseCoopers Management Consultants SRL PWC Report, 2017). In 2016, Romania was situated on the 2nd place in the European Union regarding wheat and barley exports. Last year, Romanian farmers exported over 840,000 tons of wheat in the first six weeks of the agriculture season, the exports reaching 1,589 million tons of what until the end of the year. Germany is on the 1st place in the ranking regarding European exporters, with 1,892 million tons of wheat exported at the beginning of the fiscal year 2016/17. Last year, the next positions in the European ranking are occupied by France, with 1,351 million tons and Poland with 971,000 tons of exported wheat (BASF, 2017).

According to the PWC Report, taking into account the large area of farmland and the reasonable usage rate as far as Romania is concerned (which is situated on the third place at a European level, after France and Spain), the yield is the main limiting factor of the national agriculture sector.

The volume of the annual production depends on the available farmland, on the usage rate of the available farmland and on the yield of the farmland. According to the PWC Report (2017), the theoretical yield of the farmland in Romania is of 7t/ha., a well-estimated value, given the fact that more EU

countries have had yields which exceeded 7t/ha in the last few years (France, Germany, Great Britain, Ireland), and the European average is estimated at 5.5 t/ha. If our country reached the average theoretical yield per hectare recorded at a European level, it would have an estimated wheat yield of 12 million tons annually, thus being ahead Germany and other European countries.

In order to increase Romania's real yield in the next few years, the main factors limiting the performance of the national agricultural sector should be addressed: the capitalization of farms, the improvement of the facilities used in agriculture, the training level of farmers and the average size of farms.

Nevertheless, the value of the annual production can be affected by the commodity prices and by other factors such as the fluctuations that may occur in the exchange rates.

Conclusions

Romania has the capacity to produce large quantities of wheat, ensuring the needs of the population and significant incomes for the farmers by exporting harvested quantities on the international market. The volume of the wheat yield in Romania could significantly increase if the national yield would reach the European average or at least the maximum theoretical yield of the farmland. In order to increase the average wheat yield in Romania, economic agents should apply concerted measures such as: the increase in the amount of capital invested and in the irrigated areas, the modernisation of the agriculture technologies, the improvement of the wheat varieties, correlated with government measures to increase the farmers' level of training and to alter the average size of farms. The increase in the wheat yield volume could place Romania among the most important exporters in the world, bringing important benefits to Romanian farmers and to national economy. The brief analysis of a number of potential factors which could have influenced the level of production in the last few years highlighted the fact that irrigation facilities and chemical and natural fertilizers have not influenced the high amounts of wheat obtained in Romania.

Abstract

Innovation can represent for the modern society the main way to achieve economic growth and to solve certain local and global issues related to the threat to population's health, food security or environmental concerns. European strategies in the field of Research, Development and Innovation aim at increasing the role and significance of patenting and at enhancing the protection and implementation of scientific breakthroughs. Although Europe has made progress in this area, the European office is still behind those from China, USA. Japan or the Republic of Korea. European countries, through Germany and France, are among the world's top holders of patents. Romania, although it has nationally recorded a number of progresses in the field of patent registration, registers low international shares. in particular, due to the prohibitive costs of patents registration. Romanian universities occupy modest positions in the field of patenting, registering an average of 1.4 patents / year. Supporting and encouraging national innovation and filing patent applications should be supported at governmental level, by reducing formalities, the duration of acquiring the patent and the patenting costs.

Keywords: innovation, patents, Europe, Romania

Introduction

Applied research and innovation represent a current priority for the European policy. According to Community guidelines, innovation must be a strong point for States Member in economic growth and for the creation of decent, quality and stable jobs, especially for young people, economic growth and socio-economic convergence, migration, security and the fight against populism. Research and innovation can improve the living conditions of EU citizens, representing key elements of the European Commission's policies, which seek to stimulate employment, economic growth and investments. Research and innovation can provide scientific knowledge and practical solutions for diminishing / avoiding certain short-term threats to the European area that may affect the health of the population (poliomyelitis epidemics, Zika, Ebola, etc.), food security and safety (lack of food , genetically modified production, etc.), social balance and humanitarian issues (refugee crisis, unequal distribution of incomes, etc.), or can respond on long-term to certain society challenges related to transport, climate changes or energy (European Parliament, 2017). The European Commission's recommendations to States Member aim to increase the funds allocated to research and development, being recommended to exceed the threshold of 3% of GDP until 2020 (1% of public funds, 2% of private investments), which is estimated to generate 3.7 mill. of jobs and would determine an annual EU GDP increase of around 800 billion euros. At the same time, the European Commission proposes a reduction of up to 80% in patenting costs at European level, with simultaneous recognition of patents in the 25 signatory states of the agreement, to boost the European patenting activity.

Materials

Information on patent applications filed at European level has been selected from the European Patent Office's statistical database. For the Romanian patenting, data were collected from the official statistics of the Romanian State Office for Inventions and Trademarks. The analysis period was 2006-2016, depending on data availability. For the European legislation in the field, there have been used the official releases of the European Parliament and the European Commission. National patenting legislation has been selected from the website of the State Office for Inventions and Trademarks and official publications of the Government of Romania. Where necessary, one related also to other sources, represented by scientific publications or official journals. Data have been systematized, statistically interpreted and graphically represented.

Patenting at European level

At European level, the body responsible for registering and validating patent applications is the European Patent Office (EPO), body of the European Patent Organization, an intergovernmental organization consisting in 38 countries (the Member States and 11 other European countries including Turkey).
Globally, over 80% of patents granted worldwide are granted by the European Patent Office (OEB), the Japanese Patent Office (JPO) and the United States Patents and Trademark Office (USPTO) (Rasvan, 2017).

In the statistics World Intellectual Property Organization WIPO, EPO has been the fifth in the year 2015, as number of patents registered (figure 1).

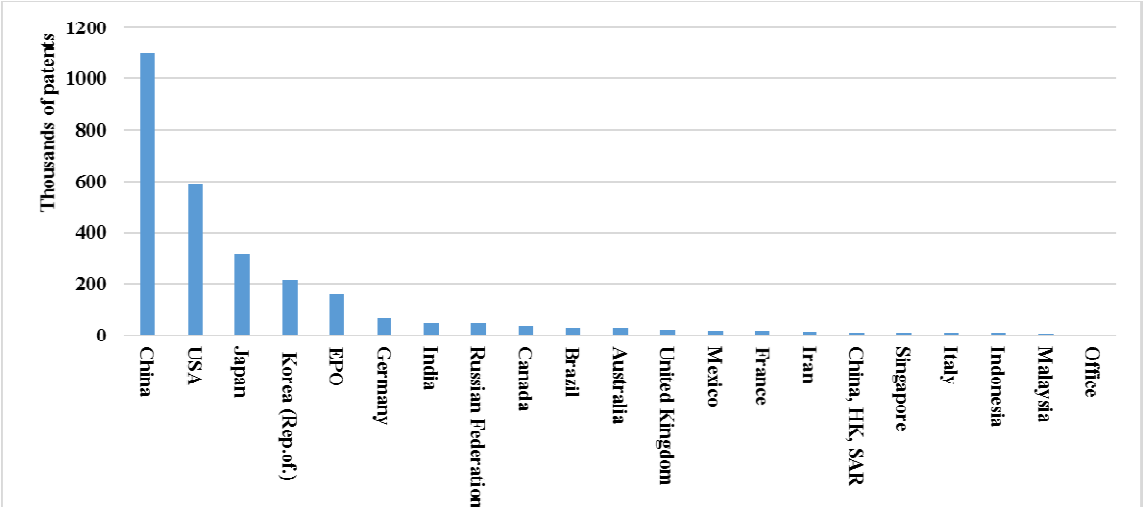

Figure 1: Patent - Applications for the top 20 offices (2015)
Source Authors, by using WIPO Data (2017)

It should be noted that in WIPO statistics, China, with an increase of 18.72% towards the previous year and with 1,101,864 patents registered in 2015, is the first state in the world to exceed the limit of 1 million patents registered. By comparison, USA and Japan, which are the second and third in Top 20 Patents WIPO registered, record cumulatively only 908,131 patents. Europe is represented by Germany, UK, France and Italy in the world top.

In Europe, the OEB examines the patent applications, being responsible for granting patents registered to the European Office if the necessary conditions are met. For the patent granted to be valid in a State Member, the inventor must apply for its national validation in each country where patent protection is sought. The process involves administrative and translation costs of up to € 32,000 when seeking for patents protection in EU-27, amount of which € 23,000 represent the translation fees. By comparison, obtaining a patent in USA costs an average of 1,850 euros. In order to preserve the validity of the patents, it is necessary to pay each year the extension fees in each country, and the patent transfer or a license agreement to use the patented invention must be registered in the same way (Romanian Permanent Representation attached to the European Union, 2017).

A statistic of patent applications registered depending on the residence state of the first author of the patent shows that 1,484,472 applications were registered to EPO during the period 2007-2016, from residents of 169 countries out of 177 registered in the European database. The dynamics of the applications registration during the analysed period is shown in Figure 2.

The largest share of registrations was recorded to EPO during 2015, when 160,004 applications were filed.

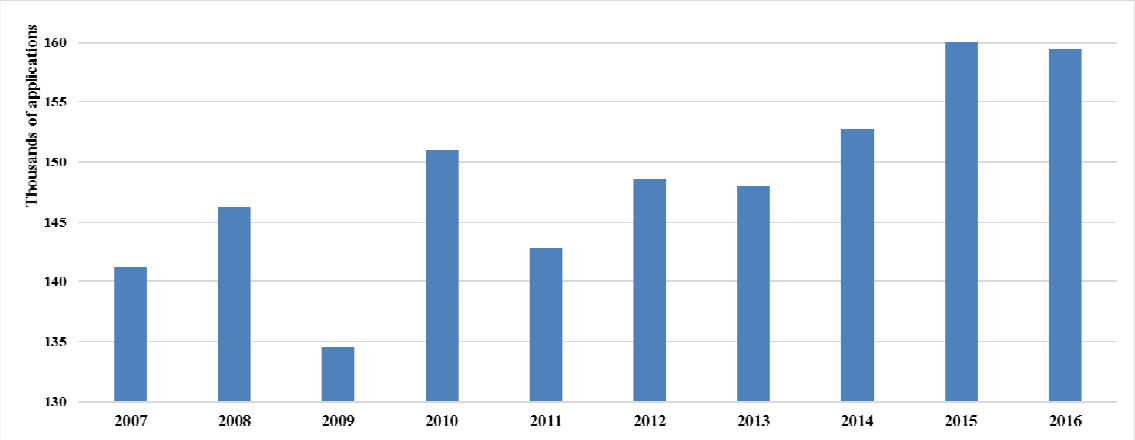

Figure 2: European patent applications 2007-2016
Source Author, by using EPO Data (2017)

Depending on the residence of the patent owner, in the top of the countries with the most applications to EPO during the analysed period, the USA ranks first, followed by Germany and Japan, covering over 50% of the total (Figure 3).

Benin, Bolivia, Botswana, Congo, Democratic Republic of Guadeloupe, Saint Helena, Vatican, and Zambia have no application registered during the analysed period.

With a total of 240 applications registered to EPO, Romania ranks 56 among the top of 177 countries from EPO base.

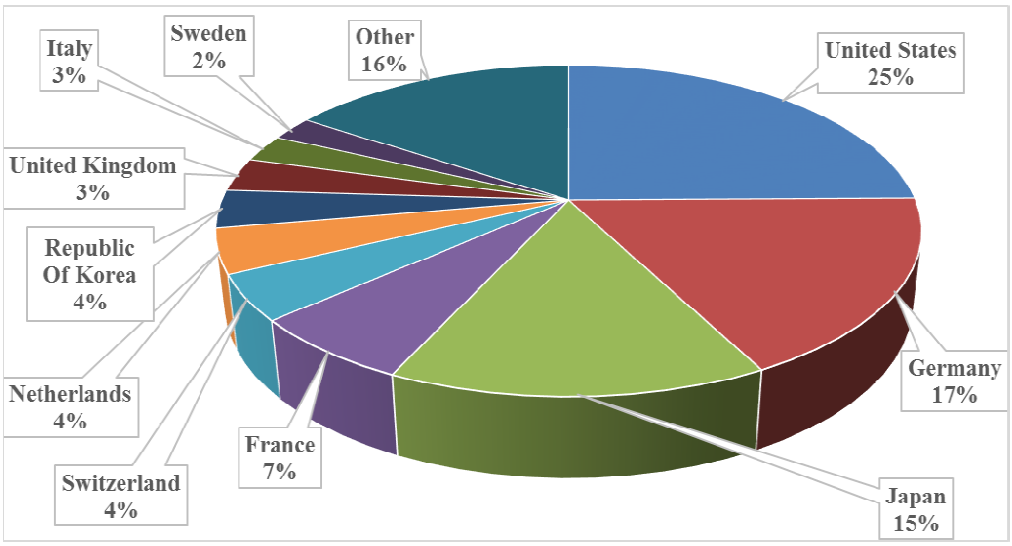

Figure 3: Top 10 European patent applications per country of residence of the first named applicant (2007-2016)

Source Author, by using EPO Data (2017)

Among the applicants residing in EPO member states, during 2016, 97,167 applications were submitted for patenting, increase with 370 units towards the previous year (Figure 4).

Germany is ranked first in the statistics of EPO members, a total of 31,815 applications being submitted last year, and representing more than a third of patent applications registered to EPO.

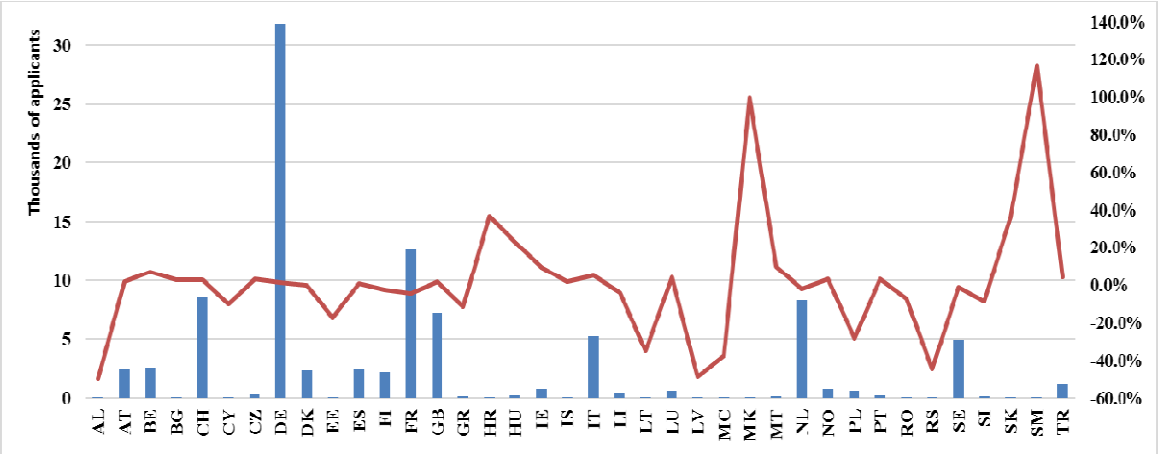

Figure 4: Patent applications registered by EPO state member during 2016 and evolution towards 2015

Source Author, by using EPO Data (2017)

France ranked second in the hierarchy last year, with 12,726 registered applications (still having a decrease of 4.3% compared to the previous year). Although it recorded at its turn a decrease with 2.1% in patent applications compared to the previous year, the Netherlands ranked third in the top from 2016, with 8,339 applications. Leading positions are completed by the Netherlands, the Czech Republic and

UK. Leading positions are also occupied by Germany, France, the Netherlands, Switzerland and Sweden, which are included in Top 10 Worldwide Patents.

Patenting in Romania

The sole authority on the Romanian territory with tasks in ensuring the protection of industrial property, in accordance with the national legislation in the field and with the provisions of the international conventions and treaties to which Romania is part, is the State Office for Inventions and Trademarks, OSIM.

OSIM operation is mainly based on the Government Resolution no. 573/1998 (Government of Romania, 1998), amended and completed by Government Resolution no. 63 from 23 February 2017 (Government of Romania, 2017). According to the legal provisions currently in force, OSIM is a specialized body of the central public administration with legal status, subordinated to the Ministry of Economy. The legislative provision issued by the Government of Romania this year passes OSIM from the Government subordination to that of the Ministry of Economy. OSIM prepares and submits to the Government of Romania the strategy for the development of industrial property protection in Romania and applies its policy in the field. OSIM is entitled to register and examine the applications from the industrial property field by releasing titles of protection conferring to the holders exclusive rights on the Romanian territory, as well as the depositary of the national registers of applications filed and national registers of protection titles granted for inventions, trademarks, geographical indications, drawings and industrial designs, topographies of integrated circuits, new plant varieties, being liable for the national collection and its correlation with international databases. If necessary, OSIM performs, upon request, specialized services in the field of industrial property, holds training programs in the field and performs any other tasks in the field of industrial property resulting from the legal provisions in force and from the international agreements. The unique protection title of inventions in Romania is the patent of invention, valid for 20 years, from the date of establishing the regular national depositary. Patenting is a formalized and laborious process that can reach Romania up to 30 months. The costs of patenting and validation of patents in Romania are quite high, although there is a tendency to reduce them, process also registered at European level. In this direction, the Government of Romania aims to reduce the formalities and costs of patenting, the new tax grid is presented in Annex 1 of the Law on Intellectual Property Taxes (Government of Romania, 2015).

The Official Industrial Property Bulletin of Romania (BOPI) is the publication of OSIM where inventions are made public and other industrial property categories patented. OSIM edits and publishes the series of invention patents, the Romanian Industrial Property Magazine and other publications intended to promote its object of activity. Romania is part of numerous multilateral agreements and treaties in the field of invention patents, the most important being presented in table 1.

Patents registered in Romania

Evolution of validated patents in Romania during 2006-2016 is presented in Figure 5. According to OSIM data, a total of 30,717 patents were registered and approved in our country, during the analysed period, out of which 27,062 after joining the EU. As share, more than 80% of patent registrations to the national office come from recognitions of European patents based on the international agreements to which Romania is part.

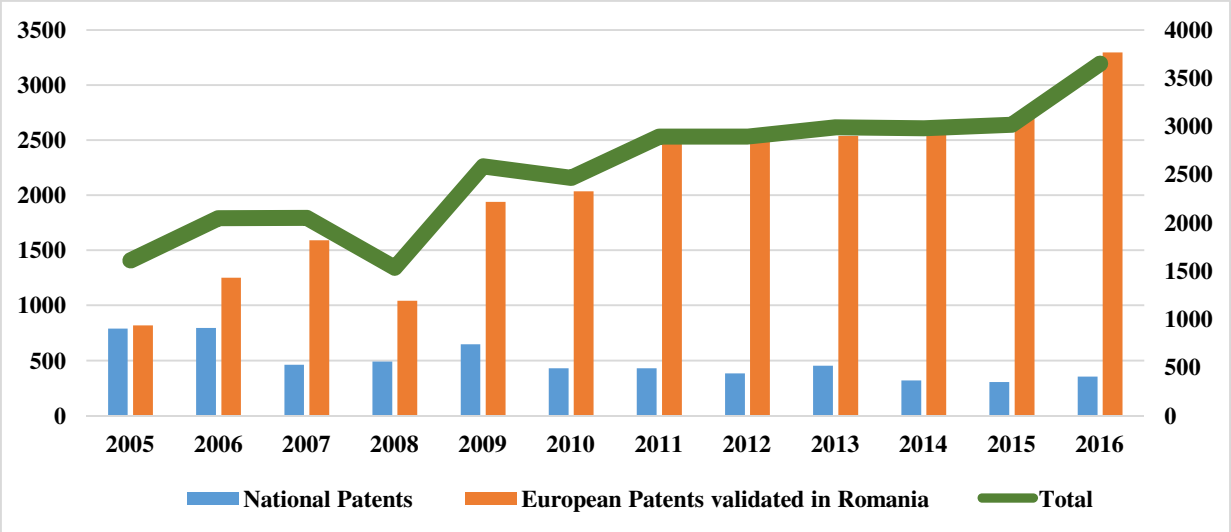

Figure 5: Patents registered in Romania (2005-2016)

Source Authors, by using OSIM data (2017b)

During the period 2005-2016, 13,331 patent applications were filed, out of which 12,672 belonged to the Romanian citizens, representing over 95% of the total. Residents abroad submitted only 659 patent applications to OSIM.
The main category of applicants for patenting research results consists in natural persons, which represent almost 50% of the total (Figure 6).

Although it has improved as share, the share of patents requested by universities accounted for just over 15% of the total number of applications registered during the analysed period, being close to the percentage recorded by private companies.

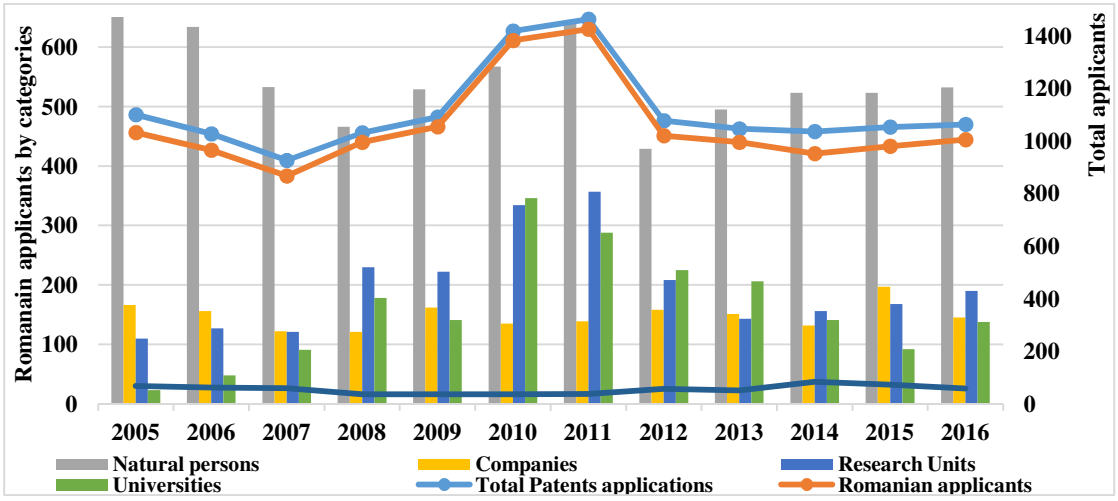

Figure 6: Patents applications submitted by Romanians

Source Authors, by using OSIM data (2017a)

The number of patent applications registered by universities has recorded a maximum in 2010, with 346 units, after which it recorded a significant decrease, reaching 92 units in 2015. Last year there was a slight increase of the applications, filed to OSIM with 138 units. Companies have registered between 150 and 200 validated patents, with a minimum of 122 units in 2007 and a maximum in 2015 with 197 patented applications. Specialized research units filed 2366 patent applications.

Patents Applications Registered and Validated By Universities

During the period 2005 - 2016 the evolution of patent applications registered by universities is presented in Figure 3. The data presented by OSIM are relatively differentiated according to the statistical department that presents them, there being small differences between the statistics from Figures 5 and 6.

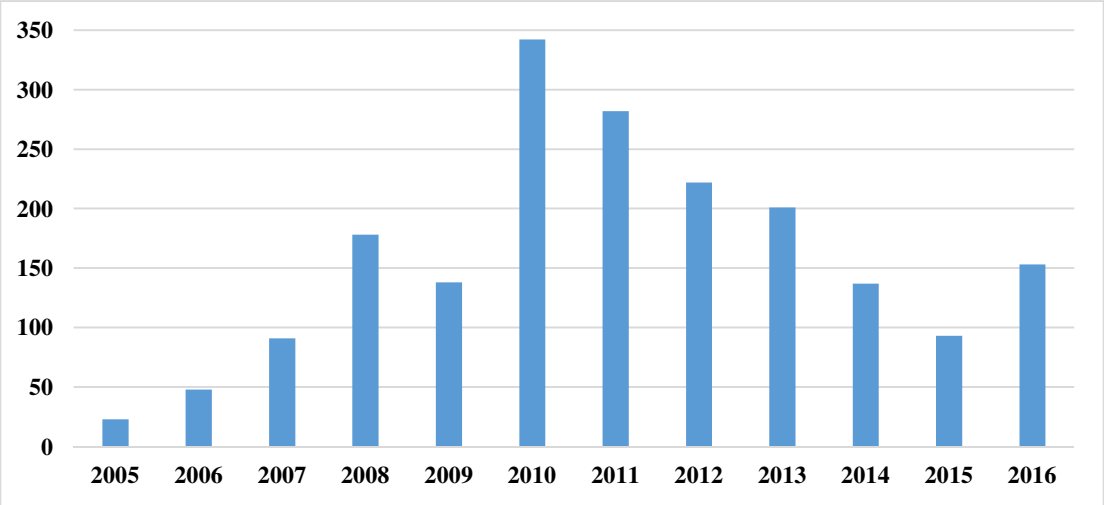

Figure 7: Invention patenting applications registered by Romanian universities
Source Authors, by using OSIM data (2017b)

The situation presented by OSIM regarding patent applications registered in 2007-2016 by the 37 universities from Romania with contributions in this field is presented in table 2.

Source Data processed by authors from OSIM statistics (2017a).

A single patent was required by the Land Forces Academy "Nicolae Balcescu" and the University of Medicine and Pharmacy of Târgu Mureş, while the first positions are occupied by Ştefan cel Mare University of Suceava, Transilvania University of Braşov and Gh. Asachi University of Iasi, with 515, 191, respectively 178 registered applications (Figure 8)

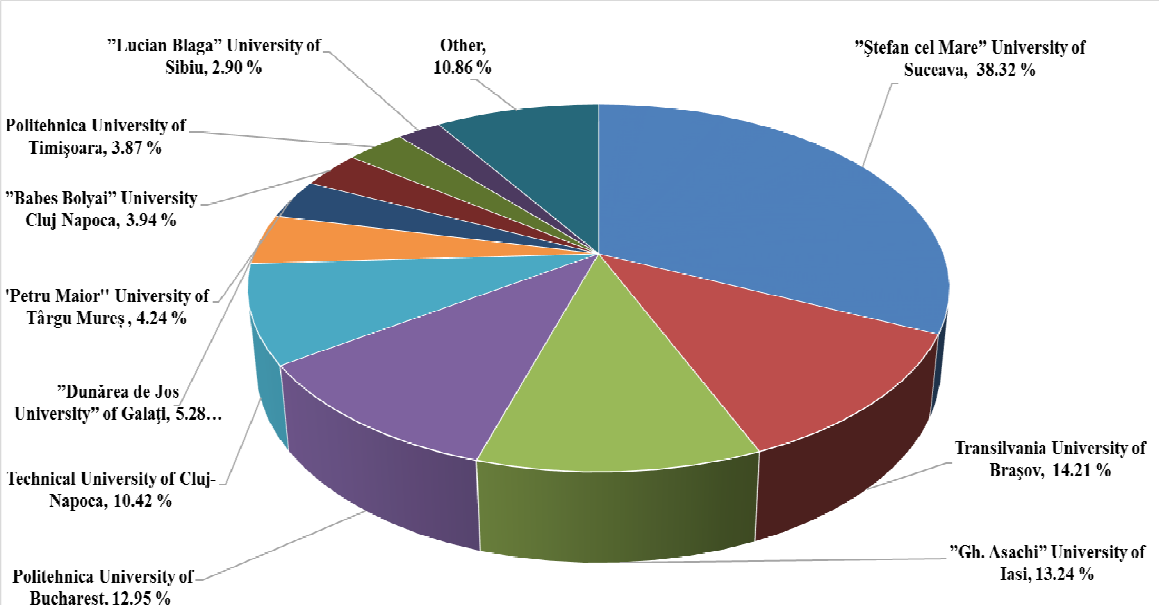

Figure 8: Patents application registered to OSIM, shares by university

Source Author, by using OSIM Data (2017a)

In fact, the first 10 universities, hierarchically ranked according to the number of registered patent applications, accounted for almost 90% of the total number of university patent registrations at national level. Engineering sciences, represented by technical universities, are the best represented in the statistics presented, the last positions being the military and medical fields.

Conclusion

Innovation and patenting of scientific research results is a priority at the European level, which has sought to maintain a leading position at international level and to reduce the gap towards the main competitors on the global patent market. Europe ranks the 5th among the patents registered to EPO, Germany being among the top 10 in the world. Romania holds modest positions at European and international level as number of patents registered, partly due to the high costs imposed by the registration and validation procedures. At national level, most patents are acquired by individuals, followed by research institutes, companies, and universities. The number of patents owned by individuals registered in the national database exceeds the cumulative value of patents validated for legal entities. The national legislation is correlated with the European rules, Romania being part of the main agreements and international treaties in the field of intellectual property.National economic growth can be sustained only by accelerating the national innovation process at national level and increasing the number of patents registered to OSIM and internationally recognized. The support for Romanian inventors should be carried out at national level through governmental measures to support RDI, both on public and on private level.

Abstract

Wheat (Tritucum aestivum) is of particular economic importance for Romania's agriculture grace to its national tradition, economic conditions of cultivation, high productivity and convenient preservation methods for long-term storage. The nutritional and technological processing potential allows multiple uses for wheat grains, both for direct human feeding and for industrial processing. The paper forwards a presentation of the multiplication plan for the surfaces sown with Romanian and imported wheat seeds lots and the certification thereof. The certification implies an extensive and rigorous series of technological sequences of the multiplication, conditioning, packaging, labelling and sealing process, procedures compliant e with the specific rules and technical norms meant to lead to the production of quality seeds. The research carried out aimed at assessing the potential of the Braila County, Romania, in the production of certified wheat seeds, in a national context, highlighting the conditions imposed by the Romanian legislation in the field. Braila County occupies the first positions on the national level in the production of certified seeds and sowing/planting material. The cultivated areas, the number of producers and the wheat varieties cultivated for seed have exhibited a positive evolution during the analysed period, on teh background of a growing demand due to a better use of the agricultural potential of the area and the interest of local farmers for this activity.

Keywords: grain, seed, quality indicators, Brăila farms

Introduction

Wheat is of particular economic importance for the Romanian economy, being a large-scale grown plant, appreciated by farmers due to economic and less demanding crop conditions, with high yield per hectare, high storage capacity, and multiple uses both the direct human food and for industrial processing.

The National Institute for Agricultural Research and Development (NIARD) Fundulea is the main research facility in Romanian agriculture, which, although in recent times is facing fierce competition from the multinational companies present in our country, occupies a preferential position in the top of the Romanian farmers' wheat-related choices (Dobre, 2016). National Institute for Agricultural Research and Development (NIARD)Fundulea is specialised in obtaining Romanian wheat varieties, productive and resistant to drought and diseases, adapted to local climatic and soil conditions. Every year, the Fundulea Institute sells about 3-4 thousand tons of basic seed for seed growers, who multiply them for sale on the market. Currently, according to National Institute for Agricultural Research and Development (NIARD) Fundulea researchers, over 65% of the total area cultivated with wheat in Romania is sown with varieties obtained by the Fundulea institute.

In order to obtain high quality seeds, with the permanent maintenance of the genetic structure and biological value at the initial level of the varieties of farming plants, it is necessary to scientifically substantiate the activity in the field of seeds, applying the theoretical knowledge from the field of genetics, improvement and seed production, respectively (Păcurar, Oprea, and Sălăgean, 2007). According to the quoted authors, the unaltered preservation of the original genetic heritage in the case

of wheat seeds is difficult, given the action of certain genetic factors: specific to genetic evolution (mutations, gene migration, natural selection, genetic drift), subjective (artificial selection in seed production) or technology (agricultural conditions, technologies, mechanical mixtures at harvest/conditioning, storage conditions, etc.) which may lead to deprecation of the biological value and the decrease of the initial production capacity of the varieties, namely the drop of the seeds vitality.

Material and Methods

The information on the technology for obtaining grain cereal seeds was selected from the National Institute for Agricultural Research and Development(NIARD) Fundulea documentation or from the technical publications. In some cases, media information from specialised journals for the agricultural sector has also been used. Data on areas cultivated with wheat for seed, authorised economic agents, yields obtained, cultivated varieties were selected from the databases of the National Seed Quality Inspection (INCS) and of the Braila Territorial Inspectorate for Seed and Sowing Material Quality (ITCSMS). The data collected were statistically processed and graphically plotted, the results being analysed and commented.

Technological Elements

The obtaining of seeds for the grain cereals varieties consists of three consecutive steps: obtaining the seed from the improver, producing the basic seed, producing the certified seed.

When sowing one used the basic seed or the pre-basic seed, organising seed-producing lots for obtaining "Certified Seed 1" (C1). This biological seed stock is used to sow about half of the areas destined to production for consumption. By using for sowing "certified seed 1" seed (C1), one organises seed-producing lots for the production of "Certified Seed 2" (C2) used for sowing about half of the production area destined to consumption. This seed, obtained in the first year by for sowing the seeds from the Basic biological category, is the „certified seed 1” (C1), and by sowing it one obtains the "certified seed 2" (C2). The seeds from the certified biological category (C1, C2) are produced in the development sector of the National Institute for Agricultural Research and Development (NIARD) Fundulea, in the agricultural research facilities and in the authorised private farms with activity in the seed-producing domain.

The technology of wheat seed production is based on the application of the well-known agricultural technology, taking into account some particularities related to the location of the crop; rotation of crops; pre-emergence plants; soil works; fertilisation; seeding; biological purification, combating weeds, diseases or pests; irrigation; harvesting, drying, conditioning and preserving seeds (Agriculture Journal, 2015). The wheat seed crops are to be sown on fertile fields, protected from insects and free of weeds. The best precursors are: soy beans, beans, corn; sun-flower is not accepted for multiplication in a soil plot that sown with wheat in the previous year due to impurification caused by samulaster. Te fertilisation of seed lots is very important fro completing the need of nutrients in the soil. The cultivation technology is done with high quality seeds and high performance machinery. The sowing period, the quantity of seed/ha, the depth and uniformity must be rigorously achieved and respected. The weed control is carried out with herbicides, the weeds are negatively influencing the quality of the seed, the twinning capacity, the frost resistance, the drought, the vegetative growth of the plants, the elements of the spike productivity, cause the occurrence and the intensification of the planting process and the fall of the plants (in the case of clinging weeds). Diseases and pests are eliminated by vegetation treatments whenever needed. The biological purification is a very important work in the seed lots and consists in the elimination of all non-typical plants in order to ensure the biological purity provided for in the certification rules. For the purpose of achieving a certain qualitative and quantitative production it is recommended to irrigate the seed crops. Seed harvesting takes place on parties of the same species, variety and biological category responsible for maintaining identity and varietal purity through measures to avoid any further contamination, by rigorously cleaning the harvesting equipment and the means of transport used, as

well as the elimination of the areas marginal or in the vicinity of irrigation channels (Ordinance 59/2011). After harvest, the seed is transported from the field to the processing stations accompanied by the Field Inspection Document with the decision „admitted" and the Transport Certificate. The processing operation is carried out by the economic agents authorised for processing which have a processing station and are monitored annually by the TIQSS in this respect. The processing operation is carried out with machines and advanced aggregates, grouped in plants that are commonly called seed conditioning plants (Bularda, 2011). Seed processing includes the sequences of seeding, pre-cleaning, cleaning, conditioning, loaning, packaging, closing, sealing and labelling, according to the Order of the Minister of Agriculture and Rural Development MARD (149/2010). After seed processing there comes their certification, lotisation and then sampling of the seed lots.

Certification of Seeds and Authorisation of Sowing Material Producers

The certification of the seed lots is registered by the economic operators who are seed owners who process their own seed or those who carry out the seed treatment on the basis of a service contract with an authorised economic agent and monitored annually in this respect on the basis of the document "Declaration of certification of seed lots". The declaration of certification is accompanied by the following documents: the document of field inspection" with the decision „admitted", the written consent of the variety keeper that it has the right of sale, the contract of "service provision in view of processing" and the "transport documents" completed with the quantity of seed harvested in the field. The determination of the variety purity is done with the metric frame in 5-20 control points, depending on the size of the wheat sown plot. At each point, all the components of the chain are determined, and the following determinations are made: the number of plants typical to the variety, the number of plants non-typical for the variety, the culture plants with difficultly separable seed, weeds with heavily separable seeds and plants attacked by quarantine pathogens. For a seed to be declared "admitted" in the field, it must meet the following conditions: the Prebase Seed G1, Prebase G2, Base must have a minimum purity of 99.9%, the Certified Seed C1 99.7%, and the Certified Seed C2 a minimum purity 99.0%. Once all the above conditions have been met, the seed shall be processed, divided by lots, packaged and stored properly. Then one must complete and sign the declaration of lots certification. The weight of a lot of wheat shall not exceed 30 tons plus 5%. The sampling of the lot shall be carried out in the presence of the seed owner or a delegate thereof, by the sampling operators certified and authorised by Territorial Inspectorates for Seed and Sowing Material (ITCSCMS). The sampler verifies the data entered in the Probing Report and verifies if the requirements are met for the lot to be sampled: lot size, uniformity, sealed packaging and official label of the same type, size and quantity except for the last fraction, accessibility of the lot and checking the storage space so as it does not affect the quality of the seed during the retention period. If the above mentioned conditions are met, the sampling of the lots shall be carried out, and, if the requirements are not complied with, the sampling operator shall refuse the sampling by mentioning the reason for rejecting the sampling.

The wheat seed lots can be made by one of the following methods: Nobble probe (used when seed is packed in bags) or baton probe (for bulk or large containers) according to SR 1633/2003. Each test sample is a separate sample. The extraction of the elementary samples is carried out from different places and depths of approximately equal weight. To obtain the composite sample, all these extracted samples will be mixed. The laboratory samples to be analysed are made from the composite sample. The samples for the determination of moisture indices are packed in plastic bags, taking into account the complete removal of the air from the package, and the other samples will be packed in bags paper. On all packages the lot identification data: species / variety, biological category, lot number, quantity/bag, treatment, if applicable, bag sealing date of the will be mentioned. The moisture sample is extracted after homogenisation from different depths and the rest of the samples, namely the analysis sample, the witness sample, the postcontrol sample and the duplicate samples are obtained by reducing the compound sample (using the divider) down to the nearest weight, but no smaller, as set out in the aforementioned Standard. In order to preserve and guarantee the identity of the samples, they are sealed with a self-adhesive tape inscribed National Seed Quality Inspection (INCS). All these tests are done to verify the quality indices for seed certification. The conditions to be met in the seed wheat laboratory to be certified and accepted for sowing the following year, as regards

germination, the purity of seed content of other plant species and humidity according to Minister of Agriculture and Rural Development MARD Ordinance 149/2010 are given in Table 1.

Table 1: Conditions imposed on wheat seed lots in the laboratory

No.	Seed biological category	Germination (%)	Purity Minimum (%)	Presence of other plant species (%)	Humidity Maximum (%)
1	Seed Prebase G1, Prebase G2, Base	85	99	4	14
2	Certified seed C1	85	98	10	14
3	Certified seed C2	85	98	10	14

Production of Wheat Seed Lots in Brăila

According to **Mureşan** (2012), the production of wheat seed lots is a complex process, which takes place within an institutionalised framework. The creation of valuable biological forms and their maintenance in an institutionalized process of seed production is an activity with important social and economic implications, which must respond to the development of the national economy. At the level of the specialised institutions, it is envisaged to receive lots of qualitative seeds, under economical conditions and in sufficient quantity. Seeds intended for sowing must be able to reproduce as accurately as possible the cultivation pattern and the set of specific peculiarities thereof and to possess phytosanitary purity, strength and cultural value according to the standards in force.

The seeds sold to agricultural producers are the result of multi-institutional co-operation, the main role of the Ministry of Agriculture and Rural Development. Te National Seed Quality Inspection (INCS) is the nationally accredited certification body for seed lots. In the territory, INCS acts through the Territorial Inspectorates for Seed and Sowing Material (ITCSMS) and the Central Laboratory for Seed and Sowing Material Quality (LCCSMS).

The production of seed material is usually done in Romania on the basis of a contract between the seed company and the farmer. In line with the new global trend in seeds and seed production, large companies produce seed multiplication near where they sell them, thus avoiding additional shipping costs and possible shortcomings due to the lack of adaptation to local climate and soil conditions.

For the production of seed lots, it is possible to register, according to the legal provisions, any natural or legal person who proves that he has the necessary technical and material equipment and personnel with appropriate knowledge for the requested activity. The methodology of the Ministry of Agriculture, Forests and Rural Development (MADR) (2009) specifies the conditions imposed on agricultural producers involved in the production of seed material and the national and county bodies in charge of controlling this activity.

Braila County is the most important region in the sector of seed production on the national level. For the hybridization with sunflower and corn, the share of cultivated areas in the county exceeds 45% National Seed Quality Inspection (INCS Braila, 2012).

According to Territorial Inspectorates for Seed and Sowing Material (ITCSMS) Brăila (2017), the area of 18,479.31 ha of seed lots of cereal, corn, sunflower, mustard, lucerne and on small surfaces coriander (5 ha), potato (2 ha), flax (2ha) and planting material (1.71 ha) on 560 registered plots (according to Table 3), of which 18,227.71 ha were admitted, 196.6 ha being rejected. The wheat seed is cultivated on an area of 4,002.5 ha fully admitted according to Table 2. The area of 3,087.5 ha is sown with Romanian wheat and the rest with imported varieties.

In the year 2015 530 plots were registered with a total area of 13,402 ha of agricultural land intended for obtaining seeds, of which 13,248 ha were admitted and 129,9 ha were rejected. For the cultivation

of seed wheat, out of the 3,187 ha recorded, on the 152 plots 3133 ha were admitted, of which 2,275 Romanian varieties and the rest foreign varieties. In 2014, an area of 18,941 hectares was registered for multiplication, representing lots of cereal seed, oil plants and fodder plants. The multiplication of the area of wheat was smaller than in previous years of 3159 ha of the Romanian grain variety seedlings an area of 2,422 ha, the rest being sown with foreign wheat varieties as shown in Figure 1 on 137 plots, of which 3,139 ha were admitted, the remaining 20 ha being rejected from multiplication.

Table 2: Situation of seed-producing surfaces in Brăila County

No	Harvest year	Plan (ha)	Plots planned	Admitted (ha)	Admitted Plots	Rejected (ha)	Plots Rejected
1	2014-2015	3,159	137	3139	136	20	1
2	2015-2016	3,187	152	3133	149	54	3
3	2016-2017	4,002.5	206	4,002.5	206	-	-

Source Author, by using ITCSMS Braila data (2017)

In the case of wheat there is a great diversity, with some drought resistant and frost-resistant varieties, others being adaptable on soils with low fertility. The choice of wheat variety must be made taking into account these factors and the genetic potential of the variety, so that high yields are obtained at harvesting. The cultivation of some wheat varieties not adapted to the crops involves very high expenses with the culture technology and the production will be insufficiently capitalized. Choosing a sort of wheat to ensure the best match between the pedoclimatic resources of the area and the biological characteristics of the variety is an essential condition for obtaining a large and stable production.

Table 3: The situation of the surfaces sown with Romanian and imported varieties in Braila County

No.	Romanian varieties (ha)	Plots cultivated with Romanian varieties (ha)	Imported varieties (ha)	Plots cultivated with imported varieties (ha)	Multiplying farmers
1	2,422	99	737	38	57
2	2,275	106	912	46	74
3	3,087.5	138	915	68	114

Source Author, by using ITCSMS Braila data (2017)

Besides the high production capacity, the varieties must also have good resistance to the main risk factors and have a qualitative potential corresponding to the requirements. Procurement of quality seed of the varieties recommended for each crop area is an important decision for the production of the next yea.

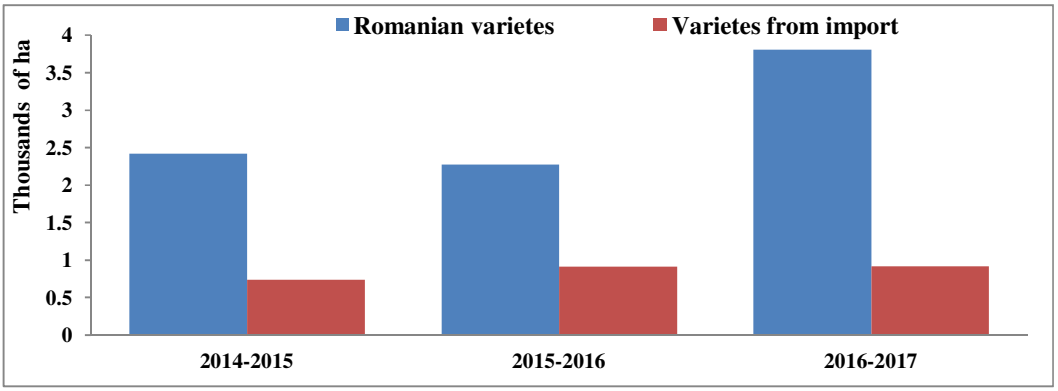

Figure 1: The situation of the surfaces of the Romanian and foreign wheat seed lots in Brăila county

Source Author, by using ITCSMS Braila data (2017)

Territorial Inspectorates for Seed and Sowing Material (ITCSMS) Braila has granted authorisations for the production, processing and/or sale of seeds or planting material to a number of 336 economic agents, with 386 working points. A total of 569 permits were issued, of which 49 new permits, and a number of 29 permits were withdrawn from the economic entities that did not fulfil the conditions for authorisation.

The main wheat varieties and the quantities certified for production in 2017 in Braila County, according to the National Seed Quality Inspection (INCS) Official Certification Database, are presented in Figure 2. In 2017, 34 wheat varieties were cultivated, 172,088 tons of wheat for seed. The common wheat varieties predominate, only 1.15% of the total, namely 2,256 kg, is originated from hard wheat varieties Atoudur and Pascadou. Almost 70% of the crop obtained is certified seed C1, and only 12% is of the basic/pre-basic seed category.

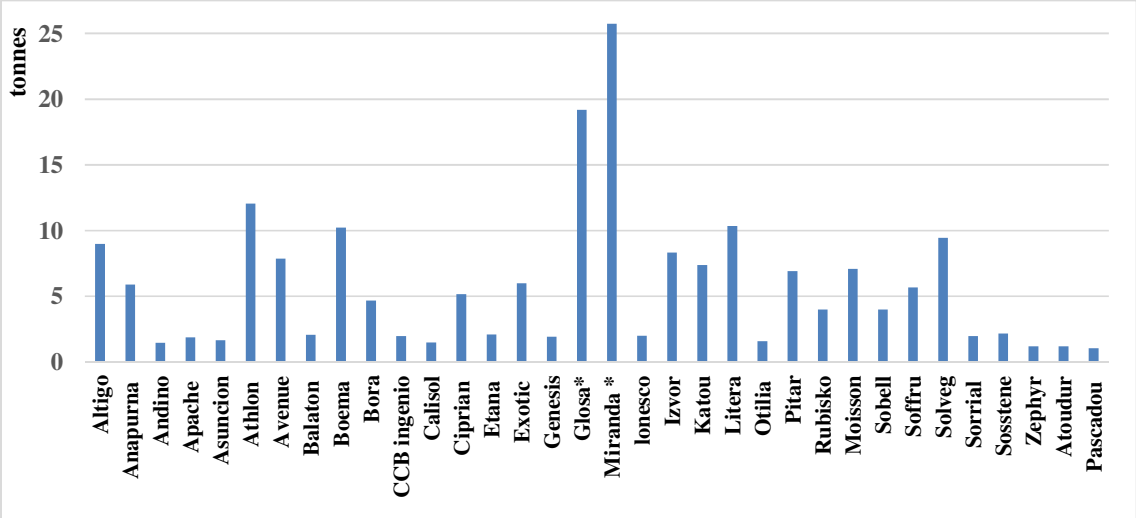

Figure 2: Certified wheat varieties cultivated for seed in Braila County

Source Author, by using INCS (2012)

More than one-third of total production in 2017 was made by the Miranda, Glosa, Athlon and Boema varieties. The Glosa variety was the most appreciated, in spite of the native wheat growth, produced at National Institute for Agricultural Research and Development (NIARD) Fundulea, being cultivated on about 35% of the total area allocated to wheat in our country (Sofron, 2016).

Pitar, with 6910 kg harvested in Brăila in 2017, is a relatively new variety, with high potential for Romanian agriculture.

Conclusions

The seed production activity involves specialists, much higher technology, technical endowment, varieties and hybrids adapted to the area, higher costs but also high incomes. The efficiency in seed production is the existence of technological links executed very rigorously and without which the realisation of lots is not possible.

A high-quality wheat seed must have good genetic and biological value, varietal and physical purity, superior germination index (mass of one thousand grains and hectolitreal mass), health and vigour. The seeds quality has always been determined to the same extent by the quality of the genetic material (seed), the soil types, the level of technologies applied, the provision of the technical materials (machinery, fertilizers, pesticides, irrigation) and the qualification of information, research and innovation of the multiplier. The process of certification of the lots destined to sowing on large areas is laborious and closely monitored by the local and national authorities.

Braila County is making progress in obtaining quality seeds and plating materials, improving its national position. Particular stress is laid on the production of seed wheat of the Romanian varieties, better adapted to the local climatic and soil conditions. Although the certification process is complex and licensed manufacturers are subject to a number of restrictive conditions, the domain is attractive for the local producers.

Risk Management Methods in Construction Projects

Petr Řeháček, VŠB-Technical University of Ostrava, Faculty of Economics, Ostrava, Czech Republic, perehacek@gmail.com

Blanka Bazsova, VŠB-Technical University of Ostrava, Faculty of Economics, Ostrava, Czech Republic, blanka.bazsova@vsb.cz

Abstract

Construction objects life cycle is full of various risks. Risks come from many sources: temporary project team that is collected from different companies, construction site, etc. Moreover, the size and complexity of construction objects are increasing which adds to the risks. The object risks can be identified and evaluated by using the Pareto analysis, Saaty´s matrix or decision tree. We can assess an uncertain events or conditions which have a positive or negative effect on at least one construction project objective. The risks cause cost and time overruns in construction projects. The paper presents risk assessment methods which aims to identify, analyze and evaluate the risks associated with the construction projects.

Keywords: evaluation, management, methods, project, risk.

Introduction

The risk factor in construction business is very high. Construction objects are unique and built mostly only once. Risk management is a concept which is used in all industries, from IT related business, automobile or pharmaceutical industry, to the construction sector. Each industry has developed their own risk management standards, but the general ideas of the concept usually remain the same regardless of the sector. Decision-making is very important in the construction management, such as risk assessment results in construction projects, contractor and supplier selection, etc. Each project manager should have a basic knowledge about risks associated to a project and how to handle them. Risk management should be conducted on all projects. The degree, level of detail, sophistication of tools, and amount of time and resources applied to risk management should be in proportion to the characteristics of the project under management and the value that they can add to the outcome. Thus, a large project that provides value to an important customer would theoretically require more resources, time, and attention to risk management than would a smaller, short-term, internal project that can be conducted in the background with a flexible deadline.

The principles of risk management should be appropriately applied based on the specifics of a project and the organizational environment. Risk management provides benefits when it is implemented according to good practice principles and with organizational commitment to taking the decisions and performing actions in an open and unbiased manner.

Types of Risk

The risk management process in construction is extreme and important. Risk measure includes risk level determination of each objective and the risk analysis estimation by applying various approaches and technology. Risk control process evaluates performance of risk control. Risk identification is the first and main step of risk management process. It is describing the competitiveness conditions and the clarification of risk and uncertainty factors (Rutkauskas, 2008; Zayed et al., 2008), recognition of potential sources of risk and uncertainty event responsibilities. According to the Zavadskas et al. (2008) the project risks can be divided into three groups - external risks, project risks and internal risks. External risks are those risks that are beyond the control of the

project management team. Internal risks can be divided according to the party who might be the originator of risk events such as stakeholders, designer, contractor, etc. There are various classification ways of risk management methods. External risks (environmental criteria) includes political risk**,** economic risk, social risk and weather risk.

Political risks are changes in government laws of legislative system, regulations and policy and improper administration system, etc. (Li and Liao, 2007).

Economic risks. There is inconstancy of economy in the country, repayment situation in manufacture sphere, inflation and funding. Considering the current economic situation, this result can be reasonably expected (Tvaronavičienė and Grybaitė, 2007).

Social risks are the growing importance to any effort at risk allocation. It is an area in which political and social pressures from parties having little interest in a project but having a great impact on such a project greatly influence its outcome. The impact of the financial aid on social and economic development of the region is analyzed by Ginevičius and Podvezko (2009), risk communication in organizations is analyzed by Conchie and Burns (2008).

Weather risk. Except for extremely abnormal conditions, it is a risk for the contractor to assume, as its impact on construction methods can be assessed by the contractor.

Project risks methodology is described in PMI book and IPMA Competence Baseline Rehacek (2017b). The specific criteria such as recognizing of the value of Risk Management, individual commitment (responsibility), open and honest communication, organizational commitment, risk effort scaled to project and integration with Project Management are included in each risk management process (PMI, 2013). The relationship between project risks and IT brought many authors (Ropponen and Lyytinen 1997, 2000; Yetton et al. 2000; Kwak and Stoddard 2004; Na et al. 2004; Zwikael and Globerson 2006; Han et al. 2007; Jiang et al. 2009). Many studies pointed out the hard side of the impact the risk management on the project success. Monteiro de Carvalho and Rabechini Jr. Brought examined the impact of risk management on project performance. They pointed out the importance of soft skills. The main groups of criteria of the construction projects risks belong (see Fig. 1):

1. Time risk
2. Cost risk
3. Work quality
4. Construction risk
5. Technological risk

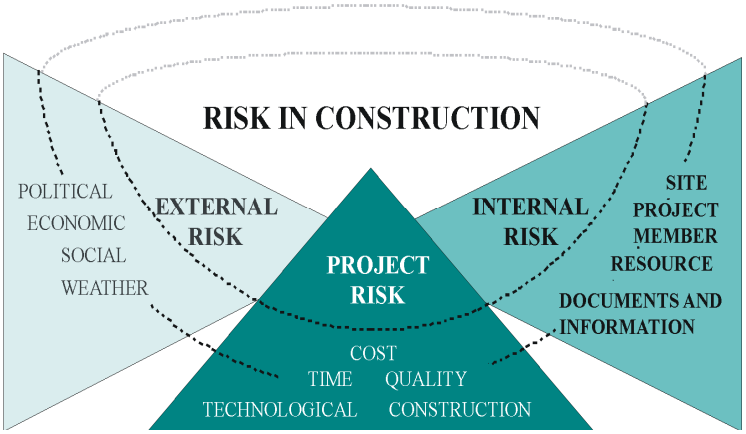

Fig. 1: The risk allocation structure in construction project (Zavadskas et al., 2008)

Time risk can be determined by appraisal of the delay at construction, technology and for all works. Cost risk. The cost of opportunity product grows due to neglecting of management (Zavadskas et al., 2008).
Work quality. Deflective work is considered a significant risk factor in this category because not only does it result in construction delays and additional cost to the contractor but it easily leads to disputes on the liability for the deflection.
Construction risk. The risks are involved in construction delay, changes in the work and construction technology.
Technological risk. Designing errors, lack of technologies, management errors, shortage of the qualified labour.

If we use Saaty´s matrix to assess the importance of these risks, we can achieve the results shown in Table 1. According to the expert ´s assessment we can calculate the weight of the particular type of risk. The highest weight has the time and cost risk (see Table 1).

Table 1: Types of risk evaluated by using Saaty´s matrix (own calculation)

Type of risk	Time risk	Cost risk	Work quality	Construction risk	Techno-logical risk	Geomean	Weight
Time risk	1	1	3	5	7	2.5365	0.386
Cost risk	1	1	3	3	5	2.1411	0.326
Work of quality	1/3	1/3	1	3	3	1.0000	0.152
Construction risk	1/5	1/3	1/3	1	3	0.5818	0.088
Technological risk	1/7	1/5	1/3	1/3	1	0.3165	0.048

Pareto analysis is based on the principle that 80-95% of the problems are caused by a small number of causes of 5-20%. These causes were formulated by Pareto and described them as a vital minority. For these reasons, it is necessary to focus, analyze them in depth and eliminate, respectively to minimize their impact. The other causes were later named by Juran to a useful majority. A graphical representation of Pareto´s claim, sometimes called the 80/20 rule, is Pareto diagram. From the Pareto diagram it is possible to determine vital causes, respectively factors that need to focus and focus on solving the problem. This diagram is composed of a bar graph and a Lorenz curve. The column graph is a cumulative number, Lorenz curve of relative frequency. To determine vital factors is a significant factor of the average factor (50%) that can be found on the Lorenz curve. Those factors above the average are a vital minority. (Bazsova, 2014)

Survey provided in 2016 with the managers of the SME showed the biggest frequency of the risk at the adverse weather. The results are displayed on the table 2 and figure 2 have shown that most companies rated the severity of the 5 most serious types of risk.

The most serious risks in a project-based organization include:

1. Risk of non-compliance with delivery date.
2. Risk of non-compliance with workflows.
3. Risk of unforeseen costs.
4. Risk of non-payment of invoices by customers.
5. The risk of adverse weather.

Table 2: The most serious types of risks from the survey

	Frequency	Cumulative share	Relative share
The risk of adverse weather	150	150	23,51%
Risk of non-compliance with delivery date	136	286	21,32%
Risk of non-payment of invoices by customers	131	417	20,53%
Risk of unforeseen costs	129	546	20,22%
Risk of non-compliance with workflows	92	638	14,42%

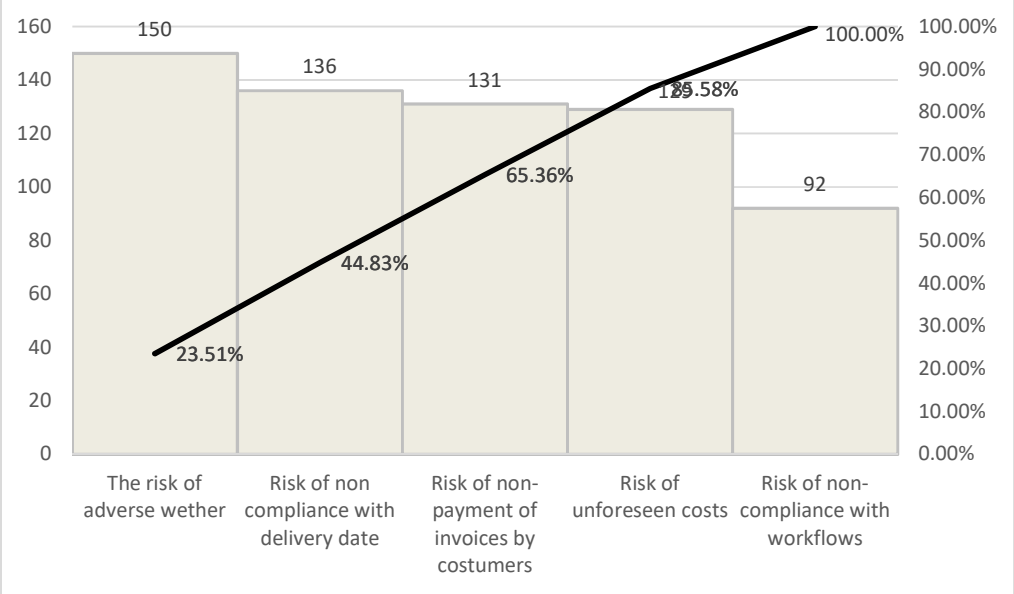

Fig. 2: Pareto diagram (own calculation)

Pareto diagram showed that the importance is at the first 3 types of risk the risk of adverse wether, the risk of non compliance with delivery date and the risk of non-payment of invoices by costumers. (see Fig. 2)

Internal (Intrinsic) Risks:

- Resource risk
- Project member risk
  - Stakeholders' risks
  - Designers risk.
  - Contractor risk.
  - Subcontractor risk
  - Suppliers risk.
  - Team risk.
- Construction site risk
- Documents and information risk

Resource risk. Materials and equipment involve considerable risks. The availability and productivity of the resources necessary to construct the project are risks which are proper for the contractor to assume (Fisk, 2003).

Project member risk. Team risk refers to issues associated with the project team members, which can increase the uncertainty of a project's outcome, such as team member turnover, staffing build up,

insufficient knowledge among team members, cooperation, motivation, and team communication issues.

Stakeholders' risks rightfully belong to the stakeholder alone and should be retained by stakeholders except to the extent that they are influenced by construction methods determined by the contractor, or created by suppliers controlled by the contractor. Stakeholders' influence on the external environment is analyzed by Mitkus and Sostak (2008).

Designers risk. The expansion of construction has placed great burdens upon the design professions. Maintaining performance standards in the face of this is quite difficult, and occasionally, design or specification deflections occur that create construction problems. Design failures or constructability errors are becoming more and apparent, and the architect should bear the true cost of such failures.

Contractor risk. The prime or general contractors are in the best position to assess the capacity of their subcontractors, and therefore it is they who should bear the risk of not assessing the risk properly.

Subcontractor risk is that is properly assumed by the contractor except where it arises from one of the other listed risks attributable to stakeholder or architect (Fisk, 2003).

Suppliers risk. Default from obligations of the supplier (Fisk, 2003).

Team risk. Team risk refers to issues associated with the project team members that can increase the uncertainty of a project's outcome, such as team member turnover, staffing build up, insufficient knowledge among team members, cooperation, motivation, and team communication issues. Working team must analyze the business activities of all alliance members and identify various risk factors in business activities and their characters (Gunstone, 2003; Li and Liao, 2007; Li et al., 2007).
Construction site risk. Accident exposures in workplace are inherent in the nature of the work and are best assessed by the contractors and their insurance and safety advisors (Fisk, 2003).

Documents and information risk. It assumes: contradiction in documents; pretermission; legal and communication. Changed order negotiation and delayed dispute resolution are significant risks during project construction. Communication is very important at all construction period and after finishing construction work.

Likewise, risk management has become a timely issue widely discussed across industries. There has been conducted by Rehacek (2017a) study in three countries which emphasizes importance of the project context considering the industry. However, with regard to the construction industry, risk management is not commonly used. More construction companies are starting to become aware of the risk management process, but are still not using models and techniques aimed for managing risks. This contradicts the fact that the industry is trying to be more cost and time efficient as well as have more control over projects. The construction industry operates in a very uncertain environment where conditions can change due to the complexity of each project (Sanvido et al., 1992). The aim of each organization is to be successful and risk management can facilitate it. However it should be underlined that risk management is not a tool which ensures success but rather a tool which helps to increase the probability of achieving success. Risk management is therefore a proactive rather than a reactive concept. These risk classifications for construction projects brought (Tsai and Yong, 2010. They point out naturel phenomenons like earthquake, fire, high gale, rainfall, economics phenomenon like materials costs, difficulty of financing, low market demand, exchange rate fluctuation, politics phenomenon like change of laws, bribery, corruption, etc.

This study brought results from the Czech republic construction companies. They have been addressed.

Table 3: Project risk structure

Natural Phenomenon	**Construction**	**Designer**
Earthquake	New technology implementation	Constructability
Fire	Too high quality standard	Vague drawing specifications
High gale	Faulty job field survey	Incomplete construction area
Rainfall	Inadequate construction planning	Incompetent supervision skills
	Inadequate procurement planning	Frequent design change
Economics/Finance		Lack of fair stance
Increased materials cost	**Job site**	
Exchange rate fluctuation	Incompetent planning	**Contractor**
Difficulty of financing	Incompetent management	Stringent contractual terms
Low market demand	Incompetent coordinator	Deficit contracting
Strong competitor		Short of manpower or experience
	Safety/Environment	Higher cost than bid taking
Politics/society	Environment damage/pollution	Short of capital/equipment
Change of laws	Accident-related loss	Local jobsite particularity
War/revolution/riot	Traffic or work hour restriction	Shortage in machine tools and workers mobilization due to clashes of several projects
Bribery/corruption	Third party's objection	
Language/cultural barrier		Low safety awareness
Lobby (legal/illegal)	**Client**	Erroneous allocation of human resource
Rigid bureaucracy	Feasibility study	Lack of trustworthy support by subcontractor
	Unreasonable demand	
Contract	Reference by subcontractors	Low working morale
Unequal contractual provisions	Relation with the third party	High personnel mobility
Dispute among entities	Late payment	
Unjust arbitrator	Reliance on architect /consultant	**Industrial characteristics**
Inadequate insurance coverage	Jobsite superintendent being incompetent	Monopolized bidding
Defect warranty	Financial problem/bankruptcy	Labour union
Misjudged cost estimation	Difficulty in choosing business dealer	

Risk Response Planning can be done by the following methods (Rajendhran and Sundar, 2011; Rehacek, 2016):

1. ***Risk Avoidance***: Risk can be warded off by removing the cause of the risk of executing the project in a different direction while still aiming to accomplish project objectives. Change project management plan to eliminate a threat, to isolate project objectives from the risk's impact, or to relax the project objective that is in jeopardy, such as extending schedule or reducing the scope.
2. ***Risk Transfer***: Transferring risk involves finding some other party who is willing to accept responsibility for its management, and who will bear the liability of the risk should it occur. Transferring a threat does not eliminate it; the threat still exists however it is owned and managed by another party. Transferring risk can be an effective way to deal with financial risk exposure. The aim is to ensure that the risk is owned and managed by the party best able to deal with it effectively.

3. ***Risk Mitigation / Reduction***: Risk mitigation reduces the probability and/or impact of an adverse risk event to an acceptable threshold. Taking early action to reduce the probability and/or impact of a risk is often more effective.
4. ***Risk Exploit***: This strategy seeks to eliminate the uncertainty associated with a particular upside risk by creating the opportunity definitely happens. Eliminate the uncertainty associated with a particular upside risk. An opportunity is defined as a risk event that if it occurs will have a positive effect on achievement of project objectives.
5. ***Risk Share***: Allocate risk ownership of an opportunity to another party who is best able to maximize its probability of occurrence and increase the potential benefits if it does happen. Transferring threats and sharing opportunities are similar in that a third party is used, those to whom the threats are transferred take on the liability and those to whom opportunities are allocated should also be allowed to share in the potential benefits.
6. ***Risk Enhance:*** This response aims to alter the "size" of the positive risk. The opportunity is enhanced by increasing its probability and/or impact, thereby maximizing the benefits gained from the project. Seeking to facilitate or strengthen the cause of the opportunity, and proactively targeting and reinforcing its trigger conditions.
7. ***Risk Acceptance:*** Ultimately it is not possible to eliminate all threats or take advantage of all opportunities – we can document them and at least provide awareness that these exist and have been identified, some term this „passive acceptance". This strategy is adopted when it is not possible or practical to respond to the risk by the other strategies, or a response is not justified by the grandness of the risk. When the project manager and the project team decide to accept a risk, they are agreeing to address the risk if and when it happens. This involves the use of a fallback (contingency) plan if a risk occurs. Contingencies can also be in the form of sometime kept in reserve to deal with unknown risks or in the form of costs to deal with unknown risks.
8. **Risk Control:** is the final step of the process (Rajendhran and Sundar, 2011; Rehacek, 2016). After we have implemented response actions, we must track and record their effectiveness and any changes to the project risk profile. Did the response actions have a positive or negative effect on achieving project objectives? Responses taken in risks should also be documented for future reference and project plans.

Risk Management Methods in Construction Projects

According to the Rajendhran and Sundar, 20011 and Rehacek, 2016 **the *Risk Identification*** can be done by the brainstorming, Delphi Technigue, Interview, Past experience, checklist and questionnaire. **Risk Assessment** can be done by the following methods (according to Rajendhran and Sundar, 2011; Rehacek, 2016): ***Qualitative Method:*** PI factor = Probability of Risk x Impact of Risk, ***Quantitative methods Sensitivity Analysis***: This is carried out to identify the uncertain and **Scenario Analysis.**

Decision Trees

The risk analysis is carried out by decision tree diagram. Decision trees are very helpful to both formulate the problem and evaluate options. In this analysis there are graphical models used to represents project and can clearly reflect the effects of each decision taken in the project. The decision tree in figure 3 displays evaluation of the project company which has three possibilities how to evolve under condition high, middle or low demand within four years. This company can even reduce its activities, or fuse with other company or to stay in the same condition as in previous years. Each edge has its utility in the decision tree. The edges together form branches. From the point of view of optimality, the optimal option for the decision maker is this, which delivers maximum usability. We can evaluate the usability The mentioned case study calculate the expected usability in the stochastic decision tree as:

$$\sum_{i,j=1}^{n} p_{ij} = 1 \qquad [1]$$

where: i - expresses i-th node, j – expresses j-th choice.

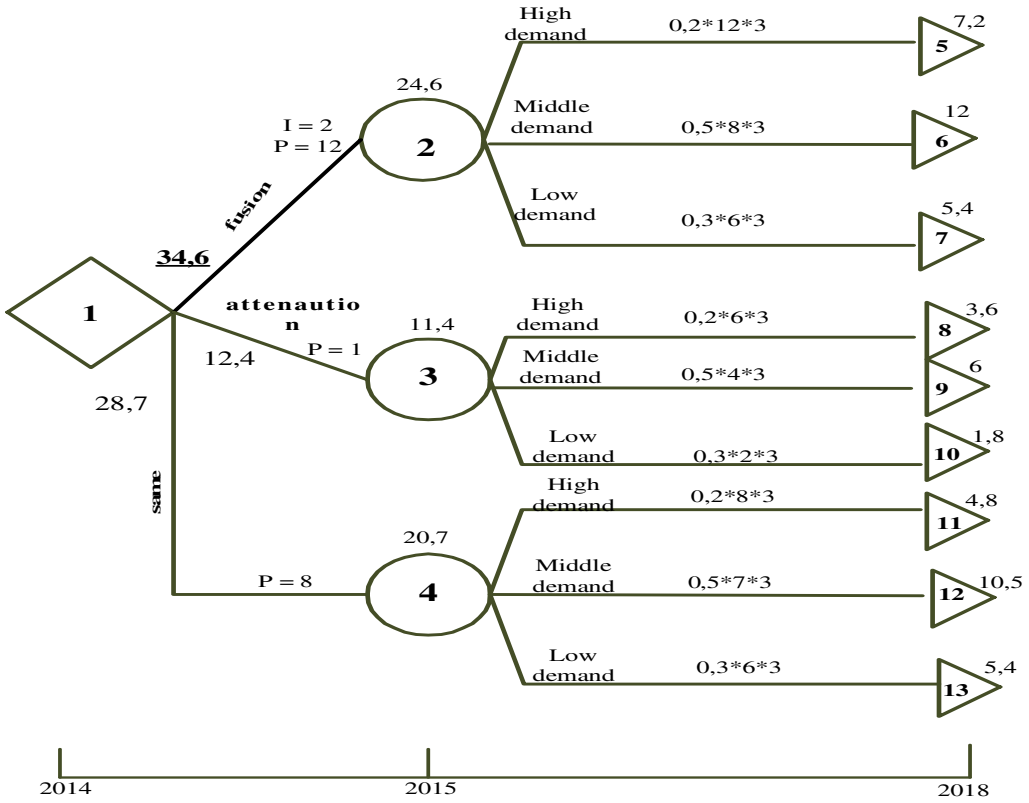

Fig. 3: Decision tree (own calculation)

Conclusions

Risks are being managed every day in the industry, but not in such a structured way as the literature describes. However information provided in those sources is rather messy. Some theories provided by risk management literature are not at all applicable to construction industry. As also other researchers confirmed, the knowledge of risk management is close to zero, even though the concept of risk management is becoming more popular in the construction sector.

Professionals in the construction industry are using techniques described in the literature concerning risk management, but are not aware of it. Risk management technique rarely used by the participants in construction projects. The participants used to handle the risks with an informal approach. This technique is not employed because of less knowledge and awareness among the construction industry. The risk management technique should be applied into any construction project at the initial stage of the project to get maximum benefit of the technique. Hence, there is thriving need to have a well-documented procedure which should be a one stop solution to all hazards that are likely to occur during project life cycle. There should be more wholesome approach towards risk management instead of the present sporadic approach towards the risks.

Problematic Mobile Phone Use among Employees in Lebanon

Souha Fahed, Notre Dame University, Louaize, Lebanon, sabdelnour@ndu.edu.lb

Rita Kmeid, Bank of Beirut, Zouk Mosbeh, Lebanon, rkmeid@bankofbeirut.com

Abstract

The mobile phone usage by employees in the workplace might influence productivity positively or negatively. We aim in this study to assess whether Lebanese employees have a problematic use of mobile phones. Moreover, to understand whether there is any correlation between personality traits and the problematic use of mobile phones. Data was collected conveniently from 244 employees and 199 (81.5%) were considered for the study. Each participant filled the Problematic Use of Mobile Phones (PUMP) and the Big Five Model questionnaires. Results revealed that 86.93% of Lebanese employees have a problematic use of mobile phones. However, a regression analysis showed that the traits of personality of the Big Five Model could not explain much of the problematic use of mobile phones. This study adds to the knowledge of managers in Lebanese companies regarding their recruits.

Keywords: Mobile phone, problematic mobile phone use, personality traits, workplace.

Introduction

In today's business world, mobile technology offer flexibility, accessibility, and entertainment for their users. For many people, cellphones have become their endless companion.

Mobile Phone Technology at the workplace

Technology and smartphones has played an important role in people's personal lives as well as in corporations. In fact, it's predicted that by end 2017, the average number of cellphone users will rise to 4.77 billion worldwide.

Today's workforce is more mobile than ever. Due to internet's global reach, business people have the capacity to obtain old and current information from any source within seconds. Mobile technology provides employees the advantage of working on the go and it increases worker availability and flexibility without being bound to a physical location (Scheck, 2016). Hence, work is freed from geographical obstacles and individual performance is enabled during periods formerly spent at home or at remote sites. Thus, companies may benefit from individual connectivity to boost productivity even when workers are away (Powel, 2006).

Mobile phone use and personality traits

Although a mobile phone is useful and attractive as a mean of communication; there might exist the risk of addictive and problematic usage of this device.

Through the decades, researchers have developed theoretical frameworks on personality traits to understand better human behavior. As it was shown, personality is a unique constellation of attitudes and dispositions that governs individuals' consistent cognitive, affective and behavioral patterns (Costa and McCrae, 1995). These attitudes and traits of character enforce certain behaviors that might be aligned

with the person's affect or influenced by his social group. It is yet unclear whether mobile users' traits influence their mobile phone use.

The main body of the paper

Literature Review

The developments and evolutions of cellphones lead to a smarter devise called "smartphone" which provides more features and advanced utilities than a basic feature phone (Litchfield, 2010).

The importance of smart phones

Smartphones are so vital due to the internet connectivity for calls, text messaging and social networking sites. Moreover, business emails can be sent and received at any time of the day. Smartphones are so efficient due to the speed at which tasks can be done. From a business point of view, employees can be connected to their colleagues, partners, suppliers, customers at all time. Smartphones are so functional; people can store important data, files, pictures, and notes on the phone, and they can save time by achieving tasks such as online banking, transfer funds and make international calls.

Smartphones are essential due to the entertainment they provide where all people children, teenagers and adults can entertain themselves through updated games, applications, music movies and TV shows that can be downloaded and uploaded easily on the phone. In this respect, smartphones have revolutionized entertainment and transformed the world of portable gaming and movies. Smartphones are important because they can be used as GPS tracker having full GPS worldwide capacity. People considered that cell phones have brought positive change in their lives since it had made very easy to contact anyone, anywhere and anytime which gave them a feeling of assurance and safety (Andrew, 2014).

Mobile Phone Usage & Productivity at Work

Mobile technologies devices impact performance, culture and the structure of the company itself (Meeker et al, 2010). Some people believe that mobile phones improve communication, thus, will have positive impact on their work.

Others think that episodic cell phones use at work will distract them from their jobs, which negatively influence their productivity. These types of interruptions at work make employees lose their focus and consequently they would not meet their project deadline (Donya and Kumah, 2011). When employees receive a call or their cellphone rings, it will have a negative effect on their productivity, whether they answered it or not. During the few seconds spent on the decision to take or ignore that call, the flow of concentration is interrupted and it takes time to reestablish efficiency (Yihong, 2010). An external interruption refers to an event such as email, phone call, instant message or notification that alters work evolution. By contrast, an internal interruption identifies changes in work tasks that are self-initiated (Elwood, 2005). One study found that employees working in the manufacturing sector had a problematic mobile phone use which influenced negatively their productivity (Wahla and Awan, 2014).

In addition to distraction, side effects of mobile use could negatively influence efficiency at work. A study on Saudi Arabian participants, mentioned that 44.4% complained of headache, concentration deficiencies, memory loss, hearing loss, and exhaustion were related to their mobile phone use (Khan, 2008). Moreover, another study showed that 3-4% of mobile phone users suffered problems such as fatigue and dizziness, and more than 20% developed headaches (Al-Khlaiwi and Meo, 2004).

Mobile Phone Use and Demographics

The use of cell phones had been associated with harmful and disturbing behaviors. Examples include drivers who remain connected while behind the wheel which reduces their attention capacities leading to fatal accidents. Recently, the National Safety Council released statistics showing that 27% of car crashes were caused by mobile phone use (NSC, 2013). Brusque and Alauzet (2008) concluded that women are less likely to use cellphones while driving than women. In addition, other negative outcomes could result from the overuse of mobile phones such as financial problems, sleep disturbance and behavioral addiction.

The impact of cellphones may be influenced by the user characteristics such as age, gender, employment position. It may also vary due to the factors specific to certain countries. Lemish and Cohen (2005) found out that there may be different behaviors among men and women toward cellphones. Rakow and Navarro (1993) noted that the mobile phone usage is an extension of the public world when used by men and in contrary an extension of the private world when used by women. Researchers found that men are more annoyed by the use of cellphones in public places than women (Tuner, et al, 2000). Debaillon and Rockwell (2005) didn't find any significant difference in the use of mobile phones between young men and women at college and high schools (Debaillon, 2005). A recent study revealed that women spend more time on their smartphones and are more addicted to the device than men. While 52 percent of female used their mobile phones for at least 4 hours a day, only 29.4 percent of male respondents did the same. Male participants uses their mobile devices typically during breaks while women participants often sneak a peek to their phone to check instant messages and social networking such as Facebook and Instagram.

Initially men were more likely to utilize information and communication technologies (Ono and Zavodny, 2005). More recently, women started building interpersonal relationship through the internet usage which might have led to greater mobile phone dependency.

Age also has its impact over mobile phone usage. Younger individuals eighteen to thirty years old, care about their self-image and are willing to spend more for a mobile phone then their older counterparts (Venkatesan, 2015). Mature consumers on the other hand are less informed about technological developments, thus are more price-sensitive and care less about brand and design (Venkatesan, 2015). Although, the study in question included Indian participants, we might have an assumption that youngsters around the world might engage in higher spending on mobile devices. Another study recently showed individuals 35 to 45 years old constitute the fastest growing age segment for researching and engaging in online transactions (Challinor, 2012). Twice as many consumers aged 35 and older had made an online purchase through their cellphones since 2009.

Objectives of the study

Very few studies investigated the problematic use of mobile phone among people. Again, no studies correlated individuals' personality traits with the problematic use of mobile phones.

This study aims at answering the following research questions: (1) Do Lebanese workers have a problematic use of mobile phones? (2) Is there any correlation between employees' personality traits and the problematic use of mobile phones in Lebanon?

Methods

Sample

Participants in this study were randomly selected from different companies belonging to the banking, engineering and telecommunication fields. Out of the 244 distributed packages, we received 199 completed, achieving a response rate of 81.5%.

Each participant received two questionnaires and was allowed two weeks to respond. The two questionnaires included the Problematic Use of Mobile Phones (PUMP) and the Big Five Model (Big Five). Demographic variables included age, gender, seniority and work sector, and was collected using an additional section in the consent letter.

Tools

This is a non-experimental quantitative study that uses two reliable and validated tools for the assessment of its variables. The PUMP developed by Billieux and his colleagues (2008) and validated by Merlo, et al. (2013) for English speaking participants. The PUMP included thirty statements relevant to phone use habits, self-evaluated on a four-point scale. The Big Five assesses five significant dimensions that underlie most significant variation in human personality. The five factors are: (1) extraversion (2) agreeableness (3) conscientiousness (4) emotional stability and (5) openness to experience. The Big Five is a 50 item questionnaire reporting a self-description of respondents. Research has found a relationship between the above stated personality dimensions and job performance: Although conscientiousness is the trait most consistently tied to job performance, the others also influence some aspects of performance depending on the situation.

Findings

Concerning the first question on the problematic use of mobile phones, assessed using the PUMP questionnaire: The results revealed that 86.93% of respondents have a problematic use of mobile phones. Regarding personality traits: the descriptive analysis primarily shows that the majority of respondents (61.31%) are extroverted. As expected by the cultural traits of Lebanese people, this trait characterizes people who are sociable, talkative, assertive, and enthusiastic. They are usually more emotionally expressive and have better interpersonal skills.

The second variable, agreeableness relates to people who are cooperative, warm and trusting. These people are usually more compliant and conforming. The study revealed that about 59.8% of participants were agreeable.

Conscientiousness characterizes people who are responsible, organized, dependable and persistent. These workers show effort and discipline in the workplace. It was shown that 58.79% of subjects have that trait of personality.

Emotional stability is a state of mind which relates to people who are calm, self-confident, and secure. People with high negative scores are usually nervous, anxious, depressed and insecure. Almost 53% of Lebanese workers show signs of emotional instability. This of course might be in relation to the downturn in the economy, long work hours and stressful conditions that an emerging post-war country like Lebanon still suffers from. Finally, openness to new experience is a trait of personality that distinguishes creative, curious, and artistically sensitive individuals. These are employees with higher adaptation to change and enhanced leadership. About 57.8% self-reported traits of openness.

A regression analysis revealed that traits of personality of the Big Five Model could not explain much of the problematic use of mobile phones with the following R^2 values for extraversion (0.02), agreeableness (0.02), conscientiousness (0.09), emotional stability (0. 15), and openness to experience (0.26).

Conclusion

Study findings highlighted problematic use of mobile phones among a high percentage of Lebanese workers. The latter have major implications on organizational behavior research and the way management should deal with the abuse and misuse of mobile phones by their employees. Again, in setting the limits for their workers if they witness conditions where the mobile addiction exceeds its benefits. Moreover, this research attempted to explain whether certain individuals with specific personality traits exhibit higher problematic use of mobile phone. However, the assumption was rejected, and there was no significant relationship between Big Five personality traits and the problematic use of mobile phones.

Promotion Techniques for A New Romanian Brand of Wine

Dospinescu Nicoleta, Alexandru Ioan Cuza University, Iaşi, Romania, dnicole@uaic.ro

Stoica Bianca Maria, Alexandru Ioan Cuza University, Iaşi, Romania, bianca.st94@gmail.com

Abstract

During the last 25 years, Romanian brands of wine have evolved very much based on consumer preferences, but at the same time they have revolutionized tastes and set new tendencies. Due to the stiff competition, many producers changed their vision and shifted towards the qualitative direction of the offer. The modern history of Romanian wine has been marked by brands such as: Grasa de Cotnari and Busuioaca de Bohotin, or Zestrea Murfatlar.
The goals of this article envisage emphasizing the promotion techniques for a new brand of wines from Romania, as well as their mechanism of functioning in the perception of connoisseurs. To make a good wine is very important part of the work, but after this is necessary to promote it according to the target audience. So an accurate communication to consumers and a smart use of the new technologies of digital marketing are in a state of evolutionary development, where new trends are likely to occur rapidly and wineries have to adapt.

Keywords: brand, marketing, promotion techniques, communication, loyalty, wine

Literature Review

The most valuable assets of a company are **brands.** According to (Aaker, 1995), a brand is a name and/or a distinctive symbol, used with the view of identifying products or services as belonging to a producer or a group of producers and differentiate between these goods or services and those of the competition.

Brands generate distinction, uniqueness in the mind of the consumer, recognition and loyalty, love mark. Which means, in economic terms, acquisition, profit margin for the organisation and market share as compared to other competitors. From (Aaker, 1995) perspective, the key to successfully achieve a ***new look*** is ***evolution***, not ***revolution***. A brand, within the development process, shapes up a personality which anchors in the mind of the target public and becomes decisive. It deserves to be kept in order to preserve categories which are already conquered, to attract new customers, to ensure loyalty, to keep the tradition, to constantly reveal the values of the product and of the organisation, to keep on telling the story. The studies (Kotler & Keller, 2015) show that, in fact, consumers by, consume and do business with an image.

(Steenkamp, 2014) speaks about the 4V model which links the directions of research regarding ***global brands***, providing a better understanding of these brands and of the way they create ***value*** for the organisation. This model is organized in four groups of elements which create value: valuable brands; source of value; delivery value, assessed results. The sources of value come from the uniqueness of the name which can awaken certain emotional or rational associations in the mind of the consumers, or from Unique Selling Proposition (USP) which decisively shapes up the product/service, or from its intrinsic characteristics.

According to (Aaker, 1995), the capital of a brand is a set of assets and liabilities linked to a brand, its name and symbol, which add to (or reduce) the value provided by a product or a service to a company and/or the buyers of a company. And this set of assets includes: loyalty to a brand, name recognition, perceived quality, brand association with other assets in the property of the brand: registered trademarks, relationship within the distribution channels. They *provide value to the buyer* increasing trust, information processing and user satisfaction. At the same time, they also *provide value to the company* by increasing the efficiency and the effectiveness of the marketing

programmes, loyalty to the brand, profit margins, brand extensions, commercial leverage and competitive advantage.

The personality of a brand is supported by ***communication to the public*** and the way ***it can differentiate on the market***, compared to other brands. Communication and publicity dominate brands, irrespective of their nature. A brand which promotes a valuable product will never be able to be efficient without an identity which transmits the same thing and vice-versa (Wheeler, 2013). Promotion has as goals increasing visibility, boosting the increase of demand on short term, securing customers' loyalty, changing the flux of demand, brand energizing and consolidating or attibuting new associations, involving the target public and connecting it with the product in a multi-dimensional experience. According to (Borkovsky, et al., 2017), if advertising is more effective at building brand equity, then the brand value would increase. There are many researches (Renton, et al., 2017), (Wang, et al., 2017), (Herstein, et al., 2017)in the food and beverage sector regarding the problem of the brand management and the future directions.

The research of (Lindstrom & Kotler, 2010) proves that 75% of our emotions are actually generated by what we smell, feel, see, taste and hear. Multi-sensorial branding is based on complete sensorial synergy, which produces a domino effect. In the same way opinions are stored in mind, when one sense is activated, it will lead to another, and then another, triggering a chain of memories and emotions. Sensorial branding helps us return to the basic senses, which remarcably influence our decisions and wishes. 5D branding may be considered an element of business which enhances the efficiency of the promotion campaigns of an organisation.

In order to increase the *visibility* of a brand, events play a very important role because they involve the target public, creating an experience, a personal relation with the brand. Some results (Fu, 2017) show that the brand strategy management based on the network is helpful to improve the turnover of the enterprise.

According to (Lee, et al., 2017), building brands with high levels of awareness and uniqueness is critical to ensuring brand strength and sustained competitiveness.

According to (Mustafi, et al., 2011), one can count on a brand interaction with the public online, as well as offline. The term of online refers to all the channels using the Internet so that the message is delivered to the public. Making websites more usable and improving the users' experience represents an important step when desiring to keep them from moving away. It's important to examinate the effects of the interactivity dimensions on users' content comprehension and their attitudes towards e-commerce websites (Dospinescu & Perca-Robu, 2017). This online promotion can be achieved by using:

- *Search Engine Marketing* where one can find Adwords, Bing Ads etc., which represent online means of publicity
- *Social Media Marketing* which includes all social media, such as Facebook, Twitter, Linkedin etc.
- *Display Media Marketing* which combines email marketing, mobile advertising and display advertising in another method of online promotion.

The advantages of online promotion consist of results measurable in real time, it is cheap and it allows fast interaction with the clients and their efficient targeting.
Offline channels by which promotion towards the target public can be achieved are represented by mass-media: press, radio, TV, OOH. The advantage provided by these channels is represented by increased credibility compared to New_Media, and placing the publicity message is close to the sale point.

Some studies (Krieger, et al., 2014), (Ramsak, 2014) analyzed the field of branding and brand management of wine production. In the case of wines, promotion (communication) is based on advertising, promotions, public relations (events, press releases, press conferences, seminars,

speeches), direct marketing and sale force (presentations addressing the theme of wine, business meetings, specialised contests, specialised tasting, catalogues with products from the respective range of products, e-mail). Starting from the organoleptic characteristics of the product, going through the story of the brand, reaching to the packaging, bottle design, label, colours, fonts, logo, logotype, symbols, USP up to endorsers and events, the promotion of grapevine products is absolutely interesting and provoking, taking in consideration the competition.
The research theme refers to the way in which promotion of new brands of wines is perceived by consumers and finding the techniques that have effect, adherence on them, in the online as well as in the offline environment. We will analize Hermeziu Winery, founded in 2014.

Research Theme and Research Methodology

In the process of finding promotion techniques for the brands of wines in the N-E of Romania, elaborating a detailed research, which is oriented towards the consumer, namely oenologists and professional tasters, who are aware of the Romanian wine market, is necessary. The goal of the research is to find out which promotion techniques function in this field, of wine, and which are the most efficient for ”Hermeziu Winery” with the of achieving the same success as that of other, well known and established wineries.

Research Methodology

For the present research, we have chosen to use ”Literature review” as first method, in order to find out the state of awareness in the field of promotion techniques and branding; then we applied a quantitative research – the questionnaire survey as an instrument of understanding the opinion of the target public as to the promotion techniques used by this winery and their efficacy; data interpreting was carried out with the help of SPSS programme.

Sampling: the researched sample consisted of 67 persons of different ages, out of which 59 were really acquainted to the brand and went through the entire quiz. These individuals are a part of the group ”oenology”, a public group where everyone interested in the field of wine can enlist. We could count on informed, relevant answers provided by specilized oenologists, as well as by sophisticated customers, committed to finding out about this field.

Research objectives and hypotheses

O1: Identifying the reasons for consuming a brand of wines and the importance of certain criteria in the decision of buying
O2: Appreciating the promotion techniques for the brand Hermeziu
O3: The impact of promotion on different media channels
The hypotheses of the research in this paper are the following:
H1: The age of the respondents is a criteria which influences the perception on the media channels
H2: The perception of the promotion techniques used by the brans Hermeziu differs according to the age group

Results And Discussions

The first question ”Do you consume the wines of Hermeziu winery?” is a filter-type question, which uses a dichotomic and nominal scale, with category variables. If the answer to this question was affirmative, the quiz continued with the following questions, and if it was negative, the quiz concluded with thanks for the time.

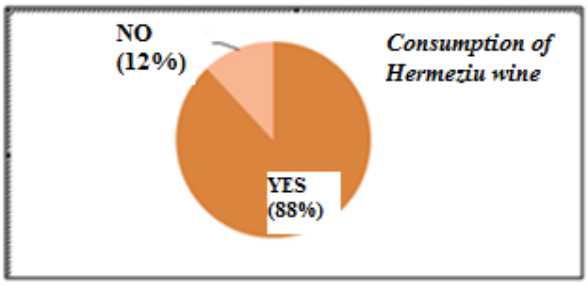

FIG 1- KNOWING THE BRAND

After centralizing the data, we find out that in a proportion of 88,1%, they know the Hermeziu brand, and 11,9% have not heard yet about this winery.

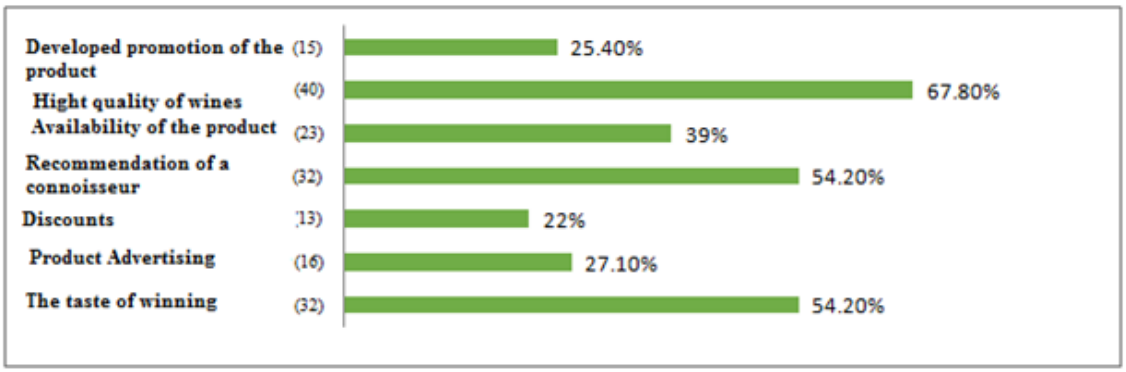

FIG 2 - THE REASONS FOR WINE CONSUMPTION

At the question: ”Which were the reasons for consuming wines from Hermeziu winery?”, we obtained important data which show that the main reason is: ”high quality of the wine”, on the second place is ”taste” and ”the recommendation of a connoisseur”; and on the third place is ”product availability”. We notice the fact that the organisation deserves to improve its promotion strategies, taking into consideration its place in the current ranking.

The third question: ”In your opinion, which characteristics you consider a premium wine brand should have, in order to be considered an ”Ideal” brand”? we obtained the following ranking:

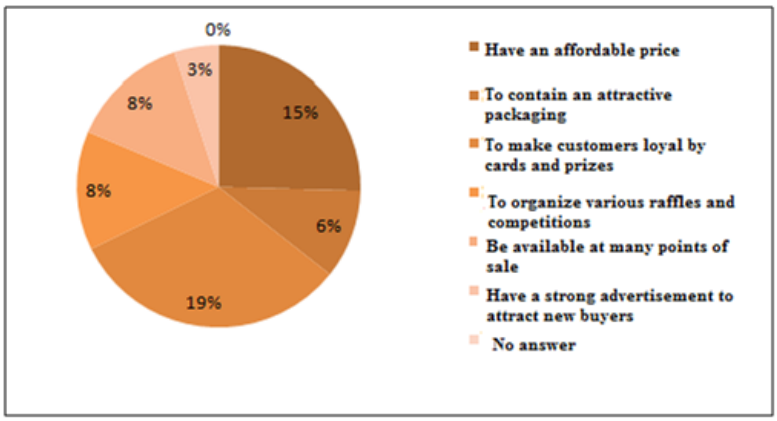

FIG 3 - IDEAL WINE

The goal of this question is intended to find out which are the promotion actions Hermeziu brand has to take in order to be considered a ”successful brand”. One can notice, from the *Fig. 3*, that the respondents of the quiz emphasise especially with securing loyalty by cards and prizes (19%), than an ”affordable price” (15%); organizing raffles and competitions, promotion (8%), but also, the avalilability of the product in many points of sale is appeciated .

These answers are very important for our research theme, that is why we are going to conduct a statystical analysis, relating this question to the answers of the question which indicates the age of the respondent. By this correlation we will find out whether there are any relations between the age of the respondent and some of the promotion techniques a premium wine brand can undertake.

With the help of SPSS (Statistical Package for the Social Sciences) statistical application, we developed a test *One-Way Anova*, by means of which we pointed out the relations that exist between the ***age of the respondent and some of the means of promotion of a brand.*** We will work witn the last column, where the „Sig” coefficient is to be found, in order to find out whether there are or there are not any differences between the two variables. „Sig” is the correlation *coefficient* which describes the intensity and the direction of the relation between the variables.
Hypotheses:

H_0 – age does not influence the characteristic ”affordable price”
H_1 – age influences the characteristic ”affordable price”
Sig = 0,763 > 0,05 => H_0 is accepted
=> H_1 is rejected
=> test is irrelevant

Table 1: ANOVA Test - The age of the respondent and the means of brand promotion

ANOVA

		Sum of Squares	df	Mean Square	F	Sig.
To have an affordable price	Between Groups	.126	2	.063	.272	.763
	Within Groups	13.207	57	.232		
	Total	13.333	59			
To contain attractive packaging	Between Groups	1.365	2	.682	2.943	.061
	Within Groups	13.218	57	.232		
	Total	14.583	59			
To make customers loyal to cards or prizes	Between Groups	.132	2	.066	.261	.771
	Within Groups	14.451	57	.254		
	Total	14.583	59			
To organize various raffles and competitions	Between Groups	.678	2	.339	1.363	.004
	Within Groups	14.172	57	.249		
	Total	14.850	59			
Be available at many points of sale	Between Groups	.866	2	.433	1.824	.001
	Within Groups	13.534	57	.237		
	Total	14.400	59			
Have a strong advertisement to attract new buyers	Between Groups	.097	2	.048	.193	.003
	Within Groups	14.303	57	.251		
	Total	14.400	59			
No answer	Between Groups	.071	2	.036	1.091	.343
	Within Groups	1.862	57	.033		
	Total	1.933	59			

Interpretation: As a result of the analysis carried out, there are no significant differences between a promotion strategy based on ”affordable prices” and the age of the respondent. There is no relation between the two, from a staystical point of view, this conclusion being guaranteed with a probability of 95%. The variables ”Having an attractive packaging”, ”securing customer loyalty by means of cards and prizes” and the variant ”no answer” have the value „Sig>0,05”, which means that there are no significant differences between the respective characteristics and the age of the respondent. For the variables ”organizing raffles/competitions”, ”product availability in various selling points” and ”strong advertising with the view of attracting new customers”, the value of the sig coefficient is calculated as follows:

Hypotheses:

H_0 – age does not influence the characteristic organizing raffles/product availability in selling points/strong advertising with the view of attracting new customers
H_1 – age influences the characteristic organizing raffles/product availability in selling points/strong advertising with the view of attracting new customers.
Sig = 0,04/0,001/0,003 < 0,05 => H_0 is rejected
=> H_1 is accepted
=> the test is irrelevant.

Interpretation: As a result of the analysis carried out, there are significant differences between the characteristics ”organizing raffles/product availability in selling points/strong advertising”, which means there is a correlation from a statistical point of view. For these variables, the test was rendered relevant. The result will determine a differentiation of the means of promotion of the products of Hermeziu winery according to age groups.

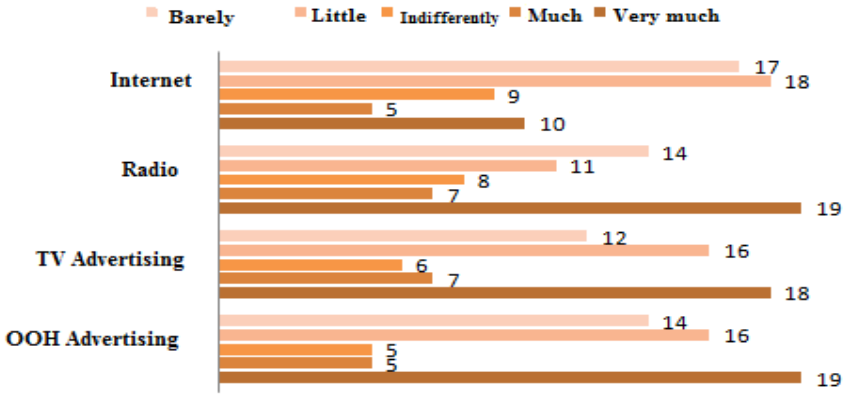

FIG. 4 - MEDIA CHANNELS

As for the media channels preferred by the respondents, we asked the question "To what extent does advertising on the following Media and New-Media channels (Internet, Radio, TV Commercial, OOH Commercial) influence you in selecting a blend of wine?" We used a 5 stages Likert scale, with possibilities of answering from 1 (very little) to 5 (very much). The results show that the main preferred channel is Internet, on the second place comes OOH commercial, on the third the TV commercial, than the one on the Radio.

With the help of SPSS application, we used the test *One-Way Anova.* By this test we will notice if there is any significant association or not, between the age of the respondent and the channels of promotion. This question answers to the goal regarding establishing the importance of promotion on different media channels according to age.

Hypotheses:

H_0 – there is no significant association between age groups and the TV commercial
H_1 – there is a significant association between age groups and the TV commercial
Sig = 0,007 < 0,05 => H_0 is rejected
=> H_1 is accepted
=> the test is relevant.

Interpretation: As a result of the analysis carried out, there is a significant association between the characteristic age of the respondent and TV commercial, which means there is a correlation, from a statistical point of view, this conclusion being guaranteed with a probability of 95%. For these variables, the test was rendered relevant, which means they are related to the theme of research.

Table 2: ANOVA Test - A significant association between the age of the respondent and media channels

ANOVA

		Sum of Squares	df	Mean Square	F	Sig.
TV Promo	Between Groups	2.458	3	.819	.496	.007
	Within Groups	92.525	56	1.652		
	Total	94.983	59			
Radio	Between Groups	5.586	3	1.862	.496	.007
	Within Groups	101.414	56	1.811		
	Total	107.000	59			
Internet	Between Groups	5.911	3	1.970	1.938	.004
	Within Groups	56.939	56	1.017		
	Total	62.850	59			
OOH	Between Groups	7.386	3	2.462	2.011	.003
	Within Groups	68.547	56	1.224		
	Total	75.933	59			

As we can notice, all the values of the „sig" coefficient are lower than the value „0.05", which means that from all the independent variables, that in "TV commercial", "Radio", "Internet" and "OOH" and the dependent variable "age" there is a significant association.

When asking the question: "How do you think the brand of wines Hermeziu should act in order to become better known on the market?" (with only one variant of answer), we obtained the following results:

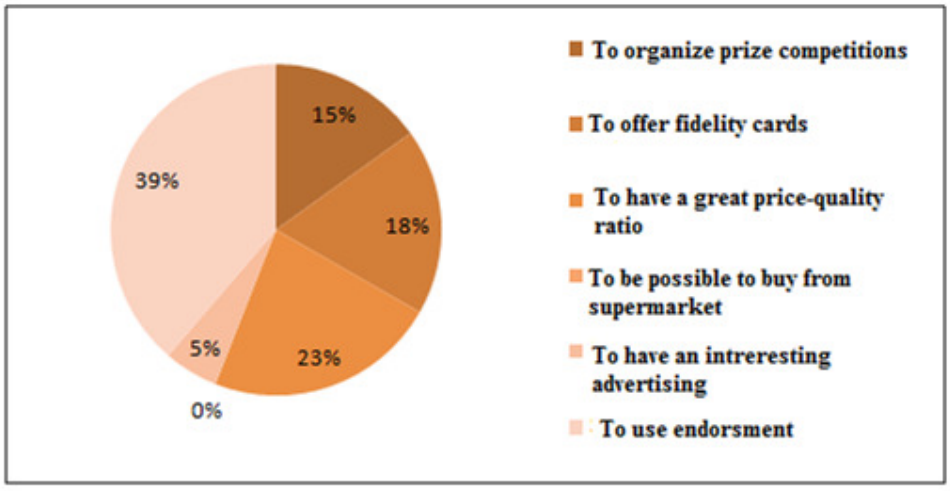

FIG 5 - THE BEST WAY OF ADVERTISING FOR THE BRAND

This question answers to the goal regarding the the respondents perception of promotion techniques. In order to analyze these answers, we will use the *One-Way Anova* test. By means of this test we will notice if there is a significant correlation or not, between the age of the respondent and the promotion methods Hermeziu brand of wines could use.

Hypotheses:

H_0 – there is no significant correlation between age groups and organizing raffles/ prize competitions
H_1 – there is significant correlation between age groups and organizing raffels/prize competitions
Sig = 0,003 < 0,05 => H_0 is rejected
=> H_1 is accepted

=> the test is relevant.

Interpretation: As a result of the analysis carried out, ***there is a significant correlation between the independent variable "age" of the respondent and organizing raffles and competitions.***

Table 3: ANOVA Test - The correlations between the age of the respondent and the promotion methods Hermeziu brand of wines

ANOVA

		Sum of Squares	df	Mean Square	F	Sig.
To organize prize competition	Between Groups	3.235	3	1.078	5.253	.003
	Within Groups	11.498	56	.205		
	Total	14.733	59			
To offer fidelity cards	Between Groups	.702	3	.234	.920	.003
	Within Groups	14.232	56	.254		
	Total	14.933	59			
To have a great price-quality ratio	Between Groups	.000	3	.000	.	.
	Within Groups	.000	56	.000		
	Total	.000	59			
To be possible to buy from supermarket	Between Groups	.551	3	.184	.962	.417
	Within Groups	10.699	56	.191		
	Total	11.250	59			
To have an interesting adevrtising	Between Groups	.000	3	.000	1.633	.
	Within Groups	.000	56	.000		
	Total	.000	59			
To use endorsemnt for brand advertising	Between Groups	.435	3	.145	1.029	.387
	Within Groups	7.898	56	.141		
	Total	8.333	59			

As we can see, the values of the "sig" coefficient for the variables ***"offer fidelity cards"***, ***"have a great price-quality ratio"***, ***"have an interesting advertising"*** are lower than the value of 0.05, which means that ***there is a significant correlation*** between these dependent variables and the independent variable "age".

For the variables ***"available in supermarkets"*** and ***"use endorsement for brand adevrtising"***, hypothesis H_0 will be accepted and hypothesis H_1 will be rejected, because the value of the coefficient "sig" is higher than 0.05, therefore for these dependent variables, the test will be irrelevant.

By means of the question "Would / Did you recommend Hermeziu winery to other people?", with the variants of answer "Yes" and "No", the level of appreciation of the winery, from the point of view of the respondents was intended. This question is accompanied by a photo which contains the logo of the brand. A number of 57 respondents, that is 97%

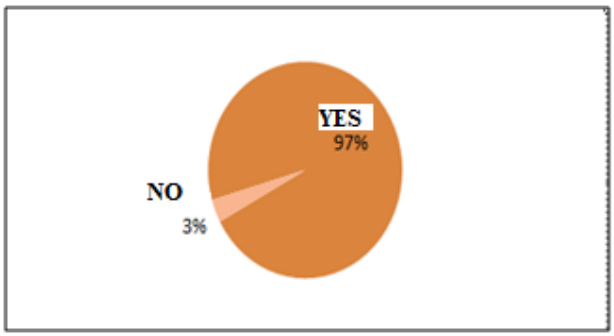

FIG 6 - BRAND RECOMMENDATION

Stated that they have or they would recommend the winery to other people, and 3%, that is 2 people would not do that.

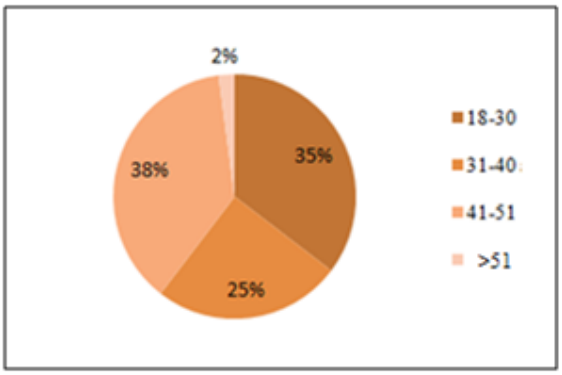

FIG. 7 - AGE OF RESPONDENTS (YEARS)

At the question regarding the age range where the respondents are situated, formulated with the purpose of dividing the questioned persons, we obtained the following results: 41-51 years old, representing 37.5%. another strong percentage is represented by 35.4%, meaning 18 people, with ages from 18 to 30 years old. The lowest percentage is represented by 2.1%, which is a sole respondent over 51 years old.

Conclusions

Taking into consideration the first goal of the research, that of ”identifying the reasons of consuming a brand of wines and the importance of certain criteria in the decision of buying” we have reached to the conclusion that for the consumers, the high quality of wine and the recommendation of a connoisseur are the main reasons why they prefer a specific kind of wine. As for the ”appreciation of the promotion techniques of the brand Hermeziu” we concluded that the respondents mostly appreciate ”promotion on the Internet” and the way the ”superior quality of the wine” is put into light.

The first objective envisaged was revealing the media/new-media channels appreciated by the public when it seeks an information / promotion about the brand Hermeziu. The results pointed out the fact that the public considered that the Internet and, OOH commercial are easier to access. With the help of the SPSS statistical programme, we designed an *Anova* table by which we emphasized whether the age range is influenced by the media channels and whether there is a correlation between these two variables. Following the analysis of the obtained results, we can state that the perception of the TV

and OOH commercials, and of the radio commercial differs depending on each age range. For this reason, adapting the content according to the target group would facilitate perception.

We have found out that the promotion techniques the consumers find adequate are represented by organizing competitions and raffles, creating loyalty cards, an individual commercial for the brand and that an advatageous ratio between quality and price is essential.

The present research has had positive results for the brand of wines Hermeziu. The winery delivered a message about the story of the wine they produce and a certain image that were perceived by the connoisseurs, as being on the whole to their benefit.

A marketing campaign that promotes the brand of wines Hermeziu would matter if the the media channels which are intended to be used for delivering the message and the age ranges of the target public would be taken into consideration. For example, they could use the Facebook social media platform more intensely, with the view of emphasizing the message they wish to deliver. The winery has to establish the target market so that it can take into account the age ranges that use the media channels. For the age range between 18-30 years old they could use the Internet and the outdoor advertising in order to promote their message, for the age range between 41-51 years old they could use radio and the OOH commercial, and for the age range between 41-51 years old they could use Radio and TV commercial. The outdoor advertising would be the most beneficial for Hermeziu winery, since it would be the mean of promotion by which all the age ranges would see the message proposed by the brand.

Promotion techniques adapted to the profile of the new brand and the age of the target public are essential for its correct perception, adherence of information, rasing curiosity, recognition, notoriety, uniqueness and its clear positioning in the mind of the consumer. The brand Hermeziu can exploit its tradition, as well as the novelty brought in a clever way, by appealing to a niche promotion.

Abstract

This article presents the implementation of "14 Quality Principles for Value Streams" in the company from the automotive industry. The Bosch Company has created a set of 14 principles and special criteria that it considered most important for its production system. Deploying them to all positions has become a superior goal for the entire organization. One of the important steps to take to achieve this goal is a thorough analysis of the prevailing conditions and careful planning of the action. Therefore, the first important step in the following work is to create an implementation plan. Then, based on a previously prepared evaluation sheet, a comparative analysis is made between the current state and the requirements contained in the 14 Company's Quality Principles.

Keywords: Automotive Industry, 14 Quality Principles, TQM, Project Management

Introduction

Economic changes in recent years have made the quality of products and services become a key criterion for the success of an enterprise (Gola (2014)). Equally important is the knowledge of the managerial staff on the potential for enhancing the results of work, which is the result of knowledge of the theoretical and practical basis for improving the company's business. Sustainable and continuous quality improvement can only be achieved by directing the organization's efforts to plan and prevent problems that occur at the source. This concept of quality management is called quality assurance, where greater emphasis is placed on advanced quality planning, training, product design, process and service improvement, process control and engaging and motivating people (Dale (2003)). Improving the quality also requires knowledge of customer expectations (Kłosowski and Gola (2016)). Is more than just collecting data from processes and from the customer.

How to more effectively manage the production company? There are many techniques and methods but not all are effective in practice. As it turns out since the early 1990s, the best results are achieved by Japanese entrepreneurs. Therefore, for many years, the eyes of all managers are headed in that direction. A good example is Toyota's phenomenon. This company is renowned for its high-quality products, cost-effective pricing, and innovative management approach. Its annual revenues are billions of dollars, so it is no wonder that it is considered one of the most profitable companies in Japan and North America. However, the main advantage of Toyota is its production model, the so-called "Lean Production", which is today widely regarded as another step in the evolution of the manufacturing process after the introduction of Ford's mass production system (Liker and Maier (2006); Bhamu and Singh Sangwan (2014); Jasiulewicz-Kaczmarek (2014); Chay et al. (2015); Liu, Wang and Peng (2015); Epler et al. (2017); Jasiulewicz-Kaczmarek and Saniuk (2018)).

High achievements in this area of Toyota have caused many companies to take an example and introduce their own system of quality improvement. Most of them are based on "Lean Production". This is exactly what happens at Bosch Company, which is analyzed in the following paper. The company has created a set of 14 principles and special criteria that it considered most important for its production system. Deploying them to all positions has become a superior goal for the entire organization.
This work presents the implementation of "14 Quality Principles for Value Streams". The deployment process is based on a single assembly area. 14 principles of quality is an important element of the functioning of this enterprise. On the basis of the experience gathered in other branches of the company, the effectiveness of the changes is very high. Significantly improve the quality of products and notice the decrease in complaints from customers in the long term.

One of the important steps to take to achieve this goal is a thorough analysis of the prevailing conditions and careful planning of the action (Anholon and Sano (2016)). Therefore, the first important step in the following work is to create an implementation plan. Then, based on a previously prepared evaluation sheet, a comparative analysis is made between the current state and the requirements contained in the 14 Company's Quality Principles. For such a complex project, an important element is also the creation of an appropriate team to make a fair assessment of the process. The whole course of the assessment with a corresponding comment to specific points is presented and described so that in the next step it is possible to draw appropriate conclusions and present them using the scoreboard. Following the evaluation, the changes to be made and the plan for their implementation is proposed. Then an example of process improvements is presented. All enhancements are based on the implementation of process-related principles. The final results are the impact of the improvements on the results of the assessment and the appropriate conclusions.

14 Quality Principles

"14 Quality Principles for the Value Stream" are the main rules in Robert Bosch company for the production system, implemented in every Bosch plant. It is very important to provide high-quality production in the automotive section. In this area of manufacturing, every single mistake or oversight could be dramatic in effect for the user (Świć and Gola (2013)). It is easy to imagine what can happen when breaks in our vehicles do not work properly. There is human life in consideration. That is why automotive companies should pay high attention to every detail which can cause any mistake.

Every rule in 14 Quality Principles is described very detailedly. It has to be clearly written and easy to understand for everyone. Most of the rules presented below have own equivalent in inside Bosch procedures. Some of them are already implemented but are not directly connected with 14 principles.

Principle 1: **Customer Complaints**. "Customer complaints are communicated within the production site and displayed at the station in question. Using problem-solving techniques, they are processed in a fast and systematic manner. The supply chain is promptly informed" (Fischer, Gemmer and Rach (2017)).

Principle 2: **Control limits applied**. "In the event of deviations in quality or if control limits are exceeded in the value stream (source, make, deliver), the employee needs to stop the process or escalate" (Fischer, Gemmer and Rach (2017)).

According to the instruction, three steps should be done after exceeding limit: Stop, Ask, Wait, when:
- 4 identical deviation are explored,
- 3 identical deviation are explored during 2 hours,
- 4 deviation for the same reference from one supplier are explored during 2 hours,
- 1 deviation is explored after one part go through all control point,
- 1 deviation is occurred caused by any problem.

Principle 3: **Instruction**. "Safety, health, production, and inspection instructions have complied with 5S standards are put in place and observed" (Fischer, Gemmer and Rach (2017)).

The instruction should be placed in space easy to access in latest document edition. The instruction should contain safety symbols and if appropriate, work instruction of manual works content right and left-hand movement description with illustrations. It concerns such instruction as TPM, health and safety, production and quality, 5S etc. The failure modes from the FMEA and special characteristics from the control plan are taken into account.

Principle 4: Process Parameters. "The target values/tolerances for all stated process parameters are observed" (Fischer, Gemmer and Rach (2017)).

Without any exception during the assembly activity of every single part, all parameters are controlled by detectors. Thanks for that it is easy to prevent dangerous situations. When the parameters are exceeded program stop the process.

Principle 5: Measuring & Test equipment. "Measuring and test equipment are defined, and monitoring intervals are observed" (Fischer, Gemmer and Rach (2017)).

Principle 6: Check the checker. "The check the checker principle is applied, and the checker's suitability is ensured" (Fischer, Gemmer and Rach (2017)).

"The suitability of processes used to prevent or detect errors (e.g. camera-monitored processes, sensor-based measurements, inspection processes) needs to be checked according to a predefined standard. Possible errors, such as loading the incorrect camera software/testing program or improper sensor calibration, need to be prevented by carrying out the inspection. These inspection processes, as well as maintenance and set-up processes, need to be evaluated using appropriate methods (e.g. FMEA)" (Fischer, Gemmer and Rach (2017)).

Principle 7: Total Productive Maintenance. "A maintenance standard is installed and observed at every station" (Fischer, Gemmer and Rach (2017)).

TPM instruction says about how to maintenance machines to prevent the unexpected damage and breaks and how to elongate machine lifetime. Document contain: who, what and how often should accomplish the defined activities. Instruction should be hang out in a place which is available for every worker of the workstation. Except for operator, TPM activities should be executed by Maintenance Department.

Principle 8: Tools. "Each tool has a defined service life; the current status must be recognizable. A quality evaluation must be carried out during removal or disassembly" (Fischer, Gemmer and Rach (2017)).

"The current service lives of all tools have been recorded. A warning system promptly displays when tools need to be serviced or replaced. Each tool needs to be inspected when removed or disassembled to check for damage/ wear and tear. In case of deviations, it is necessary to follow measures to ensure product quality is maintained. Restart is performed according to clearly defined rules (see Principle 9); the standard is regularly reviewed" (Fischer, Gemmer and Rach (2017)).

Principle 9: Regulated restart. "Restart after disruptions are clearly regulated for all machinery and equipment" (Fischer, Gemmer and Rach (2017)).

"Downtimes can alter process parameters, workflow sequences may change, and the consistency of material and supplies can change. All devices have been inspected according to a defined standard for quality risks in connection with disruptions (for example, an unplanned disruption to the welding process, the injection molding process stops unexpectedly, a product remains in thermal treatment for too long, the silicone bead is exposed to the air for too long). The standard also includes the analysis of critical wear parts (for example, drill bits or welding electrodes). Following longer disruptions

(e.g. station upgrade), it is necessary to newly release the process and carry out a process audit" (Fischer, Gemmer and Rach (2017)).

Principle 10: Labeling. "Products and containers are labeled according to the set standard" (Fischer, Gemmer and Rach (2017)).

Product must always have a clear status. All parts have the inimitable reference number. Additional identification is provided by colorful labeling system (white color – good part, yellow color – parts in testing, green color – tested, blue color – prototype, red color – scrap, white with red band – blocked). What are more "[…] red boxes must be secured against unintended access (e.g. by locking them, covering, spatial separation, covering during transport). Containers for rejects must be emptied in line with standards and the parts must be analyzed. Parts on the analysis station are spatially separated from the production flow and clearly identified. Only parts with the same status in the same container, no good parts in the red box. Products are protected against environmental influences (e.g. contamination) in line with regulations" (Fischer, Gemmer and Rach (2017)).

In the standard, the places intended for storage or direct delivery components to production, are labeled by the slate with the reference number and with photography of component. Visually presentation is more readable for workers. When the product has the wrong label or is placed in the incorrect box, the complaint should be submitted. All process is then analyzed and the risk of production danger is evaluated. Special reaction steps are implemented.

Principle 11: Rework / Scrap. "The handling of rejected parts and those to be reworked is clearly regulated" (Fischer, Gemmer and Rach (2017)).

All components are visually checked during the process. Thanks for that the negative one can be detected before causing any danger in the final product. Every defect which is noticed by the operator should be reported. If the problem is caused by nondependent reason from the production process, the preselection before delivery component on the production line is provided. During this selection, all defective parts are rejected and the scale of the problem is defined. Problem analysis help to assess on which level defects are created and prepare special activities to avoid this situation in future.

Principle 12: Dropped parts. "Any products that fall on the floor, into the machine or cannot be classified must be scrapped" (Fischer, Gemmer and Rach (2017)).

If during the process any part is dropped, regardless of its condition is scrapped in the special red container (the same as in the previous principle). Product after fell down can look untouched, but the internal structure and functionality might be broken. In that case, part qualifies as nonconformity and cannot be used in the process.

Principle 13: Correct Product. "Only the correct product may be provided for removal and assembly" (Fischer, Gemmer and Rach (2017)).

To producing the particular product, defined components are used. In some cases can happen that there is no visual differences between parts uses for various references. That is why during the changing process all delivering components must be controlled. Information about which component should be used in which references are placed in carts on the workstation.

Principle 14: Remaining Items. "The handling of remaining items/ quantities is clearly regulated" (Fischer, Gemmer and Rach (2017)).

The FIFO rule means that the parts with the oldest production date must be used first. It helps to avoid using wrong parts with exceed lifetime and maximum time of storage. The logistic department is responsible for changing components during the changeover and for delivering old components back to the supermarket.

Approach to Work Improvement and Tools Description

Continuous improvement of the organization is a prerequisite for its survival on market under conditions of increasing competition. The concept of improvement of work organization is understood as the implementation of improvement activities (organizational, technical, etc.), leading to the increased rationality of the functions carried out by the workplace, which should lead to increased economic. The issues related to the improvement of the functioning of the organization have been in the past and are currently the subject of numerous theoretical and practical considerations. The mainstream of interest in the improvement of economic organizations is focused on finding solutions to increase, broadly understood, economic effects of their functioning. The methods and tools for improving and evaluating processes of improvement are still of interest.

Nowadays, professionals seek to implement methods that will increase the efficiency of their work but will not be overly capital intensive. Often, efforts to streamline the workplace of production sites are complex and require appropriate analysis, involving production staff but above all a well-thought-out approach. In order to streamline the process with tangible benefits, it is necessary to analyze all the activities carried out in the implementation of the production process (Bartnicka (2016)).

The methodology is defined as a set of guidelines for how the procedure to be followed when performing a particular job or for achieving a specific goal (Marciniak (1989)). On the one hand, it deals with problems related to problem-solving, and on the other hand, describes their solution. The concept of methodology and its overall importance in carrying out various projects can be characterized as a way:

- a formal and detailed description of the activities carried out in the implementation process division into different stages and activities,
- covering all activities from the preparation stage to the phase exploitation of the implemented solution,
- planning activities on the basis of which implementation works are carried out,
- arranging and systematizing the implementation of the system,
- gathering principles that help guide the project (Trzaskalik (2005)).

The systematic problem-solving methodology is a multiple process that consists of activities:

- defining the purpose and modeling of the problem situation,
- analyzing running tasks,
- interpretation and interpretation of possible changes in the existing situation,
- determine the ability to target,
- planning strategies and resources,
- implementation of problem-solving in practice.

Improving work organization in an enterprise can be divided into three general phases, according to the life cycle of the project: preparation, design, implementation of change. The first phase focuses on creating the right climate for improving work. The venture must have strong support in management, otherwise, it will not produce the intended results. Activities in this phase involve the training of a working group and the provision of information to employees of production sites about their activities. Workers need to realize that their work and machine performance affect the position and competitiveness of the company they work in (Kosieradzka and Krupa (2009); Abolhassani, Layfield and Gopalakrishnan (2016)). Every employee should know what his role is throughout the system and how he or she can contribute to improving the business. The second and third phases, on the other hand, focus on designing activities and implementing methodologies for improving work organization by creating a team-based system and initiating profit-driven activities.

The application of the presented methodology allows, among others, to increase productivity, reduce product flow time, reduce waste, improve ergonomic conditions. In addition to measurable profits,

the benefits to the company include increased employee engagement, acquisition of new skills, and the release of creative potential. It includes the following steps:

- development of assumptions,
- gathering information about the workplace,
- analysis of collected data and defining major problems,
- defining corrective actions and their implementation,
- control of results and evaluation of results.

Other benefits of using the methodology include its versatility, ease of sharing knowledge, guaranteeing a thorough deepening of the problem without neglecting important aspects and maximizing effectiveness. Clarification of the organization of the work organization improves the dissemination of good practices for the whole organization and the use of elaborated solutions. The methodology is divided into following phases.

Phase I - Development of assumptions. Assumptions are information that needs to be taken into account when preparing work. They affect the direction of activities and define the expected end result. The assumptions should include elements such as:

- name and description of the area where work improvement activities will be carried out,
- objectives and expected benefits from planned improvements,
- justification of commencement of activities,
- restrictions,
- work schedule,
- defined resources.

Phase II – Data collection. The information that will be collected is intended to determine the initial situation area functioning. News must be objective and come from reliable sources. This may be in the form of descriptions, tables, diagrams, graphs, drawings. As an example can be procedures, requirements, instructions or dissemination of results and statements. It should take the time to observe, exchange information with and work within the area. The purpose of this stage is to draw conclusions about the work done, manufactured products, used machines, instructions, level of performance, etc. Knowledge of the position will help define the main problems. Occurring in the production process. In addition, this set of initial information will allow you to evaluate progress.

Phase III – Analyze the collected data and define the main problems. At this stage, data should be sort in the right order: the cause of the problem, the problem, and the effect of the problem. The analysis is based on a comparison of activities in the post with its optimized functioning. This applies to any behavior occurring in the area under investigation. It is possible to calculate what investments involve the implementation of improvements. It must be stated whether it is worth dealing with all the dysfunctions encountered, or whether only the most important ones, causing the longest downtime in production or generating the greatest losses.

Phase IV – Define corrective actions and implement them. The fourth stage is a time to reflect on the corrective measures to be taken to achieve the goals. Solution development will involve testing and simulation to select the most effective solution. There is a risk of encountering a large number of problems, technical difficulties, and employee resistance. It is important to cooperate with specialists and support the management. Once the corrective actions have been defined and their implementation is implemented, a comparison of the effects of the initial situation will be made..

The implementation of the solutions is aimed at reducing costs, improving quality, reducing the delivery time of products to the customer. Improvements should be designed so that they can be applied regularly and recognized as a new standard. Initially, pilot implementation can be carried out in only one separate area of the site and gradually expanded. Targeted personnel should be qualified and trained to use their working time effectively. Machinery and equipment are to be in good

condition, in adequate quantity to meet the needs. There should be no downtime or interruptions, unnecessary operations. Work methods are designed to guarantee safety and good organization.

Phase V - Control and evaluation of results. Once the corrective measures have been implemented to improve the job, a stabilization step is required. It means repetition of a defined working method, trained staff and achieving an optimal level of performance. Audits and the so-called. Manager's celebrations. Assuming that after the optimization has been carried out, monitoring of results will not be continued, then the level achieved will deteriorate. It is good practice to carry out a daily celebration by the manager to ensure continuity of production.

Audits are performed less frequently. During the audit, the use of working methods, quality procedures, functionality and efficiency of operations, productivity, the organization of work, order and cleanliness are verified. This ensures that the achieved performance level is maintained and shows where there are shortfalls that need improvement. The audit always ends with a feedback on the result. After the audit, actions are defined to return to a certain standard.

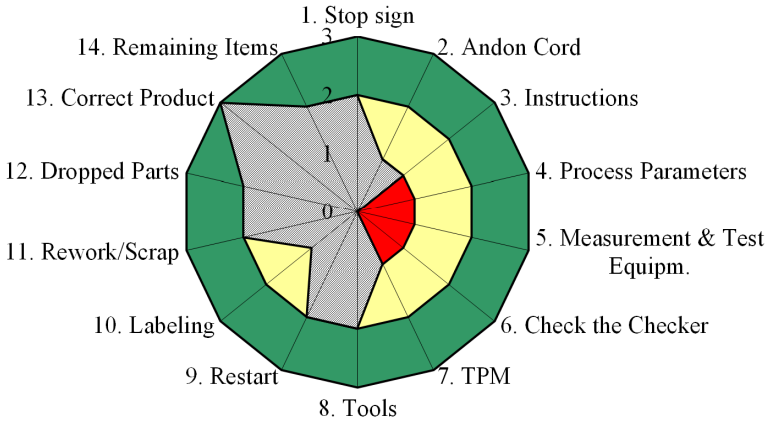
Rationality inaction leads to cost optimization, their reduction to a satisfactory level due to the economic performance of the organization and the level of quality of the products. The presented methodology for improving work organization at the production site allows for detailed analysis of problems and generating corrective actions, leading to systematize and create a structure of performing improvement actions to ensure the correct transformation of the enterprise. As a result, effective solutions are obtained and maximum efficiency is achieved. The risk of failing to meet the goals is reduced to a minimum (Bartnicka (2016)).

The concept of evaluation can be considered in various respects and meanings. In the most general sense, the judgment is a judgmental court, any statement expressing a positive or negative response to someone or something. Evaluations are psychologically and socially conditioned, they change historically according to changes in the systems of values they belong to. The objects of evaluation are called values in general, actions that determine them - evaluation or evaluation, and results - evaluations. Already the distinction between these concepts leads to the problem of expressing the difficult and complex - the objective existence of values and, consequently, the problem of objective assessment.

The use of multiple assessments in an enterprise depends on a number of factors, but the criteria for evaluating the idea and place of assessment in an enterprise are important. These criteria should be included:
- the purpose of the evaluation,
- the test methods used,
- the time to which the assessment relates,
- the detail of the study.

Depending on the destination, the rating can be divided into those for internal and external business purposes. Internal assessment is tailored to the decision-making needs of the management and other management levels in the enterprise. It allows you to assess economic events at different times, both ex-post and ex-ante, at different classification levels, using modern information processing techniques and research methods appropriate to this assessment. External evaluations are designed for the broadly understood corporate environment (shareholders, investors, shareholders, state institutions, banks). Taking into account the time to which the assessment is based, retrospective, current, and prospective evaluations can be distinguished. Prospective assessment includes the results of past actions.

Implementing Plan



The automotive industry requires very good quality from its products. Great competition in the market and dangerous consequences do not allow the products to be weak. That is why every company in this sector strives to meet these requirements best. Production management tools that

ensure high quality should be familiar to everyone in such companies. That is why Bosch decided to gather all the most important of them and to create their own list of steps to improve their product. In such a way that for each employee the rules are clear and legible. So what is the purpose behind the implementation of 14 rules for production areas? The answer is simple, improving product quality and reducing mistakes. In that case, there is no doubt that these actions make sense.

Another thing is to understand the scope of implementation and the area where it is to be implemented. To properly implement the rules, you need to know the content carefully and then gather as much information as possible about the general requirements of the business and get to know the area where the rules are to be implemented.

As it knows, no project can be held without the right team. Therefore, one of the most important steps in preparing for the implementation of the 14 principles is the establishment of the right people. Once the team has been assembled, a very important part of the project can be addressed, which is the assessment of the area in terms of the presence of rules based on comparative analysis. This will allow to identify weaknesses of the process in relation to the requirements of the 14 principles and to create a plan for the implementation of each improvement. From that point on, it is only a step away from starting to implement the principles and observing the positive aspects of this action.

Thanks to the analysis it might be deducted, the points are the weakest and most need improvement. The graph below (Figure 1) show exactly what the evaluation results look like.

Legend red: $0 \leq$ rating < 1 yellow: $1 \leq$ rating < 2 green: $2 \leq$ rating ≤ 3

Fig. 1: Assessment results, based on the book by Fischer, Gemmer and Rach (2017)

To redefine expectations, it was necessary to re-examine the criteria and to determine how many of them could improve. After our analysis, it was found that not only critical results could be adjusted. As part of a continuous process of excellence and achieving the best results, even the good ones could show themselves better.

Results and conclusion

Manufacturing companies are facing a big challenge today. In addition to high-quality goods produced by the competition, they also have to meet the high requirements of customers. These factors, among other things, force companies to continually improve their processes and products. Most often, this is done with ready-made tools. For the entire Robert Bosch Corporation, the most important of these tools have been collected as "14 quality principles for the value stream".

The main goal of this work is to implement these principles into one of the areas in the Bosch production company. The area described here is one of the few that still does not meet the corporate

standards for implementing policies. To change this state of affairs, the following steps have been taken:
- creating a plan for the various activities that help to implement the rules properly, analyze the resources needed,
- familiarize with 14 quality principles, understand and analyze them, adapt existing procedures to content and criteria,
- familiarize with the functioning of the described area, the way of functioning and the management, the knowledge of employees and the work they do,
- team instituting on the basis of skills and qualifications,
- detailed analysis of the state of the current area within the scope of the introduced rules, comparative analysis of the current state with criteria included in the assessment list,
- draw conclusions from the assessment and propose improvements to the individual principles,
- creating an action plan, assigning responsibility to individuals, assessing time spent on tasks,
- brief discussion of the actions taken,
- presenting improved results through planned activities.

As a main indicator of evaluation is the assessment list, in which thanks for comparative analysis every principle were evaluated. The list is a pre-imposed evaluation tool that has its pros and cons. The advantage is that each area can be rated in the same way across the entire corporation. However, the negative side of the list is the fact that by its generality it is not well suited to the specifications of each area. This has led to the assessment of several issues that have been described and highlighted in the assessment. In the end, however, thanks to the evaluation, we managed to find weaknesses and plan actions to improve them. Many actions have been taken to raise the rating. Some of these were based on well-known methods in manufacturing environments such as TPM, Poka-Yoke and Andon Cord. On the other hand, others consisted of raising awareness of employees and bringing order in heavily unkempt aspects. The visual side of 14 principles and the adjustment of the area to these requirements have also played a large part.

In conclusion, in spite of encountering difficult situations, the ultimate goal of the job was achieved. The most part of „14 Quality Principles for the Value Stream" has been implemented in the assembly area. For rules that have not been implemented yet, there are already planned actions. This thesis can be an example for implementing rules in the following areas. The lessons learned after the whole process can be very informative for future activities. Among other things is to plan for a longer time to do the task or better prepare the staff to implement the change. However, the important conclusion is that some seemingly insignificant counterfeit activities can bring big benefits and will certainly save many people from hard work on catching up arrears.

Gestion RSE et Création De La Valeur Partagée

Cherqaoui Mohamed Jawad, Casablanca, Morocco, Cherqaouijawad@gmail.com

Boukhima Asmaa, Professor, Casablanca, Morocco, sntex@hotmail.fr

Abstract

Durant les dernières décennies, la responsabilité sociale des entreprises a fait part de plusieurs débats en lien avec le management des entreprises, le changement climatique, la pauvreté et le chômage, etc. Les entreprises sont considérées comme étant l'acteur pouvant apporter le plus de changement possible. Au lieu de les convaincre pour s'engager dans une démarche RSE, en parlant de performance financière, on doit s'interroger sur l'utilité de ce qu'elles font pour la société, c'est l'origine de l'idée de la Gestion RSE. Une idée qui renvoie à une organisation des efforts et actions des entreprises engagées en RSE. S'agissant de la mise en œuvre, on a besoin d'un organisme qui centralise ces efforts et actions pour les orienter, et donc pour répondre aux différents besoins et défis. Le concept de Gestion RSE ressemble à celui de la création de la valeur partagée, mais en fait il l'englobe. Peut-être que la vraie contribution au développement durable est celle qui concerne, tout d'abord, une limitation d'externalités négatives, et puis l'élaboration d'un projet, ou à en participer, en faveur de la société et l'environnement.

Keywords : Gestion RSE – valeur partagée – développement durable – RSE.

Introduction

Se soucier des problèmes environnementaux et sociaux nous emmène à parler de la conscience, rôle et engagement des Etats, et efforts des organisations non gouvernementales (ONG) par rapport au développement durable, mais aussi de l'engagement des entreprises qui sont souvent condamnées de l'état des choses, que ça soit au niveau social ou au niveau environnemental, et qui, en même temps, sont considérées comme étant l'acteur pouvant apporter le plus de changement possible. Donc, on s'aperçoit que la réflexion s'oriente vers le monde de l'économie.

Et c'est dans ce monde qu'on découvre la complexité des choses, une complexité que nous pouvons résumer en disant qu'il existe, en même temps et lieu, une recherche infinie de rentabilité et une dégradation continue de l'environnement et de la situation des sociétés.

Durant le 20ème siècle et début du 21ème, plusieurs événements ont marqué l'évolution de l'économie mondiale, notamment des crises qui ont provoqué le rejet d'une théorie ou pensée et l'adoption d'une autre. Le krach de 1929 montre les limites du modèle libérale, et on assiste durant les années trente à un passage vers le keynésianisme.

La méthode de relance économique proposée par Keynes, et qui s'est poursuivie aux Etats-Unis pendant la deuxième guerre mondiale, a permis à l'économie américaine et à celle de l'Europe de connaitre, après 1945, une période d'expansion, on parle des trente glorieuses.

Avec les idées apportées par Friedrich August Von Hayek et les chocs pétroliers de 1973 et de 1979, on découvre les insuffisances du keynésianisme et on passe au monétarisme tout en ouvrant la voie au néolibéralisme.

Avec un focus sur la rentabilité, favorisé par une liberté maximale pour les entreprises, il est fort probable que le néolibéralisme prend une part de tout débat se rapportant aux questions du changement

climatique et du bien-être à travers le monde. Il se définit comme un cadre institutionnel, politique et idéologique au sein duquel le capitalisme jouit de davantage de liberté de manœuvre[i].

De même, dans le cadre du capitalisme les entreprises sont perçues comme la cause majeure des problèmes sociaux, environnementaux et économiques. Il s'agit d'un constat établi par Michael .E. Porter et Mark R. Kramer, auteurs de l'article « Creating Shared Value[ii] » parue en 2011, un article sur lequel je vais me baser pour lancer l'idée de Gestion RSE en la comparant avec celle de la création de la valeur partagée. Il ne s'agit plus d'une critique, mais d'une simple comparaison ayant pour but de passer au crible des choses afin de donner une idée claire sur cette Gestion RSE.

Lorsqu'on parle de la RSE, du rôle des entreprises dans la contribution au développement durable, notre réflexion est souvent liée à la question suivante : qu'est-ce que ces entreprises vont gagner derrière cet engagement ? Et on essaie de répondre à cette question pour les convaincre de s'engager, mais peut être qu'en voyant les choses différemment qu'on va parvenir à mieux contribuer au développement durable, d'où l'intérêt de cet article. Le présent travail est subdivisé en deux parties, la première partie traite l'engagement RSE, tandis que la seconde concerne la création de la valeur partagée.

Engagement RSE et Gestion RSE

Débutant par une mise en évidence de la différence, en économie, entre croissance et développement. Ce dernier, indique un changement de structure de l'économie et de la société en général. On donne l'exemple d'un pays mono-exportateur qui, en produisant davantage de son seul bien exportable, ne devient pas, à cet effet, un pays développé (il croît, mais ne se développe pas)[iii].

Le développement fait allusion à des transformations qui concernent plusieurs volets, plus que l'économique, c'est à ce niveau qu'il se différencie de la croissance[iv]. On qualifie la croissance du quantitatif, alors que le développement est de nature qualitative et quantitative. A noter que le développement (qui produit des effets démographiques, sociaux-culturels et économiques) et la croissance sont interdépendants[v].

Si la croissance se différencie du développement, ce dernier à son tour se différencie du développement durable où on est dans une vision plus large, il s'agit de relever des défis dont la réflexion se place à l'échelle planétaire.

De plus, si la croissance n'entraine pas automatiquement la réduction des inégalités économiques et sociales, le développement ne permet pas de combler les inégalités mondiales et de garantir le progrès du bien-être. Partant de là, le développement durable se présente comme une solution quant aux limites du mode de croissance et de développement économique tout en prenant en compte ses différents effets sur le long terme.[vi]

Pour définir le développement durable on se réfère au rapport "Notre avenir à tous" de 1987 de la commission mondiale sur l'environnement et le développement, où on trouve qu'il s'agit d'un « développement qui répond aux besoins du présent sans compromettre la capacité des générations futures de répondre aux leurs. »[vii]

Lorsqu'on parle de l'application des entreprises du concept de développement durable, on parle de la responsabilité sociale des entreprises, il s'agit ici d'une réflexion correspondant à la troisième vague de conception de la RSE.

Selon Capron et Petit, on distingue entre trois vagues de conception de la RSE. Passant d'une conception « éthique » (1950-60) indiquant l'éthique personnelle du dirigeant d'entreprise, et dont le texte fondateur est celui de Bowen (1953), à une conception utilitariste (1960-70) où on abandonne l'exigence morale à l'égard de la société, et ce en faveur d'une exigence économique qui se traduit par le fait que le comportement social de l'entreprise doit servir sa performance économique. Puis à une conception de « soutenabilité » (années 90 et 2000) qui repose sur l'idée que l'entreprise doit prendre en considération

les préoccupations sociales et environnementales, elle ne peut donc être insensible aux pressions de la société civile et aux défis sociétaux de son temps.[viii]

En outre, le fait de s'interroger sur le lien entre engagement RSE et performance des entreprises, notamment financière, a fait couler beaucoup d'encre. Certainement il vient à l'esprit qu'il existe un impact positif d'un tel engagement sur la performance financière d'une entreprise, mais nous ne pouvons pas dire, d'une manière définitive, qu'il y a déjà un lien de causalité. Tout dépend des échantillons, du contexte, de l'horizon temporel de l'analyse réalisé.

On peut trouver une explication de cela si on se réfère à la synthèse de littérature sur la responsabilité sociale et performance financière des entreprises, élaboré par José Allouche et Patrice Laroche (2005). Le lien entre la responsabilité sociale des entreprises et leur performance renvoie à celui entre la performance sociale et la performance financière. Et c'est à ce point que la première difficulté apparaît, celle de l'évaluation de la performance sociale. Ajoutant à cela une pluralité de modèles théoriques (lien positif, lien négatif, synergie positive ou négative, absence de lien, un lien plus complexe). Ainsi, au niveau empirique, la contradiction caractérise les résultats des études réalisés, chose qui ne permet pas de prouver l'existence d'un tel lien.[ix]

De ce fait, il semble intéressant de voir les choses d'un angle différent, et ce en projetant la lumière sur les effets des actions RSE, des entreprises déjà engagées, sur la société et l'environnement. L'utilité de ces actions peut être considérée comme l'un des facteurs qui influence les résultats des études axées sur la relation entre un tel engagement et la performance.

Les entreprises se trompent quant aux leurs choix d'actions et d'efforts à mener vis-à-vis de la société et l'environnement en croyant que n'importe quel choix peut leur garantir un statut RSE, et n'importe quel choix peut suffire à leur assurer une certaine légitimité dans leurs rapports avec les parties prenantes.

Lorsqu'on ignore ce dont la société et l'environnement ont vraiment besoin, on ne peut pas s'attendre qu'il y aura un impact sur la performance, surtout positif. En terme de l'amélioration de la réputation, dont les conséquences concernent à la fois les clients et les salariés, l'utilité des actions RSE s'avère cruciale.

Si les actions/projets RSE, munis par une entreprise, sont inutiles ou n'ont pas une grande importance, notamment dans la région ou ville où cette entreprise exerce son activité, quel que soit leur nombre, ses actions vont échouer à gagner une bonne perception auprès des clients, donc on perd une opportunité à assurer la fidélisation qui, en diminuant les coûts d'acquisition de nouveaux clients, permet une efficacité commerciale à l'entreprise[x].

Et elles vont échouer à gagner une bonne perception auprès du personnel, et dans ce cas on perd aussi une opportunité, celle de gagner davantage de confiance des salariés envers l'organisation, à laquelle ils fournissent leur force de travail, il s'agit d'une manière d'augmenter la productivité. Ad hoc on propose la Gestion RSE.

La Gestion RSE signifie la gestion des actions, efforts ou/et projets des entreprises engagées. Cette gestion permet de répondre de la façon la plus appropriée aux besoins de la société et de l'environnement. Il s'agit en premier lieu de connaitre les différents besoins à satisfaire et problèmes à résoudre, puis de les mettre en ordre de priorité, ensuite de passer à l'action.

Si chaque entreprise suit ces étapes, que nous pouvons qualifier de travail individuel, ça sera une démarche convenable juste pour les entreprises qui ont les moyens permettant de faire ce type d'enquête dans les régions ou villes où elles opèrent. Donc, les petites et moyennes entreprises ne seront plus concernées par cette démarche et ne pourront plus en bénéficier.

Dans une situation pareille, on risque de faire un détour au point de départ où la RSE est considérée, dans le monde des affaires, comme un ensemble de coûts supplémentaires, et où la pérennité et la prospérité des entreprises sont liées à la recherche continue de la rentabilité.

De ce fait, on voie bien que la Gestion RSE est un travail de nature collectif et non pas individuel. La Gestion RSE indique l'existence d'un organisme ayant comme rôle l'organisation et l'orientation des efforts des entreprises engagées en RSE afin d'assurer la plus grande utilité possible.

Cet organisme doit élaborer, en collaboration avec les pouvoirs publics, un travail exploratoire afin d'identifier les différents problèmes et besoins. Puis, la mise en ordre par priorité des besoins et problèmes identifiés. Ensuite, la mise à disposition, des entreprises adhérentes à cet organisme, d'informations sur la prospection menée pour que chacune d'elles puisse décider de quelle manière elle va contribuer, soit en offrant des fonds soit en assurant la réalisation du projet ou d'une partie du projet, si ce dernier correspond à son activité. Ainsi, cet organisme doit veiller à l'accomplissement des projets dont la contribution des adhérents n'est que sous forme de fonds.

De plus, pour que cette contribution soit reconnue, l'organisme de Gestion RSE se charge de la publication périodique, mensuelle ou trimestrielle, des données sur le projet réalisé ainsi que sur les participants et leurs apports.

Le rôle joué par ledit organisme facilitera la tâche aux entreprises, l'adhésion de celles qui sont déjà engagées en RSE va certainement encourager d'autres pour adhérer et donc de s'engager. Il est à noter que la Gestion RSE ne concerne que les parties prenantes externes, tandis qu'en interne de l'entreprise le déroulement des choses diffère d'une unité à une autre.

En outre, l'adhésion d'une entreprise implique qu'elle apporte différentes données, notamment celles d'ordre financier, le but est de comparer sa situation avant et après l'engagement (on parle ici des entreprises qui ne sont pas engagées en RSE et qui veulent en devenir à travers ledit organisme).

La diversité des entreprises adhérées au niveau de la taille et du secteur, et qui comprend des entreprises offrant des produits ou des services ou bien les deux, industrielles ou commerciales, exportatrices ou non, connaissant une croissance ou une difficulté, ayant un investissement en cours ou non… va enrichir l'analyse autour de l'impact de la RSE avec une base de données qui s'élargie en continuité, et grâce à laquelle nous pouvons constituer, au fil du temps, les différentes échantillons qui peuvent exister.

En associant à cette abondance d'échantillons, l'utilisation de toutes les mesures qui existent en terme performance sociale et financière, on va parvenir à des résultats plus significatifs et plus pertinents à l'égard du lien entre engagement RSE et performance des entreprises.

Tout cela nous indique que la Gestion RSE garantit un équilibre entre la société, l'environnement et l'économie. Elle répond aux attentes de la société, qui comprennent celles de l'environnement, et aux attentes des entreprises, il s'agit principalement de gagner une certaine légitimité, d'améliorer la réputation et de motiver le personnel, donc une augmentation de la productivité.

Et en parlant de la réputation, la Gestion RSE va être d'une grande aide aux entreprises en ce qui concerne, d'abord la notoriété de la marque, puis l'image de marque. Il est à signaler que les avantages peuvent s'étendre pour concerner même les futurs clients et futurs salariés, notamment dans le cadre la marque de l'employeur « Employer Branding » et/ou de l'attractivité de l'employeur « Employer Attractiveness ». Concernant ce dernier point, on note comme exemple les travaux d'Aiman-Smith, Bauer & Cable (2001)[xi] et de Turban & Greening (1997)[xii].

Une meilleure réactivité est l'importante caractéristique de la Gestion RSE. Avec la démarche déjà soulevée on répond aux besoins de la société et de l'environnement d'une manière efficiente, surtout en terme de temps, et efficace, et de ce fait on se trouve dans une optique de performance de la RSE, des actions RSE, plutôt que juste se soucier de l'existence d'un lien entre un tel engagement et la performance des entreprises.

Gestion RSE et valeur partagée

L'idée de la valeur partagée existe déjà avec celle de l'entreprise sociale qui est une initiative entrepreneuriale dont la finalité sociale ou environnementale est supérieure ou égale à la finalité économique. L'argent généré par l'entreprise sociale, nécessaire pour la pérennisation et le développement, est totalement réinvestie dans l'entreprise. Autrement dit, les revenus générés sont générés pour défendre la finalité sociale ou environnementale.

La finalité économique, dans une entreprise sociale, n'est pas une fin en soi, mais un moyen au service de la finalité sociétale et environnementale, c'est ce qui différencie ce type d'entreprise des entreprises privées qui ont une politique de responsabilité sociale de l'entreprise. Ces entreprises ont bien évidement des actions au bénéfice de la société, mais elles optent pour ces actions une fois que l'actionnaire a été rémunéré, une fois que la finalité économique a été remplie, et aussi si elles ont le temps, l'envi et la possibilité.

L'idée de la valeur partagée de Porter concerne les autres entreprises, celles qui, selon lui, ont resté piégées dans une approche caduque de la création de valeur, elles continuent de voir la création de valeur de manière étroite, et ce afin de les réorienter vers, toujours selon Porter, un nouveau capitalisme : « *The concept of shared value can be defined as policies and operating practices that enhance the competitiveness of a company while simultaneously advancing the economic and social conditions in the communities in which it operates. Shared value creation focuses on identifying and expanding the connections between societal and economic progress.* »

S'agissant de la comparaison entre la Gestion RSE et la création de la valeur partagée. Le point commun entre les deux est que les entreprises doivent prendre l'initiative de rapprocher le Business et la société. Mais la manière de le faire diffère un peu.

Lorsqu'on parle de la Shared Value on parle de la création de valeur économique tout en créant une valeur pour la société en réponse à ses besoins et défis. Les entreprises doivent reconnecter leur succès avec le progrès social, autrement dit, elles doivent lier leur engagement, responsabilité et bienfaisance à leur activité afin de créer une valeur partagée, économique et sociale. Ce n'est plus en marge de l'activité principale, mais au centre, elle touche même la stratégie de l'entreprise.

Quant à la Gestion RSE, on est dans une vision d'organisation des choses. On organise les efforts des entreprises en matière d'RSE afin de répondre, avec performance, aux besoins et problèmes à la fois de la société et de l'environnement. Il s'agit d'un travail réalisé à l'aide d'un organisme qui gère ces efforts et projets. Cette gestion facilite l'engagement RSE pour les entreprises, à travers une simple contribution par ressources financières, et à travers l'autre type de contribution qui donne une chance à toutes les entreprises, surtout aux PME, de bénéficier de la valeur partagée. Alors, la Gestion RSE englobe la Shared Value.

Si la RSE est une activité périphérique et la création de la valeur partagée est au centre de l'activité principale de l'entreprise, donc cette valeur partagée n'est qu'un degré supérieur de la RSE. En suivant le même raisonnement la Gestion RSE est aussi un degré supérieur de la RSE, plus que celui de la valeur partagée.

En effet, la diversité des projets et efforts à réaliser, au cours des mois et des années, en faveur de la société et de l'environnement, fait que chaque entreprise, parfois, est dans la création de la valeur partagée, et parfois elle est dans un simple engagement RSE.

Selon Porter et Kramer « Businesses acting as businesses, not as charitable donors, are the most powerful force for addressing the pressing issues we face », ajoutant à cette citation ce que signifie la valeur partagée en tant création à la fois de valeur économique et sociale, de ce fait la création de ce type de valeur, dont Porter et Kramer parlent, semble être un investissement. Plutôt que de limiter ou dépasser le motif de la maximisation du profit, c'est précisément ce motif qui conduit le business model de la valeur partagée[xiii].

L'idée de la création de la valeur partagée fait signe que toute entreprise cherchant à créer cette valeur va ignorer les besoins, problèmes et défis de la société ne permettant pas de créer une valeur économique pour elle.

On est dans une vision opportuniste des choses, ce qui peut servir comme principale reproche de l'apport des deux auteurs. Au second rang, on a les exemples cités dans leur article, la plupart de ces exemples sont de grandes entreprises, certaines parmi elles ont atteints le niveau de globalisation, qui ont les moyens nécessaires pour créer cette valeur partagée soit en développant des clusters locaux, reconcevoir les produits et les marchés ou redéfinir la productivité dans la chaine de valeur.

Ainsi, on risque d'avoir un impact faible en terme de réputation, puisqu'on peut qualifier tout projet, effort ou action réalisé dans le cadre de la création de la valeur partagée comme étant un investissement, donc une exploitation plus qu'une contribution. La Gestion RSE, par diversité des projets, permet de faire de la philanthropie ou bienfaisance, ainsi que la création de la valeur partagée, et ce avec une grande utilité pour la société et l'environnement, donc un impact élevé en terme de réputation.

Notons que la création de la valeur partagée est plus importante dans le cadre de la Gestion RSE, parce que cette création correspond à ce que la société et l'environnement ont vraiment besoin. En effet, la valeur partagée est beaucoup plus forte dans le cas où elle répond aux besoins et défis de première priorité, et est réalisable avec moins de coûts possibles.

A la fin de leur article, Porter et Kramer annoncent que nous ne pouvons pas résoudre tous les problèmes sociétaux à travers la valeur partagée, une faiblesse face à laquelle la Gestion RSE se présente comme la solution la plus convenable.

Conclusion

D'après Porter et Kramer, les personnes dans le secteur public et privé ont souvent suivi des parcours pédagogiques et professionnels très différents. Par conséquent, peu de managers ont une compréhension, des problèmes sociaux et environnementaux, nécessaire pour aller au-delà des approches actuelles en matière de RSE. Ainsi, la plupart des écoles de commerce enseignent encore la vision étroite du capitalisme, leurs programmes d'études doivent s'élargir dans un certain nombre de domaines. En attendant un tel changement, donnons une chance à la Gestion RSE, avec laquelle on n'est plus dans une logique d'impact de l'engagement RSE sur la performance de l'entreprise, mais dans une logique d'impact de l'engagement RSE sur la société et l'environnement.

Management of Sustainable Development in Small and Medium-Sized Companies: Driver and Network Approach

Valery M. Anshin, Professor, Department of Business and Management, National Research University Higher School of Economics, Moscow, Russian Federation, email: val_an@mail.ru

Ekaterina Skripka, MSc student, Department of Business and Management, National Research University Higher School of Economics, Moscow, Russian Federation, email: ekskripka@mail.ru

Abstract

The article aims to highlight the network approach to sustainable development and its application to small and medium enterprises (SMEs). The network approach is illustrated with a case study of a medium-sized production company. Authors also focus on the SMEs characteristics and possible ways on how to implement sustainable development principles in SMEs strategic and operating activities.

Keywords: Sustainability driver based model, sustainable driver's network, sustainable development in SMEs

Introduction

Sustainable development (SD) concept firstly mentioned in 1987 in the World Commission on Environment and Development report was identified as a way of development allowing not only current but also future generations to "meet their own needs". Taking into account sustainability principles, management of organizations all over the world stepped into a new era of sustainable growth and development. In order to provide SD, organizations implement and follow social responsibility, eco-friendliness principles, as well as reorganize its operations. Today SD principles are widespread and well-known, yet very often sustainability is associated with big enterprises, transnational corporations rather than SMEs (Bos-Brouwers, 2010; Koe et al, 2015).

Sustainable Development Concept

There are three components of sustainable development: ecological, social and economic (Anshin, 2013; Günerergin et al, 2012). *Ecological sustainability* reflects an idea of saving the planet for future generations. *Social sustainability* implies the harmonization of business and society interests that, in turn, fosters long-term prosperity of the business and transfers this business to future generations. *Economic sustainability* reflects favorable economic conditions in the market, e.g. availability of resources, including financial resources that provides a steady increase in value of business; under economic sustainability we may also imply companies with well-developed competitive advantages, low operating costs etc.

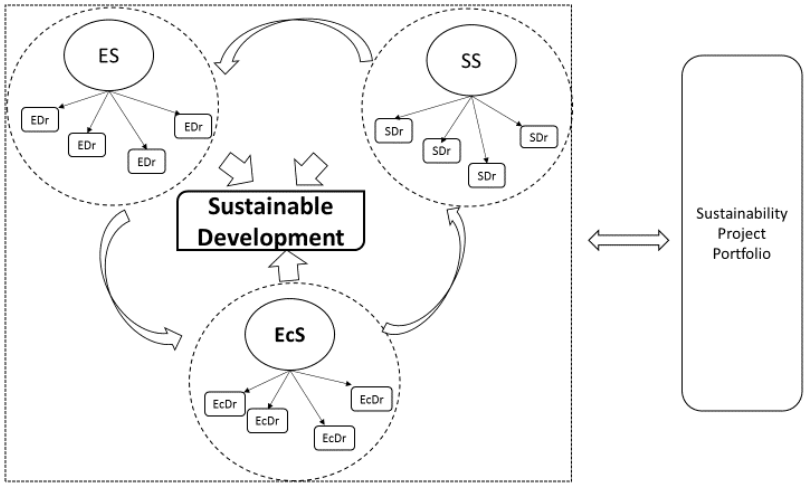
Changes and improvements in each of these aspects are forced by specific drivers. A driver of sustainable development is a factor whose change leads to a change (improvement or deterioration) in the company's sustainability.

There are two sets of drivers representing sustainable development: general drivers and individual drivers. General drivers are labor relations, relations with the society, working conditions, terms of remuneration, the quality of products and services, customer loyalty, financing opportunities etc. Individual drivers are more associated with environmental sustainability, which is determined by technological specifics, company scale, territory, etc.

Drivers of sustainable development are interrelated. For instance, favorable working conditions result in employee turnover decrease, which, in turn, increases the level of satisfaction among employees. Satisfied workers produce work of a higher quality. Further, higher product quality leads to revenue growth, increased profits, and this, in turn, creates financial opportunities to improve working

conditions and environmental protection. Many companies use a driver based model to achieve strategic goals (Heskett et al, 1997; Heintman & Marson, 2005). Authors propose to transform this model into a sustainability driver based model (SDBM).

When implementing SDBM the following steps are required:



- Determination of main sustainability drivers;

- Determination of correlation between drivers via network analysis;

- Driver prioritization;

- Selection of the most important drivers and creation of a portfolio of sustainable development projects.

Proposition 1: management of successful sustainable development as an ongoing process that may be achieved through environmental, social and economic sustainability adherence, allocation of drivers, their correlation determination, and, finally, the formation of a portfolio of sustainable development projects.

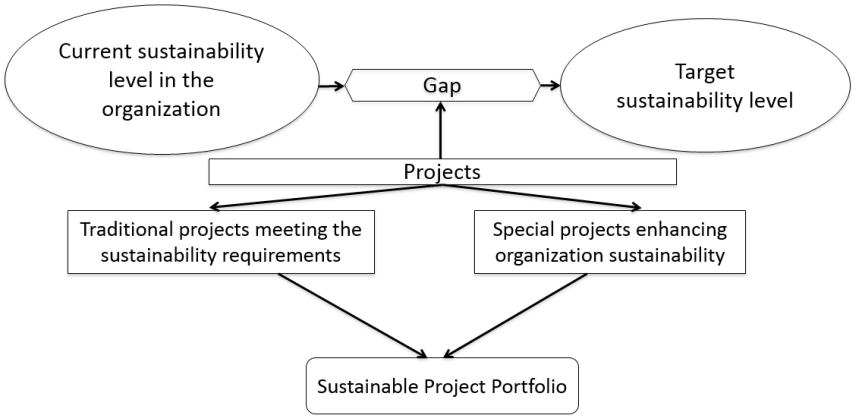
ES – economic sustainability
ECS – ecological sustainability
SS – social sustainability
EDr – economic sustainability drivers
SDr – social sustainability drivers
EcDr – ecological sustainability drivers

Network approach in managing sustainable development

As it was mentioned above, drivers of sustainable development are interrelated; several drivers compose a *sustainable driver's network* (*SDN)*. Driver relations can be analyzed and visualized via special tools related to the theory of networks (Newman, 2010).



Sustainable driver's network (SDN) can be built through the following steps:

- Creation of structure design matrix (driver correlation matrix);
- Development of a graphical representation of a network;
- Drivers' validity/ significance determination;
- Drivers' prioritization based on its validity.

Structure design matrix is the first step of the network analysis (Fang et al, 2012). The matrix represents a square with drivers located in lines and columns. Matrix cells totaling "1" are located in the intersections of the interdependent drivers and called matrix nodes. The matrix is filled on the basis of expert evaluations. Thus, the matrix represents a network illustrating the interconnections of drivers. Network analysis allows identifying the most significant drivers of sustainable development. There are several tools of network analysis (Newman, 2010). In this article, the authors use the tool called a "degree of a node". A node degree is equal to the number of connections between a certain driver and the others. There are two main types of interconnections: "incoming degrees" showing influence other nodes have on a certain node and, vice versa, "outflowing degrees" demonstrating how this node influences other nodes.

Sustainable Project Portfolio

After driver correlation analysis, driver significance determination and driver prioritization, a portfolio of programs and projects is formed (Anshin, 2013). In this portfolio, the following two sub-portfolios can be identified: sub-portfolio of "traditional" projects, which aim is primarily to improve operating activities with a respect to sustainability principles and sub-portfolio of special projects, which are developed specially to foster sustainability in the organization. A project, in terms of which a new product should be developed in accordance with ecological requirements, is an example of a project of a traditional sub-portfolio. At the same time, the project of waste treatment facilities development relates to the second sub-portfolio. To enhance sustainability, it is crucial to execute projects of both sub-portfolios; however, these projects should be evaluated differently, with a respect to their special characteristics.

Source: compiled by the author based on data available at open sources

Fig. 2. Sustainable Project Portfolio Forming

Proposition 2: Sustainability may be achieved through management of portfolio containing both traditional projects meeting the sustainability requirements and special projects supporting and enhancing current organization' sustainability.

Sustainable development in small and medium-sized enterprises (SMEs)

SMEs are truly important part of the economy. Thus, in the countries with well developed economy such as EU and Norway, SMEs build up to 90% of GDP (Bell, 2015; Airaksinen et all, 2015). SMEs

provide workplaces, satisfy various needs of the population due to its flexibility, adaptability and better understanding of particular consumerist' needs. Returning to the research question, does SD exist in SMEs and in which forms? Indeed, sustainable development cannot exist in SMEs in the same from as it exists and prospers in large enterprises. The research conducted by the authors shows that small and medium-sized businesses have the following internal and external characteristics that influence management of sustainable development:

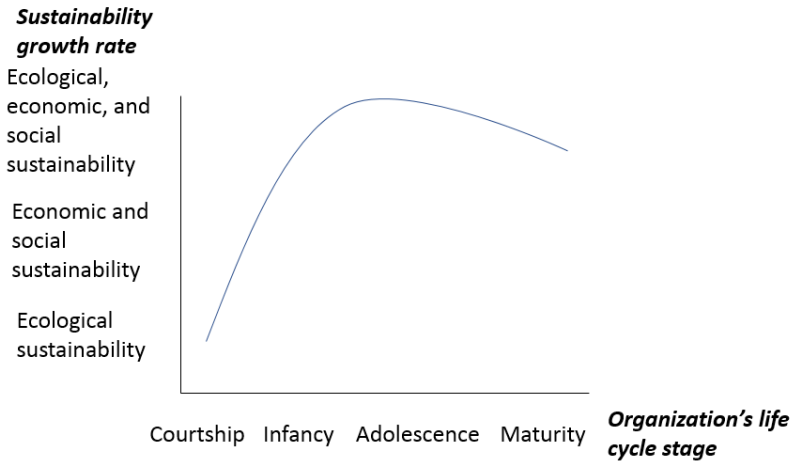
- Limited financial resources allocated to sustainable development;
- Limited opportunities to attract external financial resources;
- Insufficient managerial experience of business owners and top managers (not always, but quite often);

- In a number of cases, a low management culture, ignorance of the best practices for managing sustainable development;

- Intention to use the simplest and cheapest technological solutions not paying attention to working conditions and environmental impact;

- Low opportunities for fair pay and social guarantees;

- In some cases, violation of laws on pay and working conditions;



- SMEs are dependent on individual specialists, whose termination of employment may cause serious problems;

- The level of sustainability in SMEs depends on organization life cycle stage significantly.

According to Lazarus & Feldbaum (2011), business activity based on sustainable development principles will increase an attractiveness of SMEs for investors supporting Equator principles ("…the Equator principles is a risk management framework, adopted by financial institutions, for determining, assessing and managing environmental and social risk in projects…", The Equator Principles Association (2011)).

For SMEs, operating and strategic activities based on sustainability principles allow to solve the number of crucial problems. It is important to mention that sustainability priorities and efforts have to be related to organization's life cycle stage goals and objectives. For instance, in the early stages of the company's life cycle it is important to promote its own brand, attract more and more consumers producing eco-friendly products. Further, as we move to the next life cycle stage, economic stability becomes the priority; at the same time, during this stage it is important to improve working atmosphere, establish connections with local authorities. As the company achieves maturity, management of this organization has an opportunity to develop all aspects of sustainable development (fig. 3). Along with the mentioned transitions and sustainability principles development based on the company characteristics, there are also other means how sustainability may be integrated to business activities.

Taking into consideration the information given above, together with organization's life cycle there is business sustainability life cycle (BSLC). Each BSLC phase has to be managed using corresponding tools.

Source: compiled by the authors based on data available at open sources

Fig. 3. Business sustainability life cycle (BSLC)

Proposition 3: In small and medium-sized businesses, the structure, elements of sustainable development and the intensity of their application strongly depend on the stage of the company's life cycle and business sustainability life cycle.

Case study: Sustainable Development Network (SDN) for medium-sized FMCG company

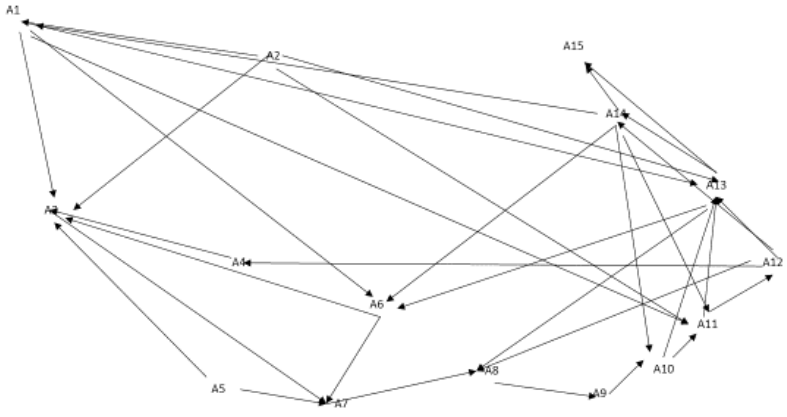
An exemplified FMCG enterprise produces meat products and sells them through the distribution network. This company has a meat processing plant and a hog enterprise. The organization uses its own raw materials and buys some on the side. According to expert evaluations, the company enters the stage of maturity in its life cycle.

The company starts working on sustainable development and identifies key SD drivers (table 1).

Table 1: Key sustainability drivers in the exemplified company

Ecological drivers	Social drivers	Economic drivers
• Land, water, and air pollution reduction (A1) • Reduction of the degree of environmental pollution with meat processing waste (A2)	• Staff turnover decrease (A3) • Fair compensation (A4) • Favorable working conditions (A5) • Non-monetary motivation (A6) • High quality of work (A7)	• High product quality (A8) • Customer satisfaction and loyalty increase (A9) • Revenue (A10) • EBITDA (A11) • Internal financial resources (A12) • External financial resources (A13) • Assets (A14) • Value of the company (A15)

Source: compiled by the author based on data available at open sources



Driver relations are represented in table 2. Each driver has both "incoming" and "outflowing" degrees. Incoming degree characterizes the impact of other drivers on a particular one; outflowing degree illustrates how a certain driver influences others. From the table 2 it can be seen that driver A13 (external financial resources) has the largest incoming degree. This driver belongs to the group of economic stability; A13 it is influenced by other economic stability drivers and ecological drivers as well. At the same time, A13 influences other drivers, and it has the outflowing degree that is equals "3". In the second place, according to the incoming influence, there are drivers of social sustainability - employee turnover, further quality of work and EBITDA (economic stability driver).

Table 2: Driver correlation matrix

	A1	A2	A3	A4	A5	A6	A7	A8	A9	A10	A11	A12	A13	A14	A15	Outflowing degree of a node
A1			1			1					1		1			4
A2			1								1		1			3
A3							1									1
A4			1				1									2
A5			1				1									2
A6			1				1									2
A7								1								1
A8									1							1
A9										1						1
A10											1		1			2
A11												1	1	1		3
A12				1				1					1	1		2
A13						1		1						1		3
A14	1					1				1	1		1		1	6
A15													1			1
Incoming degree of a node	1	0	5	1	0	3	4	3	1	2	4	1	7	3	1	

Source: compiled by the author based on data available at open sources

Based on outflowing influence, driver A14 (assets) takes the first place, and its position is absolutely justified: in order to activate other drivers it is obligatory to accumulate adequate capital expenditures and current assets. Driver A1 (land, water, and air pollution reduction) has a comparatively high outflowing degree, since this driver contributes to ecological sustainability increase and closely connected with social and economic sustainability drivers. Driver relations are illustrated in fig. 4.

Source: compiled by the author based on data available at open sources

Fig. 4. Driver interrelations in the exemplified company

Based on the characteristics described above, the portfolio containing the following sustainable projects may be developed:

1. Acquisition of biogas unit in the pig farm;
2. Acquisition of equipment for preliminary waste processing and outsourcing of the prepared wastes to specialized companies;
3. Implementation of key performance indicators (KPI) aimed at the growth of EBITDA;
4. Non-monetary motivation campaign launch.

Recommendations

Up to this point, network approach was exemplified by the certain company, yet there is a need in a broader understanding of application SDN in small and medium-sized enterprises. Ecological, economic, and social sustainability in SMEs may be achieved through the following means:

1. Development of a unique competitive advantage (it will provide conditions for economic sustainability);
2. Co-operation of SMEs and emergence of Self-regulated organizations (SRO) (such measures will also contribute to economic and social stability);
3. Project Management (a mechanism that covers all three aspects of sustainability: ecological, economic, and social).

It is important to remember that there is a tough competitions between SMEs existing in the market economy. Medium, small and especially micro enterprises are frequently forced to survive, to avoid bankruptcy, to attract consumers by any means and here, unfortunately, sustainability principles implying social responsibility, future generations care, and eco-friendliness will be always enormously violated.

The first recommendation is to develop a unique competitive advantage. Under this recommendation organizations are advised to develop and encourage information exchange, innovation, creativity, and intellectual capital (Todericiu & Stanit, 2015). Besides, niche strategies allow organizations to acquire a strong competitive advantage (unique products/services/techniques rather than cheap prices, good location, and other unstable advantages) that will, in turn, allow management to spent more time thinking over SD postulates and even implement them in days operations. It will provide organizations with confidence in the future.

The second recommendation is about creation of self-regulated organizations (SRO) and cooperation. Acting one by one, not as a united mechanism, SMEs can hardly defend its rights, present its interests etc. Here two goals can be achieved via SRO emergence. The first is a formal or informal deal or agreement, allowing each member to define itself, claim its specialization and to become a valuable unit in the whole mechanism. The second goal is lobbying of its interests in front of the government. It is worth mentioning that SMEs can cooperate not only with each other, but also with universities when developing and implementing sustainability-oriented innovation (SOI) (Jones et al, 2016).

The third recommendation may sound too general in the beginning, yet project management may become a truly important tool when implementing SD postulates in SMEs practice. Although project management is not a universal tool, yet such a complex, systematic mechanism contributes to efficiency and profitability increase, employees qualification increase, successful decision-making, acquisition of various certifications (accordance with norms and regulations). S. Marcelino-Sadaba et al (2015) in their research “Using project management as a way to sustainability. From a comprehensive review to a framework definition” suggest that project management correlates with sustainable development for the following reason. Project management is usually implemented in the organization in accordance with common standards such as PRINCE 2, PMBoK etc. Under these standards organizations work closely with stakeholders, introduce life cycle management that is nothing else than sustainability.

Outcomes

1. Management of successful sustainable development as an ongoing process that may be achieved through environmental, social and economic sustainability adherence, allocation of drivers, their correlation determination, and, finally, the formation of a portfolio of sustainable development projects;

2. Sustainability may be achieved through management of portfolio containing both traditional projects meeting the sustainability requirements and special projects supporting and enhancing current organization' sustainability;

3. In small and medium-sized businesses, the structure, elements of sustainable development and the intensity of their application strongly depend on the stage of the company's life cycle and business sustainability life cycle.

Conclusion

Society is interested in harmonization of SMEs activities, in modernization of SMEs from chaotic, constantly fighting with each other for short-term profits units to cohesive structure that may present its common interests and work under sustainable development postulates successfully. Driver-based sustainability models may become a useful tool for integrating sustainability principles to business processes. As for this study, it is currently in the process of examining small and medium-sized companies with a respect to exploration the practices of managing sustainable development and developing a driver and network approach in this area.

Abstract

The correct analysis of patent data is crucial when implementing Intellectual property rights (IPR) management in any part of a business oriented entity. The analysis is standardly performed by specialists on the IPR field which can be divided into two groups: the patent attorneys and the in-house patent experts. But there are other possibilities to reach very good results and possibly save resources and time for example it can also be performed by technical specialists on the researched field and last but not least it can be performed by low level personal, for example students, which has been properly trained. The right amount of investment in the IPR analysis can decide over the level of risk reduction but can also dry out the available resources very fast. Key factors like who is performing the analysis and research can be decisive concerning the quality of the results, the security that it provides, but also the justification for the investment. The objective of this paper is to identify the right strategy of research, analysis and expert assessment to achieve the highest possible risk reduction for the least financial and work investment. The methodology used involves 6 different Due Diligence (DD) processes which were implemented in the course of 7 years in two different global corporations by the writers as well as a literature research of the best practices on the field. It is proposed to create a practical framework which guides and supports the path to a resource sustainable implementation of previous research results.

Keywords Risk management, mergers & acquisitions, Intellectual Property Rights, Due Diligence, sustainable strategy, time and resources investments

JEL Classification: A10, A11, D21, M12

Introduction

The thorough analysis of patent data is critical when projecting and implementing IPR management in a company. The analysis is usually performed by experts in IPR area like patent attorneys and in-house patent experts. In order to save resources and time and get the same quality of results, these analyzes could also be performed by technical specialists on the researched field and low level personal, for example students, which has been trained into looking for the right points and for the right parts in the material supplying the IPR specialists with a small summary implementing only the

relevant material for the analysis. The right amount of investment in the IPR analysis can decide over the level of risk reduction but can also dry out the available resources very fast. If too much resources are used the costs can skyrocket very fast and the added value of the additional risk reduction is very small and cannot be justified by the very expensive work invested into achieving it. Key factors like who is performing the analysis and research can be decisive concerning the quality of the results, the security that it provides, but also the justification for the investment. For example: patent attorneys which are the highest level IPR specialists are also the ones that could assume the highest level quality of risk analysis and can take a lot of responsibility for the opinions that they express as a result. The attorneys will normally have a very high quality insurance which will back up the responsibility that they are ready to assume. Unfortunately, most good patent attorneys know that the analysis reports that they are writing are only one point of view and at the end of their reports they will clearly cite that. Through this they retract the responsibility level to a minimum from their point of view. This way the responsibility they assume is more for the professional mistakes than possible misreading or misunderstanding of the analyzed material.

The objective of this paper is to identify the right strategy of research, analysis and expert assessment to achieve the highest possible risk reduction for the least financial and work investment.

Research Methodology

The methodology used involves 6 different Due Diligence (DD) processes which were implemented in the course of 7 years in 2 different global corporations by the writers as well as a literature research of the best practices on the field. It is proposed to create a practical framework which guides and supports the path to a resource sustainable implementation of previous research results**.** In previous research we developed a new strategy of implementing the intellectual property due diligence (IPR DD) into the merging and acquisitions (M&A) due diligence process. We researched and in parallel implemented the results, thus going through several steps of development until we reached a resources sustainable new strategy for IPR DD for M&A. We started with the basic questions that need to be answered by an IPR DD and continued into analyzing the different phases of the M&A DD which can be seen in figure no. 1.

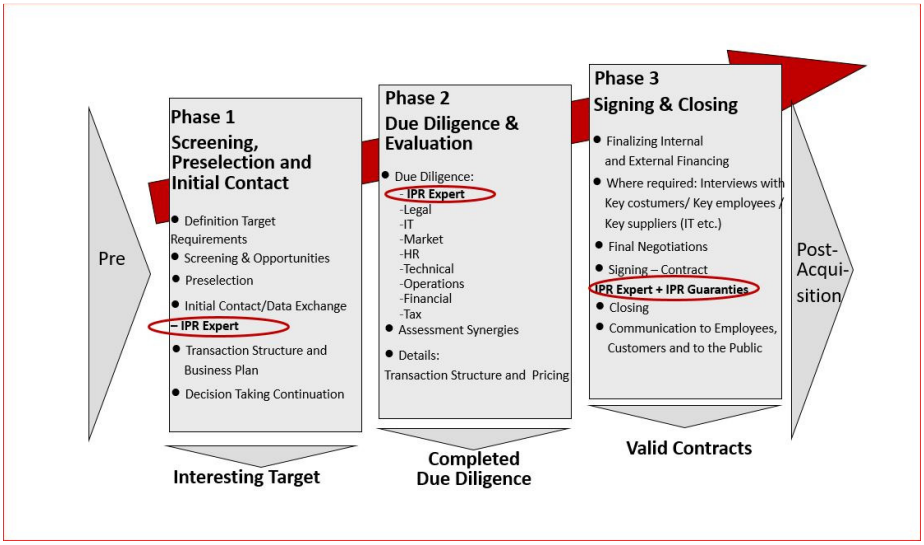

Figure 1 : M&A workflow the acquisition part and IPR expert positioning
Source: (Steven Appelbaum, 2000) and research conducted by the authors in 6 different DD cases.

Results and Discussions

To improve the efficiency of our IPR DD's we further divided the phases in 3 different stages. The first stage is defining the objectives of the phase in which the process is. The objectives are a mix between the needs of the management and the IPR management and have to be agreed together. For example, it is important to define clearly the time frame and the resources frame expected by the management and those which the IPR expert can achieve. In the second stage the IPR expert does investigation meaning he starts to research all the possible data and extracts all the information which relevant for the DD. The last is the analysis stage where the results of the investigation will be analyzed and assessed to produce a management summary with the results ad recommendations for the next phase. It is important to finish the investigation stage entirely before the analysis stage is started. In many cases the investigation case will already deliver conclusive results or the DD will be stopped before the analysis of all the results has to be started.

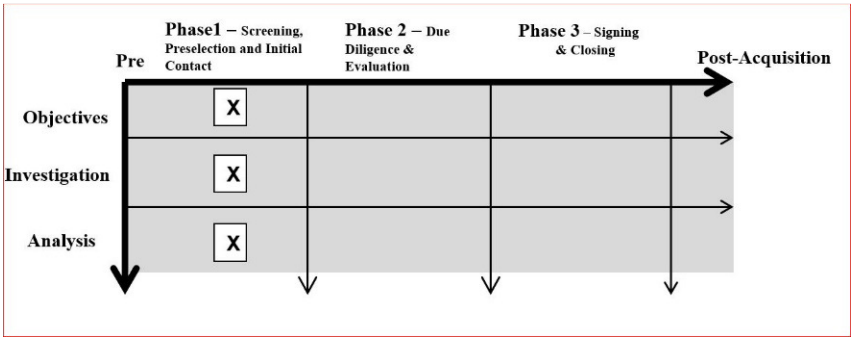

Figure 2: IPR due Diligence workflow

Source: (Bosch, 2006) and research conducted by the authors in 6 different DD cases.

This way we have reached a 3 dimensional IPR DD has the right phase and the right stage in the phase and the right questions in every stage. In this article we would like to continue developing this theory buy building the different stages and equipping them with the right questions thus giving the practical tools for implementing the 3 dimensional IPR DD

1. Phase 1 – Screening, pre-selection and initial contact

In most cases the IPR expert or most of the other experts are not directly involved in the choosing of a target company. This happens in the higher management circle and if existing together with the enterprise strategical development plan. Therefore, the actual work begins with Phase 1: screening, preselection and initial contact.

1.1 First stage - Definition and prioritization of the objectives

Some of the objectives of the management and the objective of the IPR manager may be totally different therefore it is important that the IPR manager will ask the management several questions that will define for him the business requirements and expectations and will prepare for the management in return a management summary of the target from the IP point of view in the same time repeating the business requirements of the management making sure that everyone understands these the same. We will use the word target for the company which is the subject of the DD. Though repeating experience in the research conducted by the authors in 6 different DD cases we reached the following format of questions and information that will define the objectives stage in phase 1 of the DD.

1.1.1 General information - In the first part of his research the IPR expert will gather some general information about the target with name, short company overview, management names and information about IP where their name appears, general technological concept and target approach.

1.1.2 Management Questions - These do not have to find an answer at this stage but have to be agreed upon. These define the main expectations of the management from the IPR DD results. (Cockburn, 2017)

- Are the processes of the target protected from the IPR point of view?
- Is an investment in the target accountable?

- What follow-up operations will be recommended from the IPR point of view, if a cooperation with the target will take place?

1.1.3 IPR Expert - questions that should be answered for a good prioritization and understanding and the business requirements. (Due diligence data room , 2017)

1. Is the intellectual property driving the contemplated deal or is it secondary?
   Example of an answer we received: "In phase one of this DD the intellectual property plays a central role in the decision taking of continuing the collaboration with the target"
2. Who are the companies interested in or are using this technology?
   Example of an answer we received: "The target is interested in further developing and implementing the targets products as described on their site. The problem is that at the moment the target cannot identify any concrete sellable products, therefore the focus is on the quality of the IPR that they possess."
3. Is the relevant industry litigious? Or are license programs routine?
   Example of an answer we researched: "A Google research does not reveal many patent suits or differences. Most international companies possess IPR on the field of the target but as it seems, because of the low rate of implementation they hold back with litigations."
4. Does the target company have a sophisticated or elementary IP protection policy?
   Example of an answer we researched: "The target company has an elementary IP protection policy trying to protect exactly the products that they have displayed on their page."
5. What type of transaction is being contemplated by the parties?
   Example: "Cooperation or Buy-In of the target"
6. What are the most important objectives of the transaction between the two parties?
   Example of an answer we received: "The target needs a strong financial partner to develop and deploy the products. The DD company (buyer) would like to implement the products in its platform and is looking for new business fields."
7. How do the intangible assets fit into each party's business objective?
   Example of an answer we researched and received: "The target wants to attract potential investors by protecting the IPR"," The buyer wants to invest in products with clear defined and protected USP's and wants to be sure that the target products are not infringing any third side IPR."
8. What is the timeframe that is set to phase 1 of the DD?
9. What are the resources that are allocated for this phase?

By answering the points above the expert and the management are now on the same level of understanding of the process and expectations. In short: the objectives are now clear.

1.2 Second stage - The substantive investigation

In this stage the IPR expert works mostly alone and needs to do a first real research of the target. Questions that need to be clearly answered are:

1.2.1 What are the products or services involved with this transaction?
The IPR Expert needs to identify all the products and services which could be protected by IP and have a good understanding of their functionality. This is information that can be achieved through collaboration with the technical team. The definitions can be used by both teams in their reports.

1.2.2 Does the existing IPR owned by the target cover those products?

Patent analysis of the targets patents using easy to reach information published by the patent offices (DEUTSCHES PATENT- UND MARKENAMT, 2016):

- Technical description of the protected invention as short as possible – this is needed for any future research and to make sure that the patent actually protects the products as claimed.
- An examination of the patent situation: Is it still existing? How strong is it according to the patent offices? Granted? First possible patents that may be infringed by the protected product can be easily identified here through the results of the official patent research and examination. (DPMAdirect, 2016)
- Example: Patent XAG - Protecting product 2

  "US – The US family member of this application EU was granted on

  The EPO did not grant it yet since is finds that the following (X) document:

  Patent probably not infringed by xxx - See page

  The European Patent application has good chances to be also granted in a constrained form. "

Results of the target IP analysis IPR expert opinion example:

"The company owns X patent families composed of EP and US applications protecting 3 out of the 7 products: Almost all applications are in examination phase. One patent application was granted in the US protecting the product number 2. The European patent office found prior art documents disclosing all of the applied inventions therefore it will be difficult to get them patented in the exiting form."

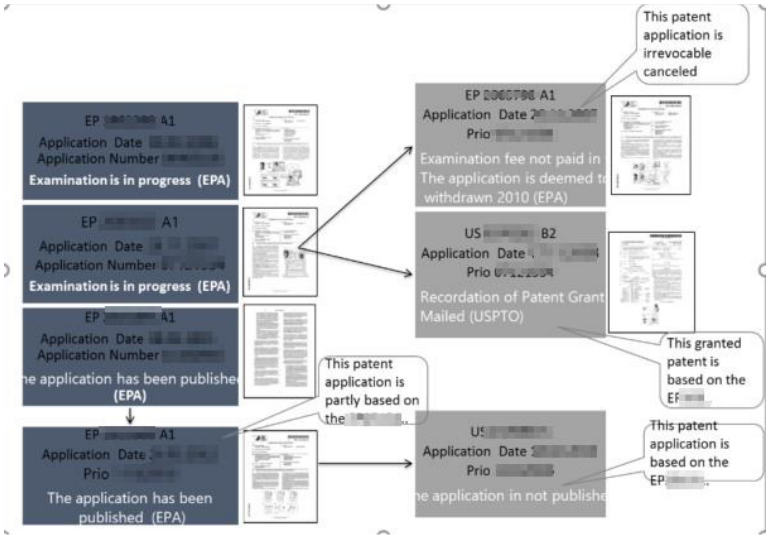

Figure 3: A visual display of the patent families of a target

Source: (Espacenet, 2017) and research conducted by the authors in 6 different DD cases.

1.2.3 Questions to the target company direct

1. Is the list of patents and patent applications as researched by us correct? In some cases the target owns further applications that have not been published yet or bought patents from other owners and that was not published yet.
2. What is the patent application strategy of the target company? It is important for the buyer to understand if such a strategy existed proving that the IP is taken serious by the target.
3. Are there any competitor patents that could be a threat to your core business? The target is committed to answer such a question to the best of knowledge. They are not allowed to hide information that they know about.
4. Who are your main competitors and how do their products work? This question is important to understand the targets sensitivity to competition as well as to get the information needed for a first level freedom to operate patent research.
5. Do you know of any other competitors which are using a similar technology as the one used by the target?
6. Have you ever had a Freedom-to-Operate patent research done? The results of such a patent research would substantially reduce the resources needed in the IPR DD especially in phase 2.
7. Is the granted patent of the company xxx a potential threat on a possible expansion of your business?
8. If through the first preliminary research any granted patents have been found which are a possible treat to a closing of a deal than these should be bespoken as soon as possible.
9. Do you have any license agreements with any external firms for example for using patented inventions or granting licenses on your patents, but also any other licenses? Licenses are normally not published but if existing are a crucial information as preparation to what further costs might come up after the deal is closed.
10. Do you have any new projects that would need patent protection? This is an important question for the post acquisition but especially because the ownership of the IP should clarified before signing.
11. List of owned Domains – Domains fall in the category of IP and therefore the IPR expert should have an inventory and make sure that the crucial domains are not under dispute from third side.
12. Do you own any trademarks and did you have any trademark disputes? As trademarks also fall in the IP category the IPR expert should have an inventory and if any complications exist he should use Trademark specialist to clarify.

    List of Trademarks online research

    - Deutsche Patent und Marken Amt
    - CTM-ONLINE Markenrecherche European/ Research Plus OHIM
    - Wipo Madrid – The International Trademark System
    - USPTO Trademark Electronic Search System
13. Who is the owner of the IP? A question that makes sure that the target does not conceal any information.
14. If the owner of the company is also inventor! Are the inventions 100% owned by target? Is the target entitled to sell the IP? In some cases, the legislation will automatically give a manager which is listed as investor on a patent application co-ownership of the patent. This needs to be clarified before a company is sold.

15. Who owns the copyright on literature, manuals, brochures etc.? These fall in the category of IP and therefore the IPR expert should have an inventory

1.2.4 The highest risk competitors and partners - should be researched for relevant patents already in this phase. These have the highest chance to own patents which could be a deal breaker for the buyer. The information and results can be gathered in a table defining the actual risk assessment for each of the patents.

Table 1: An overview of the highest risk competitors and partners patents

Company – Patent number	Status	About	Risk	Documents
The patent number is like a finger print and a clear identification for any patent that was ever applied anywhere in the world.	The status of a patent defines if the patent is in the application phase, granted, still active or dead checking this information is fast easy and can be done by any one	Short description of the invention patented	The risk level assessment - Low, middle, high and very high whereas very high would be in many cases a deal breaker from the point of view of the IPR expert	The patent document can be directly linked here for fast and easy reading

Source: research conducted by the authors in 6 different DD cases.

1.2.5 Further companies which are from the same field and also applied for patents. This is a preparation for an assessment of the needed time and resources in phase 2 of the due diligence.

Table 2: An overview companies which are from the same field

Company	Patents	Risk	Comments
Company names	Number of patent applications	Possible risk assessment	

Source: research conducted by the authors in 6 different DD cases.

1.3 Third stage - The analysis of the results – is the end of the phase 1 and brings together a management summary of the questions which decide if there is a deal breaker or not from the IP point of view.

1. Are the target processes protected from the IPR point of view? - In many cases the buyer is interested in the target only if through the deal he can reach possession of actual intellectual property for example patents. If this is not the case this could be a real deal breaker.

2. What further steps should be taken?

3. Is an investment in the target accountable? - Any concrete show stopper for an investment in target which cannot be solved by the pointed measures?

4. What follow-up operations will be recommended from the IPR point of view, if a cooperation with the target will take place?

5. Licenses
6. Ownership – is the IPR free transferable
7. Freedom to operate
8. What is the quality of the targets IPR?

These can be presented in form of a table with following form:

Table 3 : Management summary

Questions	Answers	Findings	Measures
1. Are the target processes protected from the IPR point of view?	In many cases the buyer is interested in the target only if through the deal he can reach possession of actual intellectual property for example patents. If this is not the case this could be a real deal breaker.	The risk level assessment low, middle, high and very high	Recommended measures to reduce the level of the risk in findings

Source: Research conducted by the authors in 6 different DD cases.

Conclusions

Through the repeated implementing and developing of the stages in the Phase 1 (Screening, pre-selection and initial contact of the M&A DD) we reached a point where we not only provide a check list for the IPR expert to follow. Check lists give very flat results which always look similar even dough DD's defer very much from each other, for example due to the different nature of the deal to be made for example buy or cooperation, or the different management strategies, expectations and requirements. The new framework for the implementation of a resource sustainable IPR due diligence in Mergers & Acquisitions is a full strategy that adjusts accordingly to any type of DD. This kind of implementation creates a situation in which the IPR expert does not only supply dry IP information but turns into a driving force of the whole DD team. The IPR expert is forced by the nature of the information that he needs to extrapolate from the IP material to understand the technology and strategy of the target. This information can be co-researched together with the strategy and technology teams thus saving resources for all and supplying a better inner look into the subject-matter. Thus in the practical implementation we were surprised to get more and more attention from colleagues in the strategy and in the technical team which found additional advantages in working with the IPR expert and implementing his results directly into their reports. In the next articles we will further develop the following subjects to round up the research and development of our theories in the field of IPR DD in M&A processes.

2. Phase 2 – Due Diligence and Evaluation

2.1 First Stage - Definition and prioritization of the objectives

The most important information for the IPR manager here is to exactly know the amount of resources that are at his disposal to obtain the needed results. Secondly, with the purpose of performing a resources sustainable IP DD the expert should agree with the management as early as possible upon the level of risk mitigation and risk assessment needed for each DD in separate.

2.2 Second stage - The substantive investigation

- Freedom to Operate Research (WIPO MAGAZINE, 2017) and Analysis – "begins by searching patent literature for issued or pending patents, and obtaining a legal opinion as to whether a product, process or service may be considered to infringe any patent(s) owned by others". Performing a resource sustainable FTO is a challenge on its own and will be analyzed in a separate article
- Licensing – analyzing that target is owner of all the licenses needed for selling the products that he is developing

2.3 Third stage - The analysis of the results

3. Phase 3 – Signing and Closing

3.1 First Stage - Definition and prioritization of the objectives
There is maybe no place where the management requirements and strategy should be more clearly communicated to the IPR manager like at this point. The IPR manager can supply researched data which will help to negotiate the final contracts in an advantageous form for the buyer.

3.2 Second stage - The substantive investigation
The main task for the IPR expert at this stage is to analyses the IP parts of the contracts and to negotiate the IP guarantees supplied by the target

3.3 Third stage - The analysis of the results

4. Post DD

- Secure the technological ledge of the acquired company versus other companies with the help of patent applications
- Developing and creating a patent portfolio for the acquired company as a protection against patent infringement suits
- Monitoring the competitors and the state of the art in the technological field of the company
- Freedom-to-Operate for new markets
- Generating further new revenues by selling of licenses for the owned IPR

Abstract

Nowadays, the use of online marketing and online advertising is an indispensable part of any company operating on the Slovak or international market. Online marketing and online advertising are among the most dominant tools for promotion in the field of tourism, as online marketing can not only influence but also change the buying behavior and consumer buying decisions. The aim of the contribution is the theoretical processing of tourism and internet marketing issues as well as the analysis of the use of selected types of advertising in Slovakia as well as in the foreign market.

Keywords: consumer, online marketing, tourism, purchasing habits, internet.

Introduction

Traveling has become a common part of the lifestyle of people, especially in developed countries. Larger participation in tourism is a result of the increase of leisure time. Tourism should not be hampered by the general right to tourism as a consequence of the right to rest and relaxation. The possibility of discovering and enjoying the resources of our planet should be accessible to everyone equally (Mitríková, 2014). People often regard tourism as activities resulting from services from other industries, such as accommodation, catering and transport services. If we want to talk about the tourism industry, it is likely to consist of tour operators (travel agent - tour operator, travel agent - retailer) and the start of modern tourism, based on a wide range of services, did not exist (Horner, Swarbrooke, 2003).

Literature Review

Novacká (1999) describes one of the first tourism definitions by one Austrian economist Hermann von Schullard in 1910 as a summary of activities (primarily of an economic nature) relating directly to the entry, stay and movement of foreigners outside or within the country, city or region. Jakubíková (2008) characterizes tourism as a large market that requires the satisfaction of different needs, thus attracting the attention of entrepreneurs, both private and public. It is a very progressive part of the economy. People choose to travel for two reasons, the first is duty (business, religion, visiting families, health reasons) and the other is pleasure (rest, sport, romance, fun, etc.).

Mariot (1983) divides the conditions for tourism into:

- **localization assumptions -** decisive factor is the geographical location of the site and its historical development. Using these assumptions, we can locate tourism activities in areas. Delivers natural (climate, water, relief, flora and fauna) and cultural and historical premises (museums, galleries, technical monuments, monuments of folk architecture ...).

- **selective assumptions -** represent the readiness of the country to participate in tourism (to receive or become a tourist). They can be divided into objective and subjective assumptions. Objective include political factors (peace settlement of the world without war conflicts), economic factors (the living standard of the population and the free time) and demographic factors (education, age structure). Subjective factors greatly affect travel, marketing and advertising experiences.
- **realization assumptions** - realization of the demands of the tourists in the resort with favorable localization assumptions. They are devoted to transport (quality of transport connections) and material and technical conditions (infrastructure: accommodation, catering, sports, recreational facilities ...).

Recently, internet and internet marketing in the field of tourism play a very important and indispensable role (Fedorko, Nastišin, Pollak, 2015). In the dynamic market environment, the internet plays an increasingly important role in marketing. According to Blažková (2005) Internet fulfills the role of new global infrastructure and has a new place in business processes. According to Dorčák and Pollák (2010) the use of Internet is wider:

- **Effective presentation of the company and its products.** Website added to customer loyalty program: The company provides a variety of services, on-site guides for the use of individual products or on-going technical support may be available on the web.
- **Information resources.** Internet offers space for searching for new information, searching for new suppliers and subscribers, as well as information about customers or competitors.
- **Better customer relationship management.** Internet enables intensive, easy and effective communication with customers as well as feedback. Accurate customer identification and behaviour gives businesses the ability to work better with an existing customer base, as well as the ability to reach better the future customers.
- **Efficient and new business channel.** E-commerce platforms and applications and other e-commerce offer the ability to quickly, cheaply and safely implement business transactions.
- **Managing internal business processes.** Better management of internal systems and processes and their computerization and subsequent integration will ultimately reduce costs. These include, in particular, costs such as telephone calls, printing and distribution costs and customer service costs. Savings are also due to a link to supply-chain chains.

Kita et al. (2010) among the most common e-commerce tools include:

- **www pages** - the home page of the company that provides customers with product offer information and company overview;
- **e-mail** – is a tool of customer interest, provides customers with specific information about the conditions of supply of goods, confirms product information, extends them;
- **online catalogs -** provide up-to-date information on prices, supply, inventory status and other services;
- **EDI** – Electronic Data Interchange, such as invoice, delivery note, customs documents, etc.
- **EFT** – i.e. EDI to transfer financial information - secures electronic payments - i.e. Payment orders, advice, statements from accounts.

With internet development, there is a shift in Internet trading. Companies invest in information technology and e-commerce to increase efficiency of operations and improve customer service. In order to say that everything is going through the Internet, the letter "e" (as electronic) is inserted before the common word. For example, the word e-business (electronic business), which we usually understand as a wider concept than e-commerce (electronic commerce), (Blažková, 2005; Mudrík, Fedorko, 2010).

Social networks are a relatively new type of web applications. Developers started at the beginning of the new millennium from their predecessors who served Internet users ahead of them. These predecessors were of a different nature, they were discussion servers, online photo galleries, weblogs, servers, data storage, and so on. Creators of these Internet services have long noticed that users are not only able to publish content but also want to communicate with other users. Gradually, services based on content, but on relations between their visitors (Bednář, 2011). Functions commonly offered by social networks for marketing purposes are a serious and important advertising channel that can accurately target marketing activities (Fedorko, Kakalejčík, 2015).

Results and Discussion

Destination organizations have difficulty measuring the site's visiting rates and the effectiveness of individual marketing channels. It is possible to measure the number of visitors on the website, viewing a promotional video on YouTube, downloading a digital brochure or mobile application, and tracking reservations made through partner websites, but using traditional ways of using, Motivation to fill out "visitor satisfaction questionnaires" is often the only way to identify where the visitor has come from and which marketing message has "forced" him to arrive at a destination (www.eturizmus.sk).

Picture 1 shows the Arrivalist data visualization - Red spots are the places where mobile users were exposed to a US Kansas destination organization's ad with the size of the tag reflecting their number. The blue spots feature Kansas sites that have seen the presence of devices previously hit by advertising out of the state.

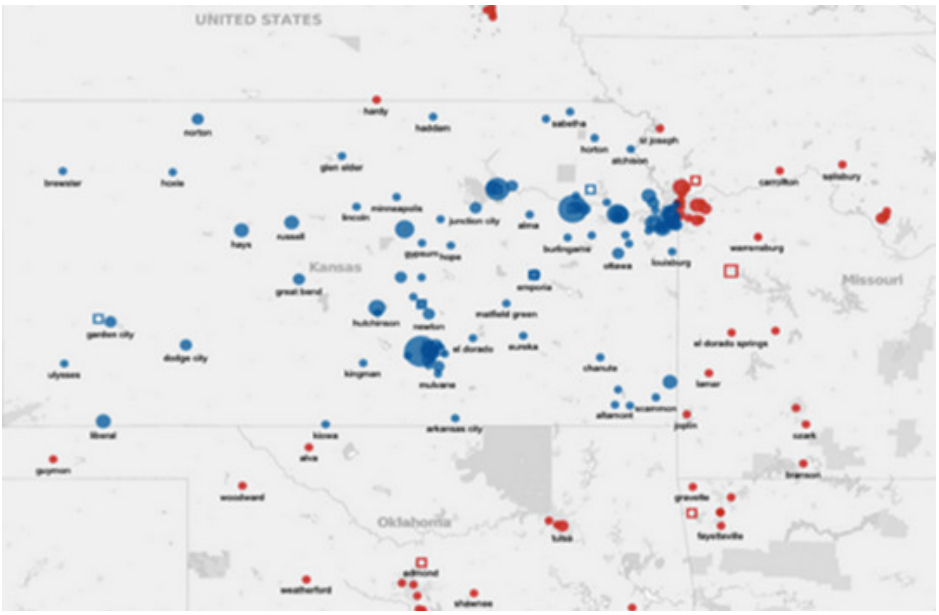

Fig. 1: Data visualization of Arrivalist

Source: http://www.eturizmus.sk

Discount portals appeared in Slovakia in 2010. Over the past 4 years, approximately 150 different discount portals have been created. Of course, not all of them could face the competitive pressure and thus ended their activity**.** Those that have managed to act now, act as a special marketing tool for companies and businesses they bring to customers. This does not mean, however, that profit increases with the growth of clients. This is confirmed by many of the top executives of specific devices. Many of them with this style of advertising and sales have bad experiences. Four-star hotels fill less solvent

customers, and this has an impact on the satisfaction of loyal clients. Expenditure also grows and, ultimately, the hotel has a decline in profits. Accommodations with such experience have terminated cooperation with discount portals and continue to acquire clients by other forms of promotion and sales promotion. Some companies, however, are grateful for their cooperation with discount portals. They perceive it as a way of advertising for the general public when they get to know as many people as possible. If the individual menu items and product are set correctly, a "faux pas" can be avoided with unsolicited clients.

Modern travelers are increasingly open to new things and cultures and require an authentic experience. The difference between "creative" tourists and cultural tourists is that they are not only aware of the first cultural heritage but also actively involved in its creation. They come into contact with the domestic population. An example might be the glass blowing in Biot, dancing the rumba in Barcelona, the baking croissants in Paris, weaving according to the majestic tradition or the creation of modern music in Ibiza. To support this new industry, Creative Tourism Network® was created in 2013. In particular, creative tourism brings the following benefits: sustainability, non-seasonality, better geographical distribution of the offer, not being tied to existing tourist attractions, increasing the confidence of the domestic population and improving local infrastructure and living standards.

Based on historical insights from marketing, we can see that marketers can use every technological innovation in their work. For the life of ordinary people, the advancement of technology is, for the most part, a forward and simplified life. Discovering the internet and creating a digital world has caused a radical change in the area of total communications. The sphere of marketing communication is immune to such massive changes. We can argue that technical news has not yet replaced existing forms of advertising, just completing them and adding new ones.

The agency ZenithOptimedia (2015) conducted the research in 65 countries around the world focusing on the use of individual media. In 2015 people spent 492 minutes a day using the media, an increase of 1.4% per day compared to 2014. The agency underlines that this increase is the result of an increased use of the Internet by 11.8%.

Long-term follow-up has shown that from 2010 to 2015 the time spent on the Internet has almost doubled (from 59.6 to 109.5 minutes per day) while the time spent with traditional media dropped from 402.2 to 375.8 minutes. The most serious aspect that was quite relevant to users was the development of mobile phones. Smartphones have brought new ways to use the media and have made the Internet open even to any activity. The trend of using mobile phones continues and we can say that it is growing more and more every day.

The GfK agency (2012) notes that even though the number of Internet users is steadily rising, it is still the mass media with the highest number of non-users (in 2012 it was up to 26% of the respondents). Evidence of the Internet growth is also the US research, which has come up with higher numbers. According to Nielsen's Q1 2016 Total Audience Report, smartphones and tablets have led to increased time spent with media. Adult US residents spent 20% more time using the media in 2016 than in 2015. The total number climbed to 10 hours and 39 minutes per day, and the internet has increased and all other media has declined. The television, the second popular one began to decline by 3 minutes per year (Lynch, 2016).

According to GfK (2012), the greatest potential for customers has the recommendation of friends, which was reported by up to 50% of the respondents. In the second place, TV got 47%, because for some people it's still an influential medium for buying. Next the printed media got 38% and the internet got 28%. At the end of the ladder, outdoor advertising got 11% and radio advertising 10%. Internet has always been a winner in the benchmarks, but it is weak in the aspect of credibility, especially since its underlying disadvantage is impersonal.

The American company, Peter J. Solomon Company (2014), made a research in July 2014 to distribute advertisements in various media. The result of the study is the Chart 1, which compares CPMs in major media. The chart shows the amount that an advertiser has to spend in order to reach 1000 views or otherwise impressed. Although this research has taken place in the US, we consider the resulting data to be relevant to us as well, because the price of advertising in individual media is comparable to the price ratio in Slovakia. However, it is important to note that this study does not include social networks, which, according to other authors, currently represent the cheapest option for paid promotion.

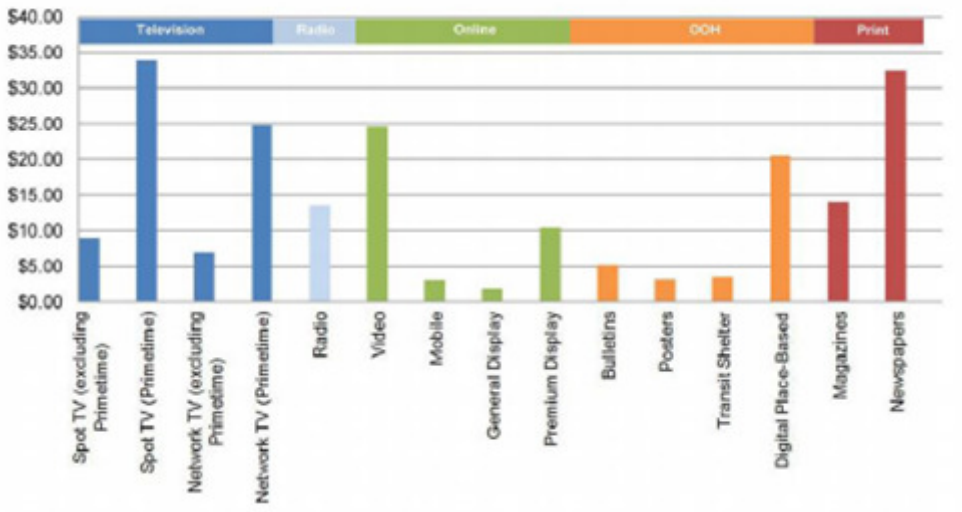

Chart 1: Major Media CPM Comparison

Source: Solomon Company, 2014

As we focus on the Slovak market, TNS Slovakia conducted research at the end of 2016 in Slovak companies and companies on their planned advertising budget for 2017. This study showed that we are also in the world trend. The Internet was the biggest increase, with companies focusing more on social networks this year. Mobile marketing also grows significantly, but not to such an extent as the above-mentioned social networks. On the contrary, in the press and television, marketers are planning to invest less in 2017.

Conclusion

Online marketing and internet advertising also have many respondents who are currently debating its merits. But every business subject needs it. The need for new forms of expression has become a major driving force not only in advertising but in all areas of human activity at the turn of the millennium. We are at a time when information technology is still affecting the economic life. It can be assumed that their role will grow in the future. Advertising is one of the most important communication tools for businesses that can influence consumer buying behavior. Recently, its impact on the successful management of the company is becoming more and more considerable. Certainly everything, as well as advertising, has many disadvantages, but they cannot be fully compared to the benefits it offers. The basis for success in creating online advertising and using online marketing is to know the company's analysis, its product, the market, and also to measure its communication effect to see if the ad has successfully passed the advertising message to the target customers.

Analysis of the Use of Marketing and Promotion in a Non-Profit Area Operating on the Slovak Market

Jaroslava Gburová, Prešov University, Faculty of Management, Prešov, Slovakia
jarkagburova@gmail.com

Radovan Bačík, Prešov University, Faculty of Management, Prešov, Slovakia
radovan.bacik@unipo.sk

Abstract

As the company and the environment of potential customers have been changed over the years, forms of promotion have also changed to the same extent. Technical progress has brought mankind to a world where everything is bigger, more dramatic and more expensive, so marketing has acquired new forms of promotion to reach new customers. Nowadays, we can talk about the social significance of the mass media as well as about the mutual overlap of mass and network communication. The aim of the contribution is the theoretical processing as well as the analysis of the perception of selected types of promotion of non-profit organizations operating on the Slovak market from the point of view of the Slovak consumer.

Keywords: marketing, non-profit organization, promotion, consumer.

Introduction

Social development, responsibility, changing lifestyles, growing human awareness, globalization, increasing competition, a huge supply of new products with ever-less differentiation, and discerning consumers force businesses to find new ways to guarantee commercial success in the marketplace.

The non-profit sector and the organizations that make it up and do not make a profit, but they are still in a competitive environment, thus marketing communication is a key aspect for them in presenting to target groups. The non-profit sector in Slovakia is made up of organizations whose main goal is not the profit-making, but like any other organizations, they are trying to create their own target groups. Affecting these groups in an adequate way allows only optimally assembled marketing communication. This communication represents an effective and continuous action on the target groups, through a purposefully constructed communication mix (Štefko, Gburová and Matušíková, 2016).

Literature Review

Marketing tools and methods are constantly evolving as well as the marketing definitions are changing. It is typical for the 21st century economy that the role of marketing has not only been in the search of customers for products but has shifted to the search for products for customers. Information technologies enable businesses to monitor each customer and turn traditional mass marketing into multiple goals for individual marketing which has just one goal (Kotler et al., 2007). The main goal of non-profit organizations is to serve customers. Therefore, the customer must have a dominant position in a public sector organization, even in a non-profit organization, because he ultimately decides whether or not to accept the offered products. He also decides whether the products have such benefits for him. Marketing in non-profit organizations is understood as:

- how to carry out selected marketing activities in a certain sequence, most often they are public relations, advertising or market research,
- a strategy promoted by management,
- how to orientate the entire organization to the needs of the customer (Bartáková et al., 2007).

Introducing marketing in non-profit organizations is a long-term issue. It may take several years. In a non-profit organization, marketing activities of the organization must be perceived positively and actively by all the members, so that the organization effectively fulfills the purpose which is the reason for its existence (Vaštíková, 2008). Nowadays, which can be considered as a time when information technologies and the Internet are beginning to weaken the familiar forms of communication and advertising, marketers are more often confronted with the question of where their steps will be taken to produce an effective communication mix. Recently, effective communication campaigns must be more sophisticated than they were in the past. Among the new forms of communication mix we can mainly include various forms of direct marketing, sponsorship, event marketing, e-mail marketing and guerilla marketing (Štefko et al., 2012; Fedorko, Nastišin and Pollák, 2015).

In a reductive manner, we can say that e-business is just an electronic form of already existing activities (Fedorko, Kakalejčík, 2015). As at present, consumers have received product brochures in paper form, an electronic presentation is preferred in e-commerce, through websites, e-mail, and etc. Similarly, cash transactions begin to be executed electronically, e.g. paying by credit cards, using electronic checks, or direct payments from a bank account on the Internet (for example e-pay). In terms of definition, the business organization includes both profit-making and non-profit entities. Their processes include production, customer, internal, or business-oriented processes (Delina and Vajda, 2008; Mudrík and Fedorko, 2010).

Methods and Methodology

The object of the research was a non-profit organization (Dobrý anjel) operating in Slovakia. The survey sample consisted of 168 respondents. Respondents were citizens of Slovakia of different backgrounds, age groups, education and places of residence. In the field of information gathering, the questionnaire method of obtaining information was applied. The data collection was carried out during the year 2016. To achieve the aim of the research, the following hypotheses were set:

- We assume that there are statistically significant differences in the perception of promotion of a non-profit organization depending on the group of respondents.

- We assume that there are statistically significant differences in the non-profit organization's knowledge, depending on the education of the respondents.

Respondents (consumers) responded to a questionnaire's closed questions. Primary data obtained from questionnaire survey were later processed in a statistical program Statistica. In confirming or rejecting the established hypotheses the method of chi-square test was used.

Survey Results

The survey sample consisted of 168 randomly selected respondents living in Slovakia. Out of the 168 respondents who formed the survey, the largest number of respondents were 70 (42%) from the age of 18 to 29. The second largest group, with the number of 45 (27%) was represented by people from the age of 30 to 39. The third group is represented by 31 (19%) respondents from the age 40 to 49, and the fourth group is made up of 20 (12%) respondents, from the age of 50 to 59. The smallest number of respondents, 2 people (1%), were respondents from the age of 60 to 69. Of the total number of the respondents in the

survey sample, more than half were women, i.e. up to 105 (62.5%). Men in the research sample are represented by the number of 63 (37.5%).

Another important characteristic which was observed in the research sample was the highest level of education of the respondents. The educational level of the respondents was needed in order to find out whether the education had an impact on the knowledge of the non-profit organization Dobrý anjel (Good angel). The structure of respondents' level of education is shown in Table 1.

Table 1: Educational level of the respondents

	N	%	Valid %	Cumulative %
Secondary school without a school leaving examination	19	11,3	11,3	11,3
Secondary school with a school leaving examination	83	49,4	49,4	60,7
Bachelor degree	32	19,0	19,0	79,8
Higher education, second level of higher education	34	20,2	20,2	100,0
∑	168	100,0	100,0	

Source: own processing

Most of the respondents (83) have a secondary level of education with a school leaving examination which is 49.4% of the total. The second largest group is formed by respondents with university education, 34 respondents (20.2%) with a second level of higher education and 32 of the respondents (19%) with a bachelor degree. The lowest number of respondents, 19 people (11.3%) have completed secondary education without a school leaving examination.

As part of our research, we also focused on finding out which element in the non-profit advertising is most likely to appeal to respondents. From the options offered, respondents chose one option, and they also had the opportunity to express their own opinion. Individual options tracked the depth of the non-profit's ad group's knowledge and thus served to confirm or dispel differences about ad knowledge.

More than half of the respondents surveyed 88 (52.4%) said they are mostly interested about the non-profit organization's human story. 45 (26.8%) of the respondents rated the content as the most interesting aspect, 18 (10.7%) of the respondents considered a slogan interesting and 13 (7.7%) of the respondents considered the aspect of the contribution to be interesting. 4 (2.4%) of the respondents chose the option "own opinion", and they also chose the option "Others". In terms of new forms of promotion of a non-profit organization, 76 (45.2%) of the respondents would most likely appeal to mobile advertising in marketing communications. Based on the results in Table 2, we can estimate that 29 (17.3%) of the respondents would welcome a viral campaign, 23 (13.7%) of the respondents the internet kiosks, 18 (10.7%) of the respondents would chose the guerrilla marketing, 13 of the respondents (7.7%) E-mail marketing, 5 (3%) podcasting and 4 of the respondents (2.4%) s expressed the opinion that they would not receive any new form of promotion.

Table 2: New forms of promotion of the non-profit organization Dobrý anjel (Good Angel)

		N	%	Valid %	Cumulative %
	Viral campaign	29	17,3	17,3	17,3
	Guerilla marketing	18	10,7	10,7	28,0
	Podcasting	5	3,0	3,0	31,0
	Mobile advertising	76	45,2	45,2	76,2
	Internet kiosks	23	13,7	13,7	89,9
	e-mail marketing	13	7,7	7,7	97,6
	Others	4	2,4	2,4	100,0
	Total	168	100,0	100,0	

Source: own processing

The aim of the first hypothesis was to find out whether there are differences in the perception of promotion of a non-profit organization depending on the group of respondents. The results are reported in Table 3 and Table 4.

In accordance with the H1 hypothesis, gender differences in the perception of promotion were assumed. This hypothesis was verified by three questions. In all cases, a chi-square test of criterion independence was used, the outcome of which is a contingency table and an evaluation of the statistical significance of the relationship. The distribution of responses is shown in Table 3.

Table 3: Evaluation of Hypothesis 1a

			o12				
			Definitely	Probably	I do not know	Probably not	Total
Gender	Male	n	10	19	25	9	63
		%	15,9%	30,2%	39,7%	14,3%	100,0%
	Female	n	24	43	32	6	105
		%	22,9%	41,0%	30,5%	5,7%	100,0%
Total		n	34	62	57	15	168
		%	20,2%	36,9%	33,9%	8,9%	100,0%

Source: own processing

Table 4: Evaluation of Hypothesis 1b

Chi-square	df	p
6,416[a]	3	,093

Source: own processing

The promotion of a non-profit organization Dobrý anjel was considered to be definitely effective by 16% of men and 23% of women, probably effective by 30% of men and 41% of women. A more positive view, therefore, was seen in the case of women, but the gender difference was not evaluated as statistically significant ($\chi 2 = 6.416$; df = 3; p = 0.093). Hence the hypothesis H1 was not confirmed in this relation.
Secondly, within the H1, the differences in credibility of the promotion of the non-profit organization Dobrý anjel were observed. The distribution of responses in the case of men and women are presented in Table 5 and Table 6.

Table 5: Evaluation of Hypothesis 1c

			o13				
			Definitely	Probably	I do not know	Probably not	Total
Gender	Male	N	8	27	16	12	63
		%	12,7%	42,9%	25,4%	19,0%	100,0%
	Female	N	27	48	22	8	105
		%	25,7%	45,7%	21,0%	7,6%	100,0%
Total		N	35	75	38	20	168
		%	20,8%	44,6%	22,6%	11,9%	100,0%

Source: own processing

Table 6: Evaluation of Hypothesis 1d

Chi-square	df	p
7,938[a]	3	,047

Source: own processing

In this case, a more positive attitude was seen in the case of women, 26% of the total number of respondents, compared with the 13% of men, while the answers „Probably“ were rather similar (43% for men, 46% for women). Overall, however, gender differences were evaluated as statistically significant (x2 = 7.938; df = 3; p = 0.047), so we can infer that greater trust is generated in the case of women by the promotion of the non-profit organization Dobrý anjel (Good Angel).

In the third H1, we were looking at gender differences in answers to the question about marketing interests of the non-profit organization Dobrý anjel (Good Angel).

Table 7: Evaluation of Hypothesis 1e

25% of men and 31% of women found it rather interesting. 25% of men and 37% of women were probably interested. Overall, the two groups had rather positive feelings about it, but there was no statistically significant difference between them ($\chi 2 = 3{,}751$; df = 3; p = 0,290). In the overall assessment of the second hypothesis a statistically significant gender difference was recorded only in one question, the H1 hypothesis is rejected.

The aim of the second research problem is to find out whether there are differences in the knowledge of a non-profit organization in relation to the highest completed education of the respondents.

Differences between groups in the case of education were surveyed by a chi-square test of independence of criteria in two questions. In one question, we tested the awareness of the non-profit organization Dobrý anjel. While respondents with the lowest level of education had the best chance of knowing, it was only 5% (1 respondent), in the other categories it was over 30%. In the case of the respondents with a bachelor degree is up to 53%. Overall, the relationship between the education and the knowledge of the organization was evaluated as statistically significant ($\chi 2 = 23{,}278$; df = 12; p = 0,025).

The second question in the H2 was focused on the main aspects that respondents took on the advertising of the non-profit organization Dobrý anjel. The distribution of responses is shown in Table 11 and Table 12.

Table 12: Evaluation of Hypothesis 2d

Chi-square	df	p
15,132[a]	12	,234

Source: own processing

Respondents with the lowest level of education (79%) were attracted by the stories about humans, which was also the first place among other groups but with a smaller percentage. In the second place, in all groups, the content of advertising ranged from 10% of the respondents with the lowest level of education to 32% of respondents with higher education. However, the difference between the groups was not statistically significant ($\chi 2 = 15{,}132$; df = 12; p = 0.234). We reject this hypothesis, because only the first of the two observed relationships is statistically significant.

Conclusion

New marketing communication tools offer a wide variety of options to a nonprofit organization to reach target groups more efficiently and more moderately. Recently, a new form of marketing communication - viral marketing - has also emerged. Its use is recommended to non-profit organizations, especially in this context: Viral marketing is a tool that spreads advertising content via the Internet, namely by specific messages. The message is spread on the basis that it delivers a benefit to the broadcaster, for example in the form of humor or a shocking effect that inspires him to spread. Applying viral marketing would, in

particular, spread advertising videos with children, bringing individual hard-hitting human stories to personal computer screens. Powerful human stories and strenuous life fates make sense of the formation of a non-profit organization Dobrý anjel (Good Angel). Using viral marketing could also be a reason for the spread among the population.

By analyzing the use of selected marketing communication tools, we have found that a non-profit organization uses mainly printed, television, radio and Internet communication tools. In the view of the results of the questionnaire survey and its subsequent analysis, we can assert that the non-profit organization through its activities has created good conditions and rich scope for improving the used marketing communications tools and also for the use of new tools.

Animal Welfare Organizations in Russia: Analysis of Structure, Typology of Volunteering Base and Functional Problems

Maria S. Gorbuleva, Tomsk State Pedagogical University, Tomsk, Russia, black_silver@bk.ru

Abstract

In the work the author attempts to analyze management of animal welfare organizations in Russia (in particular in Tomsk) on the basis of humanitarian assessment, as well as via verification of the impact of goals and symbolism of bioethics on the activities of volunteers. In the process of research, the most successful structure for implementing the statutory activities of organizations, various directions of volunteering activities, as well as internal and external problems of functioning of such organizations under the given conditions were identified. Conclusions about the consequences and possible stages of development also provide an opportunity for further research on this topic.

Keywords: animal welfare, volunteers, management, bioethics.

Introduction

In general, as of 2010, as its stated in Tetera (2007) article, All-Russian Scientific Research Institute of Hunting and Fur farming recognize the mass animal welfare movement in Russia do not exist precisely because of the disunity and ambiguity of actions and the small number of participants. Based on sociological surveys and field studies by Levchenko (2015), Gorbuleva (2012), Gorbuleva et al. (2016), Tarasenko et al. (2016a), the authors analyze some aspects of animal protection organization in Russia.

A significant part of data was obtained as a result of research of organizations located in Tomsk, where there is a favorable situation for development of animal welfare movements in comparison with larger cities, and there are a fairly large number of registered animal welfare organizations, shelters, charitable foundations, non-profit organizations, and volunteering initiatives which tend to be established as an organizations.

Protection of animals, the emergence of corresponding organizations and volunteer movements is actively occurring only during the last 5-10 years. This new phenomenon, originally spontaneous, develops thanks to the citizens' initiative, the opportunity to acquire positive experience and exploring the examples from countries with already established animal welfare protection infrastructure, fills the administrative and legal vacuum in this area on the part of the Government. Due to the growing activity of the volunteer movement, public awareness, media activity and a growing number of official organizations, only the last few years the authorities began to pay some attention to the problem of neglected animals, the control over their number, and the problems of humane treatment of them. Also the questions about the nature of the Russian animal protection movement become relevant, a well as dynamics of its development and possible forecast on its future. In this part of the research, the author will try to analyze the structure and functions of organizations, their internal and external problems, assess the possible social and anthropological consequences of emerging of the organized animal protection movement, as well as possible changes in the animal rights, based on the humanitarian assessment, described by Yudin (2006) and Tishenko (2008), Yudin and Lukov (2006).

Why it's important to change the attitude to animal rights? Because this is one of the goals of animal rights defenders. In addition to the daily protection of animals from cruel treatment, it is important to

prevent manifestations of cruelty - to achieve the adoption of relevant laws and change the current moral standards for "smaller brothers". This task is not only a legal, social, but also has moral, ethical, philosophical, and psychological context. Changes occur at the level of people's mentality, and this would take time and considerable effort. People who are used to treat animals as emotionless biorobots will hardly change their mind even in the long run. It's about the change of generations.

Methods of Research and Analysis of Results

Bioethics considers the issues relating to respect for life and individuality, as described by Melik-Gaykazyan and Mescheryakova (2015). In general, bioethics deals with the ethical issues and contradictions in medicine not only with respect to humans, but also all living beings. In Russia bioethics is a young science, but it caused the changes in the society which affect everyone in everyday life. Today, the process of restructuring and change has affected medicine, the attitude towards patients and the protection of patient rights. It can be said that the trials related to animal rights now taking place in Europe and the US are reminiscent of what is happening in Russia with respect to the rights of patients, as mentioned in works by Pervushina (2015), Melik-Gaykazyan at al. (2016), Mescheryakova at al. (2016), Tarasenko et al. (2016), Melik-Gaykazyan at al. (2017), Melik-Gaykazyan at al. (2017a), Evdokimov at al. (2016). Just as many political, economic, pedagogical and other projects require a comprehensive humanitarian assessment, movements of animal rights defenders (their activities: organizing animal shelters, training programs, volunteer communities, other activities to achieve their goals) also need ethical settlement and assessment because of complexity of the moral and anthropological problems that arise as a result of social progress in this sphere.

After all, in Europe and the United States, the process is underway, which was launched, perhaps more than a centuries ago, but received scientific confirmation only today, namely, the process of accepting (or rejecting) the possibility that animals possess consciousness and self-cognition. Since something new often provokes rejection of the majority, it requires some time to pass, both to confirm the current discoveries with new research, and for their adoption by the majority. After all, the acceptance of this fact will entail the reorganization of the moral foundations of the society and the legal system. Because if one agree with theses of the Cambridge Declaration of Consciousness, compiled by The Cambridge Declaration of Consciousness in Non-Human Animals and signed by Low at al. (2012), this will put one before a serious challenge about the animal rights in our society. It's like a bifurcation point. Among scientists there are supporters and opponents of the theory of presence of consciousness in animals. But the different studies (for example, Walker (2006), Reznikova (2007), Jones (2013) and many others) confirm that scientific progress inevitably leads us to the boundaries of this knowledge that already changes the attitude towards companion animals, animals used in food industry and agriculture, experimental animals, wild fauna, animals used in entertainment.

In Russia, over time, more and more well-structured animal welfare organizations emerge. This is provided by experience gained, availability of information through the media, the opportunity to monitor the development of other similar organizations, the opportunity to exchange knowledge not only with the Russian colleagues, but with overseas animal rights defenders as well. The official registration of animal rights protection organization adds duties and responsibilities, and at the same time opens up new opportunities for work. For example, reporting, the need for ongoing monitoring of legislation and its changes, opens up opportunities for obtaining support from the Government or funding from non-Governmental funds, grants, subsidies, etc. In addition, organizations that conduct transparent activities have more confidence, and, therefore, help from the partial citizens than the "individual animal rights defenders" or private take overs.

Most often, animal protection organizations are non-profit organizations, charitable foundations. This is in line with the primary activities and make reporting easy. In accordance with the stated charter, they can carry out both exclusively animal rights and propaganda activities, and have a take over point, a shelter, a veterinary office, and commerical projects, which profit should be spent on helping the animals.

An analysis of work of various organizations showed that an organization that has a clear internal structure and a system of interactions is more successful in achieving its goals. The core of organization is the director or other official who is its primary representative, has the right to sign and the seal. Also, most often, according to the charter, there is the council, the administration, that is, a group of persons responsible for internal activities, budget checks, reporting, etc.

One can talk about the different areas of work, but basically, an animal protection organization consists of the following units:

1. the administration: director, accountant, lawyer, coordinator / group responsible for grants and fundraising (all these "positions" can be filled by a single person or several people);

2. managing group / project coordinator: a person or several people implement the projects and actions aimed at promotion of the organization, administer the work of Internet resources, create and maintain the image and brand of the organization, produce printed and media products for promotion and propaganda (photo , video, printed matter etc.), work with the media and the public;

3. work with animals: the most important people to settle this type of work are the animal coordinator and animal curators. If there is a take over point in the organization, or the entire organization is a take over point or an animal shelter, the key figure is the take over manager. In some organizations or shelters, there are veterinary offices or a veterinary clinic where there is a full-time or part-time veterinarian.

4. work with volunteers - a recruiting of new staff, training, teaching the rules, coordination. Volunteers who help the organization, mainly work in the following areas: administrative and organizational work, transport assistance, take over at home, work with animals.

All these activities are very often interrelated. Of course, the named "positions" are not widely accepted terms for all organizations (in some of them, for example, there are such positions as "photo keeper" and "keeper of donations"), but in the process of research exactly this terminology has emerged. In addition, as already mentioned, one person can perform the different types of work. This is due to the capabilities of a particular volunteer and the level of development of the organization. But practice shows that the more people have clear boundaries of their activities and the more clear structure has an organization, the more chances for order, success and output. Sometimes the organizations which are small in terms of the number of members have greater success than a large ones, but having no idea of the internal structure and subordination, priorities and relationships in the work. Of course, the human factor, the lack of pay, and, at the same time, the demand for a significant contribution of time and effort, are destructive for charitable non-profit organizations, and sometimes one may be not able to correctly prioritize and cope with the loads, which, unfortunately, affects the image of not only a particular organization, but also all animal rights defenders.

In addition to internal problems, there are also external factors that can influence the growth and development of animal protection movement. Firstly, this is the lack of appropriate legislation. The difference between Russia and the more developed countries is that there is no animal protection law in Russia, except for Article 245 of the Criminal Code of the Russian Federation, which is ineffective in solving animal cruelty problems and this was mentioned not only by Zubchenko (2014). Under the current law, animals are considered the property and thus are not protected. In some cities and regions there are local laws or recommendations on keeping companion animals, but this does not work at all, and in the absence of legal regulation at the federal level is of little use. Even the work of ethical committees at the medical institutions and hospitals is questionable because it requires the appropriate legislation to address the issues of animal rights in experiments. If there is no animal protection at the legislative level, which provides, among other things, fines and penalties, then the work of animal rights defenders is ineffective. In fact, they deal with the consequences of a legal vacuum: cruelty and irresponsibility of

citizens towards animals. If you look at the statistics of effectiveness of the above-mentioned article 245 of the Criminal Code of the Russian Federation, it does not actually work: it is very difficult to prove the guilt, while the punishment is insignificant. It turns out that animal rights defenders are fighting not for animal rights, but rather for their welfare, which without a legal framework is also difficult.

Secondly, this is the lack of appropriate legislation. The animal rights defenders themselves are quite disconnected, as Levchenko (2015) points out, because of the human factor already mentioned. Also, the absence of unified regulatory framework significantly complicates the work. Some organizations rely on international treaties on animal rights (Universal Declaration on Animal Welfare (UDAW)), European Convention for the Protection of Pet Animals, European Convention for the Protection of Vertebrate Animals used for Experimental and other Scientific Purposes, The Cambridge Declaration on Consciousness. But this is an internal decision, more the ethic of work, which can help in internal work, but does not work at the administrative and legal level. And not all animal rights defenders use the abovementioned documents as the basis of their activities. Surveys of animal rights defenders show that a significant number of respondents are legislatively illiterate, and this, of course, affects the quality of the work, as stated in Gorbuleva at al. (2016). Thus, the internal work also becomes difficult, since in the absence of common norms and rules, there is a very high probability of negligence, or the other extreme - excessive fanatism in following the ideas of animal protection. The monitoring of such organizations is extremely problematic, because there are no clear standards and rules, which can lead to tragedies and a great resonance in society (for example BanoEco http://ria.ru/society/20160525/1439444096.html).

Thirdly, this is the lack of appropriate legislation. In the absence of a regulatory framework and legislative gaps, there is no possibility of influencing either the present generation or the future one. This is the serious anthropological problem of changing the mentality, perception of animals as an inanimate property, bio-robot or as a living creature, if not equal in rights to humans, then having an approximate rights. Very important here are the growing educational programs, which also appear due to the work of animal rights fighters and a vacuum on the part of the institution of power and legislation. A very important role in this process is played by the developing educational programs, which also appear as a result of the work of animal rights defenders and a vacuum on the part of power and legislation.

Conclusion

If one talk about the experience of animal protection abroad, in many countries the laws on the protection of animals were adopted long ago, taking into account the international treaties and recommendations. Often animal protection organizations work together with law enforcement agencies. So, in some police departments there are departments working on animal issues. They act independently or together with the Government organizations and shelters or the public charitable organizations, the private foundations and shelters. A single regulatory framework allows to coordinate the cooperation, or to strive for it. For example, in the United States there are no-kill shelters (often public, acting for donations, where animals are not euthanized, and therefore the number of places is limited) and open-admission shelters (most often the Government or State-run, staying in which is limited in time: either a new home or euthanasia upon the expiry of some period of time established by law or regulations, in order to free up the space for the newly arrived animals). In order to solve the problem of overpopulation of shelters with unlimited admission, there are the special funds, organizations and projects carrying out activities such as fairs or exhibitions to arrange a new families for the animals with "expiring time" through placing them in other shelters or take overs.

The foreign experience is a very valuable example for domestic animal rights defenders in the absence of legal support and relevant experience in Russia, as mentioned above. This makes it possible to focus on international animal related treaties and the experience of not only organizations protecting the rights and welfare of animals, but also biologists, ethologists, philosophers, bioethics which now not only simply consider the question of consciousness and its presence in various species of living beings. To some

extent, their consciousness is close to the human and how one would build relationships between "human" and "non-human" animals?

Scientists come to the conclusion that for different kinds of animals there must be the various tests and proofs about the presence of consciousness and self-cognition. Such an example can be a self-awareness study of dogs who were previously denied in self-awareness because they did not pass the mirror self-recognition (MSR) test (Cazzolla Gatti (2016)). For dogs, this test was modified into the sniff test of self-recognition (STSR) because dogs perceive the world in different way, the visual data is secondary for them. Dogs participating in the study passed the sniff test. Thus, for each animal species it is necessary to select individual options and an evaluation system.

Acknowledgment

The results were obtained in the frameworks of the RFBR (RHF) project №15-03-00598 “Bioethics: Creation of the New Symbolism”.

Abstract

The article deals with the theoretical problems of applying the NPS (Net Promoter Score) index when calculating customer loyalty in B2B market. In the article the concepts of loyalty and customer satisfaction were given. Based on the NPS research of B2B companies promoters and detractors were identified, as well as determine the level of loyalty and customer satisfaction in general.
Recommendations are given to improve the methodology for measuring loyalty and customer satisfaction on B2B markets. NPS normative values were proposed. The analysis of research results on NPS calculation for B2B is given, also methodological problems of its application for B2B markets are indicated in the article.

Keywords: Net Promoter Score, Customer loyalty, B2B marketing**.**

Introduction

Customer satisfaction is a measure that is determined by the ratio of the buyer's expectations to the actual quality of the purchased product or service. This is a feeling that the buyer has when he compares his preliminary expectations and perceived quality of the purchased product or service. (Kotler, Keller, Ancarani, Costabile, 2014)

In today's competitive market, customer satisfaction is an important indicator of efficiency and the main criterion of difference in the business strategies of competing companies. Consequently, the more customers satisfied, the stronger the customer ties with the company.

At present, questions about customer satisfaction and loyalty are very important due to the fact that companies are largely dependent on consumers, regardless of the type of activity or size of the business. It is consumers who are one of the most important factors for sustainable and successful business development. It is important to understand not only their current and future needs, but also try to exceed their expectations.

As practice shows, there is a correlation between the growth of the loyalty level and the increase in the company's profit (Yoo, Bai, 2013). Unsatisfied customers acquire fewer goods. Most often in their basket are goods whose yield is low.

The relevance of the topic is due to the fact that for successful operation, companies need to regularly monitor the level of satisfaction and loyalty. It is this measurement and choice of the evaluation system, as practice calls, which causes the greatest difficulties. Also worth noting is the fact that in Russia the issue of measuring customer satisfaction and loyalty is not given due attention, even though the

importance of the process of measuring these indicators is important for the functioning of a client-oriented business.

Measuring customer satisfaction is necessary for the following reasons:
1. Satisfied customers become loyal in the future. Loyalty is a belief that is formed due to the fact that the client is faced with a positive experience of interaction with the brand (Khan, 2013). Ensuring customer satisfaction is the process leading to loyalty in the future (Keiningham, Aksoy, Cooil, Andreassen, 2008).

2. Satisfaction is a key indicator of a company's success. Most often, the success of business is judged by time, volume and budget. Satisfaction is not taken into account when making important decisions. Nevertheless, in order for the company to be successful, it is necessary to interact with those for whom goods and services were originally created (Oliver, 2014). It is important to know, for example, whether your product meets their needs, or, is it necessary to add something.

3. The measurement of satisfaction will let you know whether the customer will buy from you again. For example, if a new customer remains satisfied with your product and service, then the likelihood that he will again acquire something will increase. Poor service will reduce the chances of their return.

4. Customers are more likely to leave because of poor quality of service than because of price considerations. The main reason for the loss of the campaign is not a change in the price of goods or services, but a poor customer service experience. For example, if a company pays attention to the needs of its customers and exceeds their expectations, it will be much easier to justify price increases in the future.

5. Acquisition of new customers will cost more than saving existing ones. Often practice shows that attracting new customers costs more than keeping those customers who already have it (Berry, 1995). That's why you need to use more resources to save existing customers, rather than trying to attract, but new customers.

6. Dissatisfied customers will necessarily tell about the negative experience of interaction with the company. This can be a strong blow to the reputation. It is important especially in the modern world, where information is spreading with enormous speed and large audience coverage (Banfield, 2015).

7. Growth of LTV (Lifetime Value) of a client. LTV is an indicator that shows the profit received from one client for all time of cooperation with him (Berger, Nasr, 1998). Accordingly, the longer the customer remains satisfied with your product or service, the longer it will stay with the company. This, in turn, will increase the chances of earning a profit for the time and money spent on acquiring the client. That is, maintaining customer satisfaction is important for achieving long-term success.

To solve such problems, B2C markets use the NPS index. It serves as an indicator of the loyalty of the company's consumers. According to the theory of this index, the most loyal consumer recommends the company, the goods or services which it uses, to others. The index is also used to assess readiness for re-purchases, mainly in commodity and consumer markets. The index was first presented in 2003 by Frederic Reicheld in Harvard Business Review.

The NPS measurement consists of the following steps (Reichheld, 2003):

1. Consumers are asked to answer the question "What is the probability that you will recommend the company (product/brand) to your friends (acquaintances/colleagues)?" On a scale from 0 to 10 points, where 0 corresponds to the answer "I will not recommend at all", And 10 -"I will definitely recommend ".

2. On the basis of the received values, all consumers are divided into three groups: 9-10 points - satisfied and active supporters-enthusiasts of the product (promoters), 7-8 points - satisfied, but neutral consumers (passive), 0-6 points - dissatisfied consumers (critics).

3. Calculation of the index. The index is a coefficient in the range from -100 to +100 (extreme points are reached if the share of promoters or critics is 100%), calculated by the formula:

$$NPS = \frac{P-D}{N} \times 100, \quad (1)$$

where N is the number of respondents, person; P - number of respondents who rated 9 or 10 (promoters), person; D - the number of respondents who rated from 0 to 6 (critics), person.

The number of companies using NPS is constantly growing for the following reasons.
If the consumer recommends the goods to others, it means that he is the most loyal. The article by F. Reicheld contains studies showing a close connection between the growth dynamics of the company and the share of promoters in the volume of consumers.

In marketing communications, the role of word-of-mouth advertising is growing, especially in connection with the development of the Internet (the emergence of social networks, blogs, etc.). The traditional model of communication AIDA (Attention, Interest, Desire, Action), many scientists and practitioners today supplement with the letter S (Share - send a link) or R (Recommend - recommend), some add S (Search - search), so modern communication models have the form AISDAS or AISDAR (Attention, Interest, Search, Desire, Action, Share or Recommend instead of Share), AIDAS (Attention, Interest, Desire, Action, Share) or even AISDA (Attention, Interest, Share, Desire, Action). In the last formula, we see that the desire to share interesting information appears with the consumer even before the purchase of the goods.

The theory of advertising by word of mouth says that people are more likely to spread negative information than positive. In addition, people remember the bad attitude towards themselves longer than good. Even if you serve the customer for a long time "at the highest score," you can lose it as a result of one negative impression. Therefore, the proportion of detractors is also important. According to the methodology for calculating the NPS index, one ill-wisher is equal to one promoter, but detractors are 0, 1, 2, 3, 4, 5, 6, and supporters are only 9 and 10 points. Thus, the proportion of "negative / positive" is 3.5 / 1. Especially you should pay attention to consumers who have put 0 and 1 point. These are embittered, offended consumers who will most actively criticize the company.

Technical implementation of the survey is simple; for research mainly used the Internet, SMS-messages and phone; most often only one basic question asked without specifying the reasons.

Literature Review and Research Methodology

Despite the simplicity of the NPS measurement technique, a number of questions arise when applying it.
1. In which markets and for what purposes can NPS be used?
2. What is the scale of scores - from 0 or from 1 to 10?
3. How to formulate the main question correctly?
4. What are the values of the "good" and "bad" index?
5. How does the share of passive consumers affect the outcome and how to use it?
6. How to analyze the answers of respondents who said: "I cannot evaluate" or "I do not know how to answer"?
7. Do you need to ask clarifying questions and ask them, should they be different for different categories of consumers?

The scope of application of NPS is expanding, extending to B2B markets (Zaki, Kandeil, Neely, McColl-Kennedy, 2016) which is also indicated by the provided research in this paper and staff loyalty studies (Bril, Kalinina, Ilin 2017), although the index was initially proposed for the B2C market.

The main question of NPS index sounds like: "How likely is it that you would recommend us to your friends?" In practical studies, you can find many different formulations:
- "With what percentage of probability from 0 to 10 would you recommend ...?";
- "What is the probability that you will recommend ...?";
- "On a scale from 1 (0) to 10, estimate how likely ...", etc.
Some formulations (for example, the first one) may be incomprehensible to the interviewee.

The sources do not represent the normative values of the "good" and "bad" values of the index, but there are data on the value of the best indices (Reichheld, 2006; Bălan, 2012). An example of the 10 companies-leaders in NPS in the US is shown in the Table 1 (Smith T. 2013). As an example of NPS of the automotive companies see Table 2 (“Предпочтения российских покупателей на автомобильном рынке”, 2014).

Table 1: Rating of companies-leaders in NPS in the US in 2013 in the markets of consumer goods

№	Company name	Industry	NPS, %
1.	USAA	Finance	83
2.	Amazon.com	Online sales	76
3.	USAA	Auto Insurance	74
4.	Trader Joe's	Foodstuffs	73
5.	Wegmans	Foodstuffs	73
6.	Costco	Department Stores	71
7.	Apple	Hardware	71
8.	USAA	Property Insurance	71
9.	Apple	Software	68
10.	HEB	Food products	68

Table 2: Rating of the automotive companies by NPS in Russia, 2014

№	Brand	NPS, %
1	Mercedes-Benz	70
2	Land Rover	68
3	BMW	62
4	KIA	62
5	Mazda	61
6	Subaru	60
7	Volvo	60
…	……..	…….
20	Great Wall	38
…	……	……..
31	Lada	5

There is no consensus on what a sufficient index value is. It depends on the market, the size of the company, the number of competitors and many other factors (Owen, Brooks, 2008).

The authors of the article suggest dividing the value of the index into four categories:
- less than 0 - "unsatisfactory";
- from 0 to 33% - "satisfactory";
- from 34% to 67% - "good";
- from 68% to 100% - "excellent."

"Unsatisfactory" values are associated with indicators of a negative index. The categories "satisfactory", "good" and "excellent" are the result of dividing the range from 0% to 100% into three approximately equal intervals.

Given the share of passive consumers (7 and 8 points) and those who found it difficult to answer, you can determine the direction of improvement in the company's activities. Neutral (passive) consumers are not involved in the calculation, however, in the extended version of the study they are asked what actions the company could increase their assessment to 9 or 10 points (Kinney, 2005). Thus, it becomes clear how to increase the proportion of the supporters of the brand. In Table 3 shows an example that clearly shows that for the same NPS (in this case it is equal to 20), companies A and B have different potential for growth due to passive consumers.

Table 3: The ratio of different categories of consumers for companies with the same NPS,%

Consumer category	Company A	Company B
Promoters	45	55
Neutral	28	2
Critics	25	35
No reply	2	8

Until now, the question of what the lower bound of the point scale is 0 or 1 point has not been clearly decided. Supporters of the scale from 1 to 10 believe that 0 cannot be considered a point, but initially F. Reicheld proposed a scale from 0 to 10. In addition, "zero" is of great psychological significance. The consumer, responding "Zero!" to the question: "What is the probability that you will recommend our company?", expresses its sharply negative attitude. His behavior deserves a separate analysis. Note also that the probability is measured from zero (Schneider, Berent, Thomas, Krosnick, 2008, June; Gloukhov V.V., Ilin I.V., Koposov V.I., Levina A.I., 2014).

As mentioned above, clarifying questions for different categories of consumers should be different. Passive consumers should be asked what could have raised their score to 9 or 10 points. Critics who have put 0 to 2 points should find out what they are so offended. Supporters (9 or 10 points) can be asked about what they would recommend to the company in terms of further development and victory over competitors, and how they see their future together with the company. Super loyal consumer is always interested in the victory of his company over the competitor.

Result

The main objective of the survey was to determine the level of loyalty and customer satisfaction in general, and also depending on the monthly costs of advertising campaigns. It was also necessary to find out what customer expectations are not met by the opportunities that already exist in the service.

Target respondents were independent B2B customers who systematically used the company services. Thus, the respondents were selected so that they simultaneously met the following criteria:

- independent clients (those who themselves are engaged in the conduct of advertising campaigns);
- customers who have replenished their balance and expenses at the time of the survey;

– customers who have committed more than three payments in the past 4 months.

In addition, customers were divided by the monthly budget, which they spend on advertising:

– less than 10 000 thousand rubles;
– from 10 000 to 30 000 thousand rubles;
– from 30 000 to 100 000 thousand rubles;
– more than 100 000 thousand rubles.

A similar division was made in order to understand whether there is a significant difference between the requirements and expectations of each of the selected segments. The total number of respondents was 262. The study was conducted with an online survey.

The level of loyalty was measured by the NPS index. Customers of the service answered a question that will allow them to know the level of their loyalty. The question was: "What is the probability that you will recommend the service to friends or acquaintances?" The answer to the question was a 10-point scale in which 0 is the smallest probability, and 10 is the largest. The answers, depending on the monthly budget, were divided as follows (Table 4):

Table 4: Share of promoters, neutral and critics of the company, depending on the customer monthly budget

Category	Less than 10 000, RUR	From 10 001 to 30 000, RUR	From 30 001 to 100 000, RUR	From 100 001, RUR
Promoters	81%	74%	65%	71%
Neutral	16%	22%	28%	26%
Critics	3%	4%	7%	3%

Thus, the NPS index was as follows, Fig. 1.

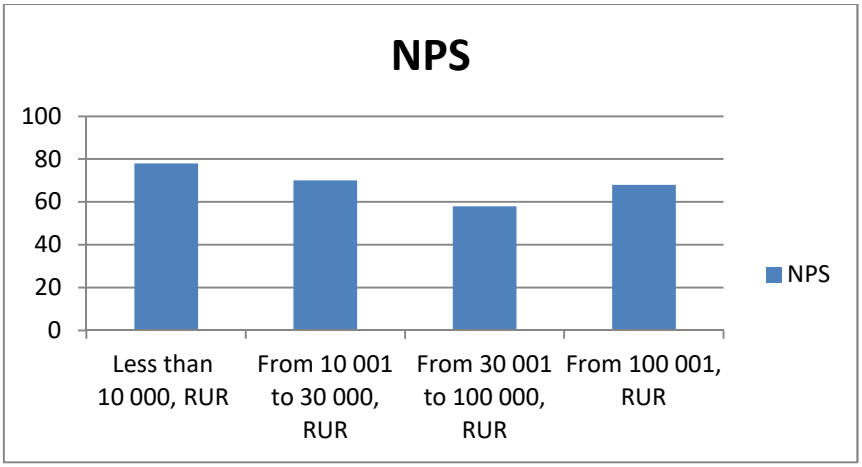

Fig. 1: NPS index depending on the monthly budget

Measuring the NPS index for all customers, the share of promoters, neutral and critics turned out the following, see Fig. 2.

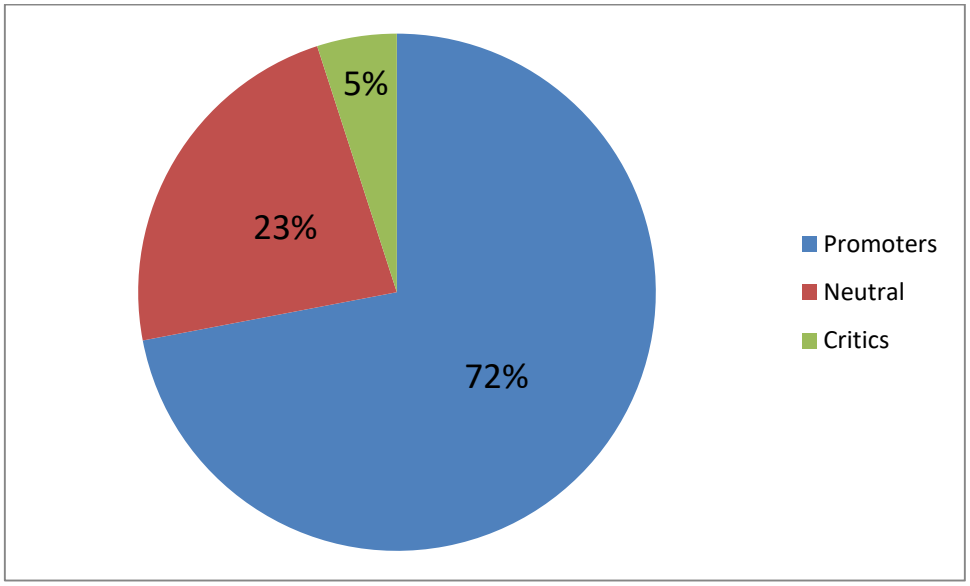

Fig. 2: Share of promoters, neutral and critics of the total

Thus, the level of NPS in the company as a whole is 67% (NPS = Promoters% - Critics% = 72% - 5% = 67%). 262 respondents mean that the maximum sampling error in this study is 6% (excluding the total number of clients). To calculate the maximum sampling error, the following formula was used (2):

$$\Delta = \sqrt{\frac{t^2 \times pq}{n}}, \quad (2)$$

where t is the normal distribution parameter (for the 95% probability the parameter t is equal to 1.96); pq is the maximum value of the share variance (equal to 0.25); n is the number of respondents.
The result is as follows:

$$\Delta = \sqrt{\frac{1.96^2 \times 0.25}{262}}$$

This indicator indicates that all results less than 6% are not significant, and the difference between responses less than 6% is also not significant.

Asking about the client's activity, it was possible to find out that the main part of users are specialists (47%) from small business (69%). Having received information about who our average client is, it will be possible to plan advertising strategies in a more qualitative way.

Customers with a monthly budget of 30 to 100 thousand rubles are the most dissatisfied segment (4.00 points), while the rest are approximately at the same level (from 4.29 to 4.30 points). Nevertheless, in general, the level of satisfaction among customers with different budgets is above average.

When analyzing the level of satisfaction of all customers, the following results were obtained. The highest scores were given to the Care Service and its speed (4.50 points) and the quality of the answers (4.52 points). Most of all the discontent was caused by training materials (4.00 points), as well as service

tools (4.01 points). The average level of satisfaction among all clients is 4.22 points, which is a good result.

The most loyal customers are those who spend on advertising less than 10 thousand rubles a month (78%). The lowest level of loyalty has customers with a monthly budget of 30 to 100 thousand rubles (58%). It is important to note that the level of loyalty among customers with different budgets in general is at a high level.

The level of NPS in the company is 67%. In order to understand whether this is a good result, for comparison, Figure 3 shows the range of the NPS index, depending on the industry.

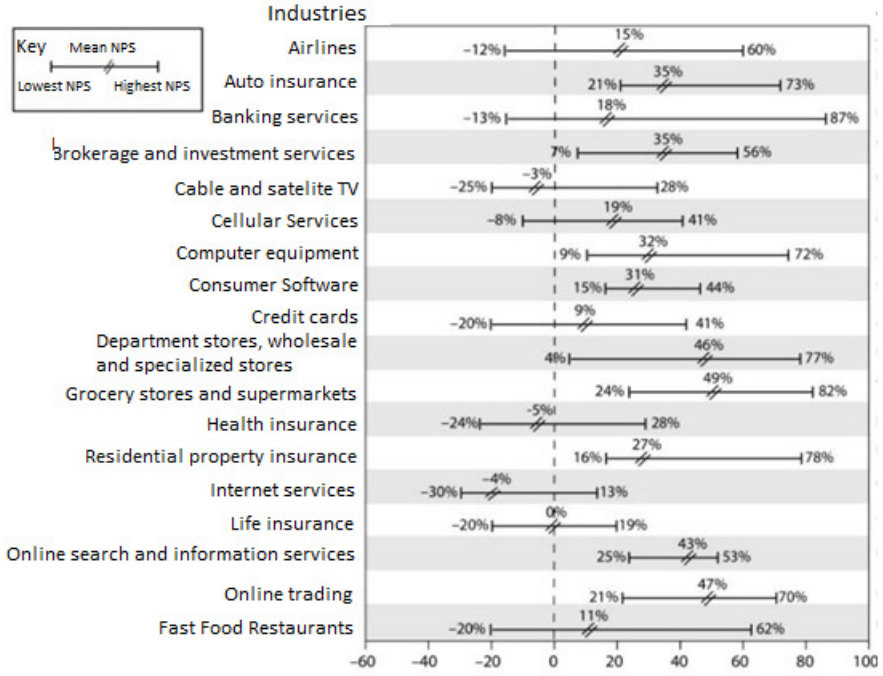

Fig. 3: NPS index range by industry (Reichheld, Markey, 2011).

The service of automation of contextual advertising can be attributed to the industry of Internet services. Figure 3 shows that in this industry, the NPS is generally not very high: the lowest is -30%, the average is -4%, and the highest is 13%. The figure of 67% for this industry is a very good result. This suggests that the researched company is one of the leaders in its market on loyalty.

Another NPS study commissioned by one of the companies in the B2B services sector was conducted for the first time for that company.
- Research method - telephone survey using the specialized computer assisted telephone interview (CATI) system.
- Respondents are divided into two categories by status.
- The total number of respondents - 2000 person.
- The total number of successful questionnaires is 687.
- The geography of the study is Russia.
The distribution of respondents by category is shown in Table. 5.

Table 5: Number of respondents to the questionnaire

Category	Respondents	Share, %
Category 1	483	70
Category 2	204	30
Total	687	100

In Table 6 it is shown the distribution of respondents by the number of points awarded when answering the question: "Estimate on a scale of 1 to 10, how likely is that you will recommend to other organizations to use our service?"

As you can see, more than 50% of respondents rated 10, which indicates a high degree of customer loyalty. Representatives of category 1 are more critical (11 respondents who put up 1 and 2 points, with 1 point put 10 people, whereas in category 2 no one put 1 and 2 points).

The final value of the NPS of 52.6% is a rather high index (according to our classification - the rating is "good"). Category 2 was more loyal (59%) than Category 1 (49.9%).

In the open source information was found about the relative value of the index value of competitors, which was 43%, i.e. the customer NPS indicator was 1.22 times higher.

Table 6: Distribution of respondents by the number of points

Rating	Category 1, %	Category 2, %	Total, %
1	2,9	0,0	2,1
2	0,3	0,0	0,2
3	1,2	0,7	1,0
4	1,2	0,7	1,0
5	6,7	4,9	6,2
6	2,3	3,5	2,7
7	6,1	4,2	5,5
8	14,3	16,7	15,0
9	12,2	15,3	13,1
10	52,2	53,5	52,6
No reply	0,6	0,7	0,6
Total	**100,0**	**100,0**	**100,0**

In Table 7 it is shown the calculation of NPS.

Table 7: Calculation of NPS

Customer portrait	Category 1, person.	Category 2, person.	Total, person.	Category 1, %	Category 2, %	Total, %
Promoters	309	141	450	64	69	66
Neutral	98	42	140	20	21	21
Critics	72	20	92	15	10	13
No reply*	4	1	5	0,6	0,7	0,6
Total	483	204	687	100	100	100
NPS, %	49,9	59,0	52,6	49,9	59,0	52,6

* Were counted as neutral for NPS calculation.

Consumers who put 7 and 8 points on the probability of recommendation (140 people), as well as those who found it difficult to answer (5 people) asked an open question: "What are your recommendations for the company in terms of improvement (quality of service), as a result of which your estimate may increase up to 9 or 10 points? "120 meaningful answers were received (high score).

The main indicator in analyzing the opinions of such respondents was that the recommendations on the price or quality of the product did not come to the forefront; mainly provided service characteristics that allow "bring" consumers to the state of loyal.

Conclusions and Discussions

Based on the results of the conducted studies on NPS for B2B companies it is concluded that NPS is suitable for B2B market, we recommend using our scale (satisfaction ranged in quartiles) because NPS for B2B would be unique for each market and it should be monitored in dynamics within the company. Comparing NPS index with competitors could make sense only within the framework of the same study
Due to the fact that the company will provide exactly the service that is really needed by clients, it can be assumed that customer satisfaction with respect to the service and the company as a whole will be increased through the provision of quality services. Satisfaction will be followed by increased loyalty, as the customer, satisfied with the service, will use it time after time, and in the future will start recommending to others.

Currently, the popularity of using NPS to evaluate customer relationships in a wide variety of markets (not just B2C, but also B2B) is growing, as well as for investigating employee loyalty.
There are unsolved methodological problems in determining NPS, which make it difficult to conduct standard studies and comparability of data from different studies.
Organizations using NPS should conduct regular monitoring studies of the indicator in order to determine the direction of improvement of their work.

In their research, competitors' brands should be taken into account, however, the data on the definition of NPS are of a closed nature, and therefore it is often impossible to compare one with competitors.

The Impact of Social Media on Tourism: A Comparison between Germany and Romania

Sonia Budz, The Bucharest University of Economic Studies, Romania, sonia.budz@yahoo.com

Kejo D. Starosta, The Bucharest University of Economic Studies, Romania, k@ksfx.de

Bastian L. Kurth, The Bucharest University of Economic Studies, Romania, bastian.kurth@posteo.de

Abstract

In the last two decades, the emergence of Web 2.0 and social media have entirely changed the way in which tourists perceive tourism, starting with the way they plan their trips and to the way their complaints are handled in the aftermath. Instant access to any kind of information gives travelers the opportunity to discover, communicate, and collaborate, regardless of distance and time. Therefore, solid relationships have formed between tourists and providers via social media, which have enabled tourism to develop continuously from many points of view, especially in terms of demand and quality.

Today's electronic word-of-mouth (eWOM) is carried out through travel platforms, which are intermediaries for social collaboration and online recommendations. These are the most important sources of travel information as well (Tripadvisor / Tripbarometer 2016).

Being one of the most powerful states in Europe, Germany has recorded a considerable growth in terms of technology and tourism. The tourism industry has reached a noticeably mature level and the behavior of travelers is more consolidated. Technology has developed at a rapid pace in Romania as well, influencing all industries, especially tourism, which is an important ring of the economic chain, since it is interconnected to everything. This technological growth has caused Romanian tourism to become a billion-dollar business, resulting in respectively three-fold and two-fold increases in the expenditures and numbers of departures.

The aim of this paper is to discover the manifold paths of evolution in Romania and Germany, which lead to the question of how coherent and different the tourism environments are today and how the relationships between tourists and providers are affected. This research seeks to make a comparison between these two environments with respect to tourism and social media, in terms of quality and transparency, by identifying the potential differences and their evolution, as well as the opportunities for improvement. This comparison will be helpful for travelers, travel agencies, businesspersons active in the tourism field, and others directly affected by this industry, in order to enhance their views and businesses, and implement different strategies for improvement.

Keywords: Tourism, eWOM, social media, relationships

Introduction

Disruptions caused by social media have changed the way in which potential tourists behave and how the tourism industry needs to handle their customers in this new digitalized world. How customers communicate with each other and with the companies changed in an extraordinary way. Two decades ago, there was almost no possibility, except the classical word of mouth, for customers to communicate with one another. The classical word-of-mouth used by friends and family members is still very influential as shown by a study of PhocusWright (PhocusWrigth 2013). A major problem with the classical word of mouth is that a recommendation of friends is not available for every travelling destination, and even if there is some information available, the sample size is generally small by nature. These problems could be overcome with the help of social media, which can facilitate a direct customer-to-customer communication that cannot be mediated the by tourism companies and is thus is more reliable (Buttle 1998). The Tripadvisors Tripbarometer shows that most travelers (73% and 86%) use online sources in order to decide their destination and

accommodation (Tripadvisor / Tripbarometer 2016). Many (55% TripAdvisor / 45% other travel review sites / 39% content posted by travelers) used a direct customer-to-customer source, as information. This electronic-word-of-mouth is for most travelers the key source of information today (Pan et. Al 2007).

Despite the globally tourist fluctuations, known to this industry, Romania's touristic expenditures more than tripled between 1997 and 2015 ($699 m in 1997 - $2.33 b in 2015). In addition, the number of departures registered a two-fold increase (6.24 m in 1997 - 13.12 m in 2015). This resulted an extraordinary revolution regarding technology and tourism in general.

Meanwhile, Germany's tourist industry recorded a non-constant period, which consists in years of a robust growth (1995 - 1999), as well of stagnation. Since 1999, the number of departures grew slightly (78.1 m in 1999 - 83.7 m in 2015) while expenditures grew stronger in this period ($59 b in 1997 - $88.84 b in 2015).

While there is comprehensive literature on the relationship between social media and tourism, there is little research on how this relationship is established in different countries, and where the similarities and differences lie.

A comparison between Romania and Germany is of interest due to the very different development paths of the tourism industries in the past. While in Germany there was only a technological revolution in a mature market, Romanian mass tourism saw the light of day resulting the emergence of a young billion-dollar market in the period of observation. The different paths of evolution lead to the question of how similar the markets are today, how young and new solutions have evolved, and where travelers are stuck in their old behavior.

Theoretical Foundations

This study will focus on the analysis of the demand side of the tourism environment in Romania and Germany. While there are several definitions of "tourism demand", we will use the plain definition of Mathieson and Wall, which is "the total number of persons who travel or wish to travel, and use tourist facilities and services at places away from their places of work or residence" (Mathieson and Wall 1982). Further, this study will focus on the social media environment where this demand is expressed and the tourist industry, the counterpart of the demand, interacts with it.

Numerical Facts

In order to compare the similarities and differences between Romania and Germany, it is essential to compare the numerical facts of demands of each country. The facts chosen are elaborated based on different tourism demand-forecasting models. Even if this study will not focus on the demand forecasting, the demand forecasting models elaborated in the previous studies, specify which parameters are the most influential ones for the tourism demands. Reviewing recent research on tourism demands modelling and forecasting, Song and Li have said: "Although the explanatory variables included in the tourism demands models vary enormously with research objectives and researchers' backgrounds, the employment of certain indicators, as the measurement of tourism demands, variables in modelling and forecasting tourism demands, have been less controversial, as suggested in Song and Witt (2000)" (Song and Li 2010). Turner, Witt, Coshall and many others suggest using tourist arrivals as an explanatory variable for tourism demands (Turner and Witt 2001, Coshall 2005). The departures can be calculated on this raw data as well. Further studies suggest that the expenditures done in the countries of destination should be used as an explanatory variable (Li et. al. 2004and many others). Additionally, some authors suggest using expenditures for specific items, e.g. as lunch, dinner, sightseeing and shopping (Law and Au, 2000). Another common variable, which is helpful in determining the tourism demands, is the revenue of the tourism industry (Akal 2004). Witt et. al. suggest using tourism employment as an explanatory variable (Witt et. al. 2004). Smeral found tourism import and export to be of interest (Smeral 2004). For members of the European Union, Eurostat adds two further explanatory variables that might be of interest for this comparison, such as: share of population participating in tourism, and the balance of

payments for travel receipts and expenditures (Eurostat 2017). The World Tourism Organization (UNWTO) further defines the duration of a trip or visit, mode of transport, and type of accommodation as important for the demand perspective (UNWTO 2010). Apart from the tourism-specific variables, older demand models rely heavily on the total or per capita income (Stone 1954, and many others).

Social Media Use in the Tourism Environment

Similar to the comparison of the numerical facts, the comparison regarding social media environments will be based on the most influential and critical aspects of online services. The literature, which analyzes the key success factors of the social media environment of the tourism industry, stems from various disciplines: marketing, business administration and computer science. Minazzi provides a comprehensive overview of how social media is used in tourism and hospitality, which covers both, the supply side and the demand side (Minazzi 2015). Today, social media is one of the absolute key information factors for travelers around the world. Pan et. al. showed that user generated content, comprising customer reviews, recommendations, and blogs etc., is a key source of information rather than just additional (Pan et al. 2007). It is common to use online sources for travel planning and booking. In fact, 73% of travelers use online sources when deciding on their destinations, and 86%, use online sources when deciding on their accommodation (Tripadvisor / Tripbarometer 2016). Some authors further distinguish the usage of online sources based on the time they are used. In this paper, generally Engel's classification is used: before leaving (pre-trip), (during stay) during-trip and (after coming back) post-trip (Engel et. al. 1990). The during-trip phase is getting increasingly important, thanks to the development of mobile technologies (Buhalis and Law 2008). Especially, the abolition of roaming fees in the European Union will facilitate further during-trip applications, and bring all customers and travelers closer together during their trips. However, is not common to use online sources only for planning and booking. An increasing number of travelers also use social media channels in order to get authentic and reliable information on a customer-to-customer basis. More than 50% (55% TripAdvisor / 45% other travel review sites / 39% content posted by travelers) actively search for customer-to-customer advice (TripAdvisor / Tripbarometer 2016). Buttle insists that they have a good reason for doing so, because this is a customer-to-customer communication, which cannot be mediated by the tourism companies and it is thus more reliable (Buttle 1998). The possibility for every individual to post messages, make recommendations, and rate products, brands, companies, services, or even destinations, takes the power away from the tourism companies and gives it to the customers (Hennig-Thurau et al. 2004). This is probably one reason why eWOM is one of the most influential factors for travelers. Hennig-Thurau et al. define eWOM as "any positive or negative statement made by potential, actual, or former customers about a product or company, which is made available to a multitude of people and institutions via the Internet" (Hennig-Thurau et al. 2004). All customer statements in any kind of online source, for any item, will be included in our eWOM definition, including traveler portals, blogs, travel diaries, rating sites, etc. Besides the classical usage pattern of social media instruments, like recommendations, blogging, likes and online diaries, Nielsen found out that customers prefer social media to interact with companies, brands, or service providers (Nielsen 2012). Hence, customers try asking questions, and making compliments as well as complaints, directly in the public environment of social media. This new habit of the customers brings up new challenges and opportunities. Several studies agree that the impact of eWOM on customers' decisions cannot be emphasized enough (Schindler and Bickart 2005 and many more). Especially for intangible products and services, word of mouth plays a significant role (Murray and Schlacter 1990). Liu, Dellarocas and many others empirically demonstrated that the sentiment in the customer reviews does have a considerable impact on the financial performances of the analyzed companies (Liu 2006; Dellarocas 2003). While the importance of eWOM is unquestionable, there are still problems that need to be considered when analyzing the implementation and usage of eWOM on the various platforms available to German and Romanian travelers. Firstly, there are some homemade problems, namely the purchasing and under-reporting biases. Secondly, there are forces in the social media world that try to manipulate eWOM for different reasons and with different objectives. Hu introduces the purchasing bias, which describes that someone who bought a product or service already and has or had a biased positive opinion about it (Hu et al. 2009). Anderson describes that

only customers who are extremely satisfied or extremely dissatisfied post reviews and comments on Social Media (Anderson 1998). This is described as the underreporting-bias, because people who are neither extremely dissatisfied nor extremely satisfied are not motivated to post their experiences on social media (Hu et. al 2009). The manipulation of user-generated contents by fake reviews, is analyzed by numerous studies in the fields of computer science, media, business administration, among other fields. The credibility of online recommendations differs depending on the platform and many other aspects. Peer-networks (Facebook, LinkedIn and Xing) are very trustworthy, because the relationships are from friends and colleagues, who usually know each other in person. However, Cheung and Lee note that public review sites offer much more content and have deeper insights due to the vast number of users (Cheung and Lee 2012). Most online travel agencies (OTAs) offer their own review systems, where only customers with bookings can write reviews. In the OTAs' systems the reviews should thus be verified. Because of these specific issues with eWOM, the credibility of the portals providing social media instruments is the key factor for success. Several dimensions influence the trust-level and credibility of travel portals and review sites. Firstly, source credibility is a key factor to determine the transparency of online reviews. Minazzi defines source credibility as "…the extent to which a source of information is perceived to be believable, competent (characterized by a certain expertise), and trustworthy by information receivers." (Minazzi 2015). The number of reviews is another key factor for most readers to assess the popularity of an item (Duan et al. 2008; Chevalier and Mayzlin 2006). An accommodation or trip with fewer reviews should thus be ranked lower than counterparts with many reviews should. Further, the writer of a review has a major impact on credibility. If the writer provides additional personal information and could be identified in the offline world, the level of trust is much higher (Xie et al. 2011). Even more important than personal information is the possibility to trace other activities of that user. It has to be transparent how many and which other reviews the user wrote to check if there is a consistent picture of that user (Brown et al. 2007). The last important point for travelers to check the validity of a review is the review itself. The information derived from the review, is often just the sentiment itself, positive or negative. However, if the review is perceived as valid, strongly depends on the details of the message and how detailed the description is (Schindler and Bickart 2005). Not only has the credibility of reviews played an important role in the success of eWOM, but also the accessibility. According to different studies, not only the share of positive or negative reviews is important. Negative reviews play a much more significant role than positive ones. Even a very small number of trusted and credible negative reviews can have a considerable impact on the decision of the customers (Tanford and Montgomery 2014).

Analysis / Comparison

In line with the theoretical foundations, we chose the parameters for comparison as described below. The analyzed numerical facts will be described first, followed by an analysis of the compared topics of the social media environment.

To spot the similarities and differences, from a quantitative point of view, in the first phase we are going to analyze the numerical facts of the tourism industries in Germany and Romania. The German and Romanian arrivals in different destinations can either be used directly to review the most popular destinations for these countries' travelers, or be aggregated to get the total departures of the travelers. This study will use both values. The total and per capita expenditures from all destinations will be used to get an overview of what the tourists experience in their destinations. To include observations from the supply side, we consider the total revenue and number of employees of the tourism industry in the comparison. On a macroeconomic scale, tourism import and export, along with the balance of payments between receipts and expenditures, will be included. Further, we will follow the definition of the UNWTO and include the duration of a trip, the mode of transportation and the type of accommodation in our analysis. All this data needs to be related to the share of population participating in tourism and to the total and per capita income.

The analyzed numerical facts are summarized as follows:

- Most popular destinations
- Total number of departures
- Total expenditure / expenditure per capita
- Total revenue of the tourist industry
- Number of employees in the tourist industry
- Balance of payments in tourism (receipts - expenditures)
- Duration of a trip
- Share of population participating in tourism

To get an overview of the German and Romanian travelers' behavior, we will evaluate which online travel portals are used and how they differ from one another. We will also analyze if there are differences in the usage of those portals and how the travelers participate in the social media channels. First, the number of travelers that use online media need to be compared, in order to have a basis of comparison for the online behavior. Next, the five biggest (by revenue) online travel portals for Romanian and German tourists will be determined to complete this basis. We will analyze if there are overlaps in the portals, if there are country-specific portals, and how the revenues are distributed within and across the countries. We will also evaluate the social media or collaboration features for a customer-to-customer communication. Further, we will try to analyze the participation in the portals with spot checks on the number of reviews of tourist hotspots. As the literature review has shown, the single most important point of the social media environment on tourism is electronic word of mouth. Therefore, this point will also be analyzed in detail when examining the differences between the German and Romanian online environments for travelers. The first important property to check is if the number of reviews is transparently shown on the travel portals. The second question is if other activities of the reviewer can be traced on the website and the history of the reviewer's activities is clear. With this feature, the customer should also be able to determine how many reviews the reviewer created and to judge how trustworthy they are. Additionally, the availability of the reviewer's personal information will be checked. Besides the reviews themselves, the theoretical foundations have shown that there is a need to have all kinds of ratings accessible, because even a single negative rating might have a considerable impact on customers' decisions. Therefore, we will also compare the accessibility of reviews, as it is a crucial point in how travelers access information on travel portals. While the review and social media instruments of the online travel portals usually cover the pre-trip and post-trip phases of the travelers, Buhalis and Law say that the during-trip phase is getting increasingly important, thanks to the advancements in mobile technologies (Buhalis and Law 2008). We expect that this trend will not just continue but also accelerate with the abolition of roaming fees in the European Union. Therefore, we will also evaluate the current instruments for during-trip social media interaction.

Table 1 - Most Popular Destinations for German and Romanian tourists

No.	Germany	Romania
1	Germany (27.4%)	Romania (87%)
2	Spain (14.8%)	Italy (3.2%)
3	Italy (8.2%)	Spain (1.8%)
4	Turkey (5.6%)	Greece (1.7%)
5	Austria (4.6%)	Bulgaria (1.5%)
6	Greece (3.5%)	Germany (1.1%)
7	Croatia (3.2%)	Turkey (1.1%) (unreliable)
8	France (2.6%)	Hungary (0.5%)

Source for Germany: FUR Forschungsgemeinschaft Urlaub und Reisen e.V., Reiseanalyse 2017 (Data of 2016). Source for Romania: Eurostat http://ec.europa.eu/eurostat/statistics-explained/index.php?title=Tourism_statistics_-_top_destinations&oldid=192301

From the comparison above, the domestic tourism is at the top of the table, recording the biggest values. Most of the Romanian population prefer to visit their origin country. In Germany things are different due to the bigger income of Germans, which allows them to travel abroad easily. We can see that both, German and Romanian tourists prefer countries with a warm climate for holidays. Europe's popular tourist destinations Spain, Italy, Greece and Turkey are in the front-placings, additionally the neighboring countries are also found in the top ten.

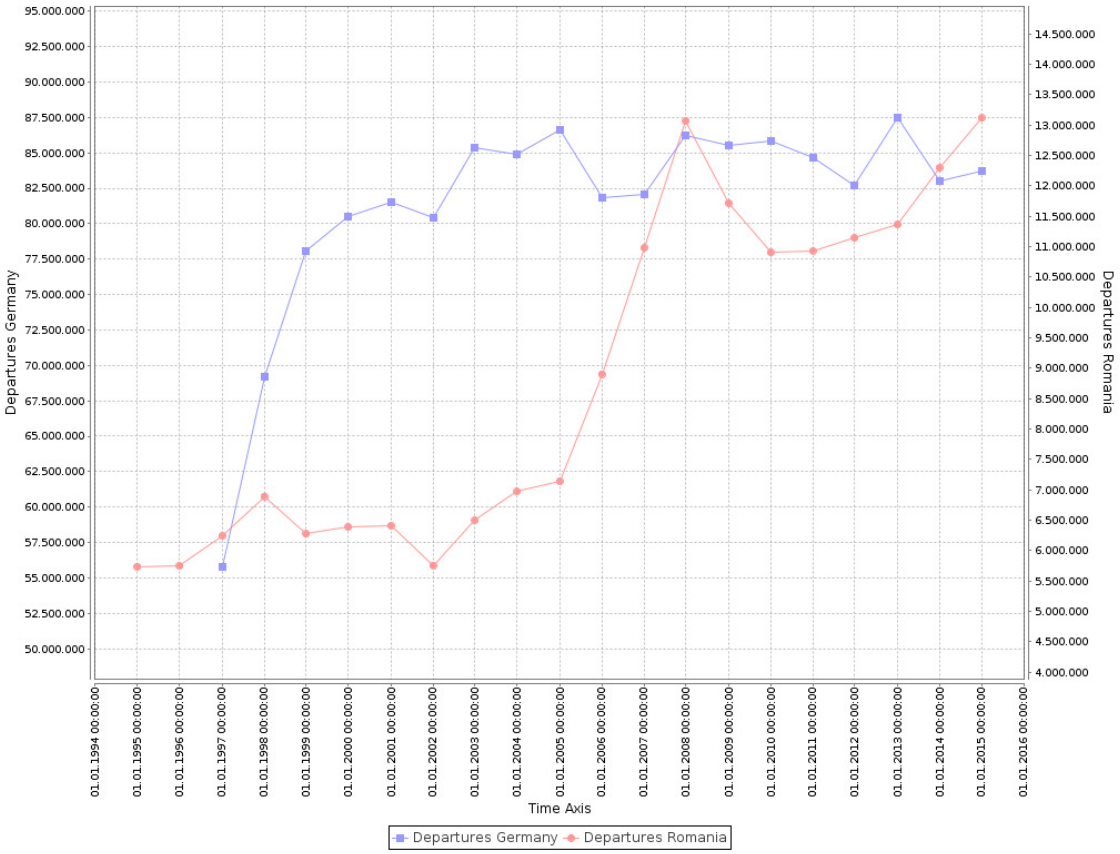

Figure 1 : Number of Departures

Source: World Tourism Organization, Yearbook of Tourism Statistics, Compendium of Tourism Statistics and data files (https://data.worldbank.org/indicator/ST.INT.DPRT?locations=DE-RO)

In the analyzed period, the number of departures is increasing with regard to both countries. In comparison with Germany, Romania's values are lower, due to the small salaries and number of population, determined as well by the large rural area. The business tourism put its mark on both countries.

Figure 2 : Total Expenditures

Source: World Tourism Organization, Yearbook of Tourism Statistics, Compendium of Tourism Statistics and data files (https://data.worldbank.org/indicator/ST.INT.XPND.CD?locations=DE-RO)

We can observe that in the second chart the situation is similar to the first. The only difference is the decreasing trend regarding Germany at the end of the analyzed period. This decrease could have been caused by the actual terrorism situation in Europe, Germans opting for neighboring countries or cheaper destinations.

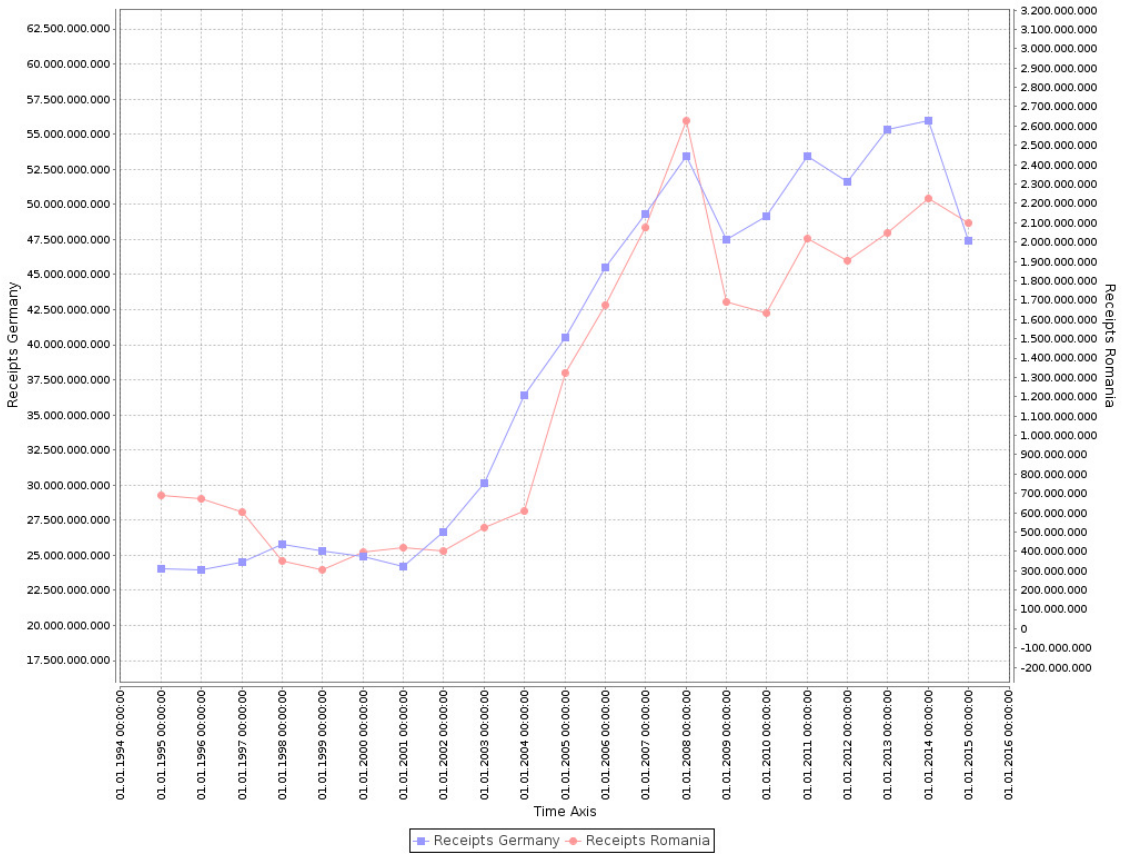

Figure 3 : Total Receipts

Source: World Tourism Organization, Yearbook of Tourism Statistics, Compendium of Tourism Statistics and data files (https://data.worldbank.org/indicator/ST.INT.RCPT.CD?locations=DE-RO)

In the chart above we can see a decrease regarding the German trend, probably due to the popularity of the Asian continent, tourists preferring the latter one. Romania's trend increased in the analyzed period, due to the beginning of awareness among foreign tourists and exploited potential.

Table 2 : Total Number of Employees in Tourism Industry

Country	Year	Number of Employees
Germany	2006	64,255
	2007	68,510
	2008	1,592,843
	2009	2,082,785
	2010	2,090,794
	2011	2,171,320
	2012	2,148,489
	2013	2,076,514
	2014	2,239,394
	2015	2,317,178

Country	Year	Number of Employees
Romania	2006	8,604
	2007	9,345
	2008	209,509
	2009	204,542
	2010	196,309
	2011	205,659
	2012	211,977
	2013	215,042
	2014	214,340
	2015	181,377

Source: Eurostat (http://ec.europa.eu/eurostat/product?code=sbs_na_1a_se_r2&language=en&mode=view) Calculation according to the definition of Eurostat: http://ec.europa.eu/eurostat/statistics-explained/index.php/Tourism_industries_-_employment

From the table above, the dissimilarity between the two countries is obvious. This difference is due to the bigger number of population in Germany, as well as the maturity of the tourism industry. The urban part predominates in the first country analyzed, which creates more demands for holidays and infrastructure. In both countries, the values are increasing and decreasing from year to year, which show the fluctuating trends of tourism.

Table 3 : Share of Population Participating in Tourism

	Year	Number of Tourists (1 Night and Over)	Population older than 15	Participation Rate
Germany	2012	54,801,532	69,554,894	78.79
	2013	54,860,590	69,840,843	78.55
	2014	53,295,033	70,125,031	76.00
	2015	53,820,334	70,510,814	76.33
Romania	**Year**	**Number of Tourists (1 Night and Over)**	**Population older than 15**	**Participation Rate**
	2012	3,874,801	16,911,747	22.91
	2013	4,230,146	16,880,465	25.06
	2014	4,201,139	16,852,702	24.93
	2015	4,357,576	16,789,563	25.95
	2016	3,961,003	16,695,321	23.72

Source: Eurostat (http://ec.europa.eu/eurostat/product?code=tour_dem_totot&language=en&mode=view, http://ec.europa.eu/eurostat/product?code=demo_gind&language=en&mode=view, http://appsso.eurostat.ec.europa.eu/nui/show.do?dataset=demo_pjanbroad&lang=en)

From the analysis above, Germany's values are bigger than Romania's, due to the number of population, urbanity and popularity among tourists. Although there is not more data available regarding the participation rate, our estimation is that the general trend in Romania is going upwards, which is underlined by the increasing number of departures and rising expenditures. In contrast, our expectation is that the participation rate in Germany is stagnating, due to the aging population and the already high level.

The analyzed social media aspects are summarized as follows:

- Share of travelers who booked online and in agencies
- Five biggest travel portals (by revenue)
- Overlaps in portals between Romania and Germany
- Highlighting of country-specific portals
- Distribution of revenues within and across countries
- Social media and collaboration features for customer-to-customer communication of the portals
- Spot checks of participation based on number of reviews on tourist hotspots
- How the credibility of the electronic word of mouth is ensured
    - Transparent number of reviews
    - Can a review be related to other activities of that user?
    - Personal information about the reviewer
    - Accessibility of reviews by rating
- Are portals offering during-trip mobile support?

To summarize, the most popular destinations among Romanian and German tourists are very similar. Europe's popular tourist destinations are Spain, Italy, Greece and Turkey, in the front-placings. Additionally the neighboring countries are found in top ten as well. An interesting fact is that Croatia seems to be far more popular in Germany than in Romania. Another interesting fact of the destinations statistics is that more German tourists travel abroad (72.6%) than Romanians (13%), due to the high poverty rate of the latter ones. While participation in tourism in Germany is more than two-thirds of the total population, it is only one-quarter in Romania (see Table 3). However, a look at the departures gives a slightly different view. There are only six times more departures in 2015 in Germany than in Romania, which is too low compared to the difference in population numbers in relation to the participation rate (see Figure 1 and Table 3). Therefore, it seems that the people who are able and willing to travel in Romania are travelling by far more often, even if the participation rate is much lower. Comparing the departures in 2015 (Germany: 83,737,000 vs. Romania 13,118,000) with the population that is participating in tourism, we can see that there are 1.55 departures per capita in Germany and 3.01 departures per capita in Romania, almost as double as in Romania compared to Germany (see Figure 1 and Table 3). An analysis of the expenditures' sheds a different light on the numbers again. The expenditures for tourism were almost 40 times higher in Germany than in Romania (Germany $88.84 b, Romania $2.33 b - 38.12 times – see Figure 2). While the tourism balance of payments is almost balanced for Romania (2015: expenditures 2.33 b, receipts 2.1 b), the Germans spend twice as much as they earn from tourism (2015: expenditures $88.84 b, receipts $47.39 b – see Figure 2 and Figure 3). The share of the biggest travel portals regarding all the tourism expenditures are as follows: Invia's revenues are more than 2.5% of the total tourism expenditures in Germany, Romania's Vola owning 1.23% of the Romanian expenditures.

Table 4 : Most Important Travel Portals in Germany (2014)

1.	Company	Invia (Former: Unister-Travel)
	Websites	ab-in-den-urlaub.de urlaubstours.de hotelreservierung.de fluege.de reisen.de
	Revenue	EUR 2B
	Social Media (review features)	The different websites use different business models; some of them are only intermediaries. When they act as seller (e.g. urlaubstours.de), they have their own review system.

	Credibility of User Generated Content	Transparent number of reviews: Yes, by age group and number of travelers (Single, Couples, Families) Can a review be related to other activities of that user? No, but the reviews are from verified customers only Personal information about the reviewer: Name, age group, date of trip Accessibility of reviews by rating: Yes, the listing can be sorted by rating
	Additional information	Trustworthiness additionally tested by Holidaytest.de
2.	Company	Expedia
	Websites	expedia.de
	Revenue	EUR 1.1B
	Social Media (review features)	Expedia powers its own review system, where only verified customers can leave their reviews. Additionally, the TripAdvisor rating and the number of TripAdvisor reviews are shown.
	Credibility of User Generated Content	Transparent number of reviews: Yes Can a review be related to other activities of that user? No, but the reviews are from verified customers only Personal information about the reviewer: No Accessibility of reviews by rating: Yes, the listing can be sorted by rating
	Additional Information	Each review can be rated as “helpful”
3.	Company	Holidaycheck
	Websites	holidaycheck.de
	Revenue	EUR 765M
	Social Media (review features)	Holidaycheck powers its own review system, where only verified customers can leave their reviews. The customers can review different aspects of each accommodation.
	Credibility of User Generated Content	Transparent number of reviews: Yes Can a review be related to other activities of that user? Yes, each user has a profile page where the activities are displayed Personal information about the reviewer: See above Accessibility of reviews by rating: Yes
	Additional information	Trustworthiness additionally tested by TÜV Süd
4.	Company	Schmetterling
	Websites	schmetterling.de
	Revenue	EUR 686M
	Social Media (review features)	No reviews, only ratings for different aspects of the accommodations are displayed
	Credibility of User Generated Content	Transparent number of reviews: Number of ratings is displayed Can a review be related to other activities of that user? No Personal information about the reviewer:

		No Accessibility of reviews by rating: No
5.	Company	eDreams
	Websites	edreams.de
	Revenue	EUR 659M
	Social Media (review features)	eDreams powers its own review system, where only verified customers can leave their reviews. The customers can review different aspects of each accommodation and even upload pictures.
	Credibility of User Generated Content	Transparent number of reviews: Yes Can a review be related to other activities of that user? Only the number of different reviews per user is displayed Personal information about the reviewer: Name, age, group Accessibility of reviews by rating: Exhaustive sort and filtering possibilities

Source: http://www.internetworld.de/bildergalerie/zehn-groessten-reiseportalbetreiber-in-deutschland-997711.html?seite=9

From the table above, we can observe that Germany has several tourism platforms due to the maturity of this industry and the population's openness regarding the online bookings.

Table 5 : Most Important Travel Portals in Romania

1.	Company	Vola
	Websites	vola.ro
	Revenue	$28.8M (2012)
	Social Media (review features)	Vola powers its own review system, where only verified customers can leave their reviews. The customers can review different aspects of each accommodation and even upload pictures.
	Credibility of User Generated Content	Transparent number of reviews: Yes Can a review be related to other activities of that user? No, but the reviews are from verified customers only Personal information about the reviewer: Full name, travelers group (Single, Couples, Families), date of review Accessibility of reviews by rating: No, the reviews are sorted descending by date
2.	Company	Direct booking
	Websites	directbooking.ro
	Revenue	-
	Social Media (review features)	Direct booking powers its own review system, where only verified customers can leave their reviews. The customers can review different aspects of each accommodation and even upload pictures Additionally, the portal provides a direct chat possibility, to contact an agency agent.
	Credibility of User Generated Content	Transparent number of reviews: Yes Can a review be related to other activities of that user? No, but the reviews are from verified customers only Personal information about the reviewer:

		Full name, travelers group (single, couples, families), date of review Accessibility of reviews by rating: No, the reviews are sorted descending by date
	Additional Information	Trustworthiness additionally tested by Trusted.ro
3.	Company	Eximtur
	Websites	eximtur.ro
	Revenue	-
	Social Media (review features)	None
	Credibility of User Generated Content	Transparent number of reviews: - Can a review be related to other activities of that user? - Personal information about the reviewer: - Accessibility of reviews by rating: -
	Additional Information	Trustworthiness additionally tested by Trusted.ro
4.	Company	Imperatortravel
	Websites	imperatortravel.ro
	Revenue	
	Social Media (review features)

	Social Media (review features)	None, but the rating of TripAdvisor is shown
	Credibility of User Generated Content	Transparent number of reviews: - Can a review be related to other activities of that user? - Personal information about the reviewer: - Accessibility of reviews by rating: -

Sources: https://seenews.com/news/romanias-volaro-again-tops-deloitte-technology-fast-50-ce-ranking-385435

The number of tourism portals in Romania is lower than Germany, due to the lack of infrastructure and openness to the online shopping system. Romanians prefer the classical way, choosing the agencies as travel intermediaries, instead of online platforms, the average age of the population, exceeding 40.

When comparing the online environment for travelers in Romania and Germany, the first thing that needs to be compared is the general usage of the internet when booking accommodations and means of transportation. The latest Eurostat statistics of 2014 show that just 7.1% of Romanian travelers, but 60% of German travelers booked their transportation and accommodation online (Eurostat 2016). Especially low are the numbers for domestic accommodations (5.6%) and means of transportation, other than air transportation (1.2% - Eurostat 2016). The comparison of popular online travel agencies in Germany and Romania, as listed in Table 4 and Table 5 respectively, shows that the champions in both countries rely heavily on the electronic word of mouth of their users and implement successful recommendation systems with lots of participants. While all online travel portals in Germany rely on user-generated content, the less popular ones in Romania provide only rudimentary or no social collaboration features.

Conclusions

The large number of departures compared to the low participation rate and the very low expenditures of Romanian tourists can be explained by the duration of the trips, the distance travelled, the price level in the destination country, and last but not least, the degree of the luxuriousness of the trip.

The low usage rate of online bookings in Romania seems to be driven by two factors, the availability and trustworthiness of online services on the one hand, and the behavior of customers on the other. Especially the online presence of domestic accommodation and domestic and international bus, train, and ship services could be strengthened. The stronger usage of online services for booking flights (23%) shows that people can and are willing to use online services if the services are available (which is the case for flights) (Eurostat 2016). This could make the booking processes in Romania more efficient and cost-effective. To make online services available today is extremely cost-efficient due to Airbnb services, for instance, which might be a solution for smaller hotels and guesthouses to expand their businesses without additional investments. In addition, direct customer contact through social networks will become more important in the future, being a good chance to improve online activities. Romanian portals with low numbers of reviews and ratings could try to display information in collaboration with the market leader TripAdvisor, as several German online travel agencies do. This could be a step forward in compensating the low numbers of tourists booking online and leaving reviews on the portals.

For both, German and Romanian markets, the local leaders' revenues are comparatively low, which might suggest that many people book via international platforms, where the revenues per country are not disclosed. This point would need further analysis in order to find empirical evidence.

The support for the during-trip phase of most platforms could not be evaluated properly. Even if some platforms offer maps and restaurant recommendations, there is always a lack of social interaction within these applications. In addition, it seems that people are more interested in information received from locals, due to the easier accessibility via mobile apps like Facebook, Jodel, Foursquare and others. The direct sharing of pictures and other experiences take place within social networks rather than travel platforms. Further research on the usage of mobile platforms, in the during-trip phase, would be required.

The Romanian and German markets reveal that online tourism portals and travelling agencies are not a winners-take-it-all markets. This fact make the online tourism services in Romania very interesting to observe. This country has a lot to catch-up in terms of tourism, and the numbers suggest that is on its way of doing so.

Providing Security in Objects of Critical Infrastructure

Hana Malachová, Kamil Bednář
Department of Emergency Management
University of Defence
Brno, Czech Republic
hana.malachova@unob.cz, kamil.bednar@unob.cz

Abstract

This paper deals with the role and tasks of Active Reserve Units of Armed Forces of the Czech Republic in providing security protection to critical and defence infrastructure objects. The article defines legal framework of the issue and presents selected exercises of Active Reserve Units dealing with fulfilling tasks in the field of critical infrastructure protection in co-operation with other components of the Integrated Rescue System. Possibilities of providing security to the object are presented as well as sets of control questions for assessing physical protection of critical infrastructure object security provision in case of emergency or crisis situation of non-military character occurrence are designed using a checklist method. Causes of disruption to the national energy critical infrastructure element are shown on its example and based on the results of the checklist application; measures have been proposed to enhance physical protection of the object.

Keywords: Critical infrastructure, defence infrastructure, object, protection, Active Reserve Units of Armed Forces of the Czech Republic, object security

Introduction

Military and non-military threats to both internal and external security are increasingly overlapping and states are seeking effective measures to address these security challenges and what is more to eliminate them to the maximal extent. Providing critical infrastructure protection represents one of the key roles of Active Reserve Units when deploying them in case of declaration of the state of emergency. With the increasing number of non-military threats such as interruptions in strategic raw material supply, migration, financial crime, terrorism, cyber-attacks and deteriorating security situation in the states bordering with the member North Atlantic Treaty Organization (NATO) states and the European Union (EU), pressure is being put on Europe in the field of military capability and readiness of the individual states to withstand security threats (Ministry of Foreign Affairs, 2015).

Analysis of the current state

At present, EU states face many security threats. A lot of these threats are directed against infrastructure. The term infrastructure, in the most general concept, includes a plurality of interconnected elements that maintain the structure together. It is used in a number of areas, but the most prolific use it has in economics where it describes physical infrastructure such as buildings or roads.

Infrastructure has been defined in many ways, for example, those physical facilities that are sometimes called public works (Grigg, 1988). Public works have been defined by the American Public Works Association as follows: Public works are the physical structures and facilities that are developed or acquired by the public agencies to house governmental functions and provide water, power, waste disposal, transportation, and similar services to facilitate the achievement of common social and economic objective (Uddin, 2013). In the Czech environment, public infrastructure is defined by the Building Act (Act, 2006) as land, structures and facilities established or used for the public interest. Public infrastructure includes transport infrastructure (e.g. road communications, railways, waterways and airports), technical infrastructure (lines, construction and related technical equipment such as water mains, reservoirs, sewers, wastewater treatment plants, transformer stations, power lines and pipelines),

civic amenities (constructions, equipment and land used for example for education and training, culture, public administration and population protection) and public space (Act, 2006). Households, houses, blocks of flats, municipalities as well as the army, in the form of training and storage facilities, also have their own infrastructure.

Critical vs. Defence Infrastructure

The Czech Republic, as well as other EU countries, feels the urge to address critical infrastructure issues, and consequently its protection and defence. Critical infrastructure issue penetrates into the sphere of public life security in the sectors such as telecommunications, transport, energy supply, food and drinking water supply and functioning of state administration (Oulehlová, 2015). Critical infrastructure is defined in the Czech legal environment by the Law on Crisis Management as *an element of critical infrastructure or a system of critical infrastructure elements, disruption of which function would have a significant impact on the state security, the provision of basic living needs of the population, human health or the state economy* (Act, 2000). Basic principles of critical infrastructure protection which are subsidiarity, complementarity, confidentiality, proportionality, avoidance of duplication and stakeholder cooperation, including sharing best practices and increasing efficiency in cooperation (Bílek, 2010), are derived from the Green Paper on a European Programme for Critical Infrastructure Protection (EPCIP) (Commission of the European Communities, 2005). Government Regulation (Act, 2010) on Criteria for determining the critical infrastructure element defines cross-sectoral and sectoral criteria for identifying a critical infrastructure element. Cross-sectoral criteria include aspect of physical disability of persons, economic loss and restrictions in basic service provision to the population. By contrast, sectoral criteria specify technical and operational values and extent of impact of their function disruption. One sectoral criterion is the energy sector, including electricity, natural gas, oil and petroleum products as well as central heat supply.

Critical infrastructure objects are selected buildings and facilities of public infrastructure and other elements owned or operated by critical infrastructure bodies (Act, 2000). Crisis Management Act understands the crisis infrastructure protection as measures for reducing the risk of disruption to the critical infrastructure element function. In addition to the Integrated Rescue System (IRS) and the owners of the CI, Czech Academy of Sciences (CAS) has its share in fulfilling critical infrastructure protection tasks. Alternatively, infantry platoons of Active Reserve Units of regional military headquarters would also be used for fulfilling these tasks.

While providing defence of the Czech Republic territory, each infrastructure is unique and only the point of view of its use purpose allows its correct identification and classification as critical or defence infrastructure. The term defence infrastructure is not defined in any legal regulation; however, its definition is stated in the Plan of Operational Preparation of the Czech Republic Territory from 2015. Here the defence infrastructure is referred to as a set of objects, structures, land and equipment including necessary services, production and non-production systems essential for their operation, regardless of the form of the ownership and way of using which destruction, disturbance or limitation to their activities would, during peace, threat to the state or war condition, threaten the fulfilment of the tasks of the armed forces of the Czech Republic in the implementation of the Defence Strategy of the Czech Republic and operational plans, including mobilization measures, other components of the Security Strategy of the Czech Republic during the implementation of their partial defence strategies, the Allied armed forces in the implementation of their operational plans and protection of the population (Ministry of Defence, 2015).

The Directive on Evaluation, Selection and Protection of Defence Infrastructure Objects and Setting the Scope of the Processed Documentation defines the principles, criteria and procedures in the selection of a defence infrastructure object, specifies the scope, content, way of keeping the documentation and determines the principles of their guarding and protection. Objects of defence infrastructure for the purpose of providing defence of the state against external attack are:

(a) Objects important for state defence (OISD),

(b) Objects that may be attacked under the threat to the state or war condition, which are assessed by the regional authorities and the City of Prague City Hall, the so-called objects of possible attack (OPA).

The selection of defence infrastructure objects is based on documents related to the planning, management and organization of state defence as well as tasks that are fulfilled by the proposers, i.e. the ministries, other central administrative authorities, the Czech National Bank, intelligence services, regional offices, etc. in the field of providing defence of the state. Objects also include entities of production and non-production spheres operating facilities and buildings or providing services in defined areas of critical infrastructure.

The Defence Strategy of the Czech Republic (Act, 1999a) defines OISD as land and constructions located in military training areas and their corresponding objects, which are of political, military or economic significance for providing state defence, in particular for providing the basic functions of the state and securing the armed forces. OISD are also:

- land and constructions to which the property rights of the state and other property rights of the state are exercised by the ministry or a legal entity established or founded by it;
- land and constructions designed to protect the population;
- land, constructions and other objects of strategic importance determined by the government;
- land and constructions which may be of strategic importance under the threat to the state or war condition and are determined by the government (Act, 1999a).

As stated above, except for OISD, there are also OPA determined on the territory of the Czech Republic which, in terms of their function in providing state defence, is of no strategic importance, but they are crucial in the administrative districts of the regions and municipalities. They are crucial for:

- ensuring mobilization of the Czech Armed Forces on the regional territory,
- implementation of measures for providing defence on the regional territory,
- providing basic living needs for the population of the region,
- functioning of state administration and self-government on the regional territory.

In their assessment, regional authorities may request co-operation and cooperate with the territorially competent Regional Military Headquarters (RMH) and other territorial competent bodies, state administration and self-government bodies. Within the category of objects for maintaining the functions of the region in providing defence of the Czech Republic, fall among others, power plants and gas and electricity distribution systems. The RMH carries out exercises with soldiers of Active Reserve Units for protection of these objects exercising tasks to provide their protection. System of guarding and protection of the object in general terms results from the importance and value of the guarded object, from the possibilities of the allocated armed forces and means of the ACR and other components of the IRS and from the potential threat and risk level of its destruction (Janíček, 2010).

ACR and protection of both critical and defence infrastructure

Czech Armed Forces are also involved in the tasks of protecting critical and defence infrastructure, especially through members of Active Reserve Units. On the basis of a government decision, the units may be deployed for fulfilment of tasks in accordance with Act No. 219/1999 Coll., On the Armed Forces of the Czech Republic (Act, 1999b). As a priority, 14 territorial infantry platoons of Active Reserve Units of RMH are allocated in ACR for implementation of object security for which guarding of OISD objects can be considered one of the priority tasks. Units are trained and equipped for such activity and they create both personnel resources for the priority replenishment of selected units and equipment of the Czech Armed Forces. Their preparation and security is in charge of the RMH which, on the basis of the requirements of military units, call them up for the military exercise (Ministry of Defence, 2012).

An example of Active Reserve Units practicing the tasks of guarding objects was the co-ordination exercise Horizont 2012, in which members of Active Reserve Units of RMH Ostrava took place. The task for Active Reserve Units was to guard and defend the selected critical infrastructure object which

was power control room. The exercise took place in real conditions with a real threat scenario with participation of the members of the IRS components, the PCR and selected units of the ACR, namely the 72nd Mechanized Battalion at Přáslavice, Stará Boleslav Protective Platoon, the Chotyně Veterinary Base and the 23rd Helicopter Air Force Base at Přerov.

Another example was the Safeguard 2016 exercise which was also aimed at protecting and defending energy critical infrastructure objects, specifically the Kletná power control room. Soldiers of Active Reserve Units of RMH Ostrava participated in building the base, securing the external perimeter and security zone of the power control room critical infrastructure object. Active Reserve members practiced, among other things, conducting people and vehicle inspections and reactions to attacking the object (Police, 2017) which are important tasks for providing object protection.

The third exercise which tested preparedness of soldiers of Active Reserve Units to fulfil tasks in the operational deployment and to allocate forces and means for fulfilling tasks of the Police of the Czech Republic was Hradba 2016 exercise. Similarly during this exercise, activities in guarding the OISD were exercised as well as further activities in protection of the state border sections. Active Reserve Units were provided with co-operation by the professional units of the ACR. In general, it can be said that such exercises increase the readiness of units to perform tasks in the area of protection of the object in crisis situations (Army of the Czech Republic, 2012).

Providing security of the object

Protection means an activity that allows its permanent functionality, protection against penetration of strangers and protection against activities that would restrict its operation. Object protection is provided by technical, physical or combined security means. A detailed security description is provided below. Basic area of providing security is protection of objects and persons which is created by a system of technical, organizational and regime measures. Property security and protection is provided by:

- mechanical protection systems,
- electrical protection systems,
- physical security guard and regime measures.

Mechanical barrier systems are designed to directly secure the object by creating an appropriate barrier system, overtaking of which requires some time. If it is desirable to achieve higher security, classical protection has to be completed by electrical security systems that are able to detect unauthorized movement both inside and outside the object and pass the information to the guard of the object who subsequently intervenes.

Classical protection in the form of mechanical barrier systems has the task of creating a firm barrier and discouraging a potential intruder from the intention to commit a crime, preventing intruder from committing this crime or at least delaying its execution. Depending on which zone the mechanical barrier system or the electronic security system protects, the perimeter, sheath, space and object types of protection are distinguished. Examples of individual types of protection are shown in Table 1.

Table 1: Basic methods of providing object security protection

	Protection			
	Perimeter	**Sheath**	**Space**	**Object**
Mechanical protection systems	provides protection of the designated area and prevents unauthorized access to the third parties (fences, razor wire, entrance gate, gates, barriers)	prevents the intruder from entering a particular object (locks, doors, grilles, safety glass)	protection inside the building to prevent or delay movement of an intruder inside the building (interior doors, windows, locks)	measures to prevent the theft and unauthorized handling the protected assets (safes, safety cabinets)
Electrical protection systems	Detects disturbance to the outdoor area of an object (specially produced external technical equipment)	Announces the violation of the guarded object shell	Indicates a violation to spaces inside a guarded object	Detects the presence of the offender near a protected asset (safes equipped with a shock sensor)

Source: (Police, 2017), (Ivanka, 2010), (Lukas, 2011), (TZB-info, 2017)

By means of a suitable combination of mechanical barrier systems and electronic barrier systems, it is possible to create so-called multi-stage protection enabling to reach increased overall performance of safety elements. In addition to the above mentioned systems, organizational administrative procedures and measures have been applied with the aim to define the rules and permissions to persons, material and information when moving both inside and outside the protected object. These are directives for entering and leaving an object, asset handling, security system operation, key use regime, object security guard service, etc. The last object security system is physical guarding provided by persons who ensure the safety of protected assets by their presence in the building. The main purpose of physical guarding is to promote efficiency of other types of protection in order to detect and detain the intruder to the object. Physical security guard security is also carried out by members of the ACR.

Methods used

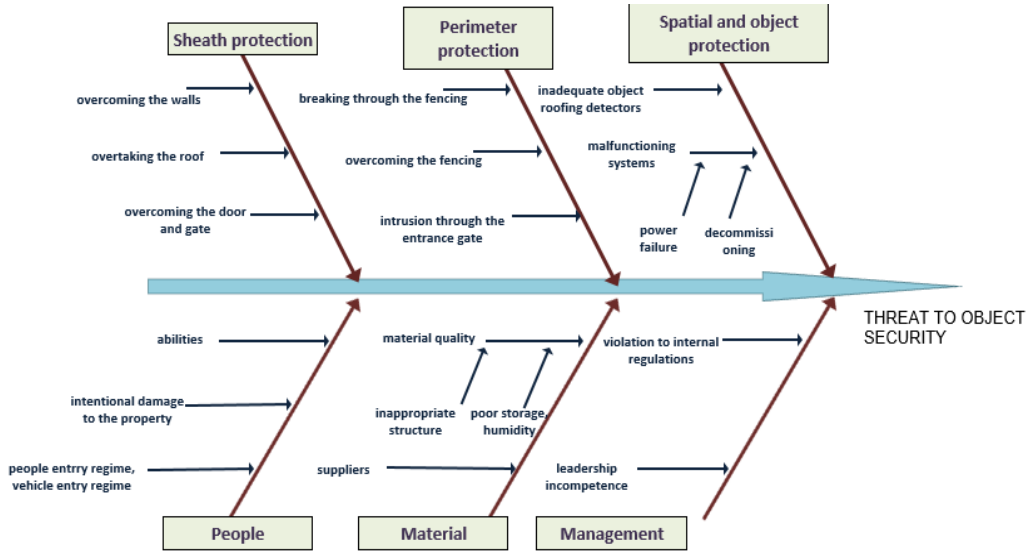
The following methods were used in the paper, namely the Iskihawa diagram for defining areas and causes related to security of critical infrastructure object, brainstorming method when searching for the ideas for determining the areas and causes of reducing security of the object, and a checklist for identifying potential threat, implementing the measures and checking them.

The Ishikawa diagram was designed to identify areas that could lead to a security reduction of a critical infrastructure object. This is a method for risk modelling developed by Professor Kaoru Ishikawa in 1960. Sometimes the method is called a fishbone diagram for its design. The basic idea of the diagram is the fact that each problem has its cause or a combination of different causes. It provides a systematic description of possible causes of a predefined problem and clearly and structurally identifies the most likely causes that may cause the problem (Your own way, 2017). The diagram is especially used for analysing and obtaining information about cause-effect relationships.

In addition to the information from scientific resources and exercises carried out (links), brainstorming method was used to compile the diagram. Brainstorming was performed in a group of four people who were suggesting areas and causes. At first, main areas (categories) leading to reducing the safety of the building were identified and subsequently possible causes were suggested for these areas. Brainstorming method is the idea search method. The principle of it is creative thinking of team members with the aim to create and clarify the list of ideas, problems and controversial issues. Subsequently, an evaluation of the ideas is made, in which each member expresses his or her own opinions on individual issues and develops them in detail. In the case of this research no idea was criticized or contradicted by other members and all ideas were recorded. In conclusion, ideas were recapitulated and scrutinised with the aim of their detailed clarification.

The Check List Analysis (CLA) was another method used. CLA is a simple technique that uses a list of items, steps or tasks to verify the accuracy or completeness of the procedure. CLA is often a basis of various sophisticated methods in the area of safety and risk. Analysis using the checklist is based on the practice and knowledge of the researched area. Checklist is created so that the manager, under the conditions of the ACR, the commander uses it to check the correctness and completeness of his or her actions or checked item status. The result can either be recorded as yes/no answers or more check options can be assigned to the checklist, e.g. almost meets the requirements, further check is needed, etc. CLA can be used as a preventive method as well as a method of retrospective investigation into the cause of a problem. It can verify the status of a device or the completeness of steps (ManagementMania, 2017). Checklists can be subdivided into sub-chapters according to risk sources (SBUSBS, 2017). Their structure can range from a simple list to a complex form that allows including different relative importance of the parameter (weight) within the set file. Checklists can arrange items by groups of homogeneous tasks, or items can be placed throughout the checklist in random order (Rick, 2017). The advantage of using the checklist for threat identification is its easy use for less experienced workers. The disadvantage of the checklist is the fact that it provokes tendency to mechanical approach without considering other possible alternatives and contexts. Checklists are also limited by authors‘ experience. It is therefore important that they are created by experts with experience, expertise and knowledge in the related fields (Ostrom, 2012).

Discussion



Application of the Ishikawa diagram while providing object security

Defining the consequence, i.e. the security of the object, was carried out clearly and briefly. Subsequently, the main areas of possible causes leading to the threat to the security were identified. Factors which were necessary to be taken into account comprised: material, management, people, facilities, and environment, in accordance with the basic ways of providing protection of the building, overcoming of the sheath, perimeter, spatial and object protection were determined as other areas.

The main areas that may lead to the threat to the safety of the critical infrastructure object are shown in Figure 1. Each area further breaks down into the main and secondary causes. These are the following areas and causes:

a) Sheath protection - overcoming the walls (poor technical condition, breaking through), overtaking the windows and grilles (breakage of door filling, damage to grilles), overtaking the roof (poor condition of the roofing), overcoming the door and gate (unlocking, force opening, smash in and inappropriate security lock),
b) Perimeter protection - breaking through the fencing (cutting through, breaking through), overcoming the fencing (crossing over due to the absence of concertina wire, going under it due to the absence of underground obstacles), intrusion through the entrance gate (absence of barrier, absence of security locks),
c) Spatial and object protection - inadequate object roofing detectors (low number, poor location, poor selection of detectors), malfunctioning systems (power failure, absence of generator, decommissioning, improper handling),
d) People - abilities (time of work, qualifications, male/female, physical condition, tiredness, skill), intentional damage to the property (cooperation with the intruder, theft of the property, sabotage), people entry regime, vehicle entry regime (insufficient entry check, employee negligence), identification elements (theft, loss, inappropriate manipulation),
e) Material - suppliers (inaccessibility of protective material, damage to packaging during handling), material quality (inappropriate structure, poor storage, humidity, dustiness, temperature),
f) Management – leadership incompetence (inadequate training, negligence, under-funding of preventive measures), violation to internal regulations (employee indifference, ingestion of alcoholic drinks in the workplace, granting unauthorized entry to a person into the building, deactivation of Alarm Security and Emergency Systems (ASES).

Figure 1 shows only the areas and the main causes. For clarity, only selected secondary causes in the

area of spatial and object protection and area of people are plotted.

Figure 1: Ishikawa diagram of causes leading to the threat to object security, author

Checklist design proposal for providing object security

By analyzing the causes, the team determined that the greatest effect on the result, i.e. the safety of the object, have three areas, namely the area people and overcoming the perimeter and sheath protection. Other areas should not be underestimated either; therefore the activities of the commander during object protection are also directed to these areas. It is imperative that all commanders have set up partial security aims and activities resulting from them. For this purpose, checklists structured into three parts, namely planning area, measures implementation area and review area were created.

When creating the questions of the checklist, it is necessary to stem from the risks that can threaten the object. The set of questions is open and it is appropriate to update it regularly and to supplement it by other questions, resulting from the views of experts. This provides more detailed elaboration of the questions and obtaining more specific answers.

Examples of questions for the first area, i.e. the planning area, cover questions 1-9 and focus on the implementation of preventive measures aiming at reducing the risk of object security violation. Subsequently, questions for the second implementation area were proposed, which was further subdivided into the area of resistance assessment, availability of materials needed for object protection and activities enhancing increase in resilience. This area is represented by examples of questions numbered 10-38. Questions focus on adopting necessary measures and supporting mechanisms for effective implementation. Measures should encourage participation and synergy of all soldiers and should also promote efficient communication to provide security of the facility. The aim is to minimize the risk. If possible, the risk should be eliminated. If this is not possible, it is desirable to be minimized by implementation of the activities and subsequent check-ups that form the third area, i.e. questions numbered 39-45. Proposed checklist questions are shown in Table 2.

Table 2: Checklist proposal

No.	1. Planning	YES	NO
1	Is the crisis preparedness plan available?		
2	Is an emergency plan of the object available?		
3	Is a fire plan of the object available?		
4	Is there a security check of people entering the building?		
5	Is the object perimeter monitored?		
6	Is the building equipped by an electronic security system?		
7	Are there any mechanical traps that trigger an alarm fitted?		
8	Is there a connection between different buildings?		
9	Are there slowing down retarders on the access roads?		
	2. Measures implementation	**YES**	**NO**
	a) Resistance of the object (guardhouse)		
10	Is the guardhouse (check point release) strong enough?		
11	Are places to build firing positions known?		
12	Is the guardhouse placed in a flame-proof area?		
13	Is the guardhouse well away from the fencing?		
14	Does the guardhouse have enough wall strength and adequate window size?		
15	Does the guardhouse have an emergency exit?		
	b) Material for providing security		
16	Are materials to increase resistance (sandbags, tires, barrels) available?		
17	Are nets as a protection against flying objects available?		
18	Are camouflage nets available to protect important sites?		
19	Is concertina wire available?		
20	Is material (sand, gravel, stones) for the construction of protective elements available?		
21	Are engineer tools available?		
22	Are emergency ammunition stockpiles available at firing sites?		
	c) Activities to enhance resistance		
23	Are there sandbags, tires, barrels distributed at firing sites?		
24	Are camouflage nets distributed at important sites?		
25	Are nets installed against thrown explosives and inflammables?		
26	Are emergency exits built?		
27	Are critical places of the object secured?		
28	Are there warning boards depicting the security perimeter distributed?		
29	Has any damage to the fencing been detected?		
30	Are the trees near the fencing, i.e. in the protected zone?		
31	Is it necessary to cut down trees and self-seeded trees located near the fencing?		
32	Is connection provided between the sites?		
33	Is concertina wire distributed in places where direct observation cannot be done?		
34	Are sandbags placed around the windows?		
35	Has the entrance been modified to ensure its protection?		
36	Have the firing sites been created?		
37	Has there been a shelter built inside the building to protect live power, ammunition and food?

Critical infrastructure component should evaluate security provision, primarily on the basis of legislative requirements. In the case of a critical infrastructure body, it is required to have a crisis preparedness plan of the critical infrastructure body elaborated which requirements and method of processing are stated in Government Regulation No. 462/2000 Coll. Crisis Preparedness Plan consists of basis, operational and auxiliary parts. It contains a description of potential threats and measures that should guarantee protection are set in it. The operational part of the plan provides an overview of the measures, the action plan, the internal security provision, regime measures, material and technical security arrangements, etc. Checklist proposal was designed as a tool for the commander when checking the implemented measures. Checklist monitors the measures, estimates the efficiency of the security system and deals with the constructions, raw materials, people, procedures and behaviour of individuals. The objective of monitoring is to find inadequate or insufficient measures and to identify the causes and consequences for security management. The critical infrastructure body should continuously review and improve the security management system, it should be built on the experience gained during exercises and subsequently it should apply corrective measures.

Conclusion

This paper deals with protection of the objects of critical, respectively defence infrastructure. The aim was to propose a procedure and measures to provide object security. Technical, physical and combined methods of securing the selected object and tasks of the ACR, in particular Active Reserve Units in protection of the selected objects were discussed.

In addition to the objects important for the defence of the state, the so-called objects threatened by the possible attack are also defined on the territory of the Czech Republic. These are objects that can be attacked under a state of emergency or state of war. Such objects include, for example, facilities providing services in areas of critical infrastructure such as power plants and electricity and gas distribution grids. The ACR is involved in the tasks of protecting the critical and defence infrastructure objects through members of Active Reserve Units. Active Reserve Units are predestined for implementation of security, for which they are materially equipped and their practical knowledge is practiced during military exercises.

Protection of the object is carried out not only by physical guard, but also by technical means and regime measures. The article describes basic ways of protecting the object security. Using the Ishikawa diagram, main areas of possible causes that can lead to the object security violation, namely the area of overcoming the perimeter and sheath protection and human factor have been defined. The measures proposal was therefore directed mainly towards the areas mentioned. However, even the area of management, material used and sheath and perimeter protection cannot be underestimated, so these areas were also taken into account when designing a checklist.

Checklist issues are based on the risks that may threaten the object. Proposed set of questions is open and can be supplemented according to the needs by further questions depending on the experience and knowledge of the commanders. In general, the degree of security is determined depending on the degree of risk of the protected object, value of the protected asset and capability of the intruders given by their knowledge, skills and technical equipment. It is important that a necessary number of soldiers carrying out activities leading to increase the object security were available if there is an increased risk

of disruption to such an object. To protect the facility, documentation is processed in compliance with the regulations which include measures to protect the site, persons and objects of protected interest from threats to facility safety. At the same time, it is necessary to assess the state of the site security by technical means, i.e. camera systems as well as electronic security systems.

Abstract

This study contributes to a better understanding of how individuals belonging to different occupational communities negotiate pressures for stability and change during cross-boundary exchanges. We describe micro-dynamics of boundary work enacted by two communities of organizational scholars and management practitioners that come together and interact during a one-year executive master's program. By looking at how scholars and practitioners negotiated multiple pressures for stability and change (i.e., conformity with or deviance from the knowledge frames of their occupational communities of reference) we identify a set of resourceful strategies called *provisional relations* and discuss a series of implications for the literature on boundary spanning. Specifically, we propose a social interactionist perspective on change that addresses issues such as occupational interdependencies, mechanisms for coping with multiple simultaneous occupational exchanges, hybrid systems of expertise, and continuous transformation.

Keywords: occupational communities, executive education, provisional relations, interaction strategies, expertise, knowledge exchange, academics, practitioners.

Introduction

Since the late '80s, an increasing number of studies have investigated how members of different communities of practice manage to engage in significant exchanges despite intercommunity differences (Bechky, 2003a, 2003b, Carlile, 2002, 2004, Lave and Wenger, 1991, Brown & Duguid, 1991, Van Maanen & Barley, 1984). The basic assumption is that individuals make sense of events from within the context of their unique work cultures (Kunda, 2006, Martin, 1992, Van Maanen & Barley, 1984). In particular, not only do they acquire the value, norms, practices, artifacts and idioms of the occupational community to which they participate, but they also carry the community's imprinting in all the exchanges in which they take part (Bechky, 2003a, Brown & Duguid, 1991, Orr, 1990). This equals to saying that members of two institutionalized occupational communities that engage in social exchanges are likely to employ different sets of knowledge, make use of different repertoires of practices and routines to handle common tasks, putting in use different patterns of communication drawing on distinct cultural and symbolical tools. However, according to cross-boundary literature, differences do not constitute obstacles to exchanges *per se,* because they can become object of negotiation. Each community is organized around a core structure that is repository of unique, well-guarded characteristics and around a periphery where less exclusive characteristics can be translated to people outside the community, such as members of other communities, lay public or amateurs (Lave & Wenger, 1991, Van Maanen & Barley, 1984). The

more exchanges relate to core-expertise, the higher their costs (Barley & Kunda, 2001, Carlile, 2002, Dougherty, 1992). It results that negotiation is more likely to occur at the periphery, in partially overlapping boundaries arrays (Carlile, 2002, Bechky, 2003, Yanow, 2004), called also peripheral participation areas (Lave & Wenger, 1990), liminal spaces (Howard-Grenville et al., 2011, Bechky, 2006a), or trading zones (Kellogg et al., 2006). Boundary objects constitute one way to govern these exchanges. A boundary object is a work artifact which is both plastic enough to adapt to the local constraints of each group, and yet resilient enough to maintain a common identity across occupational groups (Star & Griesemer, 1989). CT scanners, 3D prints, CAD systems, machine drawings and prototypes constitute examples of boundary objects (Bechky 2003a, Bertolotti et al., 2004, Boland et al., 2007; Carlile 2002, Nicolini et al., 2012). Other studies point out to the importance of brokers that facilitate knowledge exchanges among experts, reinterpreting meanings in ways that are acceptable to all involved parties (Hargadon & Bechky 2006, Pawlowski & Robey 2004).

However, studies show that members of different occupational communities that are called to negotiate expertise issues within boundary settings may become caught between the need to remain coherent with their communities of practice and the need to change in order to successfully exchange knowledge with outsiders (Bechky, 2003a, Carlile 2002, 2004, Carton & Ungureanu, 2017, Howard-Grenville et al., 2011, Kellogg et al., 2006). Studies suggest that over time individuals make efforts to construct frames that allow them to deal with new requests coming from outsiders, yet without growing too distant from the knowledge repositories they have access to as insiders of a community of practice (Brown & Duguid, 2001). Yet, some contributions also show that constantly oscillating between reinforcing community-specific knowledge and adopting it to meet requirements coming from the outside may lead to significant changes at the institutional level, such as, for instance, how a knowledge community is perceived with respect to others and how it defines its occupational jurisdiction (see Barley, 1986, 1990, Carton & Ungureanu, 2017). However, in many cases boundaries between different professional, occupational or organizational communities are blurred, and hardly can they be identified as separated fields of culture and practice (see Kellogg et al., 2006, Orlikowski, 2000). For instance, members of a given community often hold, simultaneously, memberships in different communities of practice. At the same time, members of the same occupational communities may have different positions inside a community, according to the relations that they build with outsiders (Osterlund & Carlile, 2003). It is thus interesting to understand to which extent assumptions of intra-community homogeneity and inter-community heterogeneity hold in such situations, and how they are conceptualized by individuals that are tied together in heterogeneous loosely coupled networks and with what consequences on change-stability strategies (Bruns, 2013, Edmondson & Nembhard, 2009, Osterlund & Carlile, 2003). For instance, how are systems of expertise created and maintained in conditions of overlaps and interdependencies between different practice communities? How do individuals manage to cope with multiple exchange frameworks occurring simultaneously or at short intervals of time? For instance, Carton and Ungureanu (2017) discuss the emergent case of a new professional figure, the scholar-practitioner, showing that the struggles to carve out a distinct professional space in between traditional academia and traditional business practice is not only particularly challenging but ultimately shapes how these professionals see themselves, and what they are willing to do to defend who they are. As they operate on a continuum, with pressures for role segmentation (as determined by the institutional environment) at one end, and pressures for role integration (as driven by their own professional aspirations) at the other, they run across the two worlds with the help of segmentation strategies and integration strategies.

While some have argued that members of different communities of practice enjoy rather stable patterns of interaction such as roles, organizational functions or professional careers within reference communities (Barley, 1986, Bechky, 2003a, Bunderson & Sutcliffe, 2002, Sole & Edmondson 2002), others have shown that cross-boundary exchanges are often marked by volatility, high speed, uncertainty, and rapid change, leaving thus more space for pluralism (Kellogg et al., 2006, Majchrzak et al., 2012). For instance, Faraj and Xiao's (2006) study of coordination in emergency medical procedures shows how easy it can be for different experts to suspend occupational boundaries when required to do so. The authors examine

how anesthetists, operating practitioners and recovery nurses work together in a medical trauma center - a fast-paced setting where building shared understandings is too costly in terms of time and effort, showing the centrality of the ability to temporarily suspend disciplinary boundaries and improvise. Similarly, Ungureanu and Bertolotti (2016) suggest that suspending boundaries is a trial and error process, in which members of the two communities start off with the procedures they are most familiar with and if these do not work, they try out new procedures which require an increasing degree of empathy and creativity. It is thus important to understand how more or less stable conditions of exchange shape cross-boundary relations. Most studies have been concerned either with how occupational communities create a sense of belongingness that enables them to distinguish from other occupational communities or with how they manage to share knowledge across boundaries. As a consequence, the resourcefulness of work communities in defending occupational jurisdictions has been documented just as much as their ability to move, reshape and even tear apart pre-defined boundaries to accommodate interactions with other communities (see Bechky, 2003b, Boland & Tenkasi, 1995, Hansen, 1999, Okhuysen & Eisenhardt, 2002). However, the passage from costly knowledge exchanges to interaction outcomes such as appropriating terminologies, assimilating knowledge, configuring artifacts or aligning interests and intentions (Carlile, 2004) appears abrupt and underspecified. This way, we often do not get a sense of how the two aspects interplay to constitute boundary work. As a consequence, the potential conflicts or contradicting interests that may go side by side with knowledge sharing remain difficult to grasp (Osterlund & Carlile, 2005). Specifically, it is not clear what happens between members of different occupational communities once the interaction commences that enables them to go from the almost impossibility of understanding each other to the concreteness of doing things together. At the same time, it is unclear how occupational communities manage to maintain distinctiveness once they establish common backgrounds with other communities. Understanding how individuals draw on occupational membership, expertise and public acknowledgement to engage in cross-boundary exchanges can provide an integrative framework for these questions.

Three considerations can contribute to an integrative perspective. First, to see occupational membership and expertise as homogeneous within and heterogeneous in between allows for parsimonious explanations about success and failure in intercommunity exchanges but it also precludes a fine-grained understanding of how workers with multiple memberships and hybrid knowledge systems actually manage to either communicate despite differences or maintain distinctiveness despite a common background (Ungureanu & Bertolotti, 2016). Second, boundary work should thus include the intentions of individuals that engage in knowledge exchanges and the particularities of the exchange context itself. For instance, how do individuals make sense of the different systems of social knowledge and expertise they come across with? When are they likely to draw on their knowledge repertoires and when will they combine different systems of expertise in new ways in order to meet exchange requirements? Importantly, how do we conceptualize boundaries under such complex and multi-layered conditions?

Research Context and Methods

The paper brings examples from a study of two experienced communities of management academics and business practitioners that came together during a one-year executive program and interacted about how to manage technological innovation, each from an expert standpoint. We have chosen an extreme case to study the interaction mechanisms that regulate exchanges between two communities of practice that are said to be as homogeneous and connected within as they are heterogeneous and disconnected in between. For instance, it is widely acclaimed that there is a wide gap between organization science and business practice, since academics and practitioners belong to different worlds and operate with different bodies of expertise between which exchanges are often difficult, costly, even impossible to achieve. Particularly, the gap between theoretical and practical expertise is sought to encourage self-referentiality, hamper functional exchanges, and lead to a preoccupying incommunicability between academics and practitioners (Baldridge et al., 2004, Hambrick, 1994, Starkey & Madan, 2002). By studying a mundane

context in which academics and practitioners did actually have the chance to interrelate, we were able to take a fine-grained look at their interaction strategies. In particular, we were less worried about witnessing a successful or unsuccessful case of collaboration, than we were interested in studying academics and practitioners inter-subjectively, as they became aware and struggled to make sense of each other. Additionally, studying academics and practitioners when occasionally called to interact provided information also about those times or situations in which they were not called to do so. We thus focused on what the informants developed together in classroom but also on who they were outside the classroom, in their day-to-day worlds (Howard-Grenville et al., 2011, Weber & Dacin, 2011). Specifically, we tried to pay attention to the groups and communities they identified with, to how they attributed -or refused to attribute- specific types of knowledge systems to each membership and to how these were used in classroom interaction, as they tried to make sense of each other over time. By unfolding such micro-patterns of interaction we hope to advance the literature on how cross-boundary collaboration is initiated, maintained, negotiated, and transformed, but also to generate a better understanding of how we distinguish between the core expertise –or professional jurisdictions- of members of different communities of practice, in general, and between those of organization scholars and management practitioners, in particular. We collected our data through 225 hours of participant observation in the classroom and 70 in depth, face-to-face semi-structured interviews with academics and practitioners. In addition, we had full access to documents produced during the executive program. The material collected was coded following a grounded theory approach (Strauss & Corbin, 1998).

Findings

Instead of a single gap between two distinct communities of practice, the study points to the existence of manifold cross-community gaps and tangles that academics and practitioners draw upon each time they are called to interact. We show that when they are required to come together, members of separate and self-referential communities manage to speak to each other in mutually intelligible, socially acceptable ways. Even though they initially lack the common ground for sharing knowledge effectively and the common tools to avoid conflicts and misunderstandings, they are able to enact a series of sophisticated strategies, here called provisional relations, through which they build temporary and malleable bridges to their exchange partners. This study shows that this occurs because each exchange is latently supported by myriads of exchanges in which members take part in other contexts. Specifically, scholars and managers participate in multiple social relations and hold multiple memberships as part of their day-to-day lives. Classroom exchanges between academics and practitioners were not isolated dyads. Instead, each exchange was immersed in constellations of relations that implied the peripheral involvement of many other actors. During the program, business school staff, program coordinators, tutors, organizers, consultants, management gurus and public figures came in and out of the executive classroom. Although their level of inclusion varied -not all actors were involved all the time, nor was their involvement uniform throughout -they all occupied specific places in the local relational networks. All actors co-produced management labels and ideas, enacted their own practices, and had their own vision about managing technological innovation. Through their presence, each actor had an orientation towards the trajectories of the other actors, brokering between self, interaction partners and the other actors in the business school context. However, they were not necessarily those who brokered the exchanges between academics and practitioners. Instead, academics and practitioners had to manage themselves the multiple exchanges in the program (in situ), but in order to do so, they constantly drew on exchanges they were involved in outside the classroom (ex-situ). For instance, in support of classroom interaction, both academics and practitioners mentioned their experience as researchers and managers, as teachers and students, as bosses and subordinates, as colleagues, friends, parents, citizens, learners and doers. Research sites, company offices, laboratories, scholarly journals, peer reviewers, faculty, students, co-workers and bosses were time after time symbolically brought in as to mediate classroom discussions.

In other words, managers and scholars managed to interact by drawing malleably and creatively on ex-situ exchanges, according to purposes at hand. From this perspective, even exchanges that were liminal, isolated or occasional often interpenetrated other social exchanges, becoming relational constellations - relations which draw on broader systems of relations. Exchanges were generative and transformational precisely because actors combined in situ and ex-situ elements. Yet this creative process was neither linear nor straightforward because of the multiplicity of roles and heterogeneity of the implied commitments. When they first stepped into the classroom, for instance, academics and practitioners had little knowledge of each other. Although they were supposed to collaborate, there were no rules concerning how collaboration would occur. Both academics and practitioners had to come up with strategies for building a common ground for communication, and these were based on approximations, inferences and trials and errors. For instance, actors presented themselves in ways suitable to whomever they were talking to, and they made stereotypical inferences about who they were talking to in ways acceptable to themselves. As the interactions unfolded, however, both the self-definitions and the stereotypes were challenged and revised to incorporate new elements. Participants refused predetermined labels and invited each other to explore contextualized descriptions. Over time, the task of dealing with multiple invitations and resistances increased classroom involvement but also increased conflict and tension. Although commitments inside and outside the classroom were often different, actors were nevertheless able to sustain all of them in their interactions and without trade-offs, by enacting sophisticated interrelation strategies that we labeled provisional relations. In particular, in order to nurture in situ classroom interaction, academics and practitioners temporarily dis-involved themselves ex-situ. As they moved towards ex-situ situations again, they became re-involved and selectively incorporated in situ fragments (see figure 1). For instance, when faced with misunderstandings, conflicts, resistance and challenges, academics and practitioners avoided relational breakdowns by giving the impression they understood each other as if they were part of the same occupational community (i.e., promoting involvement from the inside). They did so by expanding their knowledge and practices into the meaning worlds of their interlocutors in myriads of temporary, partial and ephemeral ways. An evocative metaphor would be that of stepping into each other's shoes, but only halfway: while one foot tries on new pairs of shoes, the other one systematically returns to base, as in a dance that balances alternations. This metaphor is well exemplified in an academic's description of the dynamics characterizing his relationship with program participants. When actors wanted to take a discussion to a new level, they had to get involved in the reactions and invitations of those with whom they were conversing. This required empathic rephrasing –summarizing what the interlocutor had said using her standpoint- and perspective taking – trying to take on the discourse from where the other had left it. For instance, as they struggled to show each other their willingness to connect, academics and practitioners adopted imitation strategies: they made use of each other's distinctions and conceptual categories, took up similar voice tones and even used similar speech cadencies.

Due to the constant dance between involvements, dis-involvements and re-involvements exchanges in the classroom were dynamic, generative and transformational: academics and practitioners explored each other's worlds and together built a series of scenarios but without tying themselves irremediably to any of them. Interestingly, while playing with provisional self-extensions, actors almost managed to switch roles. Academics passed from theorizing to practicing, and practitioners engaged in broad theorizing activities under academic supervision. These findings were surprising because they indicated that theoretical and practical expertise were not characteristics that exclusively defined the jurisdictions of the two communities, but could be transformed and manipulated, appropriated or dis-involved according to the situation and purposes at hand. In other words, theories of practices were objects of exchange that were constituted as systems of provisional relations that drew on broader systems of relationships. For instance, sometimes academics and practitioners spoke to each other, other times they seemed to address an invisible listener such as a judge or an alter-ego. Even more frequently they seemed to address their own colleagues and co-workers who were not physically present, as if they were continuing conversations initiated elsewhere, in their own occupational realms. Despite some differences between temporarily switching perspectives and aligning them sequentially, all scripts implied trials and errors that enabled

actors to cast blame and take responsibilities, to act and react spontaneously, but without remaining in the same position long enough to solidify any particular relation.

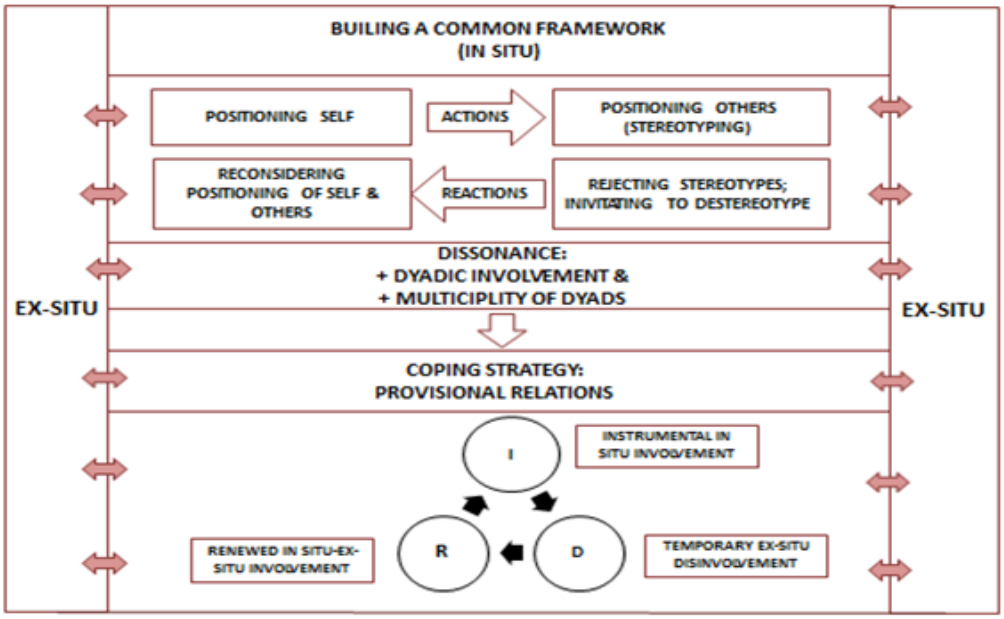

Fig.1: Mechanisms of multiple inter-community exchanges. Provisional relations

Implications and contributions to literature

The study problematizes the idea that different occupational communities have exclusive systems of expertise. By discussing the role that provisional exchanges and relational constellations play in the interaction of experts from different communities of practice, the study stresses the importance of seeing boundary work as relational rather than structural, expertise as socially entangled rather than community-specific, and exchanges as fluid, fast-paced, generative and constantly becoming instead of given. At the same time, social dynamics such as conflicts, dissonance and misunderstandings, or elements of complexity such as multiplicity and heterogeneity are treated symmetrically with respect to concepts which have received more attention in the cross-boundary literature, such as stability, homogeneity and knowledge sharing (Kellogg et al., 2006, Majchrzak et al., 2012). Generally, multiplicity, fragmentation and heterogeneity have been considered problematic for cross-community exchanges because they hinder knowledge flows, obstruct collaborations, slow down change and enhance local power mechanisms. However, this study points out that heterogeneous exchanges that become tied in relational constellations are 'windows for opportunity' (Tyre & Orlikowsky, 1994), through which transformation occurs. Thus different interests, knowledge and practices, are not necessarily what keeps different communities apart; they are 'inter-esse' (Latour, 1987), the junction points lying in between them. Just like the communities enacting them, exchanges have no beginning or end, and no definitive manifestation. Instead, they are always in the middle, between things, inter-being or 'inter-mezzo'. As such, conglomerates of management and managerial concepts, technologies, theories, rituals and practices are in a constant flux that traverses managerial and scholarly communities (Carton & Mouricou, 2017). However, a knowledge society is not simply a society of more experts and more technological gadgets and more specialist interpretations. It is a society permeated with interlocking knowledge cultures where one of the most challenging goals is to understand how interlocking processes occur (Knorr-Cetina, 1999). Our study describes the process by which actors plug and play when engaged in interoccupational exchanges (Faraj

& Xiao, 2006, Ungureanu & Bertolotti, 2006) that is, how they develop the ability to understand others' point of view, anticipate reactions, intuit preferences, and make assumptions about others' expectations and turn these into sources of personal advantage.

Abstract
Advanced agricultural production currently depends on factors such as soil quality, agricultural works, the quantity of water available to plants during cultivation (either from natural rainfall or irrigation), farming treatments applied, yearly temperature regime and others. A particularly important element is the seed material used by farmers, which may be responsible for the quantity and quality of the agricultural production, for the food security of the region and, in some cases, for the safety and health of the population. The article carried out an assessment of the national production of certified seeds, analysing and interpreting the areas assigned for this activity and the production obtained at the county level during the period 2014-2017. The assessment of the concentration of the seed market in Romania, by calculating the GS Index, revealed high values of the indicator and a high degree of concentration of the market. The research has led to interesting results on the development of this segment of the agricultural product market, which can be useful to farmers and the national business environment.

Keywords: agriculture, certified seeds, concentration of the market, Gini Struck Index, Romania

Introduction

Obtaining certified seeds represents the basis for modern agriculture. The availability, access and use of quality seeds of adaptable crops are essential elements for increasing the agricultural productivity, ensuring the food security and improving the farmers' source of income (Bishaw, Niane and Gan, 2007). In many countries, seed production and trade are important elements in rural employment, generating important sources of income for farmers (Organization for Economic Cooperation and Development, OECD, 2012). Investments in competitive agriculture, increased productivity and high yields can be optimized by giving farmers access to high-quality seed for the agricultural crops. The quality of the seed material is one of the main factors that can affect the plant production potential. The quality of certified seeds used as a basis for the consumer production is given by the key attributes of the basic varieties (genetic quality, physical and physiological characteristics, health status), by the environmental conditions in which crops are developed, the agricultural production practices, or even by the storage conditions. Maintaining high seed quality is essential because the variety must meet the expectations of farmers and consumers. Seed growers should be aware of the technical requirements and regulations needed to develop a crop intended to obtain certified seeds and ensure that all operations are carried out strictly in accordance with specific and timely regulations. The limited choice of improved seed varieties, the lack of sufficient seed quantity, mechanization problems, and high seed production costs are some of the main constraints that hinder the development of an efficient and effective seed production industry (Bishaw, Niane, and Gan, 2007).

Materials and methods

The information on certified agricultural areas, the production of seeds and seedlings obtained and the number of producers authorised in Romania in the last 4 years were selected from the database of the

National Inspection for Seed Quality INCS, an authorised national institution in the field, subordinated to the Direction General for Control and Inspections of the Ministry of Agriculture and Rural Development - MARD. For local statistics in this domain, we have used the county databases of the Territorial Inspectorates for the Quality of Seed and Seedling (ITCSMS). The databases of the International Seed Testing Association (ISTA), the International Association for the Protection of New Varieties of Plants (UPOV), the International Seed Federation ISF have been used for illustrating the international transactions with seeds. The relevant national legislative provisions (normative acts, rules and technical regulations in force) have been consulted from the MARD database. For the international norms we used the Regulations of the Organisation for Economic Co-operation and Development OECD (especially the OECD Seed Schemes), the current regulations of the United Nations Food and Agriculture Organization (FAO), or the European rules available on the European Specialized Site Commission (Food Safety-Plants-Plant reproductive material). Where necessary, data from the literature or from the Romanian profile journals, with appropriate quoting, were selected and used. The data collected were analysed, statistically processed and plotted. In order to analyse the concentration of the seeds market at the national level, the Gini Struck method was applied, with the calculation of the Gini-Struck Index, GSI (formula 1), recommended by Săvoiu, Crăciuneanu and Ţaicu (2010).

$$GSI=\sqrt{\frac{n\sum gi^2-1}{n-1}} \quad (1),$$

where - n represents the number of terms of the series under study,
- gi represents the weight factor of i variety products/producer/certified area, related to the total registered products/producers/area.

Legislative regulations

At the level of the international commerce, the quality of the seed traded is regulated mainly through the OECD Seed Schemes, applicable to the certification of the seed lots (OECD, 2017)

FAO has a series of attributions on the quality of the seeds, assisting a number of countries in developing their national seed strategy and legislation by improving their technical expertise, strengthening their capacities and facilitating the process of formulating and negotiating agricultural policies (FAO, 2017). Thus, the harmonisation of the legislations of the Member States is currently one of the main concerns of the organization, FAO supporting some economic cooperation organizations in developing cooperation and in harmonising public or private regulations on seeds, which currently hinder the international trade. The International Treaty on Plant Genetic Resources for Food and Agriculture, entered into during the Thirty-First Session of the Conference of the Food and Agriculture Organization of the United Nations (November 3, 2001), aims at the conservation and sustainable use of all plant genetic resources for food and agriculture and the fair and equitable sharing of the benefits deriving from the use thereof, in line with the Convention on Biological Diversity for Sustainable Agriculture and Food Safety (FAO, 2001).

At the European level, a particular attention is paid to seed quality standards, the European Commission adopting specific marketing regulations, rules on the conservation of the genetic background and of the variety of plants. According to the review of EU legislation on the marketing of seed and propagating material (SPPM), 12 basic acts are applied in the field, most of them from the 1960s and 1970s. Taking into account the new requirements on food safety, traceability, new technologies and the increased importance of environmental issues or the EU enlargement, the European Commission has proposed modernising the European legislative system and adapting it to the new market-specific requirements (European Commission, 2008). The process included the public consultation (May 2011) and the elaboration of a regulation proposing the rescission and replacement of 12 directives that are no longer adapted to the current needs of the community (the European Parliament and the Council of Europe, 2013).

At the national level, the regulations on the functioning of the seed and propagating material market are elaborated by MADR, the vast majority being harmonised with the European legislation in the field. Since 1999 a series of norms have been elaborated that regulate the organization and functioning of the Inspectorate for Seeds and Seedlings (GD no.716/1999), the authorisation of the genetically modified

plants (MAPDR Order no 237/2006), the registration of the operators (MAPDR Order no.769/2009, MADR Order no.57/2011), the organization of the quality and phytosanitary control on the import and export of seeds and seedlings (MADR Order no.34/2011) or the designation of the authorised representatives for the application of the legislation on the production, processing, control and certification of quality, the marketing of seeds and seedlings, as well as the testing and registration of plant varieties. The complete list of the existing or repealed legislative regulations is presented on the site of the profile institution (National Inspection for Seed Quality, 2017a)

The International background on the seeds and seedlings market

Worldwide, there are a number of international organisations, conventions and treaties that regulate the seed and seedlings market, from access to seed material to the delivery of quality seed to growers. In conjunction, they provide an international framework for regulating the seed and certified seedlings market in order to monitor the interests of both producers and consumers. The most important organizations in the field are the OECD, the International Seed Testing Association (ISTA), the International Association for the Protection of New Varieties of Plants (UPOV), the International Seed Federation ISF, the United Nations Food and Agriculture Organization (FAO) and the European Commission.

OECD has set up the OECD Seed Schemes, updated on a regular basis, which are recognised and applied worldwide for the certification of seed traded on the international market. The objective of the OECD Schemes for Certification of Seed varieties is to encourage the constant use of high quality seed ascertained for the participating countries. The schemes authorise the use of labels and certificates for seeds produced and processed for international trade, complying with the agreed principles (OECD, 2017).

ISTA was established in 1924, becoming a global network of member laboratories in more than 70 countries/distinct economies worldwide. ISTA members work together to achieve " uniformity in global seed quality assessment". ISTA develops internationally recognised standards for seed sampling and testing, accredits laboratories, promotes research, provides international seed certification and training and disseminates knowledge in the field of seed science and technology. The International Certificates for seed tests, issued in accordance with the current ISTA standards, are only available for accredited ISTA laboratories. For non-ISTA members, the certificates can be purchased from the ISTA Secretariat, with restrictions on the number and price of certificates. The ISTA's activity facilitates seed marketing at the national and international level, thus contributing to improving global food security (ISTA, 2017). According to the latest report available on the organization's website, at the end of 2016, 58 organizations were affiliated as associate members (115% more than in the reference year 2008) and 222 laboratory members (nearly 20% more than in 2008). Du Pont Pioneer, Dow Agro Science, Monsanto SAS, Bayer and Hem Zadem are Industry Members (ISTA, 2017b).

UPOV is an intergovernmental organisation based in Geneva (Switzerland), created by the International Convention for the Protection of New Varieties of Plants. The Convention was adopted in Paris in 1961 and revised in 1972, 1978 and 1991. The mission of UPOV is to provide and promote an effective plant variety system in order to encourage the development of new plant varieties, for the benefit of the whole society. In 2016 there were 74 states/organizations affiliated to ISTA (UPOV, 2017). Applicants have at their disposal the Plant Variety Database, the Genie Database and the Plant Variety Protection Data and Statistics (PVP) databases containing the information provided by the competent authorities of 55 Union members and an intergovernmental organisation. In addition, on the organisation's website there is a collection of legislation in force in the field.

ISF, established in 1924, is a non-profit non-governmental organization representing the interests of over 1,000 international seed companies spread throughout the globe. The Seed Statistics database provides information on international seed transactions conducted internationally (ISF, 2017).

Worldwide, international conventions/treaties are applicable at the United Nations Food and Agriculture Organization (FAO), providing the international regulatory framework for seed trade issues, including phytosanitary measures, access to and sharing, as well as use of plant benefits of germplasm.

The European Union focuses on the traditional production, with an increasing interest in agro-food products of certified origin obtained in certain well-defined geographic areas (Stanciu, 2014). The EU regulates the marketing of the reproductive material of plants of the agricultural, plant, forest, fruit, ornamental and vine species, ensuring the compliance with the European criteria for health and quality. The Commission shall establish the rules in cooperation with the national experts of the respective permanent committees. The European legislation applies to important plant and vegetable species for the internal market, focusing on the registration of varieties and planting material, respectively on the certification or inspection of pre-commercial seed lots and propagating material (European Commission, 2017). Seeds from the third countries must meet the equivalence criteria and those states that guarantee that they meet these criteria can be listed as acceptable to export to the European market. Under certain conditions, strictly specified by European organisations, such as reduced seed germination in the domestic production, the European Member States may temporarily market seed lots which do not fully meet the Community criteria. The European database has two sections: Plant variety database, comprising 109 agricultural species, from potatoes to beans and beets, approved at the Community level and Vegetables, which includes 37 vegetable varieties, with many varieties of crop (European Commission, 2017).

The international market

The global exports of seeds reached a global quantity of 3,865,063 tonnes in 2015 and a value of over USD 10 billion (Table 1). Although the import volume exceeded exports by 2,288 tons, the value of the international transactions was positive, with a surplus of USD 352 million.

Table 1. International transactions with seeds (2014-2015)

Seed	2014				2015			
	Exports		Imports		Exports		Imports	
	Quantity (MTo)	Value (USD Mill.)	Quantity (MTo)	Value (USD Mill)	Quantity (MTo)	Value (USD Mill)	Quantity (MTo)	Value (USD Mill.)
Vegetable crops	117,854	3,791	135,869	3,650	15,747	3,630	133,395	3,521
Flower seed	6,084	308	7,341	291	5,181	281	5,702	261
Field crops	3,386,225	7,848	2,992,579	7,213	3,744,135	6,754	3,728,254	6,531
Total	**3,510,163**	**11,947**	**3,135,789**	**11,154**	**3,865,063**	**10,665**	**3,867,351**	**10,313**

Source: the authors, by using ISF Data (2017)

The most important transactions, covering over 96.87% of the total quantities exported in 2015, were recorded for the seeds of the field crops category. Compared to this, the vegetable crops cover only 2.99% of the exports, the difference being covered by the flower seeds.

Compared to 2014, in 2015 there was a decrease in global seed transactions on the international market, both in terms of quantity and value (Figure 1). Thus, 2015 brought a reduction in imports of 141 tons of seed, worth 793 million USD, along with a reduction in exports of 109 tons ($ 352 million), as compared to the previous year. Decreases were recorded in two of the three categories of seeds, the field crops being the only one with a positive evolution in the transactions on the international market.

Figure 1. Global transactions with seeds (2014-2015)
Source: the authors, by using ISF Data (2017)

The ISF statistics used in the presentation of the data include only seed exports worth more than $ 1 million, flower seeds include herbaceous and non-herbaceous plant seeds mainly grown for flowers, field crop seeds include pulse seeds, cereals, industrial crops and fodder crops, vegetable crop seeds include seeds from all vegetable crops and do not include potato and mushroom seeds.
According to the OECD (2012), the quality of the seeds can only be ensured by applying a combination of key technical procedures and regulatory measures (Figure 2).

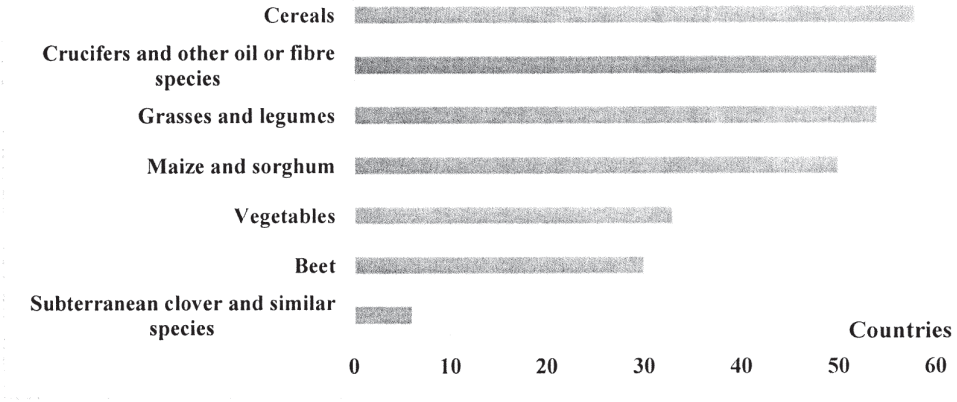

Figure 2. Countries participating in the OECD Seed Schemes (2016)
Source: the authors, using OECD Data (2016)

The quality assurance system which establishes administrative regulations and technical procedures has a supervisory role for the proper functioning and implementation of the program and for the application of regulatory measures to maintain the quality of the seeds produced. At the international level, according to OECD data, Grain Seed Schemes represent the quality assurance system to which most of the OECD member countries have adhered.

The national production of certified seeds
Romania's integration into the EU has also led to an increase in the interest of farmers in buying quality inputs and in a higher demand for certified seeds of qualitatively and qualitatively superior varieties.

Thus, in the last period, the Romanian cultivators have been convinced that the high quality seeds with biological and genetic value, as well as the varietal purity, the high health and germination indices, bring a significant contribution to the increase of the agricultural production. The certified seed preserves the full potential of the crop, has good sanitary quality and increases the agricultural productivity, through a superior germination power and a good adaptation to the cultural conditions in our country, also having an ecologically reduced environmental impact (Agrimedia, 2012).

Depending on the culture, farmers can earn 2-3 times more if they use seed lots than in case of conventional crops. If the farmer can decide each year to cultivate a particular species, depending on the weather conditions of the year in question, the seed company must plan seed production for a minimum of 4-5 years. According to Văduva (2016), in 2016 the largest areas for seed material were used for cereals. In 2007-2012, maize occupied an area of 10-25%, the rest being allocated to the cultivation of straw cereals. On average, using the seeds obtained from the production of a hectare of a batch of grain cereal seeds, 20 hectares of cereals for consumption can be sown. Compared to grain cereals, in the case of maize, the production obtained per hectare of maize hybrid batch can be used to cultivate much larger areas, reaching up to 170 hectares of commercial corn. In the analysed period, the multiplication of oil plant seeds was made on 5-10% of the total area of seed lots. Of these, the multiplication of sunflower was between 33 and 66% of the total oilseed area, and the rape multiplication plots occupied between 5 and 20% of the oleaginous plant multiplication area. For the other cultures, the areas on which multiplication lots were established were marginal (5 or less than 5% of the total).

The seed production in Romania is usually achieved on the basis of a contract between the seed company and the farmers, and the tendency of the international seed marketing companies to be marketed locally. The main counties where the seed is multiplied at the national level are Brăila, Iași and Călărași. The advantages of multiplication in these areas are the farmers' experience regarding seed multiplication technology, the possibility to provide secluded lots, equipping the farmers with specific machines (castration machines), the existence of a functional irrigation system or microclimates suitable for securing the production of seeds.

Since 2012, the Romanian Seed Industry Alliance (AISR), a private professional association, has aimed to promote and support the use of seed certified by farmers in order to increase agricultural production in Romania. AISR has as members 13 prestigious companies in the field of research, improvement, production and marketing of seeds with superior genetics, of which only two are Romanian (United Phosphorus Limited, India, the Porumbeni Institute of Phytosanitary Research, the National Institute of Agricultural Research and Development INCDA Fundulea, RAGT Semences, Procera Agrochemicals Romania, Bayer CropScience AG, Maïsadour Semences) (AISR, 2012). INCDA Fundulea has been an honorary member of the AISR since 2016, which, with the addition of the institute has reached 70% of the national market for certified seeds (*The Agriculture Gazette*, 2016). The National Institute for Agricultural Research and Development Fundulea is the most important agricultural research unit in Romania, with very good results obtained in agricultural research on cereals, technical and fodder plants and the possibility of their valorisation to Romanian farmers.

In Romania, 143 thousand hectares have been cultivated on average for obtaining certified seed in the last 4 years, the agricultural areas for this activity being between a minimum of 129 thousand hectares, registered in 2015, and a maximum of 151.4 thousand hectares in 2014.

The weight of the areas for the seed lots is almost 10% of the total agricultural area, i.e. about 15% of the arable land of the country.

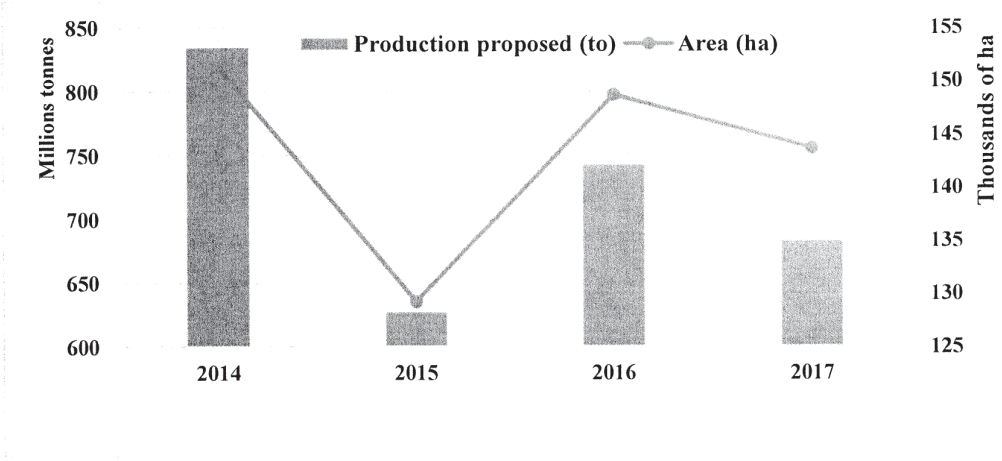

Figure 3. Evolution of certified seed areas and production in Romania
Source: Author, by using INCS data (2017)

Cultivated areas and yields vary from region to region. In 2017, Brăila County, with a weight of 12% of the total area cultivated at the national level and a production of over 94 thousand tons of seeds and seedlings occupies the first national position, followed, at a comfortable distance, by Călăraşi, with 14.8 thousand hectares, respectively Iasi, with 10.6 thousand hectares. On the last positions are the counties of Bistrita, Hunedoara, Caraş Severin, Sălaj and Sibiu, which have not reported certified seed production this year.

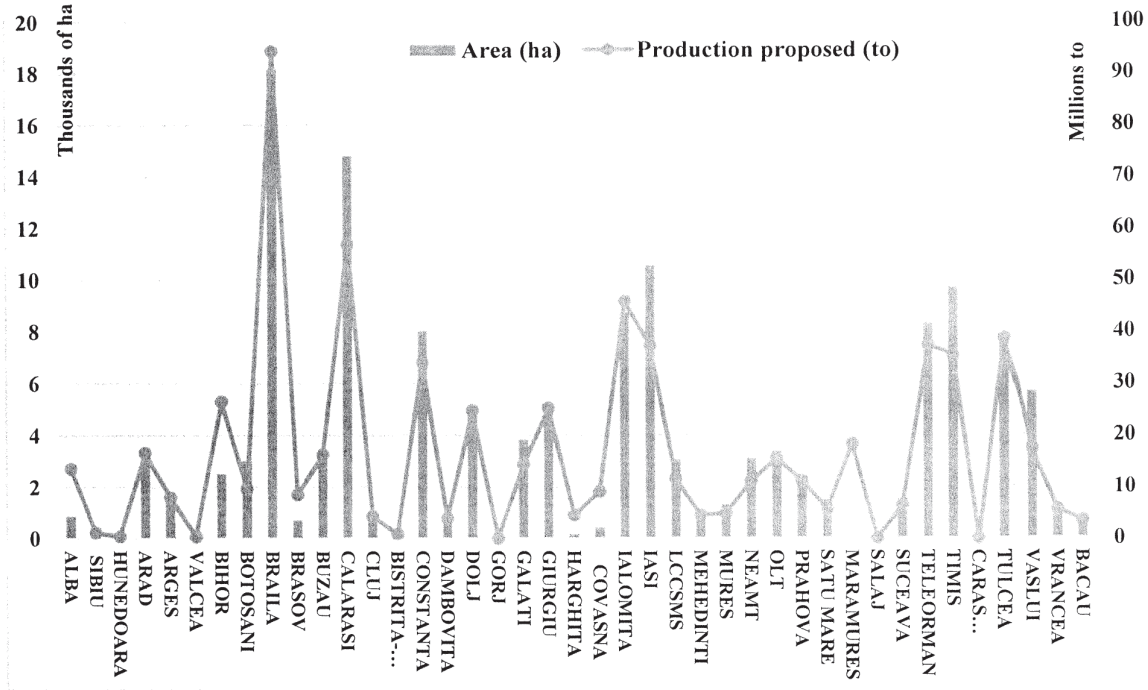

Figure 4. Areas and production of seeds certified in Romania (2017)

Source Author, by using INCS data (2017b)

According to the data presented in Figure 4, it can be noticed that out of the 41 regions analysed, only 6 counties exceeded the limit of 80,000 hectares cultivated to obtain seedlings. There are also significant differences in the average productivity for the hectare. Although the crop species are different, a summary of productivity shows a national average of 4.1 tons seed/hectare. The Alba, Vâlcea and Bihor counties have an average production per hectare of over 10 tons of seed, while most counties are in the range of 3-5 tonnes. For a proper analysis, the production should be differentiated by counties, by plant category, given the different productive characteristics.

Concentration of the seed market in Romania

The data on the cultivated areas and on the production of certified seeds in Romania provided by INCS (2017b) were statistically sorted and processed, with the calculation of the GSI index (Formula 1). The systematization of the data obtained is presented in table 2. The 41 counties of Romania, including Bucharest (n=41) were taken into consideration.

Table 2. GSI Values for the certified areas and for the authorised seed production

Year	**2014**	**2015**	**2016**	**2017**
$\sum g_i^2$ (Areas)	611.798	566.255	583.785	604.071
Valoare GSI	24.735	23.796	24.461	24.577
Market concentration	**High**	**High**	**High**	**High**
$\sum g_i^2$ (Producție)	548.341	525.535	575.216	561.887
Valoare GSI	23.416	22.925	23.983	23.704
Market concentration	**High**	**High**	**High**	**High**

Source: Author, own results obtained by processing INCS data (2017b)

The results obtained for GSI as a result of the research show relatively high values of this indicator and an average degree of concentration of the market. No significant differences were found between the values calculated over the four-year period or between the assessed values (areas or production). The national top of Romania's producing counties shows the existence of several regions with relatively high shares, respectively with quotas higher than 5%, and the national market of certified seeds has a high degree of concentration.

Conclusions

Achieving high production and quality requires the use of seeds with superior genetic characteristics, well-defined and at convenient prices. The research carried out by the authors performed an analysis of the national production of seeds and seedlings in Romania, an assessment of the international market, respectively. The authors have reviewed the main legislative regulations applicable at the international and national level, as well as the bodies with special attributions in the field. Romania, as a Member State of the European Union, has made progress in the harmonisation of national legislation with the Community legislation in the production and marketing of certified seeds. The analysis performed at the level of Romania's regions highlighted the existence of significant differences between the productions of seed lots at the level of the counties.

Applying the Gini Struck Method to analyse the concentration of the national seed and seedling market revealed high GSI index values and a high degree of concentration. Obtaining certified seeds is a cost-effective activity for farmers, although national procedures need to be respected in order to obtain the average level of productivity

The results of the study are useful for business and officials and can provide the basis for more extensive analysis of the seeds market in Romania.

Bratislava et le désert slovaque

Frédéric Delaneuville, PhD., Faculté de management de l'Université Comenius de Bratislava, Slovaquie,
frederic.delaneuville@fmuk.uniba.sk

Résumé

A l'ère de la globalisation, la concurrence entre les territoires ne se limite plus à des rivalités entre Etats-nations à la recherche de puissance pour affirmer leur souveraineté. Les continents, les régions ou les grandes villes européennes prennent part à une compétition pour le développement qui se joue à l'échelle de la planète. Les territoires et les structures démocratiques qui les administrent sont constamment confrontés à des nouvelles contraintes : changements climatiques, crise démographique, migrations de population, ou encore crises globales des finances publiques. Pour faire face à ces enjeux globaux, les collectivités territoriales européennes ont mis en place des stratégies et leurs modes de gouvernance ont parfois été modifiés. C'est le cas pour les grandes villes-capitales des pays du groupe de Višegrad qui ont connu un développement économique nettement supérieur à la moyenne des pays auxquels elles appartiennent. Aujourd'hui, la région de Bratislava est la 6ème région la plus riche d'Europe en termes de PIB par habitant. En revanche, le reste du pays peine à se développer. Les inégalités territoriales se sont creusées et la Slovaquie est devenue en quelques décennies un des pays où les différences de production de richesses entre les régions sont les plus importantes de l'Union européenne.

Mots clés : Bratislava, développement régional, gouvernance, décentralisation

Abstract

In the era of globalization, competition between territories is no longer limited to rivalries between nation-states in search of power to assert their sovereignty. Continents, regions or major cities in Europe are taking part in a development competition that is taking place on a global scale. The territories and the democratic structures that administer them are constantly confronted with new constraints: climate change, demographic crisis, population migrations, global public finance crises. To cope with these global challenges, European local authorities have put in place strategies and their modes of governance have sometimes been modified. This is the case for the major capital cities of the Višegrad Group countries, which have experienced economic development well above the average of the countries to which they belong. Today, the Bratislava region is the 6th richest region in Europe in terms of GDP per capita. On the other hand, the rest of the country is struggling to develop. Territorial inequalities have widened and in a few decades Slovakia has become one of the countries where differences in the production of wealth between regions are the largest in the European Union.

Keywords: Bratislava, regional development, governance, decentralization

Introduction

Le titre provocateur de cet article qui reprend celui d'un ouvrage de Jean-François Gravier « Paris et le désert français [1]» datant de 1947 ne vise bien évidemment aucun jugement de valeurs sur le niveau de développement des régions périphériques slovaques mais il vise à sensibiliser le lecteur sur le niveau inquiétant des inégalités territoriales en Slovaquie. D'ailleurs, cet ouvrage qui est devenu une référence était très critique vis-à-vis de la gestion jacobine des territoires en France. Cet article n'a pas la prétention de se comparer à l'œuvre de l'auteur français qui a inspiré de nombreuses politiques

décentralisatrices mais il vise à analyser les dynamiques qui ont conduit à l'accroissement progressif des inégalités territoriales slovaques. L'approche pluridisciplinaire visera à analyser les mécanismes qui ont permis l'essor rapide de la métropole-capitale de Bratislava et à identifier les facteurs historiques, économiques et politiques qui ont conduit à des écarts de développement si importants avec le reste du pays.

La compréhension du phénomène de métropolisation en Europe centrale ne peut faire l'économie d'une rétrospective historique. Bratislava constitue un exemple particulièrement intéressant. Après la scission de la Tchécoslovaquie en 1992, Bratislava a retrouvé son statut de capitale européenne. Cette ville à l'histoire très riche, également connue sous le nom de Presbourg ou de Pozsony, a traversé les empires et les régimes jusqu'à devenir le centre des efforts d'émancipation de la nation slovaque. La recontextualisation historique et politique du développement de Bratislava permet également de comprendre le fonctionnement de la gouvernance de la capitale de ce jeune État-nation qu'est la République slovaque. Inspiré des modèles dominants d'Europe de l'Ouest, la vague décentralisatrice qui a succédé au centralisme autoritaire a eu des conséquences sur la gouvernance politique de la ville de Bratislava. Ces réformes décentralisatrices, inspirés des pays d'Europe de l'Ouest, ont eu des résultats mitigés en matière de développement territorial.

I. Rétrospective Historique Du Développement De Bratislava

L'analyse du temps long permet de comprendre le processus progressif d'accumulation qui a permis à Bratislava de devenir cette importante région-métropole en Europe centrale.

La première référence écrite à Bratislava, alors connue sous le nom Brezalauspurc, se trouve dans les annales de Salzbourg, où y est décrite une bataille entre les troupes hongroises et bavaroises ayant eu lieu en l'an 907. Suite à leur victoire, les Hongrois occupèrent la partie orientale de la Grande Moravie, qui fut ensuite intégrée au royaume de Hongrie lors de sa création en l'an 1000. Bratislava a changé de nom à de multiples reprises durant son histoire mais fut toujours un centre économique et administratif important. De par sa position géographique aux frontières du royaume de Hongrie, elle fut sujette à de nombreuses attaques de forces ennemies. L'érection de fortifications autour de la ville au 12ème siècle renforcera son importance stratégique. Lors de la conquête de Budapest par l'Empire Ottoman, la noblesse hongroise se réfugie à Bratislava. Elle devient la capitale de la Hongrie en 1536. De 1563 à 1860, onze rois hongrois furent couronnés à Pozsony. Il s'en suivra un processus de magyarisation. Jusqu'en 1919, Pozsony, également connu sous le nom allemand de Presbourg mais aussi sous l'appellation slovaque de Presporok, est alors un lieu de coopération et de conflits entre les élites essentiellement germanophones et magyarophones.

Au lendemain de la Première guerre mondiale, la Tchécoslovaquie est créée et Bratislava devient de fait la capitale de la partie slovaque. Le conseil municipal adopte une délibération, le 27 mars 1919, qui donnera à Bratislava son nom actuel qui combine à la fois les mots slovaques « brat » qui signifie « frère » et « slàva » qui signifie « gloire ». Cette délibération fut entérinée par un décret le 4 octobre 1919 mais cette nouvelle appellation ne fut pas sans susciter de contestation de la part des pays voisins et les noms de Presbourg et de Pozsony continuèrent à être utilisés. La ville connaitra durant cette période un processus de « slovaquisation » (modification des noms des rues et monuments, création d'une université en vue de la formation des futures élites…). Le 14 mars 1939, le gouvernement slovaque choisit de devenir un État « indépendant » allié à Adolf Hitler plutôt que de tenter de faire face à l'invasion nazie. C'est la première fois qu'un État slovaque indépendant voit le jour. Il s'en suivra un soulèvement populaire contre les nazis, le bombardement de Bratislava par les troupes américaines et la libération par l'armée rouge le 4 avril 1945. Le 25 février 1948, les communistes assurent le contrôle du gouvernement tchécoslovaque et une nouvelle constitution est proclamée le 9 mai 1948. Cette constitution consacre Prague comme capitale de la Tchécoslovaquie et ne fait référence à Bratislava que comme le siège de l'Assemblée nationale. Dans les années 1960, Bratislava devient le centre de nombreux efforts

d'émancipation de la nation slovaque. En 1968, est signée au Château de Bratislava la Loi constitutionnelle sur la Fédération tchécoslovaque. Le 1er janvier 1969, la CSSR devient une Fédération formée d'une République socialiste tchèque et d'une République socialiste slovaque avec leurs propres Parlement et Gouvernement. L'administration est désormais représentée par des districts (okresy) et les communes (obce) ; Bratislava étant une unité jouissant d'un statut juridique particulier. La Constitution créant la Fédération tchécoslovaque lui reconnaît son statut de capitale de l'État fédéré slovaque. Ce fédéralisme fut maintenu durant la période dite de « normalisation » qui fera suite à la répression par les troupes soviétiques du « Printemps de Prague », durant lequel des responsables politiques slovaques tenteront d'instaurer un « socialisme à visage humain ». Mais ce fédéralisme n'a survécu que d'une manière formelle. « Maintenue dans les textes, la fédéralisation n'était que pure façade, les organes politiques communistes, dirigeant réellement le pays, ne fonctionnant plus selon une organisation fédérale ». « La fédéralisation de l'État était la seule réforme de 1968 qui ait survécu à l'invasion soviétique et à la « normalisation » qui suivit. Mais elle fut vidée de son contenu par la logique centraliste inhérente au système communiste ». Le régime soviétique, méfiant par rapport à toute idée d'auto-administration, n'a donc laissé à Bratislava que très peu de marge de manœuvre politique et toutes les décisions importantes étaient de fait prises à Prague.

Après la chute du Mur de Berlin et la partition de la Tchécoslovaquie, Bratislava a retrouvé son statut de capitale européenne. Si l'on fait abstraction de l'épisode de l'État fasciste durant la Seconde guerre mondiale, c'est la première fois que le peuple slovaque dispose de son propre État. La création récente de cet État-nation a entrainé la recherche de symboles fédérateurs. Avoir une capitale digne de ce nom avec des monuments historiques symbolisant la gloire passée ou la souffrance d'une nation désormais souveraine, contribue à la diffusion d'une mythologie unificatrice qui semble être un des points communs à beaucoup d'États-nations. Bratislava est le centre nerveux de la Slovaquie. Cette ville s'est dotée progressivement de symboles à la hauteur de son statut de capitale européenne comme le château récemment rénové qui domine la ville. Bratislava est une capitale européenne de taille moyenne de par sa population de 424 427 habitants mais elle représente 8 % de la population slovaque[2] mais en réalité il est difficile d'avoir des chiffres précis du fait que beaucoup de personnes résidant ou travaillant reste enregistré comme résidant dans leurs villes d'origines[3].

La globalisation exacerbe la concurrence entre les territoires. Les acteurs économiques préfèrent souvent les localisations métropolitaines car celles-ci offrent des avantages que les villes de taille inférieure ne sont pas en mesure de fournir. L'accès à des réseaux, à des services diversifiés, à une main d'œuvre abondante même dans des domaines spécialisés, permet aux entreprises à la recherche de flexibilité de faire évoluer leurs activités en fonction du contexte. Depuis la chute du mur de Berlin, des réseaux européens qui se sont constitués entre Bratislava et les grandes villes d'Europe ont favorisé son développement. Malgré les incohérences liées à l'insuffisance des mécanismes juridiques et politiques qui permettait au maire d'imposer aux différents arrondissements un développement plus harmonieux de la ville, la capitale slovaque reste très attractive même pour les familles pour lesquelles la localisation métropolitaine résidentielle à Bratislava est souvent liée à l'emploi .Bratislava présente beaucoup d'attrait : marché du travail large et diversifié favorisant la mobilité professionnelle, l'éducation des enfants, activités culturelles, l'emploi des femmes[4], etc… *« Si l'écart entre la rémunération des hommes et des femmes est également importante dans la capitale, le niveau plus élevé des salaires permet également aux femmes d'espérer une retraite plus important que dans le reste du pays*[5] *».* Ainsi beaucoup de slovaques font le choix de s'installer à Bratislava malgré les prix prohibitifs de l'immobilier dont l'inflation est amplifié par les spéculations et l'absence de réel plan de construction de logements qui seraient géré ou régulé par des organismes publics. Ainsi, l'inflation à Bratislava et l'insuffisance de la main d'œuvre a entrainé une augmentation des salaires (le salaire brut moyen dans la région du Bratislava s'élevait à 1377 euro en 2016[6]). Mais ce phénomène n'a pas pour autant entrainer mécaniquement une augmentation aussi significative du pouvoir d'achat du fait que la plus part des produits de consommation et des services sont plus onéreux dans la capitale que dans le reste du pays.

Pourtant, les écarts en termes sont tels qui poussent les jeunes à venir s'installer dans la capitale slovaque malgré la qualité de vie supérieure en province. Ainsi l'écart avec les autres grandes villes et régions slovaques s'est accru de manière très importante ces deux dernières décennies.

II. L'accroissement Constant Des Inégalités Entre Bratislava Et Le Reste Du Pays : La Conséquence De L'importation D'un Mode De Gouvernance Territoriale Inadapté ?

Dans le classement d'Eurostat des régions NUTS2 au regard du PIB par habitant réalisée en 2014, la région de Bratislava était classée en 6ème position avec un PIB par habitant qui représente 186 % de la moyenne de l'UE.

Tableau n° 2		
PIB régionaux par habitant par État membre de l'UE en 2014 en SPA[7]		
	Région	**UE28 = 100**
1	Inner London - West (UK)*	539
2	Luxembourg (LU)*	266
3	Bruxelles-Cap. / Brussel Hfdst. (BE)*	207
4	Hamburg (DE)	206
5	Inner London - East (UK)	204
6	Bratislavský kraj (SK)*	186
7	Oberbayern (DE)	179
8	Île de France (FR)	178
9	Praha (CZ)*	173
10	Stockholm (SE)*	172

En revanche, les trois autres régions slovaques de niveau NUTS 2 ont un PIB par habitant très largement inférieur à la moyenne de l'Union européenne (Slovaquie de l'Ouest 72%, Slovaquie centrale 61%, Slovaquie de l'Est 53%). Le PIB par habitant de la région de Bratislava est donc en moyenne 3,5 fois supérieure à celui de la région de la Slovaquie de l'Est (51 200 euros par habitant en standards de pouvoirs d'achat /14 600 euros/hab.)[8].

Tableau n° 2		
PIB des régions de l'Union européenne,2014, UE 28=100		
Pays	PIB par hab. en SPA	PIB par hab. en SPA
Slovaquie	21 100	77
Bratislavský kraj	51 200	186
Západné Slovensko	19 800	72
Stredné Slovensko	16 700	61
Východné Slovensko	14 600	53

La politique régionale vise à renforcer la convergence économique et sociale et, elle doit être un moteur pour l'emploi et la compétitivité[9]mais cet écart grandissant de production de richesses[10] met en évidence que cette politique européenne est insuffisamment efficace[11]. Le modèle décentralisée de gestion des territoires choisi n'a pas permis de maitriser les différences de développement économique entre les régions et qu'au contraire celles-ci se sont sensiblement accrues depuis les réformes régionalisatrices de 2001.

Les réformes visant à mettre en place la régionalisation après la chute du mur de Berlin avaient pour objectif de mettre en place une gouvernance territoriale moderne correspondant aux standards occidentaux[12]. En adoptant le modèle dominant qui faisait office de référence en matière de gestion des territoires, la Slovaquie démontrait qu'elle agissait de manière adéquate pour atteindre un objectif socialement valorisé. En l'espèce, la nécessité de l'adhésion à l'Union européenne bénéficiait d'un large consensus politique après la chute du mur et elle devint rapidement un des objectifs prioritaires quitte à faire d'énormes sacrifices. Il s´agissait également pour la Slovaquie d'attirer les investisseurs étrangers potentiels[13] qui étaient attirés par le faible cout de sa main d'œuvre qualifiée[14].

Pourtant l'importation de ces solutions nouvelles n'a pas exclu une adaptation, voire une déformation, des principes de ce modèle pour mieux les adapter aux réalités nationales. Au demeurant les réformateurs sont heurtés au phénomène d'inertie institutionnelle[15]. Les sociologues ont démontré que les membres d'une structure ne vont pas immédiatement s'investir dans un processus dont les effets attendus sont inconnus et ils vont préférer perpétuer les pratiques traditionnelles dont ils connaissent les rouages. La volonté de changement qui existait après la chute du mur a permis un remodelage complet des cadres constitutionnels mais dans la pratique les changements se sont inscrits dans la continuité de l'histoire politico-administrative de la Slovaquie.

Les principes de gestion décentralisée des territoires importés de l'Ouest ont été adaptés, voire même déformés, pour venir s'inscrire dans la continuité de l'histoire politico-administratives slovaque empreinte de centralisme. Il est possible de qualifier ce phénomène d'idiosyncrasie: « *Loin, en effet, de se conformer seulement à un modèle extérieur, celui de la mondialisation ou celui de l'Union européenne, chaque pays a pu faire valoir des traditions, des routines institutionnelles, et des groupes d'acteurs plus ou moins bien organisés. C'est à l'aune de leur force que le changement peut être compris, car c'est à partir de ces héritages institutionnels et des acteurs que les nouvelles règles du jeu ont été intégrées ou rejetées*[16] ». Il ne fut pas possible de faire table rase du passé. Les normes dominantes ont été intégrées mais elles ont été réinterprétées en fonction des contextes nationaux. Les nouveaux modèle slovaque de gestion des territoires fut le produit d'un « syncrétisme stratégique[17] ». Les divergences et les incompatibilités des principes de l'Ouest avec les réalités singulières de la Slovaquie, qui avaient été intériorisées, sont réapparues : « *Le ressort initial en est une situation de domination, le colonisateur prétextant de l'infériorité de l'autre et en provoquant l'intériorisation partielle et révoltée chez le colonisé. D'où, chez ce dernier la volonté de retrouver l'estime de soi en combinant deux systèmes de valeurs : l'un indigène, relu à la lumière de la situation nouvelle ; l'autre exogène, emprunté au dominateur. Le discours inédit, les pratiques nouvelles qui en naissent permettent de combattre sur deux fronts : l'édification d'une conscience de groupe et la lutte contre l'étranger*[18] ».

Durant la phase de préadhésion la Slovaquie s'est retrouvée en position de faiblesse vis-à-vis des pays de l'ouest et des institutions européennes. Du fait d'une opinion publique extrêmement favorable à l'adhésion, les élites politiques n'ont pas eu d'autres choix que d'adhérer formellement aux principes et standards occidentaux. Les incompatibilités ont été minimisées. Le désir de souveraineté de la Slovaquie dont l'histoire singulière est marquée par de longues périodes sous la domination de puissances étrangères a été intériorisé, voire dissimulé pour accélérer « le retour vers l'Europe », mais il est réapparu après l'adhésion.

Durant les premières années qui ont suivi la création de collectivités régionales dans les pays du groupe Višegrad, ces structures cohabiteront avec les structures étatiques dans un système dans lequel la répartition des compétences sera floue pendant plusieurs années : *« En Slovaquie la répartition des compétences entre les structures étatiques et les collectivités territoriales nouvellement crées furent peu claires pendant la période qui a précédé l'adhésion. Les limites étaient floues, mais il y avait un espoir que la situation se clarifie dans le futur*[19] *»*. Les bouleversements entrainés par la multiplication des réformes en vue de l'adhésion a créé une réelle instabilité.

Aujourd'hui malgré des compétences, les collectivités territoriales slovaques demeurent souvent très dépendantes de l'Etat central et elles sont incapables de mettre en place les politiques qui permettraient un développement endogène des territoires même si la culture de l'action s'y développe progressivement.

La notion de « path dependence » qui vient des sciences économiques permet d'expliquer certains mécanismes de résistance au changement. Certains économistes partent du constat que même si une solution optimale existe elle n'est pas forcément adoptée par les entreprises ou les institutions. Ainsi l'analyse du maintien du clavier de machine à écrire ou d'ordinateur QWERTY dans le monde anglo-saxon, malgré l'élaboration d'un clavier mieux adapté aux besoins, permet de comprendre certaines difficultés dans la mise en place des changements. Douglass C. North a utilisé cette théorie pour analyser le changement dans les institutions[20]. Il considère que ce phénomène de « dépendance au sentier » tient moins aux technologies elles-mêmes qu'au comportement des individus au sein des institutions. Ces analyses expliquent pourquoi les institutions sont stables et pourquoi elles résistent au changement. La théorie de la dépendance au sentier s'inscrit dans le prolongement du courant d'analyse appelé l'institutionnalisme historique. Ce paradigme théorique nous permet de comprendre pourquoi la diffusion des principes consacrant l'autonomie locale qui a constitué une véritable rupture institutionnelle n'a pas entraîné une révolution des pratiques en matière de gestion des territoires en Slovaquie. La théorie de la dépendance au chemin met en avant des éléments fondamentaux qui vont nous permettre de mieux comprendre ce phénomène de résistance institutionnelle au changement[21].

Les collectivités territoriales, notamment les régions, peinent à s'affirmer face aux autorités centrales slovaques. Il est possible d'expliquer ces difficultés par différents facteurs (besoin national d'affirmation de la souveraineté, tradition centralisatrice, faiblesse de la société civile et de la démocratie locale…) dont certains d'ailleurs ne sont pas spécifiques à la Slovaquie. Les contraintes liées à la nécessité d'un retour vers l'Europe ont accéléré les réformes décentralisatrices, mais elles ont également accru leur caractère formel. Il fallait intégrer les standards occidentaux dans la législation interne pour s'inscrire dans la modernité, ou plutôt dans la postmodernité, quitte à faire fi de la nécessaire consolidation de l'unité nationale. Pourtant dans ce jeune État unitaire est marqué par des traumatismes historiques, la Slovaquie avait besoin d'affirmer la souveraineté qu'elle venait de retrouver.

Avec la préparation de l'adhésion à l'Union européenne, ils durent rapidement préparer des délégations de compétences aux niveaux supra et infranational. Ainsi la volonté d'affirmation de la souveraineté fut intériorisée et les difficultés à conduire le changement dans un délai si court furent minimisées durant les négociations. Les choix en matière de gestion des territoires ont été réalisés sous la contrainte d'une décentralisation rapide, car le modèle centralisé de type soviétique semble contrevenir assez largement aux standards de l'Ouest. La dimension coercitive et brutale des réformes dans les années 90 peut permettre d'expliquer les stratégies de résistance au changement. Elle explique ce que l'on pourrait appeler les « contre-réformes » qui visent à un « retour de l'État » afin d'adapter les principes européens de la bonne gouvernance territoriale aux réalités complexes et singulières de la Slovaquie.

La mise en place d'un nouveau cadre institutionnel n'a pas permis de se débarrasser totalement des oripeaux culturels hérités du régime communiste. Dans les années 90, les élus locaux et les agents des collectivités territoriales nouvellement créées étaient dépourvus d'une véritable culture de l'action locale et ils se sont ainsi positionnés dans une position d'attente et d'infériorité par rapport au pouvoir central.

Les agents des collectivités territoriales était tous d'anciens fonctionnaires d'Etat et ils ont emporté avec eux leurs cultures administratives : *« Parfois, le personnel administratif n'a même pas dû déménager et le changement de l'enseigne apposé sur le bâtiment dans lequel ils travaillaient n'a pas pour autant fait immédiatement disparaître leurs habitudes de travail*[22] *».* Pourtant, la qualité de la formation des élites locales et le caractère méritocratique du recrutement sont des éléments indispensables à l'affirmation des collectivités territoriales.

En Slovaquie, l'aspect gestion des ressources humaines a probablement été négligé au profit d'une approche trop juridique de la transition. L'adoption de règles juridiques formelles en matière d'autonomie locale par les pays du groupe Višegrad n'a pas entraîné une modification immédiate des pratiques. La surreprésentation des juristes dans les instances européennes et leur rôle clé durant le processus d'adhésion est peut-être un facteur explicatif de cette négligence. Pourtant la gestion et la formation des ressources humaines sont des éléments clés dans tout processus de changement.

Au niveau des communes, le rapide transfert de compétences à des personnels peu formés a entraîné de nombreux dysfonctionnements. Par exemple, dans le contexte où la démocratie locale était encore balbutiante, la délégation de gestion des plans d'aménagement du territoire aux communes ne disposant pas de compétences en matière d'urbanisme a entraîné des incohérences dans les plans de développement urbain de certaines villes. Parfois, il a même mené à des abus. Le pouvoir de délivrer des permis de construire a pu permettre des enrichissements personnels au détriment de l'intérêt général comme l'illustre parfois le caractère anarchique de certaines constructions dans des zones surpeuplées, affectées par la pollution ou par des problèmes de stationnement. En l'absence d'une véritable démocratie locale, le pari du transfert de l'exercice de certaines compétences aux communes s'avérait risqué. Dans ces pays où le communisme a conduit les citoyens les plus téméraires à se résigner à accepter l'inacceptable, les citoyens ont perdu confiance dans l'action collective et ils favorisent des stratégies individuelles. Ainsi la création de collectivités territoriales en l'absence de démocratie locale a pu avoir des effets pervers. La perte de confiance dans la notion d'intérêt général qui fût pervertie par le régime et l'absence de la culture de la contestation collective ont laissé une marge de manœuvre importante pour les logiques individuelles et partisanes. Elles l'ont souvent emporté sur les intérêts locaux ou régionaux qui sont des notions encore balbutiantes.

Conclusion

Les disparités territoriales en Slovaquie sont parmi les plus importantes de l'Union européenne et l'actuelle politique régionale semble incapable d'endiguer ce phénomène. A la chute du mur de Berlin, les arguments européens en faveur d'un modèle décentralisé avaient facilement trouvé de nouveaux adeptes en Slovaquie car il y existait une volonté de rejet total des pratiques du régime communiste. Il ne semblait ne pas y avoir d'autre alternative que l'importation des modèles de l'Europe de l'Ouest perçue comme indispensable pour une adhésion rapide à l'Union européenne. Pourtant, le bilan de l'importation de ce modèle décentralisé semble mitigé. La rapidité de la mise en place des reformes territoriales a également accrue leur caractère purement formel. Certes d'un point de vue institutionnel et juridique, elles furent un succès. La reconnaissance des autonomies régionales et locales s'est matérialisée en par la mise en place d'institutions démocratiques chargées de représenter les intérêts locaux, par la reconnaissance explicite du principe de libre administration et par de nombreux transferts de compétences. Cette modification rapide du mode de gestion des territoires s'explique par la pression des institutions européennes, mais également par un phénomène de transfert de politique mais les mesures drastiques mises en place ne furent pas sans conséquences pour certaines populations notamment pour les personnes les moins mobiles vivant dans les régions éloignées de la capitale. Ainsi, il est possible de s'interroger sur la pertinence du choix politique de la décentralisation dans un pays où le communisme autoritaire avait détruit la culture politique de l'action locale et régionale. Les réformes mises en place n'ont pas entraîné une évolution immédiate de la culture administrative dans ce pays empreint de centralisme. Au demeurant, si les compétences des collectivités territoriales sont aujourd'hui

potentiellement très étendues, le manque de moyens dont elles disposent pour les exercer créé une dépendance de fait vis-à-vis de l'Etat. Un modèle « déconcentré » de gestion des territoires aurait pu être une solution plus appropriée à l'histoire politico-administrative de ce petit pays d'Europe centrale.

Le modèle actuel de gouvernance territoriale en Slovaquie semble inefficace d'un point de vue de la maitrise des inégalités territoriales. Le clivage qui oppose Bratislava aux zones périphériques s'est cristallisé après une longue de recomposition économique du territoire slovaque qui a créée à des zones de fragilité économique et sociale dans ce que l'on pourrait appeler « l'autre Slovaquie ». Avant la chute du mur de Berlin, il existait une logique d'intégration économique de la classe ouvrière qui vivait dans les zones industrielles. Aujourd'hui, la cartographie électorale montre les craintes des populations des territoires périphériques. Le vote extrémiste pour des partis comme celui de M. Marian Kotlebla « Naše Slovensko » est porté par l'anxiété des plus modestes qui vivent dans des territoires enclavés et qui ont peur des flux migratoires qui pourtant n'arriveront jamais dans leurs villes ou villages. Il est ainsi possible de mettre en corrélation l'accroissement des inégalités territoriales avec le retour en forces de la rhétorique populiste des partis nationalistes qui joue sur ces frustrations. Une partie grandissante de la population est ainsi sensible aux discours souverainistes visant à un retour d'Etat centralisé garant de la justice sociale.

Aujourd'hui, l'idéologie dominante est celle de la métropolisation et de la redynamisation des aires urbaines et il est difficile de revendiquer la promotion d'un autre modèle qui permettrait un développement économique spécifique pour les territoires ruraux. Celui-ci ne serait pas forcement incompatible avec la mise en place d'un mode de gouvernance spécifique pour la capitale slovaque. Les écarts de revenu sont d'une telle ampleur qu'ils engendrent inévitablement une certaine brutalité dans les rapports sociaux qui risque de s'accroitre avec la progression de ces clivages territoriaux. Ils permettent d'expliquer le ressentiment que peuvent avoir les citoyens des territoires enclavés vis-à-vis des résidents de la capitale. Des mécanismes de régulation, nationaux ou européens, permettant de financer des programmes favorisant le développement harmonieux des territoires en Slovaquie semblent indispensables car le modèle actuel de gouvernance territorial ne permet pas d'endiguer l'accroissement des inégalités qui risquent d'atteindre un niveau critique si des politiques volontaristes à la hauteur de l'ampleur de ce phénomène ne sont pas mises en œuvre.

Classification of the Russian Arctic zone territories according to the level of small business development

Elena V. Rytova, associate professor, Peter the Great St. Petersburg Polytechnic University, St. Petersburg, Russian Federation, E-mail: lery@list.ru

Svetlana S. Gutman, associate professor, Peter the Great St. Petersburg Polytechnic University, St. Petersburg, Russian Federation, e-mail: svelanka@mail.ru

Irina M. Zaychenko, associate professor, Peter the Great St. Petersburg Polytechnic University, St. Petersburg, Russian Federation, e-mail: imz.fem.spbpu@mail.ru

Abstract

This research was devoted to small business development in Arctic Zone of Russia. Structure of Russian Arctic territories was defined; statistical data were collected and analyzed in legislative borders of Arctic Zone territories. Arctic territories were classified by means of cluster analysis on small business development. Multidimensional classification revealed three clusters with different level of small business development. Marked clusters, which include arctic territories with similar level of small business, could be used for further factor analysis. Factor analysis helps to identify causes of differences in territorial small business development.

Keywords: Small business, cluster analysis, sustainable development, Arctic zone of Russia.

Introduction

The Russian Arctic is a unique region in terms of its economic-geographical location, resource wealth and natural conditions. The issues of social and economic development of the Russian Arctic zone is an extremely urgent task. However, according to the Decree of the President of the Russian Federation of May 2, 2014 (Decree of the President of the Russian Federation). The Arctic zone includes only some part of territory of regions having access to the Arctic Ocean. The definition of the boundaries of the Arctic zone in the Decree significantly complicates the analysis of socio-economic conditions and the creation of special measures for the development of this zone. Despite the high costs of doing business in the Arctic, the development of small businesses will contribute to the sustainable development of the region.

One of the components of the region's sustainable development strategy is the "Society and Market". Achieving the corresponding strategic goals is impossible without the development of small business. One of the most important functions in the implementation of the region's sustainable development strategy is the social function of small business: new jobs will help break the long-term downward trend in the population in the Russian North; local people can be provided with new competitive jobs; it is possible to use the initiative and creative potential of the population, especially the indigenous people; small business can become the basis of municipal budgets. In addition, it is possible to use an innovative small business initiative.

Literature Review

There are different forms of stimulating small business in the world practice (http://giac.ru/analytics/):
1. Tax relief, special tax regimes, preferential taxation of enterprises; (Japan) (Matsubara, Y. (2013), Japan's Policy on Small and Medium Enterprises (SMEs) and Micro Enterprises. Small and Medium Enterprise Agency, Ministry of Economy, Trade and Industry).

2. Grants by regional authorities, (in some countries up to 50%) for the opening of enterprises or the development of innovative products; (Sweden, Germany) (Tillmar, M. (2007), The German Mittelstand as a model for success. Federal Ministry for Economic Affairs and Energy).
3. Direct financing (subsidies, soft loans), targeted subsidies to support enterprises of priority industries or enterprises in depressed areas (also up to 50% of costs); (France, USA and other countries) (Nugent , N. (2017), Doh, S. and Kim, B. (2014), Haltiwanger, J., Jarmin, R.S., and Miranda, J. (2013)).
4. Deferment of payment, reduction or exemption of state duties for individual entrepreneurs and innovative small enterprises; (Austria, Germany, USA, Japan, etc.) (Naudé, W. (2013).
5. Creation of a special infrastruture for small businesses support; (Austria, Germany, USA, Japan, Austria, etc.) (Mc Namara A., Murro P. and O'Donohoe S. (2017), Ponomarenko, T.V. et al (2016).
6. Creation of venture funds for financing of innovative small enterprises; (England, Germany, France, Switzerland, the Netherlands) (Colombo, M.G et al (2016), Bertoni, F. et al (2015)).
7. Free of charge conducting office work, free services of lawyers; (Netherlands, Germany) (Brunswicker, S. and Vanhaverbeke, W. (2015).
8. State programs on insurance, risk reduction and reimbursement of risk losses; (Japan) (Japan's Policy on Small and Medium Enterprises (SMEs) and Micro Enterprises. Small and Medium Enterprise Agency, Ministry of Economy, Trade and Industry).
9. Legislative protection of intellectual property and copyrights; (All developed countries) (Henrekson, M. and Sanandaji, T. (2014).
10. Programs for the search for and attraction of foreign specialists for domestic innovative enterprises (Japan, USA, Australia) (Ates A. et al. (2013).
Recently, the approach to the development of regions based on clusters has become popular in Russia (Rudskaia, I.A et al (2017).
The analysis of the statistical data of Arctic Zone of the Russian Federation showed a low degree of providing of the majority of the Arctic territories by small enterprises, so it is necessary to make recommendations for the development of small business in future in this area.

Methodology

To make recommendations for the development of small business in the Arctic Zone of Russian Federation, it is necessary to classify Arctic territories according to the present level of development of small business. Classification was carried out on the basis of multidimensional statistical analysis (cluster analysis) [19]. The implementation of this method includes the following tasks (Dubnov, P.YU. (2004), Nasledov, A. (2013)):
1. Choice of clustering algorithm.
2. Selecting the clustering method.
3. Choosing a method for calculating the distance between objects.
4. Determination of the number of clusters.
The division of the territories of the Arctic Russia into groups depending on the level of development of small business was carried out according to the following system of indicators (classification characteristics) (Dzh, O. et al (1989)):
• Number of small enterprises in the territory, unit.
• Population of the territory, thousand people.
• Budget expenditures for supporting small enterprises, thousand rubles.
• Support costs for small business per capita, rubles.
The choice of the method of clustering depends on the structure of the examining clusters. The intergroup communication method was used in this investigation, because it minimizes the intracluster variance of objects that makes it possible to form the most homogeneous clusters. The clusters formation procedure has an iterative character and is repeated until the clusters characteristics obtained become in accord with the possibility of a logical interpretation of the grouping results.

Results

The "Hierarchical cluster analysis" was used to determine the optimal number of clusters and the results obtained in the "Coefficients" column of the "Agglomeration steps" table were analyzed. The resulting coefficients reflect the distance between two clusters, calculated on the basis of the selected distance

measure (Euclidean distance). The optimal number of clusters in our study was "3", equal to the difference in the number of observations (14) and the step number (11), after which the coefficient increases abruptly.
For visual analysis of the obtained distribution of regions, scatterplots were constructed, as well as histograms and dendrograms. The dendrogram shown in Fig. 1, reflects the distribution of the territories of the Arctic Zone of the Russian Federation in clusters, depending on the estimation of level of small business development (The official website of Rosstat).

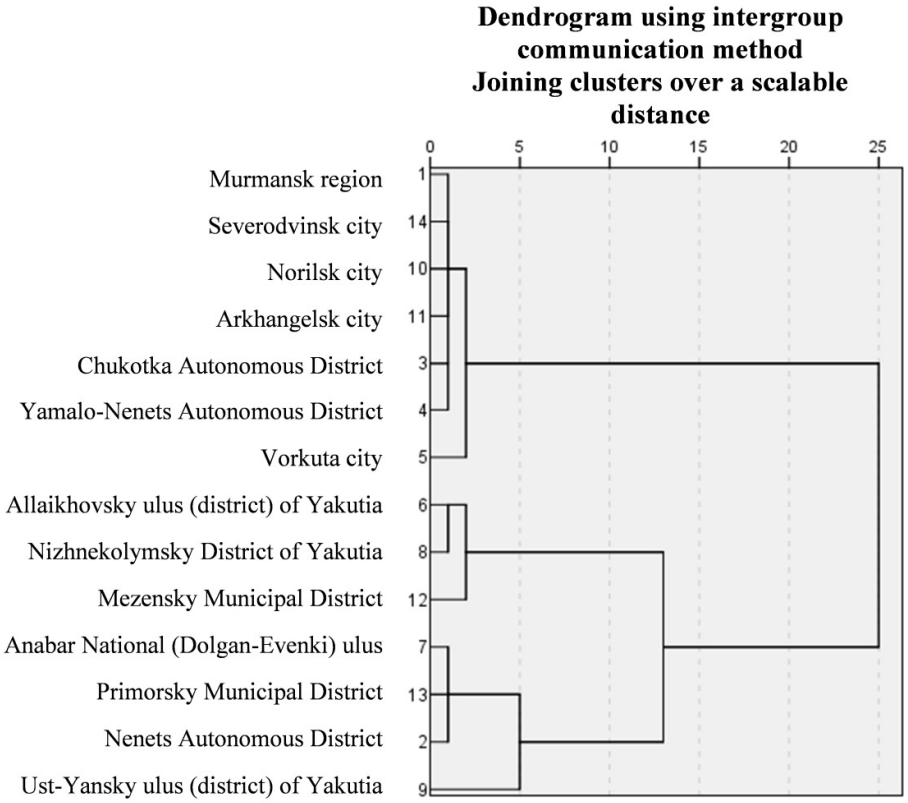

Fig. 1: Dendrogram

The multidimensional classification revealed 3 clusters with different levels of small business development (Table 1):

1 cluster. Murmansk Region, Chukotka Autonomous District, Yamalo-Nenets Autonomous District, Vorkuta City, Norilsk city, Arkhangelsk city and Severodvinsk city. This cluster - includes the most populated and economically and socially developed territories of the Arctic Zone of Russian Federation. The number of small enterprises in these territories is quite large for the northern territories.

2 cluster. Nenets Autonomous District, Anabar National (Dolgano-Evenki) Ulus (District) of Yakutia, Ust-Yansky Ulus (District) of Yakutia, Primorsky Municipal District of the Arkhangelsk Region. This cluster includes north territories of the Russian Federation with medium level of development of small business. These areas are significantly less populated. However, these territories are located in close proximity to the regional centers represented in the first cluster, which is affects positively their development in general and the small business development there.
3 cluster. Allaikhovsky ulus (district) of Yakutia, Nizhnekolymsky district, Mezensky municipal district - these territories are poorly populated, also are situated far from regional centers, have a low level of

budgetary provision. As a result they have the extremely poor level of development of small business, and quantity of small enterprises is much less than in average for north of Russia.

Table 1: Clusters

Surveillance	7 clusters	6 clusters	5 clusters	4 clusters	3 clusters	2 clusters
1: Murmansk region	1	1	1	1	1	1
2: Nenets Autonomous District	2	2	2	2	2	2
3: Chukotka Autonomous District	1	1	1	1	1	1
4: Yamalo-Nenets Autonomous District	1	1	1	1	1	1
5: Vorkuta city	3	3	1	1	1	1
6: Allaikhovsky ulus (district) of Yakutia	4	4	3	3	3	2
7: Anabar National (Dolgan-Evenki) ulus (district) of Yakutia	5	2	2	2	2	2
8: Nizhnekolymsky District of Yakutia	4	4	3	3	3	2
9: Ust-Yansky ulus (district) of Yakutia	6	5	4	4	2	2
10: Norilsk city	1	1	1	1	1	1
11: Arkhangelsk city	1	1	1	1	1	1
12: Mezensky Municipal District	7	6	5	3	3	2
13: Primorsky Municipal District of the Arkhangelsk Region	5	2	2	2	2	2
14: Severodvinsk city	1	1	1	1	1	1

Because of the lack of statistical information, three areas of the Arctic one of Russian Federation were excluded from the analysis: the Bulunsky Ulus (District) of Yakutia, the Taimyr Dolgano-Nenets Municipal District and the Turukhansk District of the Krasnoyarsk Krai. It can be assumed that the territories of the Bulunsky Ulus and the Taimyrsky District by their conditions are close to the third cluster, whereas for the Turukhansk District will probable fall into second cluster.

The proposed classification, i.e. the identified clusters, includes the territories of the Arctic Zone of Russia with a similar level of development of small business, and it gives opportunities for factor analysis of the reasons caused this differentiation of level of small business development in the identified clusters. The methodology of factor analysis of the level of development of small business clusters of the Arctic Zone of Russia provides for the identification of factors that have had a significant impact on the level of development of small business. Indicators, whose impact on the level of development of small business is most significant, will need to be taken into account first of all when developing and implementing a strategy for sustainable development of regions of the Russian Federation. Obviously, the influence of factors can be either positive or negative. Accordingly, it is necessary to split many factors into two groups: those that have a positive and negative impact on the level of development of small business in the Russian Federation.

Conclusion

As factors that affect the current level of small business development, we will consider the factors presented in Table 2 in the framework of the selected clusters.

Table 2: Factors of small business development in the Arctic Zone of Russian Federation

+	-
1. increasing the possibility of obtaining loans, reducing interest rates on loans; 1. simplifying the search for and attracting qualified personnel from other regions; 2. improvement of transport infrastructure; 3. availability of state support programs for small business; 4. presence of the richest natural resources and unique cultural environment.	2. high energy tariffs; 3. high rates for transportation; 4. decrease in purchasing power due to outflow of population and decline in living standards; 5. tax burden; 6. growth in rental rates; 7. lack of availability of office, retail, production space; 8. difficult access to new technologies.

Effectiveness of Public Spending on Tertiary Education: The Case of the Slovak Republic

Ľudomír Šlahor, Comenius University in Bratislava, Faculty of Management, Bratislava, Slovak Republic, ludomir.slahor@fm.uniba.sk

Mária Barteková, Comenius University in Bratislava, Faculty of Management, Bratislava, Slovak Republic, maria.bartekova@fm.uniba.sk

Janka Gasperová, Comenius University in Bratislava, Faculty of Management, Bratislava, Slovak Republic, gasperova.j@gmail.com

Abstract

Public tertiary education systems in the EU Member States are studied by comparing used resources with education and research outputs and outcomes. Efficiency in public tertiary education systems across EU countries and OECD countries is assessed with data analysis. Moreover, evidence is provided that public spending on tertiary education is more effective in what concerns labour productivity growth and employability when it is coupled with efficiency. The aim of this paper is to show the effectiveness of public spending on tertiary education in Slovakia. The paper contains only the partial results of our research. Delivering efficiency and value for money is an absolute operational priority. All stakeholders rightly expect efficient use of resources and in the current investment to maintain excellence mainly in tertiary education will often come through such efficiencies.

Keywords: effectiveness, public spending, tertiary education, Slovakia.

Introduction

In an economy in which public needs require public goods with high values, in the context in which the state's financial resources do not increase at a high rate, there appears a gap that mostly leads to insufficient resources necessary in performing all the economic activities and implicitly the education activities.

As a matter of fact, tertiary education is one of the driving forces of growth. In this paper we show that there is a link between labour and total factor productivity and spending in education. However, this link is only effective when spending is efficient. In other words, what really matters is that money and resources are spent in such a way that one gets outputs that in a broader layer are related to productivity and growth. Moreover, we present evidence of a link between tertiary education efficiency and employability. Unemployment rates among tertiary education graduates are lower than those among individuals that attained secondary level only, and this difference increases when public tertiary education is more efficient.

This paper examines the effectiveness of public spending on tertiary education in the Slovak Republic.

1 Slovakian Tertiary Education System

In the academic year 2015/2016, higher education in the Slovak Republic is provided by 20 public, 13 private and 3 state higher education institutions (HEI). State HEIs are founded and managed by the Ministry of Defence of the Slovak Republic, the Ministry of the Interior of the Slovak Republic and the Ministry of Health of the Slovak Republic, and funded as government-subsidised organisations. Their financing is in sole responsibility of these ministries. Public HEIs are largely financed through subsidies from the state budget provided by the Ministry of Education of the Slovak Republic based on a subsidy agreement. The state has no liability for obligations of public HEIs. Private HEIs are only entitled to a state budget subsidy to ensure the statutory entitlement of their students to social security (provision of social scholarships). Private HEIs may also apply for subsidies for study programmes, institutional

research or their development, but have no legal entitlement to them; from 2002 until the present, a subsidy for the provision of accredited study programmes was granted to private HEIs in one year only.

Figure 1 illustrates the number of academic staff in HE institutions relative to the total country population. This number varies between 7.1 (Austria) and 1.37 (Luxembourg). Romania has the second lowest figure available for an EU country. Notice that Austria and Denmark have a very high number of academics per 1000 inhabitants whereas the UK is below average (Eurostat, 2017$_a$).

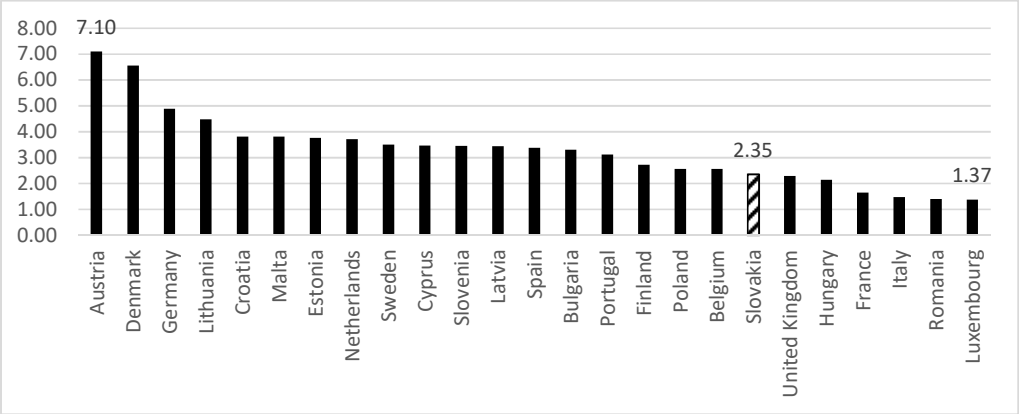

Figure 1: Number of Academic staff per 1000 inhabitants in 2015

Source: Eurostat

The average of the PISA indicator is 493. The highest scores are attained by Estonia, Finland, Slovenia, the UK, and the Netherlands. Austria have a slightly above average score and the lowest scores belong to Slovakia, Hungary and Italy (OECD, 2015). The PISA scores attained by Slovak students are decreasing.

This indicator presents a measure of expenditure on educational institutions relative to a nation's wealth. National wealth is estimated based on GDP, and expenditure on education includes spending by governments, enterprises, and individual students and their families. Investment in educational institutions as a percentage of GDP is one of the lowest across the EU: for tertiary education, the public

spending on educational institutions is only 0.97% of GDP, compared with an EU 28 average of 1.27%. This represents a decrease from the level in 2004 (1.09%) (Eurostat, 2017$_c$).

The rest of the paper is structured as follows. Section two presents the methodology used, section three provides results and discussion related to our research, while the last section concludes the paper.

2 Methodology

Our analysis consists of the following steps:

- To find appropriate data about the tertiary education in the Slovak Republic,
- To define indicators, on which the analyses will carried out,
- To evaluate results of our analyses.

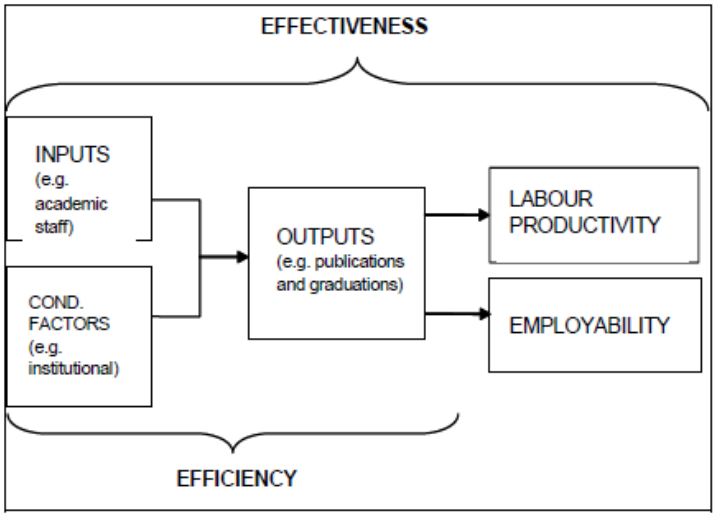

Figure 4 : The Model of Public Spending Effectiveness

Source: European Commission

While efficiency derives from a relationship between inputs and outputs, and refers essentially to the extent to which outputs are attained while minimising production costs, effectiveness refers to the connection between inputs, outputs and more general, second layer type objectives or outcomes. According to this preferred definition, while outputs from tertiary education are graduated students, outcomes to which these outputs in principle concur may be higher productivity, employability, innovation, or economic growth (European Commission, 2010).

We set just four main indicators for analysing effectiveness of public spending on the Slovakian tertiary education:

- Number of academic staff per 1000 inhabitants as the input indicator,
- Expenditure on tertiary education as percentage of GDP as the institutional condition,
- Public costs and benefits of education on attaining tertiary education as output indicator,
- Unemployment rates by educational attainment as the employability indicator.

Investing time and money in education is an investment in human capital. For adults, the labour market outcomes of higher educational attainment outweigh the initial cost of pursuing education. Better chances of employment and higher earnings are strong incentives for adults to invest in education and postpone labour market activities.

We used abbreviation "m" for missing data (e.g. break in time series) in the tables.

3 Results and Discussion

Educational institutions in EU countries spend an average of 1.7 times more per tertiary student than per primary student, but spending patterns vary widely, mainly because education policies vary more at the tertiary level.

In the Slovak Republic, expenditure per student increased between 2005 and 2013, by 69%. In the case of the Slovak Republic, this is partially explained by a steep decline (about 25%) in the number of students enrolled at primary, secondary and post-secondary non-tertiary level, the strongest decline in enrolment across EU countries. However, the lowest expenditures per student in 2013 belonged to Latvia, Lithuania, Poland, Hungary and the Slovak Republic (OECD, 2013).

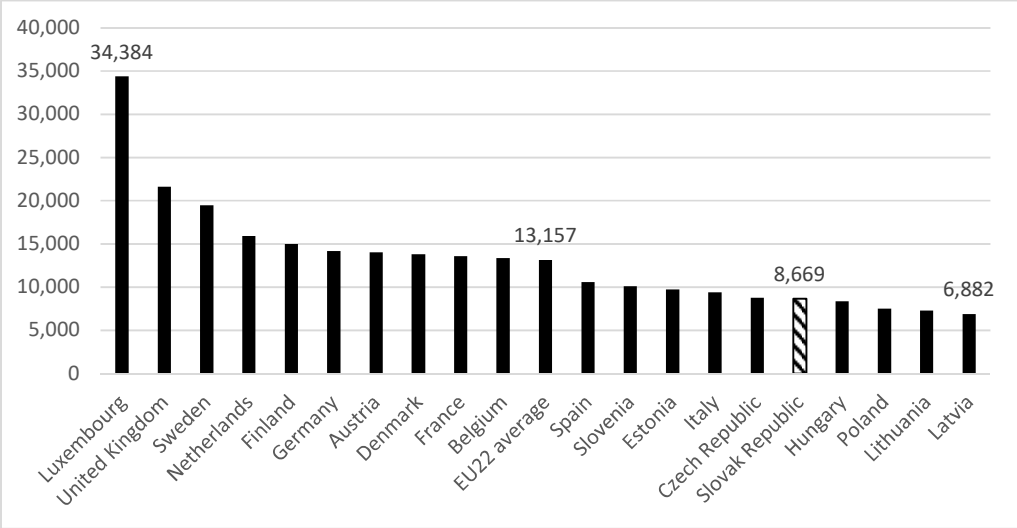

Figure 5 : Annual expenditure per student by educational institutions for all services by tertiary education in 2013

Source: OECD Database

Table 1 compares unemployment rates divided by attained education and age group in 2005 and 2015 (OECD, 2016$_b$). As one can see, the unemployment rate of young people (25 – 34 year old) was increasing between 2005 and 2015 (OECD, 2006). The same problem occurred in Denmark, Finland, France, as well as in other developed European countries.

Table 1: Trends in unemployment rates by educational attainment and age group in EU 22

	Upper secondary or post-secondary non-tertiary						Tertiary					
	Unemployment rates of						Unemployment rates of

Figure 6 displays employment rates among graduates in year 2016 (Eurostat, 2017$_b$). The employment rate of graduates reached in Slovakia is above the EU 28 average (Kajanová, 2015). On the other side, Poland, Hungary or Czech Republic had better results in this case.

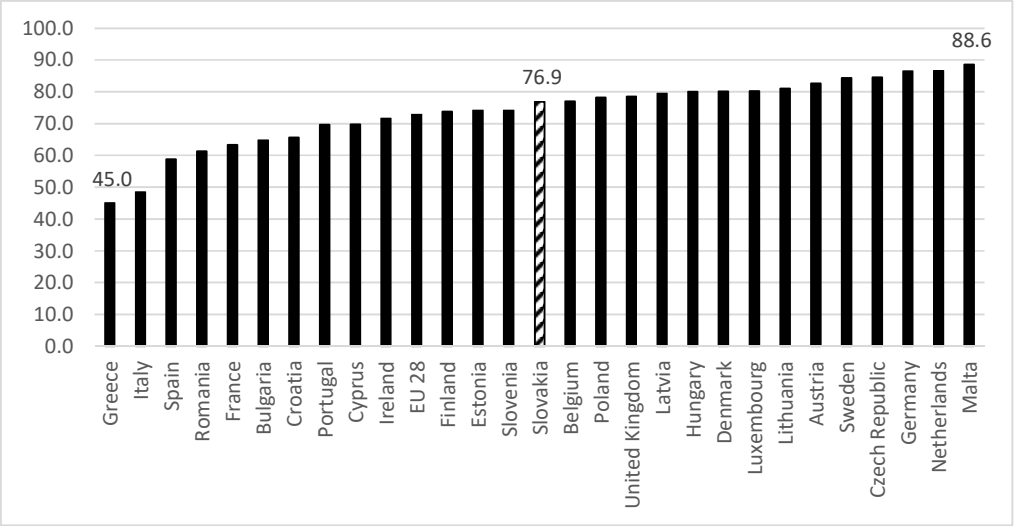

Figure 6 : Employment rates of graduates in 2016 (in %)

Source: Eurostat

While further education yields higher earnings over the career of an individual, private benefits from investing in education also depend on countries' tax and social benefits systems. Higher income taxes and social contributions, and lower social transfers related to higher earnings can act as disincentives to investing in further education by creating a wedge between the level of gross earnings needed to recover the cost of education and the final net earnings perceived by the individual. For instance, a man who chooses to invest in tertiary education will pay, on average, about 40% of his additional income associated with tertiary education in taxes and social contributions (OECD, 2014). In the Czech Republic, Estonia, Poland and the Slovak Republic, income taxes and social contributions amount to less than a third of the gross earning benefits, while in Denmark, Italy and Slovenia, they add up to about half of the gross earning benefits. As women tend to have lower earnings, they often fall into lower income tax brackets.

Total private costs, composed of direct costs and foregone earnings, generally rise with the level of education. The direct costs for a man or a women entering upper secondary or post-secondary non-tertiary education are, on average, about USD 2 500 across OECD countries, while they amount to about USD 10 500 for tertiary education (OECD, 2016$_a$).

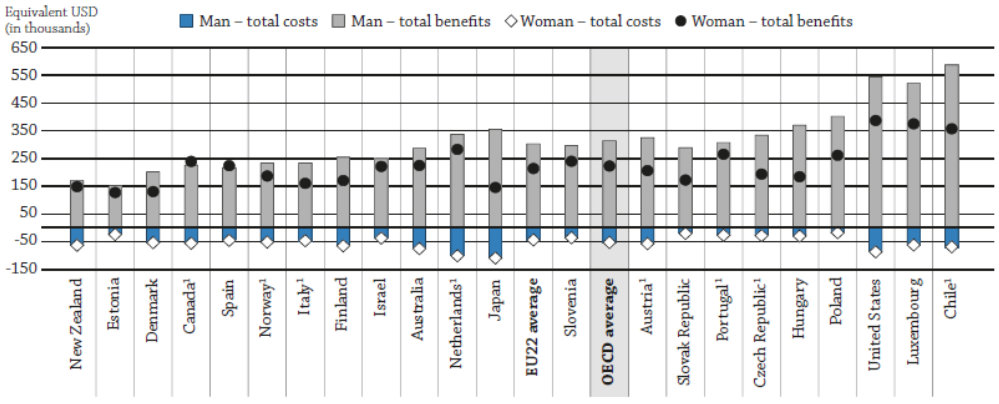

Figure 7 : Private costs and benefits of education on attaining tertiary education in 2012

Source: OECD Database

Public net financial returns are measured in a similar fashion to private net financial returns and are also based on the difference between costs and benefits associated with an individual attaining an additional level of education. Costs include direct public costs for supporting education and foregone tax revenue on earnings. Benefits are calculated using income tax, social contributions, social transfers and unemployment benefits. Total public benefits in the Slovak republic also differ between men and women, due to differences in labour market outcomes. This suggests that government have a role to play in easing the integration and participation of women in the labour market, in order to assure higher gains from the large investment of women in their education.

One can see public net financial returns were higher in the Slovak Republic than in Spain or Estonia. The highest public net financial returns were achieved by Luxembourg in 2012.

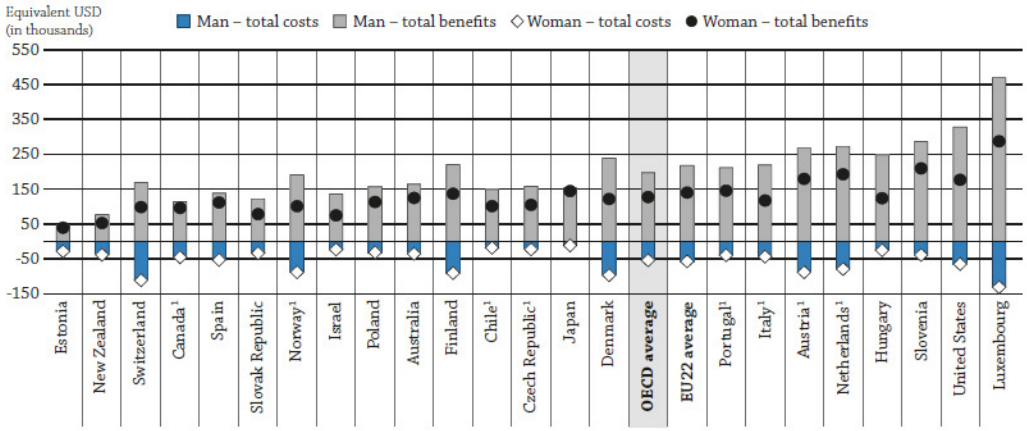

Figure 8 : Public costs and benefits of education on attaining tertiary education in 2012

Source: OECD Database

Comparison of Figures 7 and 8 shows that net financial returns on investment for governments are generally closely related to private returns. Countries where individuals benefit the most from pursuing tertiary education are also those where governments gain the largest returns. However, countries such as the Slovak Republic and Slovenia are exceptions. Although these two countries have similar net financial private returns (about USD 260 000 for a tertiary-educated man), the net financial public returns are more than USD 150 000 higher in Slovenia than in the Slovak Republic. This difference is mostly explained by larger income tax and social contribution effects in Slovenia (Rentková, 2017).

5 Conclusion

The main goal of this paper was to publish the partial results of the research linked with measurement of the public spending on the tertiary education in the Slovak Republic.

Main conclusion of our research is that the performance of the Slovakian tertiary education system is quite good. Indicators measuring the effectiveness depends also on the economic growth of the Slovak Republic. A measurement challenge is that the indicators available are crude, but that some issues are too big to be ignored while waiting for more refined indicators. There is a compelling need to evaluate the impact of tertiary education, and to assess the efficiency, and effectiveness of expenditure. It is also necessary to assess what employers seek from graduates from tertiary education, as well as the validity of available measures of teaching quality. Measuring the quality of tertiary education is as challenging as it is important.

More than a half of indicators showed that the public spending on the Slovakian tertiary education is efficient. The inadequate public spending on the tertiary education is causing the low number of academic staff in HE institutions relative to the total country population.

Effectiveness or the degree to which the objectives have been achieved is expressed in terms of benefits, respectively positive effects triggered in other domains of social-human life and which are difficult to quantify.

Semiotic Approach to Pedagogical Bioethics

Nina A. Pervushina, Tomsk State Pedagogical University, Tomsk, Russia, pervushina_na@mail.ru

Abstract

The developing convergent technologies are actively entering in all the spheres of human life, and training does not stand aside, which makes knowledge management relevant. The interrelation between the cognitive and corporal impact of information actualizes the bioethical aspect of the problem by raising the question are the consequences of information perception predictable. In its turn, the symbolism of bioethics influences the relevant competences in education for a variety of professions. Bioethics protects a person's individuality in the field of medicine, but at the moment does not affect the field of pedagogy. Since one of the current trends is a significant predominance of visual representation of information over the verbal, it is relevant to consider the very visual perception of information. In the work, the author discovers the conceptual basis for conducting semiotic diagnostics of applicability limits of perceptual theories. As a result, the rationale for choosing models of the information-synergetic approach as such basis is justified.

Keywords: symbolism of bioethics, perception of visual information, knowledge management.

Introduction

Effective knowledge management is a necessary component of forming and development of the modern man. Since, according to modern studies, in the process of learning the brain changes physically (Macajova, 2013; Chernigovskaya, 2010; Zuk et al., 2014), and the training itself is ongoing and not always purposeful, it is important which information and which way one gets. This is the determining factor in knowledge management, when the creation, storage, distribution and application of the necessary knowledge is of particular importance. At the same time, the relationship between the cognitive and corporal impact of information actualizes the bioethical aspect of the problem.

Actively developing biomedical and other technologies, called the convergent ones and combining nano-, bio-, information-, cognitive technologies (Roco & Bainbridge, 2003), are aimed in their perspective at transforming the technological sphere of mankind into an organic part of the natural environment. These technologies affect a wide range of human life spheres and thus cause sociocultural transformations, so obvious and unprecedented that it is impossible not to notice them. Bioethics becomes a sociocultural reaction to the innovation of biomedical technologies (Mescheryakova & Melik-Gaykazyan, 2015; Melik-Gaykazyan et al., 2017). It is designed to regulate, prohibit or permit the implementation of such innovations, protecting the rights, dignity and autonomy of human, one's personality and individuality. With a broader view, under its "protection" is the individuality not only of human, but also of animals (Gorbuleva, Melik-Gaykazyan & Melik-Gaykazyan, 2016; Tarasenko et al., 2016). Such protection is based on the value of life, a merciful and humane attitude to all living things. Bioethics as a form of modern culture accentuates the right of individualy to be what one wants, and the duty of the society to provide individuality with this opportunity. The symbolism of bioethics spreads itself across all the spheres of knowledge, enters into life, forms new grounds for social altruism, protects the right to remain for each participant of communication process.

The problem is bioethics protects the individuality of human (Meshcheryakova, 2011; Mescheryakova & Melik-Gaykazyan, 2015) in the sphere of medicine, but at the moment does not affect the pedagogical sphere. Although the principles and rules developed by Tom L. Beauchamp and James Childress (non-maleficence, beneficence, justice, respect for patient's autonomy, and the rules of truthfulness,

confidentiality and informed consent), it makes sense to apply them to the sphere of education (Mescheryakova, Melik-Gaykazyan & Melik-Gaykazyan, 2016). So, for example, a student and / or one's legal representatives should have the right to obtain information about what impact will be rendered, what will be the final result of education, which "contra-indications" have the methods of training, i.e. the right to implementation of informed consent procedure. Thus, the specific characteristics of modern times make it necessary to apply bioethics in the sphere of pedagogy. Firstly, the visual presentation of information largely replaced the verbal one. Secondly, the life itself became a product of technology, i.e. it became an artifact. Thirdly, the pace of innovation discovers the frailty of intellectual traditions. Fourthly, the innovations of convergent and biomedical technologies create new risks. And, finally, the existence of individual in the environment of new risks requires a new degree of responsibility for the choice made by the individuality. In this case, individuality has to make a choice constantly - both corporeal and mental. Bioethics is at the intersection of some trends: it protects individuality from arbitrariness of biomedical manipulation, assess the new risks, keeps the moral positions of philosophical traditions for determining the permissible limits of interference of artificial to natural.

As technology creates more and more visual products, it becomes important how to channel this potential into the right direction. The visual representation of information has not only entertaining usage, but it can also be a powerful tool, which makes it important to find out the optimal ratio in the use of visual aids in relation with the characteristics of individual perception of visual information. In pedagogical science, the limits of applicability of approaches are usually not specified, which creates significant difficulties in establishing, for example, their axiological limits while modeling the learning process, combining methods, techniques and technologies developed in the framework of various theories of education (Mescheryakova, Melik-Gaykazyan & Melik-Gaykazyan, 2016; Melik-Gaykazyan et al., 2017). Being within these limits, it is possible to combine the methodical techniques proposed within various approaches so that they work not as an eclectic set, but as a thoroughly measured complex. It is the combination of different concepts that maximizes efficiency and ensures the comfort of training, since any methodical technique is effective only when it corresponds with specific goals and the particular perception of trainees.

In relation with the problem posed, a research question emerged, consisting in discovering the methodological grounds for conducting semiotic diagnostics of the limits of applicability of various approaches to the perception of visual information for knowledge management.

Methods of research and analysis of results

The information-synergetic approach, which is closely related to the systemic approach in the Russian tradition (Melik-Gaykazyan, 2010), is chosen as a research method and consists in modeling (Rogotneva, Melik-Haikazyan & Goncharenko, 2015; Melik-Gaykazyan et al., 2016). The information-synergetic approach has been tested in studies of relationships within self-organization of Hi-Tech system, transformation of education systems in the context of self-organization of convergent technologies (Mescheryakova et al., 2016) and the nonlinear dynamics of sociocultural systems (Gorbuleva, Melik-Gaykazyan & Melik-Gaykazyan, 2016; Tarasenko et al., 2016), which allowed to identify the emergence of symbolism of bioethics and its linking role in the transformation of scientific, educational and cultural systems (Melik-Gaykazyan, Gorbuleva et al., 2017). To solve the problem stated in the article, attractiveness of the approach lies in the fact that it opens the possibility to measure the range of impacts occurring in the process of teaching (Mescheryakova et al., 2016).

If one consider bioethics a sociocultural reaction to actively developing convergent technologies, it becomes obvious that its goals are embodied in its symbolism, which manifests itself, among other things, in visual images. In this regard, it is important to determine how the value of symbols is read. Or in other words, how these visual images are perceived. Therefore, the initial point of searching for solution will be addressing to interpretation of information perception as the stage of the information

process (Tarasenko, Melik-Gaykazyan & Melik-Gaykazyan, 2016; Melik-Gaykazyan, Tarasenko et al., 2017). The information approach is worth considering from the point of view of post-non-classical methodology (Tarasenko, Melik-Gaykazyan & Melik-Gaykazyan, 2016; Evdokimov et al., 2016; Melik-Gaykazyan, Tarasenko et al., 2017). The perspectives of researching perception in the framework of post-non-classical paradigm are associated primarily with rejection of traditional views, transition to a new vision of the world, based on the ideas of universal evolutionism, systemic, multivariate and poly fundamentalism.

It is possible to indicate the initial ideas underlying the post-non-classical vision of the world, according to Vyacheslav S. Stepin: the unity of the universe lies in the fact that the common laws act at all the levels of its organization; systemic vision as opposed to the mechanistic understanding of the world; the synthesis of determinism, multivariance and eventuality; rejection of the concept of reductionism (Stepin, 2003, 2015, 2016). These ideas are based on the following basic theses: the random and the regular are equal partners in the Universe; probabilistic self-organization of open nonequilibrium system, i.e. spontaneous transition to an ordered state, accompanied by redistribution of matter in time and space; approach to research of organism as an open system; the basic forms of cooperative behavior inherent to the living organisms have their analogues among inorganic systems (Stepin, 2003, 2015, 2016; Knyazeva & Kurdyumov, 2002). Proceeding from these theses it was established that the phenomena of self-organization include information processes, including the stages of generation and evolution of valuable information as an initial stage of this general process (Tarasenko, Melik-Gaykazyan & Melik-Gaykazyan, 2016; Evdokimov et al., 2016; Melik-Gaykazyan, Tarasenko et al., 2017).

In addition, within the post-non-classical paradigm, perception is understood as a dialogue, where a human is a full participant, determining its parameters. On the contrary, within the frameworks of the classical approach perception supposes contradistinction of subject and object, while the nonclassical approaches consider the complementary relations of the observer and the environment. As we see, in the post-nonclassical paradigm (Stepin, 2003, 2015, 2016; Lektorskii et al., 2016; Raitina, 2015; Trufanova & Gorokhov, 2014) a "human dimension" is introduced, supposing the inclusion of value-semantic factors. In this new space, new interactive cognitive strategies are formed, taking into account the multifaceted relationships between a man and the world.

This was especially evident in synergetics, where the new approaches to research of human and culture are being formed on the basis of natural science (nonlinear analysis, theory of deterministic chaos, theory of dissipative structures). The humanitarian orientation of synergetics, related to the ideas of irreversibility, the variety of possible development options that arise when the system passes through bifurcation points, the ideas of the organic relation between self-regulation and cooperative effects, allows us to talk about the emergence of "synergetics with a human face" (Knyazeva & Kurdyumov, 2002; Knyazeva, 2011, 2017).

The non-linearity of system has an ideological meaning. In the works of Yelena N. Knyazeva and Sergey P. Kurdyumov, the non-linearity in ideological meaning is manifested through: the idea of multivariance, alternative ways of evolution; ideas of choice from the given alternatives; ideas of evolution pace; ideas of evolution irreversibility (Knyazeva & Kurdyumov, 2002, p. 36). Describing the phenomenon of nonlinearity, researchers distinguish the following features: the principle of "small growth" or "amplification of fluctuations"; certain classes of open nonlinear systems demonstrate a "sensitivity threshold"; nonlinearity generates a "quantum effect" - discreteness of nonlinear systems' ways of evolution; unexpected changes in the direction of processes flow are possible (Knyazeva & Kurdyumov, 2002, p. 36).

The perceptual system is non-linear, since perception is determined not only by a combination of stimuli. Attempts by adherents of some psychological concepts to construct a theory of perception via "summing up" its elementary properties turned out to be insolvent, since the whole is not reduced to the sum of its parts. Sensory signals only "supply" the brain with the data, the choice of system leads to the birth of new

qualities, to restructuring of the structure. The perception of the same elements included in different contexts is variable, since, from the point of view of Lev Vygotsky, the psyche is "a sieve that filters the world" (Vygotsky, 1982, p. 347). A well-founded approach to perception as an open non-linear system is promising in the methodological plan, since it allows (Tarasenko, Melik-Gaykazyan & Melik-Gaykazyan, 2016; Evdokimov et al., 2016; Melik-Gaykazyan, Tarasenko et al., 2017) to discover the limits of applicability of various psychological concepts of perception from information-synergetic point of view and streamline them.

Perception of information as a non-equilibrium process allows to research the information-synergetic approach, since reception means the emergence of a certain orderliness in perceptual system (Mescheryakova, Melik-Gaykazyan & Melik-Gaykazyan, 2016). Information processes associated with reception of information, as revealed in the works of Irina V. Melik-Gaykazyan, are possible only in open and nonlinear systems. This understanding of perception is corresponding with psychological theory (Mescheryakova, Melik-Gaykazyan & Melik-Gaykazyan, 2016). The process of perception acts as a reception for selecting action algorithms in order to choose the method of further action. In this case, the selection of algorithms can occur both from memory and in real time (Mescheryakova, Melik-Gaykazyan & Melik-Gaykazyan, 2016). In other words, the reception process becomes the stage of information transmission in diachronic and synchronous mode.

The information-synergetic approach to research of perception is promising, because it is based on interrelation of the three theses: the phenomenon of information is the process irreversible in time; the beginning of this process is a random result of a spontaneous event; information processes are the mechanisms of self-organization of open complex systems. Each thesis is manifested in a specially developed conceptual model, and their combination is a method of solving problems in interdisciplinary studies of nonlinear dynamics of complex systems (Melik-Gaykazyan, Gorbuleva et al., 2017). It is these models (the conceptual and schematic types of which are exhaustively presented by Irina V. Melik-Gaykazyan in a number of articles (Tarasenko, Melik-Gaykazyan & Melik-Gaykazyan, 2016; Melik-Gaykazyan et al., 2017; Evdokimov et al., 2016; Mescheryakova, Melik-Gaykazyan & Melik-Gaykazyan, 2016)) that allow to conduct the semiotic diagnostics of limits of applicability of various approaches to perception of visual information.

The concept of perceptual system as open, complex and self-organizing, and therefore understanding of perception as a stage of information process that is irreversible in time and which is a random result of spontaneous event, makes it possible the diagnostics of limits of applicability of psychological theories of perception on the basis of models of information-synergetic approach. The usage of such diagnostics is relevant in pedagogy, since it allows to protect the autonomy of individual.

So, the conceptual basis for conducting semiotic diagnostics of limits of applicability of various approaches to perception of visual information will be the model of information process stages that represents the spectrum of impacts of these stages on human and anthropological perceptions of these impacts. The model allows to present the trajectories of impacts of normative, verbal, prognostic, critical, adaptive and compensatory functions. This becomes the key to ordering of psychological theories in the spectrum of their understanding of human perception essence, which is important in pedagogical bioethics and knowledge management.

Conclusion

To effectively use visual aids, it is necessary to rely on cultural traditions of perception and individual traits of trainee, since everyone has the right to autonomy. The relevance of application of bioethics principles in pedagogy determines modification of adaptive function of education to the reality that is constructed by convergent technologies. This reality initiates the new challenges and determines the

content of professional training of specialists in almost all spheres of activity. At the same time, the reality of the present and the near future is formed by semiotic means, among which the means of visual symbolism dominate. This dominance implies a new direction of adaptation - an adaptation to the preservation of one's own autonomy under the active impact of visual information. The ability to meter this impact in doses necessary for pedagogical purposes is based on solving the problem of measurement in humanitarian studies and the principles of bioethics that protect the autonomy of individual. The combination of different approaches and designation of limits of their applicability becomes a necessity, the very combination of different approaches makes sense, because each of them corresponds to one aspect. Understanding the scope of these aspects is fundamental, which is demonstrated in a clear form by the model of information-synergetic approach. The opportunity to categorize the theories of perception of visual information is relevant for the methodical regulation of their application in pedagogy and construction of "semiotic attractors" of education, the form of which is created by symbolism of visual information, and the meaning - by symbolism of bioethics.

Abstract

The purpose of this work is to highlight the major role that intellectual capital plays in the intrapreneurship, defined as an entrepreneurship process within an existing organization. The relationships between the intensity with which the opportunities are identified and exploited in the process, and the innovation radicalness resulted from it, are leveraged by the intellectual capital.

Keywords: Intrapreneurship; Entrepreneurship; Intellectual Capital; Innovation; Opportunity;

Introduction

Intrapreneurship is known as the entrepreneurship developed within an existing organization (Antoncic, 2007). This phenomenon is highly worthwhile for firms: it can be used as a strategy to maintain a high level of innovation in the dynamic environment of today (Ulhoi, 2005). In this competitive scenario, one of the best ways for reaching firm competitive advantage position comes directly from achieving higher levels of innovation radicalness (Marvel and Lumpkin, 2007).

For the last two decades, entrepreneurship has been widely studied and through many approaches. Nevertheless, there seems to be a consensus with a process-approach, derived from the seminal paper of Shane and Ventakaraman (2000). In fact, to tackle the entrepreneurship phenomenon from this process-approach offers the advantage that it can also be applied in an organization context. That is why, some authors claim that the intrapreneurship and the entrepreneurship are both the same process by which entrepreneurial opportunities are identified and exploited (Ulhoi, 2005). Even if opportunities are a fundamental requirement, they are not sufficient to explain the entrepreneurship process for the reason that someone has to identify and exploit them (Ramos-Rodríguez, et al 2010): in the individual entrepreneurship case, the human capital represents the knowledge and skills that entrepreneurs bring to the process they set out to perform (Dimov, 2010) while the social capital refers to the entrepreneur´s social network that help to ensure success. In a firm context, the human capital, the social capital, together with the organizational capital represent the intellectual capital that allows for the process to be completed.

In this sense, this work attempts to clarify the distinction between individual entrepreneurship and intrapreneurship in a practical way, considering the process-approach for the study and proposing a model including the key concepts underpinning entrepreneurship. To our knowledge little work has been carried out on the relationships between intrapreneurship, innovation and intellectual capital, all together. Wu et

al (2008) propose some relationships including moderator effects, but in this case, entrepreneurship, tackled from another perspective, is not defined as a process. This work fills some gaps in the intrapreneurship literature proposing a model where intellectual capital plays a major role leveraging the relationship between the intensity with which the opportunities are identify and exploited in the intrapreneurship process, and the innovation radicalness resulted from the process.

The work is structured as follows: first of all, we provide a review on the existing literature in order to lay the theoretical foundations of the study. Then we propose the model, based on a process-approach, and finally we formulate the hypothesis.

Literature Review

The Intrapreneurship Concept

Since it was first coined by Pinchot (1985), intrapreneurship had been referred to by many as "corporate entrepreneurship", "corporate venturing" or "internal corporate entrepreneurship" (Antoncic and Hisrich, 2001). Ulhoi (2005) defines intrapreneurship as the process within an organization; by which opportunities are identified and exploited, establishing that is the same process as in the individual entrepreneurship case. In this sense, a process is defined as a series of actions that transform inputs into outputs through use of resources (ISO 9001:2000).

The Entrepreneurial Opportunity

It corresponds to the input of our process-model. Scholars are focusing on it and this literature is growing very rapidly. In fact, opportunities have become for many researchers the core construct in the entrepreneurship framework (Uygur, forthcoming). Nevertheless, there is no consensus on the definition and some authors criticize the approach proposed for this construct (Dimov, 2010). Davidsson (2015) highlights the minority of works that offer a definition of opportunity and argues that the lack of construct clarity is the major reason why there is little progress on the study of entrepreneurship. "Opportunity" carries a connotation of favorability and, a priori, denoting success. In fact, we can only confirm that an opportunity is a truly opportunity once the product or service has been launched successfully into the market (Eckhardt and Shane, 2010). If we define opportunity as a set of circumstances that makes it possible to do something, the causes for failure in the entrepreneurship process are attributed solely to the entrepreneur (Dimov, 2010). Consequently, the term opportunity becomes tautological, proof of which Gaglio and Katz (2001) distinguish between opportunities and successful opportunities.

In its most elemental form, an opportunity is an underemployed or underutilized resource (Ardichvilli et al, 2003). The term "underutilized resource" does not necessarily imply success a priori. That is the reason why we propose to use the term "underutilized resource" instead of "opportunity". Although it is true that discoveries provide new opportunities, we suggest adding "undiscovered resource" to the term. In this way, "underutilized or undiscovered resource" depends on its own characteristics, on the entrepreneur and on the entrepreneurship process. Having verified at the end of the process some success, it could consequently be described as an opportunity.

Intrapreneurship and the Resource-Based Theory

To employ the term "under-employed or undiscovered resource" rather than opportunity offers the advantage to use the same unit of analysis as in the resource-based theory RBT: the resource. This helps us to frame the entrepreneurship on the RBT, together with the fact that the entrepreneurship process

could be developed within an organization, as seen it before. The RBT suggests that endogenous factors explain the sustainable competitive advantages of a firm. In this sense, Alvarez and Busenitz (2001) integrate the theory of entrepreneurship into the RBT arguing that not only both adopt precisely this same unit of analysis that is the resource, but they overlapping interests, such as knowledge, firm adaptation to environmental change, modes of organizing and the exploitation of opportunities.

The Identification of Opportunities

It corresponds to the first process step and is defined as the sub process comprising the action of entrepreneurial alertness (Shepherd and DeTienne, 2005), and the action of evaluation and decision-making (Davidsson, 2015). Kirzner (1979) defines entrepreneurial alertness as the ability to notice opportunities that have hitherto been overlooked (Gaglio and Katz 2001). In practice, this means scanning and searching for information and connecting previously-disparate information (Tang et al 2012). After that phase, an evaluation and decision-making action arises. At this stage the entrepreneur has to decide whether or not to continue with the process (Shepherd and DeTienne, 2005; Davidsson, 2015).

The Exploitation of Opportunities

It corresponds to the last process step and is defined as the sub process comprising the action of planning the business (Dimov, 2010) and the action of the gestation activities (Davidsson and Honig, 2003). Business planning deals with the information corresponding to the identify opportunity (Castrogiovanni, 1996). This involves the processes of analyzing information, evaluating required tasks, identifying risks and strategy, projecting financial developments, and also, documenting these things (DelMar and Shane, 2003). After planning, the process becomes more complex, redirecting or recombining resources in order to create and deliver value superior to that currently available (Ardichvilli et al, 2003). All the activities that might be undertaken in the process of trying to get a new venture up, is what we call gestation activities (Davidsson and Honig, 2003).

The Intellectual Capital

Opportunities do not explain by themselves the entrepreneurship phenomenon, for the reason that someone has to identify and exploit them (Ramos-Rodríguez, et al 2010). Several authors study "entrepreneurship" through the entrepreneur´s personality, knowledge or social networks (Shepherd and Grégoire, 2012). Those knowledge and skills that individuals bring to the process they set out to perform, is commonly known as human capital (Dimov, 2010). Originally developed to predict the influence of education on economic growth (Becker, 1964), the human capital is considered a vital factor to discover opportunities (Marvel et al. 2016). Individuals with more or higher quality human capital perceive profitable opportunities (Davidsson and Honing, 2003). However, human capital is neither the sole factor nor, often, the most important, because there are some external factors that also play a critical role, as social capital which represents all the resources resulted from social relationships of the entrepreneur, and provided by family, friends and colleagues (De Carolis and Saparito, 2006). Entrepreneurs with networks that are comprised of a large number of contacts are better able to identify opportunities and to acquire the resources to exploit them (De Carolis et al, 2009).

In the field of intrapreneurship, the human capital, the social capital and together with the organizational capital, represents what is called intellectual capital. The intellectual capital is defined as all the intangible resources related to knowledge which provides sustainable competitive advantage to the firm (Subramaniam and Youndt, 2005). In this context, human capital does not refer to an individual person, but to the knowledge and the skills of each employee as a whole. Social capital represents the firm´s knowledge gained from social exchanges, as customers and suppliers relationships, but also in networks

of their own employees. Organizational capital is defined as all the know-how, methods, processes, procedures, routines, task, activities, in short, all the intangible resources which leverage the organization's productivity. Organizational capital only makes sense in an intrapreneurship framework because the firm is already established.

In the proposed model of entrepreneurship process, the intellectual capital is identified as a resource by which identification and exploitation of opportunities are developed. Given the universality of the entrepreneurial opportunities, and given the fact that the process to identify and exploit them is the same; the intellectual capital should be the differentiating element between the individual entrepreneurship and the intrapreneurship.

Innovation

Traditionally, entrepreneurship has been associated with the creation of new ventures, but also with innovations. In the proposed model, the innovations are identified as an outcome of the process. From the literature review, there is no consensus definition of innovation, and several approaches have been proposed to study it, being the process approach and the result approach, the most relevant. This study opts for the result approach and innovation is defined as the introduction to the market of something new that can be a sustainable competitive advantage over time. Innovation literature typically distinguishes between radical innovations and incremental innovations. Radical innovations have very high economic and social impacts, increasing technological knowledge and providing new products or services. In contrast, incremental innovations are more common and the reward is smaller, leading to small incremental improvements in an existing product or service (Laursen and Salter, 2006).

The Model

This study proposes a model based on a process-approach and which integrates the key concepts underpinning entrepreneurship. The next figure represents a synoptic model summarizing the entrepreneurship process:

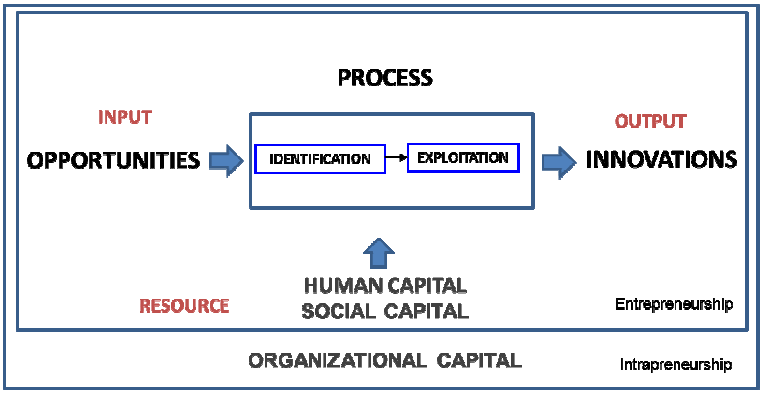

Fig.1: synoptic model

The Hypothesis

To our knowledge, little work has been carried out on the relationship between the identification and exploitation of opportunities, in terms of intensity, and the degree of novelty of innovations at the end of

an intrapreneurship process. Shepherd and DeTienne (2005) affirm that a positive relation exists between the number of opportunities identified and the degree of novelty of the entrepreneurship process. It is clear that the higher the number of opportunities identified, the greater the sample, consequently there is more variety to choose from (Ucbasaran et al. 2009). In the case of exploitation of opportunities, Stuetzer et al (2013) state that the higher number of gestation activities achieved the more chances of success in the entrepreneurship process. Samuelsson and Davidsson (2009) highlight that to obtain radical or incremental innovations depend on the number of gestation activities achieved. In this sense, Liao and Welsch (2003) note that radical innovations require more recombination of resources and large number of gestation activities because the process is more complex. Therefore, we propose the following hypotheses:

H1: The innovation radicalness is positive influenced by:

a. The intensity with which the opportunities are identified in the intrapreneurship process.

b. The intensity with which the opportunities are exploited in the intrapreneurship process.

Existing literature provides empirical evidence with respect to the relationship between intellectual capital and innovation. Marvel and Lumpkin (2007) suggest that radical innovations are the result of individuals with high experience and level of education, while Subramaniam and Youndt (2005) highlight that strong-tie with suppliers increase radical innovations. Tseng and Goo (2005) affirm that high levels of organizational capital in a firm, allow for faster knowledge transfer, having a positive impact on innovation.

Wu et al (2008) propose some relationships include moderator effects, but in this case, entrepreneurship has not a process approach and it is not defined has the identification and exploitation of opportunities. Therefore, we propose the following hypotheses:

H2: The relationship between the intensity with which the opportunities are identified in the intrapreneurship process and the innovation radicalness, is moderated by:

a. Human capital.

b. Social Capital.

c. Organizational Capital.

H3: The relationship between the intensity with which the opportunities are exploited in the intrapreneurship process and the innovation radicalness, is moderated by:

a. Human capital.

b. Social Capital.

c. Organizational Capital.

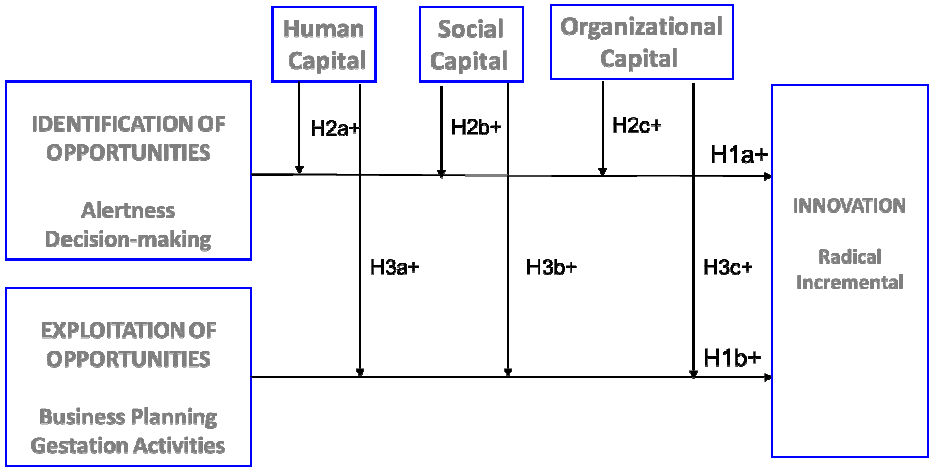

Fig.2: Theoretical model and hypotheses

Conclusions

Nowadays, the dynamic environment forces the firm to launch radical innovations. To achieve this goal, intrapreneurship can be a good strategy. This work highlights the important advantages to use a process-approach to explain it, and proposes a model including the key concepts underpinning intrapreneurship and their relations. Intellectual capital should be the differentiating element between the individual entrepreneurship and the intrapreneurship given the universality of opportunities, and given the fact that the process to identify and exploit them is the same in both cases. In the proposed model, intellectual capital facilitates the integration of an extensive literature focused on knowledge, capabilities, social relations, and other intangible resources, in the field of entrepreneurship. From our study, we expect that intellectual capital plays a major role moderating the relationship between the intensity with which the opportunities are identified and exploited in the intrapreneurship process, and the innovation radicalness resulted from the process. Empirical literature proposes many dimensions and items to measure the intellectual capital and the degree of novelty of an innovation, but it is not the case for the intensity with which the opportunities are identified and exploited in a firm context. This work suggests the dimensions of alertness and, evaluation and decision-making, for the identification of opportunities, and the dimensions of business planning and gestations activities for the exploitation of opportunities, always taking into account the context of the firm.

Résumé

Les outils de Business Intelligence offrent aujourd'hui une chance aux Managers de bénéficier d'une aide à la décision en temps réel en transformant des flots de données éparses en informations utiles et pertinentes, élaborées sous forme de reportings et de tableaux de bord. Dans le monde turbulent des opérateurs de télécommunications, les systèmes de BI, qui trouvent un essor remarquable, conditionnent aujourd'hui la survie et le développement de ces entreprises. A ce titre, ce papier se propose d'examiner les composantes clés de ce projet aux plans humain, technologique et des processus à travers une application des modèles d'évaluation de maturité au niveau des opérateurs de télécommunications en Tunisie.

Introduction

L'évolution frénétique des outils et technologies de communication basée sur l'internet soumet les entreprises de télécommunications à l'obligation de renouveler sans cesse leurs offres et de mettre en place une veille technologique et commerciale à même de faire face à un contexte concurrentiel de plus en plus dur . Cette exigence s'accompagne d'une croissance exponentielle du volume des données auxquels accèdent ces entreprises du fait de la diffusion des objets connectés, des nouveaux usages d'internet qui s'ajoutent aux données issues du réseau (trafic, qualité de service), les données via les connexions sur les plateformes (portails, transactions web).

Pour rester au cœur de ces évolutions ces entreprises ont été amenés à constituer des entrepôts de données et à mettre en place des systèmes de Business intelligence (BI) de plus en plus sophistiqués. Un système qui s'appuie sur l'analyse de larges volumes de données passées et présentes pour comprendre les déterminants de l'activité et influencer la prise de décision dans l'entreprise. Une BI en temps réel qui contribue à la mesure quotidienne des indicateurs d'activité, à l'estimation des prévisions et l'actualisation des objectifs, autorisant les outils et les processus BI à occuper aujourd'hui une position centrale dans la gestion de ces entreprises.

C'est justement pour mesurer le niveau de développement de ces systèmes sur le plan technologique et organisationnel que se sont développés différents modèles de maturité construits à l'instar du CMM (Capability Maturity Model) et autres normes ou référentiels de bonnes pratiques des entreprises. Ces modèles permettent de rendre compte non seulement de la capacité technique de ces systèmes à stocker, traiter , analyser les données et à les transformer en informations pertinentes pour la prise de décision, mais , de plus en plus, de mesurer le niveau d'appropriation par les managers des informations fournies par le système décisionnel pour en faire un véritable levier de réussite au sein de l'entreprise. La dominance des aspects liés à la technologie informatique ne doivent pas en effet occulter l'importance fondamentale de l'évaluation de l'apport des systèmes BI au management de la performance via les outils d'aide à la décision et au pilotage que sont notamment les tableaux de bord.

Les considérations d'ordre technique relatives aux outils, à l'architecture du système et technologies choisis doivent être optimisés en vue de fournir une véritable assistance aux responsables métiers organisée dans le cadre d'une stratégie décisionnelle globale et cohérente avec les objectifs visés. C'est bel et bien cette dynamique que l'on essayera d'évaluer dans l'environnement turbulent des opérateurs de

télécommunications, les plus outillés sur le plan technique pour profiter des vertus liés à l'exploitation des entrepôts de données.
Aussi après avoir présenté une brève description des composantes de base d'un système de BI, ce papier mettra en lumières les évolutions récentes du concept de BI avant de faire le lien avec les besoins spécifiques des opérateurs de télécommunications dans ce sens. Nous présenterons par la suite le modèle de maturité de BI et de gestion de la performance qui nous servira d'étalon pour une évaluation critique de la stratégie des opérateurs de télécommunications opérant en Tunisie en matière de Business intelligence.

I Les Composantes D'un Système De Business Intelligence

Par opposition au système d'information produisant des données, ou système d'information transactionnel, la Business Intelligence s'appuie sur un système d'information spécifique, ou système d'information décisionnel (SID). D'un point de vue technique, Power(2007) soutient que le processus de BI vise à collecter les données brutes (extraites de différentes sources notamment d'un ERP ou d'un CRM, des données de marché, des données provenant de sources externes clients/fournisseurs..), à les transformer en informations et à les diffuser sous forme de tableaux de bord ou de reporting.

Un système BI doit remplir quatre fonctions fondamentales : la collecte, l'intégration, la diffusion et la présentation des données, selon wikipédia. À ces quatre fonctions s'ajoute une fonction d'administration, soit le contrôle du SID lui-même. Ainsi:

- La fonction collecte (parfois appelée datapumping) recouvre l'ensemble des tâches consistant à détecter, sélectionner, extraire et filtrer les données brutes issues des environnements pertinents compte tenu du périmètre couvert par le SID. Comme il est fréquent que les sources de données internes et/ou externes soient hétérogènes tant sur le plan technique que sur le plan sémantique , cette fonction est la plus délicate à mettre en place dans un système décisionnel complexe. Elle s'appuie notamment sur des outils d'ETL (extract-transform-load pour extraction-transformation-chargement).
- La fonction d'intégration consiste à agréger les données collectées dans un entrepôt de données. Celui-ci permet aux applications décisionnelles de masquer la diversité de l'origine des données et de bénéficier d'une source d'information commune, homogène, normalisée et fiable.
-
- La fonction de diffusion met les données à la disposition des utilisateurs, selon des schémas correspondant aux profils ou aux métiers de chacun. L'objectif à ce niveau sera de segmenter les données en contextes informationnels fortement cohérents, simples à utiliser et correspondant à une activité décisionnelle particulière. Chaque contexte peut correspondre à un datamart, correspondant souvent à un processus métier donné. Très souvent, un contexte de diffusion est multidimensionnel, c'est-à-dire modélisable sous la forme d'un cube; il peut alors être mis à disposition à l'aide d'un outil OLAP(On Line Analytical Process).. .
- La fonction de présentation régit les conditions d'accès de l'utilisateur aux informations. Elle assure la prise en charge des requêtes, la visualisation des résultats le plus souvent sous forme de Tableaux de bord.
- La fonction administration, enfin, permet le pilotage du processus de mise à jour des données, la documentation sur les données (métadonnées), la sécurité, les sauvegardes et la gestion des incidents.

II Evolutions du concept BI

Historiquement le concept de BI, traduit couramment par l'appellation Informatique décisionnelle, a été introduit par Howard Dresner, expert du groupe Gartner, en 1989 : la livraison de l'information factuelle pour aider les gestionnaires à améliorer leur prise de décision. Une définition avec une portée restreinte axée sur les possibilités de traitement des données à l'aide des technologies informatiques, qui a été par la suite affinée et élargie. Liautaud B, et Hammond désignent la BI aux moyens, outils et méthodes qui permettent de collecter, consolider, modéliser et restituer les données, matérielles ou immatérielles, d'une entreprise en vue d'offrir une aide à la décision et de permettre à un décideur d'avoir une vue d'ensemble de l'activité visée".

Citant plusieurs auteurs, Olzak (2013) distingue, historiquement, une évolution en trois temps de la BI. Dans un premier temps, jusqu'en 1990, la BI dite1.0, s'est étroitement liée aux systèmes d'information de gestion (Management Information System), aux systèmes d'aide à la décision (Executive Information systems) et des systèmes d'aide à la décision (DSS).
La Business Intelligence telle qu'on la connaît aujourd'hui, a évolué à partir de la recherche opérationnelle qui a commencé dans les années 1960, suivie par la supervision (Decision Support Systems) dans les années 1970, l'aide à la décision dans les années 1980 (entrepôts de données, OLAP et BI). Focalisée sur la production de tableaux de bord périodiques et de reportings statiques écrits par des programmeurs experts, la BI 1.0 était orientée sur la 'livraison au consommateur', selon l'expression de Olzak'(2013).

L'essor connu par la fouille des données (data mining) dans les années 1990 a permis d'envisager une nouvelle ère de la BI. Le datamining étant considéré comme une partie intelligente de l'informatique décisionnelle, il a favorisé la délivrance d'informations analytiques permettant une meilleures compréhension de faits complexes, un développement des techniques de prévision associés à des outils BI robustes. Parallèlement, de nouveaux champs d'intérêt sont apparues pour gérer des systèmes BI plus complexes: intégration de données, gouvernance de données, qualité de données, services Web, SaaS.. Ces systèmes devenus complexes et lourds ont empêché une plus grande diffusion des outils BI 2.0. On leur reprochait notamment leur caractère peu intuitif et peu collaboratif.

A partir de 2005, on remarque une nouvelle évolution des outils de BI amenés à conjuguer avec le développement des réseaux sociaux, des données mobiles et du cloud. Une évolution qui exige des outils qui non seulement permettent de mieux prendre en compte les données peu ou non structurées mais qui répond au souci des utilisateurs qui souhaitent davantage de réactivité aux données. Il s'agit désormais de centrer la BI sur l'utilisateur-décideur : grâce à un accès rapide et convivial, à une meilleure visualisation des données et à l'affichage rapide d'indicateurs de performance. La nouvelle B.I 3.0 , désormais popularisée, doit faciliter la prise de décision instantanée et l'alerte en pseudo temps réel, à tous les niveaux de l'entreprise.

Iii Les Besoins Et Spécificités De La Bi Des Operateurs De Télécommunications

L'industrie de télécommunications produit et stocke une quantité énorme de données (*Gary , 2005).)*. Ces données incluent des données de détail d'appel (Call Detail Records ou CDR), qui décrivent les appels qui traversent le réseau de télécommunications, des données de réseau, qui décrivent l'état du matériel et des composants logiciels dans le réseau et des données clients, qui décrivent les clients de télécommunications.

La collecte et l'intégration de ces données au sein d'un entrepôt de données consolidés constitue de ce fait une exigence fondamentale pour assurer leur exploitation en soutien du système transactionnel d'une part et pour fournir une base fiable d'aide à la décision dans un contexte concurrentiel très mouvant, d'autre part.

En effet, au fur et à mesure de la diversification des produits et service offerts de plus en plus personnalisés, les entreprises de télécommunications ont été amenées à développer des systèmes de facturation complexes. Les besoins de discrimination tarifaire en lien avec les différents segments de clientèle visés ou en relation avec le besoin d'optimiser l'exploitation du réseau ont généré des systèmes de facturation spécifiques et nombreux. La fiabilité de ces systèmes de facturation et leur cohérence avec les CDR transmis par les antennes relais et collectées par des services de Médiation, sont justement assurées par la collecte et la confrontation de l'ensemble de ces données dans le DW.

Cette mission de "Revenue Assurance' visant un contrôle systématique en soutien du système transactionnel, ou OLTP. Les outils BI permettent également de satisfaire à un autre objectif, la lutte contre la fraude. En effet, les techniques frauduleuses utilisant des générateurs d'appels (SIM Boxing) ou des liaison voIP illégales en trafic international (by pass) permettent aux fraudeurs de bénéficier d'une gratuité de service dommageable aux opérateurs qui sont obligés de coordonner leurs actions dans ce sens.

Les autres sources classiques d'alimentation de l'entrepôt sont constituées par les applications ERP ou CRM. Les outils BI classiques (reportings, tableaux de bord) permettent notamment le suivi des ventes sur stock (smartphones, tablettes, cartes SIM..), de contrôler la gestion des abonnés et d'élaborer les indicateurs de suivi des demandes de services des clients. Mieux, le développement de la fouille de données et les techniques de segmentation client autorisent un meilleur ciblage des besoins clients et permettent aux services marketing la construction d'une offre de plus en plus personnalisée permettant de limiter le taux d'attrition ('churn') des clients ou d'en capter de nouveaux. Le système BI se charge également du scoring des clients, autorisant ainsi les clients les plus importants à bénéficier d'une qualité de services spécifique (rapidité de traitement au call center, offres personnalisées, Value Added Services spécifiques)..

Dans un rôle plus classique, la BI peut accélérer le reporting financier au service du contrôle de gestion de l'entreprise. Elargi aux ressources humaines, les outils BI peuvent autoriser un meilleur alignement de la politique de gestion des compétences sur les objectifs stratégiques de l'entreprise. les indicateurs clés de performance

IV Les Modèles De Maturité Des Systèmes De BI

Dans la littérature, il existe plusieurs définitions de maturité mais il n'y a pas une définition générale pour expliquer ce qu'est la maturité d'une organisation ou d'un projet. D'après Andersen (2003), la maturité est la « qualité ou l'état de devenir mûr ». Pour Kerzner (2003), la maturité est « liée au développement des systèmes et des processus répétitifs qui représentent une haute probabilité de succès d'un projet » .

La mesure de la maturité permet, elle, de « montrer l'état atteint par rapport à l'état dans lequel le projet devrait être », selon Cooke-Davies(2003).

Le concept de modèles de niveau de maturité s'est maintenant étendu à toute une variété de disciplines. Dans les systèmes d'information, les modèles de niveau de maturité sont utilisés pour décrire les cycles de vie et évaluer les normes de qualité. Les modèles de niveau de maturité contribuent donc à créer de la transparence concernant l'état actuel du marché ou permettent, en terme de référencement, des comparaisons avec d'autres entreprises du secteur ou du marché. Les modèles de niveau de maturité sont également utilisés pour identifier les implications stratégiques pour les futures actions potentielles en fonction de leur positionnement actuel dans le modèle (Rapport Steria, 2013).

Un des modèles les plus reconnus est le Modèle Gartner de Maturité BI et de Gestion de performance. La plupart des modèles usités sont généralement centrés objet, ou centrés sur les processus voire centré sur la composante humaine. Le modèle Gartner a l'avantage d'être un modèle mixte reliant les hommes, les processus et la technologie.
Une revue de la littérature relative aux modèles de maturité nous permet de savoir qu'aucun modèle seul n'a atteint l'état d'une norme, pour que des certifications soient disponibles, comme ceci est, par exemple, le cas avec CMMI, comme le précisent Lahramann et al. (2012). Certes, comme la majeure partie des modèles fournis par des professionnels, sa documentation reste sommaire, ses soubassements théoriques sont jugés faibles ,note Rajterič (2010) *qui* reste assez critique à cet égard. En contrepartie l'expérience de ses auteurs et sa référence aux meilleures pratiques sectorielles demeure assez pertinente.

Comme suggéré dans le titre, Modèle Gartner de Maturité BI et de gestion de performance évalue aussi bien la maturité des outils et technologies BI que leur intégration au service de l'amélioration de la performance des processus métier. Le modèle décrit une feuille de route pour les organisations qui veulent situer le niveau de développement de leurs choix managériaux transposés aux pratiques BI. Il fournit un chemin pour le progrès par lequel ils peuvent profiter d'initiatives BI. Le modèle Gartner (version 2010), reconnaît cinq niveaux de maturité: inconscient, Opportuniste, Normalisé, entreprise (stratégique) et transformant (pénétrant).

L'évaluation inclut trois zones clés: les ressources humaines, les processus et la technologie.

Le premier niveau est souvent décrit comme "l'anarchie de l'information". Cela signifie que les données sont incomplètes, incorrectes, incompatibles et l'organisation n'a pas la métrique définie. Les utilisations d'outils de reporting sont limitées.

Le deuxième niveau de maturité BI signifie que l'organisation commence à investir dans la BI. Le processus engagé soutient la prise de décisions tactique et stratégique. Les sponsors du projet BI relèvent de la plus haute direction.

Au dernier niveau de maturité, la BI pénétre tous les processus métiers. La culture d'entreprise aidant, la BI fournit la flexibilité pour s'adapter aux changements rapides de l'environnement et à la demande de l'information. Les utilisateurs ont accès aux informations et aux analyses nécessaires pour créer de la valeur et améliorer la performance. L'utilisation de la BI est même disponible pour des clients, des fournisseurs et d'autres parties prenantes. Le déplacement d'un niveau de maturité à un autre exige des changements de toutes les caractéristiques qui composent ces étapes (Hagerty et Hostmann, 2010).

Les domaines principaux d'évaluation concernent les ressources humaines, les compétences, les processus et les technologies. Les sous-domaines incluent les éléments de BI traditionnel (requêtes ad hoc, les rapports, OLAP, l'intégration de données, l'entrepôt de données) de même que les applications analytiques ainsi que les applications de gestion de la performance . Le modèle aborde également la confiance des parties prenantes dans le système d'information décisionnel, l'adaptabilité au changement de l'environnement des affaires et l'intégration des utilisateurs externes au développement de la BI comme les fournisseurs, associés et clients. (Hagerty et Hostmann, 2010).

Tableau 1: Vue générale des niveaux de maturité du Modèle Gartner

Niveau	**Ressources Humaines**	**Processus**	**Métriques et technologie**
Inconscient	Les utilisateurs ne connaissent ni leur propre exigences en terme de données ni comment les utiliser	Les utilisateurs ne connaissent pas les processus métier. Les données sont de mauvaise qualité.	Manque de matériels et logiciels appropriés ; Les métriques ne sont pas définies ; l'utilisation du reporting est limitée.
Tactique	Les utilisateurs prennent les premières initiatives BI. Soutien fiable des cadres supérieurs.	Identification des processus métier de base.	Des « entrepôt de données » régionaux sont mis en place. Analyse des tendances et des données anciennes. Premiers outils interactifs de « reporting ». Les métriques sont souvent utilisées au niveau département seulement.
Facteurs de succès : support pour les cadres supérieurs, outils BI appropriés, qualité des données, métriques et processus métier définis.			
Normalisé	Les utilisateurs essayent d'optimiser l'efficacité des différents départements en utilisant la composante BI	Standardisation des processus métiers et élaboration des meilleures pratiques en BI	Des tableaux de bord de gestion sont utilisés; des « entrepôts de données » centralisées sont mis en place; ad hoc« reporting », Drill-down
Facteurs de succès : Le développement de la culture d'entreprise est basé sur des faits, exposant clairement la stratégie BI, mettant en œuvre le système d'apprentissage sur BI			
Entreprise (Stratégique)	Les utilisateurs ont de hautes capacités BI mais	Gestion de processus métiers basée sur des	Données de haute qualité ; ont une stratégie

	souvent non alignées avec leur rôles et responsabilités	faits	BI ; utilisant la prédiction et des outils de modélisation plus complexes ; fouille de données
Facteurs de succès : Soutien du DG, motivation des utilisateurs à collecter, analyser et utiliser l'information			
Transformant (pénétrant)	Les utilisateurs ont les moyens et le temps pour utiliser BI; formation qualifiante en BI ; les utilisateurs sont encouragés pour collecter, analyser et partager l'information; Enthousiasme du DG et large engagement de la direction	Largement supporté, esprit orienté processus Basé sur : les faits, l'apprentissage et le partage de Connaissance	Large architecture BI d'entreprise en grande partie implémentée; Rapports Personnalisés; BI et processus métier sont alignés et coopératifs
Facteurs de succès : soutien important de la part du PDG, bonne gouvernance des ressources humaines, les différents utilisateurs ont confiance en BI			

V Etude du cas des opérateurs de Télécommunications

1-Méthodologie de Conduite de l'étude

L'étude a touché l'ensemble des trois opérateurs de télécommunications. Des entretiens en profondeur ont été réalisés avec les premiers responsables des départements BI , des hauts cadres relevant de la direction Système d'Information (DSI) ou des services utilisateurs. Nous avons confectionné un guide d'entretien standard récapitulant les principales questions de recherche. La standardisation des instruments de recueil des données est nécessaire pour appuyer la validité, la généralisabilité et la maniabilité interne des résultats de l'étude multi-cas (Miles et Huberman 2000). Pour englober les différents points de vue, nous avons à chaque fois interviewé séparément des informaticiens et des opérationnels impliqués dans la prise de décision.

2-Présentation des Résultats

Avant de présenter les conclusions de l'étude, il y a lieu d'apporter certains éléments d'informations pertinents pour mieux comprendre l'environnement des départements BI au sein des opérateurs de télécommunications opérant en Tunisie.

- La création et par la suite le développement des départements BI au sein des DSI des nouveaux opérateurs de télécommunications s'est fait naturellement dès leur implantation sur le marché. Le transfert de technologie lié à leur appartenance à un groupe international spécialisé dans les télécommunications a largement facilité l'acquisition de savoir faire. L'opérateur historique, qui s'est lui aussi associé à des bailleurs de fonds étrangers, a créé ce département depuis 8 ans.

- Les moyens budgétaires alloués aux départements BI des trois opérateurs sont très disparates (variant de 0,3 à 2,5 M$), leur part dans le budget informatique de l'opérateur est néanmoins plus stable autour de 15%.

- Le marché des télécommunications qui connait une explosion du marché des smartphones vient de bénéficier du lancement de la 4G. L'opérateur dominant sur le marché du GSM, n'est pas présent sur le marché de la téléphonie fixe, largement dominé par l'opérateur historique. Le marché du GSM arrive à maturation avec un taux d'équipement qui dépasse 130%, il fait l'objet d'une forte concurrence tirant les prix vers le bas.

- L'instance nationale des télécommunications, instance de supervision légale du secteur, vient d'imposer le régimes de portabilité des numéros pour la téléphonie fixe et mobile. Ceci va encore libéraliser le marché et induire une plus grande volatilité des clients.

Ceci dit, le traitement des informations collectées nous a permis, au regard du modèle de Gartner, de positionner chacun des opérateurs de télécommunications sur trois niveaux différents, soit les trois niveaux 3, 4 et 5. Cette analyse peut être compartimentée sur les trois rubriques suivantes:

a/ Aspects Humains

Acquisition et développement des compétences: Il est important de signaler que le processus de mise en place des entrepôts de données et autres solutions de data-mining correspondante s'est fait différemment d'un opérateur à l'autre, intégrant de façon disparate, l'apport des consultants extérieurs. Il s'ensuit que l'acquisition de savoir faire et le développement des compétences se sont produits de façon différentes. Entre une équipe restreinte exigeant des compétences polyvalentes et un département, cinq fois plus étoffé, impliquant spécialisation des membres, les stratégies, la durée d'apprentissage et les besoins de formation sont très différents. Ces projets étant assez anciens, le personnel étant recruté auprès des meilleures écoles d'ingénieurs en informatique, il n'existe pas à priori de problèmes de compétences.

Compétences transversales et formation: La nature transversale de la BI nécessite de la part de l'équipe BI une parfaite connaissance des processus métier. Elle permet de ce fait à l'équipe BI de mieux cerner la demande de son client et donc de mieux utiliser le référentiel de données de l'entreprise. Ceci est particulièrement valable dans le cas de la conception des campagnes publicitaires ou la formulation d'une nouvelle offre commerciale ciblant une catégorie particulière de consommateurs. cela nous ramène sur le concept de segmentation basé sur des méthodes de classification hiérarchique connues par les statisticiens ou marketeurs. L'utilisation de ces techniques de data mining pour éviter le 'churn' des clients constitue un axe stratégique pour les opérateurs de télécommunications. Les opérateurs leaders sur le marché qui ont investi en formation ont vu leur investissement rentabilisé. I L'expertise cumulée à ce niveau a permis à certains opérateurs d'enregistrer des succès et de capitaliser de nouvelles compétences qu'il s'agit de préserver. Le faible turn-over des équipes BI constitue un signe de valorisation des ressources humaines par ces opérateurs.

b/ Aspects liés aux Processus

Processus d'amélioration continue: Les outils d'évaluation et de mesure du taux d'utilisation des solutions BI doit être prévu en accompagnement du projet BI. Il est curieux que le département BI qui communique aux processus métier l'évolution de leur indicateurs clés de performance, n'en dispose pas. Si l'on peut, à la limite comprendre cette faille pour les opérateurs classés au niveau de maturité 3, compte tenu du faible investissement effectué, on ne peut l'admettre pour les autres opérateurs.

Collaboration avec les processus Métier: Les projets BI sont en théorie des projets communs entre les DSI et les processus métier cibles. Le degré de collaboration entre les deux dépend de l'urgence et de l'importance des données fournies à la prise de décision. Si l'apport d'un datwarehouse dans la fiabilité du processus de facturation et des outils BI dans le recoupement des informations comptables enregistrées dans les ERP et applications ad-hoc sont fondamentaux pour garantir la qualité des états financiers et la rapidité de leur élaboration, ceci n'apporte pas forcément une grande marge de progression dans la prise de décision. Par contre, les divisions marketing, soumises à une concurrence acharnée, trouvent dans les outils BI, toute l'information dont ils ont besoin pour assurer l'alimentation de son système de veille. On comprend dès lors quels processus métiers sont plus motivés que les autres à mener des projets communs avec le département BI.

Appropriation par les utilisateurs: Le nombre de reportings standards livrés chaque jour varie suivant les opérateurs dans des proportions variant de 1 à 22,5. Le niveau d'exploitation de ces rapports est variable, il est estimé par certains opérateurs à 40%. l'appropriation des solutions BI passe par une stratégie de communication interne et une méthodologie forte de conduite de changement auxquelles les départements BI doivent être partie prenante.

c/ Aspects Technologiques

Infrastructure: Les opérateurs les plus matures ont atteint un volume tellement important atteignant 9000 reportings et tableaux de bord quotidiens. Un volume qui nécessite des investissements couteux qui limitent le choix des solutions de plateforme BI aux éditeurs les plus performants. Le choix des éditeurs et les conditions d'achat sont généralement négociés au niveau du groupe auquel appartient l'opérateur de télécommunications. Bien que coûteuse, cette option offre la garantie de la prestation efficace et efficiente des services nécessaires (en particulier ressources externes, licences, matériel) pour le développement et l'exploitation des applications de la BI.

Architecture des entrepôts de données: Les réseaux de télécommunication et commutateurs associés, systèmes de facturation et les services d'entretien produisent typiquement plus de 100M CDRs par jour. L'analyse complexe des données historiques combinées de ces sources oriente les activités de gestion de la relation client, l'assurance de revenu, la prévention de fraude et les programmes de reportings opérationnels. Le stockage et l'accès à toutes ces données est certes important mais techniquement coûteux. Le choix d'échantillonner et résumer les CDRs comporte des risques de changement dans les modèles d'appel ou dans les relations entre les données (Kumar,2012), il passe par une maitrise des techniques de l'intégration et la consolidation des données, que l'ensemble des opérateurs semble avoir atteint.

Qualité des données: La qualité des données est un sujet très sensible tout comme leur fiabilité , cohérence et leur consolidation. Ces risques augmentent chaque fois que l'on augmente le nombre de canaux sources et la variété d'informations peu ou non structurées. Les opérateurs de télécommunications ont choisi comme principe la mise en œuvre d'un environnement d'entreposage de données central, consolidé et évolutif qui est idéalement sur le concept d'entrepôt de données d'entreprise. Pour garantir la transparence des données, des tâches transversales (telles que la gestion de la qualité des données et des métadonnées et la gestion des données de base) sont professionnalisées .

OLAP et Tableaux de Bord : La personnalisation des reportings et tableaux de bord semble facilitée par l'émergence d'outils de visualisation interactifs, qui offrent aussi l'avantage de fonctionner In memory, ce qui permet de pallier au problème de volume de données(14). Cette technologie repose principalement sur le stockage des informations en mémoire vive, et prend en compte les avancées technologiques au niveau matériel et logiciel.

BI en pseudo temps réel: L'importance des enjeux financiers dans le secteur des télécommunications impose aux preneurs de décision un suivi régulier des paramètres et indicateurs de performance. A défaut de faire de la BI en temps réel, compte tenu du volume des données gérées, le reporting se fait de façon journalière. La fréquence avec laquelle les informations sont transmises aux utilisateurs a fait dire à un responsable du département BI, *" Aujourd'hui on ne fait pratiquement plus de distinction entre système d'information décisionnel et transactionnel"*.

Conclusion

L'utilisation des modèles de maturité pour évaluer les systèmes de BI au niveau des entreprises, n'est pas une fin en soi. Il s'agit en effet d'un outil diagnostic qui permet de saisir la qualité et la flexibilité de l'architecture de la solution d'entreposage des données adoptée et d'identifier les axes d'amélioration et de développement mais également de vérifier dans notre cas, la fluidité de la relation Equipe BI-Métiers à même de garantir une réelle mise à profit au service de la performance. Cet aspect lié à la qualité des sponsors de la BI, à une conscience collective des exigences d'un alignement de la BI sur les objectifs et stratégie de l'entreprise, met en valeur l'importance d'une culture d'entreprise favorable à ce type de projet pour qu'il soit réellement stratégique.

La complétude du projet BI au regard des modèles de maturité s'apprécie également par sa capacité à fournir un retour sur investissement favorable. Nous avons remarqué une certaine prise de conscience chez certains opérateurs de la nécessité d'encadrer les dépenses évoquant justement l'aspect de rentabilité. Même si la question est épineuse et que les aspects immatériels restent toujours difficiles à

quantifier, il y a toujours lieu de s'interroger sur la performance du projet BI à travers des indicateurs clés de performance adaptés.

Notons que le classement que nous avons opéré pouvait être différent si l'on avait adoptés d'autres modèles moins centrés sur l'aspect humain ou sur la culture d'entreprise. Par ailleurs les entreprises de télécommunications ayant atteint le stade ultime de maturité encourent le risque de noyer les utilisateurs dans un flot d'informations ingérable. Une BI en temps réel risque d'occasionner un couplage trop fort avec les systèmes d'information opérationnels avec des décisions de court terme qui sont alors privilégiées au détriment des décisions de long terme, comme confirmé par Marsal et Travaillé (2006).

Ce papier aura enfin servi à mieux comprendre les enjeux BI des opérateurs de télécommunications et mis en évidence le chemin qui reste à parcourir pour des opérateurs davantage freinés par l'aversion au changement organisationnel et culturel que par une technologie de plus en plus accessible et conviviale.

BPMN as a Quality Tool for the Efficient Functioning of the Company

Jan Nisler, Faculty of Informatics and Management, University of Hradec Kralove, Hradec Kralove, Czech Republic, jan.nisler@uhk.cz

Hana Tomaskova, Faculty of Informatics and Management, University of Hradec Kralove, Hradec Kralove, Czech Republic, hana.tomaskova@uhk.cz

Abstract

Today's companies are trying to make the most efficient operation possible. To optimize the company is necessary to know the complex firm functioning - ie corporate/business processes. Using the UML (Unified Modeling Language) or BPMN (Business Process Model and Notation) syntax, complex diagrams and methodologies are created to make the best use of these syntax. This article introduces this useful notation from its inception to the present and points to some problematic aspects of its use.

Keywords: BPMN, UML, History, methodology, syntax, workflow patterns

Introduction

The non-profit group BPMI was the founder of the BPMN(Barry, 2005; Rouse, 2005). Since the start of its existence in 2000, this group has sought to promote the business processes standardization as a means of supporting B2B development. The group was created by 16 e-business leaders such as Black Pearl, Blaze Software, Bowstreet, Entricom and others. In addition, the group grew to include more than 80 companies involved in the development of such an auxiliary concept. As sub-objectives, they set out: to promote and develop the use of BPM by creating standards for process design, deployment, implementation, maintenance, and optimization. BPMI wanted the whole process to be easier and more efficient for businesses in the global marketplace. At the time of the emergence of e-business, it reflected the unconventional ways in which business processes operate within the organization. There are several terms for the same item, each department uses a different process that should be uniform. The overall goal was to overcome these problems and create a standard to communicate, share data and applications more effectively. The concept itself contains three main components, namely the public interface and two private implementations. The public interface (two business partner interactions) is supported by protocols linked, such as BizTalk, ebXML, and RosettaNet. Other models are private, which are specific to each partner. The concept, however, was to build these private models into a common language that would define the same rules for each partner. This puts the first basics of BPML, which is a language based on XML syntax, so the language can be used to model enterprise data components. The associated language that held the questioner role was BPQL, and was the standard for management, and it was used to deploy and run defined business processes. These languages were open specifications, and anyone could download them from the official BPMI site. It was, however, necessary to present these languages in a single, graspable form that everyone would understand.

BPML

In order to understand what BPMN is and why this syntax is created, it is good to look at what this notation represents. According to the official BPMI 2002 source (BPMI.org, 2002) it is a methodology for modeling business processes and business data. Provides an abstract model of collaboration and transactional business processes. The ability of BPML is intended for mission-critical applications so that it supports synchronous and asynchronous distributed transactions. It offers a reliable security mechanism, it is used in integrated development environments, managing the home design and business

process models over the Internet (Wong & Gibbons, 2011). BPML also has an associated business query language to implement business processes (Dubray, 2002) (BPMI.org, 2004).

Another explanation from the article (Assaf & Intalio, 2002) can be: BPML usually defines the abstract model used to express the general procedure. Such a language can be used to define business processes, complex web services, and pluralism. The basic parts that make BPML are abstract BPML XML syntax constructs and BPML specifications that are Namespace, Features, Imports, Target namespace. BPML activities perform specific functions and are either simple or complex. Simple actions, such as call, compensation, etc, cannot be decomposed and it performs a single operation. Complex activities are all sequences, switches and so on. They consist of one or more activities and manage the performance of a certain activity through a set of activities.

First mentions and ideas of BPMN

The BPMI's notation for BPML's graphical representation was BPMN, and as is shown by the paper (BPMI.org, 2002) aims to: Provide a notation that is easy and understandable for all business users. From the business analyst who creates the initial process design to the technical developer responsible for implementing the technology that will perform these processes. So BPMN creates a bridge that overcomes the gap between process analysis and process implementation. Sometimes, however, there is a problem with the process timing (Wong & Gibbons, 2009) Another goal is that XML-based languages (BPEL4WS and BMPL (BPMI.org, 2002, 2004; Dubray, 2002)) can be formulated visually using one standard.

Furthermore, BPMN (BPMI.org, 2002) describes that the concept will be modeled in a business process diagram (BPD), where the individual elements (objects) will be linked and will be created using sequential, parallel or alternative paths. The BPMN concept must be clear and comprehensible to all users, but also complex enough to cover all possible processes that will be modeled today or in the future. As the authors (Mohelska & Tomaskova, 2010, Tomaskova, 2009) have said, understanding and modeling of business processes and knowledge are very important.

Workflow Patterns

In this document (Aalst, Barros, Hofstede, & Kiepuszewski, 2000), there are already formulations of the individual elements that are used in the BPMN syntax. At this stage of development, basic elements have been created, where for example interrupted and noninterrupted events have not yet been taken into account. This is understandable because the document is routed to BPMN 0.9 (BPMI.org, 2002) and some of the things that are widely used today are only in BPMN 2.0 (OMG.org, 2011). However, already in this version, the first version of the design templates, which was in the initial document of about 10 in the document (Biernacki, 2012), is now defined, but it can be assumed that the group wanted to use the syntax of Getting Started Standards and model it in the same or similar style. The group did not think of a completely new way of thinking but wanted to adopt rules and define how to model, create something new. Therefore, it has only created a graphical concept for modeling, maintenance, and business process innovation, for which the definition was established in the past years before BPMI was created. However, workflow patterns were defined in the 1990s as described by the Eindhoven University teacher, as documented in the "Advanced Workflow Patterns" (Aalst et al., 2000). Another 2002 paper from the same university entitled "Work patterns" (Aalst, Hofstede, Kiepuszewski, & Barros, 2003) is described in detail in 20 workflow patterns currently in use.

The Idea of BPMN

The primary language for this notation was BPEL4WS and BPML(Aalst et al., 2003; BPMI.org, 2004; Dubray, 2002), so BPMN will only apply to these languages. Aalst (Aalst et al., 2003) said that it is difficult to predict which mapping will be preferred by BPMN because the language specification is a volatile area. As another essential information that every "system architect" should realize is that the BPD is not designed to graphically pass on all the required information about running the business processes. Excessive detail in modeling leads to chaos, and its initial description lacks sense and is therefore unusable.

What versions we have (White, 2012) :

BPMN 1.x

- May 2004, version 1.0 was introduced
- In January 2008, following the merger with the OMG Group in 2006, version 1.1 (BPMI.org, 2002)outlined some errors that were in version 1.0 .
- Year later was released the version 1.2 (OMG.org, 2009), which was only a look at version 1.1, only minor bugs that were not created in the previous version and modified.

BPMN 2.X

- January 2011, version 2.0 was created (OMG.org, 2011), which changed the concept of previous versions. This version is also seen as a turning point when this concept was an increased interest in its diverse expressions of situations. The former leader of this concept was more of a diagram in the UML syntax. Although some authors think that the concept of UML with charting activities is better than BPMN. It is rather the opposite. Many ideas and articles have already been created on this subject that does not agree with this conclusion. A number of diploma theses have been developed on campus, which is just addressing the difference between the UML Activity Diagram and the BPMN. For example, you can read that these syntaxes are aligned, but some processes do not represent their complexity using UML.
- The latest version, which was so far presented to the public, was 2012 version 2.0.2 (OMG.org, 2014)

So, What Exactly Will BPMN Look Like?

BPMN will show the processes of each participant, each participant can view the scheme differently. This means participants have different angles of view on how these processes will behave. These processes may be for the participant by an internal process, that is, a process that is related to the participant), or these processes will be external, that is, when the participant will be present as a mere user. Therefore, each participant will have a different perspective on how to look at all processes with regard to internal and external processes. This is another aspect of the participant's view, but the diagram, model or process itself remains the same. Although the chart itself is very important to the viewer in order for the viewer to understand the process, BPMN will not currently support (version 0.9) (BPMI.org, 2002)to identify any mechanism that will determine what the view is. At present, BPMN is already different in terms of processes (OMG.org, 2011, 2014). BPMN is divided into several kinds of diagrams, each of them representing a different view of processes). The concept is open to modelers, but can also be utilized (and recommended) as a suitable help for vendors who can mold their processes into a visual page to better outline and characterize their processes to customers.

In the other parts of this paper, the individual elements are described as they were used. Interestingly, the descriptions contained in this document are still being used and have been changed only on a small or no scale. So even after the merger of the BPMI group with OMG, a similar terminology was used before.

At the beginning, the intention was also set out by the founders:

„BPMN will give businesses the ability to understand their internal and external business practices with graphical notation and will give organizations the ability to communicate with this syntax with others.“

And though many users were down with this concept, many were dissatisfied with the version, because some procedures could not be modeled and a more complex solution could not be rendered.

Several years since its inception (10 years), the BPMN syntax is already used as a standard without which it can not exist. In 2012, 45 firms that have still used BPMN version 1.X and 25 companies have fully switched to BPMN 2.0 (White, 2012). Although this information is based only on presentations, this author, S. White, has published many publications that are valuable and highly valued. As is the case in 2016, it is not yet known, but thanks to the openness of the syntax, several thousand end-users are already in line.

If we were to define whether their target had been fulfilled, we must say that BPMN has grown and other diagrams have been created that further deepen their importance for companies. Internal processes have become more controlled normative types, and external processes are modeled through newly created diagrams (2012) Collaboration, Conversation and Choreography (OMG.org, 2014). Unfortunately, at the moment, it also depends on the type of tool we model. We can not model using a tool that does not fully support the BPMN syntax, or which partially changes it for its use. Although this syntax is loose, the basic rules that follow will apply. However, we can say that BPMN has evolved into a concept that is also used to model organizational processes. Thus, the manager uses this notation more, and when a crisis situation occurs or when a culprit is sought for a possible failure, by modeling processes, for example in manufacturing, he knows what kind of person or activity could cause the problem.

In addition, the new elements that were added to the syntax in version 2.0, such as ad-hoc, which is described here as a badly named element, are described. In the document, we can also read that the BPMN notation itself has made many changes on the market. End-users have realized the potential of this syntax, as evidenced by the fact that only in 2012 was 70 independent tools (White, 2012) that supported this syntax to create the appropriate modeling environment for this concept. However, it demonstrates that the syntax will constantly evolve, like everything else. For modeling, and while version 2.0.2 (OMG.org, 2014) is already well equipped and provides a good user experience for the user, there are still many places where imagination needs to be used and a bit of abuse of notation rules to map the situation. So the syntax bends and is not used correctly. Although the notation is free and our imagination is necessary.

But what will they do next years for BPMN syntax? Today, we also have the ISO code for ISO / IEC 19510: 2013 (OMG.org, 2013), so we have to stick to certain rules to make it clear and clear. The notation will definitely evolve, but we too can be well-behaved and properly modeled by end users, we will need to constantly evolve, so we need to develop more sophisticated methodologies to model. This is very necessary in today's world. Every company modeling itself, but what we really need as a user is a methodology, unified and clear. Unfortunately, companies will never publish it because they are their know-how, and such knowledge is valued by gold. Here I see the possibility of universities and subsidy frames, when higher education institutions may be holders of these methodologies. In the past, it has proven to be a workflow pattern. Such a methodology would be highly valued and the founder will be recognized.

What Problems Can Occur When Defining BPMN Methodologies?

In a practical world, using the BPMN syntax to model business processes, the given syntax must be used according to the rules that are defined.

The question, however, is according to which methodologists should lead the modeler when there is no continuous methodology of using the given syntax. Although the BPMN syntax or other modeling tools are taught in schools, they do not teach the methodological part of this syntax. We have a free syntax that allows us to model complex diagrams and involve the given activities in status and type models, but we do not have a uniform modeling approach. The BPMN syntax gives defined elements for modeling, but it does not tell us how to proceed uniformly in process modeling. At this point, we do not have to worry about this problem, however, until we discuss this model with another company using BPMN. One company creates a model according to its own methodologies and the other according to its own. However, each company uses a different approach, and can not lean on the definition of a methodology. This creates disparate methodologies that only one company understands. There is a misunderstanding between companies. The definition of one methodology is not easy as the BPMN syntax is very extensive and provides modelers with over 100 modeling elements. When examining individual elements, some vague elements also come to light. It is thanks to these elements that different understandings of the modeling are made using syntax, and it is good to create a clear definition of these elements in order to avoid undesirable understanding. These aspects then lead to the unambiguous creation of methodologies that the modeling world would combine. When we talk about an exclusive gateway, there is still a question of the openness and closeness of this element. When we consider the side to which we are inclined is not such a difficult question. For example, see Figure 1 : Unification of **Activities**. When we have this example:

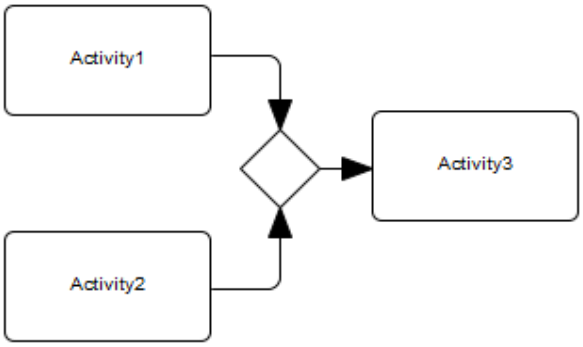

Figure 1 : Unification of Activities

1. Under the closed gateway condition. So when the flow passes, the element is closed, this example is clear. When one of the activities 1 and 2 is complete, the flow runs through the exclusive gateway to activity 3. The exclusive gateway is closed so that the flow from the second activity that is completed stops in the exclusive gateway.
2. In the second case, when we think that an exclusive gateway is open, this example is interpreted differently. When the first token goes to the gateway, it continues to activity3, because there is no condition in the gateway and the flow continues according to the flow direction. However, the second stream also passes through this gateway because the gateway is open. So, the flow that happens as a second goes into activity 3. We can compare it with the example where activity 1 goes flowing to Activity 3 and Activity 2 goes straight to Activity3 as in Figure 2- Direct unification of activities.

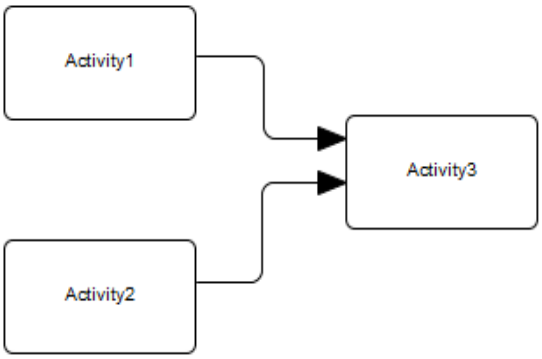

Figure 2: Direct unification of activities

Direct unification of activities

This example is one of many that can be addressed using an exclusive open or closed gateway. Solving this problem can be a problem. To avoid having to deal with this case, when the gateway is open or closed, it is better to use a different gateway that specializes in unification or distribution of a given stream. This element is a complex gateway, in which we can define how many flows must come to the gateway in order to unify the flow and move on. But to determine if this solution is correct, we must go through all cases of using the gateway exclusively and resolve the issue of openness and closeness of this element.

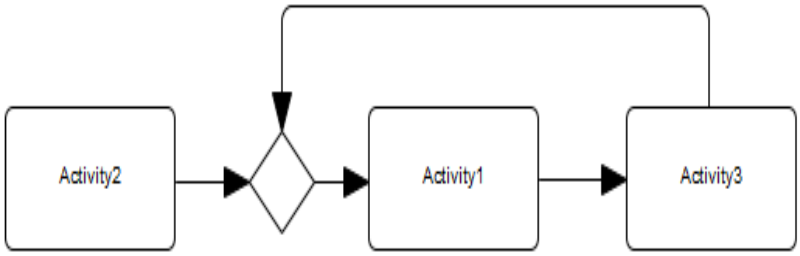

Figure 3: Repetition

Another example of the openness and closeness of the exclusive gateway is the repetition step.

> This is an example when the activity returns the flow back to a certain point in the process. The flow is linked to the exclusive gateway, which is solved here as open. In dismantling these two situations, namely Figure 1 : Unification of **Activities** and Figure 3: **Repetition**, we can see exactly the same situation. There are two flows at a given gateway at different times, and the flow passes through the gateway to the next element. This flow is in the same mixture. Therefore, there are the same rules as in the previous example, with no complex gateway here. So, from the first example, we get the solution that instead of the exclusive gateway you can use the complex diagram. However, in the second example, we must already take that complex diagram as unnecessary, since we are taking the exclusive gateway here. In this case, it is better to take the given exclusive gateway as open and we have everything well mapped. When analyzing the results, it is clear that a closed exclusive gateway is not needed, as it can be replaced by a complex gateway with the same result. This conclusion is based on these most common examples.

Conclusion

The BPMN syntax has been in the enterprise world for over 16 years, and for system development, system awareness is a relevant helper. But some aspects of this syntax have to be defined. It is necessary to define a unified methodology that would clearly determine how the object world is to be modeled. Unless problems are solved, methodologies will be developed that approximate the same subject matter, but each of them will solve the problem in its own way and will not take into account the wider framework of the methodology at all. It is not easy to define a uniform methodology because everyone understands this syntax in your own way, it is necessary to stop this uncontrolled syntax transformation. Although it is not possible to model all the elements in a single diagram, it is necessary for modelers to have subconscious definitions of the individual elements and situations that may occur. Unfortunately, all the syntax questions are not answered. Therefore, it is necessary to focus more on the issue of the global methodology.

Abstract

Technological development has been moving too fast and is becoming unpredictable day by day. The new era that human race has been experiencing with the powerful use of IT tools is yet to reform itself into something bigger than it used to be in the past. Internet of things enabled cities to get more connected to deliver the optimum value to their citizens by adopting "Smart Cities" concept. However, at the same time, it introduced several challenges that this paper has covered by studying a given set of literatures to produce a list of common challenges; which have been divided into two categories: technical and non-technical.

Keywords: IT, Smart cities, Challenges, Internet of things, Literature review

1. Introduction

Cities are the main poles of human and economic activity, more than 50% of the world's population today live in urban areas. An increase is expected because of population migration to these regions to make lives of citizens better. Urban areas need to manage their development, supporting economic competitiveness, while enhancing social cohesion, environmental sustainability and an increased quality of life of their citizens (*Monzon, 2015*). With the development of new technological innovations smart cities concept emerged as a means to achieve more efficient and sustainable cities. Smart cities consists of set of systems and solutions that are used to build, or rebuild, a more sustainable city by utilizing resources and available data in intelligent ways to make living for citizens better (*Ferraz, 2014*).

Smart city concept brings new challenges that are directly related to the concepts and structures of a city (*Ferraz, 2014*). These cities are developing themselves for attractive lifestyle like cultural and natural amenities, knowledge infrastructure like universities and businesses and technologies like sensors, mobile technologies and Internet of things (IoT) (*Bajracharya et al., 2014*). It is necessary to get a comprehensive overview of the Challenges that Smart Cities can face. There are multiple challenges that need to be studied before implementation a smart city." From technical infrastructure, that needs to be put in place, to adaption of system by citizens various technical and non-technical obstacles are to be dealt with" (*Bawanya and Shamsi, 2015*).

The purpose of this paper is to identify the key challenges in smart cities based on the review of literature on smart cities. The structure of this paper consists of four main sections: the definition of smart city, the methodology used to write the paper, a discussion about the technical and non-technical challenges, and at the end the conclusion with given recommendations are provided.

2. Research Question

Many of smart city research studies have determined several key challenges while implementing smart city as shown in table 1 (Findings section). These studies, however, discuss the key challenges from different perspective.

The aim of this study is to define the common challenges which may face cities while developing a smart city concept according to the given recent publications from year 2011 to 2017. The intended outcomes of this study are preliminary as it is a subset of bigger scope. Those results will be mapped to a specific geographical area (Sultanate of Oman) at later stage by conducting a field work and further analysis in order to predict challenges that could be faced by the upcoming national projects in this domain and provide proactive solutions and a list of recommendations.

3. Smart City Definition

There is no single definition for smart cities. As the concept is being known on the whole but used everywhere in the world with different names and in different circumstances, there are many conceptual variants generated by replacing the word smart with other alternative adjectives (*Nam and Tpardo, 2011*). In what follows, a few such definitions are given, originating from different papers.

According to Cassandras (2016), smart cities use information and communication technologies (ICT) to be more smart and active in the use of resources. This leads to saving costs and energy, improved service delivery and quality of life. Smart cities are able to take advantages from ICT implementation to growth efficiency in city's activities (*Arman et al., 2015*).

Furthermore a smart city is implements solutions by support of devices and interconnection of sensors, actuators, and mobile devices (*Novotny and Kadlec, 2014*). Moreover, it's the city that monitors and integrates of all of its critical infrastructures including roads, bridges, tunnels, rails, subways, airports, seaports, communications, water, and power (*Ermia et al., 2017*).

A smart city is all about connecting both of physical infrastructure, IT infrastructure, social infrastructure, and business infrastructure to leverage the collective intelligence of the city (*Chourabi et al., 2012*). However, Cocchia (2012) says "Smart city is the product of digital city combined with the Internet of Things".

On the other hand, Meijer (2015) defined smart city as a city which use smart computing devices to make the critical infrastructure and services of cities, which includes city administration, education, healthcare, public safety, real estate, transportation, and services more intelligent and efficient.

4. Research Design and Methodology

This study is a review of literatures on smart city. We decided to focus our study on papers that discuss the smart city challenges. Those papers are published in google scholar, Science Direct, Sparing, IEEE and Communications of the ACM journals and databases. The follow diagram illustrates the methodology used for literature review in this research. First, the main key words used for searching literatures are: smart city, challenges, and literature review. Second, the authors have collected research papers from multiple resources.

The authors considered all papers that were published for time period from 2011 to 2017. Forty nine research papers were collected and filtered. Out of those papers, twenty nine research papers were analyzed and used as references to obtain the required information. On this paper the authors summarized the definition of smart city based on information provided by eleven papers. Finally, the authors elicited challenges of smart city that were discussed in eighteen papers. The results were categorized into two

different categories: Technical and Non-Technical. Each category consisted of a number of sub-categories that have been studied further to generate the final conclusion.

5. Results

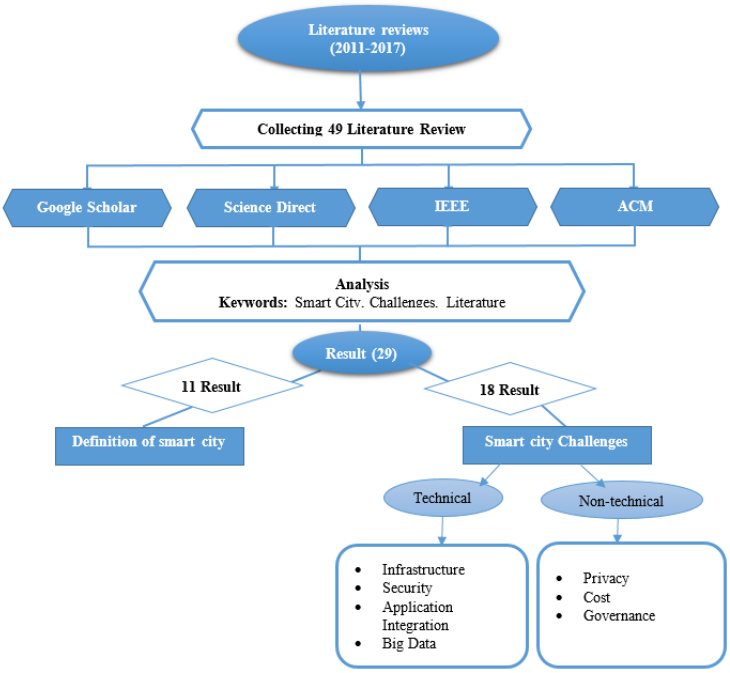

Figure 1: Methodology Structure

In this section, the eighteen selected papers are analyzed in order to define the key challenges for smart city implementation. These challenges classified into two sections: technical and non-technical challenges each sub-domain. In the following, each of these seven sub-domains are discussed.

5.1.Technical Challenges

Intuitively, smart city development is an attempt to integrate innovation in the city. Incorporating innovations in the city's infrastructure causes many challenges. In the following subsections, these technical challenges are identified.

5.1.1. IT Infrastructure

The smart city infrastructure is the introductory step for establishing the overall smart city framework and architecture. ICT infrastructure development in the physical space constitutes a huge barrier while applying smart city. Besides, reliable, scalable and high-speed network connectivity and infrastructure are the key fundamentals of integrating information systems in cities and this has to be ready before smart city is presented to citizens (*Bawany and Shamsi, 2015*).

Moreover, Raaijen (2017) noted that ICT infrastructure will connect a collective representation of interconnected smart devices which have to re-configure themselves through learning. Also, these smart devices depend on the vast of infrastructure in order to communicate with each other and the challenge is to create a flexible communication interface.

Table 1: Smart City Challenges

No.	Relevant Study	Technical Challenge				Non-Technical Challenge		
		IT infrastructure	Security	Applications Integration	Big data	Privacy	Cost	Governance
1	AlDairi & Tawalbeh (2017)		✓			✓		
2	Baig et al. (2017)		✓					
3	Mohammadi (2017)		✓		✓	✓		
4	Raaijen (2017)			✓				✓

16	Ferraz & Guimarães (2014)		✓					
17	Elmaghraby (2013)		✓			✓		
18	Chourabi et al. (2012)							✓

4.1.2 Security

Recent, concerns over security have been an important part of the debate over the impact of smart cities and smart grids (*Elmaghraby, 2013*). Furthermore, various risks face the cyber-physical infrastructure used in smart city. However, these modern cyber-physical infrastructure systems are massively used and there is no sufficient insight for their vulnerabilities and threats. Generally, accidental threats on cyber-infrastructure for smart city cause serious consequences according to city's maturity and smartness (*AlDairi and Tawalbeh, 2017*). Bawany and Shamsi (2015) mentioned that threats from hackers, intruders, viruses, worms, Trojans etc. has the potential to disrupt and interrupt the services and bring down the whole system resulting in enormous losses. For example, transportation management systems face the most critical hacks and threats as they cause disasters, especially in air traffic systems or trains control systems. Furthermore, they cause huge traffic damage that may stay for hours by attacking control systems of traffic lights and their sequencing, road signs and speed limit signs (*AlDairi and Tawalbeh, 2017*).

Bawany and Shamsi (2015) insisted that an extended security approaches required to secure sensitive data at all levels of collecting, processing, storing and disseminating. It needs international collaboration, which includes experts from all over the world (*AlDairi and Tawalbeh, 2017*).

4.1.3 Applications Integration

The Smart cities vision is often focused on different domains and consider a heterogeneity services which require an action to address cross-thematic issues. According to Raaijen (2017), these different domains needs to be integrated together in one layer on top of the technology innovation that addresses heterogeneity systems. The challenge of this layer is the incorporation of different sensing techniques to monitor and address service specific challenges and this is referred to "service discretization".

On the other hand, application development and innovation needs to be fast which will lead citizens to get the maximum advantage of data that is being collected. Because if the development was limited to city management, citizens will be disappointed *(Bawany and Shamsi, 2015)*.

4.1.4. Big Data

Big data offer the potential for cities to gain valuable insights from a massive amount of data collected from various sources. In addition, data in smart city collected from various objects and devices. It requires new algorithms and visualization techniques, which affect smart city-focused activities in order to gain the insights of this data and to make decisions *(Hashem et al., 2016)*. In a research study by Al Nuaimi et al. (2015) it mentioned that, because of the massive data collected from smart city systems, it requires huge processing capability and this leads to the need of scalable and reliable software and hardware platforms.

Nowadays, data integration is one of the hardest challenges within organizations in the IT world. The smart city vision holds out the concept of integrating data from several organizations, different environments, and variety of intelligent devices. The volume, velocity, variety and variability of data makes data quality difficult to be ensured *(Hashem et al., 2016)*. Bawany and Shamsi, (2015) stated that data integration and analytics requires an efficient big data management system and it has to be reliable and scalable with no downtime.

4.2 Non-Technical Challenges

The coexistence of non-technical aspects besides technical aspects indicates the importance of balancing the two perspectives to successfully integrate smart city innovations. In the following, the challenges of these formal and informal aspects are identified.

4.2.1 Privacy

Privacy is a key policy and legislation challenge of the 21st century. A large part of smart city data comes from individuals and they may not prefer their data to be available in public *(Mohammadi and Al-Fuqaha, 2017)*. In addition, smart cities will allow authorities to track a person's location at all times by using video across the city, facial recognition, and other sensors. Although a person's activity may take place in public, this information can be extremely private *(Elmaghraby and Losavio, 2014)*. Bawany and Shamsi, (2015) argued that the privacy is not only about protecting data it also build citizens trust and confidence in order to use these systems. AlDairi and Tawalbeh (2017) defined that if cities want to ensure privacy while implementing smart city initiative they have to consider five privacy-related issues. These issues are protecting identities, protecting people areas that indicate to protect each one's space and properties, protecting locations, communication protection and transactions protection.

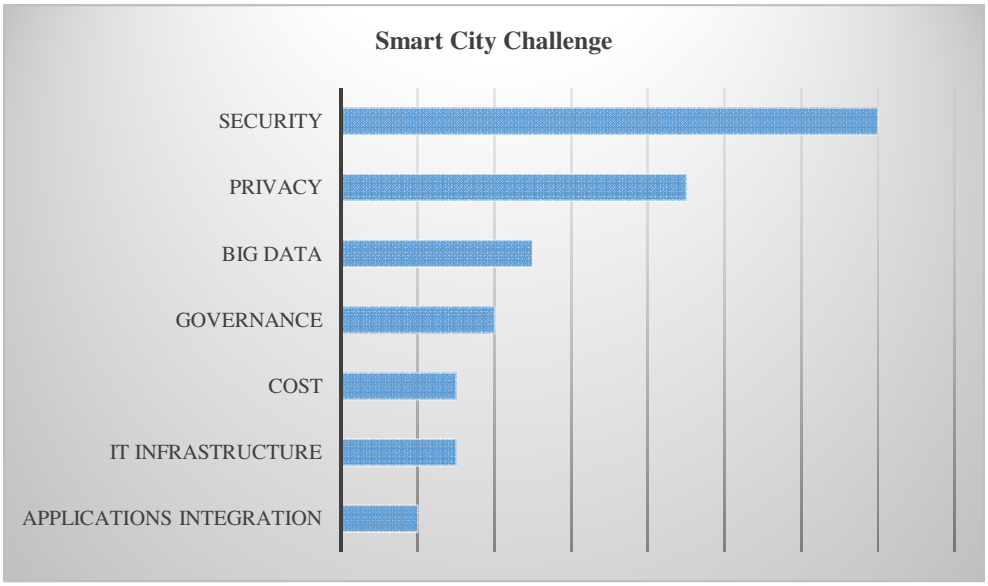
On the other hand, Zoonen (2016) states that there are three main factors influencing people's concerns about privacy. First is the type of data whether it is sensitive or not. Also, author defined that what it may be a privet information for one person it is not necessary to be private for others. Second factor is the purpose of collecting data, the usage and weigh the value that providing their data. Third, people's also concerns about who is dealing with their personal data. Zoonen (2016) says that "Eurobarometer data from 2011 indicate that across Europe people trust medical organizations and banks the most when it comes to their (most sensitive) data (Eurobarometer, 2011). On the lowest end of the spectrum, the Eurobarometer found telecom and internet companies, including social media and search engines; they are least trusted and sometimes even seen to threaten privacy".

4.2.2 Cost

Cost is one of the non-technical challenges for smart city adoption. Bawany and Shamsi (2015) stated that the requirement of IT consultancies, professional, number of devices, sensors, thousands of networking equipment and computing devices will create a considerable amount of expense. Also, these devices and equipment need to be integrated and embedded with each other this may be costly because of the lake on natural and human resources. Furthermore, this cost is not limited to one time only, the operational and maintenance cost for such a huge real time system will be much higher *(Hashem et al., 2016).*

4.2.3 Governance

Governance defines the formal aspects of initiatives which aim to achieve administrative modernization. Moreover, there are two main characteristic perspectives towards governance regarding smart cities. First, governance managing smart city development and its helps promoters to have a clear strategy which will help to receive in-depth insights into stakeholder's needs and values. Second, smart city initiatives shaping governance in order to understand which technologies shape governance, such as the availability of big data does and who benefits from the integration of new systems in terms of power and control *(Raaijen, 2017).*



One of the major barriers to developing smart city application is the ownership of data and the regulations and arrangements to make it open. A case study done by Bajracharya et al. (2014) mentioned that due to the data ownership arrangements, developers in Costa Gold were unable to create smartphone apps which provide information such as weather warnings in real time. Nonetheless, many of the challenges faced by smart cities exceed the capacities and capabilities of their traditional institutions and their classical processes of governing. Therefore modern and innovative forms of governance are needed to meet these challenges (*Bolívar, 2015*).

6. Discussion

The analyzed literatures revealed a common pattern of challenges that have been facing smart cities implementation. From the given chart below, we can conclude that most of the authors agreed that Security and Privacy come at the top of the challenges list. This could be due to the emerging internet of things and smart grids concepts along with their associated complexity to control these both aspects: security and privacy *(Elmaghraby, 2013).*

Big data comes second as a challenge for smart cities. As interaction with many agencies at different sectors would be heavily active between government agencies and other industries, boundaries of data collection and sharing become very vague. The most challenging part here is that each organization might have its own privacy policies for protecting personal information and ensuring commitment to the various given policies for all is a fine line *(Al Nuaimi et al., 2015).*

Governance, IT Infrastructure, and Cost, come next in the challenges list at which these challenges will require adopting certain strategies and planning to ensure proper arrangements for developing smart cities concept in an effective manner. Surprisingly, Application Integration comes at the bottom of the list, assuming that technical challenges dissolve by time to support the overall implementations.

s

7. Limitations and Future Research

Since the concept of Smart cities is new, the number of published work related to challenges of this concepts is somehow limited. Also, as it is an emerging domain, it`s components are evolving everyday including technological and non-technological aspects. Various industries are getting involved and requirements of IT to accommodate their needs and provide the needed capacity has changed. That re-defines the challenges over a short period of time.

This paper have only covered the previous studies conducted to find out the challenges of Smart Cities. The next phase of this study will provide a further field analysis on a specifically given geographical scope. The results will be much richer to carry future studies that will enable practitioners and decision makers to put proactive plans that will overcome the Smart Cities challenges and enable the development of this area.

8. Conclusion

This paper starts with an argument on the definition of smart cities, and this new concept appears with new challenges. The main purpose of this paper was shedding light on smart city challenges, this paper has examined the challenges of smart cities through a collection of literatures review was published in different resources. Our studies smart cities challenges have revealed are many different challenges not just technical there is also some of non-technical challenges, we discussed seven category that could be face and each category consisted of a number of sub-categories that have been studied. Through this article we have provided a thorough insight about smart city technical and non-technical challenges.

Abstract

Customer satisfaction is one of the management's main priorities in today's business world as it leads to customer retention. To satisfy and retain the customers in the e-retailing, there is a need of offering quality services. Despite a good number of studies conducted on e-retailing in recent years, a very limited attention has paid towards e-services provided by the e-retailers in Malaysia. Keeping this in mind, this study aimed at identifying the determinants of e-service quality that may help to retain the Malaysian customers in e-retail business. This study has taken up the quantitative approach to achieve the research objectives. The survey approach helped to know the perception of the customers towards e-retailing. This study developed domains from the literature review to represent the key features of the research questions and to pose 26 the questions in a systematic manner. The study setting was in Klang Valley, Malaysia. The sample selected for this study is the customers who were willing to do e-retailing and the existing customers doing e-retailing of the products in Malaysia. Total 400 questionnaires were distributed among the respondents using random sampling technique. Structure equation modeling was employed for data analysis. This study was able to find three dimension representation of e-service quality which was found statistically significant. However, the variables were not enough to indicate the total gap of the research. Thus, this study suggests to analyze the dependent variable in future research with different other variables.

Keywords: Service quality, customer retention, E-retailing, Malaysia.

Introduction

The growth of e-commerce has created special interest among scholars to measure the e-service quality towards e-retailing (Chen, Shen, Lee & Yu, 2017; Sobihah, Mohamad, Ali & Ismail, 2015). Customer satisfaction is one of the management's main priorities in today's business world. Lee and Lin (2005) noted that customer satisfaction is a function of perceived service quality. Customer satisfaction also leads to customer retention which can be a positive move by the e-retailers and would be less costly than the customer replacement (Kim, Donald & Rao, 2009). However, to satisfy and retain the customers in the e-retailing, there is a need of offering quality services. The concept of customer satisfaction and customer retention are interrelated. Hence, it becomes essential for the e-business providers to offer better e-services to its customers that will ensure the growth of e-retailing. Kaur and Kiran (2015) found that the internet based interactive environment leads to greater level of adoption by the customers. Thus, it can be said that through providing superior e-services, customer satisfaction and customer loyalty can be enhanced. Therefore, this is very important for the commercial sector to make the e-customers to believe on the

product and the ease of use of the online service technology. Online retailers are more focusing on increasing the e-service improvement that makes e-retailing more efficient and effective for the customers.

Despite a good number of studies conducted on e-retailing in recent years (e.g. Akram & Sultan, 2014; Mekovec, Bubas & Vrcek, 2007; Ndubisi, Malhotra & Wah, 2009; Rossiter, 2007), a very limited attention has paid towards e-services provided by the e-retailers in Malaysia (Li et al., 2009). E-commerce in Malaysia is still in its early stage and is not very advanced as compared to that of the western countries (Sheng & Liu, 2010). Lack of security and reliability as well as the increasing numbers of fraud in e-retailing has limited the e-retailing industry to grow in Malaysia. Besides, little knowledge towards e-retailing among Malaysian consumers is also a reason for low adoption of e-retailing in Malaysian market (Chu, 2009). Hence, there is a need to understand e-retailer and consumer relationship to identify with of the decision making process of consumers. Keeping this in mind, this study aimed at identifying the determinants of e-service quality that may help to retain the Malaysian customers in e-retail business.

The factors that were considered in this study are information quality, website security, website reliability, e-service quality and customer retention. The main focus of this research was to seek the major factors that have high influence on the e-retailing in Malaysia. This makes the study more interesting as on e-service quality dimensions explaining e-retailing sector of Malaysia is still considered a new area for academic research.

Literature Review

The theoretical foundation of this study is based on Vroom (1964)'s "Expectancy Theory" that defines expectancy as a belief that is concerned to likelihood to follow the outcome. This is based on the idea of learning expectations of the peoples. For example, the customer believes, for a given response that is followed by the positive or negative event. Rosenberg (1986) was the first to introduce instrumentally the value model to investigate the attitude of the customers. The author further suggested that attitude is mostly influenced by beliefs of object like an action or policy for the attainment of a valued state. When an individual choose between various alternatives that have uncertainty in their outcomes, it says that behaviour is attacked not only by preference of the results, but also from the degree of belief on the results. Thus, expectancy theory is the best example to motivate the customers to do online purchasing (Lee & Lin, 2005).

Given the influence of shoppers' perceptions of quality on an online retailer's market share and profitability, the evaluation of performance quality is critical to both practitioners and researchers (Al-Hawari, 2014; Siadat, 2008). To assess it accurately, the attributes or dimensions perceived as the most important by the purchaser or recipient needs to be identified (Cronin & Taylor, 1992). In the context of online retailing, these include perceptions formed by interaction at the web site and throughout the entire purchasing experience, including web interactivity and delivery (Porter, 2001; Rolland, 2010). After the pioneer work done by Zeithaml et al (2002), quality of service in the electronic area has been explored in some depth through measures across different market sectors including e-retailing. To capture all dimensions of e-service, however, these conceptualizations must be expanded to be global level, and must take into account all aspects of the transaction including service delivery and customer support service.

Information Quality

Information quality means providing accurate information for the product or services in the website. The accurate information quality makes customers always accessible to the online service offered by online companies that can help customers to have a good image of online companies (Sobihah et al., 2015). Customers usually switch over to other companies due to lack of ease of use of online service by online companies. Consumers are helped to select products based on price rather on quality which suits best the

desire and needs of customers. Hence, higher transparency of product price and quality will increase profitability to the electronic retailers (Joia & Sanz, 2005). Posselt and Grestner (2005) indicated that the online tools such as accurate information on products, online navigation, product evaluation, and decision making towards buying products, deliveries, returns and customer support service have very high influence on the customer satisfaction and gains high positive attitude of the customers towards online shopping. Wang and Head (2001) showed that successful web based information is very critical for the e-retailing market to attract customers and deliver business function and strategy. Furthermore, this field still considered as a new field of study (Wang & Head, 2001).

E-service quality is a critical business factor for both customers and e-retailers. The main importance for e-service quality is the overall support by internet retailers and customers. If there is a gap between the retailers and customers then the business may suffers some issues. Many studies show the significance importance and effect of information reliability, understandability and awareness in terms of information quality. Amin (2016) quoted in his research that understandability includes ease of understanding and clearness of information. Since the main purpose of technical support in websites is to provide information and after-sales service, they do not emphasize online transactions. To date, few studies have explored factors that determine customers' service quality perceptions of technical support for websites. The present study, therefore, aims to fill this research gap (Chu, 2009). By identifying these e-service quality dimensions, online retailers will be able to assess their service performance (Yang, 2004). E-quality research is very complex and has produced non responsive results suggesting that more research on this area is required.

H1: Information quality of the website is having positive influence on the customer retention in e-retailing.

Website Security

Freedom from danger, risk or doubts during service process is considered as security. In terms of online purchase, most customers find this as barriers towards online shopping. Protection of personal data of customers, terms and conditions of payment and positive reputation has always been the basic idea on the research of service quality on internet. Studies by Zeithaml et al. (2002) on e-retailing context shown that e-service quality has seven dimensions including efficiency, fulfillment, reliability, and privacy and recovery of e-service quality including responsiveness, compensation and contact. Privacy and security is found to be the key factor to evaluate the online service. They are very closely related to each other. According to Al-Ajam and Md Nor (2015), there are things to be considered for the online service. First is the quality of information provided should be reliability, timely, customized, complete. There were various website security issues which stops the consumers to go for the e-retailing. Thus, security is very important to the online shopping for the customers.

Furthermore, due to lack of interaction between consumers and retailers, consumers prefer high importance to the technical aspects of online transactions as well as receiving products (Liu & Arnett, 2000). Therefore retail managers need to assess the sites including technical support of clarity, ease of use and adequate shipping options. Furthermore, measures to be taken for the website trafficking to ensure acceptable downloadable times. Besides, testing of the website needs to be done with different information system tools including testing of internet connection speeds, and system use. The interactive between customers and companies provides companies an opportunity to get information like purchase habits, needs, preferences which make the companies to provide personalized service to the customers. Personalized service can improve the customer satisfaction rather than switch over to other companies. Along with service and products, payment and delivery is also one of service process that needs to be meted by the companies on the demands of the customers.

H2: Website security of the website is having positive influence on the customer retention in e-retailing.

Reliability

Service reliability is the promises or assurance made by the providers during a service purchase. It grantees the promised services will be available during the mentioned period. Reliability in e-service quality deals with technical aspects. Parasuraman et al. (1988) explained reliability as the dimension of traditional service quality approach. Information quality must fulfils certain criteria like accuracy, timeliness, relevance and understandable by customers arising both the experience and product purchase (Al-alak, 2014; Amin, 2016;Chen et al., 2017; Kuo, 2003). The research on the reliability towards service quality has passed more than twenty years which says that it is one of the most important dimensions for all the services provided. Santos (2003) quoted that the ability to perform the promise accurately replying to the enquiries of the customers and online purchasing accuracy is the main job to explain reliability. It is very important for the providers to make sure that customers trust on the promises made by the organization towards the fulfilling of the works. Thus, exploring the contribution of e- service quality can change the customer's retention in e-retailing in Malaysia.

H3: Reliability of the website is having positive influence on the customer retention in e-retailing.

Methodology

This study has taken up the quantitative approach to achieve the research objectives. The use of quantitative is appropriate in this research because it explains a social phenomenon (Davis & Cosenza, 1993; Gray, 2004). Furthermore, Most of previous studies related to these research variables have been used quantitative approach. The survey approach helped to know the perception of the customers towards e-retailing. This study developed domains from the literature review to represent the key features of the research questions and to pose 26 the questions in a systematic manner. Pallant (2007) noted that a questionnaire should be as short as possible, constructed in clear and unambiguous language, and devoid of unwarranted assumptions on the part of the researcher. This study created questions to generate responses specific to the research problems and avoided leading questions to limit response bias. The study setting was in Klang Valley, Malaysia. The sample selected for this study is the customers who were willing to do e-retailing and the existing customers doing e-retailing of the products in Malaysia. Kothari (2004) and Sekaran and Bougie (2013) describes that for population more than 100,000, the sample size should be between 30 and 500. Accordingly, Total 400 questionnaires were distributed among the respondents using random sampling technique. Total 338 questionnaires were returned out of which 329 were found usable for further analysis. Finally, structure equation modelling was employed for data analysis.

Results and Discussion

This study was further extended by investigating on the customer's experience on e-retailing before. This investigation would seek to know the confidence level of the customers. Below are the demographic profiles of the respondents.

Table 1: Demographic profile of respondents

Gender			Age		
	Frequency	Percent		Frequency	Percent
Male	207	62.9	30 years and below	170	51.7
Female	122	37.1	31 - 40 years	132	40.1
Total	329	100	41 - 50 years	23	7
			51 years and above	4	1.2
Educational Background			Total	329	100
	Frequency	Percent			
Diploma	11	3.3			
Bachelor Degree	180	54.7			
Postgraduate	138	41.9			
Total	329	100	Monthly Income		
				Frequency	Percent
Daily Usage			RM 3,000 and below	33	10
	Frequency	Percent	RM 3,001 – RM 5,000	68	20.7
Less than 2 years	68	20.7	RM 5,001 – RM 10,000	77	23.4
2 - 6 years	199	60.5	RM 10,001 and above	115	35
Above 6 years	62	18.8	Does not apply	36	10.9
Total	329	100	Total	329	100

From the demographic results, it can be seen that out of total 329 respondents, 207 were male while the rest 122 were female. This also shows that male customers prefer e-shopping more that the female customers. In terms of age, the younger generation prefer e-shopping than the older generation as reflected in the table above. The next question asked to the respondents was regarding the internet access availability. Almost more than 80% of the respondents were having access to internet via hand phone or through internet connection or broadband. After the access of internet the next question that was asked to the respondents was regarding the internet usage in their daily activities. The response was quite positivistic as majority of the respondents use internet of more than 5 hours daily. This shows the importance of internet in their daily life. Rest of the category also explained in the above table.

Reliability Test

The reliability test was performed using the Cronbach's alpha test. It achieved an overall alpha value of .831. It seems very reliable as mentioned by Hair et al. (2010) who mentioned that a minimum alpha value of 0.70 is required to be reliable.

Structure Equation Modeling

Finally, SEM was conducted to find out the structural relationship among the variables of the study. The measurement model shows that it explained total 69.71% of the total variances. Furthermore, none of the five variables are highly correlated which proofs that all the five variables are independent to each other. The path relationships are shown in the figure 1 below.

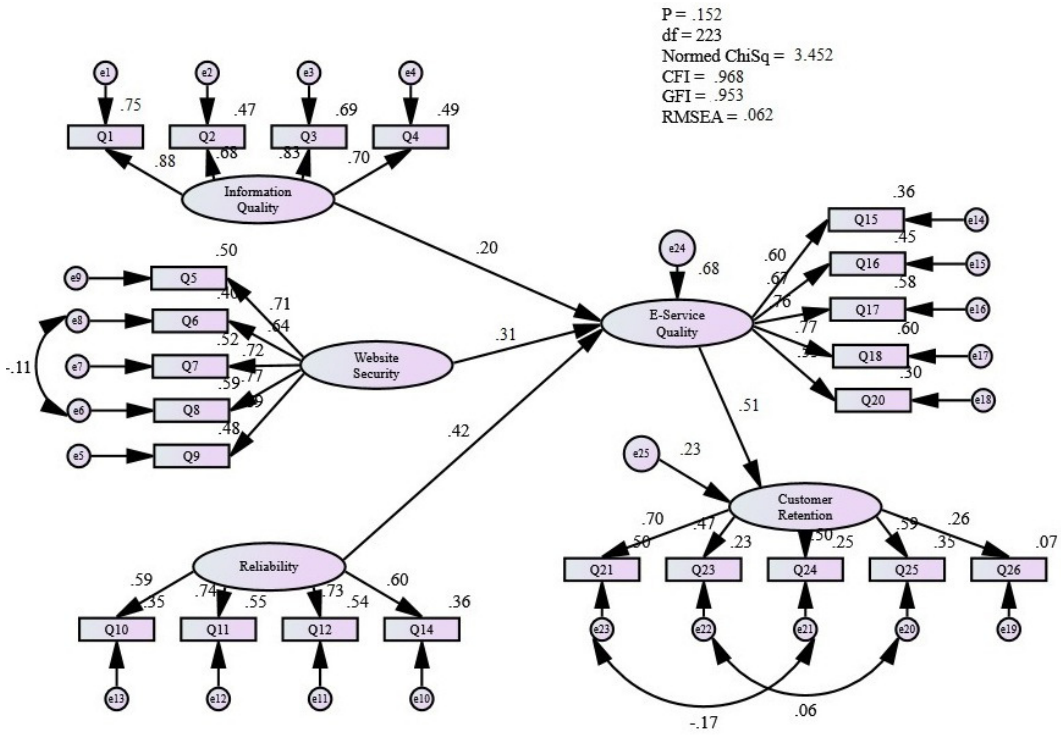

Fig. 1: Structural Model of the Study

Hypothesis Testing

From the coefficient analysis, it can be seen that the reliability and the website security plays significant role in enhancing retention of the customers to adopt e-retailing and make easy online transactions. From the findings, it seems that the information quality of the products and the transaction information are very important in order to increase the online purchase increase and marketing by the producers. In the above figure, we can see the significant level of all the three independent variables is having high path values and have statistical significance of less than 0.01. The figure also shows high correlation between information quality and e-retailing from all the other independent variables. Thus, it proofs that there is a strong relation exists between all the independent and dependent variables.

Table 2: Final Output

			Estimate	S.E.	C.R.	P
E-Service Quality	<---	Information Quality	.201	.092	2.184	.001
E-Service Quality	<---	Website Security	.314	.040	7.850	.001
E-Service Quality	<---	Reliability	.423	.091	4.644	.001
Customer Retention	<---	E-Service Quality	.512	.045	11.378	.001

For H1, there is a total influence of 20.1% of the independent variable information quality on the dependent variable customer retention on e-retailing in Malaysia. For H2, the analysis found that there was in total 31.4% of influence on the customer retention for e-retailing in Malaysia. For H3, in total there was 42.3% of influence of service reliability on the customer retention for e-retailing in Malaysia. By using the empirical model through SEM analysis, we have noticed that the service reliability on the retail product is the main factor to watch for an increase in the customer retention on e-retailing. These findings are also supported by the past studies (e.g. Aksoy, 2014; Al-Ajam & Md Nor, 2015; Al-alak, 2014; Amin, 2016; Chen et al., 2017; Kim et al., 2009; Kuo, 2003; Liu & Arnett, 2000; Park & Kim, 2003) who have noted that the quality of information availability needs to be speculated and demonstrated at every moment which will help the customer to make a decision on online purchasing.

From the analysis it was found that all the factors are having positive relationship with the customer intention of e-retailing. That means all the factors are playing there part for enhancing the retail business in Malaysia with an influence of having great impact on the minds of customers. From the analysis the main contribution was fulfilled by the Information quality factor and Service reliability factor. This shows a positive relation between Information qualities with the Customer retention on e-retailing in Malaysia. Findings also show that when there is an increase of one unit in the information quality, then there is an increase of around 20.1% in the customer retention on e-retailing in Malaysia.

Conclusion and Recommendation

In contrast to the previous studies it was found that the information quality was having less influence on the customer retention on e-retailing. Thus it is highly recommended to investigate in deep on this result accuracy. This study able to find three dimension representation of e-service quality. Chen et al. (2017) had quoted that customers prefers to multiple channel of transactions to execute most transactions over website. The variables were not enough to indicate the total gap of the research. Thus it is necessary to analyze the dependent variable in future research with different variables. However, no study is beyond limitation. There are various other factors affecting the customer retention on e-retailing in Malaysia which were not included in this research. Thus only 69.71% of the influence was explained by the variables and the rest of 20% were still remains to evaluate.

It was known from the current research that there are various other factors which affect the customer's retention in Malaysia, thus it is highly suggested to include these variables in the further research. It is also highly suggested to know the key areas that have high effect on customer retention on e-retailing have to look to increase the customer's importance on the retail products in Malaysia. There must be involvement of the other factors like user friendliness, Efficiency, Site organization and several others as a variable in the further research. Retail firms should look upon the improvement on the products and service quality to increase the value of the product in customer's retention.

Résumé

Le système relationnel développé par une culture agricole et les différentes expressions scientifiques qui visent l'impact des conditions naturelles, techniques et économiques sont utiles pour identifier les facteurs limitatifs quantitatifs et qualitatifs qui peuvent affecter ce genre de culture.

Cette étude analyse la manière dans laquelle certains facteurs climatiques (radiation solaire, température et humidité) influencent le développement de la vigne dans l'un des plus importants périmètres viticoles de la Roumanie – les Subcarpates de la région de Vrancea, et plus précisément les vignobles de Panciu, Odobeşti et Coteşti, où les surfaces cultivées avec des catégories de raisins de table couvrent 20% de la région et les surfaces avec des cépages pour le vin couvrent 80%.

Dans ce but, nous avons utilisé les données climatologiques provenant de quatre stations météorologiques de la région - Adjud, Tulnici, Odobeşti et Râmnicu Sărat, pour la période 1965–2015. L'analyse quantitative des importants paramètres et indices agro-climatiques (le coefficient des précipitations, l'indice hydro-thermique, le coefficient hydro-thermique Seleaninov etc.) relève que la valorisation de l'interférence des facteurs climatiques qui influencent la qualité et la quantité de la production peut constituer un important critère pour choisir l'emplacement des périmètres viticoles et les solutions techniques adéquates.

Mots-clés : température, précipitations, indices climatiques, vigne, Subcarpates de Vrancea.

Introduction

Les exigences climatiques et bioclimatiques participent activement à la croissance et au développement des cultures agricoles, influençant dans des proportions différentes les processus physiques, chimiques et

biologiques, la qualité et la productivité agricoles. Les facteurs climatiques deviennent pour les cultures les principaux facteurs restrictifs d'ordre qualitatif, qui, par leur variation annuelle, deviennent des facteurs décisifs pour leur réussite car le cycle biologique dépend des facteurs.

La vigne est une culture multi-annuelle avec des certaines particularités de croissance et fructification, adaptable aux conditions de l'environnement a attiré l'attention des agriculteurs dans les pays où les conditions climatiques correspondent aux besoins biologiques de la vigne, qui peut être cultivée sur cinq continents, étant une culture économique spécifique aux climats tempérés, sous-tropicaux et tropicaux, la majorité se trouvent entre les parallèles de 30° et 50°, dans le nord aussi que dans le sud (récemment on a trouvé ces cultures à une latitude de 10°, dans des pays comme le Brésil, la Colombie et le Pérou).

Le réchauffement global produit des fréquents dérèglements des écosystèmes agricoles (Cornelis van Leeuwen et Philippe Darriet, 2016). Les chercheurs Kenny et Harrison ont signalé depuis 1992 que ce réchauffement peut être bénéfique aux cultures de vigne dans le nord, et désavantageux pour les plantations dans le sud. La culture de vigne doit adapter ses cycles annuels de végétation, ce qui affecte la quantité et la qualité de la production de raisins. L'influence climatique a été étudiée maintes fois car le climat est celui qui conditionnent le déclanchement des phénophases et le métabolisme de la vigne qui, avec d'autres facteurs édaphiques (Duchêne et Schneider, 2005), influencent la croissance et la fructification de la culture, la quantité et la qualité des raisins, la densité et la durée de vie de la plantation, la résistance aux maladies, sécheresse, la gelée etc.

L'impact de la variabilité climatique sur la croissance et le développement des cultures agricoles se quantifie par le potentiel des paramètres météorologiques. La production agricole étant dépendante des conditions de l'environnement naturel, dont les facteurs climatiques jouent un rôle dominant (Gerós et al., 2015).

À partir de ces hypothèses, cette étude analyse la manière dont certains facteurs climatiques dans un périmètre sous une évidente influence des foehns en Roumanie – les Subcarpates de Vrancea. Ces caractéristiques influencent l'extension des vignes dans l'un des plus importants périmètres viticoles de la Roumanie, qui consiste des vignobles de Panciu, Odobeşti et Coteşti.

Région d'étude et données utilisées

Les Subcarpates de Vrancea sont situés dans l'est de la Roumanie, constituant une sous-unité des Subcarpates de Courbure entre les vallées de Trotuş et Slănic, dominés à l'ouest par les Carpates Orientales et à l'est, ils font la transition, tantôt lente et tantôt brusque, vers la Plaine du Siret (Ielenicz et al., 2003) (figure no.1).

Leur complexité structurale, l'alignement approximativement parallèle des dépressions et des collines avec les rangées des montagnes, la fréquence des foehns, le réseau hydrographique transversal (IG, 1992) créent des conditions favorables à la culture des vignes, qui a une ancienne tradition dans ce périmètre, des temps des Gètes et des Daces.

Pour aboutir aux objectifs et finaliser cette étude, nous nous somme basés sur l'existence et l'exploitation des données météorologiques et statistiques, des connexions de données qui ont assuré une analyse qualitative et quantitative.

L'analyse quantitative des principaux facteurs climatiques (température de l'air, les précipitations atmosphériques, le vent etc.) et l'évaluation de la relation entre le climat et la culture de la vigne est basée sur des observations et des déterminations météorologiques et le traitement des données enregistrées dans les stations météorologiques locales – Tulnici, Adjud, Odobeşti şi Râmnicu Sărat (figure no.1), entre 1965–2015, et des informations agro-météorologiques provenant de l'Administration Nationale de

Météorologie (ANM). Les quatre stations météorologiques sont représentatives pour le périmètre analysé par leur position géographique et la différence d'altitude (figure no.1).

La base de données climatiques a été enrichie avec les valeurs calculées des indices agro-climatiques, calcules possibles avec les données climatologiques des quatre stations météorologiques. Nous avons fait une analyse quantitative des indices agro-climatiques importants - l'indice de Mayr, le coefficient des précipitations, l'indice hydro-thermique, le coefficient hydro-thermique Seleaninov et l'indice bioclimatique de la vigne, qui met en évidence le degré de favorabilité climatique du périmètre analysé pour la culture des vignes (tableau no. 1).

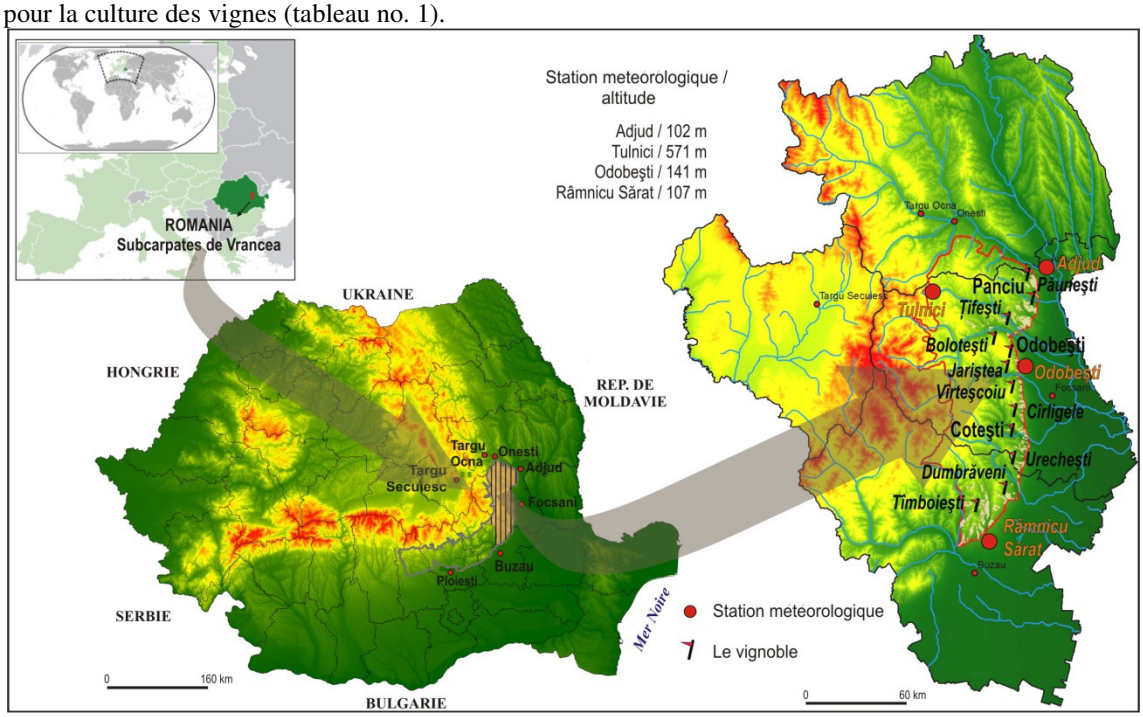

Figure 1 : Localisation géographique des Subcarpates de Vrancea en Roumanie et en Europe (à gauche) et emplacement des stations météorologiques dans les Subcarpates de Vrancea (à droite)
Source: les auteurs

Tableau: Indices agro-climatiques –caractéristiques

L'indice de Mayr	°C	est calculé comme moyenne des valeurs de température des mois de mai, juin, juillet et août
Le coefficient des précipitations	mm	Cp = P/Nzv; représente le rapport entre la quantité annuelle des précipitations et le nombre des jours de végétation
L'indice hydro-thermique	unités	Iht = (T·P/100)·k1·k2 (Teaci, 1980) ; est un indice qui résulté du produit entre la température moyenne annuelle de l'air et la quantité annuelle des précipitations, rapporté à 100, et multiplié par les coefficients de correction k1 et k2 pour les zones à fréquences différentes des mois de sècheresse, et pour les zones à température moyenne négative
Le coefficient hydro-thermique Seleaninov	mm/°C	CH = (∑mm/∑t°a)·10 où: CH – coefficient hydro-thermique Seleaninov; ∑mm – quantité annuelle des précipitations; ∑t°a – somme annuelle des températures actives; 10 – constante; est utilisé pour la caractérisation hydro-thermique
L'indice bioclimatique de la vigne	unités	Ibcv = (Ct·Ci)/(Cp·10) rapport entre le produit du coefficient thermique (Ct) et le coefficient d'insolation (Ci) et le produit obtenu par la multiplication de 10 fois du coefficient des précipitations (Cp) (Constantinescu et al., 1964)

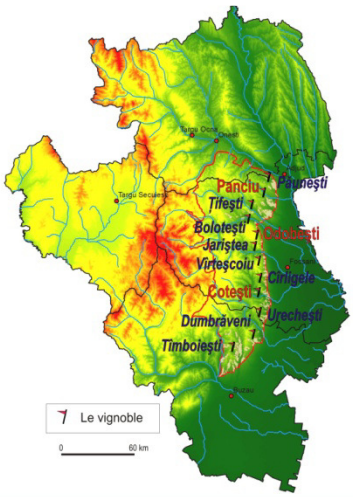
L'interprétation statistique a été faite à base des informations fournies par l'Institut National de Statistique (INS) et des données fournies par la Direction pour Agriculture du département de Vrancea (surface cultivée, production réalisée pour chaque variété cultivée etc.).

Les méthodes utilisées dans l'analyse, l'interprétation et la représentation des données météorologiques sont les méthodes classiques, des analyses logiques, spatiales et comparatives, complétées par des méthodes modernes comme des opérations Corel Draw, Microsoft Office Excel, GIS. En plus, nous avons la recherche bibliographique et les observations dans le terrain.

Résultats Et Discussions

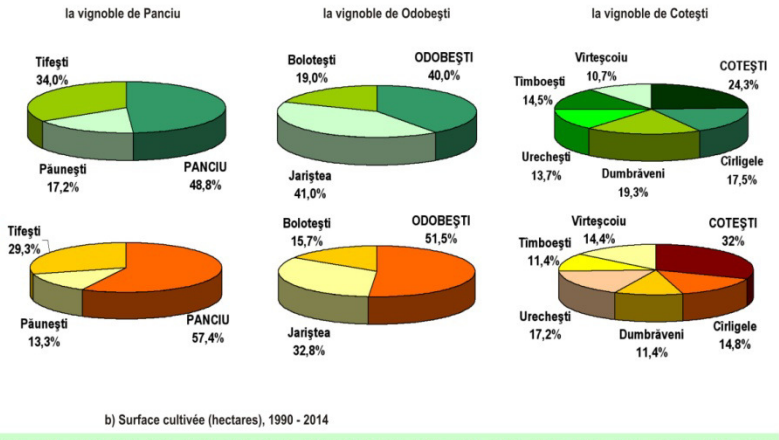
Le désir des producteurs d'avoir des récoltes de qualité qui correspondent à la direction de production dans des conditions d'efficience économique implique le respect des conditions de sécurité et amélioration des technologies de culture (protection, irrigation, travaux et opérations en vert, éliminations etc.) car les besoins des plantations différent d'un an à l'autre, et d'une phase de végétation à l'autre.

Dans la zone analysée, Subcarpates de Vrancea, sont l'un des plus importants périmètres viticoles de la Roumanie qui consistent des vignobles de Panciu, Odobeşti et Coteşti (une surface total de plus de 32.600 ha) (figure no.1). Par exemple, en 2015, de la surface totale de 224 100 ha cultivés avec des vignes en Roumanie (INS, 2016), 32610 ha appartenaient aux Subcarpates de Vrancea (DAJ Vrancea, 2016), ce qui représente 14,5 % de la surface totale. La Roumanie se situe ainsi sur la 10ème place dans le monde et la 5ème en Europe, étant une région viticole importante.



Le vignoble de Panciu (une surface de 9701 ha) est l'un des plus anciens de Roumanie, datent de la fin du 16ème siècle, un nom respecté parmi les producteurs de vins mousseux et inclut trois centres viticoles d'importance nationale: Panciu, Ţifeşti et Păuneşti.

Le vignoble d'Odobeşti (une surface de plus de 7792 ha) avec les centres: Odobeşti, Jariştea, Boloteşti se caractérise par une grande répartition de la marque *Galbena de Odobeşti*, qui trouve ici les conditions pédoclimatiques optimales, un symbole étant données ses caractéristiques organoleptiques spécifiques, est encadré, en fonction du périmètre de production, soit dans la catégorie de qualité supérieure, soit dans la catégorie des vins de consommation courante. Parmi les vins de cette zone viticole, la *Plăvaia* (marque autorisée) qui fait partie de cette catégorie depuis longtemps, est un vin de consommation courante.



Le vignoble de Coteşti (une surface de plus de 15117 ha) ayant une histoire de 600 ans, formé par les centres de Coteşti, Vîrteşcoiu, Cîrligele, Urecheşti, Dumbrăveni et Tîmboieşti, se fait remarquer par une production à part des vins parfumés et équilibrés de la variété Fetească grâce aux conditions climatiques, et par un vin avec un bouquet à part, une arome de rose de confiture obtenue de la variété locale *Şarbă*. Les variétés cultivées dans la région sont conformes avec les variétés stipulées par la Loi de la vigne et du vin dans le système de l'organisation commune du marché de la vigne et du vin no 244/2002.

En ce qui concerne la surface cultivée, la centralisation statistique du Figure 2 indique une croissance de la surface cultivée avec la vigne à partir de l'an 2010. Croissance signifiante dans le cas des vignobles de Panciu et Coteşti, où la surface est devenue double, de 4874 ha à 9644 ha, et de 7867 ha à 15374 ha, tandis que dans le cas du vignoble de Odobeşti, la croissance a été d'environ 3800 ha. Cette croissance a été possible après une période où la surface cultivée a été en baisse. En Roumanie, la viticulture est un secteur de l'agriculture d'un niveau de productivité conforme aux normes de l'UE, car l'encadrement des zones viticoles dans les zones viticoles de l'UE a été possible à base des études faites par les institutions roumaines autorisées par l'état.

Les producteurs dans cette région analysée, pour assurer la sécurité de la production des vins d'origine contrôlée, respectent, d'abord, le régime d'autorisation concernant le respect des conditions de culture, des normes techniques de production et de commercialisation élaborées par l'Office National des Dénominations d'Origine des Vins (ONDOV) et l'Office National de la Vigne et du Vin (ONVV). Ils ont aussi choisi un système de Management de la Qualité et la Sécurité des Aliments conforme aux exigences du système d'assurance de la sécurité des produits alimentaires HACCP, élaboré à partir de la Directive du Conseil de la Communauté Européenne no 93/43/EEC/14.06.1993, Ordre du Ministère de la santé no 1956/1995, les standards SR EN ISO9001:2008, SR EN ISO 22000:2005, car ils veulent fournir aux consommateurs des produits surs et de qualité, et ils adoptent une politique appliquée adéquate, efficiente, efficace et d'améliorer la responsabilité conformément aux mesures établies.

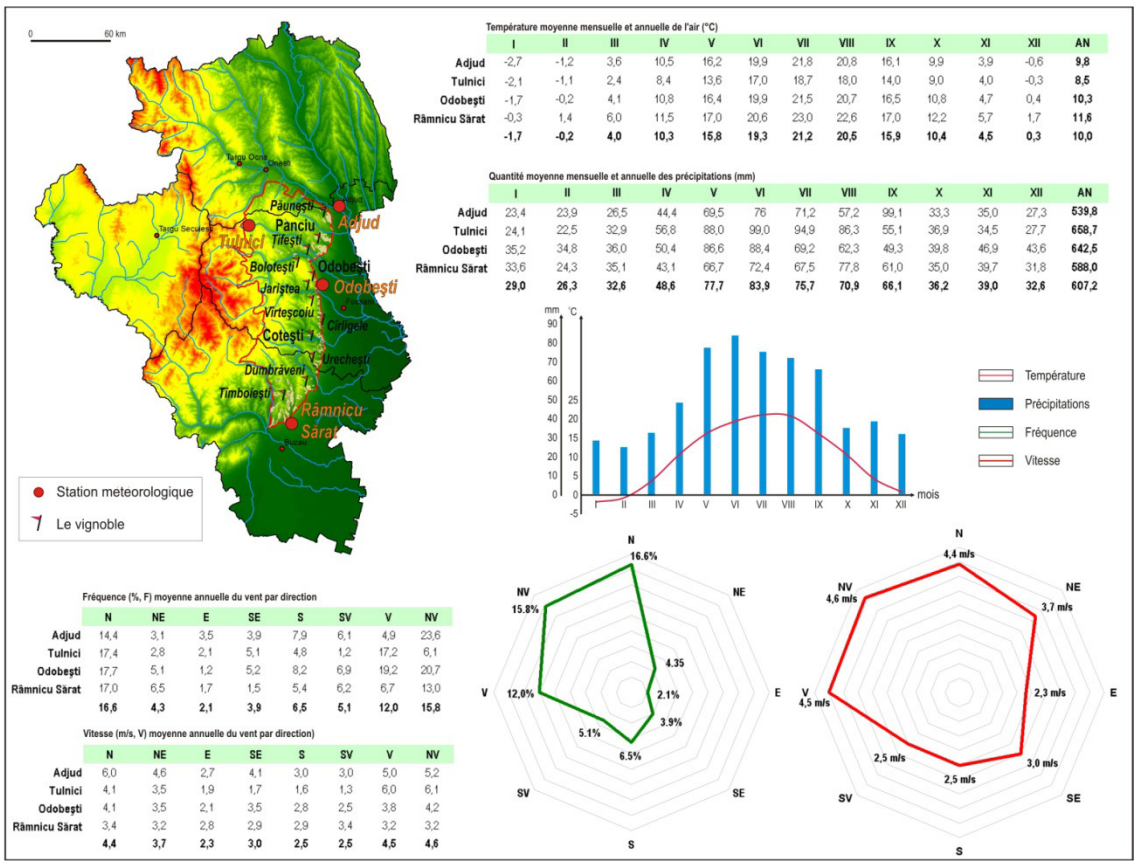
Figure 2 : Evolution des surfaces cultivées avec la vigne (ha) et dynamique de la production de raisins (tonnes) entre 1990-2014

Source: les auteurs et données traitées selon l'INS, 2016

Dans le domaine spécifique du vignoble des Subcarpates de Vrancea, qui consistent des vignobles de Panciu, Odobeşti et Coteşti, catégories des raisins de table détiennent 20%, et les cépages pour le vin

détiennent 80%. Les principales catégories cultivées ont aussi une grande valeur commerciale: *Chasselas Dore, Fetească Regală, Merlot, Băbească Neagră, Treminer, Pinot Gris, Galbena de Odobeşti, Fetesca Albă et Riesling Italian*. En ce qui concerne la production annuelle de raisins, on voit de variations signifiantes d'un an à l'autre dans tous les 12 vignobles identifiées dans la région étudiée. En général, les hausses et les baisses des productions annuelles varient entre 5.000 t et 30.000 t. Sauf le vignoble de Panciu où la production annuelle a une oscillation annuelle relativement réduite entre 2006–2008. Dans la période analysé, les productions ont varié entre 19.000 t et 55.500 t - Panciu, de 7.000 t à 50.000 t - Odobeşti et de 34.500 t à 90.000 t - Coteşti (figure no.2).

Maintes vins obtenus dans ces vignobles ont reçu des médailles aux compétitions nationales et internationales dans le domaine: le produit *Fetească regală* – an de récolte 1998, le vignoble de Panciu, médaille Maque d'Or au concours Salon international du vin „Casa Vinului"; produit *Şarba* – an de récolte 2002, le vignoble d'Odobeşti, médaille de bronze au Concours international OIV édition 2004; produits *Galbena de Odobeşti* et *Cabernet Sauvignon* – an de récolte 2000, le vignoble d'Odobeşti, médaille Marque d'Or au Salon Alcorom 2005 etc. (ONVPV, 2015). Le plus récent succès a été enregistré à la 14ème édition de International Wine Contest Bucharest IWCB – 2017, le plus grand concours des vins de l'Europe de l'Est, où les vins de cette région ont remporté trois médailles d'or (ONVPV, 2017).



Du point de vue **climatique** les Subcarpates de Vrancea se caractérisent par une circulation atmosphérique générale dans laquelle prédominent les composantes occidentale et polaire. Le rôle orographique des Carpates Orientales se rajoute, ce qui détermine l'ascendance forcée des masses d'air humide, de l'ouest, sur les pentes des montagnes, pour favoriser la descendance sur les pentes orientales, abritées, vers les Subcarpates de Vrancea, à des caractéristiques nouvelles – des foehns. Les Subcarpates de Vrancea disposent d'un apport moyen annuel de radiation globale d'environ 120 – 122,5 kcal/cm^2 (IG, 1979) et la plus grande durée de l'ensoleillement de l'entière région des Subcarpates, de 2144,4 heures/an à Odobeşti (IG, 1992). Ces particularités des Subcarpates de Vrancea la fréquence des foehns et un grand nombre d'heures d'insolation ont une signification à part pour la culture des vignes, qui est une plante prétentieuse en ce qui concerne la lumière et la chaleur (Berbecel et al., 1970).

La température de l'air détermine et influence les processus vitaux de la plante, marquant le début ou la fin d'une phénophase, Sa sensibilité, pendant les premières phases de végétation, est plus grande à la température de l'air par rapport à l'humidité (Huglin et al., 1998). Les Subcarpates de Vrancea se caractérisent par une température moyenne multiannuelle de 8,5°C à Tulnici et 11,6°C à Râmnicu Sărat, pour la période 1965 – 2015 (figure no.3).

Dans le régime annuel de la température de l'air, la température minimale enregistrée aux quatre stations en janvier est -2,7°C à Adjud et -0,3°C à Râmnicu Sărat. De plus, dans les mois d'hiver, les inversions thermiques sont moins fréquentes dans le périmètre des Subcarpates de Vrancea. Les plus grandes valeurs moyennes mensuelles multiannuelles sont enregistrées au mois de juillet, 18,7°C à Tulnici et 23,0°C à Râmnicu Sărat. Entre avril – août, des forts réchauffements sont enregistrés à cause de la pénétration des masses d'air tropical du sud ou des vents catabatiques.

Pour le régime phénologique de la vigne, les moyennes des saisons et semestrielles sont aussi importantes, car elles varient entre: 17,9°C en été et -1,2°C en hiver, à la station de Tulnici; 20,7°C en été et -0,5°C en hiver, à la station d'Odobeşti; 20,8°C en été et -1,5°C en hiver, à la station de Adjud; 22,0°C en été et +0,9°C en hiver, à la station de Râmnicu Sărat. Pour les saisons de transition, les valeurs sont supérieures à 8,0°C dans les quatre stations, et gardent la différence de presque 2,0°C entre les deux stations Tulnici et Odobeşti. Les valeurs sont inférieures dans la station de Tulnici à cause de la différence d'altitude, de 430 de m et son emplacement en bas des montagnes de Vrancea. La moyenne du semestre chaud (01.04 – 30.09) qui correspond à la période de végétation de la vigne a un écart entre 15,0°C à Tulnici, 17,5°C à Adjud, 17,6°C à Odobeşti et 18,6°C à Râmnicu Sărat, tandis que la moyenne

thermique du semestre froid varie entre 2,0°C à Tulnici, 2,1°C à Adjud, 3,0°C à Odobeşti et 4,4°C à Râmnicu Sărat.

Figure 3 : Distribution des principaux paramètres agro-climatiques, dans les Subcarpates de Vrancea, entre 1965 – 2015

Source: les auteurs et données traitées selon l'Administration Nationale de Météorologie

Les valeurs thermiques extrêmes sont le résultat de l'interaction entre les processus advectifs et les processus locaux générés par le bilan calorique de la surface subjacente, reflétés dans la viabilité des bourgeons et du bois. Par exemple, dans les Subcarpates de Vrancea les températures maximales absolues varient, pour la période 1960 – 2015, entre 18,6°C en janvier 1999 et 38,0°C en juillet 2000 à la station de Tulnici et entre 16,6°C en janvier 1971 et 38,3°C en juillet 1987 à la station d'Odobeşti. Les températures minimales absolues ont eu des valeurs entre -23,0°C en janvier 1963 et 6,4°C en juillet 1976 à la station de Tulnici, et entre -22,7°C en janvier 1963 et 6,4°C en juillet 1976 à la station d'Odobeşti.

Les précipitations atmosphériques en quantités moyennes annuelles de 400–700 mm/an, dont 250 mm sont concentrés dans la période de végétation, permettent des cultures de vigne sans irrigations. La vigne, par son fort et développé système radiculaire, et sa grande capacité d'absorption de l'eau et des sels du sol, est plus résistante à la sécheresse.

La quantité des précipitations multiannuelles augmente, dans les Subcarpates de Vrancea, de l'est vers l'ouest, de la 539,8 mm à Adjud, 588,0 mm à Râmnicu Sărat, 642,5 mm à Odobeşti à 658,7 mm à

Tulnici. Entre juillet – septembre, le seuil agro-climatique minimal des valeurs nécessaire à la phase de croissance et maturation des raisins de 50 mm (Azzi, 1956) est dépassé à la les quatre stations météorologiques, ayant une valeur plus basse de 0,7 mm en septembre à la station d'Odobeşti. Le manque de précipitations pendant cette période intensifie le processus de mûrissement, les grains des raisins restent sous-développés et par conséquent, la récolte se diminue. Dans la distribution saisonnière des quantités de précipitations, la saison la plus pluvieuse est l'été avec 280,2 mm enregistrés à Tulnici, c'est-à-dire 42,5% de la quantité annuelle et 219,9 mm à Odobeşti, c'est-à-dire 34,2% de la quantité annuelle de précipitations. Les plus basses valeurs saisonnières sont pendant l'hiver, entre 74,3 mm à Tulnici et 113,6 mm à Odobeşti. Dans les saisons de transition, les quantités de précipitations représentent entre 20% et 27% de la quantité annuelle. La quantité de précipitations dans la période de végétation (semestre chaud) varie entre 480,1 mm à Tulnici et 406,2 mm à Odobeşti, représentant plus de 60% de la quantité annuelle des précipitations (figure no.3).

L'humidité relative de l'air, par son distribution spatiale dans la région des Subcarpates de Vrancea, reflète les effets de barrage orographique des sommets des montagnes, ainsi que la moyenne multi-annuelle est située entre 85% à Adjud (82% à Tulnici) et 76% à Râmnicu Sărat (79% à Odobeşti). Pour que l'assimilation se déroule normalement, les demandes de la vigne par rapport à l'humidité relative de l'air se situent entre 50 – 80%, ce qui signifie que, de ce point de vue, la vigne répond aux conditions optimales de développement.

Le vent a une grande importance pendant la période de floraison, assurant le transport du pollen. Le vent sec à intensité modérée limite l'attaque de la manne, et lorsque le vent est fort, il rompt les pousses ou abat des soutiens. Par exemple, à Tulnici ce sont les vents de nord et de l'ouest qui prédominent, et à Odobeşti, le vent de nord-ouest. À Adjud et Râmnicu Sărat ce sont les vents de nord et de l'nord-ouest qui prédominent. Les plus grandes vitesses correspondent aux mêmes directions, nord-ouest - de 6,1 m/s à Tulnici et de 4,2 m/s à Odobeşti, nord - de 6,0 m/s à Adjud et de 3,4 m/s à Râmnicu Sărat. Les valeurs du calme atmosphérique reflet aussi l'influence des conditions locales, de 43,3% à Tulnici et de 15,8% à Odobeşti et assurent les conditions d'abri climatique relatif (figure no.3).

Le synergisme des facteurs climatiques est reflété par l'utilisation des **indices agro-climatiques**: l'indice Mayr, le coefficient des précipitations, l'indice hydro-thermique et le coefficient hydro-thermique Seleaninov, qui mettent en évidence le degré de favorabilité pour la culture de la vigne dans les Subcarpates de Vrancea (Ionac et al., 2015) (tableau no.2).

Tableau 2 : Valeur moyenne des indices agro-climatiques entre 1965-2015

Indices agro-climatiques	Stations météorologiques			
	Adjud	Tulnici	Odobeşti	Râmnicu Sărat
L'indice de Mayr	19,6°C	16,8°C	19,6°C	20,8°C
Le coefficient des précipitations	2,5 mm	2,9 mm	2,7 mm	2,4 mm
L'indice hydro-thermique	5,5 unités	5,6 unités	6,6 unités	6,8 unités
Le coefficient hydro-thermique Seleaninov	1,76 mm/°C	1,93 mm/°C	1,78 mm/°C	1,76 mm/°C

Source: les auteurs

L'indice de Mayr a des valeurs entre 16,8°C à Tulnici et 20,8°C Râmnicu Sărat. Cet indice exprime la valeur optimale thermique de la végétation pendant la période à une activité biologique maximale. Les valeurs baissent au long de la direction est – ouest, avec l'augmentation de l'altitude, mettant en valeur un léger refroidissement du climat au long de cette direction.

Après avoir calculé *le coefficient des précipitations*, nous avons obtenu les valeurs de 2,9 mm à Tulnici et 2,4 mm à Râmnicu Sărat. Ces valeurs indiquent un régime hydrique supérieur qui favorise les phases de formation des grains.

L'indice hydro-thermique a des valeurs entre 5,5 unités à Adjud et 6,8 unités à Râmnicu Sărat. L'indice donne des informations sur le degré d'approvisionnement avec l'eau des précipitations, et sur le complément d'eau par irrigations lorsque l'eau ne satisfait pas la demande optimale de la vigne. Selon les valeurs de cet indice, dans les Subcarpates de Vrancea, le nécessaire d'eau provenu des précipitations satisfait la demande optimale de la vigne.

Dans les Subcarpates de Vrancea *le coefficient hydro-thermique Seleaninov* a des valeurs entre 1,93 mm/ºC à Tulnici et 1,76 mm/ºC à Adjud et Râmnicu Sărat. Les valeurs entre 1 et 2 indiquent un régime à humidité suffisante pour la culture de la vigne et par conséquent, pour obtenir de vins supérieurs, à condition d'assurer les cépages adéquates des vignes (Oşlobeanu et al., 1980).

Pour le vignoble d'Odobesti il *l'indice bioclimatique de la vigne* a été calculé (Constantinescu et al., 1964). Cet indice permet d'établir le potentiel du vignoble pour une certaine ligne de production, dans le cas des nouvelles plantations viticoles. Par exemple, la valeur obtenue la station d'Odobeşti est de 7,72 unités, ce qui indique des années de production riches en ressources hydriques. Cet indice permet d'établir le potentiel du vignoble pour une certaine ligne de production, dans le cas des nouvelles plantations viticoles.

Toutes les valeurs climatiques analysées ci-dessus montrent en fait que la valorisation de l'interférence des facteurs climatiques, qui influencent la qualité et la quantité de la production peuvent constituer un critère important de choisir les emplacements des périmètres viticoles et l'utilisation des solutions techniques adéquates.

En printemps, les températures élevées et les précipitations sont les plus importantes car la vigne recommence la période de végétation, mais en même temps, la saison des maladies et des organismes nuisibles commence aussi, et l'été, par la période de floraison, donne des indices sur la qualité de la récolte. En été, la plantation a besoin d'un temps chaleureux et ensoleillé, aussi que sec, pour effectuer des tailles pour régler le processus de croissance et fructification, des tailles qui donnent des indices sur la dimension de la production et qui facilite la circulation de l'air à travers la vigne et permet l'exposition des raisins au soleil. L'arrivée de l'automne permet la maturation de la culture et le temps doit être optimal, avec des températures élevées et des précipitations réduites, pour commencer la cueillette des raisins et le contrôle de qualité du produit cueilli. L'hiver est une période de végétation latente pour la culture de vigne, bénéfice par ses périodes de gelée et neige, car ces périodes détruisent les organismes nuisibles et les maladies d'une manière naturelle, et les précipitations permettent la restauration des réserves de l'eau dans le sol. En hiver on peut aussi effectuer des travaux de régénération des branches pour améliorer la fertilité et la productivité de la variété visée.

Les trois vignobles analysés, même s'ils bénéficient des conditions climatiques adéquates au développement des variétés de haute qualité, maturation de la culture et amélioration de la concentration des sucres et des arômes des raisins (par exemple: climat tempéré-continental – Panciu et Odobeşti; climat de silvosteppe – Coteşti; influences scandinave-baltique et méditerrané-tropicale; diversité héliothermique, flux radiatif, durée de l'éclat du soleil et des précipitations adéquates etc.) sont affectés aussi par des phénomènes hydro-météoriques accidentels (températures en dessous de -30ºC, gelée, tempête de neige, invasion d'air tropical, pluie à torrent etc.) dans la région de Panciu, et les chercheurs de la Station de Recherche d'Odobeşti disent que, pendant les derniers 40 ans, un réchauffement climatique a eu lieu dans la région d'Odobeşti et Coteşti.

La plantation de vigne devient productive dans des conditions optimales et, comme il résulte de l'analyse de ces facteurs, cela arrive dans la région des collines, dans ce cas, des Subcarpates de Vrancea. Même dans cette situation, étant données les conditions climatiques, analysées en fonction des données météorologiques fournies par la station la plus proche de cette région, les résultats ne met pas en évidence

la vrai possibilité du terrain. Par conséquent, il faut prendre en considération les conditions climatiques aussi que les facteurs modificateurs de climat et le sens d'influence, c'est-à-dire l'altitude, l'exposition du relief, la végétation, les eaux, le sol etc.

Conclusions

Le but de cette étude est de motivation scientifique qui a certains avantages. Ce processus de motivation est utile dans l'élaboration des méthodes biotechnologiques spécifiques, des équipements pour le développement durable de la production et de la sécurité alimentaire, qui maintiennent les paramètres optimales pour les générations à venir. Toutes les actions sont conformes avec les objectifs établis par la Stratégie Europe 2020, parmi lesquels l'utilisation efficiente des ressources et la croissance intelligente, durable et favorable.

A présent, l'optimisation de l'écosystème viticole a comme but l'utilisation rationnelle des ressources écologiques et économiques, la conservation de l'habitat contre la pollution, la minimisation des coûts et de la force de travail ainsi que la maximisation de la production, de la qualité et du profit.

Dans un environnement économique où les résultats à effet économique sont quantifiables, avec une concurrence des dépenses, où les résultats se retrouvent sous forme de production réalisée et vendue, et dans les recettes et les pertes enregistrées, il faut tenir compte des facteurs limitatifs comme le type ou le système de plantation, les conditions agrobiologiques, les technologies, l'offre écologique, et le fait que nous ne pouvons pas contrôler l'évolution des facteurs climatiques et bioclimatiques et il n'est pas possible d'annuler entièrement leur effet sur les cultures de vignes.

La variation du rendement per hectare, chaque année, détermine des déséquilibres de la production totale de raisins. Les conditions climatiques par l'alternation d'un an à l'autre, l'intensité, la durée et l'expansion, le manque de systèmes d'irrigation se reflètent, en général, dans la production de raisins. Si nous avons des informations sur les facteurs climatiques et les besoins des variétés de vigne, on peut gérer de manière responsable la production, la protection et l'amélioration de la qualité. La production de raisins dans la région analysée a fluctué d'un an à l'autre, selon l'analyse présentée en dessus, à cause de l'avance du déroulement des phénophases végétatives et du changement du métabolisme de la vigne, et des situations hydro-météoriques imprévisibles, très fréquentes dernièrement en Roumanie aussi qu'en Europe. Toutes ces conditions aussi que d'autres facteurs ont contribué activement à la diminution quantitative et qualitative de la récolte dans certaines périodes, ce qui impose l'optimisation de la technologie de la production et d'assurer à temps les inputs nécessaires.

Le périmètre des Subcarpates de Vrancea est l'un des plus importantes périmètres viticoles de la Roumanie, avec les deux vignobles des 37 dans le pays, dont les types de vignes ont été approuvés pour être cultivés, par l'Ordre no 225 de 31 mars 2006, émis par le Ministère de l'Agriculture, des Forêts et du Développement Rural en Roumanie.

Abstract

The comparative study of the economic profitability of building new coal blocks on supercritical parameters without and with CCS technology, with economic cost-effectiveness of modernization of already existing, amortized blocks is analyzed. Modernization will allow them to continue operation for several decades.

Keywords: CCS, electricity, power plant, economy, CO2

1. Introduction

The catastrophic in consequences for the state and energy sector finance signed by the Polish government in December 2008, the climate and energy package, and its subsequent enlargement at the beginning of 2015, necessitates strategic decisions on which technologies to invest to minimize the effects of the package. Fundamental are the certainty, stability and continuity of electricity supplies and, what is extremely important, Poland's energy security.

From 2020 there will be no free allocation of CO2 emissions and energy companies will have to pay for every tone of carbon dioxide emitted, for a total of around 30 billion PLN a year. It is clear that the optimum technology is the one for which the specific cost of electricity production is the lowest. The answer to the question is whether to build new zero emissions coal power plants with CO2 capture, transport and storage facilities in deep geological formations, or to modernize existing blocks, taking into account the economic necessity of purchasing CO2 allowances? If modernization is better, than which technology to use?

Bartnik and Hnydiuk-Stefan (2016) presents an economic analysis of specific cost of electricity production in newly built power units in different production technologies. Work of Bartnik and Hnydiuk-Stefan (2016) presents the investment strategy methodology. This article compares the

economics of the profitability of building new coal units with supercritical steam parameters without CCS technology, and the economic cost-effectiveness of modernizing existing, amortized blocks to allow them to continue operation for several decades rather than to exclude them from work, which would be necessary because of climate and energy package.

It should be recalled that the Polish power industry is based entirely on amortized and gradually excluded from the operation of 24 power blocks of 120 MW, 63 of 200 MW blocks, 16 blocks of 360 MW and two 500 MW units. In addition, 3 newly built units with supercritical parameters with a total power of 1800 MW are exploited and another 4 with a combined capacity of 3800 MW are under construction.

Two modernisation variants of the depreciated block are subjected to economic analysis. One is the modernization of the block to the operation with higher thermal parameters of fresh steam, the second is its revitalization with the simultaneous superstructure of gas turbine and recovery boiler to gas-steam dual fuel, according to Bartnik (2013, 2017). In addition, the modernization of the newly built block with supercritical parameters to the CCS-based oxy-combustion block was analyzed by its cryogenic oxygen superstructure by Bartnik and Hnydiuk-Stefan (2016).

2. Methodology for calculating the specific cost of generating electricity in a modernized power unit

Fig. 1 presents the time diagram used to construct a mathematical model for analyzing the economic efficiency of block modernization.

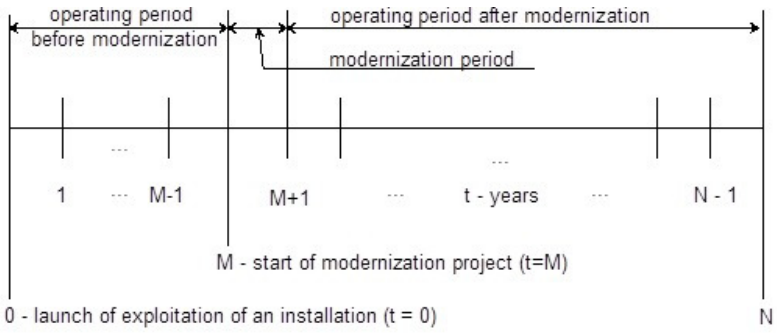

Fig. 1. Diagram of working time of modernized power plant

The average specific cost of electricity production $k_{el,av}$ in the modernized block can be estimated from the formula, according to Bartnik and Hnydiuk-Stefan (2016):

$$
\begin{aligned}
k_{el,av} = \Bigg\{ & \frac{N_{el} t_A}{\eta_{el}} (1 + x_{sw,m,was}) \frac{e_{fuel}^{t=0}}{a_{fuel} - r} \left[\mathrm{e}^{(a_{fuel} - r) t_1} - 1 \right] + \\
& + \frac{N_{el} t_A}{\eta_{el}} \frac{\rho_{CO_2} p_{CO_2}^{t=0}}{a_{CO_2} - r} \left[\mathrm{e}^{(a_{CO_2} - r) t_1} - 1 \right] + \frac{N_{el} t_A}{\eta_{el}} \frac{\rho_{CO} \; p_{CO}^{t=0}}{a_{CO} - r} \left[\mathrm{e}^{(a_{CO} - r) t_1} - 1 \right] + \\
& + \frac{N_{el} t_A}{\eta_{el}} \frac{\rho_{NO_X} p_{NO_X}^{t=0}}{a_{NO_X} - r} \left[\mathrm{e}^{(a_{NO_X} - r) t_1} - 1 \right] + \frac{N_{el} t_A}{\eta_{el}} \frac{\rho_{SO_2} p_{SO_2}^{t=0}}{a_{SO_2} - r} \left[\mathrm{e}^{(a_{SO_2} - r) t_1} - 1 \right] + \\
& + \frac{N_{el} t_A}{\eta_{el}} \frac{\rho_{dust} p_{dust}^{t=0}}{a_{dust} - r} \left[\mathrm{e}^{(a_{dust} - r) t_1} - 1 \right] + \frac{N_{el} t_A}{\eta_{el}} (1 - u) \frac{\rho_{CO_2} e_{CO_2}^{t=0}}{b_{CO_2} - r} \left[\mathrm{e}^{(b_{CO_2} - r) t_1} - 1 \right] + \\
& + J (1 + x_{sal,t,ins}) \frac{\delta_{serv}}{r} \left(1 - \mathrm{e}^{-r t_1} \right) + zJ \left[1 + \frac{1}{T} - \left(1 + \frac{1}{T} - \frac{t_1}{T} \right) \mathrm{e}^{-r t_1} \right] + \\
& + \frac{N_{el}^M t_A^M}{\eta_{el}^M} (1 + x_{sw,m,was}) \frac{e_{fuel}^{M,t=t_1}}{a_{fuel}^M - r} \left[\mathrm{e}^{(a_{fuel}^M - r) t_2} - \mathrm{e}^{(a_{fuel}^M - r) t_1} \right] + \\
& + \frac{N_{el}^M t_A^M}{\eta_{el}^{\mathrm{M}}} \frac{\rho_{CO_2} p_{CO_2}^{M,t=t_1}}{a_{CO_2}^M - r} \left[\mathrm{e}^{(a_{CO_2}^M - r) t_2} - \mathrm{e}^{(a_{CO_2}^M - r) t_1} \right] + \frac{N_{el}^M t_A^M}{\eta_{el}^{\mathrm{M}}} \frac{\rho_{CO} p_{CO}^{M,t=t_1}}{a_{CO}^M - r} \left[\mathrm{e}^{(a_{CO}^M - r) t_2} - \mathrm{e}^{(a_{CO}^M - r) t_1} \right] + \\
& + \frac{N_{el}^M t_A^M}{\eta_{el}^{\mathrm{M}}} \frac{\rho_{NO_X} p_{NO_X}^{M,t=t_1}}{a_{NO_X}^M - r} \left[\mathrm{e}^{(a_{NO_X}^M - r) t_2} - \mathrm{e}^{(a_{NO_X}^M - r) t_1} \right] + \frac{N_{el}^M t_A^M}{\eta_{el}^{\mathrm{M}}} \frac{\rho_{SO_2} p_{SO_2}^{M,t=t_1}}{a_{SO_2}^M - r} \left[\mathrm{e}^{(a_{SO_2}^M - r) t_2} - \mathrm{e}^{(a_{SO_2}^M - r) t_1} \right] + \\
& + \frac{N_{el}^M t_A^M}{\eta_{el}^{\mathrm{M}}} \frac{\rho_{dust} p_{dust}^{M,t=t_1}}{a_{dust}^M - r} \left[\mathrm{e}^{(a_{dust}^M - r) t_1} - \mathrm{e}^{(a_{dust}^M - r) t_1} \right] + \frac{N_{el}^M t_A^M}{\eta_{el}^{\mathrm{M}}} \left(1 - u^M \right) \frac{\rho_{CO_2} e_{CO_2}^{M,t=t_1}}{b_{CO_2}^M - r} \left[\mathrm{e}^{(b_{CO_2}^M - r) t_2} - \mathrm{e}^{(b_{CO_2}^M - r) t_1} \right] + \\
& + \frac{(J + J_M) \delta_{serv}^M}{r} \left(\mathrm{e}^{-r t_1} - \mathrm{e}^{-r t_2} \right) + zJ \left[\left(1 + \frac{1}{T} - \frac{t_1}{T} \right) \mathrm{e}^{-r t_1} - \left(1 + \frac{1}{T} - \frac{t_2}{T} \right) \mathrm{e}^{-r t_2} \right] + \\
& + J_M \left[\left(1 + \frac{1}{T - t_1} - \frac{t_1}{T - t_1} \right) \mathrm{e}^{-r t_1} - \left(1 + \frac{1}{T - t_1} - \frac{t_2}{T - t_1} \right) \mathrm{e}^{-r t_2} \right] +
\end{aligned}
$$

$$+\frac{N_{el}^{\mathrm{mod}}t_A^{\mathrm{mod}}}{\eta_{el}^{\mathrm{mod}}}(1+x_{sw,m,was})\frac{e_{fuel}^{\mathrm{mod},t=t_2}}{a_{fuel}^{\mathrm{mod}}-r}\left[\mathrm{e}^{\left(a_{fuel}^{\mathrm{mod}}-r\right)T}-\mathrm{e}^{\left(a_{fuel}^{\mathrm{mod}}-r\right)t_2}\right]+$$

$$+\frac{\left(J+J_M\right)(1+x_{sal,t,ins})\delta_{serv}^{\mathrm{mod}}}{r}\left(\mathrm{e}^{-rt_2}-\mathrm{e}^{-rT}\right)+zJ\left[\left(1+\frac{1}{T}-\frac{t_2}{T}\right)\mathrm{e}^{-rt_2}-\frac{1}{T}\mathrm{e}^{-rT}\right]+$$

$$+J_M\left[\left(1+\frac{1}{T-t_1}-\frac{t_2}{(T-t_1)}\right)\mathrm{e}^{-rt_2}-\left(1+\frac{1}{T-t_1}-\frac{T}{(T-t_1)}\right)\mathrm{e}^{-rT}\right]\Bigg\}\times$$

$$\times\frac{r}{N_{el}\left(1-\varepsilon_{el}\right)\left(1-\mathrm{e}^{-rt_1}\right)t_A+N_{el}^{M}\left(1-\varepsilon_{el}^{M}\right)\left(\mathrm{e}^{-rt_1}-\mathrm{e}^{-rt_2}\right)t_A^{M}+N_{el}^{\mathrm{mod}}\left(1-\varepsilon_{el}^{\mathrm{mod}}\right)\left(\mathrm{e}^{-rt_2}-\mathrm{e}^{-rT}\right)t_A^{\mathrm{mod}}} \tag{1}$$

where:

$a_{fuel}, a_{\mathrm{CO}_2}, a_{\mathrm{CO}}, a_{\mathrm{SO}_2}, a_{\mathrm{NO}_X}, a_{dust}, b_{\mathrm{CO}_2}$ – controls representing variable CO_2, fuel prices, etc. (exponential values, e.g. $e_{CO2}(t)=e_{CO2}^{t=0}\mathrm{e}^{a_{CO2}t}$)

b – duration of power block construction expressed in years,

$e_{pal}^{t=0}$, $e_{CO_2}^{t=0}$, $p_{CO_2}^{t=0}$ etc. – initial values of the prices of fuel, CO_2 emission allowances, tariffs on the use of the environment,

J – actual investment made in the construction of a power plant,

J_M – actual investment made in the modernization of a power plant,

N_{el} – gross electrical capacity of the power plant,

r – interest rate on investment capital (calculations assume r = 7%),

t_A – annual operating time of a power plant,

t_1 – the year of the block start modernization,

t_2 – year of block modernization completion,

T – expressed in years, calculating time of the block exploitation (calculations assume T = 20 years),

u – ratio of chemical energy of fuel to its total use, for which it is not necessary to purchase CO_2 emission allowances,

$x_{sw,m,was}$ – coefficient accounting for the cost of supplementing water, auxiliary materials, waste disposal, slag storage and waste (in practice, the value of $x_{sw,m,was}$ is equal to around 0.25),

$x_{sal,t,ins}$ – coefficient accounting for the cost of remuneration, taxes, insurance, etc. (in practice, the value of $x_{sal,t,ins}$ is equal to around 0.02).

z – discounting coefficient (coefficient of capital freezing) on the investment J at the instant of the completion of power plant construction,

$\square_{el}$ – internal electrical load of a power plant,

δ_{serv} – annual rate of fixed cost relative to the value of the investment (cost of maintenance and overhaul of equipment),

η_{el} – energy efficiency of a power plant,

ρ_{CO_2}, ρ_{CO}, ρ_{NO_x}, ρ_{SO_2}, ρ_{dust} – emission of CO_2, CO, NO_x, SO_2, and particulate matter per specific unit of chemical energy of the fuel.

In the case of modernization power plant to CCS oxyfuel combustion technology, the cost of emission of pollutants into the atmosphere resulting from the burning of coal and the purchase of CO2 emission allowances are not included in the cost of operating the modernized block, i.e. in the time interval from t_2 to T, in formula (1). Instead, there is the cost of transporting carbon dioxide to the place of storage. In the case of modernization of the block to the dual-fuel gas-steam unit, the power of the steam turbine must be taken into account along with the power of the gas turbine, and the annual operating costs of the used gas and the costs of the emissions generated by the combustion, according to Bartnik (2013, 2014).

3. Discussion and analysis of the example calculation results of the economic profitability of existing coal power blocks modernization

The economic profitability analysis is subject to modernization of the 120 MW depreciated block to the block for higher steam parameters and to the dual-fuel gas-steam system. In calculations it was assumed that, during the modernization (t_2 - t_1 = 2), regardless of the method, the block power is zero $N_{el}^{M} = 0$ (formula (1)). The block is therefore excluded for 2 years from operation.

The modernization of the newly built power block with a power of 460 MW with supercritical parameters to oxy-combustion CCS technology, based on research by Bartnik and Hnydiuk-Stefan (2016) has also been analyzed. It was assumed that $N_{el}^{M} = 460\text{MW}$, as the block operates in two years during cryogenic oxygen unit is built.

In all variants of modernization, the share of the chemical energy *u* in the fuel in its total annual consumption for which CO2 emission allowance is required is zero, *u = 0*, as there will be no free allocation since 2020. It has also been assumed that the zero values of exponents $a_{fuel}, a_{\text{gas}}, b_{\text{CO}_2}$ etc., correspond to the current prices of coal, gas, CO2 emissions, etc. For example, in the exponent $e_{fuel}(t) = e_{fuel}^{t=0} \text{e}^{a_{fuel} t}$ illustrating the coal price change, the present value is $e_{fuel}^{t=0} = 11.4\ \text{PLN/GJ} = 41\ \text{PLN/MWh}$. The results of calculating specific cost of electricity production in power blocks are presented in Figures 2-17 for several selected, from an unlimited number of possible scenarios of time changes in fuel prices and CO2 emissions. Figures 2-5 present the specific cost of electricity production in the newly built power block with the supercritical steam parameters in conventional technology, ie, in the combustion of coal in the air atmosphere and in CCS combustion technology in the atmosphere of technical oxygen and recycled in the appropriate proportion of carbon dioxide (so-called oxy-fuel process).

The results are presented, as already mentioned, multivariate, i.e. for different average coal prices over a period of time $\langle 0, T \rangle$ in accordance with the exponential equation above and for different average purchase prices of CO2 emissions in accordance with the exponent $e_{CO_2}(t) = e_{CO_2}^{t=0} \text{e}^{b_{CO_2} t}$. As is apparent from the results of calculations, the specific cost $k_{el,oxy}$ of electricity production of the power plant operating in CCS is at least two times higher than the cost of a conventional block. In order for this cost to be less than the cost in the power block without CCS, it will only be possible to meet the relation $k_{el,oxy} \le k_{el}$ if the average purchase price $e_{CO_2}^{av}$ of the emission allowances is higher than the 400 PLN/Mg_{CO2} (current price $e_{CO_2}^{t=0} \cong 29\ \text{PLN/Mg}_{\text{CO}_2}$) - Figure 4. It seems unlikely that this could ever happen. The cost $k_{el,oxy}$ would then be much higher than the cost of generating electricity in nuclear units, which is about 420 PLN/MWh, according to Bartnik and Hnydiuk-Stefan (2016). Therefore, the construction of blocks with CCS installations in this situation would be completely devoid of economic sense.

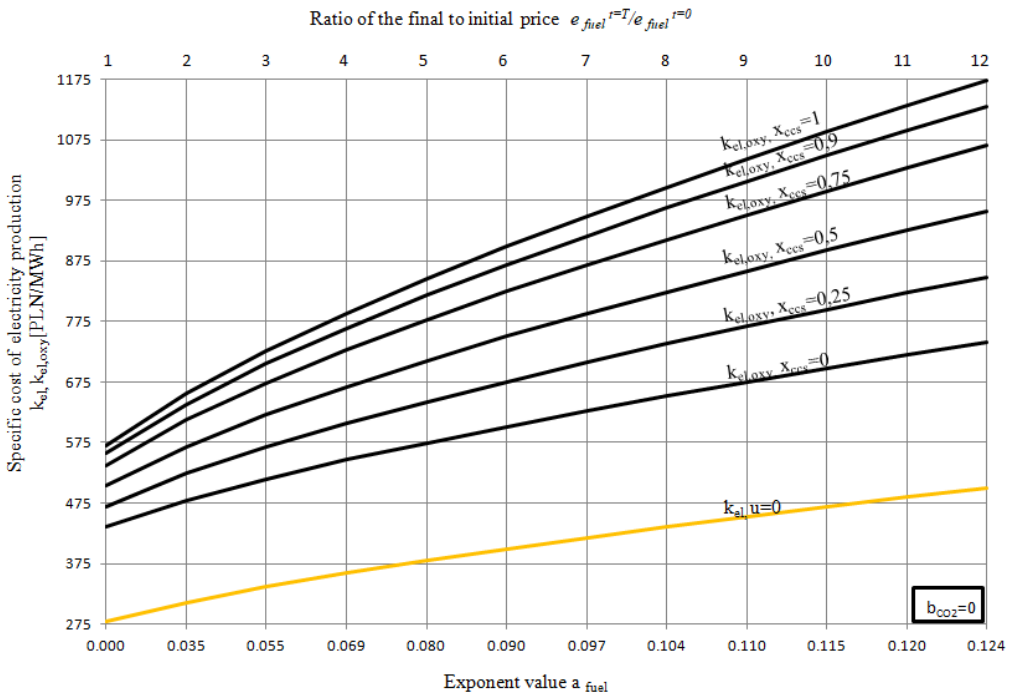

Fig. 2. The specific cost of electricity production in the 460 MW power block for supercritical parameters as a function of exponent value a_{fuel} and price ratio $e_{fuel}^{t=T}/e_{\text{fuel}}^{t=0}$, where: k_{el} - refers to coal power plant in air combustion; $k_{el,\ oxygen}$ - refers to the coal power plant with oxy-combustion; x_{ccs} - a factor that takes into account the cost of transporting carbon dioxide to its capture, injection and storage, according to Bartnik and Hnydiuk-Stefan (2016)

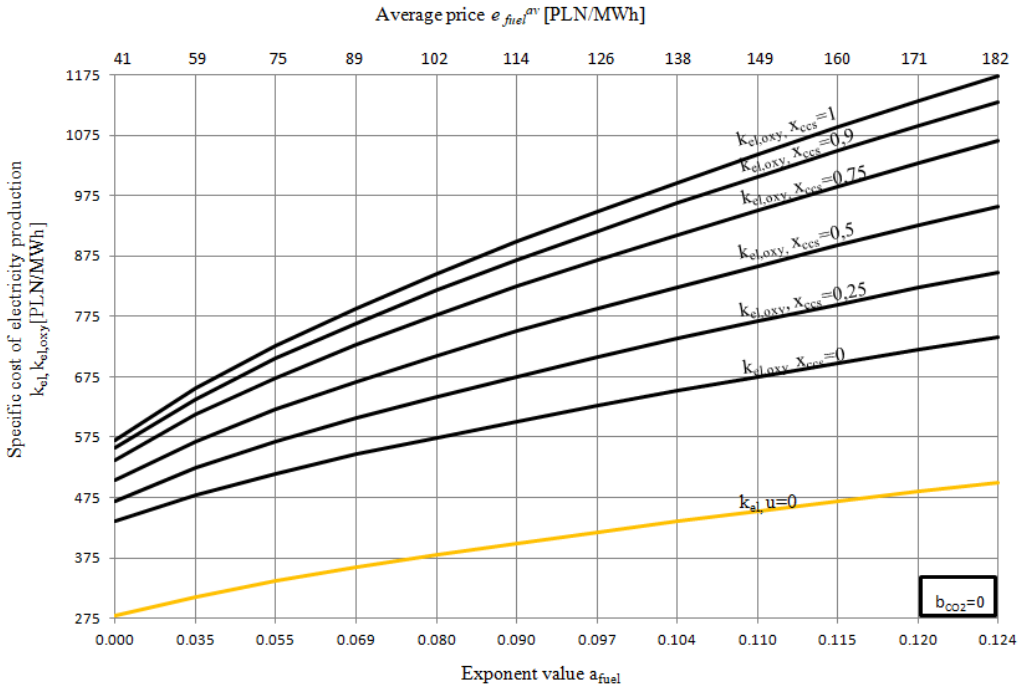

Fig. 3. The specific cost of electricity production in the 460 MW power block for supercritical parameters as a function of exponent value a_{fuel} and average fuel price e_{fuel}^{av}, where: k_{el} - refers to coal power plant in air combustion; $k_{el,\ oxygen}$ - refers to the coal power plant with oxy-combustion

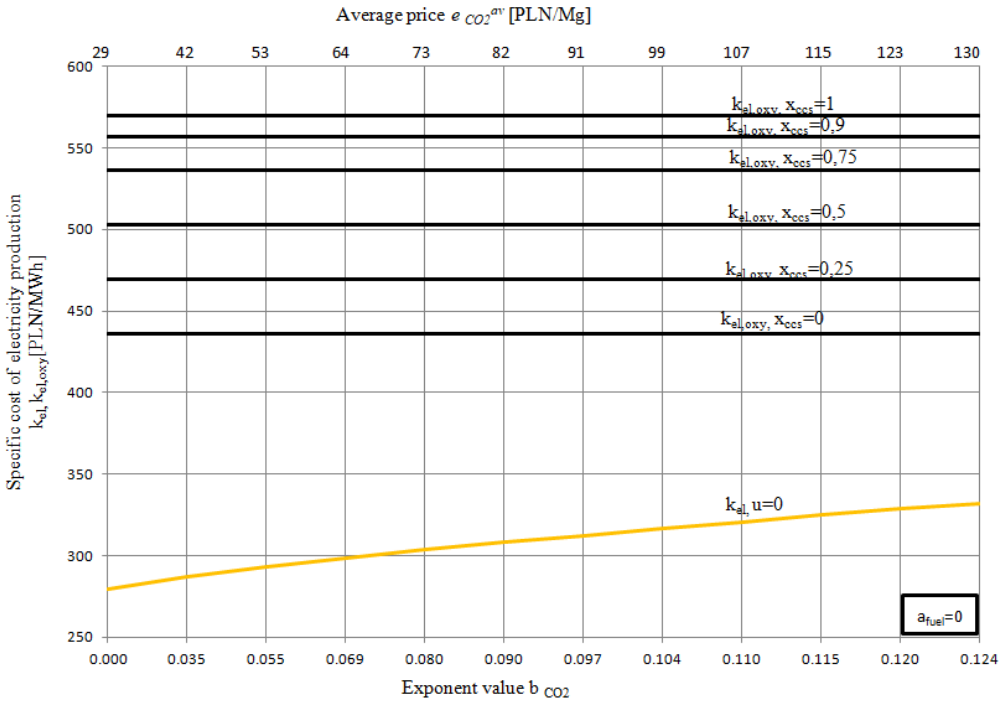

Fig. 4. The specific cost of electricity production in the 460 MW power block for supercritical parameters as a function of exponent value b_{CO2} and average CO2 tone purchase price $e_{CO_2}^{av}$, where: k_{el} - refers to coal power plant in air combustion; $k_{el,\ oxygen}$ - refers to the coal power plant with oxy-combustion

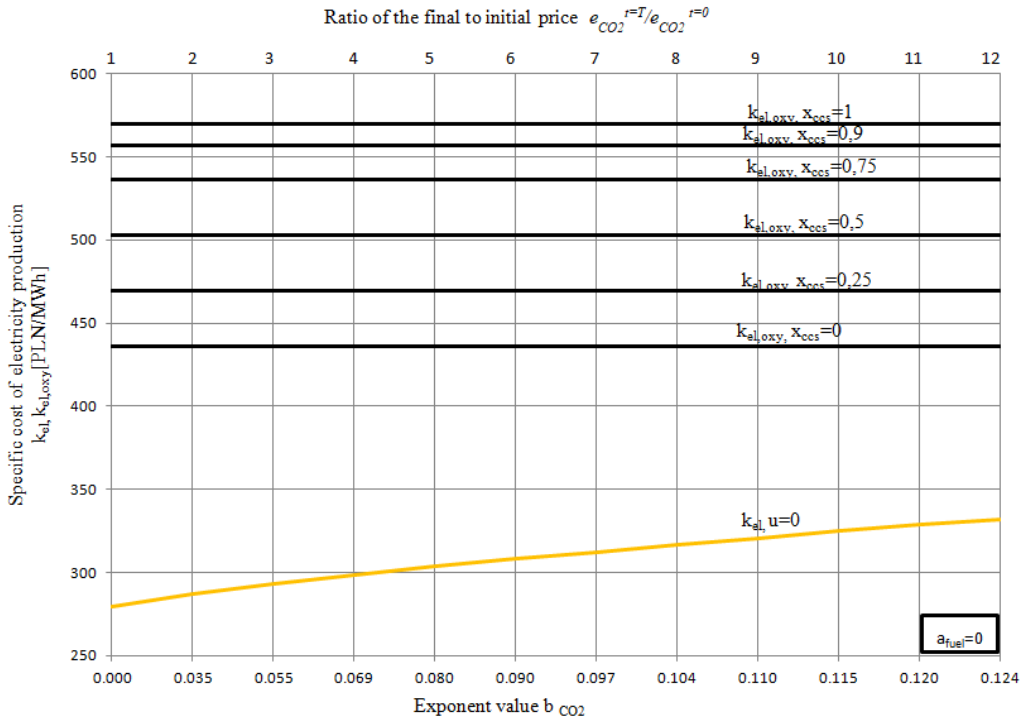

Fig. 5. The specific cost of electricity production in the 460 MW power block for supercritical parameters as a function of exponent value b_{CO2} and price ratio $e_{CO_2}^{t=T}/e_{CO_2}^{t=0}$, where: k_{el} - refers to coal power plant in air combustion; $k_{el,\,oxygen}$ - refers to the coal power plant with oxy-combustion

Figures 6-9 show the results of calculating the specific cost of generating electricity in a block for supercritical steam parameters modernized to CCS oxy-combustion technology. They are presented according to the year t_1 of the modernization start. Investment expenditures for modernization are assumed at J_M = 1.196 billion PLN (unit costs are i_M = 2.6 mln PLN /MW).

As the figures show, the t_1 year is longer, the smaller the specific cost of electricity production. This is obvious because the cost of a CCS block is at least two times higher than the cost without this technology, so the start year of modernization is far more distant, the specific cost in the modernized block is lower. It is therefore clearly say that the modernization of the block to the CCS oxy-combustion is completely unprofitable. It is better to purchase CO2 emissions allowances rather than modernize the power block and not emit CO2 into the atmosphere, despite the fact that the cost of CO2 emissions allowances is high. Its value at current specific (per unit of energy) coal price is 11.4 PLN/GJ and the price of CO2 emission equals 29 PLN is 25% of the cost of coal. This cost is therefore the third in terms of cost, after the purchase of coal and capital,

as part of the annual operating costs of the plan operation, and thus significantly increases the specific cost of electricity generation. Even more than a dozen times the price e_{CO_2} increase does not, however, make CCS technology more profitable - Fig. 4, 5, 8.

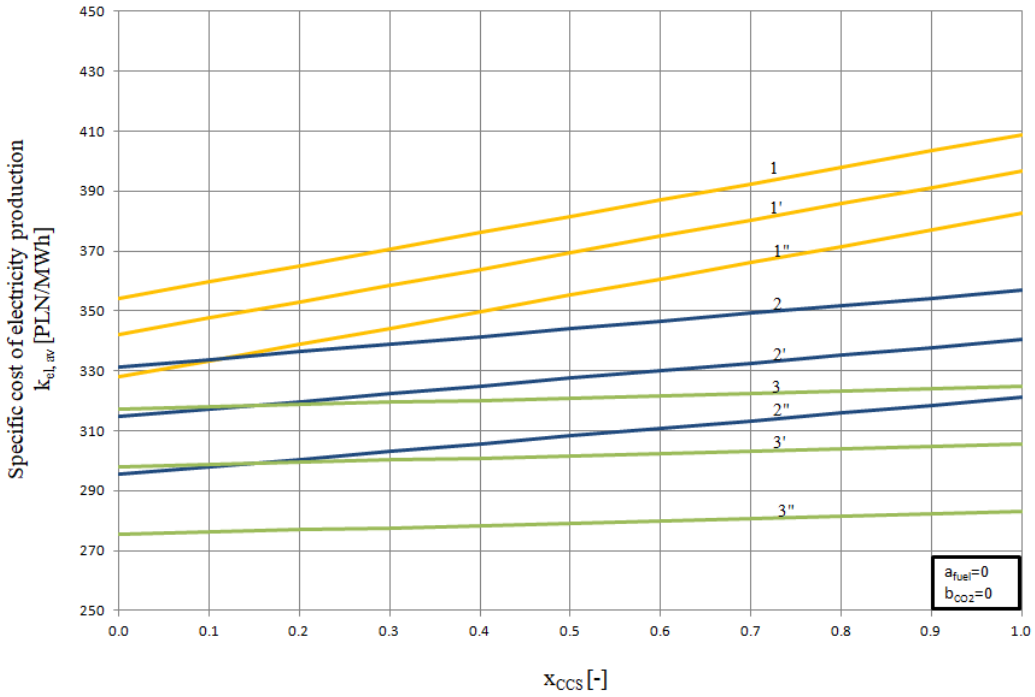

Fig. 6. Specific cost of electricity production in a 460 MW unit for supercritical steam parameters modernized to *CCS* combustion technology as a function of the x_{ccs} factor taking into account the cost of transporting carbon dioxide to the place of its capture, injection and storage, where: 1 – applies to t_1 = 5 years, e_{CO2} = 20 euro/Mg_{CO2}; 1' – applies to t_1 = 5 years, e_{CO2} = 14 euro/ Mg_{CO2}; 1" – applies to t_1 = 5 years, e_{CO2} = 7 euro/Mg_{CO2}; 2 – applies to t_1 = 10 years, e_{CO2} = 20 euro/Mg_{CO2}; 2' – applies to t_1 = 10 years, e_{CO2} = 14 euro/Mg_{CO2}; 2" – applies to t_1 = 10 years, e_{CO2} = 7 euro/$Mg_{CO2;}$ 3 – applies to t_1 = 15 years, e_{CO2} = 20 euro/$Mg_{CO2;}$ 3' – applies to t_1 = 15 years, e_{CO2} = 14 euro/$Mg_{CO2;}$ 3" – applies to t_1 = 15 years, e_{CO2} = 7 euro/Mg_{CO2}

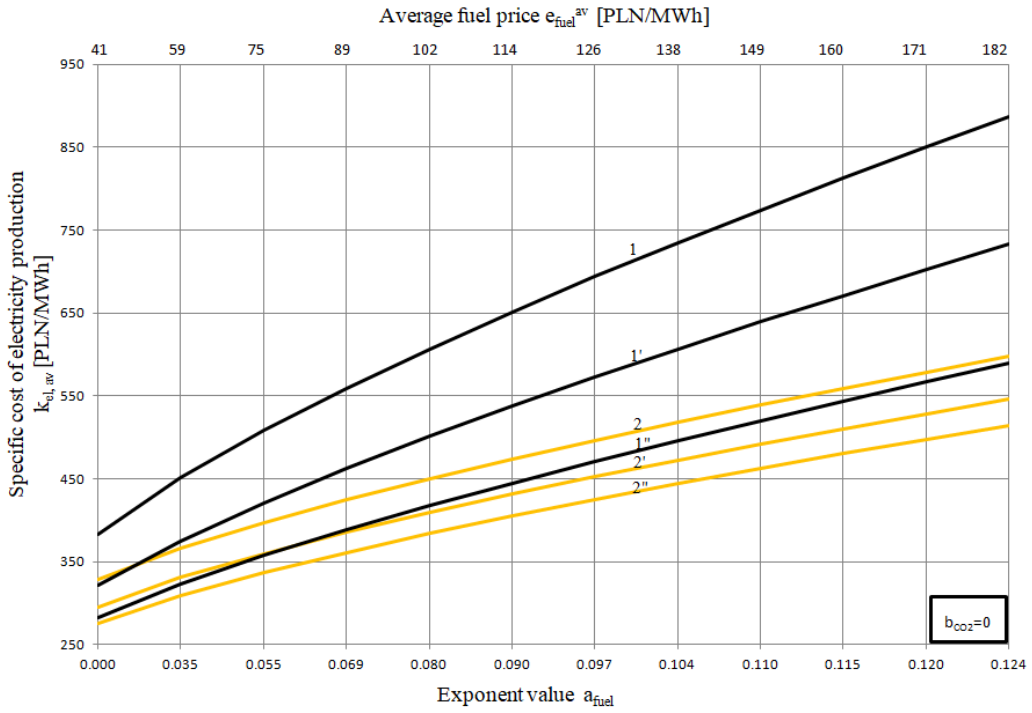

Fig. 7. The specific cost of electricity production in a 460 MW unit for supercritical steam parameters modernized to *CCS* combustion technology as a function of the average fuel price e_{fuel}^{av} and of exponent value a_{fuel}, where: 1 – applies to $t_1 = 5$ years, $x_{ccs} = 1$; 1' – applies to $t_1 = 10$ years, $x_{ccs} = 1$; 1" – applies to $t_1 = 15$ years, $x_{ccs} = 1$; 2 – applies to $t_1 = 5$ years, $x_{ccs} = 0$; 2' – applies to $t_1 = 10$ years, $x_{ccs} = 0$; 2" – applies to $t_1 = 15$ years, $x_{ccs} = 0$

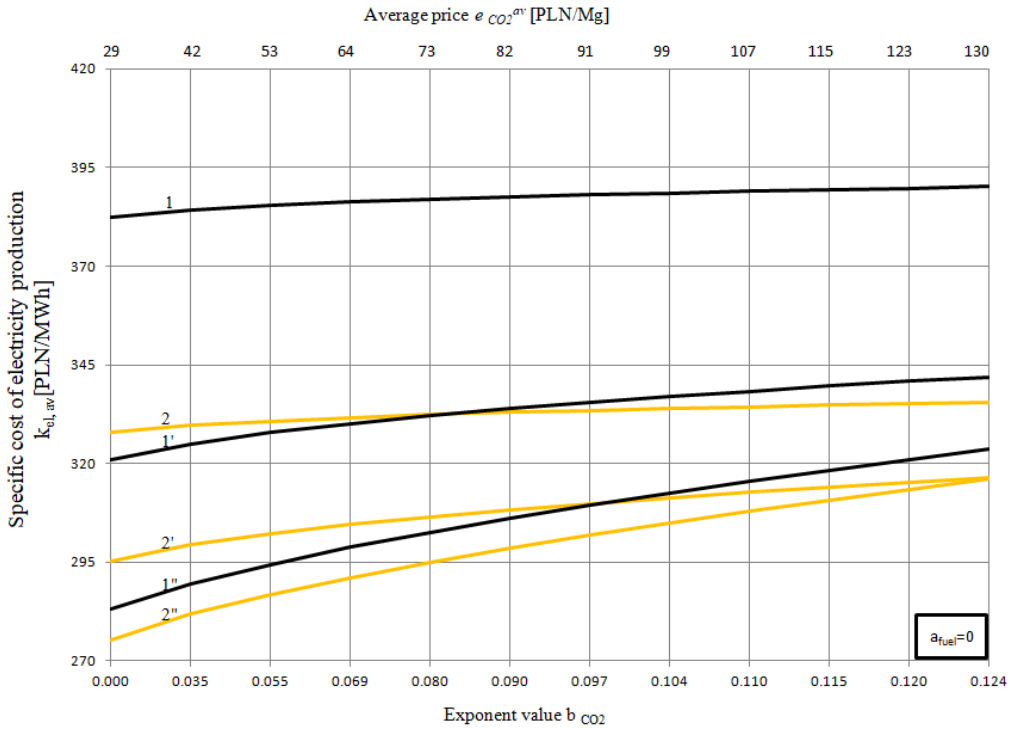

Fig. 8. The specific cost of electricity production in the 460 MW power block for supercritical parameters modernized to *CCS* combustion technology as a function of exponent value b_{CO2} and average CO2 emission price $e_{CO_2}^{av}$, where: 1 – applies to t_1 = 5 years, x_{ccs} = 1; 1' – applies to t_1 = 10 years, x_{ccs} = 1; 1" – applies to t_1 = 15 years, x_{ccs} = 1; 2 – applies to t_1 = 5 years, x_{ccs} = 0; 2' – applies to t_1 = 10 years, x_{ccs} = 0; 2" – applies to t_1 = 15 years, x_{ccs} = 0

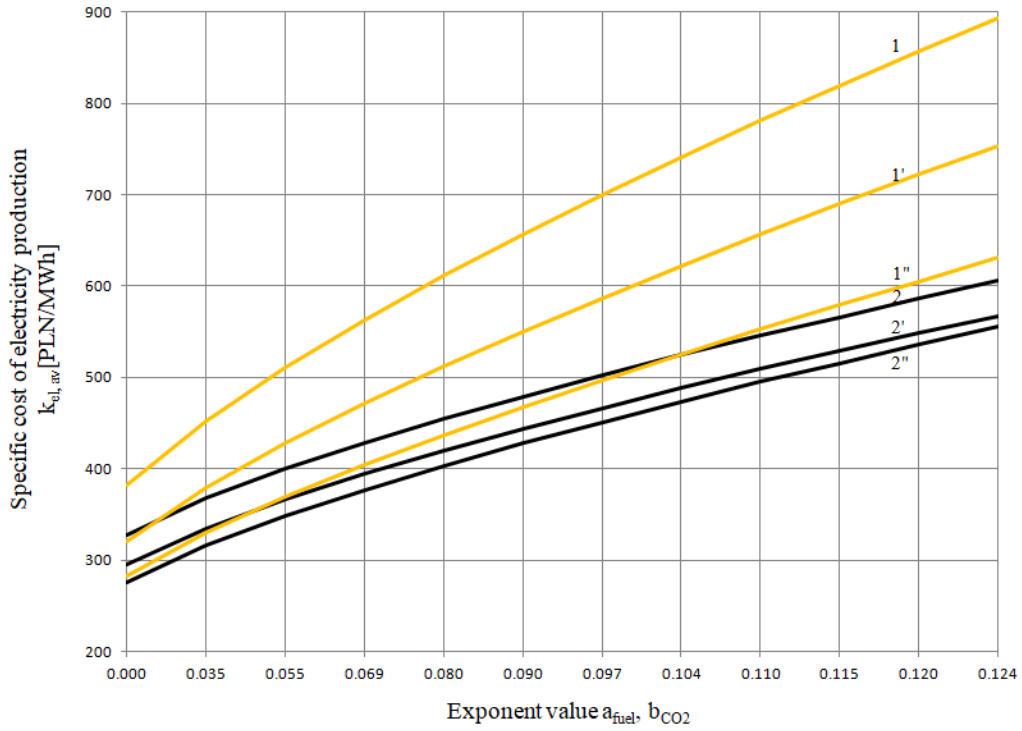

Fig. 9. The specific cost of electricity production in the 460 MW power block for supercritical parameters modernized to *CCS* combustion technology as a function of exponent values a_{fuel} and b_{CO2}, where: 1 – applies to $t_1 = 5$ years, $x_{ccs} = 1$; 1' – applies to $t_1 = 10$ years, $x_{ccs} = 1$; 1" – applies to $t_1 = 15$ years, $x_{ccs} = 1$; 2 – applies to $t_1 = 5$ years, $x_{ccs} = 0$; 2' – applies to $t_1 = 10$ years, $x_{ccs} = 0$; 2" – applies to $t_1 = 15$ years, $x_{ccs} = 0$

Figures 10-14 illustrate the specific cost of electricity production in a 120 MW depreciated power block modernized to a dual-fuel gas-steam unit. The power of the gas turbine assumed equal to $N_{el}^{TG} = 120\text{MW}$. Investment expenditures for modernization are assumed at J_M = 420 mln PLN (unit cost is i_M = 3.5 mln PLN/MW). The specific cost of electricity production in the modernized block is significantly lower than the cost in block for supercritical steam parameters, Fig. 2-5, despite the fact that it burns expensive natural gas alongside coal.

Moreover, for current coal and gas prices (i.e. when a_{fuel}=0 and a_{gas} = 0) it is relatively little higher than the specific cost for 120 MW block modernized to the block for higher parameters of fresh steam, which burns 3 times cheaper coal - figures 15 - 17.

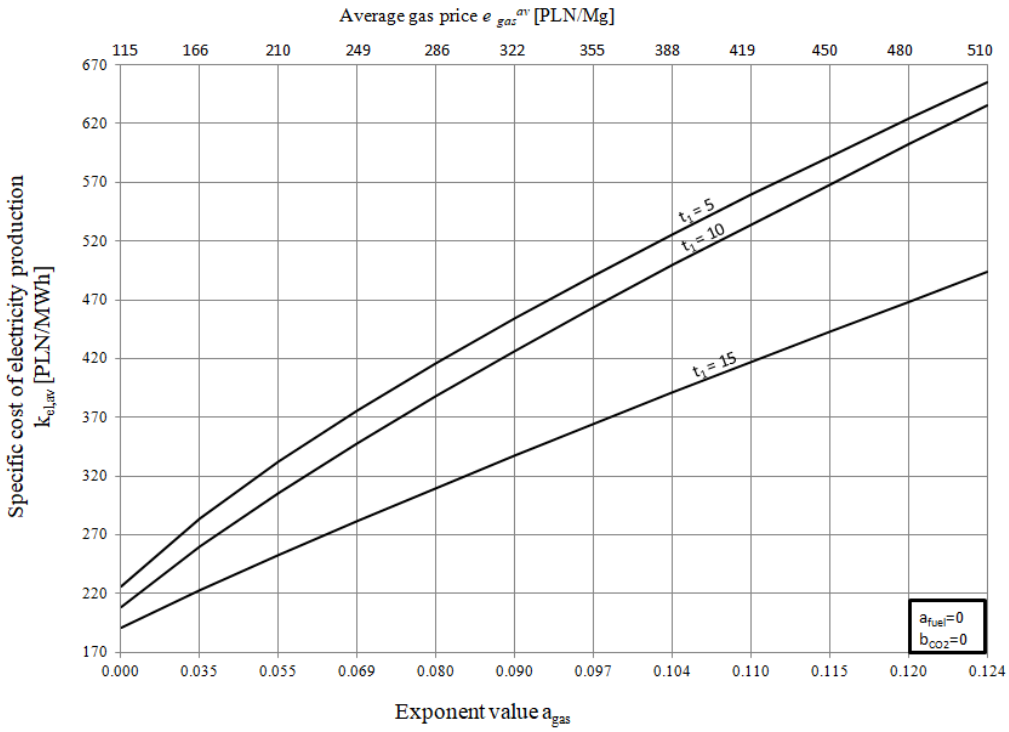

Fig. 10. The specific cost of electricity production in a 120 MW power plant modernized to a dual-fuel gas-steam system as a function of the exponent value a_{gas}.

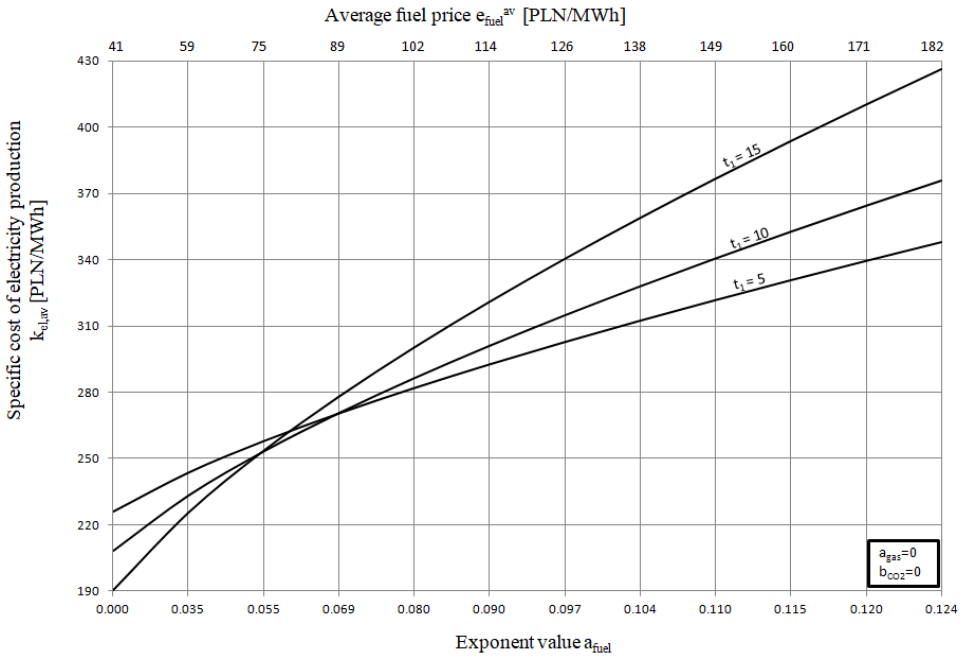

Fig 11. The specific cost of electricity production in a 120 MW power plant modernized to a dual-fuel gas-steam system as a function of the exponent value a_{fuel}.

As can be seen from the analysis of the curves in Figure 11, the lower ratio of the gas price to coal price, the quicker modernization of the block to the dual-fuel gas-steam system is more profitable.

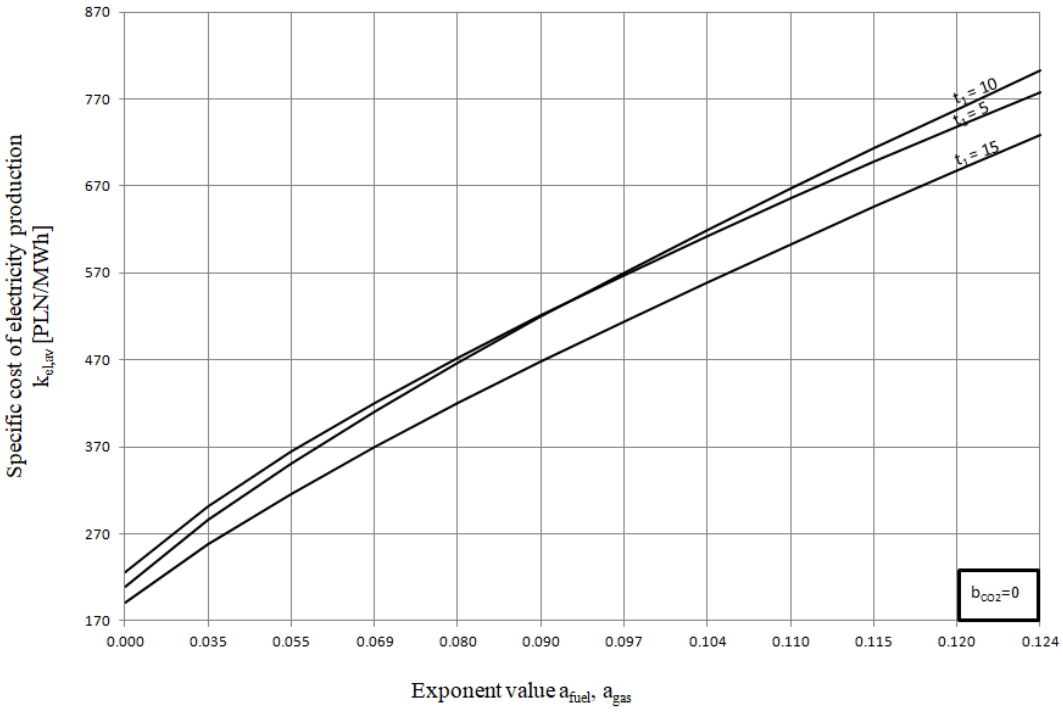

Fig. 12. The specific cost of electricity production in a 120 MW power plant modernized to a dual-fuel gas-steam system as a function of the exponent values a_{fuel} and a_{gas}

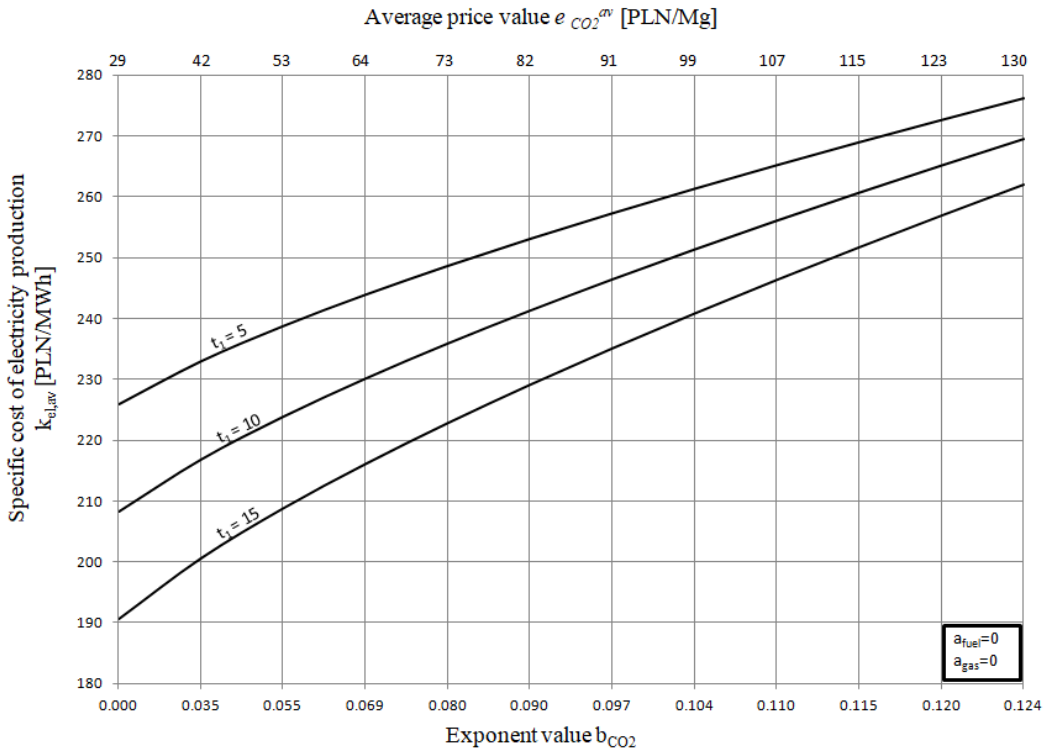

Fig. 13. The specific cost of electricity production in a 120 MW power plant modernized to a dual-fuel gas-steam system as a function of the exponent value b_{CO2}

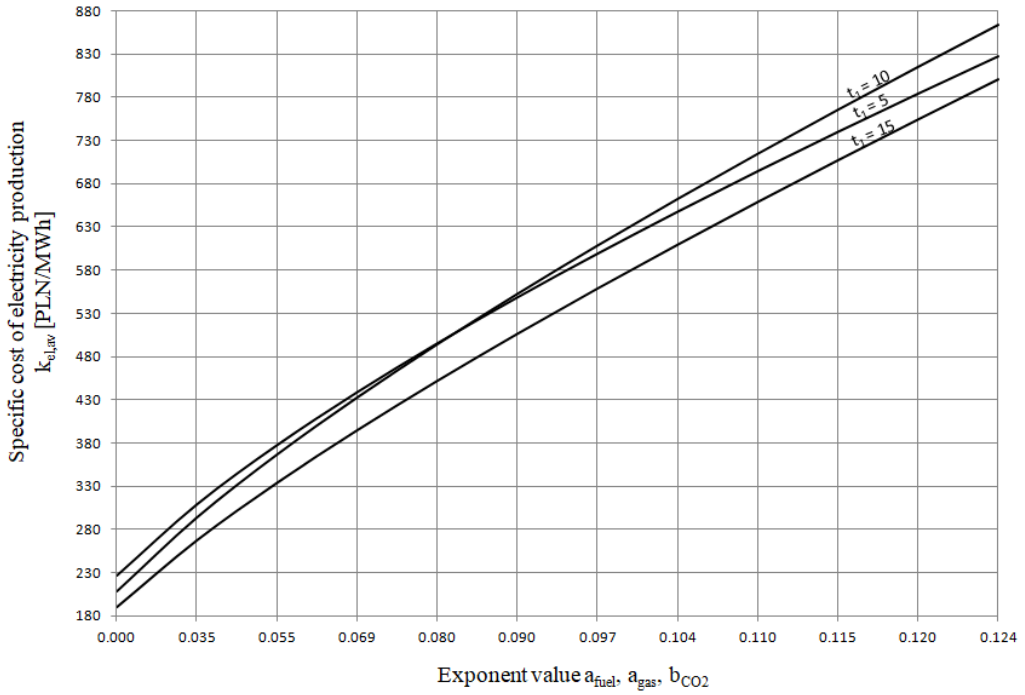

Fig. 14. The specific cost of electricity production in a 120 MW power plant modernized to a dual-fuel gas-steam system as a function of the exponent values a_{fuel}, a_{gas} and b_{CO2}

Figures 15-17 illustrates the specific cost of electricity production in a 120 MW amortized block, which has been upgraded to the block for higher thermal parameters of fresh steam. The block power after modernization is 130 MW. The calculations assume two values of investment for modernization: J_M = 240 mln PLN and J_M = 360 mln PLN (unit costs are i_M = 2 mln/MW and i_M = 3 mln/MW; for comparison, the unitary outlays for building "from the grass" power blocks for supercritical parameters are 6.5 million/MW). By analyzing the curves in the figures, it is possible to draw a misleading conclusion from the economic account that modernization is unprofitable, as the specific cost of electricity production in a modernized block is the smaller, the year of t_1, fig.1., the start of modernization is farer, when the modernization will occur as late as possible, and preferably at all.

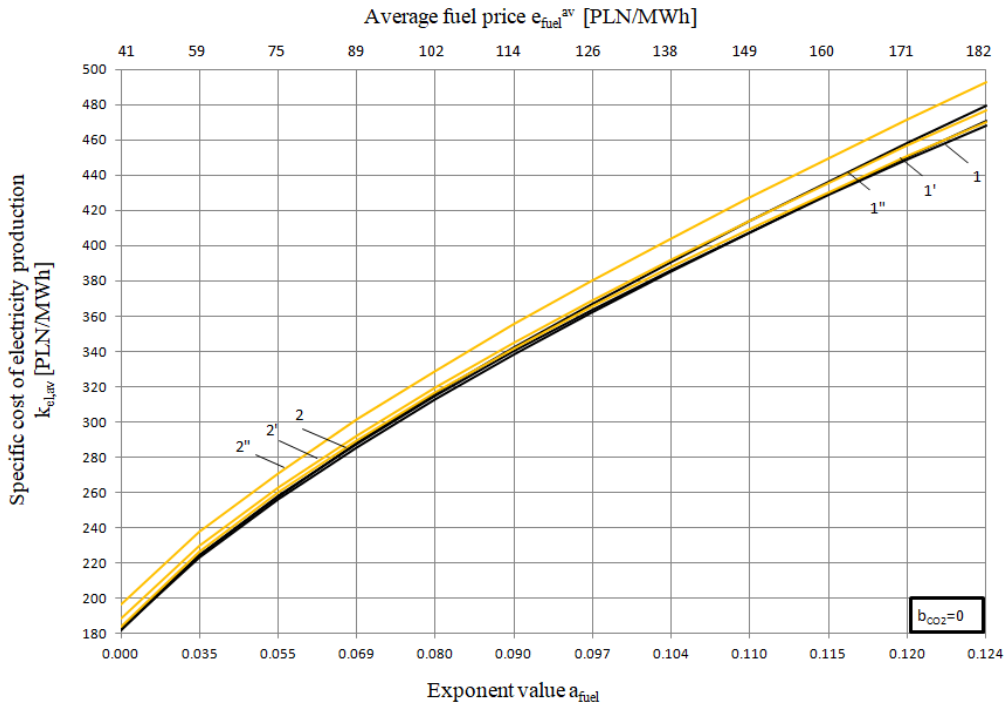

Fig. 15. The specific cost of electricity production in a 120 MW block modernized to block for higher thermal parameters of fresh steam as a function of exponent value $a_{fuel,}$ where: 1 – applies to t_1 = 15 years, i_M = 2 mln PLN/MW; 1' – applies to t_1 = 10 years, i_M = 2 mln PLN/MW; 1" – applies to t_1 = 5 years, i_M = 2 mln PLN/MW; 2 – applies to t_1 = 15 years, i_M = 3 mln PLN/MW; 2' – applies to t_1 = 10 years, i_M = 3 mln PLN/MW; 2" – applies to t_1 = 5 years, i_M = 3 mln PLN/MW

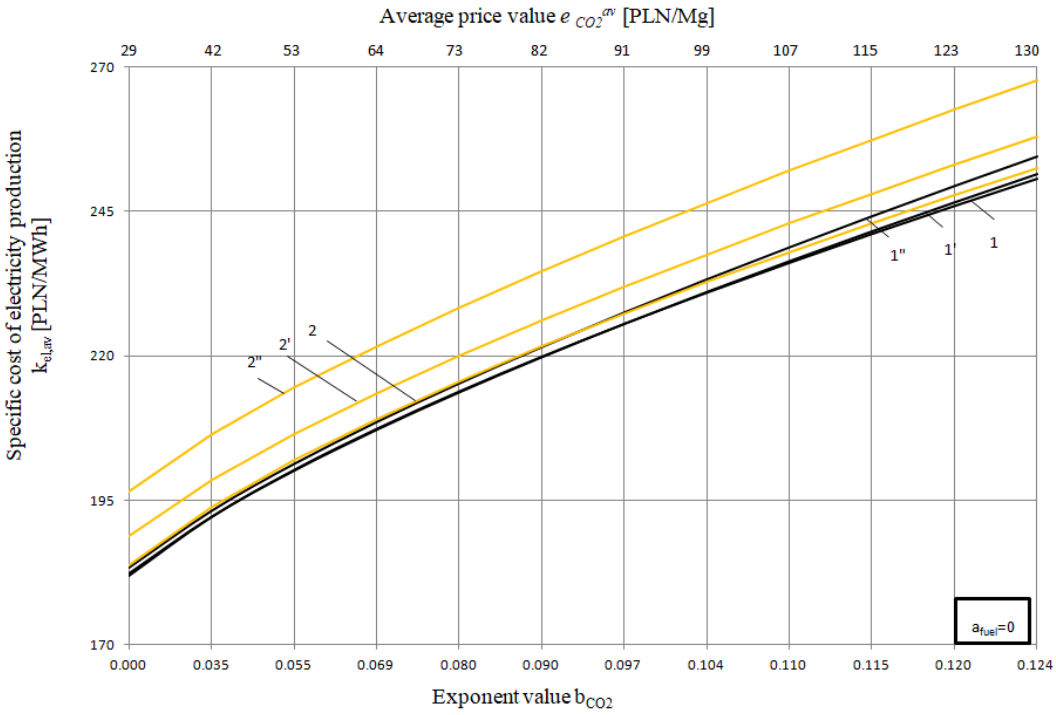

Fig. 16. The specific cost of electricity production in a 120 MW block modernized to block for higher thermal parameters of fresh steam as a function of exponent value b_{CO2}, where: 1 – applies to t_1 = 15 years, i_M = 2 mln PLN/MW; 1' – applies to t_1 = 10 years, i_M = 2 mln PLN/MW; 1" – applies to t_1 = 5 years, i_M = 2 mln PLN/MW; 2 – applies to t_1 = 15 years, i_M = 3 mln PLN/MW; 2' – applies to t_1 = 10 years, i_M = 3 mln PLN/MW; 2" – applies to t_1 = 5 years, i_M = 3 mln PLN/MW

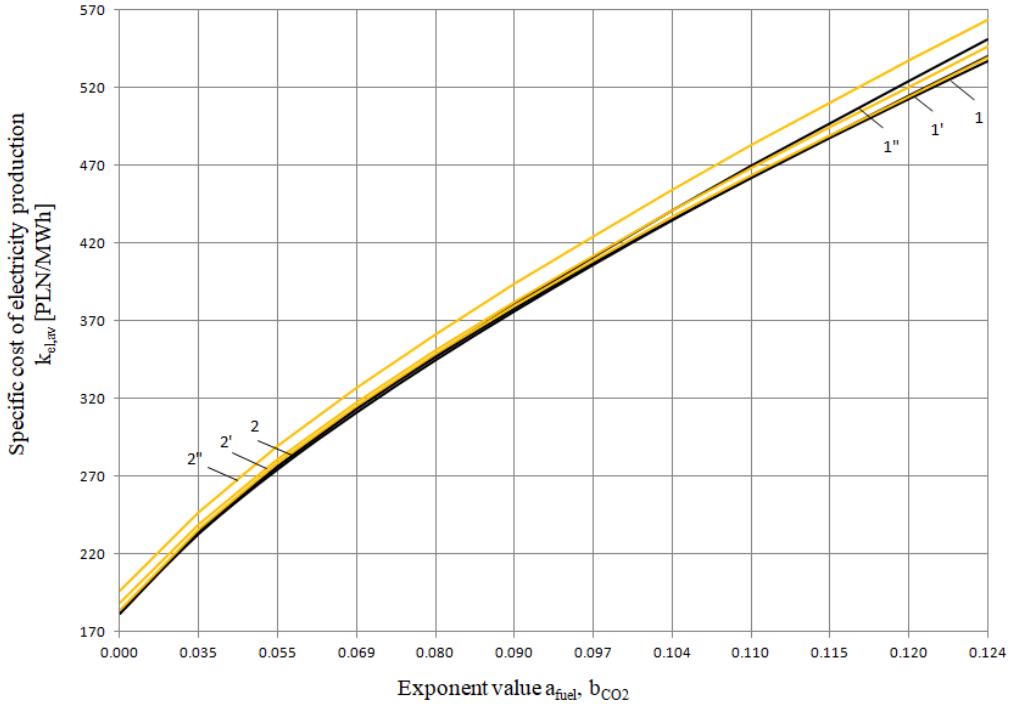

Fig. 17. The specific cost of electricity production in a 120 MW block modernized to block for higher thermal parameters of fresh steam as a function of exponent values a_{fuel} and b_{CO2}, where: 1 – applies to t_1 = 15 years, i_M = 2 mln PLN/MW; 1' – applies to t_1 = 10 years, i_M = 2 mln PLN/MW; 1" – applies to t_1 = 5 years, i_M = 2 mln PLN/MW; 2 – applies to t_1 = 15 years, i_M = 3 mln PLN/MW; 2' – applies to t_1 = 10 years, i_M = 3 mln PLN/MW; 2" – applies to t_1 = 5 years, i_M = 3 mln PLN/MW

The smallest specific cost is for t_1 = 15 years. This is because, in the modernized block, in its annual operating costs are again the cost of capital (installment depreciation of investment outlays J_M with its interest, according to Bartnik (2014)), the cost of which in the depreciated block is no longer apparent. Thus the annual cost of producing electricity in it is low, because its production is only the cost of exploitation. However, without upgrade the block, its further exploitation will be impossible, due to technical consumption it will need to be off from further operation. Hence the need to upgrade as quickly as possible. The specific cost of electricity production in the modernized block is significantly lower than the cost of the newly built block for supercritical parameters, even without oxy-combustion CCS technology - Fig. 3, 15. However, this cost is comparable to the cost in the modernized block for the dual-fuel gas-steam system – fig. 11, 15.

4. Summary

The results of the analyzes show unequivocally that modernization of already existing power plants rather than the construction of new coal power plants is the most important investment strategy in the country's electricity supply, while guaranteeing the country's energy security and, most importantly, stability, security and continuity of supply. Modernization expenditures, even when replacing boilers and steam turbines with new higher thermal parameters of fresh steam, are small compared to the costs of new supercritical coal blocks, where the entire power plant infrastructure needs to be built and which are already in retrofit. At most it will also need to be revitalized. The specific cost of generating electricity in such modernized blocks even at the time of purchase of the CO2 emission allowances is significantly lower than the costs of new coal blocks, and hence the rise in energy prices in the country will be small. When they are mixed with the costs of newly built nuclear power plants, they will continue to increase in small increments. An important opportunity for modernization of existing coal blocks is their superstructure with gas turbine despite expensive natural gas. The energy efficiency of these modernized blocks, what is very important, will increase significantly to around 50% and carbon dioxide emissions per MWh of produced electricity will decrease by half. At the same time, the specific cost of electricity production in them is also relatively low. For current prices of coal and gas is slightly higher than the cost from modernized coal power blocks for higher parameters of fresh steam. Moreover, and very importantly, according to Bartnik (2013, 2014) this superstructure doubles the electric power of the block.

In addition to the modernization of existing coal blocks, "clean", fully economically justified nuclear power stations should be built. It is necessary to significantly increase the power of the Polish National Power System, as the projected increase in electricity consumption in Poland is one of the highest in Europe.

Abstract

The article analyzes the research of language competence of subjects of bilingual environment and modern educational Internet resources. The authors of the paper give definition to the term "language competency" and define its structural components. The paper includes the results of diagnostics of language competency of students of Psychological and Pedagogical Department of Mari State University as subjects of bilingual environment. The research reveals typical mistakes made by bilingual people in the Russian language and the paper includes explanations of such speech disorders. The authors enumerate different opportunities of language virtual space in correcting speech disorders and increasing the level of language competency of subjects of bilingual space.
Keywords: language competence, bilingual environment, language virtual space, speech disorders.

Introduction

The term "competency" has appeared recently in the scientific literature, although the terms, connected with it, have existed in linguistics and pedagogics for a long time. Competency is a certain amount of knowledge and experience that are necessary for the effective activity in a certain subject area. Another term – competence – is connected with competency. Competence stands for a certain number of questions that a person is qualified in. It is a basic quality of a person that includes some closely-related qualities that are necessary for qualitative and productive activity (Burns, 1995). The research of language competency is mainly connected with competence that was analyzed by D.Himes, American sociolinguist stated that in order to establish communication it is not enough to know language signs and the rules of their usage, it is necessary to know "cultural and socially relevant situations" in which they might be used (Communicative competence as a component of key competencies, 2017). The notion "communicative competence" appeared in Russian scientific literature in the 1980s (M. N. Vatutnev, I. L. Bim, A. R. Artunov and others) and it was defined as the ability of a person to maintain communication. Speech is the main means of establishing contacts with people, expressing thoughts and emotions.

According to A.N. Shchukin, language competence is possessing the system of knowledge about the studied language at different levels: phonological, morphological, lexical and syntactical (Azimov and Shchukin, 2009). A person possesses language competence if he has understanding of the system of the language that he studies and he can use this system in practice.

In the research of the threshold level of the knowledge of the Russian language competence was defined as the ability of a student to construct grammatically correct forms and syntactical structures as well as speech syntagmas that are used and made up according to the rules of the Russian language and their use as if they were used by the native speakers in isolated position.

In Russian psychological, psycholinguistic and methodological researches language competence is analyzed as a combination of knowledge and abilities of a person. Scientists define two components: cognitive component (knowledge) and activity component (abilities and skills). Consequently, language competence can be analyzed as the knowledge of linguistic units, the rules of their formation and use as well as the ability to use them in the process of communication. Thus, it becomes possible to conclude that language competence is the knowledge of linguistic phenomena and the ability to use them in speech production and understand speech of other people; consequently, language competency is possessing of knowledge and experience that are necessary for communication and effective activity in the subject area.

It is possible to divide language competence into phonological, lexical, grammatical, orthographic competences. Let us analyze the mentioned competences as understanding of their essence is necessary in order to study the level of language competency of the subjects of the bilingual environment.

Phonological competence is the knowledge of the language system, stress, rhythm, intonation, melodic, the ways of phonetic speech production and the ability to use them in the intercourse (Azimov and Shchukin, 2009). For the Russian-language speakers the most important components of phonological competence are the abilities to stress the words correctly and to pronounce the sounds accurately.

Lexical competence is not only knowledge of lexis of the language, including words, word phrases, collocations, phrasal units, patterns of speech etiquette, but also the knowledge of proverbs and sayings and their use in speech.

Grammatical competence includes knowledge of grammatical elements of the language and the ability to use them in the process of speech. Grammatical competence includes the ability to understand and express certain meaning, make up phrases and sentences that are built according to the rules of the Russian language.

Orthographic competence is knowledge of spelling and punctuation norms, common conventions, symbols, etc.

Except for the competences mentioned above, linguists define competences in oral speech and competences in written speech, in the recent decade scientists analyze a new competence – competence of the Internet communication.

It is important to connect language and the ability to use different functional styles (business literature, scientific literature, etc) (Work Book, 2017).

Thus, we can see that language competence is part of a multilevel system that is connected with the speakers. People have certain language knowledge and experience, thus, language competences are necessary for effective communication in any subject area.

Purpose of the Study

The purpose of the study is the analysis of the level of language competence of future teachers, subjects of bilingual environment.

Research Methods

The main methods of the study are as follows: theoretical analysis of literature on the research subject, survey, observation, testing and analysis of the results.

Results of the Study

The study has included diagnostics of the level of language competence (phonological, lexical, grammatical and orthographical) of the students of Mari State University. 88 students (of the 1-4 courses of the pedagogical department) took part in the experiment. The level of language competence of future teachers was defined according to three diagnostic methods, including phonological, lexical, grammatical and orthographical competences: "A series of tests designed to define linguistics abilities" by I.N. Lukashenko, I.A. Zimney, "Methodology of diagnostics of verbal creativity" adapted version of method by S. Mednik, test on the norms of the Russian language elaborated by I.N. Andreeva (Andreeva, 2012).

The study of language competence of future teachers allows to reveal certain problems that exist in speech and measures to eliminate them.

The study showed the results of all diagnostic methods that are presented in Table 1.

Table 1: Results of Diagnostics of Language Competence of Subjects of Bilingual Environment according to Three Diagnostic Methods

Competences	A series of tests designed to define linguistics abilities	Methodology of diagnostics of verbal creativity	Test on the norms of the Russian language
Phonological	67%	-	58%
Lexical	63%	75%	26%,
Grammatical	54%	68%	39%
Orthographic	62%	-	78%

Diagnostic method "A series of tests designed to define linguistics abilities" by I.N. Lukashenko, I.A. Zimney allowed to figure out that 67 percent of respondents possess phonological competence, 63 percent of respondents have lexical competence, 62 percent of respondents have orthographical and only 54 percent of respondents posses grammatical competence.

"Methodology of diagnostics of verbal creativity" covers only lexical and grammatical competences. 75 percent of surveyed have coped with tasks on lexis successfully, 68 percent of surveyed have been successful in completing grammar tests.

Low percentage of grammatical competence of respondents, as it was revealed, might be explained by the difficulty of Russian grammatical rules that arise some predicaments. It is a fact that even Russian native speakers face such problems.

It is necessary to analyze the results of tests on the norms of the Russian language as these results were the worst among the three diagnostic models. The analysis has shown the following facts.

Students have made mistakes with the words *"kvartal", "logopedia", "zhaluzi"*. Students try to find out the meaning of the word *"kvartal"* by saying that different stress means different lexical meaning. In general, 88 people have made mistakes 145 mistakes in this task.

In the second task students have made 80 mistakes, mainly in words: *khodatajstvovat', shchavel'.*
The third task was easier as students have made only 68 mistakes, they mainly were in words: *svekla, novorozhdennyj.*

The forth task checked the norms of morphology, students have made 97 mistakes, the main problems were connected with the forms of the words: *brelkov-brelokov, shofyory-shofera, dzhins-dzhinsov.*

The lexical rules were checked in the fifth task in which students have made 115 mistakes as almost all collocations seemed difficult. When explaining the expressions, students commented that they heard such collocations in oral speech: *svobodnaya vakansii, narodnyj fol'klor* and they thought that it was a norm of the language.

Tasks number 6 and 7 were devoted to checking of morphological norms of numerals. Students have made 39 mistakes in task number 6, 89 mistakes in task number 7. Students decline cardinal numbers incorrectly as they have made a lot of mistakes in such tasks.

Task number 8 checked knowledge of grammatical norms, correct spelling of prepositions. Almost all students gave incorrect version of the use of the preposition: *"po priezdu"* instead of *"po priezde",* in general, they have made 113 mistakes.

Tasks 9, 10 and 11 were connected with the correct filling of business papers although task number 9 checked the knowledge of morphological norms of nouns that is knowledge of proper nouns (declining of surnames). There have been 116 incorrect answers in this task. Task number 10 was rather difficult as it required grammar knowledge where there have been 117 mistakes despite the fact that the similar task is used in papers for the General State Exam (correct use of dangling participle).
Task number 11 checked how to make up a written request, more than half of students (50 pupils of 88) could not find the mistakes in the test although they deal with requests regularly. Almost in all official papers signature is written to the right, date is written to the left and a line above the signature.

Task number 12 checked knowledge of punctuation in which students have made 138 mistakes and it shows that some basic knowledge was partially acquired at school.

Task number 13 was devoted to knowledge of orthography (spelling of suffixes of participles and adjectives), the result was rather bad (145 incorrect answers).

Having analyzed the results, we have concluded the following:
55 percent of students have problems with norms of orthoepy, 26 percent make lexical mistakes, 29 percent cannot cope with morphology of numerals, 49 percent – of nouns, 46 percent make mistakes in spelling of prepositions, 30 percent of students cannot deal with dangling participles.

The worst result was shown while completing the tasks in orthographic and punctuation norms (78 percent of students have made mistakes) and writing business documents (58 percent of students), 80 percent of students have made orthographic mistakes.

Representatives of the Mari nationality make a lot of mistakes. It is mainly connected with aural-oral skills and stylistic colouring of speech. A lot of Mari representatives make typical speech mistakes. Thus, speech of bilingual people does not contain some sounds as they are absent in their native speech *[v'] [v]* that is why they make some phonetic mistakes. Some Mari consonants, namely, *k, t, s, z, n, m, b* in isolated pronunciation coincide with Russian phonemes: *k, t, s, z, n, m, b.*

Let us analyze consonant phonemes of the Russian language pronunciation of which is different from the Mari language: *l, r, g, d, j, zh, sh, ch* and the words that cannot occur in the Mari words and with borrowings from the Russian language (sounds *f, ch, ts, sh*, orthographically *shch*). Specific sounds of the Mari language *[v, ng]*.
Consonant sounds of the Mari language *[r, j, zh, sh, g, l]* are pronounced differently than in the Russian language although they resemble Russian sounds.

Sound *[l]* in the Russian language is fricative and front. While pronouncing Russian sound *[l],* the tip of the tongue touches the upper teeth, the tongue fringe does not join, the air goes through the edge of the tongue, the sound is called lateral in linguistics. Mari sound *[l]* is milder than the Russian one. The difference between Russian *[l]* from the Mari sound is that while pronouncing Russian sound *[l],* the back side of the tongue takes an active part in speech production, rising up to the soft palate and in this part of the tongue there is tension. While producing Mari sound *[l],* the back side of the tongue does not rise or the soft palate rises a little.

Sound *[j]* is fricative, noisy sound and dorsal. While pronouncing Russian sound *[j]*, the tip of the tongue touches lower teeth, lateral borders are close to the lateral teeth, the lateral part of the dorsum rises to the hard palate and the air goes through the hole between the back of the tongue and the hard palate. This sound is called fricative. While pronouncing theMari sound *[j],* the dorsum, as it happens in Russian, the tongue comes closer to the hard palate. In the Mari language the sound *[j]* is pronounced with a bigger force at the beginning of the word than in the Russian language (it is produced with a greater affinity with the hard palate and with bigger force of exhalation. At the end of vowels of the first row sound *[j]* almost disappears. The Mari people tend to use this peculiarity of pronunciation of the sound *[j]* in the Russian language. For example, *desli* instead of *esli*.

Sound *[ts]* is a front, voiceless, plosive sound that exists in the Hilly accent of the Mari Language and in some accents of the Meadow accent of the Mari language.

Thus, instead of literary *"kochkash" (to eat)* these accents have *"kotskash", "tserkve" (church).* The sound *[ts]* appears in the Mari literary language in words borrowed from Russian. In old borrowings the sound *[ts]* was replaced with *[ch]* or *[s]* by the Mari people. For example: *chygan (tsygan), purys (perets).*

Sound *[kh]* is a noisy, voiceless, fricative, velar consonant. In Meadow-Eastern accents of the Mari language the sound *[kh]* has a relatively rare use (only in words borrowed from Russian). In the Hilly accent the sound *[kh]* occurs in originally Mari words (*khanga* – board, *khyyak* – sedge). Mari pupils sometimes replace the sound *[kh]* with their native sound *[k]*. This happens both in oral and written speech: *otdokni* (otdokhni).

In order to eliminate such cases and mistakes in speech, increase lingual competence of subjects in bilingual environment, we decided to try the use of language virtual space. We have already analyzed its meaning for modern teenagers in some papers before (Fedorova & Vorontsova, et al. 2016).

In our point of view, virtual space gives unlimited opportunities in the sphere of language training and practice of its use by different means: skype lessons, electronic textbooks, educational programs, computer didactic games, training systems, etc. Using these techniques pupils can train reading, writing, speaking, listening in this or that language, check their knowledge, etc.

Currently there is a wide variety of interactive programs, educational Internet resources that are aimed at teaching the most popular European languages: English, German and French. It becomes evident that it is necessary to use the opportunities of virtual space in teaching the languages of Russian peoples because Russia faces the problem of preservation the national languages.

Modern educational Internet resources are focused on the studies of national languages of Russian peoples. On-line school of national languages Ethnoschool http://ethnoschool.ru, founded by Eradil Tenghezov form Dagestan, was the first school of such kind. The project was aimed at preserving and

studying of native languages of different regions of Russia for those people who live outside the country and its regions.

Nowadays the school offers online courses of the Nogai, Tatar, Chechen, Avar, Dargin, Kumyk, Lak, Lezgin, Ingush, Kalmyck languages. Moreover, the course of Finno-Ugrian and Turkic languages of Russia is being elaborated. Education is based on the concept of interactive "pupil– teacher" in which the teacher inetrectcts with the pupil and train him with the help of presentations, by pronouncing sounds, talk with him in chat and answers pupil's questions (The first online school of Russian national languages, 2017).

Educational resource "Tatarschool.ru" http://tatarschool.ru draws a certain attention as it contains some multimedia applications to the textbooks of the Tatar language that were written on demand of the Ministry of Education and Science of the Republic of Tatarstan. Multimedia applications to the textbooks are the instruments of wide opportunities as the main advantage of such books is interaction.

Electronic applications to textbooks offer the possibility for distant learning as pupils can study independently, on their own and check their progress. If a person fails the task, multimedia application allows to complete the test once again and choose the individual pace of work. It is necessary to structure the presented material which is divided according to the year of studies (from 1-4 forms) and different parts: topics, dialogues, grammar, listening, dictionary, cartoons (Educational resource TATARSCHOOL.ru, 2017).

In 2016 2 mobile applications were created that supported learning of the Udmurt language "Udmurt-Russian-English Phrase Book" and manual for self-tuition "Kyldysin: Let's Learn the Udmurt Language ". The phrase-book is created to overcome difficulties in communication with the speakers of the Udmurt language. Having heard some phrases, the user will be able to mark it as the selected one and the system will find the necessary words with a certain combination. The second application "Kyldysin: Let's Learn the Udmurt Language" will serve to master the language skills in practice by reading, speaking, listening. 30 topics in different areas of grammar will deepen grammar, this part contains 50-100 words and phrases in the Udmurt language. The application as a real teacher will trace the progress and achievements of the user. For example, lesson 2 will not be available for opening without studying lesson 1. An interesting structure elaborated by the creator can encourage the user to achieve progress by getting score for completing tasks correctly. The results are put into the Table – Rating of Participants (Information Agency «Udm-Info», 2016).

A special attention deserves the Internet site «UROK95.RU» which contains a series of lesson in the Chechen language covering the whole syllabus of school subjects (Literature, History, Geography, Ethics, Local History, History) including the Chechen language (1-11 forms) that were placed in open access. Lessons consist of videos, papers, tests and training tasks. Students who study the Chechen language have access to the following parts: theory, library, set of words, training tasks (tests, exercises, word-builder, translator). The initiator, author and creator of the project is the Ministry of Education and Science of the Chechen Republic (Educational portal «UROK95», 2017).

The analysis of educational resources created in Russia and directed at the development of national languages of peoples has revealed that despite diversity of languages and cultures of Russian peoples, the quantity of qualitative educational content, including those that are placed on the Internet and available for many users, the number of people using such sites is relatively small. The most qualitative resources were created with the support of the Ministry of Education and Science of the national republics (Tatarstan, the Chechen Republic).

Conclusion

Language virtual space gives certain potential for shaping language competence of a person. Our research is directed at the developing the concept of language virtual space while arranging language

competence of the subjects of bilingual environment of the Russian and Mari languages, based on the structural-functional model of lingual virtual space. It is evident that there must be the system of diagnostic materials that reveal the level of language competence of a bilingual subject in case of Russian-Mari bilingual environment. It is necessary to create scientifically accurate useful methodical recommendations how to use language virtual space in shaping language competence of subjects of bilingual space. Another important step is the elaboration of electronic educational resources, Internet magazine, Web-site "Russian-Mari Language Virtual Space".

Abstract

It is important to make a right choice of a future profession while studying at school. A senior high school student should know what professional activity to choose. The choice should depend on personal psychological characteristics of a student. They will help to self-fulfil in a chosen profession. Professional direction of a senior student is determinative while choosing profession. The article gives research data of educational and ascertaining experiments in personal and psychological characteristics influencing over professional direction on senior high school students. There are cases of professional direction changing while conducting the educational experiment when psychological and pedagogical activities were held according to personal psychological characteristics.

Keywords: professional direction, senior high school students, individual psychological characteristics, research, profession.

Introduction

Modern society needs professional mobile specialists. They should be ready to make their own decisions and complete important professional tasks in rapidly changing conditions. It should be taught since school age. Educational psychologists have an important role. They help solve problems of life journey decision, search of professional future, profession choice, and development of professional characteristics. Despite the investigation in the theory of this question, annually a lot of senior high school students have problems with professional direction.

In this regard great attention is given to special education modules and psychological support of senior students in forming their professional direction (Zagaynov & Blinova, 2017). Search and choice of profession, self-fulfillment – everything is influenced by individual psychological characteristics of a senior student. Based on the results of comprehensive schools practice we can see that development of professional direction of senior students receives little attention, it lacks interrelation of teaching educational subjects and educational work in the context of the outlined problem.

The Method

The problem of professional direction formation was studied before by different scientists. But there is little information about the influence of individual psychological characteristics over professional direction of senior high school students.

Methodological basis of our research was: principle of person's development at senior high school age (Alferov, 2008, and others); psychological conception of person's professional direction (Derevtsova, 2015, Ivannikova, 2013, and others); data about influence of personal characteristics over person's professional direction (Kovalevskaya, 2014, Koryagina, 2009, and others).
We used the following methods of research of individual psychological characteristics and professional direction: "I prefer" differential diagnostic form by E.A. Klimov; B.Bass technique of diagnostics of personal direction; "Big Five personality traits" technique by A.G. Gretsov.

The Research

The research was held among 45 senior students of a village school. The obtained results are useful for teachers, psychologists, school management.

Modern scientists consider professional direction of senior students as an integrated characteristics of motivation of professional activity determined by impulses in motivational sphere expressed by interests, relations, purposeful efforts. At senior high school age a system of stable life views and own place in the world is formed. Individual psychological characteristics have great influence over professional direction of senior students. For example, students who have inclination to professions of a "man-man" type are sociable and have a need in liability of emotions. In a "man-machine" type rigidity of behavior, vividness and independence appear. A "man-word picture" type shows liability of emotions and need in communication, ability to abstract away, impulsivity. A "man-sign system" type is marked by rigidity of behavior and affect persistence, vividness and independence. In a "man-nature" type sensitivity and a high emotional and feeling level are shown.

At the summative stage of the research we figured out that 38% of students of the experimental group and 32% of students of the control group were characterized as a "man-man" type of professional direction; 24% of the experimental group students and 26% of the control group students – as a "man-machine" type; 19% of the experimental group and 18% of the control group – as a "man-sign system" type. "Man-nature" and "man-word picture" types were less significant for the students. 33% of the experimental and 36% of the control groups showed their focus on themselves and communication, 38% and 32% respectively – on activity. 60 % of the experimental group and 62% of the control group are emotionally stable. 51% and 53% respectively are ready for new experience, 42% and 45% respectively are conscious to their future professional choice, 60% and 62% respectively are benevolent.

The research was conducted in the area of influence of individual psychological characteristics and interrelations of senior high school students over their professional direction. Therefore, we paid attention to rise of social status of senior students, development of benevolence, consciousness, emotional stability, activation of interrelation, motives to soaring to success. Hereby, we conducted the work on development of self-awareness (abilities and characteristics); environment and different professions.

The work on forming basic skills in self-awareness and self-esteem, self-development, effective interrelation with the environment, planning of professional advancement was conducted.
In forming professional direction and self-determination of students, development of individual psychological characteristics the important thing is existence of motivation, need in self-development and self-fulfillment.

We also defined extra personal psychological characteristics to characterize a successful person: energy, sense of purpose, emotional stability, consciousness, self-dependence, responsibility for actions, stability of life standards and values, openness to new actions.

According to the results of the control stage of the research we came to the conclusion that individual psychological characteristics of senior high school students influence over their professional direction: extraversion and vividness are specific for the "man-man" professional type and communication focus; consciousness and openness to new experience are specific for the "man-sign

system" and "man-machine" professional direction types and activity focus. If students are focused on themselves they show neuroticism and hostility.

As a result of the educational experiment a part of students changed their professional direction type. For example, in the experimental group there was a rise of number of students of the "man-man" (43%), "man-sign system" (24%) types; in the control group there was an inconspicuous rise of the "man-sign system" type of students. In the experimental group we observed the number of students focused on activity (up to 47%), communication (up to 43%), and the number of students focused on themselves decreased. In the control group the change of professional direction was inconspicuous. Students of the experimental group increased emotional stability (up to 79%), openness to new experience (65%), consciousness (65%) and benevolence (79%). In the control group the number of students with consciousness characteristics rose (49%).

Conclusion

The summary of the research: emotional stability, openness to new experience, consciousness and benevolence influence over the professional direction of senior high school students; development of individual psychological characteristics of senior students can correct properly their professional direction. Thereby, it can help make a right decision of future profession and develop professional skills according to individual psychological characteristics which will lead to professional self-fulfillment.

Neuropsychological Correction in Support of Preschool Children with Disabilities Living in the Multicultural Region

Elena Y. Borisova, Mari State University, Yoahkar-Ola, Russia, elenaborpsy@yandex.ru

Irina B. Kozina, Mari State University, Yoahkar-Ola, Russia, kozira@list.ru

Abstract

The main objective of the research presented in this article was the development and approbation of the technology of psychological and pedagogical support for pre-school children with disabilities being raised under the conditions of polylingual sociocultural environment. Implemented comparative analysis of dynamics of indicators of mental development of preschool children of different nosological categories living in polylingual and monolingual environment. Analysis of the results suggests that implementation of a neuropsychological approach to support for children with disabilities provides a positive change, characterizing both the regulative and praksis and gnostic processes, with a more pronounced positive effect is ensured with a sufficiently long correctional and developmental impact. It was revealed the effect of the specifics of the language environment on the effectiveness of correctional-developing work

Keywords*:* neuropsychological diagnostics, psychological and pedagogical support, polylingual and monolingually environment, children with disabilities

Introduction

Describing mental health of the child population the majority of researchers recognizes its progressive deterioration, notes the increasing number of children with deviations in mental development as well as indicators of CNS ill-being. For this reason, it is important to look for the methods and approaches that allow diagnosing difficulties in proper time and preventing development of maladjustment. Both in assessing relevant child development and in planning effective psychocorrective work increasing attention is being paid to neuropsychological approach that allows revealing weak cognitive mechanisms causing most of the difficulties that appear when getting training (Akhutina T.V., Pylaeva N.M. and Hotyleva T. Y., 2011; Akhutina T.V. and Pylaeva, N.M., 2008; Borisova E. Y.,2015; Borisova E. Y. and Kozina I.B., 2016).

Nowadays effectiveness of neuropsychological methods in work with children with disabilities is generally recognized; therefore, school neuropsychology is being promoted in modern teaching practice. However, most of the developed programmes focus on primary school age. Furthermore, issues of developmental characteristics and interaction of the brain systems and mechanisms during child languages acquisition are often overlooked areas in a research. As multiculturalism is characteristic of our country, the majority of pre-school children is being developed in polylingual environment. This fact defines importance of consideration of neuropsychological and psychological mechanisms and factors of higher mental functions development under the conditions of language diversity.

The main objective of the research is the development and approbation of the technology of psychological and pedagogical support for pre-school children with disabilities being raised under the conditions of polylingual sociocultural environment. This technology is based on neuropsychological approach. The assumption that the programme of correctional and developmental training, based on the results of the differentiated and system neuropsychological diagnosis, can be sufficiently effective appeared as the hypothesis of the research.

Materials and Methods

Comparative analysis of factors dynamics of pre-school children (the fifth year of life) mental development from different nosological categories, who are being raised in polylingual and monolingual environment, was made in terms of this research implemented and supported by RFBR (the project № 16-16-12004). Factors dynamics was monitored in the implementation of psychological and pedagogical support that includes neuropsychological diagnosis and correction. 70 pupils of secondary groups from pre-school institutions with general speech underdevelopment of the third level and with developmental delay took part in the experiment. The experimental group included 40 pre-school children and the control group included 30 pupils. Groups were formed on the basis of decisions made by psychological, medical and pedagogical commission as well as upon indicators of teachers (speech therapists) expert analysis.

Speech therapists, education psychologists and kindergarteners of groups took part in the implementation of the tested support programme.

Diagnostic programme of our research included individual samples of child-friendly battery of tests by A. R. Luria (T. V. Akhutina et al, 2012; J. M. Glozman et al, 2012). Complex correctional and developmental work based on the combination of kinetic and cognitive correction was being implemented individually and in groups on the forming stage during the academic year. Gaming methods including those ones that involve kinetic mediation of cognitive processes were predominantly represented in correctional and developmental programmes. Selection of game tasks, its number and complexity were personalized as they were determined by neuropsychological status of the child.

Results

To assess factors dynamics the intermediate diagnosis on individual tests (dynamic praxis, reciprocal coordination, tardive motor memory, correction task and compilation of the story according to the pictures) was made after the 1st stage of the support programme (two months of correctional work). Positive changes on the majority of the test items representing age-specific dynamics of regulatory functions formation were observed in both groups. Changes comparison of the studied characteristics in the control and experimental groups according to the Mann-Whitney U-test revealed more significant positive dynamics in the experimental group on such characteristics as programme realization ($p=0.036$), mistakes of multiple organization ($p=0.008$) in the test for tardive motor memory, effectiveness of the correction task implementation ($p=0.043$) and compilation of the story ($p=0.003$) (Borisova E. Y. and Kozina I.B., 2016).

The programme of the resulting diagnosis that accomplished the support programme was completely on a par in its composition with the primary one. Comparison of positive changes intensity in the control and experimental groups (Mann-Whitney U-test) revealed statistic significant differences for the following: programme assimilation ($p=0.019$) and the element order ($p=0.015$) in the test for dynamic praxis; programme execution in the test for reciprocal coordination ($p=0.023$); effectiveness of task execution in the test for postural pose praxis with the left hand ($p=0.033$) and interhemispheric reciprocal interaction in the same test ($p=0.001$); effectiveness of task execution on oral praxis ($p=0.00001$); quality of redrawing ($p=0.021$); effectiveness of realistic images identification in the test for visual gnosis ($p=0.003$); logical correspondence of the story ($p=0.030$) in the task on compilation of the story based on the series of meaningful pictures; understanding of logical and grammatical schemes ($p=0.011$). These characteristics do not attain statistical significance but they can be considered as a tendency to improve time of compilation ($p=0.065$) and the number of words in the story based on the series of meaningful pictures ($p=0.065$). Generally, it can be stated that the implementation of the neuropsychological approach in support of the children with disabilities provides positive changes characterizing regulatory, praxic and gnostical processes.

Discussion and Conclusions

Comparison of the results of primary and final diagnosis allows to claim that without the introduction of neuropsychological correction elements in support of the children with disabilities it is difficult to expect a significant dynamics of the regulatory functions formation. At the same time, data of intermediate diagnosis clearly illustrates the need for long-term rather than short-term exposure.

One of the research tasks was the results analysis from the perspective of the linguistic environment specific features influence on the effectiveness of the correctional and developmental work. For this purpose, two subgroups matched according to the nosological characteristics were formed within the selection: 1 - children raised in families and speaking the same language, 2 - raised in a polylingual environment (mainly bilingual).

The statistical analysis (Mann-Whitney U-test) based on the results of the intermediate diagnosis did not reveal significant differences in the changes of the studied characteristics in the monolingual and polylingual experimental groups, but there was a different sensibility to the correctional influence of pre-school children from bilingual and monolingual families. In particular, it turned out that the improvements in the performance of the acquired kinetic programme were more characteristic for bilingual pupils. At the same time, training influence in the group of monolingual pupils is more noticeable in terms of reducing the mistakes of multiple organization. According to other characteristics that specify voluntary regulation, changes observed under the influence of training in the group of monolingual and polylingual pupils did not differ significantly in the intermediate diagnosis.

Comparative analysis of the results of primary and final diagnosis allows to observe significant differences in the changes intensity in mono- and polylingual experimental groups according to the following sixteen characteristics: programme assimilation in the test for dynamic praxis ($p=0.038$), programme execution in the test for reciprocal coordination ($p=0.11$), effectiveness of execution ($p=0.11$) and the character of the left hand execution ($p=0.041$) in the test for the postural pose praxis, as well as the number of kinesthetic ($p=0.05$) and areal ($p=0.038$) mistakes in this task ; effectiveness of tasks execution on oral praxis ($p=0.026$); quality of redrawing ($p=0.006$); the effectiveness of superimposed images identification in the test for visual gnosis ($p=0.005$); the productivity of rhythmical structures evaluation in the test for the auditory-motor coordination ($p=0.001$); auditory and verbal memory ($p=0.006$); the number of specific situational explanations with the exception of excessive things ($p=0.021$); naming of objects and actions ($p=0.006$); phrases composition ($p=0.023$), the story compilation according to the picture ($p=0.016$); time of story compilation based on a series of meaningful pictures ($p=0.034$). In all the above characteristics with the exception of the time of story compilation based on a series of meaningful pictures the more significant positive changes occurred in the experimental group of monolingual pupils. This allows to conclude that realization of the neuropsychological approach in correctional work with children has a more intensive impact on pre-school children who are brought up in monolingual families.

In order to clarify the situation typical for pre-school children who are brought up in polylingual families we consider the results of both experimental and control groups. Significant differences in changes intensity between the control and experimental groups turned out to be more characteristic of polylingual pupils, since in these subgroups there were revealed statistically significant differences in the greater number of diagnosable characteristics (5 in the monolingual group and 15 in polylingual group). This fact allows to suggest that absence of special support which takes into account the neuropsychological status of the child affects more negatively on pre-school children who are brought up in polyilingual families.

According to the results analysis the following can be stated:
1. The implementation of neuropsychological approach in support of the children with disabilities provides positive changes that characterize regulatory, praxic and gnostical processes.

2. Absence of correctional work that takes into account the neuropsychological status of the child with disabilities does not allow to provide a significant dynamics of the regulatory functions formation.

3. The more significant positive effect is provided if the correctional and developmental work is implemented for a long time (at least 6 months); short-term programmes are not sufficiently effective.

4. Implementation of the neuropsychological approach in correctional work with children has a more intensive impact on pre-school children who are brought up in monolingual families. Absence of special support that takes into account the neuropsychological status of the child has a more negative impact on pre-school children who are brought up in polylingual families.

Generally, the results analysis of the research confirms the effectiveness of differentiated correctional and developmental influence that is based on the important child possibilities that are defined according to neuropsychological status. The revealed tendencies determine the necessity of realization of psychological and pedagogical support of pre-school children with disabilities with a glance to both the neuropsychological status of the child and the specifics of the polylingual social and cultural environment.

State Support of Small Forms of Economy in the APK of the Republic of Mariy El as the Condition of Improving their Investment Activity

Firdaus Z. Gumarova, State University, Yoshkar-Ola city, Russia, gumarovaf@mail.ru

Elena N. Potekhina, Mari State University, Yoshkar-Ola city, Russia, vilor@mail.ru

Marina V. Kazakovtseva, Mari State University, Yoshkar-Ola city, Russia, marina290576@mail.ru

Abstract

The directions of the state support of small forms of managing in agrarian and industrial complex of the Republic of Mari El. The problems for concessional lending to agribusiness, recommendations to improve the investment activity of small agribusiness. One of the priority directions of the State program for the development of agriculture and regulation of markets for agricultural products, raw materials and food for 2014-2020 is the stimulation of the development of small forms of management, including peasant (farm) farms, individual entrepreneurs engaged in the production, processing of agricultural products and its sale.

Keywords: State support, small forms of management (ICEM), the peasant (farmer) economy, private farming, preferential loans, investment activity of subjects of agribusiness.

Introduction

The current state policy of development and support of the agroindustrial complex is now determined taking into account the really established multifaceted nature of agricultural production. Over the years of market reforms in agriculture the conditions have been created for contribution of the formation in the country of exactly multi-structure by forms of ownership, the organization of labor, the size of production and other parameters of agricultural production.

The Main Body of the Paper

First of all, these are the terms of land supply, the independent choice of the type of activity, the conditions for the production and marketing of its products. However, the adaptation of small forms of management to market conditions is connected with difficulties and problems that are now the subject of attention for the authorities and society (Gumarova, F., 2014).

The state today really realizes the importance and significance of small forms of management in the countryside, because they are no less effective than large and medium-sized farms. The development of small forms of management is an essential condition for the maintenance and further development of agricultural and non-agricultural activities in rural areas. Small forms of management provide employment for the bulk of the population engaged in agriculture. (Gumarova, F., 2014).

Support of the small forms management development is caused not only by the need to solve the problem of providing the population with domestic products. Large agricultural enterprises usage in this case is more profitable.

However, the course for the development of only large-scale production is industrially high-cost, besides, it does not solve the problem of rural residents' employment and the preservation of rural life. Solving problems on sustainable development of rural areas, providing the population with domestic food,

demographic problems, maintaining the ecological balance in the biosphere, increasing the interest of farmers in agricultural activities is possible only with systematic state support for the development of small forms of management.

As of 01.01.2016, there were 2046 peasant (farm) households in the Republic of Mari El. In the structure of agricultural output, the share of the farming sector and personal subsidiary farms in 2015 accounted for 39.4%. These forms of management account for 95% of potato production, 87% of vegetables, 56% of milk, 48% of meat.

Since 2012, the Republic of Mari El has been implementing measures for farmers start-up support and the development of family livestock farms, which provide grants for the creation and development of peasant (farm) farms.

The state program "Development of agriculture and regulation of markets for agricultural products, raw materials and food in the Republic of Mari El for 2014-2020" provides for measures to stimulate the development of small forms of management in the agro-industrial complex.
These measures are presented in the subprogram "Support to small forms of management" in four main steps:

1. "Support for Beginner Farmers". Within the framework of the main event to support start-up farmers, grants are provided for the creation and development of peasant (farm) farms.

2. "Development of family livestock farms on the basis of peasant (farm) farms." Within the framework of the main event for the development of family livestock farms, grants are provided for the construction or modernization of a family cattle-breeding farm. This support is aimed at increasing the number of family livestock farms established in peasant (farm) farms, in which activities are organized on the personal labor participation of members of the economy.

3. "State support of small business loans". This step provides grants for compensation of a part of expenses for payment of percent on credits of banks and the loans received in agricultural consumer credit co-operative societies by country (farmer) economy, personal part-time farms

4. . "Peasant (Farming) farms land plots ownership registration". In this direction, about 50% of the total costs required for cadastral work are provided from the federal budget, the remaining funds are from the budgets of the constituent entities of the Russian Federation and municipalities.

Evaluation of small business support of the Republic of Mari El

In the Republic of Mari El in 2012-2015, grants for the creation and development of peasant (farm) holdings to 69 start-up farmers and 15 peasant (farm) farms for the development of family livestock farms have been granted under the subprogram "Support to small forms of management". To implement these measures, 164.8 million rubles of budgetary funds and 54.4 million rubles of own funds of peasant (farm) farms.

The ongoing state policy of supporting small forms of farming in the countryside has allowed to expand the opportunities for access of small agricultural enterprises to subsidized bank loans and loans to agricultural consumer cooperatives within the framework of the State Program.

In 2015 credit institutions issued 161 loans and a loan of 38.7 million rubles on the development of small forms of management. The main beneficiaries were citizens, leading personal subsidiary plots that received 79.9% of the total amount of credit resources, peasant (private) farms accounted for 20.1% of the total volume of loans issued (Table 1).

Table 1: 2015 year small forms managing credit indicators

	Credit institutions Total		**For credit institutions, as % of the total volume of credits (loans)**				
	Contracts qty	Mln Rub	MYFF of JSC "Rosselkhozbank"	Branch of Mari El PJSC "Sberbank"	Other Banks	Credit Cooperatives	Total
Credits received for the development of the IFC	161	38,7	83,33	16,5	0	0,17	100,0
Including:							
LPH	157	30,9	99,79	0	0	0,21	100,0
KFH	4	7,8	18,1	81,9	0	0	100,0

The Mari regional branch of JSC "Rosselkhozbank" remains the largest creditor of small forms of management, the share of which in the total volume of loans granted in 2015 was 83.33% (compared to 2014, decreased by 13.06%). The share of Sberbank of Russia in the total volume of loans increased from 3.6% in 2014 to 16.5% in 2015 (Gumarova, F., 2014).

As of January 1, 2016, the volume of subsidized loans attracted by small forms of management was 289.7 million rubles. In 2015, subsidies were paid in the amount of 11.641 million rubles, including 9.748 million rubles from the federal budget and 1,893 million rubles from the republican budget of the Republic of Mari El.

Most actively for providing state support in the form of reimbursing part of the interest rate on long-term, medium-term and short-term loans, citizens who own personal subsidiary plots (94.6%) apply.

Analysis small business lending

The structure of subsidized loans in 2015 is presented in Table 2 (Gumarova, F., 2014).

Table 2: Structure of loan funds by directions of use in 2015

Loan objectives	**% to total volume of credits (loans)**	
	LPH	**KFH**
1	2	3
1. Crop production	14,8	100,0
Including:		
Season works	0,4	3,1
Construction (reconstruction) of greenhouse complexes	0	71,7
Purchase of equipment	14,4	25,2

2. livestock	77,6	0
Including:		
Season works	8,4	0
Construction (reconstruction) of livestock complexes	22,0	0
1	2	3
Purchase of equipment	1,2	0
Farm animals purchase	46,0	0
3. Spare parts and materials for the repair of agricultural machinery	6,3	0
4. Other purposes	1,3	0
Total	**100,0**	**100,0**

The problem of inaccessibility of credit resources for investment purposes for the medium and long term remains a particularly significant problem for the small-scale sector.

Evaluation of Investment Attractiveness

Increase of investment activity in the agrarian sector of the economy will be facilitated by the introduction of a new mechanism of concessional lending at a rate of 5% per annum from 2017.
Decree of the Government of the Russian Federation No. 1528 of December 29, 2016 approved the Rules for Granting Subsidies from the Federal Budget to Russian Credit Institutions (10 Authorized Banks) for a refund in the amount of the Central Bank of Russia's key interest rate for the incomes received by them for loans granted to agricultural producers and individual entrepreneurs engaged in the production, Processing of agricultural products and its implementation.

21.3 billion rubles were provided for these purposes from the RF budget. In accordance with the new procedure for subsidizing the compensation of part of the interest rate on loans is planned to be provided directly to authorized credit organizations, which will significantly simplify the process of obtaining state support for farmers, eliminating the diversion of their own working capital to pay interest on loans.

The state now sees the role and functional purpose of the peasant farms and private farms not only in the production sector, but also a little bit wider: first of all, the preservation of rural settlement and the rural way of life, the social development of rural areas, the development of forms of local self-government and the strengthening of their active representatives of small agribusiness, for self-employment, upbringing of the younger generation and, in general, preserving the health of the nation, its culture, the natural environment (Gumarova, F., 2014).

State support measures are applied to all forms of agricultural activities, including peasant farms, citizens who carry out entrepreneurial activities in the countryside without forming a legal entity.

The principle of fairness is observed. However, only those entrepreneurs who provide established reporting, declare their income, have legal land and technical means of production, can use the appropriate state support - that is, the state is now pursuing a policy of supporting a civilized, market-oriented entrepreneur capable of competing in matters not only of production, but also effective distribution, in access to credit and leasing resources, information and consultation provision.

Today, and moreover in the long term, state support is available only to effectively functioning economic entities, which give a return in the form of additional production growth, paying taxes that can pay off on loans and leasing payments that have liquid assets and a positive balance sheet structure.

I must say that the share of the small sector in the subsidies received from the federal and republican budgets is insignificant. But in recent years, it has a dynamic of substantial growth. And they use various forms of state support precisely those entrepreneurs who are actively interested in all regulatory information, show business enterprise, who are really interested in strengthening their business, clearly sees their future prospects and is confident in the possibilities of developing their production.

A serious disadvantage and omission in the field of small-scale production is the lack of a coherent system of procurement and marketing of agricultural products produced in this sector, as well as the supply and maintenance of the private sector. It is the lack of an effective sales system based on high self-organization and cooperation that leads today to the lack of demand for this product, its noncompetitiveness in comparison with large suppliers.

In this regard, it is necessary to develop and support the creation of agricultural consumer cooperatives - marketing, supply, servicing, processing. As of early 2016, 37 agricultural consumer cooperatives were registered in the Republic of Mari El, including 18 credit, 3 processing and 16 supply and marketing cooperatives (Gumarova, F., 2014).

Preconditions for the Development of Small Business

Nowadays entering the auction individually, participation in competitions, form batches of certified products is almost impossible, and it is very expensive.

We need to unite in these issues, build a system of mutual relations based on cooperation and integration, taking into account the mutual interest and economic opportunities in the market.

Prerequisites for this are - there is still and still potential in the sector of private household plots and farm production, there is an economic incentive for the production of agricultural products - and it is determined primarily by the effective demand for food. Therefore, the small sector of agrarian entrepreneurship needs to intensify and coordinate work in terms of winning and retaining its positions in the market.

Within the framework of the State program in the development of small forms of management, the activity of rural entrepreneurs and residents remains very low. The reason for this, first of all, is the insufficient work at the municipal level of rural settlements with the population, its awareness and counseling.

Today, it is not enough just to convince the population, it is necessary to cover the positive experience of the work of farmers, personal farmsteads, and saturate the regional press with the necessary information that contributes to the increase of entrepreneurial activity of the population. The village will be able to survive and become rich only when each of its residents becomes an enterprising and diligent master.

The introduction of the food embargo against Russia caused a radical revision of the state program for the development of agriculture. The agrarian complex faces new tasks, including ensuring food security of the country in conditions of sanctions pressure.

Direct import restrictions cause, on the one hand, an increase in domestic food prices, and on the other hand, these same restrictions open large commodity niches for the domestic commodity producer. A sharp weakening of the ruble also increases the competitiveness of domestic goods, and given the improvement in the economic situation in the industry and the increase in the level of state support, agriculture has every chance to reach a higher level of production.

Summary

For Russia, the increase of competitiveness of agricultural products is essential, since today the main task is to provide the country with quality food of our own production and substitution of imported goods due to the pro-duction of competitive, best-selling products in the domestic market.

Among the important characteristics of the competitiveness of agricultural products, raw materials and food, you can highlight the presence of the optimal ratio of quality and cost indicators, achieving better results than competitors, and correlation with effective demand (Potehkina E. N. 2014)..

The product is competitive on the market if it has a set of attractive consumer, quality and value of properties, which in the conditions of a broad proposal provides customer satisfaction and commercial success to producers.

There is a direct dependence of production efficiency from the level of product competitiveness, as competitive products is more fully meet the needs and always finds its market, guarantee the financial stability of the company, as well as getting the profit.
For improvement of the competitiveness of agriculture in Russia will be contributed: Improvement of the secondary market of agricultural machinery; the use of resource-saving and environmentally friendly technologies; innovation in the sector; regulating the volume of exports of mineral and organic fertilizers; wage increases; the reform of credit policy.

Formation of a balanced system of management accounting will promote a competitive advantage to agricultural producers as part of their marketing activities through trading networks (Potehkina E. N. 2014).

At the same time, the understanding and attention of society and the state to the general problems associated with the technical backwardness of the industry, the disparity of prices, its high energy costs, high production risks are perceived by the Government of the Russian Federation as urgent, and therefore will certainly be resolved.

Abstract

The article considers the problem of Russian fixed funds depletion, primarily, the industrial companies' funds depletion caused by the absent or insufficient investments. The method to study the investment volume is based upon the statistical reports provided by Rosstat and the Bank of Russia. The purpose of the paper is to analyze the provisions on fixed capital investment at Russian companies within 2014-2016 both in general and structural terms, to identify the reasons for investment bust and the deformation of the investment activity financial&resource base. The companies' fixed funds require investments to provide their technology upgrade. It is necessary to develop a nationwide finance and investment strategy aimed at the investment activity boosting in Russian companies and resolving of financial issues. This is the only way to make the Russian economy develop and grow as well as to push its international competitiveness. The main source of funding the investments into fixed assets of the companies is depreciation deductions and a depreciation reserve developed by a company. However, the situation is the following: due to high fixed assets physical wear and funding absence, depreciation deductions are formed as a result of the re-evaluation of those fixed assets that are seriously worn-out. Indeed, it cannot provide for a real depreciation base. The article is finished by the summarizing of regression peculiarities of the investment financial support in Russia and the conclusion emphasizing the great importance of industrial investments.

Keywords: investments, reproduction rates, depreciation deductions, financial&resource base.

Introduction

Investments into fixed capital are the most important means ensuring the economic crisis overcoming and technical re-equipment of Russian companies. The intensification of investment activities in Russian companies as one of the key strategic directions for the national economic system stabilizing and development requires integrated financial support.

The current economic situation in Russia significantly complicates the financial support of investment activities intended at fixed assets renewal. The introduced international sanctions dramatically limited the access Russian companies and banks have to the international system of long-term borrowings and led to the decrease in foreign investment inflow. The mid- and long-term solution of these issues relates to the specific nature of market positions, the sectoral structure and financial support of the companies' investment activity. It is necessary to conduct the investment activity strategic planning with the account of the formed international and national economic conditions based upon the analysis and evaluation of diversified financial sources.

Despite the achievements in the investment theory development within foreign and national Economics of the XXth - beginning of the XXIst centuries, the methodical basis of this activity type does not sufficiently meet the contemporary and more complicated requirements laid down for the funding of the finance&investment strategy implementation by the companies. Under current economic conditions one shall pay special attention to the funding of Russian industrial companies' development strategy, boosting of their investment activity which will provide for a multiplicative effect and result in the economic growth in all the sectors of the Russian economy. However, the national literature does not pay sufficient attention to the study of investment activity financial support issues at large industrial companies as opposed to the study of investments to the financial and trade sectors. Under contemporary market competitive requirements and the implementation of measures within the public policy aimed at the Russian industry upgrade the aforementioned problem is even more relevant.

Results

The research of finance&investment strategy development issues occurring at Russian industrial companies is impossible without a preliminary consideration of their current investment activity and funding problems. The actual level of insufficient investments and fixed assets obsolescence at Russian industrial companies as well as the total costs necessary for their recovery are clear if we analyze fixed funds reproduction rates (Fig. 1) (Investments in Russia, 2015).

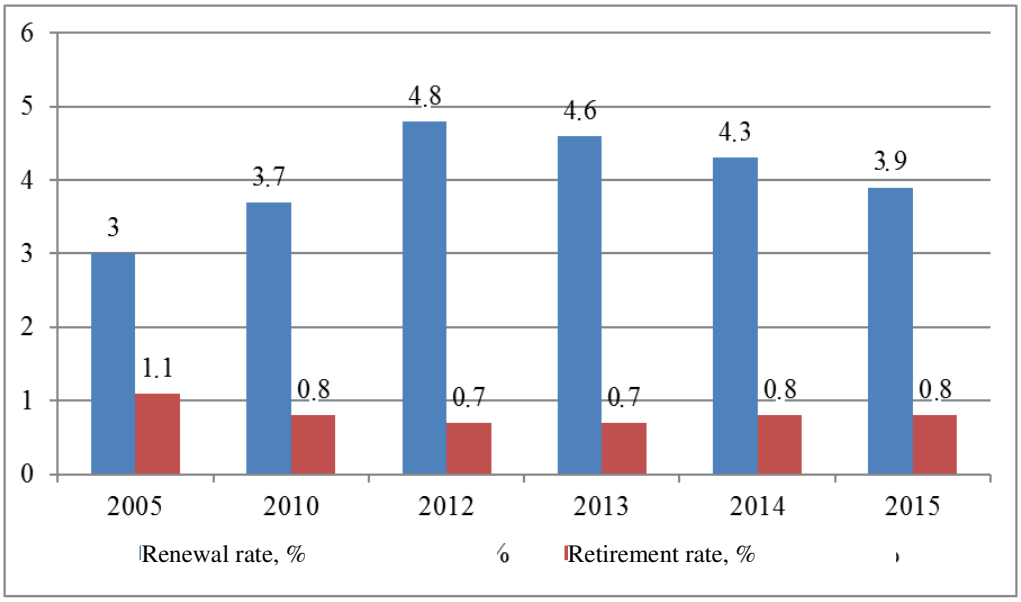

Fig. 1. Dynamics of fixed funds reproduction

Q2, 2016, was the 10th consecutive quarter of the fixed capital investment reduction (in comparable prices over a full range of organizations) in Russia. The reduction in 2014-2016 was preceded by a virtually zero investment dynamics in real terms during 2013. In 2014 the investment volume decreased by 1.5%, in 2015 - by 8.4% (returning to the value of 2008) while the annualized decrease in the 1st half of 2016 was 4.3%. The decrease rate is becoming slower, and in general, in 2016 the investment volume decreased by 2.7% while in 2017 the investments are anticipated to grow by 0.3%.

In the first half of 2016 the investment reduction rates in large and medium organizations slowed down even more compared to a full range of organizations with the annualized value of 1%. The investment reduction in 2014-2016 is different from the crisis occurred in 2008-2009 in such a way that during the previous crisis the investment bust was harsh and significant while the second period is characterized by a prolonged gradual decrease due to the opportunities that changed for the worse in terms of capital investments over a wide range of sectors and regions.

Let us consider a specific structuring of investments in 2005-2016: into dwellings, in buildings (except for residential ones) and erections, in machines, equipment and vehicles (Fig. 2).

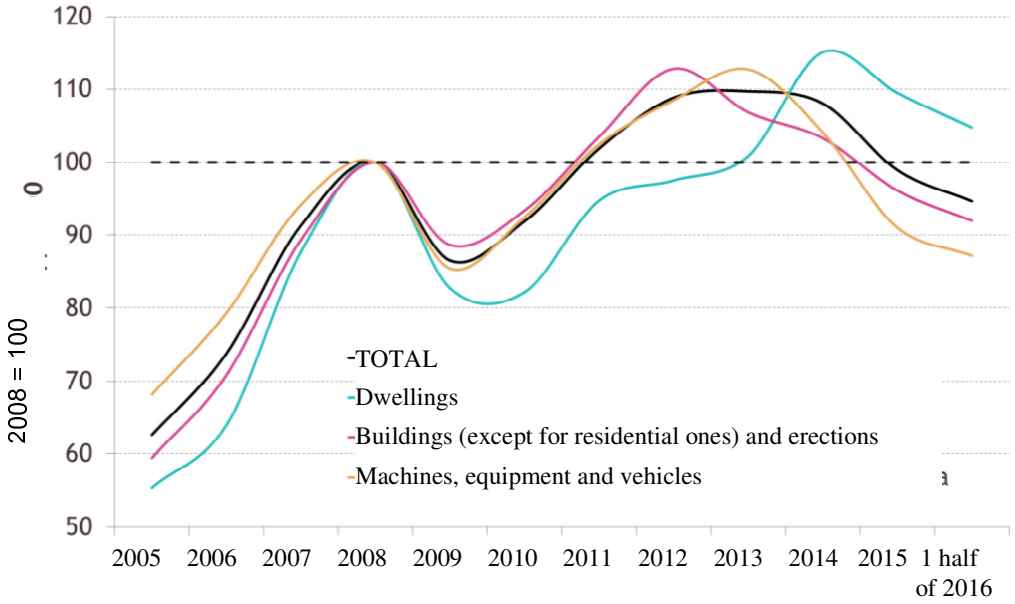

Fig. 2. Dynamics of investments on the fixed funds types in fixed prices, 2005 – Ist half of 2016 (Fixed Capital Investments …, 2016)

The investment volume reduction (large and medium organizations) was quite even among the key fund types for the last year which resulted in quite an insignificant change of the investment specific structuring in the 1st half of 2016 comparing to the 1st half of 2015: the investments in buildings (except for the residential ones) and erections made 47.9% of a total volume of capital investments (47.7% in the 1st half of 2015), in machines, equipment and vehicles - 34.4% (34.2%), in dwellings - 6.1% (5.6%). As more than a half of capital investments are intended for construction purposes, the investment reduction leads to stagnation at the construction market: by the end of the 1st half of 2016 the scope of construction works decreased by 5.7% in per year terms.

Reasons and consequences of negative dynamics

Besides equipment obsolescence, it also suffers from physical wear; these factors resulted in emergence of the Russian production structure characterized by its raw material orientation. One can observe a large-scale degradation of the production funds of Russian industrial companies, and the economy is now going through a structural crisis.

The Russian economy investment area suffered the greatest damage from the international crisis. Its consequences manifested not only in a significant decrease of the scope of works but also in a dramatical distortion of the investment activity's developed trends. The analysis conducted for the structure of investments made into fixed capital according to the funding sources revealed significant deformations of a finance&resource base of the investment activity. The share of proprietory funds in the structure of funding of the fixed capital investments increased up to 57% in the 1st half of 2016 due to a harsh decrease of the raised funds volume. As a rule, the access of organizations to the raised funds is limited during the investment slowdown period. Back in 2014, because of such limitation of the access to external funds (due to increased interest rates as well), the share of raised funds in the fixed capital investment funding structure at large and medium organizations dropped below the level of 50% (Table 1) for the first time since 1999. The data for the 1st half of 2016 demonstrate the situation did not significantly changed over the previous year: the proprietory funds share reached 56.5% being equal to 56.2% in the 1st half of 2015 (by the end of the year this value is usually lower) while in the 1st half of 2014 it was 52.5% (Table 1) (Kiryanov, Ye. O., 2017).

Table 1. Dynamics of investments into fixed capital (large and medium organizations) on financing sources as of the 1st half-year results, 2014-2016

	1st half-year, 2014		1st half-year, 2015		1st half-year, 2016		Change of fixed prices, 1st half-year, %

from corporate bond issuance	4	0.1	48	1.3			1105		
from stock issue	41	1.2	16	0.4			-69.1		

*Since 2016 Rosstat stopped publishing separate data for the category "other".

The capital spending nominal volume keeps growing but the investments made in the 1st half of 2016 lowered by 8.2% in comparable prices to the 1st half of 2014. This decrease is mainly due to the raised funds which have reduced by 16% for the last two years while the proprietory funds decreased only by

1.2 for the same period. The greatest part of such drop was made by "other raised funds" (-161 billion rubles in the prices of 2016, essentially, the overhead organizations' funds), bank loans (-126 billion rubles) and public funds (-47 billion rubles). At the same time, in 2016 the decrease rates slowed down while certain funding types started to recover, primarily, the debt funds of other organizations (apart from banks).

Investment activity funding sources

The market-driven economy conditions stipulate for the companies' proprietory funds to be the basis of the investment activity funding. In terms of the problem analysis it is logical to make the next step towards the specification of the self-funding opportunity for the companies' development bearing in mind their proprietory funds - depreciation deductions and profit (Daskovskiy, V. and Kiselev, V., 2014).

The developed trend for investment activity real funding does not correspond to the existing concept of the companies' development self-funding; their development opportunities keep reducing and are close to the end (Moskvin, V., 2015). That is why one can observe a continuing decrease of the proprietory funds share in the fixed capital total volume.

Government lending and borrowing in relation to the companies' development that lightens the budget burden by means of the reduction of grant funding for a number of investment programs and increasing the number of paid ones at moderate prices as well as by means of repayment of the credit resources contributing to the public budget is not organized in Russia. This means there is no opportunity to alleviate the investment funding for the budget and companies or to boost competition in the bank system to reduce the number of the speculative operations and interest rates of commercial banks.

Continuous deteriorating of the production means quality in the national economy leads to the reduction of the depreciation base. To limit the negative impact of this process as well as to control inflation, in 1992-1996 fixed assets were re-evaluated on the nationwide level (Daskovskiy, V. and Kiselev, V., 2013). Initiative never-ending re-evaluation of the companies' fixed assets has been conducted since the mentioned period until the present moment. The reported level of production means wear was 49.4% as of the beginning of 2015. These data demonstrate that, in compliance with the official numbers, more than a half of the depreciation base having physically worn out fixed assets is preserved by means of the accounting procedures. Today there is an abnormal situation in Russia's economy when fixed assets are renewed not by replacement with the new ones but by means of their cost re-evaluation which becomes higher after their upgrade (Daskovskiy, V. and Kiselev, V., 2014).

Most developed countries are characterized by the trend when the investment activity funding is performed by means of proprietary funds with a significant increase of a depreciation share. In Russia we can observe the opposite. Even at the favorable economic development stage the dependence on raised funds and profit demonstrates the growth trend while the significance of depreciation funds becomes lower.

Overview of the current state of the issue

The overview of Russian leading industrial companies' activities makes us draw a conclusion on the low level of their economic activities' efficiency. Thus, machine construction companies representing the key industrial sector are not capable of providing production means renewal and increasing the output products competitiveness. At the moment, Russian industrial companies are not ready to implement large-scale programs for technical re-equipment and production capacities reconstruction. Taking into account the profitability of the business activity implemented by Russian industrial companies, one can draw a conclusion on the depreciation base depletion (Chernenko, V. A. and al., 2015).

Low efficiency of modern Russian companies' functioning creates a vicious circle. The leaders of the economic sector are not capable of carrying on a large-scale investment activity due to the absence of any opportunity to use the depreciation reserves and profit. In its turn, the depreciation fund and profit cannot grow due to the absence of renewed fixed assets in the company; such renewal is impossible due to the absence of investments.

Unfortunately, by today the information on the specific large companies has not been issued anymore. However, with the account of the fact that in 2005 the profitability of sold goods and services was equal to 13.5%, decreasing to 9.3% by 2015, one can make a conclusion that there are no conditions to perform investment activities aimed at the renewal of the real production companies' fixed assets. Today the situation has seriously changed for the worse. Even the leading companies of the national economy are not capable of providing for production means renewal and financial state stability under contemporary conditions. Large business is focused on the infrastructure improvement, redistribution of the national and accretion of the foreign property. The article shows a severe deficit of investments which not only provide for the current needs but also cannot reach the level of 1990 which stipulates for the necessity to introduce a special responsibility and discipline while using the available opportunities for investment resource formation.

Let us consider investments from a structural point of view. The most efficient investments are direct ones as they are capable of direct embodiment into up-to-date technology and equipment. But their retardation comparing to other investment types is 3.4 times according to the statistical data.

A great part in the development of the national economy is given to foreign investments. However, they have their disadvantages which include their unpredictable nature as the volume, the time, the territory and the sector of such investments are unknown. Besides, in contrast to the national investments, the foreign ones can be exported in the form of depreciation deductions and net profit (Gerasimov, P. S., 2013).

Similar to the first decade of this century (except for 2006 and 2007), in 2015 the financial account of Russia's payment balance was closed with the exceedance of private capital export over its import. In relation to the private capital flow such exceedance was equal to 58 billion of dollars and, although it was lower than the record-breaking value of 153 billion dollars (for post-Soviet Russia) in 2014, it was not lower than in 2012-2014. Such exceedance of export over import has remained a characteristic one for all the forms of international capital flow both in and from Russia: direct investments, portfolio investments, derivative financial tools, other investments (Table 2) (Bulatov, A. S., 2016).

Table 2. Balance of payments of Russia, billion dollars

Indicator	2013	2014	2015

The reduction of direct investments' export and import started in 2014 and continued - in 2014 their flows were reduced to the minimum value since the middle of the last decade. Combined with the cheapening of the Russian companies' cost abroad due to the economic growth fluctuations in most world countries as well as the foreign companies' cheapening in Russia, it led to a further decrease in the volume of direct investments accumulated abroad by Russian residents (by 1.4 times for 2013-2015) as

well as in the volume of direct investments accumulated by non-residents of Russia (by 1.6 times for the specified period). Besides, one could observe the reduction of foreign derivative financial tools accumulated by Russian residents and even a greater reduction in Russian derivative financial tools accumulated by non-residents.

The situation is different in the area of portfolio investments. Since the middle of the last decade Russian investors continued to buy foreign bonds in a record-breaking scope which resulted in the growth of the accumulated portfolio investments from 54 billion dollars in 2013 up to 57 and 71 billion dollars in 2014 and 2015, correspondingly. At the same time, foreign investors disposed of Russian shares and bonds and, as a result, the volume of their accumulated Russian securities kept reducing - from 195 billion dollars in 2013 to 111 billion dollars in 2014 and 102 billion dollars in 2015 (International Investment Position …, 2016).

The flows of other investments were versatile in 2015. Thus, Russian residents kept reducing their foreign cash as well as their foreign currency savings at current accounts and deposits (especially in the 1st half of the year due to slowing of a harsh drop of the ruble value) while non-residents kept reducing their savings in rubles (due to ruble devaluation). The reduction of the non-residential accumulated volume of loans and borrowings that started in 2013 but stopped in 2014 continued despite the fact the trade credits and advance payments become available for them again. Considering the loans obtained from non-residents, similar to 2014, the volume of such loans kept reducing, and moreover, the accumulated volume of trade credits and advance payments received from non-residents started to reduce as well due to decrease in the volume of Russian services and goods import. The greatest reduction was observed for foreign currency liabilities of Russian banks (by 60 billion dollars).

We want to underline and draw your attention to the reduction in the volumes of the item "Questionable Transactions" which has been continuing for the 3rd year; this item includes the transactions that are characterized by fictitiousness features and relate to the trade of such services and goods, purchase/sale of such securities and allocation of such credits and transfers to the proprietory foreign accounts which have the purpose of trans-border funds movement. One can assume this is the result of the intensification of bank and customs supervision in our country as well as the campaign of a higher transparency of the offshore activity; such campaign is dynamically developing both in our country and abroad.

Harsh drop in the currency interventions implemented by the Central Bank in 2015 combined with the growth of the current transactions' account balance in the middle of the previous year stopped the reduction of the reserve assets (international reserves) while in the second half of the previous year such reserves slowly started to recover (up to 386 billion dollars by the year-end). As a result, the financial account balance was closed with the record-breaking exceedance of net lending over net borrowing registered after 2011 (by 74 billion dollars). Such increase of the financial account balance was observed in 2010-2011 when Russia's economy was recovering from the crisis of 2009. One can suggest that the growth of the financial account balance started in 2015 also demonstrates the recovery of the economic growth in Russia.

According to the preliminary estimates of the Bank of Russia, the proficit of the current transactions' account for the first four months of this year has been equal to 16.3 billion dollars against 37.3 billion dollars in the comparable period of the previous year. This is the result of a slower reduction of goods import with a high reduction of goods export. It is possible that slowed import rates also speak for the Russian economy recovery from the crisis. The trend of increasing the global oil prices for the considered period is also a piece of good news.

The financial account for January-April 2015 is characterized by similar trends: the volume of foreign assets accumulated by residents kept reducing very quickly while the volume of assets accumulated by non-residents in Russia (i.e., Russia's external liabilities) reduced slower. As a result, net capital export was equal to 12.8 billion dollars which is more than 3.5 times less comparing to the similar period of the previous year (Evaluation of Key Payment Balance …, 2016).

The growth of reserve assets which started in the second half of 2015 continued - from 368 billion dollars in the early 2016 they grew up to 396 billion dollars by May mostly because of monetary gold the reserves of which reached their record-breaking value of 1478 tons (Evaluation of Coming Changes …, 2016).

However, taking into account the physical facilities wear and the weakness of Russia's financial system, there are still no prerequisites for annual admission of 100 billion dollars of the foreign direct investments. We believe that such situation resulted from an obvious corruption component and a permanent crisis state of Russia's economy nullifying all other investment climate advantages existing in the country.

Today's foreign investments attracted to the mineral deposits extraction and initial processing cannot be satisfactory both in terms of their volumes and results, neither they can be considered as an important factor of the investment upgrade in Russia's economy.

At the contemporary stage one can observe the trend for the increase of direct investment volume in the Russian companies abroad. The general growth of direct investments is also impressive. The large-scale expansion plans of the foreign economies are developed by public companies. Alongside with the natural resources and intellectual capacities, financial resources are becoming a significant factor of Russia's presence in the global economy. The investments made into foreign companies decrease the level of production expenditures and provide for special conditions both in terms of export and products sale at the national market. Besides, the cost of borrowed financial resources is lowering while the offer price at IPO is increasing. Summing up the aforementioned, one can conclude that direct investments to abroad provide a synergistic effect for the development of a parent company which involves positive changes for the Russian economy in general.

However, one shall consider negative aspects as well. The investment outflow to abroad deprives Russia's taxation base of the opportunity to expand, but at the moment the taxation system is not able to support the public budget at the non-deficit level without any income from the sale of hydrocarbons at high prices at the international market. As the investments are intended for the purchase or manufacturing of the production means (including innovative ones) abroad, it leads to the loss of thousands of jobs in Russia. Investment resources and tax deductions thus develop foreign countries instead of solving Russia's internal problems. At the same time, in terms of the integration of transnational corporations, the production means takeover abroad is aligned with their strategy and promotes business efficiency enhancement at the global market.

Under these conditions Russia is characterized by industrial technology underdevelopment, losses and a humiliating role of the raw material supplier but not the supplier of ready products. This view leaves in serious doubt the assumption on the efficiency of investment export abroad. Thus, if one invest the financial resources exported abroad in the national agricultural sector, it will be possible to decrease the share of food import and increase the volume of tax deductions in the budget. Besides, it will improve a social an economic situation in villages.

Investing in national companies can result in a much wider range of possible advantages for the Russian population comparing to one from investing abroad. Thus, 28 key oil refining companies in Russia include six that were commissioned before 1940, six more were commissioned before 1950 while eight of them - before 1960. It turns out that 20 of 28 companies are 50-60 years old. As a result, oil refining capacities decreased to 83% of the 1994 level due to retirement because of a critical physical wear of assets. The loading of the remaining capacities is not full as well: low quality of products, insufficient refining depth, and high net cost. Additional loading of the oil refineries is provided by the refining depth deepening and making the oil product quality correspond to the export standards which requires 12 billion dollars that cannot be found in the internal turnover. Due to technical underdevelopment the income from oil products export is lower than one from crude oil sales.

From the economic point of view, the situation when the investments, in contrast to the foreign ones, are exported abroad under the conditions of a sever investment lack in the country is inadmissible. Furthermore, it is absolutely inappropriate that raw material companies forward large credit facilities abroad and not for the development of the national industrial production pledging natural subsoil resources they do not own for foreign loans' obtaining.

The investment mobilization for innovative production upgrade from the public savings is recognized as undesirable although the economy transition to a higher level requires to take this measure (Yegorov, A. Yu. and Selskov, A. V., 2015).

It is necessary to specify the situation of the economy innovative renewal with the account of all investments (Table 3). One shall take into consideration that starting from 2013 the fixed capital investments include the ones made into the intellectual property items: scientific, literature and artistic works; software and data bases for computers, inventions, utility models, industrial samples, selection achievements, costs for performed intangible development, costs for research, development and technological work, etc.

Table 3. Investment patterns and structure in Russian Economy (Russian Statistical Annual Report, 2016)

	2000		2008		2012		2015	
	billion rubles	%	billion rubles	%	billion rubles	%	billion rubles	%
Total volume of Russian and foreign organizations' investments	3162	100.0	40,693	100.0	89,945	100.0	141,818	100.0
Intellectual property items, R&D and other non-financial assets investments	18	0.6	89	0.2	173	0.2	148	0.1
Fixed capital investments	1165	36.8	8782	21.6	12,586	14.0	14,556	10.3
- dwellings investments	132	4.2	1194	2.9	1534	1.7	2189	1.5
- buildings' (except for residential ones) and erections' investments	502	15.9	3742	9.2	5560	6.2	6028	4.3

- machines, equipment and vehicles investments	427	13.5	3312	8.1	4732	5.3	5052	3.6
- other investments	104	3.3	534	1.3	761	0.8	1288	0.9
Financial investments	1245	39.4	26,402	64.9	67,725	75.3	127,114	89.6
Foreign investments, billion dollars	11		104		155		–	
Foreign investments billion rubles	308	9.7	2579	6.3	4803	5.3		
Russian organizations investments into foreign economies, billion dollars	15		114		150		–	
Russian organizations investments into foreign economies, billion rubles	426	13.5	2841	7.0	4658	5.2		

The investments made into machines, equipment and vehicles that were equal only to 8.1% in 2012 dropped down to a critical value of 5.3% while the funding of intellectual property, R&D alongside with other non-financial assets stopped at the level of 0.1-0.2%. The investment structure is intensively deteriorating: financial investments were 3 times higher than the investments in non-financial assets in 2008 while in 2012 they were 5.4 times higher. Their share in all investments over the considered period increased from 65 to 75.3%. The organization financial investments shall be understood as the investments of monetary funds or any other tangible assets into the securities of other legal bodies, interest-bearing bonds of public and local loans, authorized (joint-stock) capitals of other legal bodies incorporated in the territory of the country or abroad, etc. as well as the loans provided to other legal bodies. The excessive development of the considered direction is the result of the absence of control and management of the investment activity in Russia.

There is great discrepancy between the volumes into the active part of fixed assets and the retirement volumes of such fixed assets registered by Rosstat explained by the fact that 85% of these investments account not for non-recurrent but for the current cost the companies incur due to the repair of the equipment with its simultaneous upgrade. Only 15% of the investments made into the fixed assets active part participate in technical re-equipment. In 2008 the investments into equipment and vehicles were equal to 3312 billion rubles while the retirement of all fixed assets' types is registered in the volume of 429 billion rubles. Only 13% of the investments participated in the actual technical re-equipment.

In 2012 the investments made into equipment and vehicles in the amount of 4731 billion rubles resulted in the retirement of 0.6% of all fixed assets (702 billion rubles). Of course, this retirement included buildings and erections. However, even under the assumption that such retirement included only the active part of fixed assets, only 702 billion rubles were spent for its replacement. The remaining 4029 rubles (85%) accounted in the upgrade validated form as the investments are current assets the companies spent for the repair of the equipment with its simultaneous upgrade and not the lump ones. The division of the recorded investment into real capital spending and repair costs, 702 and 4029 billion rubles, correspondingly, demonstrates that only 15% of them participate in technical re-equipment.

In 2014 the investments made into the active part of fixed assets according to the statistical reporting show the tendency towards decrease and are equal to approximately 4856.3 billion rubles but only about 1540 billion rubles are forwarded for real technical re-equipment. They define the small part of retirement registered by the statistical numbers.

Summary of the issue

On the basis of the conducted research, one can identify the following peculiarities of the investment activity funding proving its regression:

1. The key purpose of the investment activity intended for fixed assets upgrade is the replacement of equipment with the highest wear level. Very often the replaced equipment is impossible to be operated due to its full physical wear.

2. The expansion of the market of the pre-owed fixed assets is under way with the increase of their purchase volumes by 2.89 times and their sales volumes by 3.61 times in the period of 2005-2014.

3. The equipment which does not change the production technology but increases the labour intensity of specialists and managers instead is being in a higher demand.

Conclusions

1. Today a great number of the industrial companies' fixed capital investments are the companies' investment costs for overhaul. Due to this peculiarity, the underdevelopment of physical facilities owned by Russian companies is conserved and aggravated as compared to the general global level.

2. The urgent issue of the Russian industry is deformation of the fixed capital investment funding structure and continuing inaccessibility of the "pre-market" volumes of the fixed capital funding (with an increased need in such funding) due to an incredible obsolescence of fixed assets over the last 20 years.

3. Due to the depreciation base depletion, the investment activity funding, including fixed assets renewal, is mostly provided with profit but not with depreciation deductions.

4. The bank system makes the minimum contribution to solve the problem of the innovative renewal of industrial companies. In general, the system of the institutional support of the economic material and technical facilities is not developed and built.

5. Industrial investments are the key factor ensuring the country's economic growth and development. The only way to protect the country from the global depression on the verge of which the global economy is to develop the national economy, fund the fixed capital investments and innovative development.

Abstract

Globalization of economics contributes to advancing innovation, developing inter-firm collaboration and network organizational structures, functional integration and technology transfer between firms, as well as with state, private laboratories, and universities. Consequently, there is a need for the search of partners, resources and ideas outside the company. In this connection, the concept of innovation intermediaries is gaining strength and recognition, which serve to establish or improve the relationship between all participants of the innovation system with complementary skill sets or interests. These intermediaries pursue the aim to support the generation and diffusion of innovation. Due to the active development of information and digital technologies in the international practice have gradually emerged new forms of innovation intermediaries, based on digital technologies. The article is also focused on the studying of network approach in the digital age and economic globalization. It reveals the causes of transition from the concept of national innovation system which dominated for years in economic theory and practice to the concept of regional innovation system with the use of innovation intermediary approach. The role of innovation intermediaries within regional innovation system is investigated in the paper.

Keywords: inter-organisational network, institutions, intermediaries, innovation system development, digitalization

Introduction

Russian policy makers are in the search of the optimal strategy of social-economic development. The escalation of geopolitical tension is aggravated by low functioning efficiency of the Russian economic system. It is believed that in a medium-term perspective, Russia is likely to curb recession and resume growth of GDP.

To reach this objective, along with effective political solutions there is a need for a new economic policy focused on consolidation of the economy, the development of which should follow, according to the majority of experts, the innovation path. The geopolitical crisis and the sanction policy towards Russia have revealed multiple implicit problems aggravated by the fall of oil prices as the main source of revenue, as well as by an extreme deployment of the import substitution and economic modernization

policy. It is worth noticing that the reverse side of the critical situation may become a powerful impulse of mobilization of implicit reserves for the development and implementation of existing capacities and capabilities of the Russian economic system. Consequently, the current situation should be considered as a real chance of fostering innovation and international economic integration of Russia. We must pay due attention to the fact that antimonopoly regulations and competition have played out. There are new challenges requiring a cardinally new methodological approach to the analysis and scientific understanding of principles and mechanisms of economic development (Vasin et al., 2017).

According to a number of researchers (Jill, 2002; O'Hagan, 2017), the world economy is becoming global, and globalization of economics is understood as the economy which functions as a whole in real time and space independently of the fact if it is concerned with capital, management, labour, technology, information or markets. In modern research literature on globalization the term "glocalization" is more and more often used. According to its dictionary meaning, the adjective "glocal" and the noun "glocalization" are formed by "merging the concepts of global and local".

In the early 1990s R. Robertson (1987), an English sociologist, defined this term as universalization of particularization and particularization of universalization. For Ritzer (2003), globalization is glocalization plus globalization. Globalization means imperatives of growth inducing "organizations and nations to expand globally and prevail over local". Regionalization of innovative activity is closely connected with the process of globalization. K. Ohmae (1993) states that in the world, where borders are gradually and increasingly disappearing, the region is becoming a "natural" economic area. Consequently, the efficiency of the national innovative system functioning, its competitiveness depends significantly on dynamization of innovative processes at the level of particular regions. The given fact is supported by the practice of foreign countries development where the current intensive economic growth is mostly provided by effective regional systems in innovative sphere.

In this context the scientific world as well as the world politics increasingly demand theories of regional development. Among them the following theories are worth mentioning: neoclassical development theory, agglomeration theory, M. Porter's competitive advantage theory, regional clusters theory, regional innovative growth model, technical and economic paradigm concept, etc. Currently, the interest of the scientific world in this issue causes the emergence of new theories and concepts of regional development.

Literature review

An important point is considering the changing essence and content of the concept "region" under the conditions of globalization. According to a number of researchers (Held et al., 2000) there is intensification of various relations on the global scale, and globalization means expanding, advancing and accelerating world-wide relations. Economic globalization is understood as a tendency to establish common investment environment and an integrity of national capital markets. Thus, it is a combination of processes of spatial merger of capital markets, goods, services and financial tools which are accelerated under the influence of competition at the innovation technologies level. Under globalization there is a growing importance of network as a form of representing complex systems. Recent research of innovative process emphasizes the importance of network in providing success for innovations, thus transforming the traditional model, which characterizes innovations as a linear sequence originating from fundamental research by means of product design, manufacturing and marketing. Currently innovations are viewed as

an interactive process which requires intensive movement of facts, ideas and data in the firm's internal and external environment.

Inter-organisational networks have been one of the fastest developing topics in management science over last two decades. Recently the concept of network has made a breakthrough in the theory of territorial economy after it began to be actively used in different forms and meanings in many disciplines. The concept of innovative network has a wide character. This definition encompasses innovative networks promoted by large European programmes which connect firms and other establishments from different countries, sectors into competitive innovative environment that is used by small and medium-sized business to implement innovative projects. If the purpose of cooperation is not connected with innovative activity, the mere fact of cooperation with other firms increases innovative opportunities. In its easy sense, network can mean a group of cooperating firms; the particular group can represent an innovative system, supply chain, cluster, or any other type of interfirm relations. Networks can connect only a couple of firms, or they can be quite wide, including the whole industry. They can focus on one type of activity, for example, education or a particular engineering problem, or on activity within the framework of the whole value chain. The duration of network can be limited by lifecycle of one product or current ones, or by that of all projects. Network can be supported by formal relations or it can be not.

In our opinion it is Tijssen's (1998) definition that reveals the most adequately the major features of network approach. In his view, a network is a developing system of mutual dependence based on resource interconnections where the system character of the latter is the result of interactions, processes, procedures and institutionalization. Creating, integrating, exchanging, transforming, incorporating and using resources within a wide range of formal and informal relations constitutes activity within the framework of such network.

It is evident that the nature of networks is quite diversified. Networks are so complex that theorists are not able to define an ideal network, although, as the experience shows, some functions can provide particular benefits. An ideal network is a network whose key actors are closely located; connections are long-term and stable, each connection is the key part of participants' business-strategy; there are close informal relations, the relations are running smoothly; all network members are equal, and the number of actors is big enough to provide a rich source of knowledge, and at the same time it is small enough to be manageable.

Networks are considered as a new way of organizing economic activity, which gives an opportunity to neutralize the disadvantages existing in deeply integrated firms as well as the disadvantages which appear under direct market contacts. Networks enhance the advantages of specialization (through easy access to external sources of knowledge) without provoking price rise (Powell, and Grodal, 2006; Vasin, and Gamidullaeva, 2015). Networking method of allocating resources gives an opportunity to conduct transactions through the network of individuals or institutions engaged in mutually beneficial and supportive activity, and not through odd exchanges and administrative orders.

Greater emphasis may be placed on a single activity, for example, education, or specific technical problem, or on the activity within the framework of value chain. The length of a network may be limited by the period of the life cycle of one project, by the current or by the duration of all projects. The network can be backed by formal relations.

According to H. Chesbrough (2003) in the framework of open innovation paradigm the flow of knowledge creates knowledge landscape which is an open access space with a great deal of databases of scientific ideas. The knowledge landscape emerges due to incoming (inflows) and outgoing (outflows) of knowledge. These ideas are accessible for the use and specialists may be employed by the other companies. Gloor's (2006) model of Collaborative Innovation Networks implies that innovations are increasingly becoming more interactive and economic growth involves various groups of society forming and unfolding a certain innovation ecosystem. Great contribution into mutual understanding of collaboration' importance have made I. Ansoff and A. Campbell (Ansoff, 2007; Campbell A., 1995).

They have shown that synergetic effects of innovation economy are the unique implicit resources, which may be found when company instead of the independent closed activity chooses cooperative activity in the field of using a common experience, use of common personnel and equipment. Businesses therefore join with other economic actors, diversify their activities and functions, create web sites, joint ventures, logistics systems, agro-industrial complexes, innovation clusters, strategic alliances, merge with and acquire other companies, search for synergy effects in various forms of firms' associations, in holding company models, consortiums, in the spatial distribution of productive forces.

The complicated and global changes in economic environment have caused serious challenges for firms related to the necessity to create value by working in alliances and networks. Authors (van Lente et al, 2003) highlight that intermediaries' significance is in maintenance of creation and coordination of networks of interdependent and different actors. These agents are called to coordinate firms within networks through contracts, agreements, etc. Innovation intermediaries use boundary spanning to identify and select previously unidentified solution-providers for the knowledge-seeker.

Authors J. Howells (2006), J. Steward and S. Hyysalo (2008), E. Almirall and J. Wareham (2011) highlight different approaches and significant propositions applied by innovation intermediaries propose a typology of innovation intermediaries. The authors investigate the emerging phenomena of ‘Living labs’ as entrepreneurial intermediary that presents a high level of involvement with users and engages the external stakeholders.

Results

Notoriously, innovative process can be considered within technological zone, industrial park, global value chain, region, cluster, community, etc. In this connection, it is necessary to answer the question what advantages exist in researching innovation processes at the regional level. As a result of thorough analysis conducted by the authors, the following advantages of research of innovation processes at the regional level were revealed.

1. As it has already been mentioned, first scientific works on innovative process concentrated on enterprise as a subject initiating it. Later, the accepted role of knowledge spillover contributed to changing the focus on the territorial aspect as the basis for innovative activity. It means, that there was a transition from enterprise to territory where the innovative process is taking place (new knowledge is produced and it is commercialized in innovation). According to M. Fischer (2001), territorial proximity between economic agents plays an important role for simplifying exchange of implicit knowledge, without which many radical innovations are impossible. Thus, an institutional context of innovative

process appears, which gives an opportunity to localize it and to do comparative analysis of different territories.

2. Within the framework of region there appears an opportunity to conduct complex innovative policy, as it is region that is able to identify strategic priorities on behalf of the state, establish relations with other regions, which, basically, gives it an authority of political jurisdiction.

3. Region openness allows them to be flexible and to easily adapt to fluctuations of global innovative network. M. Kahler (2017) states that globalization, which is understood in the narrow sense as "economic integration into international system", has caused problems connected with the necessity of taking decision-making into non-governmental sphere. Control changes its place. Governments either delegate more responsibilities for decision-making to supranational establishments or transfer authority of decision-making to subnational political entities. Such type of analysis points at the fact that as a result of globalization national economic sovereignty is becoming weaker while local economies, those which K. Ohmae (1993) calls "city states" are becoming the main actors in the global economy.

4. Changing forms of innovative process participants' communication, increasing role of horizontal connections, interactive communications also causes to single out the regional level of innovative process.

5. The regional level provides the presence of a variety of producers offering specialized services timely and flexibly in reply to requests, emergence of local labour force funds with concentration of specific skills and education forms, cultural and institutional infrastructure, which constantly appears inside and outside industrial clusters and which is very important for effective work of a single local social and economic system.

6. Region is a place of economic interaction and innovative activity. Region has specific and inherent to particular region resources to stimulate innovative opportunities and competitiveness of enterprises. Porter stated that strong competitive advantages in the global economy are often linked to the place. Earlier research of regional innovative systems confirm that innovative activity of enterprises is based on localized resources (specialized labour market, labour force, suppliers, intellectual resources, traditions of entrepreneurial activity, clients, sponsors, etc.).

7. Innovations are phenomena that belong to the system of social relations. In the regional context there is a set of rules, norms, and regulations of firms' behavior, which are derivatives from economic and social and cultural factors. A set of informal relations on the particular territory defines the image, a sense of belonging to the structure, which increases innovative potential of the territory by means of synergetic exchange, information and knowledge exchange.

Region has additional nonmaterial assets (internal dynamics of regional social, cultural, and political assets, informal knowledge spillover, etc.) which represent a specific form of capital that is derivative from social relations, norms and values within the framework of society. This capital helps to overcome difficulties on the market by supporting stable and mutually beneficial relations.

Consequently, the main factors influenced the formation of regional innovation system concept include:

1. increasing significance of regions as the basis for global economic competitiveness of companies;
2. focusing on significance of norms, procedures and conditions identifying the work of infrastructure providing regional economic competitiveness;
3. recognizing informal relations between firms along with formal organizations as mechanisms of maintaining trustworthy relationships between firms;
4. re-evaluating factors of geographical proximity or agglomeration for assisting exchange of implicit knowledge and other externalities;
5. recognizing the importance of ability to institutional and organizational learning for developing regional economy;
6. developing small innovative business and recognizing its role in building the economy of knowledge;
7. acquiring new interactive nature of innovative processes.

Proceeding with the research problem it seems to be important to understand the benefits from using innovation intermediaries within a region.

It must be noted, that innovation infrastructure that is commonly understood as a set of interrelated structures, which serve and provide the implementation of innovation activity, has a low level of interaction between participants in Russia. Hence, there needs to be a shift to the network organization of infrastructure that ensures high level of participants' cooperation. The process of developing objectives and problems, which need to be solved in the framework of such networks, should be the most transparent and interactive. It implies an open communication between representatives of the manufacturing industry, science, society, government ministries and departments. This would obviate and overcome market failures through the self-organization of science and business.

Generally, the use of innovative intermediaries in the region pursues the following major objectives: to promote their own ideas and projects; external expertise of ideas; exchange of experience and knowledge; search of partners, resources mobilization needed for implementing projects. Thus, the development of innovation intermediation in the region provides an opportunity for the companies to reduce the costs on the innovation development, to adjust sustainable innovation processes that are distributed in space, link them into a single chain of production, distribution, exchange and consumption of innovative product in the region.

A typology of intermediation should provide a great contribution into understanding of innovation intermediaries.

First type of intermediaries is "anchors". In this case, intermediaries collaborate with other actors, coordinate their activities and purposefully have a subjective interest regarding the innovation process. This type of intermediary links together networks and public organizations. They provide maintenance and establish social communication, identify trends and encourage supporters to new technologies. Their integrative potential provides communication, development and implementation of innovation opportunities of all stakeholders.

The second type of intermediaries so-called "bridges" links two disconnected parties and coordinate the information flow. These intermediaries provide consultancy services, manage customer's identity, access and broadcast a two-sided market, identify new opportunities and capabilities. Intermediaries - "bridges" provide the following services: development of engineering products/services, innovation project

evaluation, licensing transaction, help definition of the problem, evaluation of outcomes and market identification.

Third type is intermediaries "pumps" providing interaction and collaboration with other actors in order to create of new knowledge. They are oriented towards mediation, promotion collaborative research between various actors, providing commercializing mechanisms and facilitating knowledge transfer. These intermediaries speed up innovation process due to their intensive participation and coordination of innovation activities with universities and industry. The main advantages of these intermediaries are concerned with their ability to address opportunities for the region to generate and share new expertise, human capital and knowledge, to provide innovation actors with access platform for various types of knowledge, interdisciplinary collaboration, financial and human capital resources. These intermediaries provide the following services: advising, provision of resources, for example, knowledge and physical resources.

Last type of intermediaries is "door". They are often examined as market intermediary (Spulber, 2003). These intermediaries provide an augmented product for buyers, foster partnership and provide preferential access, and also provide liquidity. They exploit such coordinating mechanisms as web-enabled commerce, services, seller, buyer and independent alignment and financial support. These intermediaries can enhance organizational capabilities through changing portfolio strategy and network design, providing of new services enabled by ICT. Their functioning is based on information and communication technologies e.g. data warehousing and integration, sensor networks, collaborative filtering and time-and-place utility.

According to the opinion of many authors, the most significant functions that innovation intermediaries perform in the innovation systems, are the following:

1. Knowledge creation and dissemination.
2. The impact on the direction of the search (research and development).
3. Entrepreneurial experimentation.
4. The new markets creation.
5. Creating a legitimate entrepreneurial business environment.
6. Resources mobilization.
7. Development of positive externalities.

Innovation intermediaries operate between actors of the innovation system, create the necessary links, form and create opportunities for the development of relations and cooperation. That is, they establish and coordinate a relationship between the actors of the innovation system. Their main task, therefore, must be understood not as the generation and implementation of innovations, as well as the creation of opportunities and conditions for the development of innovation.

The emergence of new forms of innovation cooperation is the result of development of information technologies and digitalization processes. Increased use of the Internet has predetermined the emergence of virtual innovation intermediaries (for instance, virtual business incubators, operated in various subjects of the Russian Federation). These virtual innovation intermediaries have attracted increased attention because of its ability to cross geographic distances and scale the large amount of activity. The further development of this type of innovation intermediaries has continued with the occurrence of two-sided platforms operating on the technology markets.

A particular attention should be paid to the new form of innovation intermediary co-called Living Lab, which have spread through Sweden, Belgium, Finland and Spain since its inception in 2006. Living labs provide physical interactive platforms for interactions between users, organizations, research centers, and entrepreneurs for the development of new technologies. In collaboration with firms the early phase user-driven innovations are created. Living Labs provide regulation and offer a platform to the participation of users in the innovation process. They support groups of users, provide different services, contribute to the increasing of public involvement in the innovation processes. Their role is especially significant in interdisciplinary projects. Almirall and Wareham (2011) give the following definition to the Living Labs: "open innovation intermediaries that seek to mediate between users, research, public and private organisations, advance our concept of technology transfer by incorporating not only the user based experimentation, but also by engaging firms and public organisations in a process of learning and the creation of pre-commercial demand."

Currently, throughout the world there are more than a hundred Living Labs. This mediation service was created mainly as a public-private partnership for the realization of potential benefits to a region where user-driven innovations are integrated into the collaborative process of creating new services, products and infrastructure. They represent form of innovative cooperation, focused on the creation of a functional area where all stakeholders involved in a public-private partnership (e.g., universities, government agencies, institutions and society) can interact, with the aim of creating, prototyping and testing new technological products in real-time. This resulted in the emergence of a general platform to accelerate the innovation process and ensure the provision of medium- and long- term services for the development of new technologies that support innovation processes within various organizations (Vasin, et al., 2017).
Now we should consider more deeply Living Labs as one type of intermediary acting as system builders of a larger network of organizations. Living Labs were formed mainly as Public-Private Partnerships to enforce regional advantage, where innovation is integrated within the collaboration process of creation of new services, products and infrastructures.

Conclusion

Living Labs contribute to the generation of innovation through knowledge development, new markets formation, development of external economies, mobilization of resources (Lopez-Vega et al, 2016).
As a result of the analysis conducted Living Labs as innovation intermediaries perform the following main functions within the regional economy:

1. Facilitate the cooperation in the field of research. Living Labs act as connectors, seeking technological complementarity and generating links on this basis. At the same time, they contribute to cooperation through medium- and long-term studies of possible types of technologies with all stakeholders, including future users, who are brought in at the research and development stage.

2. Providing complementary services to stakeholders. As a rule, research and development centers are continually expanding their range of services through the inclusion of additional activities, such as rationale for a project, inspection, marketing analysis and so on. The feature of Living labs is that they offer complementary services, including not only the creation and development of technology, but also the provision an experimental platform with a large number of users who are involved in a joint invention process through the use of products' prototypes.

3. Linking science and the state. Living Labs contribute as intermediaries to the development of individual regions when initiated by universities and public authorities sharing a desire to collaborate over science-driven innovation. Although only few in number, these kinds of Living Labs aim to accelerate the development of new technologies in the region, promote certain directions of research, and create synergistic effects between regional actors (Vasin, et al., 2017). These Living Labs play a decisive role in the regional economy.

In conclusion, 'Living Labs' have a great impact on the knowledge development, new markets' formation, development of the external economy and resource mobilization. Hence, innovation intermediary approach has a great potential to make a significant contribution to the regional innovation development in Russia.

Acknowledgment

The research results were obtained while working on order of the Ministry of Education and Science of the Russian Federation.

Abstract

In the context of global upward trends in international innovation and high technology competition and the urge to increase the share of high-tech industries in the country's GDP, developing a national innovation system becomes a key problem to gain an insight into the directions and methods of modernizing the economy and integrating science, education and business. Russian universities are being transformed in terms of business processes to boost their integration into the national innovation system. The purpose of this study is to develop methodological tools for the management of such university transformations in order to increase their revenues through the enhancement of their innovation activity. The analysis of theoretical NIS studies revealed their structure, the specifics of the innovation process and the model of interaction of its main elements. With a system approach applied to the national innovation system, this study analyzes the impact of leading universities on the innovative development of regions and makes recommendations for their development. The suggested methodical approach to the comprehensive assessment of integration of a university into the innovation system is validated on a group of leading universities which participate in the federal Project 5-100. The results of this study will manage the transformation of the university to increase the level of its integration into the innovation system and boost the innovation activity and competitiveness of the country's economy.

Keywords: national innovation system, university, integration, innovative activity of the university, level of integration in national system

Introduction

In the background of global competition, formation of the knowledge economy and constant reduction of the share of government financing in the universities' budget, the country's competitiveness can only be maintained by transforming the activity and modifying the universities into integration centers for the generation and commercialization of new technology. In the knowledge economy, innovation-generating institutions come to the forefront (Etzkowitz, H., Leydensdorff, L., 1997). Therefore, the performance of the national innovation system (NIS) depends on the availability of favorable conditions and the ability of the institutions generating and commercializing new knowledge to produce and implement innovations (Lundvall, B., 1992). Universities are characterized by their integrity, the ability to represent both of these institutions and influence the innovation activity in the region and the country (Cowan R., Zinovyevac N., 2013). To this end, however, the activity of universities should be transformed into business so that the interaction between the university and the environment results in a "structural association" between the university and the region (Ropke, J., 1998).

By initiating innovative processes, universities are able to enhance the country's innovation activity to reflect the intensity of business innovation use by entities. The university's integration into the innovation

system indicates the effectiveness of its innovation activity. Different countries have different environment and mechanisms for implementing the innovation process at universities (Wessner, C.W. et al., 2012). This requires the development of adaptation tools to manage the innovation process at the university according to its specific characteristics.

Subject

The purpose of this study is to develop methodological tools for the assessment of integration of universities into the NIS based on the analysis of changes to the business processes of universities and provide directions for enhancing the innovation activity of the NIS. To this end, the following tasks were set: 1) to analyze the concept and composition of the NIS, demonstrate the model of interaction of its elements and establish the role of universities in the NIS; 2) to conduct a critical overview of the available methods for assessing the university's integration into the NIS, classify the university's innovation activities and develop a methodical approach to assessing the effectiveness of its innovation activities; 3) to validate the suggested approach on leading Russian higher education institutions and give recommendations to enhance the innovative activity of the universities; 4) to reveal the influence of the activity of universities on the innovative development of the country's regions.

Concept and structure of the national innovative system

The NIS is intended to ensure and maintain the generation and commercialization of new knowledge in the country. There are various approaches to the definition and structure of the NIS. The developers of the NIS concept defined the NIS as a network of public and private institutions the interaction of which determines the innovative performance of companies (Freeman, C., 1987, Nelson, R., 1993), located or established in the same country (Lundvall, B., 1992). A tighter definition of the NIS accentuates the institutional context which manages interactions and processes between organizations and individuals involved in the creation, distribution, adaptation and application of socially and economically important knowledge (Hall, A. et al, 2003). Others concentrated on the educational aspect of the NIS as creating, accumulating and transferring knowledge, skills and products (Metcalfe, J., 1994), determining the level and focus of technology education in the country (Patel, P., Pavitt, K., 1994). A broader concept of the NIS includes all important economic, political, social, organizational and other factors (Edquist, C., 1997), all scientific and technical resources (Archibugi, D., Alberto, C., 2005) that influence the development, diffusion and use of innovation.

With an institutional approach, we defined three groups of institutions within the NIS: institutions of new knowledge generation, institutions of new knowledge commercialization and a set of innovation infrastructure institutions. The latter group of institutions provides the interaction of the first two and includes the institution of innovation mediation, national development, registration and protection of intellectual property, civil society and financial institutions (see **Error! Reference source not found.**).

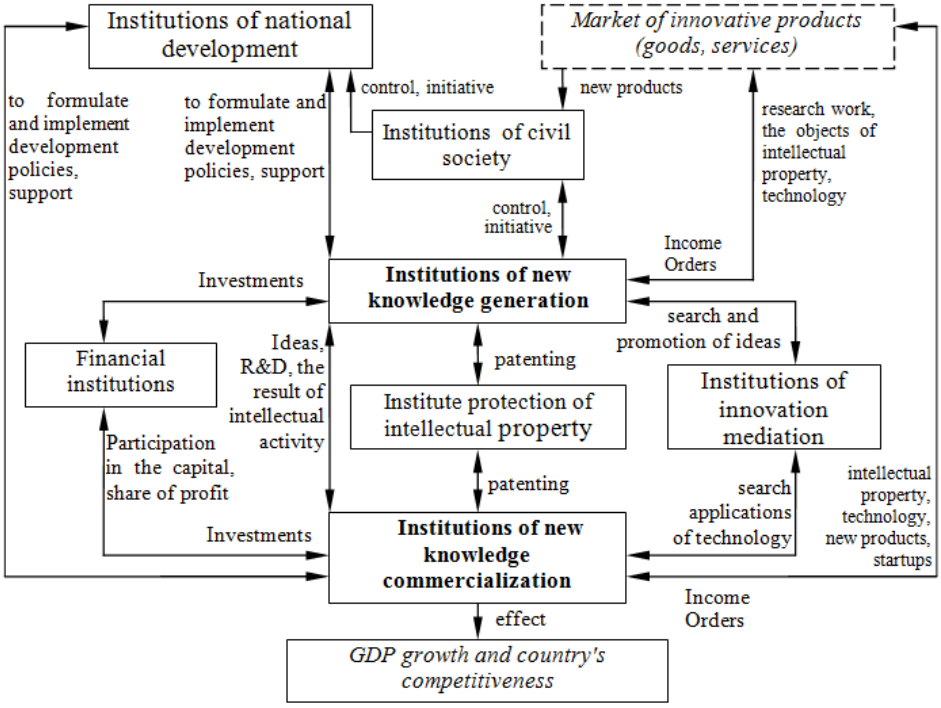

Fig .1: Model of interaction of NIS elements

Source: developed by authors

The key NIS elements are institutions of new knowledge generation and institutions of new knowledge commercialization, the interaction of which ultimately results in the growth of added value.

The main feature and advantage of the university is that it can act as a majority of the institutions: as a generation institution - through groups and teams of scientists, laboratories, university departments; as a commercialization institution - through the activity of small innovative enterprises (SIE), university research and innovation complexes; as institutions of innovation mediation - through the activity of technology transfer centers (TTC), business incubators, fundraising units, departments and centers using innovative educational programs; as a financial institution – by investing extra-budgetary funds in promising projects, through endowment funds; as a civil society institution - through associations, unions, communities.

The best practice of US universities such as Stanford, Massachusetts Institute of Technology, Georgia Tech, University of Texas-Austin shows their transformation into powerful engines of innovation, generating new promising companies and industries (Wessner, C.W., Wolff, A.Wm., 2012). This transformation was directly launched by a series of acts adopted in the 80-s of the XX century, authorizing institutions of knowledge generation to sell and license technology obtained as a result of government financing. These are the Bayh-Dole Act (1980), the Stevenson-Wydler Act (1980) and the Federal Technology Transfer Act (1985). By 2000, these measures have activated the innovative activities and increased the revenues of universities. The number of universities conducting technology transfer and technology licensing has increased 8 times (to 200), the number of university patents has increased 4-12 times according to different estimates, and revenues received from these licenses have increased 5.4 times (to $862 mln) (Mowery, D.C., Shane, S., 2002).

The Russian equivalents of these acts are Federal Law No. 217 (August 2, 2009) which ensured the establishment of small innovative enterprises in higher education institutions and Federal Law No. 273 on education in the Russian Federation (December 29, 2012), and a number of Government Decisions adopted In April 2010 to support and promote the development of innovation in higher education institutions.

These measures also proved to be effective – for the period 2000-2014 domestic research and development (R&D) expenditures increased 11 times, while the share of high education institutions (HEIs) in the total volume of domestic R&D expenditures increased from 3.62% to 9.16%. We observe the changing structure of funding sources of domestic R&D expenditures: the share of HEIs funds increased from 3.87% to 7.58%, the share of business funds - from 18% to 25.6%, and the share of public funds decreased from 64.9% to 61.6% (Federal state statistics service, 2017). The above illustrates the transformation of the existing NIS model.

Thus, in modern conditions, universities should develop mechanisms for the management of innovation processes to ensure the establishment of interaction between organizations included in the NIS. The development of such mechanisms should be carried out comprehensively and involve all innovation management and direction functions.

Methodology

Having analyzed the available methodology, we revealed that the suggested indicators are very diverse and data collection is difficult due to the lack of reports on specific groups of indicators.

There is currently no specific approach to evaluating the generally accepted set of indicators of the university's integration into the NIS. There are approaches to developing indicators and assessing the university's integration into the NIS, but the suggested sets of indicators reflect the innovative potential of the university rather than its innovation activity.

In order to evaluate the university's integration into the NIS, we assessed the effectiveness of integration with the indicators classified by the following fields: science, education, innovation (Kuznetsov A.V., 2012). Such an approach may reflect the integration of the university into the socio-economic system of the country rather than the NIS.

A system of indicators classified by the blocks: science, education, business (Volosevich K.E., 2011) is designed to evaluate the activity of the university as an integrated structure and rather evaluates the university environment, since the method is based on the analysis and evaluation of the university's innovative potential. However, the innovation potential is a broader concept, while the level of integration only reflects its implementation.

Even though other authors added a block of social indicators to education, science and business (Vorozhbit O.Y. et al., 2015), the suggested system of indicators still reflects the innovative potential. Moreover, the methodology is difficult to validate due to the complexity of obtaining and ambiguity of the optimal values of the indicators provided.

In order to determine a system of indicators to assess the university's integration into the NIS in terms of effectiveness of its innovation activity, we classified the HEI's business processes by three types according to the field: educational, research and entrepreneurial. Indicators of education field shows how demand University's education services. Research indicators shows how active University impact on economy growth through its publication and patents activity and its citations (Leonid Kogan, et. al., 2017,

p. 667). Entrepreneur indicators shows how much do University earn with its activity. Thus, commercial-potential indicators may act as indicators of the university's integration into the NIS. To calculate the indicator of the university's integration into the NIS, the following indicators were selected (**Error! Reference source not found.**).

Table 1: Indicators to calculate the HEI's integration into the NIS

Indicators of educational activities, K_1		**Indicators of research activity, K_2**		**Indicators of entrepreneurial activity, K_3**	
X_{11}	Number of foreign students, persons	X_{21}	Citation of publications databases (Web of Science), units	X_{31}	University's income from the use of the intellectual property, rub
X_{12}	Number of educational double degree programs, units	X_{22}	Citation of publications databases (Scopus), units	X_{32}	Number of patents received with external investments, units
X_{13}	Number of foreign scientists, working in high school more than 1 semester, persons	X_{23}	Citation of publications databases (Russian citation index), units	X_{33}	Number of active SIE in the University, units
X_{14}	Number of participants from other organizations, which trained refresher courses programs, persons	X_{24}	Amount of funds raised for R&D, rub.	X_{34}	University's income from the activities of the SIE, rub.
X_{15}	Presence of distance education courses on open platforms	X_{25}	Number of intellectual property objects (including patents), units	X_{35}	Number of new employment created in SIE, units
X_{16}	Number of students working in SIE and research laboratories, persons	X_{26}	Number of laboratories outside organizations on the basis of the HEI, units		
X_{17}	Number of contracts for consulting activities, units	X_{27}	Number of clusters which include a university, units		
X_{18}	Number of established programs of additional professional education, units	X_{28}	Number of grants received for R&D, units		
		X_{29}	Income from R&D (from contracts with business), rub.		

Source: developed by authors

According to the system approach, an element is effectively integrated into a system when the "output" processes of the integrated element become the "input" processes of other elements, while increasing the effectiveness of the entire system as a result of a synergetic effect. So, we believe that the university's integration into the NIS reflects its incorporation into the innovation processes within the NIS, that is, the intensity of interaction with other NIS elements. Therefore, we selected Xij indicators from the established innovative component of the HEI's activity according to their performance. In this case, the method can be used for both internal use by HEIs and ranking HEIs by their integration into the NIS.

The integrated indicator of integration of U university into the NIS is generally calculated as the sum of relative non-dimensional estimates of K_{iU} indicators (formula 1):

$$F_U = \sum_{I=1}^{I} K_{iU} \quad (1)$$

where: F_U – the level of integration of the university U into the NIS;

K_{iU} – the integrated relative indicator for each type of innovation activity;

i – the reference number of a group of indicators, i = 1,2,3…, n;

I – the amount of types of innovation activity;

U – the reference number of a university.

The integrated relative indicator for each type of innovation activity K_{iU} is calculated as the sum of standardized X_{ij} values given in a comparable form and weighted using the expert method (formula 2).

$$K_{iU} = \sum_{l=1}^{L} k_{ijU} \times p_{ij} \quad (2)$$

where: l = 1, 2, …, L – the amount of indicators for type 1 of innovation activity.

k_{ijU} – the relative value of indicator j for type 1 of innovation activity in U university;

p_{ij} – the weight of relative indicator j for type 1 of innovation activity as calculated with the expert method;

M – the amount of indicators in the system used.

In addition to the indicator of integration, it is reasonable to estimate the effectiveness of costs as the ratio of the growth in revenues from innovation activity to the growth in innovation-associated costs for the period. In view of the lagged effect of innovation activity, it is proposed to make a calculation for five years (formula 3).

$$E_{MU} = \frac{\sum_{\Omega=1}^{\Omega} \Delta T_{RI}}{\sum_{\Omega=1}^{\Omega} \Delta T_{CI}} \quad (3)$$

where: E_{MU} – the multiplier of innovation activity costs (by types: educational, research, entrepreneurial),

ΔT_{RI} – the amount of growth in revenues from innovation activity, mln rubles;

ΔT_{CI} – the amount of growth in innovation activity costs, mln rubles;

Ω = 1, 2, …, 5 – the study period.

By comparing the F_U and E_{MU} indicators, we can develop a matrix of effectiveness of the university's integration into the NIS and determine the direction of its development.

Data Description and Analysis

The suggested method was validated on a group of 21 leading Russian universities. The selection for validation was determined by competitive groups within the Federal Project "5-100" to increase the international competitiveness of leading Russian universities among the world's leading research and educational centers.

The major sources of primary and secondary information for the analysis of the universities were official university websites, strategic development program reports, and personal interviews and e-mail correspondence with university employees.

The aggregate base for the valuation of X_{ij} was the number of students and the number of scientific and pedagogical employees in HEIs. Further, we weighted k_{ijU} indicators with an expert assessment method after selecting experts from the university staff and conducting a survey (Silakova, L.V., Petropavlova, G.P., 2016). The total number of the experts interviewed was 11, including representatives of the educational, scientific, entrepreneurial and managerial activities of the university.

The estimation of the university's integration into the innovation activity involving a group of 21 HEIs participating in the project "5-100" is reflected in **Error! Reference source not found.**.

Table 2: Indicators to calculate the HEI's integration into the NIS Rating of a group of leading Russian universities by integration into the NIS

№	Universities participated in the federal program "5 into 100"	K_1	K_2	K_3	index value, F_U
1	National Research Nuclear University "MEPhI"	17,19	34,88	26,18	78,25
2	National research Tomsk State University (TSU)	16,28	16,11	21,98	54,37
3	Moscow Institute of Physics and Technology (MIPT)	18,59	14,65	12,84	46,08
4	Saint Petersburg National Research University of Information Technologies, Mechanics and Optics (ITMO University)	11,40	17,36	14,56	43,31
5	Novosibirsk State University (NSU)	14,49	13,05	15,18	42,72
6	Tomsk Polytechnic University (TPU)	14,27	15,98	11,72	41,97
7	Peter the Great Saint-Petersburg Polytechnic University (SPbPU)	10,72	8,77	19,57	39,06
8	National University of Science and Technology "MISiS"	8,93	12,82	14,09	35,84
9	South Ural State University (SUSU)	7,52	9,51	12,06	29,09
10	Lobachevsky State University of Nizhni Novgorod (UNN)	7,68	8,89	11,87	28,43
11	Samara National Research University (SSAU)	10,03	11,28	4,68	25,99
12	Higher School of Economics (NRU HSE)	12,19	7,72	3,82	23,72
13	Saint Petersburg Electrotechnical University "LETI"	8,54	9,10	5,29	22,93
14	University of Tyumen (UT)	6,09	5,83	8,29	20,21
15	Siberian Federal University (SFU)	5,51	9,91	4,10	19,52
16	Kazan Federal University (KFU)	8,64	7,05	3,73	19,41
17	Far Eastern Federal University (FEFU)	6,91	8,44	2,90	18,25
18	Russian University of friendship of peoples (RUDN University)	10,17	6,03	0,62	16,81
19	Ural Federal University (UrFU)	4,29	5,18	5,85	15,33

20	Immanuel Kant Baltic Federal University (IKBFU)	7,20	3,90	3,01	14,11
21	Sechenov First Moscow State Medical University (MSMU)	7,35	4,50	1,48	13,32

Source: developed by authors

The suggested methodological approach to the comprehensive assessment of the university's integration into the NIS implies the comparison of two indicators - the level of integration into the NIS and the multiplier of the university's costs. The state values of these indicators were calculated in accordance with **Error! Reference source not found.**.

Table 3: Qualitative scale for calculated indicators

Scale	Characterization
1. The level of integration University in NIS, F_U	
30-100	high relevance of the University activity; positive engagement with NIS elements
<30	relatively low relevance of the University activity; loose engagement with NIS elements
2. The multiplier cost, Ef	
>1	effective
<1	non effective

Source: developed by authors

However, as it was impractical to calculate the multiplier of innovation activity costs for all the universities analyzed (due to the lack of reports on the types of innovation activity in the universities), we used a multiplier of the university's total costs for the period 2014-2015 to validate the methodology (Monitoring of effectiveness of higher education Institutions, 2016), (Bikkulov, AS, et al., 2016), (Financial Support of Higher Educational Institutions subordinated to the Ministry of Education of Russia, 2016). As a result, we developed a state matrix of effectiveness of the innovation activity (see **Error! Reference source not found.**).

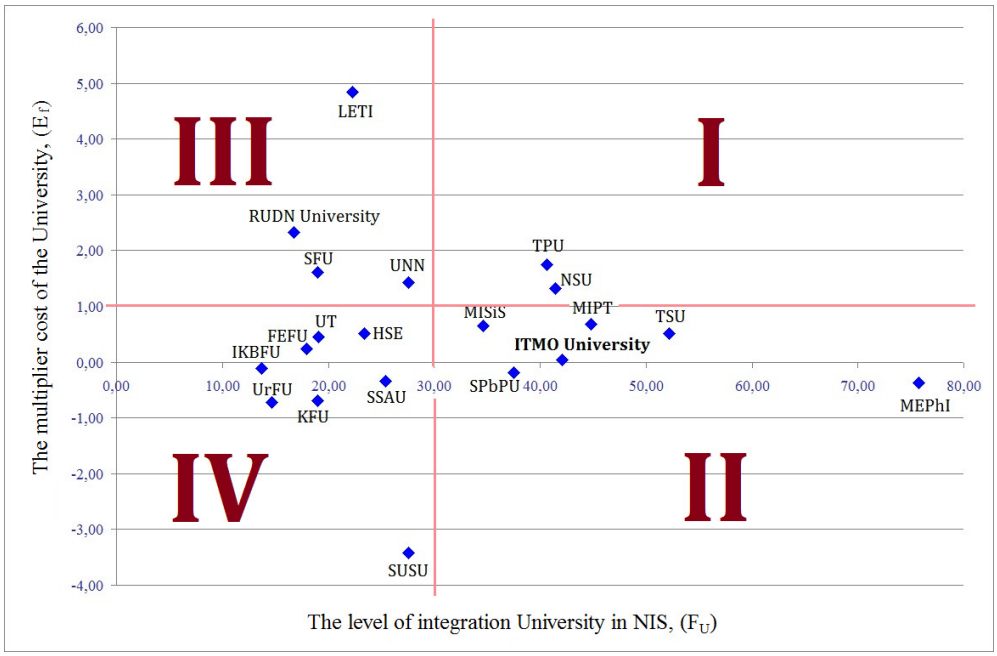

Fig. 2: State matrix of effectiveness of the universities integration processes in NIS

Source: developed by authors

As we can see, the universities most integrated into the NIS (MEPhI, SPbPU, ITMO, etc.) constitute group III of universities and can be characterized as universities that actively invest in innovation development while having insufficient economic returns on the use of results (growth in costs exceeds growth in revenues). A decrease in revenues with the growth in costs is typical of SPbPU (-0.19) and MEPhI (-0.38) and can affect the financial status of the university.

Low integration indicators of LETI and RUDN University (22.93 and 16.81 respectively) come along with high returns on costs (the multiplier is 4.84 and 2.32 respectively). These universities constitute group II, characterized by rational resource use, but also an increased risk of lower revenues in the future.

Grouping universities by level of integration will provide the development of specific measures to enhance each type of innovation activity. Thus, group 1 universities may need measures to enhance innovation. Group 2 universities need to reduce the risks of lower revenues in the future, for example, through the regular organization of exhibitions and competitions. Group 3 universities may need to intensify the process of generating new knowledge by creating a favorable creative environment at the university and encouraging employees. Group 4 universities require a range of measures to develop a creative environment, encourage employees to improve the process of generating new knowledge, and interact with the market, attract and establish long-term cooperation with customers.

Effect of Universities' Location on Integration into the NIS: Innovation Activity of Russian Regions

We assumed that the university's location in the region and its interaction with institutions integrated into the NIS will favorably influence the innovation activity of the whole region. The level of innovation

activity reflects the share of innovative and active institutions in the country. To establish the role of universities in the innovative development of regions, we undertook to discover a correlation between the location of entrepreneurial universities and the level of innovative activity in the regions. To this end, we analyzed the level of innovation activity of the regions for 2014 and determined 4 value ranges (**Error! Reference source not found.**.

Table 4: Qualitative and colour scale of Russia's regions innovation activity

Scale	Characterization	Color on the map
>15	relatively good	green
8-15	middling	orange
5-8	"poor"	pink
<5	inferior	red

Source: developed by authors

The following scale allowed us to create a map of innovation activity of Russian regions (see **Error! Reference source not found.**).

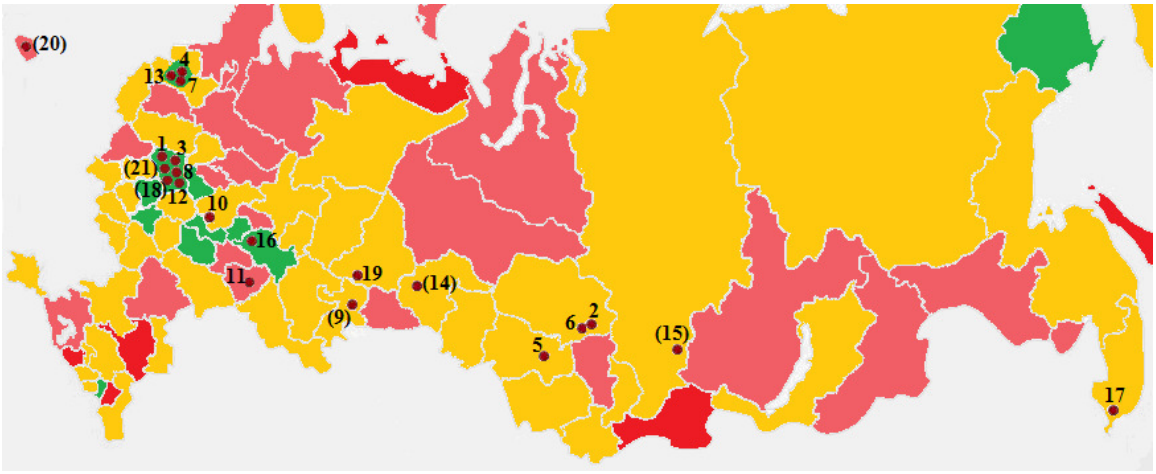

Fig. 3: Rating of entrepreneurial universities integrated into the NIS and their location on the map of innovation activity of Russian regions

Source: developed by authors

The universities put in a parenthesis did not participate in "5-100" in 2014. Their indication on the map had no effect on the general conclusion on the absence of leading universities in the regions with low innovation activity.

The overall picture of Russia's innovation activity according to the Federal State Statistics Service shows a wide scatter of integration level values across the regions, which even complicates and aggravates the problem of assessing "hidden champions" (Andreeva, E.L. et al., 2016). This is a promising area of further research.

Conclusion

Universities in Russia are undergoing a transformation of activities. The validation of the author's methodology shows that most universities of the country, even the leading ones, have insufficient returns on innovation activity. However, the process of transformation of universities' activities has already been launched, with active changes occurring to the structure of the NIS.

And so, a university in today's reality becomes an integrative center for the development of the NIS. The level of its integration into the NIS is determined by the intensity of interactions with its elements within the innovation activity. Therefore, monitoring the level of the university's integration into the NIS and assessing its contribution to the economy of the country will provide measures to enhance the innovation activity of the regions and increase the extra-budgetary revenues of the university.

The use of the methodological tools suggested will improve the change management process in Russian universities, while increasing their innovation activity and influencing the innovative development of the regions and the entire country.

Employer Branding: The importance of retention

Susana Silva, School of Hospitality and Tourism, CEOS.PP, Polytechnic Institute of Porto, Vila do Conde, Portugal, susanasilva@esht.ipp.pt

Inês Calisto, Portugal, inesdiazcalisto@gmail.com

Abstract

Employer Branding is a new tool used in Human Resources Management which develops a corporate branding as well as creates an active relationship between the organization and the qualified candidates to recruit and retain. Nowadays, the organizations have to take special care in the retention of its employees. The retention of employees is a priority for the Human Resources Management, as it leads the businesses to achieve high levels of profitability and success. The main goal of this research is to understand how the organizations settled in Portugal retain their employees and what practices are used to do so. It is also important to realize if the organizations think that the retention of employees is indeed important, and if so, what is their vision on the subject and, if it is through the Employer Branding process that they can achieve higher rates of retention and satisfaction of their employees. For this study were analysed eleven companies in Portugal, from distinct business areas and different locations. The qualitative methodology was used and the main technique of data collection was the semi-structured interviews. Altogether, eleven interviews were held to the responsible for Human Resources of each organization, or one of the department's employees who were linked to people management. The final results of this investigation suggest that the process of Employer Branding begins to gain ground in human resource management and that the companies in Portugal are concerned with the retention of its employees, using different practices and sometimes, creative strategies to achieve it.

Keywords: Employer Branding; Retention; Human Resources Management; Employee retaining.

Introduction

Companies are increasingly faced with problems of attracting and retaining employees due to a shortage of key competencies in individuals. Employer Branding is a relatively new concept that can act as an important tool for organizations to position themselves in the labor market as a reliable and inviting employer, thus attracting and retaining employees.

In addition to the products and capital, there is no doubt that it is human resources that hold the leading role in a company. They are responsible for the creation of products and services capable of attracting customers and of making the organization in constant growth.

The importance of this practice is even more visible when analyzing the financial and business landscape where there is an increasing demand for specialized labor and with specific skills and knowledge. Thus, due to the changes that are taking place in the labor market, it has become essential and challenging to recruit employees with key competencies and retain those already existing in the company.

Employer Branding can be used both externally to attract potential employees, and internally to increase commitment and loyalty among current employees. Therefore, Employer Branding's primary objective is to differentiate companies in the labor market and truly support them in their approach to acquiring and retaining the most talented employees. Employer Branding, on one hand, develops the corporate brand as well as puts it on a level where it is seen as a reliable and attractive company in the market. On the other hand, it creates an active relationship between the organization and the qualified candidates to be recruited and retained (Sullivan, 2004).

A more thorough study of this new process in Human Resources is therefore relevant, which may be the key to ending many of the problems that affect organizations, for example when linked to retention practices. The objective is to perceive, in the perspective of the companies, how they implement the Employer Branding process and manage the retention of employees. It is important to collect data that is as close as possible to the reality of organizations in Portugal, and for such a qualitative approach is assumed as more adequate, since it allows a more in-depth understanding of the process under study.

Literature review

Employer Branding

Employer Branding addresses issues related to the potential of attracting and retaining employees. This process, in addition to creating a "brand image" for the employer, is also related to corporate policies, procedures and actions (Mandhanya & Maitri, 2010).

In the literature, there is an agreement that the gradual interest in Employer Branding arose with the changes that occurred in society, both economically and demographically (Moroko & Uncles, 2008). This has led companies to increasingly understand how important it is to attract and retain top talent, understanding the value of Employer Branding and the maxim of making a desirable organization work (Mosley, 2007).

Employer Branding aims to promote, internally and externally, the desirable aspects of working for a company, thus attracting and involving employees (Backhaus & Tikoo, 2004). Thus, this practice makes a company become the company in which everyone wants to work and everyone wants to be part, due to their organization, procedures, ways of working, and communication. (Backhaus & Tikoo, 2004).

One of the first definitions of Employer Branding was proposed by Ambler and Barrow (1996) describing this practice as being the employer's functional and economic benefits package, where it has as its main role to provide a coherent framework that simplifies management and focuses on management priorities such as: increasing productivity and improving the recruitment, retention and commitment of all employees.

Some authors (Minchington & Estis, 2009) focus on the view that Employer Branding is the sum of an organization's efforts to continue its existence and promote the image of an employer of choice or a place where it is desirable to work (Moroko & Uncles, 2008; Backhaus & Tikoo, 2004). Davies (2008) defines this practice as a long-term strategy, aimed at organizing the knowledge and perceptions of current and future collaborators, and of other stakeholders.

Many authors (Minchington & Estis, 2009; Backhaus & Tikoo, 2004; Sullivan, 2009) define the employer brand as the image that an organization has as a great place to work for the employees' and external market's vision of the organization, that is, as quoted by its competitors, where there is a clear view that it is a different and desirable company when compared with others.

The dissemination of this corporate image is, for the most part, demonstrated to the outside of the company through its own employees (Miles & Mangold, 2007).

Thus, according to Backhaus and Tikoo (2004), the Employer Branding process is divided into three phases. First, the company must develop a concept that is enveloped in the value it has to offer its employees and potential new employees - the image of being a great company to work with. The next step will be to externalize this image, so that there is attraction for the organization and, finally, the execution of what was developed in the previous phases, that is, to incorporate the organizational culture in the recruitment of new employees and in the retention of the existing ones.

In addition, Sullivan (2004) explains that the Employer Branding to be successful must have some components, being: a culture of sharing and constant improvement; have external recognition to the organization; make the organization a reference organization; there is a balance between productivity and good management practices; make employees aware of organizational culture and with high levels of proactivity and make a company highly recognized. Employer Branding consists of the associations that an employer / organization reproduces in current and potential employee's new collaborators, these associations being many times symbolic and that affect the corporate image of the company as a good or bad employer. (Backaus & Tikoo, 2004).

The literature and the studies surrounding the Employer Branding concept are not yet very extensive, but when this concept arose by the authors Ambler and Barrow (1996), they associated it with three distinct dimensions for its analysis. These dimensions are the functional, psychological and economic dimensions. According to the authors (Ambler & Barrow, 1996) the functional dimension refers to the existence of continuous training and development activities for all employees; the psychological dimension is linked to the employees' sense of belonging to the institution, the recognition and the organizational culture itself, and finally the economic dimension represented by rewards, awards and remunerations.

A new perspective on the analysis dimensions of Employer Branding emerges, where Berthon, Ewing and Hah (2005), based on the concept of employer attractiveness, present five dimensions of analysis of this human resources management practice. In this approach, much less deductive than the first, the authors (Berthon et al., 2005) describe the five dimensions of analysis as being five maximum values: social value, economic value, development value, application value, and interest value. Berthon et al. (2005) describe social value as one in which a worker is attracted to working in a given company because of his or her organizational culture, work environment and values. Economic value is described as the package of benefits that the company has to offer, such as above average earnings, career progression, compensation among others. In the dimension related to the development value, Berthon et al. (2005) describe how employees in a given company are able to develop their skills and the confidence and recognition they show in relation to their qualities as employees. In the value of the application, this dimension is described as the opportunity that the organization gives to the employee to apply all their knowledge in practice when it develops its functions and also to give opportunity that there is a sharing of knowledge among collaborators. Finally, the last value of interest is described as being closely linked to innovation and creativity, where the company allows and wishes employees to exploit these competencies, making companies with these ideals desired by employees who are looking for challenges and stimulating companies.

In general, we can compare both perspectives and match the dimensions of the Employer Branding analysis of Ambler and Barrow (1996) with those of Berthon et al. (2005), where in the functional dimension of the former the values of development and application are inserted, in the psychological dimension are the social and interest values and the economic dimension is compared to the economic value.

Recent research has shown that human capital is becoming an increasingly important asset and creates competitive advantages for firms (Barney, 1991; Mosley, 2007). Lievens and Highhouse (2003) argue that scarcity in the labor market increases the importance for companies to attract, recruit and retain appropriate employees.

Employer Branding can be used as an instrument to position the organization as a good employer. When creating an employer brand, organizations are using ways to communicate the characteristics of the workplace and in turn are also informing how the company differentiates itself as an employer of other organizations and therefore have a comparative advantage in comparison to other organizations.

Retention of employees is also one of the most important benefits that Employer Branding can bring. Obviously, if a company has a strong employer brand and is seen as an attractive and desirable employer by employees, they in turn find it unnecessary to look for other companies to work for. Thus, the task of the Employer Branding, in the context of retention, is to affect how employees feel towards the employer, creating feelings of belonging and pride for the employer increases the self-confidence of employees and their esteem for the company (Backhaus & Tikoo 2004).

Another of the benefits that can be acquired through Employer Branding is the ability of employees to have a high degree of performance. It is about reducing absenteeism and improving job performance (Barrow & Mosley, 2006; Ambler & Barrow, 1996). Employees who are proud of their jobs are likely to enjoy their jobs and therefore have fewer reasons to neglect their obligations. Pleasure for the work that is done helps improve performance and, for the most part, the individuals who enjoy their jobs, are good professionals.

An important role of Employer Branding is to differentiate an employer from all others by combining various particularities and attributes that will make it stand out from other employers (Keller, 2003).

However, for Employer Branding to work as a competitive advantage you need to follow a few criteria. Between the employer and the employee there is a psychological contract, and expectations regarding obligations for both parties are resolved during the recruitment process (Backhaus & Tikoo, 2004). The employer must offer and provide the employee with training so that there is a constant evolution, in exchange for a good performance by the employee. If this psychological contract is fulfilled it is more likely that there is a high degree of loyalty and involvement of the employee towards the company (Morocko & Uncles, 2008) and according to Backhaus and Tikoo (2004) loyalty and commitment bring increased productivity in company. Employment itself is a category that strongly affects the attractiveness perceived by employees and includes issues related to the work environment, the relationships existing between the different employees, the existing management style, the rewards, the type of work and the strength of work (Maxwell & Knox, 2009).

Therefore, the main objective of this study is to explore the use of Employer Branding by Portuguese companies. The specific objectives are: (1) to know the methods and tools used by the organizations in the retention of collaborators / talents; (2) to characterize the way organizations structure employee retention; (3) to understand the vision companies have about the process of Employer Branding and (4) identify the use of Employer Branding by companies in their employee retention processes.

This paper is organized as follows: in the next section are presented the methodology used to realize the study, namely the sample characterization and the description of process and data analysis. The following section presents the results obtained, and the paper ends with a section of discussion of results and main conclusions of the study.

Methodology

This study was conducted according to the interpretative research paradigm, based on the method Grounded Theory, using as technique of information gathering the semi-structured interview. To analyze all the interviews was used the technique of codification and data analysis recommended by the method Grounded Theory. According to Strauss and Corbin (1998), the Grounded Theory is a qualitative method of research that allows to carry out a vast analysis of the data and to know the relations between the collected information being essential that the participants know and understand in some detail the area of study. However, participants are not expected to understand all the concepts that are not part of their daily lives (Seale, 1999).

Participants

Considering that the study was intended to explore the implementation of Employer Branding by Portuguese Companies, it is clear that the sample in this study are companies that: 1) worked in Portugal; 2) medium-size or large companies; and 3) had a human resources managers. Therefore, the participants were a group of 11 companies in Portugal, from distinct business areas and different locations. All the interviews were conducted to the responsible for Human Resources of each organization, or one of the department's employees who were linked to people management. The participants have ages between 25 and 53, and most of them have undergraduate degrees. They worked in this function from eight months to 26 years.

Procedure and Data Analysis

In order to answer the objectives of the study, the procedure adopted followed several phases, and data collection and analysis occurred from March to August 2016.

In the first phase, all the companies received an e-mail with the objectives of the study trying to evaluate the availability to integrate the study and to conduct a semi-structure interview. The objective of this semi-structured interview was to interview the human resource manager, creating a more informal conversation, but focusing in the topic of the study. It should be noted that was also developed an informed consent document to all the study participants to sign.

Eleven interviews were conducted. Most of the interviews were conducted at company headquarters; however, some of the interviews had to be done via Skype, since some of the human resource consultants were far away. The interviews lasted approximately 40 to 50 minutes.

The third phase involved the treatment and analysis of the information collected. The interviews were transcribed in full verbatim, that is, word by word, being reviewed at the end, and everything that was transcribed corresponds to what each consultant answered in the interview. The analysis of data was realized using the coding and analysis procedures of Grounded Theory (Corbin & Strauss, 1990). Each interview was analyzed line by line to extract its meaning, coding it initially in open codes, and later organizing it in central themes, form where rise the axial and selective codes. This phase culminated with the formalization of the concepts that emerged from the information collected, and then confronted with the scientific literature of the area.

At the end of this process, were obtained a set of concepts and relationships between them, based on the information analyzed and confirmed by the literature, that explain employer branding has been used in the companies.

To ensure the validity of the analysis and the coding process, two researchers were consulted as auditors (independent researchers that discuss and validate the categories) throughout the entire data analysis process to assist the primary author by challenging ideas and assisting in the construction of the categories. The main results are presented in next section.

Results

Analyzed all the interviews emerged three central dimensions that organize all the data in order to explore the use of Employer branding by Portuguese companies, namely: (1) Retention; (2) Employer Branding; and (3) Attractiveness of employers.

The retention dimension is characterized by everything that organizations do and think about the permanence of employees. Retention is characterized as the efforts that companies make to keep their employees. The retention category emerged from the subcategories: problems in retention of employees, challenges in retention of employees, practices to retain employees, and changes in retention processes over the times.

The category problems in employee retention, is characterized as a particular issue or a particular subject that requires a solution. At the organizational level, it is a private matter that, once solved, becomes beneficial to the organization, that is, the term problem was analyzed as something that can be modified in the short term and in which there is knowledge about it and about your change. Thus, we speak of the problems felt by organizations regarding the retention of their employees. The main problems raised by the interviewees regarding the retention of their employees were the abrupt growth of the organization, problems related to leadership and to the organizational strategy itself. Other problems were raised during the retention dimension analysis. We speak for example of problems related to the age of employees; harassment by other competing companies; problems related to wage expectations; balance between professional and personal life; problems related to the adequacy of employees in relation to the organizational culture; lack of an evaluation system; high standards of competitiveness; lack of career progression and even the location of the company itself as mentioned in “we are in a very strong growth phase, and this causes a wear and tear on the team, because there is more work for everyone. The only way we have to compensate for this is by trying to reward and try to compensate people, even during their own time of work” (Company 5).

The subcategory retention challenges is characterized as something that must be overcome and where there is knowledge about the same but has not yet been thought and / or analyzed how to solve it.

Practices are another subcategory of the retention dimension, which are characterized by the efforts that companies use to retain their employees. In this way, organizations must have full knowledge of their employees so that they can implement practices that adapt to the reality they have. The practices most mentioned by the participants are the offer of food, fruit and drinks to employees; the commitment to active communication among all employees of the company, including managers; health and / or life insurance; medicine at work; activities, parties, physical activities and team buildings; premiums; career management and career advancement; flexibility of schedules; training and fostering teamwork. This can be illustrated by “we have many and I think we are a company known for it. We try our best to make our employees feel at home, there is always the idea of being the second house. We always have food available [...] The floor is all carpeted, people if they want to walk barefoot as they can at home, we have lots of sofas spread out here for people to have their moment of respite, to recover energy ... On our site there are some references and gives you the idea to get an idea, such as surf and yoga classes, the games room and the nap room. [...] We have a very open mind, when you walk around here you can not really understand who the managers are or not, although there is a hierarchy and everything [... [there is a great proximity between us. [...] We have the Occupational Medical Doctor who comes here. We have health

insurance for both workers and families. When an employee has a child we open an account with a value so that they can use it in any way they see fit" (Company 8).

The category changes made by the organizations in the retention processes over the is characterized by the explanation of everything that the companies did in the human resources management, more precisely in the retention of employees, everything they have implemented again, to adapt to reality and thus keep their employees. The changes most mentioned are the implementation of an evaluation system; conducting a satisfaction survey; competition analysis; improvement in the treatment given to employees; benefits package adapted to each employee and, to create changes whenever the need demands it. We can refer the example "in recent times, and having as main objective the monitoring of labor market practices, our organization has adapted and changed in the way of thinking about retaining the best employees. It is no longer enough to think only that to keep them we only need to pay the salary on time and on time. The market is increasingly competitive and if we want to retain and maintain those who contribute most to our success, we have to define strategies that require an ever higher investment" (Company 11).

The Employer Branding dimension is characterized as a structured process aligned with organizational values and business objectives, and where there is internal and external communication of the most important configurations about the identity of a company. The goal is to create a distinctive image with other companies and make them an employer of choice. Employer Branding makes a company become the company in which everyone wants to work and to be part, due to its organization, practices, forms of work, communication, etc. Each company has an image as an employer between current and potential new employees. To manage this image, it is necessary to create a positive impression of the company as an employer and convey the message that it is a great place to work.

The category Employer Branding emerged from the subcategories: process / knowledge, advantages, disadvantages, success in implementing Employer Branding practices, and failure to implement Employer Branding practices.

In an overview of the interview analysis, it was possible to perceive that most companies have a notion about the concept and maxim of this practice of human resources management, but that the idea is not really used in its fullness. That is, most interviewees know the practice and / or the concept of Employer Branding, but in the management of their teams and in the human resources management of the companies they represent, this practice is not known, and there is no full use of the benefits that this practice can bring to an institution.

The most pointed challenge is related to employee satisfaction and how challenging it is to maintain high levels of satisfaction. Other challenges inherent in retention have been identified, such as employee requirements; confidence in the company; the arduous task of balancing personal and professional life; career plan and benefits package; lack of approval of heads of department on certain matters; the lack of encouragement and encouragement to employees; individual treatment to some employees and challenges related to employee development. Another challenge mentioned, and which can not be generalized to most companies, is that other factors completely external to retention are the fact that they are not known in the foreign market, that is, people do not know a company what can lead to some discomfort and insecurity in our employees. the main idea of the interviewees about Employer Branding is related to corporate image and external recognition and prestige, but there is also the idea that is practical should be transversal to all areas and people of companies, as it is an excellent tool of communication and retention of employees and where you can see the pride of the employees for being part of the company and where they will be the brand ambassadors themselves. In this way the first subcategory, which concerns the process of Employer Branding, and the knowledge of this practice is identified. "It is the brand image of the company, that is, the way they come to me as an employer. What

I convey as an employer, as a company that can be attractive or not. Creating this image is very important. We here try to use this practice and create a strong corporate image of our company, we try to convey the reality of our company out, attract the best talent, we want the ideal people for each function." (Company 6).

In the subcategory advantages of the process of Employer Branding are analyzed all the benefits that this practice can bring to a company and its management of human resources, that is, all the benefits and positive aspects that can be achieved with the use of this process. The most mentioned advantages were the existence of recognition by the employees and the external recognition and also the existence of a very strong brand image associated to the company, which leads to another advantage that is the attractiveness that the company earns.

The subcategory of disadvantages is characterized by all the negative aspects that the sample pointed to the process, that is, the inconveniences and damages that can happen to an organization with the implementation of this practice. More than half of the respondents pointed out no disadvantage in the Employer Branding process, claiming that they saw no disadvantage in the method. However, some drawbacks have been identified such as the fact that it is a continuous and time-consuming process and where there may be a misinterpretation of the concept and practice. Disadvantages related to competition and competition from other companies in the industry were also identified as mentioned in "one of the main disadvantages is the unreasonable ambition. As it is obvious when something becomes very attractive, the greater the aggressiveness to conquer and to enjoy. In this way, when the conquest is not healthy you can fall into the error of forging the policies and good practices of the company. Another disadvantage may be the conformists, who when reached a level that they consider reasonable will not work for a continuous improvement, or even, a prosperous growth" (Company 11).

The success measurement subcategory refers to how companies get feedback from practices implemented with respect to Employer Branding, ie if a new tool is put in place, organizations need to realize if they are this should measure the success of the implemented practice. In order to measure success, satisfaction and opinion surveys and employee suggestions were identified as the predominant techniques of employee feedback on company management.

The subcategory measurement of failure is characterized by the analysis of the form and method that companies use to calculate the failure of practices implemented against Employer Branding, that is, if the tools they use bring a return to the organization. The respondents' feedback is similar to the subcategory presented previously, where the techniques used by the organizations are the surveys of satisfaction and opinion and the suggestions of the collaborators. This is how organizations analyze the failure to implement employee engagement practices.

The dimension attractiveness of companies, which is characterized as all factors linked to a company that make it pleasant and attract attention, that is all aspects that make a quality and desirable organization. In the attractiveness of companies, we consider the ability to attract, select, hire and retain people, maintaining good levels of employee satisfaction and excellent service standards. This dimension arose from the categorization of the subcategories: the opinion about what makes an employer attractive, the characteristics that a company must have to be considered the best company to work for, and finally the opinion about the employees' view of the company in that work.

In the subcategory employees 'opinion about the company, the interviewees' opinion on the company employees 'overall opinion was given, and in all the interviews the answer was the same, that is, all the interviewees stated that the employees' the company was quite positive and they consider the company where they worked, a good company as mentioned in "That's a good company to work with. Luckily we feel it, yes!" (Company 1)

The attractive employer subcategory is characterized by the personal opinion of the interviewees about what makes a company as an attractive employer, that is what captivates a company, whether in its management or even in relation to the services they provide and / or organizational culture.

In this subcategory was identified the good work environment and the career progression as the most relevant factors and those that really make an employer attractive. The permanence in the function was also one of the factors of reference, and there is a concern on the part of the employees with their own retention, because it is important to know that there is some security and duration in their functions. Other factors of relevance were the identification with the culture and values of the organization; the importance that companies give to employee satisfaction; the existence of constant feedback; the bet on the training of employees; the salary and benefits package; the autonomy and freedom given to employees as well as the diffusion of management based on active communication.

The last analyzed subcategory of the attractiveness dimension of employers is the characteristics of the best company to work for that is characterized as the attributes that companies must have to be considered as a great place to work and to be successful. Here we talk about the most important and essential characteristics that organizations must possess in order to have high standards of excellence. The most presented characteristics were the existence of a good work environment among all employees, including managers, autonomy and possibility of decision making and a compromise between the organization and the task performed. It was also presented as important characteristics the possibility of a balance between personal and professional life, issues related to business leadership, working conditions, the possibility of career progression, the exchange of feedback between employees and managers and the bet training of employees.

In the analysis of this subcategory is notable the variations between the opinions of the interviewees, once it was the analysis of the personal opinion of each one of the interviewees it is possible to identify a panoply of different characteristics, that is, it is a category where there can not be a great generalization since everyone has their idea about what makes a company the best company to be able to work, “I honestly do not know what the best features are, because it depends on company to company, and sector and depending on the employees themselves and all companies work differently ... Here, what are good characteristics, are exactly that flexibility that exists, this autonomy, that freedom of the employees can say what they feel, what they agree what they do not agree” (Company 3).

Discussion and Conclusions

The purpose of the present study was to understand the reasons for companies to use the Employer Branding process, and if they use it in human resources management, more precisely in the retention of their employees, realizing which practices they use to retain. Thus, this qualitative research focused on the panorama of eleven companies in Portugal and their contributions regarding the process of Employer Branding and retention of employees.

It is possible to conclude that, although Employer Branding (Mosley, 2007) is a relatively recent process in human resources management in Portugal, it is already beginning to gain ground and is based on the strategic plan of many companies. Organizations increasingly attach importance to the external recognition they have and to the company's image of society and its collaborators (Lloyd, 2002). Although there are some disadvantages associated with this process, most of them are only given advantages by human resource managers. When Employer Branding processes are implemented in human resources management, they are successful and guarantee a better performance and sense of belonging to employees.

It is also possible to conclude that employee retention is increasingly important for organizations, not only because of the extra expenses that the turnover entails but also, closely linked to the Employer Branding maxim, internal and external recognition is very important for the longevity and success of an organization. Collaborators are no longer seen as a number, but rather as the driving vehicle for a company's success at a structural, organizational and business level.

The management of resources (and managers) are increasingly present in their tasks the well-being of employees and, in turn, the idealization and organization of a retention plan that is appropriate and adapted to all employees. To do so, they use a range of tools and retention practices, ranging from a salary package and attractive benefits to raising awareness for an open and active communication policy among all.

Within the three large dimensions under analysis in this research, retention of employees, Employer Branding and attractiveness of employers, it was possible to perceive that companies are beginning to give more and more importance to employees, and human resources management is beginning to make progress with regard to concern with employees.

In general, it can be said that, although it is a complex process, retention (Chaminade, 2006) is a matter of importance to companies and that they are concerned with changing processes in their human resources management and performing some practices, in order to difficulties are reduced. The major problems with employee retention were the organization's abrupt growth, leadership problems, and organizational strategy itself (Singh & Rokade, 2014) and the great challenge with regard to retention is related to employee satisfaction and the difficulty of maintaining high levels of satisfaction among all employees (Hytter, 2007).

In order to maintain employees, organizations use a set of practices and procedures that work perfectly as strategies for retention. The practices described by the sample of this investigation regarding the retention of employees were immense. The most common are the supply of food and beverages to employees; the commitment to active communication among all employees of the company, including managers; health and / or life insurance; medicine at work; activities, parties, physical activities and team buildings; premiums; career management and career advancement; flexibility of schedules (Kaliprasad, 2006; Hytter, 2007).

Regarding the theme of Employer Branding, it was possible to perceive that most companies have notion about the concept and maximum of this process. Although the idea of being a fashionable process is obvious, the existence of the Employer Branding can be a strong weapon for the management of human resources. The central idea that exists about Employer Branding is related to corporate image and external recognition and prestige (Backaus & Tikoo, 2004), as well as an excellent communication tool (Hytter, 2007).

Limitations

The phenomenon of Employer Branding in the business world is relatively recent, hence the difficulty in obtaining more information and data in greater depth among the interviewees, which gave to realize the lack of knowledge about this process. Also, the retention issue has some limitations to this investigation, since it turns out to be a delicate topic, where none of the representatives of the companies that integrated this study had an interest in passing a negative image about the companies that represented them, always having neutral answers. This made the results turn out to be quite positive, that is, never mention was made of something less positive that was done in companies in terms of retention.

Social desirability is a problem that arises whenever one wants to investigate something using people's opinions and discourse, since there is a tendency for them to respond in a way that they consider to be the most acceptable in social terms. This is because the social subjects interviewed want to convey a positive image and give socially acceptable answers or that they consider to be correct. It should be noted that social desirability depends greatly on the situation, thematic and the issues that are presented. This happened despite the confidentiality and anonymity of all the information provided. When we do an investigation involving people and their opinions and assessments it is important not to forget the social side and the tendency to respond in accordance with what they think is right and in this case the fact that they talk about issues related to their jobs poses even more obstacles and fears.

Future research and implications

In this way, the present study raises some new questions. In future studies it is convenient to approach this topic through quantitative studies so that various perspectives can be analyzed, as well as different types of companies, that is, from small companies and companies more familiar to multinationals, so that there may be a larger spectrum of analysis.

It is also important, in future investigations, to replicate this type of approach to small businesses, in order to understand if there is a concern about retaining employees and creating a brand image around the organization, that is, understanding if small businesses also care with the external image they possess and if they think it is something that must be changed and adapted.

These are some of the rationales that may encourage the succession of new investigations in the future, since retention of employees will continue to be a very important issue in terms of human resources management and Employer Branding, even though it is a relatively new concept, is already beginning to gain ground, making its analysis essential.

These are also thematic that provide several contributions to the professional practice of human resources. Firstly, we begin to think about the work of a human resources professional who is not only concerned with bureaucratic matters, but rather the fundamental role that these professionals have in creating a strong employer brand in companies and in creating an image external force.

It is also important to realize that these professionals are endowed with skills that lead to high levels of employee retention and to high standards of profitability and profitability of organizations, thus becoming central for companies to have professionals of human resources with skill and knowledge on issues such as Employer Branding and Retention.

Abstract

The purpose of the research is to figure out impact of Succession planning, Decision making authority and Successor influence on sustainability of Family Owned Businesses in Pakistan. This research will provide insights and recommendations to entrepreneurs and specifically family owned businessmen that how to make business sustainable for long term. Data will be collected from Family Owned Business Owners from Pakistan. Respondents will be selected on the basis of purposive sampling technique. Four big Cities of Pakistan (Lahore, Islamabad, Karachi, Hyderabad) has been chosen for sample population from which data will be collected. Respondent will be interviewed with semi structured survey questionnaire. Narrative analysis will be used to interpret results.

Keywords: Sustainability, Financial management, Succession planning, control of ownership, Successor Influence

Introduction

Background

Since the independence of Pakistan, in 1950s and 60s, there were 22 family oriented successful businesses in Pakistan (Deloitte, 2010) Out of them only few have managed to sustain. As the new generations -whether in shrinkage or in expansion-come in front and takes the front seat and conflicts nurtured. Family owned businesses in Pakistan are being handled by more than one family member, every member has its own vision, mission, way of leadership and management which in turn ultimately creates differences and led to bankruptcy of the family own company. Research shows that only 15% of the family owned businesses survive in Pakistan and 85% of them distributed or vanished till its third generation (Haq, 2010)

In 1987, people of the view that running family business is the toughest job on globe. As family businesses have to compete with multiple values, family norms, more competitive environment with more discussion on technology implementation with changing political situations (Kleiman & Peacock, 1996). Ten years before, family businesses don`t have to consider technological implications on success, participation of women in business, use of social media and the international market impact on domestic industry (Kleiman & Peacock, 1996). It was like to compete to the domestic industry and to cut off the interest rate at their maximum level (Carlock & Ward, 2001).

It was very much difficult for family businesses to stay in to the market. As market faced lots of changes. According to Fortune 500, since 1955, only seventy-seven family owned business succeed to compete the market, rest 80% failed to sustain, some sold their businesses, some got bankrupt (Perry, 2015). Reasons behind these drastic changes are technology development, more mature markets (domestic, international), more competitive strategies, more competition, customized suppliers and quick reaction to strategies from competitors present in the market. Mostly family businesses face more family conflicts on their management and share (Carlock & Ward, 2001). It is due to:

- *Unresolved personal conflicts*
- *Lack of trust*
- *Difficult family relationships*
- *Family Demands on business.* (Carlock & Ward, 2001)

For the success of the family business, there should be a separation between family problems and business is the key to success. For the achievement of this equilibrium, family businesses should devise a plan with policies under these five Cs:

- *Control*
- *Career*
- *Capital*
- *Conflict*
- *Culture* (Carlock & Ward, 2001)

The purpose of this research is to explain the perception of values in a philosophical standpoint, to analyze the business principles of world`s largest family owned businesses and non-family businesses and to highlight if there are certain specific values behind the success of the family owned businesses. Ceja, Agulles, & Tàpies (2010) concluded with three important results. 1st, on the basis of philosophical literature, authors have developed a description, categorization and chain of command of values. 2nd, authors found that values highlighted by top most successful organizations of the world, among them common among both family businesses and non-family businesses were ***(integrity, respect and customers).*** 3rd, at the end, authors succeed to find some important values behind the success of family owned businesses, that are "generosity, humility, communication, service, quality, excellence, creativity and entrepreneurship". (Ceja, Agulles, & Tàpies, 2010)

Family owned businesses are treated as the backbone of any economy because they contribute a lot in terms of wealth, jobs and also family owned businesses have very deep insights within their territory (Gideon A., 2015). Every business have both positive and negative aspects, so same is the case with family owned businesses throughout the world. Their negativities are their family conflict, incompetent next generation who ruins the business entity and their glitzy standard of living. Schwas (2013) research on family owned businesses throughout the world got succeed to achieve some cavernous insights which either help family businesses to sustain to many generations or they make them collapsed. Authors suggested two lessons that are:

- Each Successful family to more than two generations creates its own history composed of profits and losses but its success it based on immovable commitment and strong cultural ties.
- Every family business is like a tale composed of people, entrepreneurs and families. They left irremovable impact on the business that led family business to succeed over generations. (Schwas, 2013)

Schwas (2013) quoted "Family business is the people business" and that is the key point that most of the family businesses forget and lead to failure. Author has highlighted key points for the success of the family business:

- Family business owners enjoy freedom of business by having their own private entity and they apply self-possessed strategies with strong values for the business growth which make their family business to run over four generations.
- Family business owners incorporate strongly family roles within and out of family business but is succeed on condition that member have fine balance between their rights and duties. The business governance they have, provide clarity, leadership vision and trust within the members of the family (Schwas, 2013).

According to Family Firm Institute, most of the family business owners want to see their businesses to be transferred to next generations. Among them, 70% do not stay alive to next generation and 90% fail to stay alive till third generation. On these statistics Ward J. in the Perpetuating the Family Business 2004 states that the most grave concern in the family businesses are family issues than real business issues (Walsh, 2011).

The paper is based to ask for the help of the family entrepreneurs to evaluate and analyze the impacts of family ownership on businesses. For the highlighted purpose, authors have exemplified the business creation as it is buoyant by the policymakers and predicted the entrepreneurial activity done by family member round the globe. Authors have comprehended the data on entrepreneurship and analyzed the work done by scholars on impacts of families member in businesses. Authors have concluded that it is better is highlight the research aims for family businesses and giving them sample questions which can impact family dynamics and comfort (Jennings, Breitkreuz, & James, 2013)

Scope

The scope of the research is to boost the entrepreneurship culture in Pakistan, which will also help to increase sustainability of family owned businesses. Therefore, this research aims to know the factors involved in sustainability of family owned businesses in Pakistan over future generations. This research is based on Pakistani cities (La) what to do here

Objective

The general objective of the research is to find out factors involved in sustainability of family owned businesses in Pakistan. Whereas, precise objectives of the research are:

1. To figure out reasons which influence sustainability of family owned businesses?
2. To derive solutions from results to help strengthening sustainability of family owned businesses.

Problem Statement

To find out whether selected independent variables from literature have impact on sustainability of Family Owned Businesses.

Literature Review

Definitions

Sustainability

It is a Policy theoretical concept with beginning from the report-Brundland in 1987 (Kuhlman & Farrington, 2010). Sustainability is defined as to meet one own needs by not sacrificing future of future generations` needs. Sustainability is not only limited to just environmental needs, but it also is used for social as well as economic needs and development (Alberta, 2014).

Financial Sustainability (Definition)

Financial Sustainability is defined as the capability of an organization to take revenues reference to their demand to achieve sustainability in their production with a growing rate and to achieve financial targets. (León, 2001).

Financial Management

Walker and Brown in 2004 worked on Success factors influencing Small business entrepreneurs highlighted that whereas financial factors treated as the key factors to measure the business success, but finances may not only be the key gauge business triumph. Authors pointed out that entrepreneurs not only work to achieve financial goals, but they work to achieve targeted life style, personal accomplishment, pride and honor as well. Authors selected sample size of 290 small business owners based in Australia. Respondents in the research were questioned to rate importance to their lifestyle and financial goals in accordance with business achievement. Results concluded that bendy lifestyle, pride and target achievement were healthier signs than financial achievements. Concluding it, Walker and Brown summarized as it will be more beneficial to look for subjective measure than to gauge financial objective achievement (Wallace J. S., 2010).

Paper is about the impact on financial performance of businesses in Pakistan with reference to family possession. Authors have collected the secondary data from 2007 to 2011 and selected four family businesses in Pakistan. Two are from the manufacturing side and two are the financial firms listed in the Pakistan Stock Exchange. Authors have selected Financial Performance as the dependent variable whereas ROE and ROI are treated as the independent variable. To check their impact authors have used regression and correlation method. Authors concluded that financial performance has the positive relation with the ROE and ROI. Better management and governance increase the overall presentation of the company (Ahmad, Nadeem, Ahmad, & Hammad, 2014).

The Paper aims to explore the impact of strategic orientations` implications in the family owned business performance and their impact on their growth, sustainability and financial stability in Turkish family owned business. A simple regression following Descriptive Statistics of the sample have been used. Highlighting the factors, authors have applied factor analysis to verify the impact of the highlighted factors (Altindag, Zehir, & Acar, 2011).

Succession planning

Planning for succession of the business owned by family gathered importance in terms of research and literature (Sonfield & Lussier, 2002). Founders of the business have difficulties in “letting their business”

in other hands. Research suggest that family owned business see succession planning in more of a conceptual manner. The favor family-relationships and family bonding where as non-family business do succession planning in organized and task oriented way (Fiegener & Prince, 1994).

Several authors have identified factors for the success of the succession, growth and the stability of family owned businesses in multi generations. The survey of Australian family businessmen of 242 to know the reasons for the success of the business. Authors concluded the study with important factors ***Governance and Management***. The use of Pro Active tactics i.e. ***meetings, boards of directors, family councils, and codes*** of conduct played a major contribution in the success of the family business (Dana, Smyrnios, & Bi, 2015).

Authors say the succession planning and to regulate/systemize the management is the most important stage in the alteration of family business. The family members` impact is much worthy to impact the decisions regarding alteration of family business from one generation to the other (Walsh, 2011). To conclude authors stated that family business is not like giant organizations in which best strategic practices applied without any customization in it but for the family business a customization is required with a heavy family element in it. Author has highlighted the importance of communication in family members for succession planning. with the aim to set and achieve family business succession goal. For the better communication integration among family members and the ownership of family business among family members is a must (Walsh, 2011).Variable of the study taken from (Mahmoud, 2012). Variable is constructed on 5 items based on Likert scale.

Decision Making Authority

Authors have identified positive, negative, and neutral associations involvement in family business success. Authors investigated some challenges and identified that some are because of level of family member's involvement in the family business. Authors have quoted that family businesses are not like industrial organizations referred as binary organizations, whether family businesses are treated are heterogeneous composed of customized elements within every family business. Authors have selected sample of 6592 companies, and concluded that selective customizations within family business are related to outstanding financial output of the firm (Aguilera & Castro, 2014).

In family owned business, management is the main hurdle for the growth because it is much more different from a non-family owned business. Especially, when family members, relatives work together in a family business, they interfere business decisions with their emotions and the ultimate result is the failure of family owned business. Author also stated another type of problem in family business is "***to control day to day operations"*** and in other companies growth is the problem, this is due to other members of the family do not want to reinvest the profit back to the business (Centre, 2011).

Successor Influence (Ownership Transition)

For the stable family businesses, their key to success is to prepare their future leaders who lead their family business to next generation. For the established and winning family business, their tricks are mostly same at their three stages which are pre-entry, entry and succession. Whereas, in less winning family businesses expresses their difficultly in the succession stage. Another issue highlighted is the role adjustment during the phase of succession planning is missed between the father/1st owner and the successor. There is lack of documentation during the succession planning phase in all the three stages. Authors have observed the makeover from 1st generation to the other for the three stages. If the family industry is having low managerial function with small scale production and less use of technology, it will be in the same level till the second generation succeed to takeover and make some changes. The second generation have made known technological innovation with some expert managerial skills. Moving from

the second generation to third, they have shown world class managerial and operational skills, with sound knowledge of human resources, finance and marketing. Authors have identified the major challenge that family business face is to keep all the family members amalgamated without division in the business and to manage family members issues for the family business managerial roles (Afghan & Wiqar, 2007)

Methodology

Participants for this study will be selected on the basis of purposive sampling because authors need participants on the basis of certain characteristics. Four cities of Pakistan selected for the study because these four cities are considered as big cities of Pakistan and most of the family businesses are well developed in these cities. Cities are Lahore, Karachi, Islamabad and Hyderabad. No of participants is not restricted as this is an exploratory study and method of data collection is interviews so authors will conduct at least 30-35 interviews. Also authors will continue till a saturation point in data.

Limitations

Every research comes out with analysis of the data from different perspectives and angles, but it cannot be concluded here because criticism and suggestions are always welcomed in the research. This research is also limited in its scope as it is conducted in four cities of the country not over all Pakistan so generalizability of this research will not be broad. These cities have different environment and education level, demographics and living standards so other small cities or villages can have different factors which might impact on sustainability of family owned business.

Unethical Leader's Identity: A Simple Model and its Methodological Application

Mgr. Marian Stančík (Ph.D)

Institute of Management at Faculty of Management, Comenius University in Bratislava, Slovakia marian.stancik@fm.uniba.sk

Abstract

Since a leader can hide unethical actions and/or pretend ethical communication, an ethically positive self-image of an unethical leader can be intentionally achieved in the eyes of followers. This conference paper presents a simple model of unethical leader's identity (consisting of moral actions, communication and values) and its complementary potential for further research in the field of unethical (as well as ethical) leadership.

Keywords: Unethical leader's identity, ideology-based research approach, unethical leadership

Introduction

Many known authors, diverse empirical frameworks (see: Theoretical background) and popular conceptualizations (Padilla et al., 2007; Thoroughgood et al., 2012) are available, nevertheless (un-)ethical leadership stays a social phenomenon with a variety of conceptually different definitions.

But, how can anybody tell who is actually an unethical leader, if environmental factors like e.g. national culture (Ferencikova et al., 2016; Scholtens and Dam, 2007), individual factors like e.g. moral awareness (Rest, 1986) or individual development (Rest and Narvaez, 1991), as well as diverse situational factors e.g. information availability (Akerlof and Dickens, 1982) or salience of moral norms (Nye and Forsyth, 1984) and a whole spectrum of conflicts due to economic rationality play important roles besides? And, how to deal with observed paradoxes, when an ethical leader at work behaves unethically in private (Riggio et al., 2010)? Or, how to address a phenomenon when a direct leader is reported more cynically, but the one at the top of the hierarchy, personally unknown to the follower, is reported positively (Lord and Maher, 1991)?

The herein suggested theory bases on the Leader-Member-Exchange theory (Graen and Uhl-Bien, 1995) abbr. LMX which introduced the importance of a dyadic leader-follower relationship and the Implicit Leadership Theory (Rush et al., 1977) abbr. ILT which introduced the importance of follower's perception. But, opposite to recent trends in the field of (un-)ethical leadership, the suggested theory is derived from the author's working thesis *"consequences of an unethical leadership do not need to appear immediately"*.

To overcome the matter of time-dependent information processing, let us suggest moving object of research from its tangible area of a leader-follower dyad (any behavior, traits and characteristics) to its intangible but still descriptive and measurable area (cognition based on moral values and ideology) which is independent on the matter of leader's observable behavior and/or follower's perception. Hence, an alternative approach to study a well-known topic of (un-)ethical leadership attempts to uncover details which have not been considered so far.

Theoretical Background

To address the scientific chances and challenges of the research presented in this paper, let us first outline the situation using a selective analysis of four frameworks previously developed to measure ethical leadership (abbr. ELp).

The first analyzed tool to measure ELp is called Ethical Leadership Scale (Brown et al., 2005). Abbr. ELS bases on a social learning perspective. Brown et al. divert from a classical philosophical point of view "how leaders ought to behave" and propose a descriptive behavioral approach to measure ELp. According to social learning (or also cognitive) theory (Bandura, 1971), one's behavior can be acquired by observing and imitating others. Hence, Brown et al. build up a correspondent model to measure ELp through the follower's perception accordingly. The first comment that catches the reader's attention is when the authors discuss limits of this approach due to perceptual biases behind the self-other-agreement; one knows that leaders are almost certain to rate themselves favorably on the ethical dimension of leadership. Another comment that catches attention is the discussion on the levels of management; the extent of hierarchical distance from leader to follower plays an important role since the substance for a personal relationship disappears but the matter of an image-based relationship increases. Let us for now note that these two observations are important for further conceptualization because leader's formal power (thus hierarchical position in logical extent too) and his own perspective-taking (as a crucial precondition for an ethical leadership) correlate negatively (Galinsky et al., 2006; in Pink, 2012, p. 70)

The second analyzed tool to measure ELp is called Leadership Virtues Questionnaire (Riggio et al., 2010). Abbr. LVQ bases on four cardinal virtues (originally mentioned it texts written by Aristotle). Riggio et al. distinguish their work by pointing out the social learning approach limits of ELS. They mention the fact that leaders develop their own ethical leadership behavior by emulating admired, ethical leader role models; but, due to ethical relativism, leaders hence might get easily misguided. Let us here note that this is one of many reasons due to which unconscious leader's behavior plays an important role and thereby any methodology based on measuring tangible behavior must deal with the same troubles when interpreting results. Therefore, as a solution, authors propose to refocus the object of measurement at leader's traits and characteristics because characterological elements are independent of leader's behavior. Let us again mention two interesting limits that catch the reader's attention. Authors of LVQ discuss that the correlation with follower's moral identity, empowerment and organizational identification were better scrutinized longitudinally or experimentally than measured at the same time as the follower's perception of leader's virtues; ethical leadership impact is thus questionable since followers e.g. might not be morally capable of recognizing leader's virtues. While the second limit towards LVQ predictability roots in the fundamental emphasis of social psychology; one knows that the power of the situation overrides characterological factors. Again, let us for now note that these two observations are important for further conceptualization since the difference between intended and effectuated moral behavior is as old as humanity per se can remember and carries over.

The third analyzed tool to measure ELp is called Ethical Leadership at Work questionnaire (Kalshoven et al., 2011). Abbr. ELW bases on a multi-dimensional measurement whose authors critique ELS and LVQ as unidimensional tools that are too simple to measure the complex topic ELp. Therefore, Kalshoven et al. developed a complex set of dimensions to measure and evaluate leadership in terms of ethics and thus contribute to overcoming deficits of previous tools. No matter how complex and comprehensive this model is, let us note that it relies on measuring leader's behavior according to follower's perception and thus have empirical limits in common with many other behavioral frameworks. One comment that catch the reader's attention is the discussion about its predictability towards cultural environment; e.g. the importance of "power sharing" dimension might vary based on the well-known cultural "power distance" dimension. Hence, let us note that this reflection is important for further conceptualization; Since the interdependency of the ethical and the cultural systems is tricky for any social research application (e.g. Scholtens and Dam, 2007), its separation on the other side is a doctrine for an organizational anthropology in cross-cultural environment (Hofstede and Hofstede, 2006).

The forth analyzed tool to measure ELp is called an Improved Measure of Ethical Leadership (Yukl et al., 2013). Abbr. ELQ integrates Leader-Member-Exchange model (known as LMX) and puts work unit performance into focus. In comparison to previously analyzed approaches, the ELQ authors consider leader's individual moral balance of competing goals when influencing work unit performance; ethical leadership might have unethical consequences and, vice versa, e.g. unethical leadership towards individuals might have ethical consequences towards an organization etc. The reader's attention catches the discussion in terms of managerial effectiveness; being an ethical leader is not only commendable but also effective. Even though Yukl et al. count with the importance of leader-follower relationship, let us here note that they do not distinguish nor discuss the correlation of formal (positional at work) and informal (personal as friends) level of their dyad. Since formal and informal relationships coexist in practice all the time everywhere, let us note that this is a very important dimensionality especially in terms of chances for an unethical leader's behavior (e.g. corruption in public sector).

To sum up the analysis of four selected frameworks let us point out that neither applying the recommended 360-degree approach nor the self-other agreement correlation of any of these tools would in the future provide comprehensive answers to the questions introduced in this paper. No matter how many times mentioned in diverse studies, none of the known theoretical frameworks nor research approaches conceptualize the phenomenon of "ethically behaving leaders on workplace behave unethically in private life and/or vice versa" as an integrated as well as interdependent model. Hence, there is a chance for a new model and methodology that is to be presented in the following chapters.

Materials

According to Hunter, all reviewed materials related to unethical leadership have at least one similarity: complexity. And, as he also notes, at least one common need for further investigation: identity (Hunter, 2012). Let us therefore focus on identity closely and suppose that simplification is a strategy to deal with troubles of a current field of research.

The first instrument to build up a comprehensive model of an unethical leader's identity is a definitional analysis of unethical leadership. Known authors like to describe leadership with adjectives e.g. narcissistic, toxic, destructive, dark, dysfunctional, psychopathic, self-serving, despotic or even tyrannical. According to an extensive conceptualization of current theoretical trends by Lašaková and Remišová, "unethical leadership is a process of intentional or unintentional, passive or active, and recurrent influencing that harms others, being it individuals, organizations and/or society as a whole." Authors also define the following preconditions for an unethical leader: a) leader acts badly (lacks certain ethical virtues and engages in unethical acts), b) leader allows bad acts to happen, c) leader is ethically silent (does not voice the importance of ethics at a workplace), d) leader is absent (avoids contact with others or absents it at all), e) leader is self-centered, self-protective and self-serving, f) leader lacks respect to rules and g) leader is professionally incompetent (Lašáková et al., 2016; Lašáková and Remišová, 2015).

The second instrument to build up a measurable model of unethical leader's identity is an applicational analysis of ethical ideologies. According to the fundamental Theory of Ethical Positions (Forsyth, 1980) there are 4 ethical ideologies (or also called Ethical Position) derived from a 2x2 matrix. This concept is defined by dimensions of "ethical relativism" and "ethical idealism" (see: Table 1) and can be evaluated by using Ethics Position Questionnaire (abbr. EPQ).

Table 1: Adapted from the Taxonomy of Ethical Ideologies (Forsyth, 1980)

	Low Relativism	High Relativism
High Idealism	Absolutists: Principled idealists who believe people should act in ways that are consistent with moral rules, for doing so will in most cases yield the best outcomes for all concerned.	Situationalists: Idealistic conceptualists who favor securing the best possible consequences for all concerned even if doing so will violate traditional rules that define what is right and what is wrong.
Low Idealism	Exceptionalists: Principled pragmatists who endorse moral rules as guidance for actions, but admit that following rules will not necessarily generate the best consequences for all concerned.	Subjectivists: Pragmatic relativists who base their ethical choices on personal considerations, such as individualized values, moral emotions, or an idiosyncratic moral philosophy.

According to Forsyth, ethical relativism is interpreted as "while some personal moral codes emphasize the importance of universal ethical rules … others maintain a posture of relativism that skeptically rejects universal principles" (Forsyth, 1980). Based on this interpretation, let us suppose that *breaking, bending or respecting rules* in general refers to *one's own belief about the frequency of behaving in line with social norms as well as legal rules*. Further, the meaning of ethical idealism is interpreted by Forsyth as "while a fundamental concern for the welfare of others lies at the heart of some individuals' moral codes, others do not emphasize such humanitarian ideals; the former assume that we should avoid harming others, while the latter assume harm will sometimes be necessary to produce good" (Forsyth, 1980). Based on this interpretation, let us suppose that *caring less/more about others* in general refers to *one's own belief about the quality of behaving towards others or at the expense of others.*

Based on the argumentation above, let us further defined **unethical leader** (abbr. ULr) as *a leader who a) breaks/bends rules/norms more than a follower expects and/or b) cares about a follower less that a follower expects of him.* Regardless of this simplification, let us note that such a definition of ULr is in line with all preconditions of ULr by Lašaková and Remišová and, at the same time, in line with Forsyth's Theory of Ethical Positions; while the follower's expectation is thereby anchored to his own experience with ULp and thus grounded to the social learning theory (Bandura, 1971).

To conclude in other words, *an ULr is and/or behaves more subjectivistic than a follower expects of him*. And, since the meaning of "ethical" excludes "unethical" and vice versa, let us analogically suggest that *an ELr is and/or behaves more absolutistic that a follower expects of him*.

RESULTS

Based on two selected instruments and one definition, let us now suggest that the "Who is an unethical leader" question can be answered with the help of a simple model of an (un-)ethical leader's identity.

Firstly, to deal with diverse terminologies and frameworks used by behaviorists, let us suggest that *one's moral behavior can be understood in detail through his moral actions (abbr. a) and communication (abbr. c); while one's moral values (abbr. v) can be understood in detail through his Ethical Position.* Where the *moral decision making is understood as a process from an intended to an effectuated behavior*.

Secondly, based on the suggestions above, let us define an auxiliary model of one's identity flowingly: **one's identity** *consists of actions (abbr. -a), communications (abbr. -c) and own values (abbr. -v) in the way as they are perceived by one's self or by others*. And let us note, that such a definition is in line with basic ontological assumptions for social research.

Finally, let us induce and thereby define **(un-)ethical leader's identity** *as a set of (un-)ethical actions (abbr. -ra), (un-)ethical communication (abbr. -rc) and (un-)ethical values (abbr. -rv) a leader recognized of himself (or, also, consciously holds) as well as a follower so far perceived of his leader*. Thus defined, there are 6 independent parameters to consider.

So, how is a follower actually going to perceive a leader? In respect to the model of unethical leader's identity the following picture appears (see: Figure 1 and related discussion).

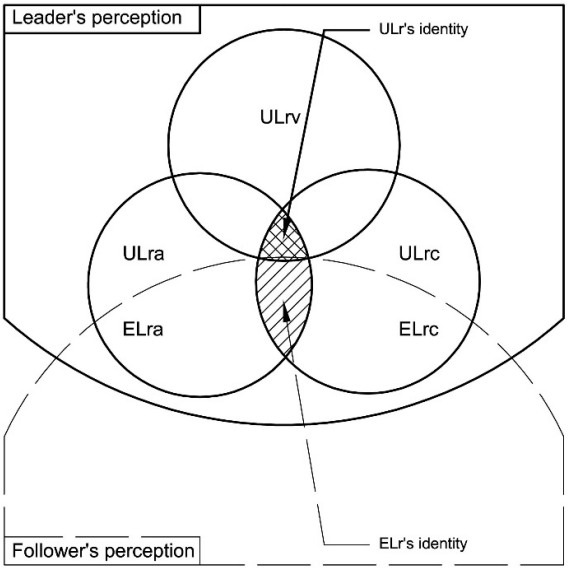

Figure 1: Ethical vs. unethical leader's identity (source: own production)

Discussion

Now, to test this model out, let us firstly remind that (1st premise) *the consequences of ULp do not exist until recognized by followers*, secondly that (2nd premise) *the leader's action can be hidden and/or communication pretended*, while thirdly (3rd premise) *the leader's value system is a moderator between his own actions and outside communication*.

Although a leader might behave unethically because he is unconscious of the consequences his behavior produces and/or is not aware of the follower's moral expectations, the first and second research premises imply that the *meaning of „is" relates to one's values, neither to actions nor communication.* Going back to the definitions of an (un-)ethical leader, one can assume that *if a follower perceives an ethical leader's behavior, it does not automatically mean that the same leader „is" ethical indeed.* And vice versa.

Supposing that a follower does not know a leader personally (see: Figure 1), the application of the first and second research premises explains why *the moral values a leader holds of him and the moral values a follower holds of his leader do not technically need/have to be the same values.* Going back to the definition of an unethical leader's identity, an *ULr might be able (intentionally) to achieve a positive (ethical) image of himself at the level of the follower's perception.* But the follower might never know.

Hence, the vagueness of antecedents and consequences related to unethical leadership might be rooted in (intentionally) shifted perceptions of a dyadic reality; *the leader's Ethical Position*

according to the follower's perception is not/does not have to be the same as an Ethical Position a leader holds in real.

No matter if such a shift in Ethical Positions is a product of legal rights and duties varying across the hierarchy, status of social groups or only individual interests. No matter if this vertical, in terms of social structures, shift in ethical ideologies is a personality antecedent for a successful rat racing or a consequence of national and/or organizational cultural dependencies. Let us for sake of this paper deduce (in relative terms) that *ULr holds a subjectivistic moral ideology, while ELr holds an absolutistic moral ideology* per se.

Although the measurability and result interpretation foresee its own limits, a further development of this model and related research methodology is open to integration with e.g. the theory of Cognitive Dissonance (Festinger, 1962) which could allow a more complex scientific and empirical application in the future. In terms of practical application, this simple (un-)ethical leader's identity model foresees a usefulness wherever any form of management and communication take place e.g. in the field of human resource management, political marketing strategies, cultural and organizational anthropology, negotiation and conflict-solving styles etc. Finally, this paper is a partial work towards understanding Slovak business culture and author's further research is therefore intended to achieve its unique conceptualization.

Besides that, once so openly defined for any other application, future research might take different directions. In terms of theoretical conceptualization, the new theoretical definitions of *a naive follower (the one who believes his leader is more ethical than he is in real)* and *a distrustful follower (the one who believes his leader is more unethical than he is in real)* need to be alternatively stipulated and, thereby, their coerced coexistence related to the model of (un-)ethical leader's identity is to be underlined. In terms of methodological development of an ideology-based approach of (un-)ethical leadership, the original EPQ must be adjusted to reflect the leader-follower dyad as technically as possible. In terms of philosophical groundwork, the bias for the result interpretation must be defined at front: Is one's state of mind (matter of subjective perception e.g. ethical consequences) an antecedent or a consequence of a state of reality (matter of objective fact e.g. cultural standard as a reference point)? And, since these two main ontologies are interdependent, how do they interfere with each other in practice?

Conclusion

The conference paper proposes a simple model of unethical leader's identity, in terms of moral actions, communication and vales, and its complementary potential for further research on ethical and unethical leadership.

The suggested theory and research approach propose to divert from researching follower's perception of leader's behavior in terms of ethics; it suggests researching follower's cognition based on own experience with leadership style over time which is independent on the matter of leader's observable behavior and/or follower's perception in the current situation and/or moment of time.

Discussing its methodological application, a variety of possible interpretations can be conducted. According to the definition of one's identity, an unethical leader has two "scientific faces" to be researched separately; one for himself and another for his followers. But, opposite to other methodologies, these two faces are clearly interconnected and, thus, a descriptive, causal, nomological, comprehensive, cross-culturally applicable, integrated and still measurable grounded theory to solve some empirical dilemmas e.g. self-other-agreement is herein offered for discussion.

Hence, an ideology-based approach to researching (un-)ethical leadership is proposed. Let us hope that the idea behind this conference paper helps the scientific community to understand observable (un-)ethical paradoxes at the individual level of leader-follower dyad and many irrational phenomena observed at the organizational, institutional or even public-government level too.

Determinants of Organizational Commitment: A Study on Teaching Staff at a Public University in Vietnam

Pham Thi Bich Ngoc, Ha Noi, Vietnam, ngocpb@neu.edu.vn

Le Hieu Hoc, Hanoi, Vietnam, hoc.lehieu@hust.edu.vn

Abstract

In the recent years, research on organizational commitment has increased. However, few of them have empirically addressed the issue in educational context. Thus, the purpose of this paper is expected to fulfil such gap in the literature by examining the impact of organizational factors on teacher's commitment. A survey of 161 teaching staff from a public university in Hanoi was conducted in 2016. Multiple regression techniques were used to analyse the data. The research findings indicated that job characteristics, workplace friendship and financial rewards significantly associates with overall organizational commitment and affective commitment of teaching staff in the university. Despite of that, job characteristics have the strongest impact on continuance commitment, and financial rewards is the strongest predictor of the normative commitment.

Keywords: Organizational commitment, teaching staff

Introduction

The concept of organizational commitment (OC) has become a hot topic in the literature of industrial psychology and organizational behavior. In the recent years, interest in OC research had increased. The majority of OC studies has focused on industrial and organizational settings, but not in the educational context. Empirical evidence regarding OC and factors affecting OC of higher education teachers are still scarce in the international literature.

Moreover, an integrative model linking several factors like job characteristics, workplace friendship, financial rewards and OC seems limited. Some researchers focused only on the relationship between job characteristics and OC (Dunham et al., 1994; Faraji et al., 2015), while others concentrated on the relationship between financial rewards and OC (Anavari et al., 2011; Kee et al., 2016). Very few researches investigated the link between workplace friendship and OC. Additionally, previous studies have been conducted primarily in business sectors, and in foreign countries. Very few researches examine the joint impact of job characteristics, financial rewards and workplace friendship on OC of teaching staff at educational context in Vietnam.

Thus, the aim of this research is to contribute to the body of literature by examining the relationship between all three above mentioned factors on the overall OC and commitment dimensions of teaching staff at one public university in Vietnam.

Literature Review

1.1. Organizational Commitment

There have been various studies in the literature addressing the concept of OC. Commitment refers to attachment and loyalty. It is the relative strength of the individual's identification with, and involvement in, a particular organization. Mowday et al. (1982) defined OC as an attitude, which exists between the individual and the organization. It is considered as a relative strength of the individual's psychological identification and involvement with the organization. Organizational commitment is viewed as being more than a passive loyalty to an organisation; it involves an active relationship with the organisation such that the individuals are willing to give something of themselves in order to contribute to the organization's well-being. Meyer et al. (1993) defines OC is "a psychological state that (a) characterizes the employee's relationship with the organization, and (b) has implications for the decision to continue or discontinue membership in the organization". This is one of the most widely recognized approaches in OC literature. They suggested that OC was a multidimensional three-component model where (1) affective attachment to the organization is defined as affective commitment; (2) perceived cost associated with leaving the organization is defined as continuance commitment; and (3) an obligation to remain with the organization is defined as normative commitment.

1.2. Job characteristics and its relationship with organizational commitment

Job characteristics have received increasing attention in recent researches due to the fact that understanding job characteristics will help in designing job that may improve performance and OC of employee in an organization. Job characteristics theory of Hackman and Oldham (1975) was built upon the premise that specific core job characteristics must exist in work settings so as to create job outcomes of high job satisfaction, high job performance, and low turnover.

Several job characteristics including variety, autonomy, task identity, task significant and feedback have been proposed by Hackman and Oldham (1975). Skill variety refers to the degree to which a job includes a variety of different activities and involves the use of a number of different skills and talents. Task identity refers to the degree to which the job requires completion of a "whole" and identifiable piece of work. One that involves doing a job from beginning to end with a visible outcome. Task significance is the degree to which the job is important and involves a meaningful contribution to the organization or society. Autonomy refers to the degree to which the job gives the employee substantial freedom, independence, and discretion in scheduling the work and determining the carrying out procedures. Task feedback refers to the degree to which carrying out the work activities provides direct and clear information to the employee regarding how well the job has been done.

The congruence between the characteristics of the individual and of the organization itself is important for researchers to examine the relationship between job characteristics and OC, since such an organization-person fit may have an impact on job incumbents' attitudes and behaviors. It is argued that the greater the fit between the person and the organization and the job, the greater the commitment to the organization (Kristof-Brown et al., 2005). In addition, Dunham et al. (1994) identified job characteristics such as task autonomy, task significance, task identity, skill variety, and feedback as antecedents of affective commitment. In similar vein, Faraji et al. (2015) also found a direct and significant correlation between job feedback and OC. Sabella et al. (2016) also found that job characteristics were an important determinant of commitment among employees. A challenging work and high-quality supervision are necessary for OC. Thus, the paper proposed the following hypotheses:

Hypothesis 1: Job characteristics predict OC of teaching staff at a university

Hypothesis 1a: Job characteristics have significant relationship with affective commitment of teaching staff at a university

Hypothesis 1b: Job characteristics have significant relationship with continuance commitment of teaching staff at a university

Hypothesis 1c: Job characteristics have significant relationship with normative commitment of teaching staff at a university.

1.3. Workplace friendship and its relationship with organizational commitment

Berman et al. (2002) defined workplace friendship as "nonexclusive voluntary workplace relations that involve mutual trust, commitment, reciprocal liking and shared interests and values". The friendship is characterized by the levels of self-disclosure and trust, support and personal feedback and communication among individuals. Several studies highlighted the positive outcomes of the friendship at work. Workplace friendships can facilitate communication, support, trust, respect, cooperation, growth, energy and security that, in turn, influence work related attitudes and behaviors (Riordan and Griffeth, 1995). The study of Ellingwood (2001) revealed that having a good friendship at work is related to how committed an individual is to his/her organization; and 90 percent of dismissals are the result of poor attitudes, inappropriate behavior and difficulties with interpersonal relationship. This results highlights the importance of friendship relationships at work. Thus, the friendship at work seem to have significant effect on OC of employees (Richer et al., 2002). The following hypotheses are formed.

Hypothesis 2: Workplace friendship significantly associated with OC.

Hypothesis 2a: Workplace friendship significantly associated with affective commitment.

Hypothesis 2b: Workplace friendship significantly associated with continuance commitment.

Hypothesis 2c: Workplace friendship significantly associated with normative commitment.

1.4.Financial Rewards and its relationship with OC

Financial reward consists of basic pay, variable pay and benefits (Rose, 2014). Financial rewards play an important role in determining an employee's level of OC. Several researches have confirmed the relationship between financial reward and OC of employees in different settings. Anavari et al. (2011) found that compensation is an important component associated with employee behavior and attitude towards improving organizational achievement by increasing OC and motivation among the workers. Basic pay may influence the workers' behavior as well as attract, and increase the intention to stay and lead to the higher employee performance in the organization (Tella et al., 2007). Especially, pay satisfaction had a significant positive relationship with the OC (Ramay, 2011). Similarly, Munap et al. (2013) and Kee et al. (2016) indicated that salary was also a factor that influences the probability of the workers to join, leave or stay in the organization, as well as their OC. In addition to the basic pay, merit-based pay plays a vital role to bring job satisfaction, OC and job performance (Gorton, 1994). Umoh et al. (2014) also found that employee benefits have significant influence on continuance commitment.

Moreover, equity in salary and fringe benefits appear important to employee's job satisfaction. Greenberg (2010), argued that unfairly treated individuals tend to exhibit more negative attitudes and behaviors. Thus, perception of fairness of distribution may lead to positive emotional feelings and behaviors, and thus pay equity was considered as one of the main sources of commitment. According to Folger and Konovsky (1989), employees who perceive they are not being treated fairly due to unfair interpersonal treatment or unfair procedures, develop low job satisfaction and commitment and may seek alternative employment in pursuit of equity. The findings of previous studies imply that feelings of commitment are likely to occur when there is a belief that the rewards are equitable in comparison to others. Thus, it is hypothesized that:

Hypothesis 3: There is a significant positive relationship between fairness in financial rewards and OC.

Hypothesis 3a: There is a significant positive relationship between fairness in financial rewards and affective commitment.

Hypothesis 3b: There is a significant positive relationship between fairness in financial rewards and continuance commitment.

Hypothesis 3c: There is a significant positive relationship between fairness in financial rewards and normative commitment.

Based on the literature review and the above-given research hypotheses, the following conceptual model is proposed:

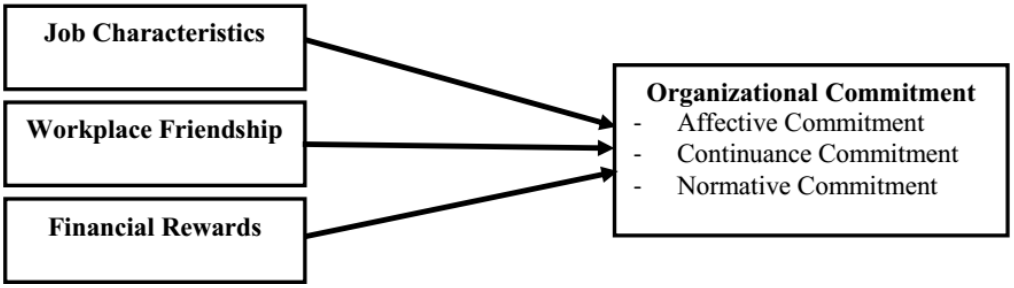

Figure 1: Conceptual Model

Methodology

This study applied the quantitative methodology to empirically clarify the relationship between different factors of teacher's OC and was concentrated on a public university in Vietnam. Several in-depth interviews with managers, lecturers and researchers in the public university were carried out in order to understand the current situation of job characteristics, workplace relationship, reward system and OC of teaching staff. Those qualitative research activities helped to prepare for the survey questionnaires.

3.1. Sample and Data Collection

Survey method has been used for the empirical analysis. Table 1 shows that the respondents in this study are those teaching at a public university in Hanoi. The total number of participants was 161 of which 65 were male (40.4 %), and 96 were female (59.6%). Nearly one third of the respondents had working experience of less than five years. Most of them had working experience more than 5 years. Regarding work positions, teaching staff constituted 63.4%, while 36.7% were head and deputy head of departments and faculties.

Table 1: Demographic Profile of Respondents

Demographic Variables	Frequency	Percentage
Gender		
Male	65	40.4
Female	96	59.6
Work seniority		
Less than 5 years	44	27.3
5 to <10 years	47	29.2
10 years – <20 years	35	21.7
More than 20 years	35	21.7
Work positions		
Teaching staff	102	63.4
Head and Vice Head of Department/Faculties	59	36.7
Educational Level		
Master degree	115	71.4
Doctoral degree	46	28.6

Measures

The questionnaire used self-developed and prior measurements corresponding to each variable in the literature and taking the context of the university into account. 5-point Likert scale (1: strongly disagree; 5: strongly agree) was employed for all questionnaire items. Multiple-item scales for all constructs in the conceptual model were either newly developed or grounded from previous researches to ensure the reliability and validity of the measurement.

Measurement of OC was grounded in the work of Meyer and Allen's (1991) where scales assessing normative, affective and continuance commitment are proposed. Affective commitment is based on an emotional attachment, and has as its basis a desire to be a part of the organization. The degree to which an individual feel as though he or she belongs to the group, and to which he or she is satisfied with the involvement in the organization is reflected in this component of commitment. The second component, continuance commitment, is based on an exchange between the individual and the organization. The strength of this commitment, therefore, is based on the degree to which the employee views the exchange as being in his or her favor. It results from an individual choosing to continue to work for an organization because the rewards and benefits to that individual outweigh the costs, or because the costs of not staying with the organization are greater than the benefits of leaving the organization. The third component of OC proposed by Meyer and Allen (1991) is normative commitment. This component is based on a belief that one has a responsibility to the organization, that one "ought" to be committed to an organization. This component of commitment reflects an individual's perceptions of what behaviors are considered acceptable in an organization.

In order to measure five job dimensions (skill variety, task significance, and task identity, task autonomy and task feedback), the adaptation of the job diagnosis survey (JDS) originally developed by Hackman and Oldham (1975) has been done. The scale of workplace friendship is adapted from the study of Morrison (2004).

Main Results

4.1 Reliability and validity of the proposed constructs

Reliability and validity tests are conducted for each of the constructs with multivariate measures. To measure the internal consistency of the multivariate scales, Cronbach's alpha was used. In this study,

the Cronbach's α of each constructs is greater than 0.7. According to Kline (1998), a set of items with a coefficient alpha greater than or equal to 0.7 is considered internally consistent.

Table 2. Internal consitency of the multivariate scales

Contructs	Number of Items	Mean	Standard Deviation	Cronbach's alpha
Job characteristics	5	4.16	0.48	0.65
Relationship with colleagues	5	4.03	0.47	0.80
Financial rewards	6	2.97	0.61	0.87
Affective commitment	4	3.88	0.69	0.85
Continuance commitment	4	3.47	0.74	0.82
Normative commitment	2	3.43	0.67	0.72
Organizational commitment		3.68	0.53	

In addition, an exploratory factor analysis was performed to ensure the reasonable constructs of the instrument. Using principal component analysis and varimax rotation, factors with eigenvalues greater than one and factor loadings greater than 0.6 were retained.

4.2 Correlation analysis

A Pearson correlation analysis was performed on the independent and dependent variables. Table 3 presents the correlation matrix addressing bi-variate relationships among the variables in the study. Most of the correlations were considered low (less than 0.4) and some were moderately correlated (between 0.4 and 0.7) and very few correlations were higher than 0.8. As expected, job characteristics, workplace friendship, financial rewards positively correlated with overall OC and its components.

Table 3: Correlations among variables

	JC	WF	FR	AC	CC	NC
Job Characteristics (JC)						
Workplace Friendship (WF)	.170*					
Financial Rewards	.244**	.381**				
Affective Commitment (AC)	.394**	.404**	.619**			
Continuance Commitment (CC)	.334**	.202*	.200*	.333**		
Normative Commitment (NC)	.218**	.276**	.403**	.662**	.361**	
Overall OC (OC)	.474**	.384**	.520**	.846**	.650**	.833**
*. Correlation is significant at the 0.05 level (2-tailed).						
**. Correlation is significant at the 0.01 level (2-tailed).						

4.3 Descriptive Statistics

Most of the respondents agreed that teaching and researching job is meaningful and gave them a lot of autonomy. In addition, those features of the job play crucial role in motivating the teaching staff at the university where knowledge is considered as critical asset.

Table 4: Mean Results of Job characteristics (n=161)

Scale Items	Mean	SD
- Skill variety	3.9	0.35
- Task significance	4.5	0.49
- Task autonomy	4.3	0.79
- Task feedback	4.3	0.84
- Task identity	3.8	0.43

Concerning the relationship with colleagues, most of the respondents agreed that they satisfied with it (Mean = 4.03, SD=0.67). There is a trust among teaching staff in the university. They have friendly relationship with colleagues and feel comfortable in communicating and sharing with peers. However, not many respondents agreed that they received support and helps from other colleagues.

Table 5: Mean Results of Workplace friendship (n=161)

Scale Items	Mean	SD
- Trust among colleagues	4.1	0.70
- Opportunity to develop close and strong friendships at workplace	4.2	0.70
- Communication among teaching staff is encouraged	3.9	0.57
- Opportunity to talk informally and socialize with colleagues outside the workplace	4.3	0.66
- Supports and helps from colleagues	3.6	0.71

Financial Rewards

Financial rewards are monetary compensation given to employees in return for their performance and contribution to the university. Financial rewards play an important role in determining teaching staff's level of OC. The survey results indicated that most of the respondents slightly dissatisfy with financial rewards provided by the university (Mean = 2.96, SD = 0.8). Most of the respondents agreed that income from university can not cover for all expenses in life (Mean = 2.8, SD=0.86), their performance was not rewarded in equitable manner (Mean = 2.8, SD=0.8).

Table 6: Mean Results of Financial rewards (n=161)

Scale Items	Mean	SD
- Income from university can cover for all expenses in life	2.8	0.86
- Salary reflects individual performance	3.2	0.77
- Teaching staff's performance were rewarded in equitable manner	2.8	0.86
- Having monetary incentives for individual having outstanding performance	2.8	0.87
- Benefits were provided to teaching staff in addition to the salary and	3.1	0.83
incentives	2.9	0.69
- Pay system of university motivate teaching staff		

Organizational Commitment

The mean scores for OC of teaching staff are not so high (Mean=3.9, SD=0.65). The affective commitment level of the university's teaching staff seems to far exceed the continuance and normative commitment (Table 7). Most of the respondents agreed that they feel emotional attachment to, identification with, and involvement in, the university. **Table 7. Mean Results of OC (n=161)**

Scale Items	Mean	SD
Affective Commitment		
- I would be very happy to spend the rest of my life with this organization	4.15	0.87
- I enjoy discussing my organization with people outside of it	3.87	0.87
- I really feel as if this organization's problems are my own	3.5	0.9
- This organization has a great deal of personal meaning for me	4.01	0.64
Continuance Commitment		
- It would be very hard for me to leave my organization right now, even if I wanted		
- Too much of my life would be disrupted if I decided I wanted to leave my organization now	3.4	1.01
- I feel that I have too few options to consider leaving this organization	3.64	0.85
- One of the major reasons that I continue to work for this organization is that leaving would require considerable personal sacrifice	3.2 3.5	0.98 0.8
Normative Commitment	3.3	0.75
- One of the major reasons that I continue to work here is that I believe that loyalty is important and therefore, feel a sense of moral obligation to remain.	3.4	0.83
- Things were better in the days when people stayed with one organization for most of their careers		
Overall organizational commitment	3.9	0.65

4.4 Hypotheses Testing

This section presents the statistical tests of the research model and for the research hypotheses examined in the study. The emphasis of the study is on assessing the statistical significance and relative influence of the independent variables on the three dimensions of OC.

Firstly, a test for the multicollinearity among independent variables is implemented to ensure not to violate the assumption of multiple regression statistics. To this end, the tolerance statistic was examined to identify any variables with a tolerance close to zero. The Variance Inflation Factor (VIF), which is the inverse of the tolerance value, was calculated. VIF of independent variables in all regression models ranged from 1.36 to 2.43. According to Chatterjee, Hadi and Price (2000), Hair et al. (1995), the value of VIF less than 10 is acceptable. Thus, the data is not subject to multicollinearity problems.

To analyze the first hypothesis, simple regression analyses were performed to establish the predictive power of job characteristics on OC. The statistical results indicated that the predictability of job characteristics was significant (Adj. R^2 = 0.22; 0.15; 0.106; 0.042.; $p<0.01$, respectively). Job characteristics contributes to 22% of the variance in overall OC and 15% of the variance in affective commitment; 10.6% in continuance commitment and 4.2% in normative commitment. The statistical result indicated support for the hypothesis 1, 1a, 1b and 1c.

To analyze the second hypothesis, simple regression analyses were performed to establish the predictive power of workplace friendship on OC. The statistical results indicated that the predictability of workplace friendship was significant (Adj. R^2 = 0.142; 0.158; 0.035; 0.07; $p<0.01$, respectively). Workplace friendship contributes to 14.2% of the variance in overall OC and 15.8% of the variance in affective commitment; 3.5% in continuance commitment and 7% in normative commitment. The statistical result indicated support for the hypothesis 2, 2a, 2b and 2c.

To analyze the third hypothesis, simple regression analyses were performed to establish the predictive power of financial rewards on OC. The statistical results indicated that the predictability of financial rewards was significant (Adj. R^2 = 0.266; 0.379; 0.034; 0.157; p<0.01, respectively). Financial rewards contribute to 26.6% of the variance in overall OC and 37.9% of the variance in affective commitment; 3.4% in continuance commitment and 15.7% in normative commitment. The statistical result indicated support for the hypothesis 3, 3a, 3b and 3c.

In order to test the joint impact of all proposed independent variables on affective commitment, continuance commitment, normative commitment, OC, and several multiple linear regression models were used. As observed, there is a significant improvement in the predictive power of this model in comparison with previous models with the explained percentages of total variance being 41.6% for the affective commitment, 12.3% for continuance commitment, 17.7% for normative commitment and 41.8% for overall commitment. Table 8 presented the results of multiple regression models.

Table 8: Multiple regression results for Organizational Commitment

Variables	Affective commitment	Continuance commitment	Normative commitment	Overall organizational commitment
	Beta	*Beta*	*Beta*	*Beta*
Job characteristics	0.245***	0.294***	0.117	0.354***
Workplace friendship	0.175**	0.121	0.133+	0.185**
Financial rewards	0.492***	0.082	0.324***	0.364***
Adjusted R2	0.461	0.123	0.177	0.418
F Statistics	46.685***	8.467***	12.462***	39.232***

Note: + p<0.1, * p<0.05, ** p<0.01, *** p<0.001

Discussion

It was found that all three factors have the significant relationship with OC. Among three independent variables, financial rewards have the strongest impact on overall OC, affective and normative commitment. In addition, job characteristics have a significant relationship with overall OC, affective and continuance commitments. Regarding the relationship between workplace friendship and three dimensions of OC and overall OC, workplace friendship has the biggest impact on affective commitment.

Consistent with previous studies (Kee et.al, 2016; Korir at al. 2016; Jensen, 2014; Ramay, 2011), this research found that financial reward is significantly associated with OC among teaching staff at the public university.

The results of the study confirmed the role of financial rewards in enhancing OC of teaching staff. It also provides deeper discussion of the impact of financial rewards on different aspects of OC. To enhance OC, it is needed to focus on building and ensuring an equitable financial reward system. The reward package for teaching staff should be closely associated with their performance and competence. As a result, a performance management system with clear and appropriate performance standards, performance criteria and appraisal methods then should be reexamined to ensure the accurate evaluation of faculty performance. In addition, salary reviews should be carried out in order to develop a reward system that is externally competitive, internally fair and consistent with the regulations of the government.

Moreover, the results of the study also recognize the importance of job characteristics in enhancing OC of the faculty. The study confirmed the importance of job characteristics in enhancing affective and continuance commitment. To enhance OC of teaching staff, it is needed to design the job that cover all five main dimensions. Skill variety can be improved by assigning different tasks for

teaching staff to do. Faculty members should be required to teach several subjects at different levels (undergraduate and post graduate). Providing opportunity for them to carry out consulting project and researches also help to increase their skill variety and then teaching staff's OC. Providing feedback on teacher's work also another issue which university manager need to take into account. Student feedback system and supervisor feedback should be facilitated and provided to teaching staff timely in constructive manner.

Workplace friendship also appears very important in enhancing teaching staff's OC. When teaching staff have opportunities to build and invest in interpersonal relationship with colleagues, their affective commitment and normative commitment are enhanced. They tend to stay in a university since they feel to be obligated to do so. The results imply that university managers (dean of schools, head of department) should create an opportunity for teaching staff to get to know each other, to communicate, to support each other. When the good interpersonal relationship is built, they tend to have higher commitment.

Conclusion

The study builds on and extents the findings of the previous researches on the determinants of OC of teaching staff with the data from a public university in Vietnam. It contributes useful information and creates a better understanding towards the job and organizational factors which will lead to OC of teaching staff in a public university. From this study, the university can identify the dominant factor that can lead to the strongest relationship between the financial rewards, job characteristics; workplace relationship and OC. This study also creates awareness on the importance of the building financial rewards system to minimize turnover of the teaching staff.

Although having certain contributions to the growing body of literature on OC, the study has several limitations. Since the data were collected from 161 individuals a public university, the findings may not be generalized at large, and/or in other settings. Additionally, there is a potential risk for common method bias due to the use of self-administered questionnaire with mainly perceptual measures.

The future study could attempt to extent the sample size, incorporate demographic and other factors to the existing model to create a more comprehensive model or conduct a comparative analysis on OC of teaching staff in public and private universities in Vietnam. On the other hand, future researchers can also focus deeply on the impact of different types of financial rewards on OC.

Research of the Region Industrial Sphere in the Branch Section: Statistical Aspect

Tatyana A. Ignasheva, Mari State University, Yoshkar-Ola, Russian Federation, E-mail: samofeeva@mail.ru

Abstract

Important condition of increase in efficiency of social production is steady improvement of the industry branch structure reflecting the level of industrial development of the region, his economic independence, degree of technical equipment of production. The aggregate of key indicators of industrial production of the Mari El Republic defining the direction of the statistical analysis of the region industrial sphere in a branch section acts as a subject of the conducted research. The results of the analysis, best in the substantial plan, are received on the basis of application of modern economic-mathematical methods, in particular, methods of the multidimensional statistical analysis. Carrying out classification of industries by the level of profitability allowed allocating three classification groups. The most profitable industries of the Mari El Republic are the branches relating to the first cluster. Branches of the second cluster are intermediate. Branches of the third cluster treat the least profitable branches. The carried-out analysis of the available industrial potential shows on existence in the republic of the developed industrial complex, high technologies and conditions for expansion existing and opening of new productions. Results of a research can be useful to use in practical activities of economic development services of the region when developing strategy and forecasts of development, both separate industries, and an industrial complex in general.

Keywords: industries; classification; clusters; K-means method

Introduction

The Mari El Republic belongs to industrial and agrarian regions. Its industrial complex is represented by the organizations making industrial output, uniting the enterprises for mining, the enterprises of the processing productions, the enterprises for production and distribution of the electric power, gas and water. Ibragimova et al (2015) mentioned that the efficiency of the industrial sector development defines a condition of production capacity of the region, provides steady functioning of the main branches of economy. 27% of a gross regional product fall to the share of the industry, the enterprises of branch provide about 50% of tax revenues in budgets of all levels. The average number of employees of the industrial complex enterprises is 61,6 thousand people or 27,3% of the average number of employees of the republic organizations. Klunko (2012) mentioned that the leading branches are the mechanical engineering and metal working (20,8% of the total amount of industrial production), power industry (19,3%), the food industry (18,6%), the wood, pulp-and-paper and woodworking industry (14,5%), fuel industry (8,2%), medical, easy and the building materials industry (on 3 - 4%). In recent years the Mari El Republic was among the most dynamically developing regions of the Volga Federal District. In the region dynamic work on creating favorable conditions for the industry development, attraction of investments, increases in production competitiveness is conducted. In a research study by Beskaravaynykh (2015) it was concluded that the important value for programs development of progressive development of industrial branch complex has existence of the scientific base allowing to reveal the available weak points of branch structure and to offer an algorithm on prospect development.

Empirical Analysis

Due to the social and economic importance of the planned problem a research objective is carrying out classification of the region industries by profitability level. The base of a research was made by data on development of 15 industries of the Mari El Republic for 2015 year.

For carrying out the substantial analysis of the industry branch structure the cluster analysis allowing to pass from item-by-item to group representation of industries set is applied. Ignasheva (2015) mentioned that the task consists in association of industries in clusters on indicators of economic activity, using some measure of similarity or distance between objects and in creation of the corresponding hierarchical tree.

There are about 100 different algorithms of a clustering. In this research two methods of the cluster analysis are applied: the classification based on the description of classes by "kernels" (a clustering by K-means method) and hierarchical classification. Algorithms of hierarchical classification are applicable for classification of sets of rather small volume, but allow receiving in some cases fuller analysis of structure of the objects studied set.

As the main criteria of a clustering 6 indicators characterizing development of the region industries are selected:

x_1 - number of the operating organizations (on the end of the year), units;
x_2 - the volume of the shipped goods of own production, the performed works and the rendered services by own forces, million rubles;
x_3 - the index of production, as a percentage to previous year;
x_4 - the average annual number of the organizations employees, the people;
x_5 - balanced financial result (profit minus losses), million rubles;
x_6 - profitability of the sold goods, production (works, services), %.

When carrying out a research the following industries of the Mari El Republic were exposed to the analysis:

- the extracting productions;
- production of foodstuff, including drinks;
- textile and sewing production;
- production of skin, products from skin and production of footwear;
- processing of wood and production of products from a tree;
- pulp-and-paper production, publishing and printing activities;
- chemical production;
- production of rubber and plastic products;
- production of other nonmetallic mineral products;
- metallurgical production and production of finished metal products;
- production of cars and equipment;
- production of electric equipment, electronic and optical equipment;
- production of vehicles and equipment;
- production and distribution of the electric power, gas and water;
- other productions.

The results of classification, best in the substantial plan, are received with use of Ward's method and Euclidean distances. The method algorithm on the first step defines each of observations as a separate cluster, further on each step there is an association of two closest observations, then two closest groups of observations (clusters). Work of an algorithm comes to an end when all initial observations are united in one cluster. Process of such consecutive association is visually displayed on graphics in the form of a tree diagram (fig 1).

Results of classification demonstrate expediency of splitting industries into 3 clusters. The first cluster included branches of processing of wood and production of products from a tree, pulp-and-paper production, publishing and printing activities, metallurgical production and production of finished metal products, production of cars and the equipment.

The second cluster is formed by branches of the extracting productions, productions of skin, products of skin and production of footwear, textile and sewing production, chemical production, production

of rubber and plastic products, production of other nonmetallic mineral products, production of vehicles and the equipment, other productions.

The third cluster included branches of production of foodstuff, including drinks, productions of electric equipment, the electronic and optical equipment, production and distribution of the electric power, gas and water.

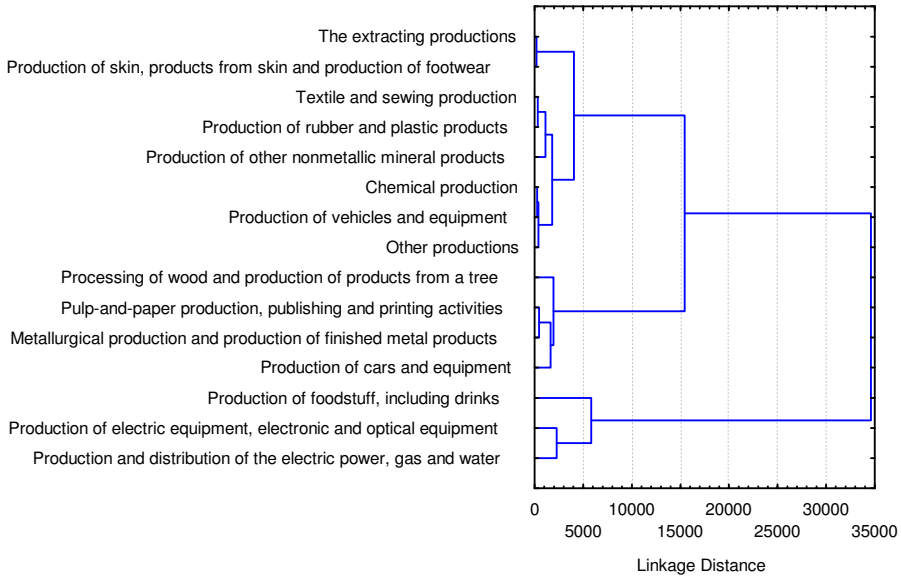

Fig. 1: Tree diagram of industries uniformity on operational indicators

Comparison of industries classification structure with the results received by K-means method is made for confirmation of the achieved results reliability. This method belongs to group of interactive methods. Process of classification begins with a task of some entry conditions, quantity of the formed clusters. Unlike hierarchical procedures the K-means method does not demand calculation and storage of a matrix of distances between objects. The algorithm of a method assumes use only of reference values of variables.

The K-means method made splitting the studied set of the region industrial branches into 3 classification groups. The analysis of the received results shows that the structure of the clusters created by a hierarchical method completely coincided with structure of the clusters received by K-means method except for their sequence that is explained by methodical features of algorithms. The first cluster included branches of production of foodstuff, including drinks, productions of electric equipment, the electronic and optical equipment, production and distribution of the electric power, gas and water. The second cluster consists of the branches forming the first classification group in hierarchical classification. The third cluster includes the extracting productions, textile and sewing production, production of skin, products from skin and production of footwear, chemical production, production of rubber and plastic products, production of other nonmetallic mineral products, production of vehicles and the equipment, other productions. Average values of the analyzed indicators for each cluster are presented in table 1.

Table 1: average values of classification indicators by K-means method

Indicators	Cluster 1	Cluster 2	Cluster 3
Number of the operating organizations (on the end of the year), units (x_1)	233	263	67
The volume of the shipped goods of own production, the performed works and the rendered services by own forces, million rubles (x_2)	8147,500	2895,525	985,050
The index of production, as a percentage to previous year (x_3)	96,83	97,35	91,35
The average annual number of the organizations employees, the people (x_4)	9067	4525	1210
Balanced financial result (profit minus losses), million rubles (x_5)	455,933	35,950	37,737
Profitability of the sold goods, production (works, services), % (x_6)	8,90	6,98	1,56

For more evident image average values of classification indicators are presented in figure 2.

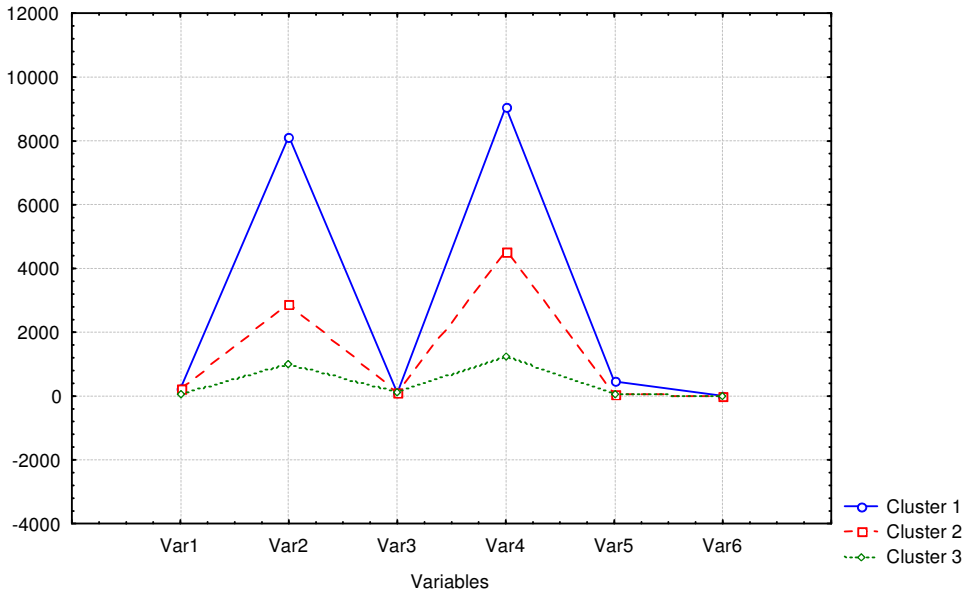

Fig. 2: Plot of means for each cluster

The analysis of means of classification indicators allows to draw a conclusion that the most profitable industries of the Mari El Republic are the branches relating to the first cluster: production of foodstuff, including drinks, production of electric equipment, electronic and optical equipment, production and distribution of the electric power, gas and water. They are characterized by the highest values on such important indicators as the volume of the shipped goods of own production, the performed works and the rendered services by own forces, balanced financial result, profitability of the sold goods, production (works, services). The received values of indicators can be explained with the fact that, for example, at the enterprises for production of foodstuff there is a continuous improvement of quality and expansion of the range of the made production, introduction of innovative technologies. Fedorova and Dovzhenko (2015) mentioned that the increase in production of electric equipment, electronic and optical equipment was reached due to reconstruction of the operating capacities, modernization and technical re-equipment of productions, introductions of resource-saving technologies and increase in production of production separate types.

The second cluster is intermediate. The branches forming it are in the lead on number of the operating organizations. Now the increase in domestic and external demand for production of a machine-building complex is observed, defining value have machine-tool constructing and tool production, mechanical engineering for the light and food industry and production of household appliances. Increase of production volume on processing of wood and production of products from a tree is reached due to reconstruction of the operating capacities, introduction of progressive technologies at the large and medium-sized woodworking enterprises. Cellulose and packing paper are a considerable part of an export turn of the region, increase in production is provided due to reconstruction and replacement of processing equipment at the enterprises of pulp and paper industry and development of new sales markets. At the enterprises for production of finished metal products modernization of productions, expansion of production spaces, mastering and output of new types of production is carried out.

Branches of the third cluster as the least developed in production sector of the region treat the least profitable branches.

Conclusion

The carried-out analysis of a social and economic situation in the region showed that in the republic are available the developed industrial complex, high technologies and the conditions for expansion existing and opening of new productions. The industrial enterprises are given the state support on subsidizing of a part of leasing payments and a part of percentage expenses on the loans attracted for implementation of the investment projects aimed at the development of production and creation of new jobs.

In the republic purposeful work on reconstruction and modernization of operating plants is carried out. More and more attention is paid to the knowledge-intensive productions. So, prime attention has to be paid to maintaining the reached level of production, strengthening of control over timely payment of the salary.

In a research study by Uzdenov (2014) it was concluded that in the solution of problems of ensuring sustainable development of economy the paramount role will belong to the innovative development capable to provide continuous updating of technical and technological base of production, development and release of new competitive production and entry into foreign markets of goods and services.

Abstract

The article deals with the basic aspects which influence the transformation of universities in contemporary educational and social-cultural paradigm. Social-cultural, legal, practice-oriented, educational aspects are distinguished as the main ones. Problems of continuity of local cultural policy, social-cultural adjustment mechanism of the youth and formation of a new cultural paradigm of education are included in the research discourse. The necessity of development of own Russian paradigm of university space in conditions of external and internal challenges is proved. It is concluded that the main task of university education is to form a unique ground for transfer and maintenance of cultural background, communication models of a cognizing subject.

Keywords: university, cultural policy, legal culture, patriotism, youth policy, educational strategies, global processes.

Introduction

In the era of permanent reforming of education more attention is given to transformation of higher school, to which truly monumental tasks are set today. The discussions about crisis of contemporary university continue not only among university professors but also in society as a whole. Contemporary education discourse leads to devaluation of background knowledge, loss of conceptual and systematic knowledge (Malakhova, 2002). This is especially evident in regions. Today a lot of regions of Russia face a serious problem related to a threat of social-economic, demographic and cultural degradation of the region, the cause of which can be closure (or reorganization) of a university which has a backbone nature. Higher education forms a level of cultural environment of the region. If general population is prevented from higher education, it may exacerbate stratification of the society because very few families will allow to train their children outside the region. It will be an additional factor in the outflow of the reproductive population to more advantaged regions of the country and, as a result, in increase of the age level of the population in the republic. In the long term the consequences of this process will be an economic decline of the region and domination of a simplified common cultural standard (Wyn, 2015).

Hypothesis

Functioning of university of classical type in a provincial town promotes to develop intellectual potential of the youth, its social and cultural activity. Continuity of regional social-cultural policy and formation of legal culture will allow ending further intellectual crisis of the Russian society.

Research Design and Methodology

The Mari State University was chosen as a model to confirm the hypothesis. The University has a serious impact on social-cultural environment of the region because the processes of socialization and education of the youth are taking place here. Particular attention is now given to educational policy,

which largely helps to form patriotism, tolerance and civic stand. The priorities of state youth policy for the period until 2025 are determined at the federal government level.

The formation of active civic stand of an individual, civic self-determination, perception of inner freedom and responsibility for own political and moral choice, respect for historical background of the country and activity of previous generations, desire to protect the country from external and internal destructive impacts, desire to work not only for satisfaction of own needs but also for the sake of the Fatherland, increase its authority among other countries of the world community – overall, the student of the university should have specific moral and psychological qualities: civic courage, boldness, honesty, decency, conviction, ability to defend own point of view (Chou et al, 2017).

Patriotic education is intimately connected with international one because Russia was and is a multinational country. Thereby, patriotism should have an international character based on necessary of different nationalities to live in the unique Russian State. In conditions of a multinational region education of culture of the international society is an important component of the system of personality formation in universities of humanistic type and the development of patriotic and national self-consciousness among the youth.

Legal culture is an integral part of general culture of the society which is intimately connected with civic-patriotic consciousness. Formation of legal culture among the youth is one of the priorities of the university and should be a scientifically based process to manage moral and legal formation of the personality of a student which is carried out to get a general image of a specialist, who is ready for fulfilling different social responsibilities and has high moral and civic qualities. Legal culture affects legal consciousness and influences the behavior of citizens in the society (Moreau, 2016). Principles of legal democratic society should become a basis to form legal consciousness of the youth and an evaluation criterion of own behavior and behavior of other people. Indicator and criterion of the level of formation of legal culture of a young specialist is a degree of consciousness of own rights and duties, conviction in necessity of their observance and realization on practice.

Sociological survey based on the social-cultural approach, which essence consists in an attempt to consider society as a unity of culture and sociality formed and transformed by human activity, has become a research tool of social-cultural policy conducted at the Mari State University. 2127 students, including 1475 girls and 652 boys, took part in the survey.

Results

Following the question “Whom do you feel in a greater extend?” 79,5% of the interviewed students said “citizen of the country” (Fig. 1). The differentiation of the answers by courses and gender of the respondents is insignificant.

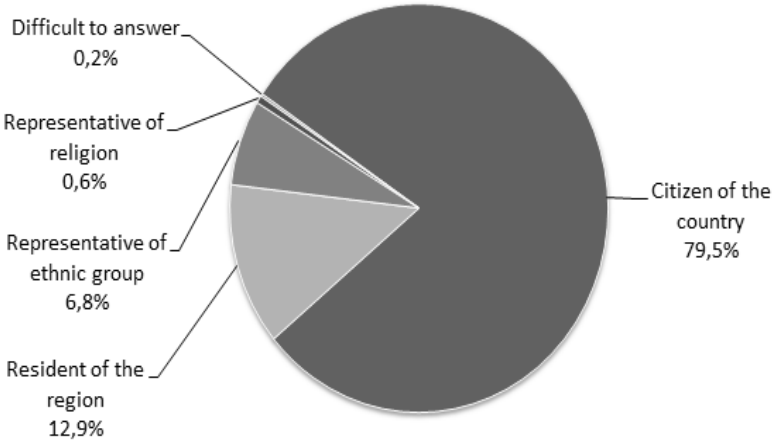

Fig. 1: Whom do you feel in a greater extend?

The obtained data allow to conclude that by self-identification students of the regional university is not only inclined to differentiate by national or religious grounds but, on the contrary, tends to emphasize their belonging to all-Russian society.

Thereby, the distribution of priority values of students shows their internal orientation to private welfare. Following the question "What is the most important for you in your life?" most of the students said "family" (86,1%). Less than 10% of the students chose such priorities as "welfare of the Motherland", "power and influence on people" (Fig. 2). The answers of the students are less differentiated by faculties, courses and gender of respondents.

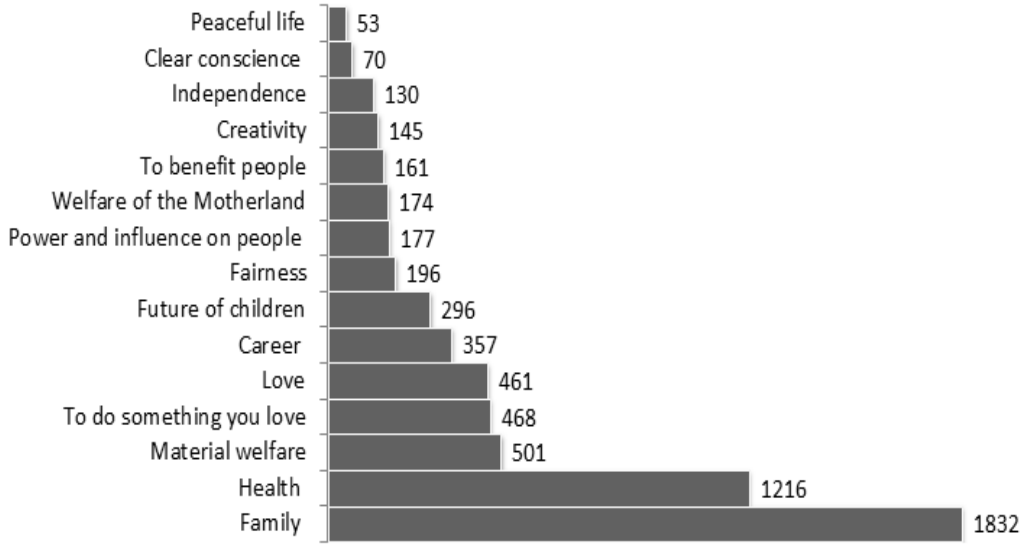

Fig. 2: What is the most important for you in your life?

Therefore, self-identification of the majority of the students of the regional university as citizens of the country does not determine an axiological choice of a student in favor of strictly civic values, a desire of a regional student is aimed at integration to all-Russian society on the basis of formed system of private values.

The analysis of the answers of the students to the question "When studying at a university, what do you do in addition to your learning activity (would like to do)?" showed that the vast majority of them is aimed at participation in extracurricular activities (Fig. 3).

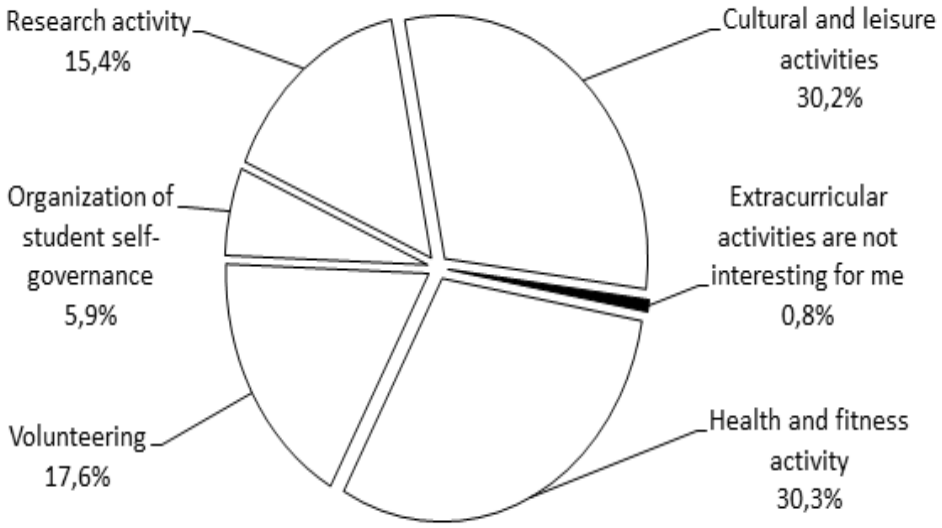

Fig. 3: When studying at a university, what do you do in addition to your learning activity (would like to do)?

One of the most popular directions of extracurricular activities in the Mari State University is volunteering. Promotion and popularization of values and voluntarism in the society is an effective mechanism of realization of social partnership and an important consolidating factor in conditions of the regional society. At the present time every third full-time student of the Mari State University participates regularly and systematically in volunteering (Smyshlyaeva, Obidina, 2016). The students of the Mari State University are actively involved in federal, regional and university volunteer activities through participation in both independent programs and programs of volunteer projects of different level. There are projects in the field of legal education and civic-patriotic initiatives among the most important directions of these projects.

Discussions

Obviously, undeveloped social-cultural mechanisms of adaptation of the youth to new conditions compound a problem of choosing value orientations and behavior (Beloshapka, 2015). The destruction of previous forms of adaptation of a person to ambient conditions, the growth of internal conflict is determined, according to Toffler, on the one hand, by spread between images, mental models of the reality and what it actually is (Toffler, 1970). Civic-patriotic education and formation of legal culture of the youth has an important meaning in the process of formation of value orientation.

However, education system in virtue of its conservatism cannot keep up with changeable social-cultural processes and create mechanisms of adaptation of the youth to the reality of the modern world. The system of student self-governance, under which social activity of a student of the regional university, can be a condition to create such a mechanism. Interests of young citizens are realized, to a large extent, in extracurricular activities and spread to a broad social space including volunteering and other socially useful initiatives.

In modern Russian science the view is expressed to form a new cultural paradigm of education that considers society and a person in their integrity, cultural and individual dimension instead of the

former one, in which education was aimed at transfer and acquisition of uniquely interpreted knowledge (Emikh, 2011). Personality passes the process of transformation and degeneration to a new personality through education. Personality becomes capable to transform the social reality (Agapov, 2014). Therefore, the more importance is being attached to the training of a specialist, who is capable of self- actualization in the process of social and labor activity, having such personal and professional qualities which ensure the solution of the tasks in all types of activity and the responsibility for their solution.

The importance of the university will increase due to establishment of close cooperation with the state authorities of the region, organizations, and companies – potential employers of the graduates of the university.

Net cooperation of science and practice allows to:

- attract additional extra-budgetary funds (Elsukova, 2015);
- introduce net forms of realization of educational programs;
- organize a probation of students in organizations of the region with subsequent employment of the graduates;
- effectively respond to real demands of the labour market and correct curricula;
- organize mass additional professional education of specialists in a particular field;
- provide continuity of professional and university education of the region.

Conclusions

Therefore, today an important task of university education is to form new mechanisms and a unique semantic field of transfer and preservation of cultural experience, models of communication of a cognizing subject. Under the influence of such processes new professional values are confirmed, social trends change, scientific and pedagogic practice adopts to the reality of our life. Not least this happens under the influence of self-preservation mechanism of the society which forms its new identity.
