Figure 5: Response of Question No. 4

The analysis of the data regarding this question shows that 72% of the respondent were strongly agreed and above but still reasonable percentage of respondents i.e. 20% strongly disagree and prefer to use desktops. So, the desktop will remain in use for future.

Analysis of the response of Question No: 5; "Is setting up a wireless connection on computer easy?" is shown in Figure 6.

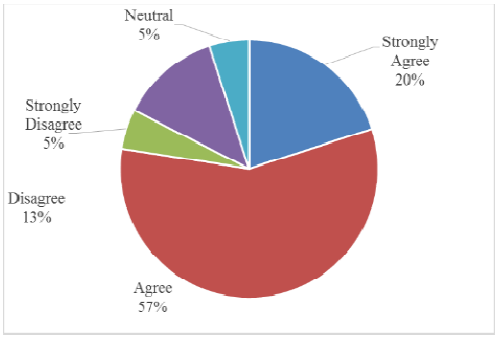

Figure 6: Response of Question No. 5

The analysis of the data regarding this question shows that 77% of the respondent were strongly agreed and above but still reasonable percentage of respondents i.e. 23% strongly disagree and lower. The HCI research should address the issue of easy usage of new technologies that are to come in future. It is recommended that videos based tutorials should be part of the user manuals.

Analysis of the response of Question No: 6; "Is it very difficult to complete the tasks on interface?" is shown in Figure 7.

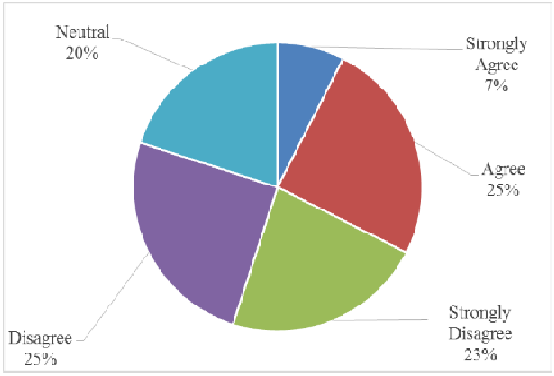

Figure 7: Response of Question No. 6

The analysis of the data regarding this question shows that 32% of the respondent were strongly agreed and above in completing the task on the user interface of the application. But, 48% were of the opinion that it is not difficult. Therefore, we can conclude that GUIs of the application should provide the facilities to complete that tasks on one interface.

Analysis of the response of Question No: 7; "Do various instructions and commands which appear on computer's screen difficult to understand?" is shown in Figure 8.

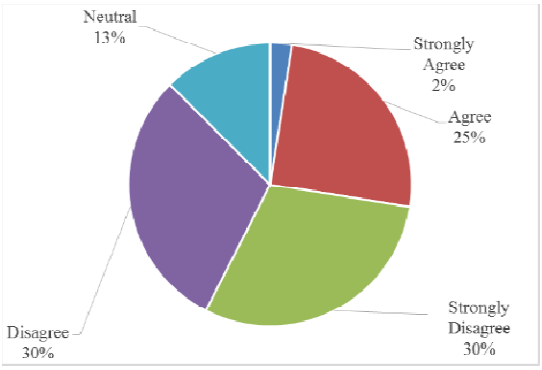

Figure 8: Response of Question No. 7

The analysis of the data regarding this question shows that 27% of the respondent were strongly agreed and above in understanding the commands and instructions that appear on computer screen. But, 60% were of the opinion that it is not difficult to understand. Therefore, we recommend that each that appear on the computer screen should have help feature that could be displayed when mouse is hovered on it.

Analysis of the response of Question No: 8; "Is every task on computer performed in a straightforward manner?" is shown in Figure 9.

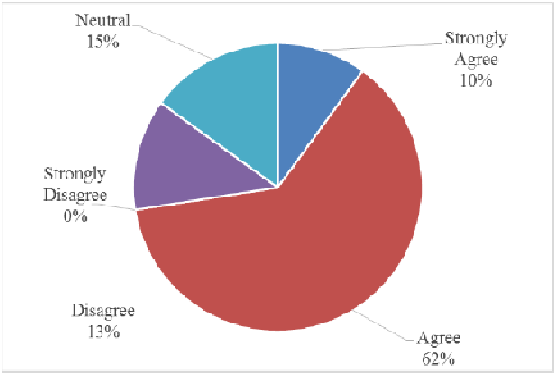

Figure 9: Response of Question No. 8

The analysis of the data regarding this question shows that 72% of the respondent were strongly agreed and above in completing that tasks on computer in straightforward manner without any problem. There are only 13% who disagree with this aspect.

Analysis of the response of Question No: 9; "Is your system's speed faster?" is shown in Figure 10.

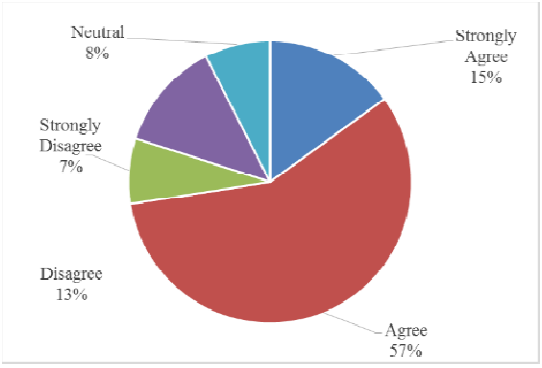

Figure 10: Response of Question No. 9

The analysis of the data regarding this question shows that 72% of the respondent were strongly agreed and above were satisfied with the computer specifications. Hence, it could be concluded that organizations and people are continuously updating their computing resources. This is a healthy sign for the flourishing the IT industry.

Analysis of the response of Question No: 10; "Have your computer good feedback system?" is shown in Figure 11.

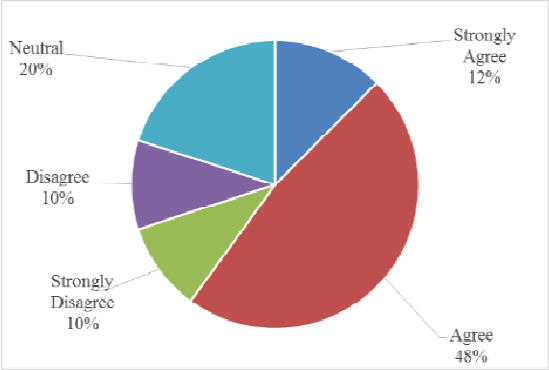

Figure 11: Response of Question No. 10

The analysis of the data regarding this question shows that 60% of the respondent were strongly agreed and above were satisfied and only 20% did not agree.

Conclusion

The HCI is in simple words relationship of human mind to the computer and computer's relation to the human. We presented the analysis of a survey conducted to find out what user thinks and feel when they interact with the computers. We also presented some recommendations for the researchers in the HCI field to further improve some aspects of HCI for layman users.

Abstract

Currently, the urgent problem of managing the development of socio-economic systems is the search for optimal mechanisms and methods for organizing internal resources and potentials with the ability to adapt flexibly to a dynamic external environment. Therefore, new methodological approaches are needed to evaluate and manage the processes of integrating the potentials of a balanced development of enterprises, taking into account the characteristics of external impulses that affect the development of the economic system. The aim of the study is to find approaches to improving the management of enterprise development through the organization of processes of integration of potentials and their balancing in development indicators.

Keywords: economic potential, balance of potentials, processes of integration of potentials, balanced development, management of development of socio-economic systems.

Introduction

Modern conditions of functioning and development of enterprises are characterized by an increase in the dynamism of internal and external factors of various forms of manifestation that determine the ability of economic entities to realize the accumulated economic potential. In these conditions, the realization of the aggregate potential of the economic system is largely determined by the level of integration of local potentials for balanced functioning and development. Such a set of local potentials must take into account a set of resources and resources that ensure the achievement of an adaptive dynamic equilibrium of the economic system in the face of multidirectional factors of different forms and characteristics (Alabugin, 2005).

Inadequate performance of unbalanced development can largely be explained by the inconsistency of the capabilities of internal subsystems of the enterprise to prevent multidirectional negative effects of external factors. This is reflected, in particular, in the inability of the enterprise to ensure the balance of operational processes and to function successfully in a competitive environment. In addition, internal imbalances in the integration of internal capacities are not capable of ensuring the sustainability of the enterprise's development in the long run and increasing the level of economic potential (Trusova, 2016).

The need to identify the interrelations and interdependencies of determinants that contribute to or hinder the enhancement of the economic potential of an enterprise, it is necessary to investigate the entire system of contradictions associated with its functioning. Identifying and determining the level of influence of factors-the determinants of contradictions, as well as evaluating their relationship with the results of their combined effect, allows forming a mechanism for a balanced development of the enterprise in dynamic environmental conditions. For this purpose it is expedient to use the laws and principles of taxonomy.

Characteristics of types of contradictions in realizing potentials of balanced development of enterprises

The inherent methodological connection and the conditionality of the contradictions in the realization of the potentials of the system make it possible to systematize the types of contradictions according to the signs of the closeness of the cause-effect relations (Fig. 1)

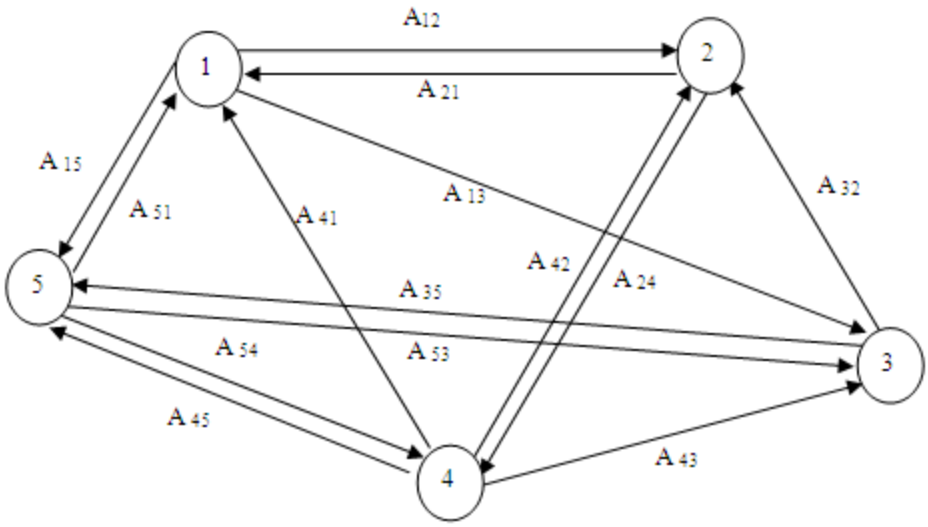

Fig. 1: Graphical model of the set of interrelated and interrelated contradictions of the potentials of the system

In the conditions of systematization, it becomes possible to compare the types of contradictions among themselves by the similarity (difference) in characteristics. This distinguishes the systematic approach from classification, which does not provide a comparison of the identified types of objects (contradictions). The variety of types of contradictions in the context of the integration of potentials is determined by the large number of directions of integration and its impacts on the balance of enterprise development (Dudin, 2015).

The main system-forming contradictions in the processes of integrating the potentials of a balanced development of an enterprise will allow us to systematize the diversity of contradictions and the types of problems they determine. The whole set of signs of the contradictions in the development of economic systems can be represented in 4 groups, differing in the level of analysis of contradictions (Camelo-Ordaz, 2015):

1. Theoretical level.
2. Methodological level.
3. Methodological level.
4. Application level.

At these levels, contradictions are determined by determinants based on the need for changes in the system and the possibilities of theory, methodology, management methods, and experience in their implementation.

At the theoretical level, such determinants are:

- need to define the main complex concept of "integration of the potentials of balanced development";
- clarification of the concepts of "integration of potentials" and "development balance";
- tightness of the relationship and the impact of quality management of the integration of potentials on the balance of development;
- stabilizing effect of the cyclicality of the processes of integration of potentials on the reduction of imbalances in development.

At the methodological level, the determinants are:

- impact of imbalances of the goals of the supporters of preferential development of individual potentials;
- impact of the conditions for minimizing imbalances of the goals of the supporters of the primary development of individual potentials;
- influence of conditions for minimizing imbalances of sustainability and efficiency objectives on the stability of potential integration processes.

At the methodological level, the following determinants can be identified:

- achievement of positive synergistic effects of integration of potentials;
- change in the entropy of the synergy of the potential integration processes;
- flexibility and controllability of processes of potential integration;
- ensuring the stability of integrating impacts of the integration of development potentials on the development balance.

At the application level, the factors-determinants include:

- increasing uncertainty and dynamism of environmental factors;
- unbalanced development of local potentials of the enterprise;
- imbalance of integrating and disintegrating influences of the goals, strategies and structures of the enterprise related to the realization of its economic potential.

Evaluation of contradictions in integration of enterprise development potentials

The need to manage the contradictions of the integration of development potentials at the applied level implies the formation of a system for managing the integration of potentials in the context of three groups:

- operational potential;
- investment potential;
- financial potential.

From the point of view of describing the state of the economic system, the operational potential (O) can be represented as a characteristic of the functioning and organization of operational business processes, expressed in their ability to take the properties necessary for the effective functioning and development of the enterprise in changing environmental conditions. At the same time, this group of potentials includes a set of local potentials that characterize the level of resource use efficiency in the context of individual operational business processes.

The investment potential (I) of an enterprise is characterized by a demonstrated and potential opportunity to carry out investment activities in the conditions of existing organizational and resource constraints. In turn, the investment potential also includes a number of local potentials that determine the ability of the enterprise to make effective investment decisions, as well as to carry out investment activities with the required level of profitability and an acceptable level of investment risk.

The financial potential (F) of the enterprise is characterized by the current and potential opportunity to provide financing for the operating and investment activities of the enterprise, using both internal financial resources and external opportunities associated with the use of various financial instruments capable of achieving the required profitability and business value with an acceptable level of financial risk.

In general, we can distinguish the following types of potential imbalances that characterize the applied level of research:

- Corporate contradictions are caused by discrepancy of interests of separate participants and stakeholders in relation to business;

- operational contradictions characterize imbalances in the implementation of individual business processes that form an added value; degree of reaction of business processes to required changes; current state of the resource base that ensures the implementation of the current activities of the enterprise.

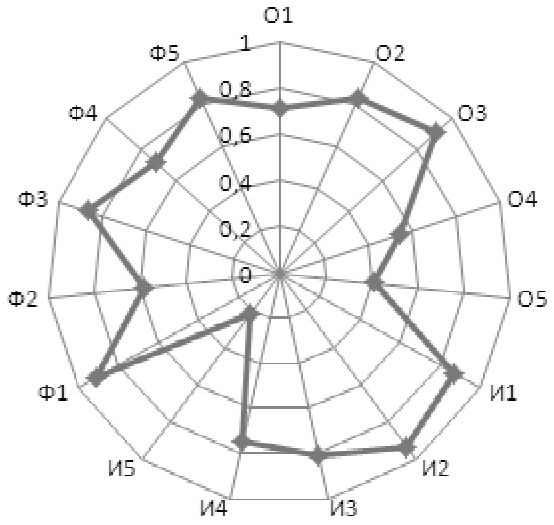

Fig. 2: Characteristic of imbalances of integration of enterprise development potentials.

At the same time, the whole set of local potentials and contradictions of the economic system is characterized by a high level of entropy caused by existing imbalances in the directions of functioning and development of individual business processes, priorities for using resources, the interests of individual participants, the level of reaction of individual enterprise processes to changes in the external environment and other factors that determine the direction of movement and development of both individual local potentials and the entire economic system.

The most important internal potential of the economic system is the organizational or managerial potential, characterized by the ability to purposefully balance the activities of individual processes, and the associated potentials to achieve system-wide (corporate) goals. In this case, the necessary effectiveness of the processes can be improved on the basis of a stabilizing cyclical model of integration of the potentials of a balanced enterprise development:

$$GP = f\{x_1, x_2, x_3, \ldots x_n\} \rightarrow \max, \quad (1)$$

where GP is the general (cumulative) economic potential of the system; x1, x2, x3…xn – a set of interconnected and interdependent local potentials; f is a functional describing the interconnection of potentials among themselves and parameters of environmental constraints.

Such a theoretical model should be able to harmonize the potentials in the iterative processes of evolutionary development by the criterion of compromise of the goals expressing the interests of the proponents of preferential development and expressing the properties of the individual potentials of the economic system. To implement such processes, it is necessary to form an integration management mechanism (IMM) that improves the quality of management in order to achieve and stabilize the sustainability of a balanced development of the enterprise.

The development balance is achievable in the context of the integration of potentials according to the criteria for the positive synergy of the manifestation of potentials. In this case, the task of the management system is also to find the optimal compromise and determine the priorities of the current functioning and long-term development, which also forms a set of limitations in the choice of the optimal control structure for the manifestations of the system potentials. Such initial assumptions of the model determine the need to include methods for identifying and implementing a set of potentials in the enterprise management system. The variety of potentials determines the importance of improving and supplementing the methods of impact management. At the same time, the toolkit for advanced investment, transforming management and change management, even with the use of knowledge management systems and balanced indicators, is insufficient.

In modern conditions of spatio-temporal disintegration and scales of integration processes, in the development of enterprises, the relevance of the balance of internal subsystems as carriers of development potential increases.

Stability of integration processes in the management mechanism can be achieved by the criterion of minimizing the imbalance of the sustainability goals and the effectiveness of the balanced development of the enterprise. Currently, the underestimation of the potential for stabilizing the quality of management of potential complexes is explained by the lack of a methodology for managing the processes of integration of potentials, aimed at balancing the development and stability of the results of integrating the processes, resources and interests of various business stakeholders. This implies the improvement of theoretical models of convergent dynamics of processes, the development of concepts, principles, indicators and methods of managing the processes of integrating the potentials of a balanced development of the enterprise (Xingyi Liu, 2016).

Substantiation of factors, directions and methods of improving the quality of management will help to identify strategies and structures that ensure the stability of the processes of integration and the balance of development of the enterprise's aggregate potential. The lack of quantitative assessments of stability and balance increases the likelihood of risks of economic losses from erroneous management decisions in the context of these imbalances. The lack of indicators and criteria for the integration of potentials in enterprises reduces the effectiveness of strategies and plans for balanced development. In this regard, it is necessary to improve the theory and methods of improving the stability of a balanced development of enterprises in terms of the integration of potentials. Forming a mechanism to improve the quality of management contributes to improving the organization of processes, the use of resources, as well as the interests of various stakeholders of the enterprise, which in turn determines the possibility of achieving positive effects of synergies of potentials (Niculiță, L., 2010).

Research and management of the balance of local potentials from the point of view of managing the total potential of the economic system presupposes an assessment of the ability of the enterprise's business processes to increase the added value per unit of time, despite the increase in the inertial forces of the system and an increase in the total entropy, expressed in increasing aggregate risks. The final assessment of the balance of the potentials of the enterprise implies the study of the compliance of their parameters

with the established requirements, determined for each group of parameters of the enterprise development potentials.

The manifested result of local potentials can be considered as a point in n-dimensional Euclidean space, while the coordinates of the point are the values of the indicators of local potentials over which the estimate is made. The standard in this case is the required value of the parameters of the state of individual potentials, based on the required characteristics of its quality with respect to any higher-level potential (Raffaele Fiocco, 2016).

By the combination of the correspondence of the parameters of local potentials to the established requirements, the evaluation of the potential balance is estimated as:

$$K_i = \sqrt{(1 - x_{11})^2 + (1 - x_{21})^2 + \cdots + (1 - x_{ni})^2}, \quad (2)$$

where xni – a standardized indicator of compliance with the n-th required (normative) indicator of the i-th type of development potential.

$$X_{ki} = \frac{a_{ni}}{a_{norm\ ni}}, \quad (3)$$

where ani – value of the n-th indicator of the i-th type of development potential, anorm ni – required (normative) value of the n-th indicator of the i-th type of potential (Pollack,2016).

Conclusion

Achieving the required level of integration of potentials for long-term development of enterprises is one of the key tasks of modern research in the management of socio-economic systems, and at the present time, integration processes are not sufficiently studied by methods of improving the quality of management based on additional functions and quality indicators of their application to achieve stable Results of balanced development of the enterprise. At the same time, this approach can be implemented on the basis of the formation and management of the integration of balanced development potentials at various levels.

At the enterprise level, the result of the assessment of the development potential allows us to determine the balance of local potentials, and to identify their compliance with the parameters of the development of the enterprise as a whole. In addition, this approach allows us to analyze the current state of the total economic potential of the enterprise, and to identify key imbalances that restrain its development. This analytical information can serve as a basis for management actions, including the development of management regulations to improve the operation of the enterprise and the balancing of its individual business processes and regulations.

Willingness to Accept for Municipal Waste Recycling:

A Case Study from Lima, Peru

R. Oliver Castañeda Limas, Universidad San Ignacio de Loyola, Lima, Peru, olivercl23@yahoo.com
J. Fernando Larios Meoño, Universidad San Ignacio de Loyola, Lima, Peru, flarios@usil.edu.pe

Abstract

Waste management seems to be a wide challenge for cities in developing countries. Resource constraints and inefficient institutions inevitably call for labour from the informal sector in this activity. We employ the contingent valuation method and a logit model to estimate recyclers' Willingness To Accept (WTA) to participate in recycling household's waste in Lima (la Victoria District). We examine various aspects, including socioeconomics factors, awareness and recycling activity.
The required WTA estimate is 1,355.86 Soles (USD 413.13), higher than both the minimum living wage fixed at 750 Soles and the monthly per capita productivity of recyclers, calculated at 986.05 Soles (USD 300.45), using a market prices method in the latter. The economic value of solid waste finance more than 70 percent of the recyclers' monthly willingness to accept, considering recyclers productivity. Although this is a promising outcome, there is a need for further research on the effects of education, attitudes, and awareness of solid waste management from both the public and private sectors.

Keywords: Waste management, contingent valuation, informal sector, Lima.

Introduction

Overview

Municipal waste management in developing countries is characterized by the weak participation of the public sector, although it implies a large part of the municipal budget, between 3-15 percent according to estimates (Masood and Barlow 2013, Wilson et al., 2012). The presence of resource constraints and inefficient institutions imply the role of the informal sector in this management (Gutberlet, 2008). In the case of Peru, around 100,000 people work as recyclers, more than 50 percent of them in Lima Metropolitan (Diaz and Otoma, 2012). Informal sector in waste management is characterized by its diversity of practices (waste collection, disposal and resale of recyclable products,...) and profiles: recyclers, sellers, micro enterprises, NGOs, communities, etc. It is also defined by its low productivity level and the presence of high risks for health by emissions of harmful substances impacting workers and their families living near landfills. However, the role of the informal sector is essential for the municipal waste management, through the interrelations between the public sector and private enterprises in the formal sector. Similarly, governments and cities in developing countries have an increasing responsibility to develop an integrated and inclusive approach to waste management (Gutberlet, 2008; Sembiring and Nitivattananon, 2010).

We employed the contingent valuation method to estimate the recyclers' perception of Lima (la Victoria District) to recycle. We examine various aspects of recyclers' perception of municipal

waste collection, in particular. First, we investigate the factors that can improve participation in municipal waste collection, including socioeconomics factors, awareness and recycling activity. Then, we analyse average incentive levels, approximated by the willingness to accept (WTA) required attracting recyclers' participation in municipal waste collection and whether incentives are appropriate, given the current recyclers' productivity and municipal waste market price.
The contributions of this study are twofold. First, few studies include the informal sector in contingent valuation approach (Afroz et al., 2009). This study is probably the first to concern evidence about recyclers' perception in Lima about municipal waste. Second, most of studies concern evidence for willingness to pay (Damigos et al., 2016; Afroz & Masud, 2011; Akhtar et al., 2017; Challcharoenwattana & Pharino, 2016; Ezebilo, 2013; Hazra et al., 2013; Rahji & Oloruntoba, 2009) and few concern willingness to accept (Basili et al., 2006; Cho et al. (2015).

Waste Management in Lima and la Victoria District

La Victoria (Lima City) is one of the smallest district of Lima (8.74 km²), but the waste production per capita is almost double, compared on average to the other districts (0.976 kilograms<1.94 kilograms). The commerce and industry generate waste represented by the so-called Gamarra Mart, which includes thousands of shops (fruit markets and popular kitchens and restaurants). The streets are contaminated by solid waste, affecting hospitals and other places that clearly seek an improvement in the quality of life. As presented in Figure 1, the main component of the Municipal waste is the organic waste, approximately 45% of the total waste.

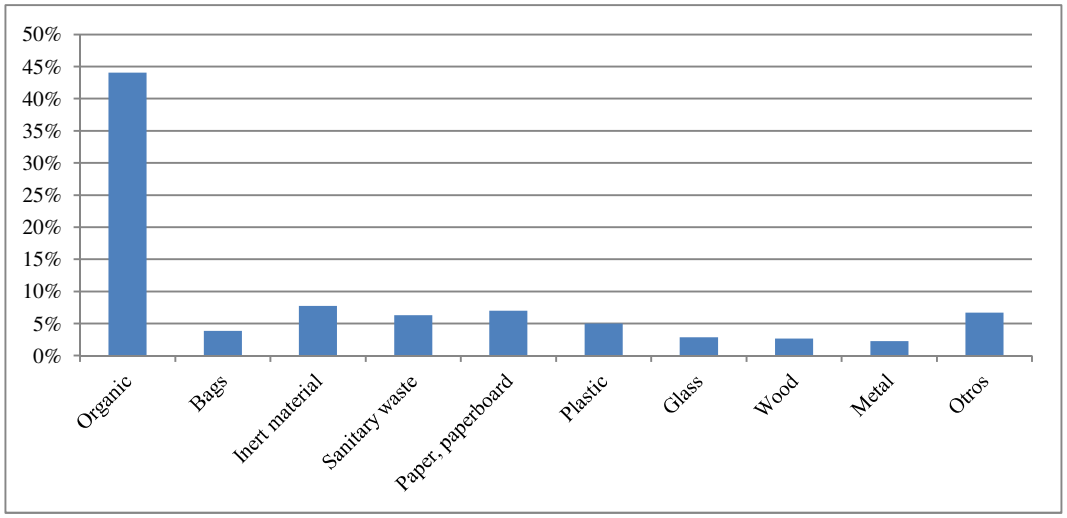

Fig 1: Main components of the municipal waste in the Coast Region of Peru, 2013. Source: 6th National Report on Solid Waste of Municipal and No Municipal Management, 2013.

Since 2011, the Ministry of the Environment has been implementing a national program called the Program for Sorting at the Source and Selective Collection of Solid Waste. According to the Ministry (2014), the criterion of a recycling economically efficient implies the collection of waste at the source by 100 percent community support of a locality.

Methodology

Measuring

The contingent valuation method attempts to measure changes in the welfare of people in money, due to an increase or decrease in the quality and / or quantity of a good, this measure in monetary units is usually expressed in terms of the maximum amount that a person would pay for a good, also known as the Willingness to Pay, or the minimum amount that a person would accept to be compensated for not having a good or service, also known as the Willingness to Accept.
To model willingness levels for tolerating loss, the utility function is defined as follows,

$$u_j = v_j(p, y; q_j) + \varepsilon_j$$

Where j=0 is the initial situation and j=1 represents the changed situation, in this case the improvement in the quality of the environment, and *y* represents the family income, p is the vector of prices that individuals face to get their goods and q represents the quantities that individuals ultimately consume, ε the error term.
Hanemann (1984) describes the mathematical behavior equivalent to the willingness to pay, in this investigation we represent in a similar way the mathematical behavior for the willingness to accept.

$$\Pr(si) = \Pr\left[v_1(p, y; q_1) + \varepsilon_1 < v_0(p, y + A_t; q_0) + \varepsilon_0\right]$$
$$\Pr(si) = \Pr\left[v_1(p, y; q_1) - v_0(p, y + A_t; q_0) < \varepsilon_0 - \varepsilon_1\right]$$
$$\Pr(si) = \Pr\left[\Delta v < \varepsilon_0 - \varepsilon_1\right]$$
$$\Pr(si) = \Pr\left[\Delta v < \eta\right]$$
$$\Pr(si) = F_\eta(\Delta v)$$

Where F_η remains the cumulative distribution function of η which also remains η =$\varepsilon_0 - \varepsilon_1$, and Pr represents the probability of such a situation occurring. It is understood that the payment is an amount to receive (Hanemann, 1984), so A_t is positive in the equation, in addition the initial situation and the amount received are more useful than the final situation. If the indirect utility function is linear we have for the initial situation:

$$v_0 = \alpha_0 + \beta(y + A_t) + \varepsilon_0$$

Finally we observe:

$$v_1 = \alpha_1 + \beta y + \varepsilon_1$$

The difference between these two utilities represents the change in well-being:

$$\Delta v = v_1 - v_0 = \alpha_1 - \alpha_0 - \beta A_t + \varepsilon_1 - \varepsilon_0$$
$$\alpha_1 - \alpha_0 + \varepsilon_1 - \varepsilon_0 = \beta A_t$$
$$\alpha - \eta = \beta A_t$$
$$A_t = \frac{\alpha - \eta}{\beta}$$

Where A_t represents the disposition to Accept.

Logit model

The participation in recycling is influenced by socioeconomic factors, awareness of recycling activity and initial bid amount. These potential determinants are examined by estimating the following binomial logit model,

$$P_i = \frac{1}{1 + e^{-Z_i}}$$

where $Z = \beta_0 + \beta_i X_i$

P_i represents the probability of an event occurring given certain variables called X_i, the utility of the model consists in that Z_i as takes infinite values, the probability that the event occurs will be a dichotomous variable with a value of one if the respondent states that they do want to accept the amount of S /.1200 soles per month to recycle and a value equal to zero if the respondent states that he does not want to accept the amount. β_0 represents the intercept of the model. X_i represents a set of explanatory variables of the model, corresponding to the survey questions to recyclers. The subscript i refers to the number of variables included in the model (5 exogenous variables). β_i represents the set of betas parameters related to each of the explanatory variables, the subscript i in this case is related to the explanatory variable that we mentioned in the previous paragraph. The coefficients are 6, one for each model variable and one intercept. u_i represents the error of the econometric model. Finally, the average productivity of a recycler has been defined using the market price method.

Questionnaire design

The questionnaire included five sections. The first and fifth section presented questions about the recyclers' socio-economic characteristics, such as gender or education. The second section included questions related to awareness. The third section reported information about willingness to accept and the fourth to the recycling activity.

Data description

Sample selection

The population analyzed is the total of recyclers working in the La Victoria district, Lima. Due to the lack of formal data on the amount of recyclers in the district of La Victoria, a short random interview with some recyclers in the La Victoria district was carried out. From this interview it can be seen that there are approximately 400 recyclers in this district. This data was corroborated with personnel working in the municipality of La Victoria who were not clear about how many recyclers are currently working in La Victoria. To make the calculation of the sample of analysis, we use the characteristic formula for the calculation of a sample for a finite population of individuals, according to the following equation:

$$n = \frac{N\ (Z^2)\ p\ q}{d^2(N-1) + Z^2\ p\ q}$$

Where n represents the sample size, Z the Degree of reliability (1,645), p the probability of occurrence of the event (0.5), q the probability of non-occurrence of the event (0.5), d the level of significance (0.10) and N the size of the total population (400).

Therefore, our total sample represent 58 persons. In addition, a pilot survey was carried out on 20 recyclers, which were added to the research sample for the purpose of improving the sample size and thus moving away from the problems that can present a small sample, because while the

samples are larger the estimators have diverse desirable statistical properties. Finally, 78 surveys were carried out.

Socio-economic characteristics

The population surveyed consisted of among 400 recyclers from La Victoria district aged from 20 to 82 years old. A questionnaire was administered to 78 individuals. The survey was conducted via face-to-face interviews in 2016.

Table 1 summarizes the socio-economic characteristics of the respondents. The target population included recyclers. Due to particularity of the recycling activity, mostly occupied by men; the sample was composed by 98.7% male and 1.3% female. The respondents' ages ranged from 20 to superior to 71, with the majority (38.5%) between 51 to 60 years old. The education level corresponds from basic school completed (29.5%) to high school uncompleted (34.6%).

Table 1: Descriptive statistics for recyclers' socio-economic characteristics

Characteristics	Number of respondents
Gender	
Female	1(1.3%)
Male	77(98.7%)
Age	
20-30	9(11.5%)
31-40	5(6.4%)
41-50	12(15.4%)
51-60	30(38.5%)
61-70	17(21.8%
> 71	5(6.4%)
Education	
High school completed	18(23.1%)
High school uncompleted	27(34.6%)
Basic school completed	23(29.5%)
Basic school uncompleted	10(12.8%)

Awareness of and attitudes toward recycling

The respondents were generally concerned about the problem of municipal waste (Table 2), according to the mean statement (6). However, the respondents seem not concerned about health impact of recycling activity (3). The awareness about environment seems moderate (5). Then, the respondents reported the awareness on their activity, comparing to other collectives. The impact activity is higher (14), considering other groups (authority (6.2), community (6.8)). Finally, the respondents are very concerned to improve their labor situation and occupy a formal job.

Table 2: Awareness of the socio-environmental effects of waste management in La Victoria district (Lima, Peru)

Variable	**Mean (S.E)**
Problematic of urban waste (0=no problem-10= high problem)	6 (2)
Awareness on waste impact on health (0= no impact-10= high impact)	3(3)
Awareness about environment (0= no impact-10= high impact)	5(3)
Awareness of the recycler's activity on environment (0= no impact-20= High impact)	14(2.5)
Awareness of the authority's activity on environment (0= no impact-20= High impact)	6.2(4.2)
Awareness of the community's activity on environment (0= no impact-20= High impact	6.8(4.3)
Willingness to occupy a formal job (0=no; 1=yes)	0.8(0.4)

Results

Factors influencing participation in recycling activity

Table 3 summarizes the definitions and descriptive statistics for the explanatory variables.

Table 3 Definitions and descriptive statistics for explanatory variables

Variable	Definition		Mean (S.D)
WTA	Willingness to accept		1567.3 (1323.4)
DAY WORK	Number of day worked in a week		6.2 (1)
DISTANCE	Number of kilometers covered in a week		16 (9.1)
PROD	Productivity per Capita		1469.9 (1282.1)
HEALTH	Awareness of the health effect of Waste Municipal Collection (1-10: 1 not at all concerned; 10 very concerned		0.3 (0.3)

The results to estimate the minimum wage for a recycler of the La Victoria district would be willing to accept to carry out future activities of recycling, is on average S /. 1,355.86 soles per month (Table 4). The econometric model was corrected for heteroskedasticity problems with the standard errors and Huber-White (QML) method of covariance.
On the other hand, the test of significance for the variables is checked with the z-statistic that is analogous to Student's t of linear models and has a null hypothesis of non-significance for each of the variables, therefore for all variables model can be verified to reject the null hypothesis raised in this test, which means that all coefficients of the model are significant, except the intercept coefficient, fulfilling the expected results in a model with logistic cumulative distribution.
Similarly we can evaluate the joint significance of the variables of the models with the statistical LR (likelihood ratio) which is also equivalent to the statistical F for linear models and has as null hypothesis the joint significance of the estimated coefficients, so we can observing that there is no probability to accept this hypothesis, and for this reason the coefficients as a whole are significant to explain the behavior of the probability of the event.

The R^2McFadden in parallel with the account R^2 are the most suitable indicators to analyze the goodness adjustment of the model. We can observe the first value obtained is equal to 0.79 which is totally acceptable for these cases , despite not being a relevant data of the model. For the case of account R^2 we obtained a value of 94.87 and we must take into account that for this value is expected a behavior above 60%. This value implies that the model is predicting correctly 94.87% of the cases. Therefore we can conclude that the goodness adjustment of the Logit model is adequate.

The coefficient associated with the variable WTA indicates the probability of accepting the labor supply decreases by 0.507% when the amount earned at least by a recycler increases from S/. 1 sol. Additionally, we observe when current productivity of the recycler increases from S/. 1 sol, the probability of the recycler accepting the labor proposal decreases by 0.424 percent. When the current recycler travels one kilometre more, the probability of accepting the labor supply decreases by 39.55 percent.
The positive sign on the coefficient for the variable DAY WORK indicate recyclers working more days are more likely to accept the job offer. Finally, the perception of the health problem is positively related with the labor proposal.

Table 4: Determinants of participation in recycling activity

Productivity of Recyclers

According to the Sixth National Solid Waste Report for the Management of the Municipal and Non-Municipal Scope 2013 of MINAM (2014), the composition of urban solid wastes from the coast Region, including Lima Metropolitan is shown in figure 1. Table 4 reports only 4 types of recyclable materials.

SINIA (2016) in its environmental indicators, reports that in the district of La Victoria in 2013 a total of 126,997 tonnes of municipal solid wastes was recorded, that is, if we count the total of paper, cardboard, glass and plastic which could have been obtained in that year would have the calculation of table 8. We report the economic value of these materials at market prices with the prices of 2016, obtained from the survey applied to recyclers for these materials.
The evidence shows that for a minimum wage equivalent to S / .1,355.86 soles per month, it seems a total of S / .16,270.32 soles by year, it would have been possible to cover the annual salary of 487 recyclers (Table 5). To conclude, we observe that the estimated population registered in SIRTOD (2016) for the district of La Vitoria in 2016 concern 169,239 inhabitants, so we estimate that each recycler in this group of 488 must attend to 346.8 inhabitants of the district and thus be able to cover 100% of the area, collecting solid waste in source of origin, minimizing the use of energy, maximizing the use of recyclable materials, improving the working conditions of recyclers, generating formal employment, reducing pollution, and of this sustainable development, achieving eco-efficient self-financing of eco-efficient recycling.

Table 5: Economic value of the material recycled from 2013 (2016 price)

Category of waste	Proportion	Total Kg	Average Price 2016	Economic Value
Papel	3.79%	4´813,186	S/. 0.36	S/. 1'732,747
Paperboard	3.26%	4´140,102	S/. 0.25	S/. 1'035,026
Glass	2.88%	3´657,514	S/. 0.12	S/. 438,902
Plastic	5.56%	7´061,033	S/. 0.67	S/. 4'730,892
				S7. 7'937,566

Conclusion

With the use of a contingent valuation method and a logit model, we have estimated that a recycler from the La Victoria district would be willing to accept (WTA) a minimum monthly wage of S / .1,355.86 Soles on average. We built an indicator of recycler's monthly per capita productivity in the district of La Victoria by the amount S / .986.05 Soles at market prices.

The economic value of the average recycling activity in the district of La Victoria, estimated at S /. 7,937,566 Soles, can currently finance up to 72.72 percent of the recycler's monthly disposition to accept recycling glass, paper, plastic and cardboard in 2013 in the La Victoria district, at 2016 prices. The WTA fixed at a monthly salary of S/. 1,355.86 Soles can finance up to 488 eco-efficient recyclers. Given that the district of La Victoria currently has an estimated population of 169,239 inhabitants, each eco-efficient recycler could meet 347 inhabitants' needs for waste management. Under a future scenario of eco-efficient recycling, 100% of workforce could be financed by the value obtained from municipal solid waste in the district of La Victoria.

In addition to the willingness to pay method, the present work focused on the WTA can serve as a complementary reference for local governments, NGOs and recycling enterprises to maximizing the use of recyclable materials, improving the working conditions of recyclers, generating formal employment and achieving sustainable development goal self-financing recycling.

Abstract

The article is devoted to testing the analytical potential of free cash flow in macro- and microeconomic research on the financial stability of nonfinancial businesses. Using the example of Russian companies in the transport industry, it is shown that the possibilities of applying this indicator in conditions of an undeveloped financial market are limited. An analysis of available information about Russian companies in the industry under study in the Bloomberg Professional system revealed that the FCFF to net debt ratio data, which could theoretically be successfully applied in monitoring the financial stability of the corporate sector, is not indicative. In particular, there are inaccuracies and inadequate information on companies of interest. At the level of individual enterprises, the potential for free cash flow in assessing financial stability should be generally assessed positively. For this purpose, it was proposed to apply the ratio of the company's value, estimated on the basis of the adjusted value of FCFF, and its net debt, which corresponds to the concept of assessing the corporate liabilities by Black-Scholes-Merton. It is argued that the accuracy of the assessment largely depends on the completeness of the information on the company's investment and financial plans, the possibility of their implementation, in turn, is often limited in the Russian financial market.

Keywords: free cash flow, free cash flow to firm, financial stability, corporate financial stability.

1 Introduction

Assessing financial stability of nonfinancial businesses is in demand when justifying a wide range of management decisions (Bobyleva and L'vova). Moreover, we are talking about macro- and micro-levels of analytical problems. In first case, as suggested by I. Fisher (1933, p. 341-343) and later argumented by H. Minsky (1992, p. 7-8; 2017), the financial instability of nonfinancial businesses is a factor of the financial systems' fragility, which actualizes monitoring the financial stability of the corporate sector. In the second case, the financial stability of the company, which in the most general sense is associated with an acceptable low probability of financial insolvency (bankruptcy), is analyzed by external analysts as a factor of creditworthiness, investment attractiveness, and payment discipline of the counterparty. At the same time, internal analysts are interested in a systematic assessment of financial stability in order to justify decisions on the operating, investment and financial activities of an economic entity.

The scope of practical application of the commented assessment in the context of microeconomic problems is detailed in the classic works of the bankruptcy forecasting school by W. Beaver (1966, p. 71), E. Altman (1968, p. 609), J. Wilcox (1970, p. 11), J. Argenti (1976, pp. 16-17), J. Taffler (1983, pp. 295-296, 306) and others.

It should be noted that the methodology for assessing the financial stability of nonfinancial businesses is not unified and requires development (Lvova et al, p. 682). Macroeconomic research on this issue is mainly limited to a small set of indicators. The assessment appeals to individual macro indicators (including the volume of industrial production, the volume of investments in fixed assets, the volume of direct investment) or is based on financial ratios calculated from the aggregate financial statements (Financial Soundness Indicators). Particular attention in the context of financial stability is paid to the level of the debt burden of the nonfinancial sector (Drehmann and Juselius) which is also evaluated on the basis of macro-indicators or using aggregated micro-indicators (Adrian et al, p. 30; Donets and Ponomarenko; Donets and Mogilat, Financial Position of the Largest Enterprises).

The toolkit, which can be used for microeconomic research of financial stability in this case, is more diverse. However, traditional financial ratios are generally used as benchmarks for a variety of models. In particular, despite the high importance of cash flows in assessing the financial health of enterprises (Beaver; Wilcox; Altman and Hotckiss, p. 110-115) and the priority role of assessing solvency in modern insolvency systems (Abramishvili et al, pp. 362-363), preference is given to the indicators of the balance sheet and the financial results report. Thus, the analytical value of cash flows is somewhat underestimated, which determined the general direction of the study. In this paper, we refer to the free cash flow of the firm, analyzing the analytical potential of the indicator in order to assess financial stability on the example of Russian transport enterprises.

Methodology

At the *first stage* of the research, the potential of free cash flow on the example of FCFF to net debt ratio is tested for macroeconomic analysis of the financial stability. Based on the financial meaning of the coefficient, it is assumed that if its average value for the sample is more than one, then the analyzed companies in the period under study with a common equal are characterized by financial stability. Negative dynamics of the average value of the coefficient, from the position of assessing financial stability, is undesirable.

As an example, selected Russian companies specializing in commercial cargo transportation[1], that correlate with the second stage of the study. Initially, the sample included 28 public companies, that had information about them for the query of interest are available in the Bloomberg Professional. According to the results of the company data analysis, the sample had to be reduced to 17 units, because, firstly, the economic activity of individual companies did not correspond to the investigated sector; Secondly, even for a three-year period (from 2012 to 2016) for some companies, financial reporting data was completely or partially absent; Thirdly, cases of duplication of financial data on companies in 2015 and 2016 were noted.

Information on the companies excluded from the sample is presented in tab. 1.

Table 1: The list of the companies excluded from the sample

#	Name	The reason(s) to delete from the sample	Short Description
1	Molkom	Misclassification	The Company produces a wide range of dairy products. Its products include milk, yogurt, butter, cheese and diary desserts.
2	Aviapark		The Company produces general construction works for the aviation industry.
3	UPPO		The Company, also known as Ulan-Udenskoe Priborostroitelnoe Proizvodstvennoe Obiedinenie, manufactures electro technical and electronic equipment for aviation. It also offers a variety of consumer goods, as well as industrial and

#	Name	The reason(s) to delete from the sample	Short Description
			technological products.
4	Sovfracht	No relevant financial data available	The Company provides transshipment of oil via ports and rails and provides a range of related services.
5	Koltsovo Airport		The Company operates an airport in the Urals on the border of Europe and Asia. The airport offers international air passenger transportation services.
6	Novorossyisk Grain Plant	No relevant financial data available for 2014, 2015	The Company operates a grain terminal and services related to grain cargo transshipment. Its infrastructure includes railways and roads, transport garages, mechanical workshops, power plants, and laboratories. Novorossyisk Grain Plant operates in Russia.
7	Passenger Port	No relevant financial data available for 2014	The Company provides passenger transportation and tourism related services.
8	Yakutia Railways	The data for 2016 duplicates the previous year	The Company primarily transports coal and metal ores.
9	Vostochny Port		The Company is located in the Russian Far East and provides mainly coal handling with usage of conveyer equipment. It also transports metals, timber, ore, chemical cargoes, cement, and other commodities.
10	Kuban Territory Agency of Air Transport	Misclassification; besides, the data for 2016 duplicates the previous year	The Company provides electronic services for customers and travel agencies with ability to access flight schedule information, as well as book reservation and tickets for airlines.
11	Transsignalstroy		The Company provides automatic control, teleautomatics, radio-communications, power supply, fire-alarm and protective signaling, and traffic safety equipment.

Source: Bloomberg Professional.

The final list of the analyzed companies is given in tab. 2.

Table 2: The analyzed sample

#	Name	Short Description
1	Vanino Commercial Sea	The Company offers shipping port services: loads, unloads and stores shipping containers, loads and unloads general cargo and provides other related services.
2	Uralpromaheldortans	The Company provides cargo handling and industrial rail transportation services. It manages enterprises of power industry, building materials manufactures, as well as wholesale and retail trade in Russia.
3	Transstoursevice	The Company operates a bus service in Moscow: offers rides and tours around the city, corporate transportation, renting out buses for intra- and intercity routes, airport shuttles, and bus repair.
4	TAXF	The Company operates a taxi service in Russia.
5	Taganrogsky Morskoy Torgovy	The Company operates a port facility. It loads and unloads ships; forwards freight; warehouses goods; offers customs services; moors

#	Name	Short Description
	Port	and tows ships; and loads and unloads shipping containers.
6	Omskiy Aeroport	The Company provides a full range of services including domestic and international air transportation, air traffic control, terminal management and cargo handling.
7	Omsk River Port	Omsk River Port, or Omsky Rechnoy Port, operates a port facility in Western Siberia.
8	Novorossiysk Commercial Sea Port	The Company owns and operates the Novorossiysk Port on the Black Sea. It processes, loads, and unloads cargo. Novorossiysk Commercial Sea Trade Port handles mainly crude oil but also services dry cargo such as metals, cement, sugar, grain and containers.
9	Novoroslesexport	The Company is a large universal port, located on the northeast coast of the Black Sea. It handles cargoes, with priority to container handling and transshipment of timber goods.
10	Murmansk Commercial Seaport	The Company owns and operates commercial seaport on a territory of Murmansk, Russia. It processes, loads, and unloads cargo and crude oil.
11	Kurumoch International Airoport	The Company operates the Kurumoch International Airport and offers domestic and international air transportation services, including traffic management, storage, airplane maintenance and other related services.
12	Commercial Sea Port of Magadan	The Company, also known as Magadanskiy Morskoy Torgoviy Port, provides cargo processing, storage and warehousing services.
13	Commercial Port Posiet	The Company operates a seaport and warehouse in Russia that provides shipping services and cargo processing.
14	Commercial Port of Vladivostok	The Company handles a variety of cargoes, including bulk, liquid cargo, forest products, and general cargo, including containers as well as passenger ships. The port operates an oil terminal and provides storage and transportation services.
15	Center for Cargo Container Traffic	The Company (also named as TransContainer) provides rail container transportation services: offers freight-forwarding, logistics, terminal services, container trucking, and rail transportation services.
16	Anapa Airport	The Company offers scheduled flight services. The Company serves a resort zone of the Black Sea coast of Caucasus.
17	Aeroport Tolmachevo	The Company operates an airport in the Ural Region, Russia. The Airport offers domestic and international transportation services, including traffic management, storage and airplanes maintenance.

Source: Bloomberg Professional.

In the *second stage* of the study, the potential of free cash flow is tested for microeconomic analysis. In particular, the assessment of financial stability is proposed to be carried out by the value to debt ratio, which is calculated on the basis of free cash flow and net debt of the enterprise.

In this case, we are talking about the valuation of the company on the basis of a revenue approach, one of the methods within which the DCF model, traced back to J.B. Williams (1938) and I. Fisher (1930), acts Depending on the purposes of modeling the cash flow, it can be presented to the owners of the company (cash flow to equity) or to all people that finance the company's activities (cash flow to invested capital). There is the free cash flow to equity (FCFE – free cash flow to equity), with which valuation of the company's shareholder value is associated (Lucasevich, p. 105), and free cash flow to invested capital, which can be countered by the total value of the company (FCFF – free cash flow to firm). Discounting a particular type of cash flow, we get either the value of the company's equity, or the value of the total invested capital, which must be adjusted for the amount of debt.

Following the Black-Scholes-Merton corporate liabilities model (BSM-model), net debt is proposed to be considered as the price paid to creditors by owners for the possibility of further business continuation. In the event that the value of the company as acting exceeds the corresponding price, it is advisable for the owners to satisfy the demands of creditors, which allows a positive assessment of the financial stability of the business. Positive dynamics of the indicator also positively characterizes the company being analyzed.
Note that in the original model of BSM it is not a question of net debt, but of the total debt which, moreover, in the original version of the model is represented exclusively by 'the simplest case of corporate debt' (Merton, p. 452). However, an estimate based on net debt is more correct, since, if necessary, part of the debt can be repaid by cash. In addition, it is proposed to make corrections to the formula FCFF (fig.1).

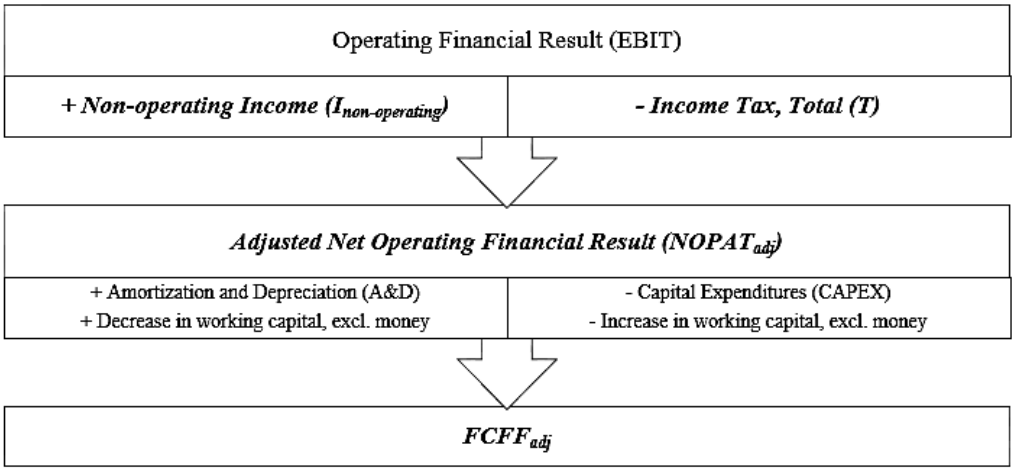

Fig 1: The model of $FCFF_{adj}$ evaluation[2]

The model is reasoned by the initial financial meaning of the indicator. Applying this approach, we can obtain the correct value of the residual income for investors. It is critical for Russian companies since they are usually characterized by the regular substantial rate of non-operating income. This situation contradicts the principles of reasonable and fair representation of financial statements. However, it cannot be ignored.

This model was tested on the example of a transport company operating in one of the major ports of the Baltic Sea. The company in question provides services for the supply and cleaning of wagons on the territory of the port, services for renting a locomotive with a crew, freight forwarding services and so on. The choice of the company is due to the growing role of the large ports of the North-West of Russia in the conditions of fulfilling the instructions of the President of Russian Federation, who ordered to export Russian cargo only through native ports. Only in St. Petersburg and Leningrad region the owners of Russian port terminals until 2025 invest in the development of capacities of more than 1 trillion rubles[3]. The fact that the industry under consideration will develop dynamically in the coming years makes it, undoubtedly, an interesting object for research.

3 Results

According to the results of the *first stage* of the study, it was revealed that the analytical potential of free cash flow for macroeconomic analysis of the financial stability is limited. Information necessary for the calculation, even with respect to public companies, is often absent (tab. 3).

Notes: # – the number of a company in a sample (see tab. 2); FCF/ND ratio is calculated by the authors.
Source: Bloomberg Professional.

It should be noted that the analyzed companies repeatedly observe a negative value of net debt. This means that the FCFF / ND ratio for these companies will not be correct. Thus, conclusions about financial stability using the analyzed indicator are possible only for five sample companies, which even in this case is not indicative.

Consider the results of the *second stage* of the study.

It should be revealed how the difference in cash flow estimation can change the business value using the discounted cash flows model for the FCFF. To demonstrate the differences the authors applied the case of the company that has significant other income and expenses that reflects on the FCFF estimation. All calculations are based on retrospective analysis of financial statements and subsequent forecast. The WACC model, based on the cumulative approach, was used to determine the discount rate (tab. 4, 5).

Prepared by the authors.

The tables show that there is the huge difference between results, getting by the alternative models. This demonstrates how it is important to estimate the FCFF correctly. In summary, we note that the traditional method of calculating the FCFF requires revising. It seems that the research results are potentially demanded to develop the methodology of financial analysis, business valuation and value-based management.

Further, for the second (correct one, from our point of view) cost calculation option, the forecast value to debt indicator was determined, which made it possible to assess the financial stability of the company in question. To do this, we used the forecast data on the schedule of repayment of the existing debt in the amount of 234,8 million rubles. In addition, information was taken into account about the lack of plans to attract new borrowings. Net debt was correlated with firm value assessed on the FCFF basis (tab. 6). The calculation results are presented below (tab. 7).

Table 7: Value to debt ratio for company

Figure	2nd half-year 1	Year 2	Year 3	Year 4	Year 5	Year 6
Net debt	186,593	109,857	60,576	-13,991	-79,916	-131,027
Debt	234,765	198,476	135,786	80,567	38,897	10,789
Δ Debt	-	*-36,289*	*-62,690*	*-55,219*	*-41,670*	*-28,108*
Interest paid	*-26,552*	*-22,448*	*-15,357*	*-9,112*	*-4,399*	*-1,220*
FCF	*74,724*	*147,355*	*153,258*	*158,889*	*164,882*	*171,144*
Cash and equivalents	48,172	88,619	75,210	94,558	118,813	141,816

Firm value / Net Debt	6.00	10.37	19.60	-	-	-

Prepared by the authors

Obtained results let us assume that the analyzed company is financially stable and its financial position is expected to improve. However, it also shown in the table that net debt often takes on negative values, which does not allow a correct assessment of the company's financial stability by the proposed method. This indirectly suggests that the company has limitations in attracting additional sources of financing. In addition, a significant amount of cash indicates the existence of restrictions on the available forms of investment for relatively small Russian companies. However, it is possible that, given the rapid development of this industry, the company will still adjust its investment and financial plans.

Conclusions

The study showed that the potential of free cash flow for macroeconomic analysis of the financial stability in case of the Russian nonfinancial business sector is inadequate. Although the free cash flow to debt ratio (or its modifications) is widely used in practice, in the Russian context free cash flow is often replaced by marginal profit[4], which is a very significant simplification and, accordingly, can lead to inaccurate conclusions. The reason for such a replacement is completely explained by the lack of necessary information, which was illustrated by the example of the Russian Railroads and Transportation Services Sector.

It should also be noted that the number of companies, based on the results of a detailed analysis of the sample, eligible for research, has decreased almost twofold. This situation reflects the features of the financial market, which is characterized by a low level of development of the corporate segment. The share of public companies, characterized by liquid shares, relative to the total population of companies is extremely small (Darushin et al, p. 820-821). At the same time, the level of transparency of financial information about companies is unsatisfactory, which allows to judge the high level of information asymmetry, which, in turn, is an important factor of financial instability (Mishkin, p. 6). It is also worth noting that the data of information and analytical systems requires

careful verification and, therefore, partly limits the ability to work with large data sets about companies.

With regard to the possibility of applying free cash flows to assess and forecast the financial stability of a particular company, the success of its application will largely depend on an understanding of its investment and financial plans. Thus, the assessment of financial stability using this indicator will be relevant exactly for as long as the company's plans for investments and sources of financing its activities are detailed. Equally important is the overall level of development of the financial market, which influences the implementation of the company's investment and financial plans.

Endnotes

[1] In the Bloomberg Professional, there is a combined 'Railroads, Transportation Services Sector (ICB)', which is correspondingly comprised of the 2 775 and 2 777 sectors by the FTSE Industry Classification Benchmark.

Abstract

The austerity implementation experience of the Estonian Government during the European financial crisis has high value both in practical terms when improving preparations for future crises, but also as a case for academic research, especially when compared with the other Baltic States and Visegrad countries. The crisis response was even more complicated as a simultaneous goal was set to fulfil Eurozone accession criteria. When studied carefully and Estonian experience is valuable from the wider future perspective as it offers experience and answers as to whether extreme austerity is an efficient solution to counter a financial crisis, the economic and social costs it includes, the best administrative practices too be suggested when implementing austerity and some hints how to implement unpopular austerity politically.

Keywords: European Union, austerity, public sector, financial crisis, management

JEL Classification: E42, E58, G18, H12.

Introduction

The economic developments, financial choices, political dilemmas and final achievements of the Baltic States in the years of financial crisis (2008-2011) offer both valuable practical experience and academic inspiration for research. These countries, while following similar goals and paths between regaining independence and accession to the European Union (EU) in 2004, have chosen in many aspects different priorities after the EU accession, which led them into different economic and political situations at the beginning of global financial crisis in the year 2008.

Comparative regional research on financial, economic and social stress management during the financial and economic crisis in 2008-2011 is extraordinarily interesting, as it includes a set of very similar states historically and economically, but these states chose rather different strategies in 2008-2011 to counter the crisis. The financial crisis management experiences in the Baltic States and Visegrad countries also offer bases for theoretical analysis in terms of transition models and strategies, as the region consists of countries following the shock-therapy model, like Estonia and Latvia, and countries following a model of gradual adaptation, like Lithuania or Poland.

From the Estonian perspective, financial crisis management provided the valuable possibility to research the social and political reaction to the “broken hopes” of long term stability and economic growth, which was expected to arrive after Estonia´s accession to the eurozone and Schengen visa-free regime as a reward for years of reforms and efforts.

Estonia´s path through the financial crisis in the years 2008-2011 was in many aspects different from the rest of the Baltic States, the Northern countries and the Visegrad states, as during the process of fiscal stabilisation, Estonia also set the goal of fulfilling the eurozone accession criteria (the Maastricht criteria) and joining the eurozone with any cost. This additional demanding goal defined clear limits to the stabilisation and rescue strategies during the hottest stages of crisis. As a result, Estonia was one of the rare societies in the EU and the eurozone where austerity was chosen by the government to combat the financial crises, and this led to strict austerity measures in the years 2009 and 2010.

But the final costs of austerity and financial stability where even higher, as joining eurozone forced Estonia to participate in financial stability mechanisms and bail-out programmes in 2013-2017. Accordingly, the Estonian experience is valuable from the wider future perspective of the European Union and eurozone, as it offers experience and answers as to whether extreme austerity is an efficient solution to counter a financial crisis, the economic and social costs it includes, and the best practices when implementing austerity.

Economic choices for radical fiscal consolidation and actual economic outcomes

There are two central research questions to be addressed in the following analysis. First, it should establish if the Estonian government can be considered as a passive policy-taker or an active policymaker during the financial crisis. And second, which were the central variables of governmental policy and strategic communication during the crisis?

The recessions in Estonia can generally be divided into two distinct periods: the first phase lasted from the second half of 2007 to the intensification of the global financial crisis in the autumn of 2008, and the second phase from the autumn of 2008 until the end of the recession by the end of 2009.

The starting economic and fiscal circumstances in Estonia in 2007 were quite specific when compared to its regional neighbours or euro area members. First, there were several positive variables easing the entrance to the crisis: there existed a tradition of balanced central budgets, small central government debt (4.4% from the gross domestic product (GDP)), and a special reserve fund for a crisis situation. There were also no government bonds issued in the whole history of re-independence.

As Estonia was using the currency board system, government was a passive actor in terms of money supply and interest rates. Additionally, the Estonian budgetary law did not allow to submit budgets even with minor deficit, even when in the EU level the Maastricht rules allowed a 3% budget deficit for the states applying for euro area membership. There were no limitations to sovereign debt, but at the beginning of the crisis Estonia did not have a tradition of national bonds. The government's ability to finance a budget deficit was also influenced by the actual interest rate asked by the commercial banks.

The first phase of the recession was relatively mild and saw a domestic demand-led adjustment that was primarily related to a deceleration in credit growth. The second phase of the recession, which started with the deepening of the global financial crisis in September 2008, saw a sharp reversal of foreign capital flows and a steep fall in exports. The austerity measures taken in Estonia in 2008–11 were triggered by the fall of foreign capital inflows and lending in the first quarter of 2008, which resulted in FDI dropping from its previous level of 2 billion euros in 2007 to 1.2 billion euros in 2008, causing an immediate drop in GDP in the second quarter of 2008 and a fall in budget revenues (Statistics Estonia, 2013a). As a reaction to the fall in budget revenues, a budget reduction was passed by the parliament of Estonia in June 2008, reducing spending for the rest of 2008 by 384 million euros, which was almost 7% of the budget.

To reduce growing expenditures, public sector wages were first reduced by around 20% in the last quarter of 2008 and investments and numerous state procurements were cancelled. Despite these austerity measures, even after the correction the total revenue side of the budget remained in deficit in 2008. The government's austerity policy caused a chain reaction where the reduction of public wages and cancellation of investments and state procurements reduced the government's tax revenues and payments to commercial banks too; as a result, the purchasing power and the ability of the private sector to service the existing debt declined. The only group which fully escaped the cuts in political reasons was pensioners, as the average monthly pension even grew by about 20% in 2008, which has been described as the government's 'insurance policy' to maintain political support among voters in an ageing society.

Table 1: Main economic indicators for Estonia, 2007–2012

Economic indicator	**2007**	**2008**	**2009**	**2010**	**2011**	**2012**
GDP (chain-linked volume growth, %)	7.5	-4.2	-14.1	2.6	9.6	3.9

Source: Bank of Estonia, 2013.

In 2009, despite previous hard efforts Estonian budget planners had the even more complicated task of fiscal consolidation in front of them, as government decided to make drastic expenditure cuts across the board in December 2008. The latter were preferred to the targeted cuts which were not used as consensus was not reached on the priority of sectors. The majority of the expenditure cuts were seen as temporary and planned to last for two years (Government of Estonia, 2008). The cuts resulted in a central government budget deficit of 2.9% which narrowly met the Eurozone accession criteria on government budget deficit (maximum 3% from GDP is allowed), but was extraordinarily large under the current budget law (which is not allowing deficit at all).

Thus for the first time since Estonia had regained independence, a budget with deficit was planned in 2009. As a result of the drastic budget cuts Estonia experienced a fall in GDP reaching 14.1% and a decline in industrial output of 24%, while average monthly gross wages and salaries dropped by 5%

and unemployment increased by 8 percentage points. At the same time, as in 2008, pensions were not cut in 2009 but grew again by 8% from an average of 278 euros per month in 2008 to 301 euros in 2009.

Although the Estonian economy showed some signs of growth in 2010, the budget for upcoming year was planned in a conservative way. The revenue side of the budget remained in general on the same level as in 2009 at around 5.8 billion euros while spending was cut by about 7% from 2009. Spending and revenues were balanced mainly due to the government's drastic decision to halt payments into the second pillar of the Estonian pension system. Although payments were restored after two years and the state even increased its contributions to compensate for the losses, the popular belief that the pension system is firm and unshakable has not been restored. In 2010, Estonia finally fulfilled the Maastricht criteria and decided to adopt the euro and join the euro area in 2011. Seen as political success for the government, it also softened public reactions against austerity policy implemented and justified by government.

The government budget for 2011 was planned rather optimistically, based on the view that both the Estonian economy and government spending would be growing. As the Estonian economy saw growth both in terms of GDP and industrial output, a budget deficit was avoided, and revenues exceeded the expenditures by 1.2% (relative of GDP). Salaries grew together with pensions, and while the growth in the average pension was largely nominal at 1 euro per year, average salaries grew by around 5% (Statistics Estonia, 2013a). While fiscal factors began to normalize, social tensions and pressure continued, caused by the high unemployment level (12.3%), reduced healthcare accessibility, high inflation (5%) and limited credit options by private banks. As a result, labour migration especially towards Nordic countries grew (consisting both highly educated doctors and construction workers with low education).

In 2012, the GDP growth in Estonia stabilized at 3.9% and aggregate gross domestic product reached the highest level in the country's history (Bank of Estonia, 2013). Although the budget proposal for 2012 was initially planned to be in deficit with expenditures exceeding revenues by 0.68 billion euros, at 6.80 billion euros to 6.12 billion euros, in actual terms of fulfilment the budget was more balanced at 6.4 billion euros (Ministry of Finance, 2012). Both wages and pensions continued to grow as average salaries increased by 5.7% and the average monthly pension by 2.5% (Bank of Estonia, 2013).

Which were the social effects of austerity measures taken by the government in 2008–11? Despite the government's efforts, costs for social policy were also growing during the crisis, pushed by a quickly growing consumer price index and political promises to raise pensions every year. According to Organization for Economic Co-operation and Development (OECD) data, Estonian social costs grew from 12% of GDP in 2007 to 18% of GDP in 2011 (OECD, 2011). To the Estonian labour market, the influence of crisis and budget cuts was evident but arriving late. If before the crisis in 2007 the unemployment rate was 4.7%, then in 2008 it rose only to the 5.6% level since employers tended to hope that the crisis would be short and preferred temporary salary cuts instead of reducing the labour force (Statistics Estonia, 2013a). In 2009, however, unemployment more than doubled to the level of 13.8%, and in 2010 it reached the top level of 16.9%, and lowered to the 12.5% level only in 2011 (Masso & Krillo, 2011).

Average monthly wages, reached 724 euros in 2007, followed by more than 10% growth to 825 euros in 2008, a decline to 783 euros in 2009, a small growth in 2010 to 792 euros and a 5% growth in 2011 to 839 euros. What differed in the Estonian wage correction process and dynamics from the other Baltic States was that at the beginning of the crisis Estonia's public sector salaries were higher than private sector salaries, which turned in opposite way to the end of austerity (Masso & Espenberg, 2013).

Tax revenues were growing during the years of crisis – starting from 31.5% of GDP in 2007, the tax percentage grew to 31.8% in 2008 and to 35.8% in 2009 (falling slightly to 34.3% in 2010). While this level is significantly lower than the EU-27 average (39.6% in 2010) it is higher than tax levels in Latvia (27.5% in 2010) and Lithuania (27.4% in 2010). Also, the trends in both southern Baltic States and Europe-27 have been different from Estonian choices – while the Estonian government grew the tax share in terms of GDP, the EU-27 kept it stable, and Latvia and Lithuania were able to reduce it.

During the years of crisis, social pressure started to influence migration (starting from the year 2010), when emigration grew by 25% on a yearly basis. In 2011 this growth continued with the speed of 20% and reached a remarkable 80% growth in 2012 (Statistics Estonia, 2013b).

Political choices and communication during the austerity period

How did the Estonian government use the toolbox to achieve fiscal consolidation prescribed by the laws, which were the main actions indicating the government's role in initiating the austerity policy and which were the main principles of Estonian austerity policy?

To implement austerity the Estonian government chose to achieve fiscal consolidation by taking the path of across-the-board measures (Pollitt, 2010, 17–18) rather than targeted cuts. Although it is easier to achieve consensus for across-the-board measures, the targeted cuts approach would in an ideal case offer higher economic returns or less social stress. Analysing the duration of the measures (i.e. whether the cuts and the immediate burdens are being introduced as a temporary or a long-term measure), we can see that the government acted exactly according to the theory described by Rubin (1980) and started with the minimum possible cuts in expenditures across the board to compensate for the lack of revenues while hoping that the crisis would prove temporary. Later the government continued 'slicing' the costs to reach a balance, which it followed with unsuccessful attempts to increase revenues as the economic situation deteriorated and drastic cuts in spending were needed to avoid a budget deficit in 2009 and 2010. There were not many alternatives to austerity for the Estonian government. Since Estonia had a currency board at the time, the government was unable to influence money supply and interest rates.

Although there were no limitations on sovereign debt, Estonia had no tradition of issuing national bonds at the beginning of the crisis, and although the government had a legal right to change the exchange rate, in practical terms it rejected this option as it would have resulted in failure to meet the euro area accession criteria. And so austerity focused only on budget corrections. Maintaining and increasing Estonia´s investment grade was set as one main priority by the Estonian government during the crisis. At the end of 2011 Estonia had managed to keep an A1 rating by Moody´s, AA-/Stable by Standard and Poor's and A+/Stable by Fitch (which was better than Italy´s grade and equal to Span's grade). Estonian grades have also been higher than the grades of its Baltic neighbours, which both scored in the range of BB+/BBB. Despite its efforts Estonia never joined the countries with triple a AAA rating, symbolising balanced state finances and a stable economy.

With regard to long-term crisis management, the fundamental issue facing the Estonian government during the economic crisis was the question of whether fiscal consolidation should be achieved through cutting costs, increasing revenues or going for both options simultaneously. Since meeting the euro area accession criteria (the Maastricht criteria) was a parallel goal for the government alongside crisis stabilization, the Estonian political elite decided to choose the first option. In this way the Estonian experience also offers a valuable contribution to the theoretical framework of fiscal consolidation which would generally tend to support the opposite model of immediate gains through revenue-based measures, with spending cuts following only in case revenue raising proves insufficient (see Wolman & Davis, 1980).

In terms of strategic political communication the Estonian government followed the logic discussed by Katzenstein (1985) and Pierson (1996) for a small state corporatist government where the government presents itself as a policy 'taker' in a partial force majeure situation.

The government purposely took the role of partial actor (policy-taker) who merely tries to save the situation caused by a global crisis. And the government did succeed in convincing the voters that the fiscal situation was desperate and its choices were limited but that full commitment to austerity would save the situation and even if the government did not succeed, it was morally and economically the most sustainable solution.

Was austerity a necessity or the only option for the Estonian government to achieve fiscal consolidation?

In terms of macroeconomic conditions, the decline of the GDP by 14.1% in 2009 was one of the highest in the EU, but it was lower compared to the Latvian economy which dropped by −17.1% and quite equal to the Lithuanian economy decline of −14.8%. At least in the Baltic context, the Estonian GDP suffered less than the Latvian or Lithuanian GDPs (Statistics Estonia, 2014). In the Baltic context Estonia was also the most stable country in terms of budget balance. The highest deficit in Estonia occurred in 2008 reaching 2.9% only to be followed by 2% in 2009. In 2007 and 2011 the Estonian budget saw surpluses. Estonia was also the only country among the Baltic States having a special stabilization reserve for the case of economic shocks. Next to witnessing a balanced budget, also Estonian tax revenues were growing during the years of crisis – starting from 31% of GDP in 2007 and reaching 34% in 2010. While this level is significantly lower than the EU-27 average (39% in 2010) it is still higher than the tax levels in Latvia (27.5% in 2010) or Lithuania (27.4% in 2010). Estonia started the debt crisis with the lowest debt level (4.6% of GDP in 2008) in the EU and euro area; Latvian debt reached 19.5% in 2008 and Lithuania met the crisis with a debt of 15.6% in 2008. In 2009 governmental debt was growing in Estonia, in all selected reference countries and in the EU on average. While Estonia almost doubled its debt level to a mere 7.2%, Latvia reached 36% and Lithuania 29%. The average governmental debt of the European Union's member states in the same time increased from 61.6% in 2008 to 73.6% in 2009. One further indicator which can explain Estonia choosing austerity during the financial crisis is inflation. Estonian inflation increased by 6.6% in 2007 and reached 10.4% already in 2008. While there was no direct economic need to counter inflation with austerity, austerity nevertheless offered Estonia an excellent possibility to bring inflation below 3% which was the main obstacle in its way to fulfilling Maastricht criteria and entering the Eurozone.

Based on the above described indicators, it can be admitted that austerity was not the one and only fiscal choice for the Estonian government. In terms of GDP dynamics the Estonian situation was better or equal to its Baltic neighbours and in respect of the fiscal deficit and governmental debt Estonia scored the best results in the euro area and the whole European Union. Hence, the main reason for choosing austerity seemed to be the willingness of the Estonian government to reduce the inflation level in order to be able to access the euro area. When looking back to austerity choices from year 2017 and comparing Estonian post-austerity development with Latvian and Lithuanian development two specific differences are visible. First Estonia ended up with remarkably lower public sector debt (9,5% in Estonia compared to 40% in Latvia and 40% in Lithuania), but it also ended up with lower economic growth in 2013-2016, which led to the situation where former slowest economic performer Lithuania has bypassed both Latvia and Estonia in terms of GDP per capita per purchase power (27900 USD in Lithuania vs 27700 USD in Estonia).

One major argument used to legitimize austerity as a partial force majeure was the fact that in 2007–13 Estonia was allocated more than 3.4 billion euros from the EU Structural Funds and so Estonia

simply had to follow European guidelines. The need to find active support among the member states of the euro area for Estonia's entry was used as another argument.

At least the Estonian government itself considered its ability to manage the economic crisis and simultaneously maintain voters'support to be an example to follow to others – the Estonian prime minister and the government coalition have expressed the opinion that Estonia was one of the most successful EU members in combating the financial crisis and that other member states of the EU should learn from the experience of Estonia (Ansip, 2012).

Conclusion

Among the CEE countries and the Baltic States, Estonia has been often symbolizing opened, innovative, competitive economy, social shock therapy models, balanced governmental budget and low debt level. While the years of economic boom in 2004-2007 offered numerous temptations in terms of social spending and institutional investments, the following years (2008-2011) of pressure and austerity tested the hidden values of political elite, survivability of economy and preferences of population.

When Baltic States were hit by global financial crises the starting points and strategies chosen for the fiscal consolidation were different. First, the aim to join the OSCE and the Eurozone played important role for Estonia when choosing its strategy and in many aspects different tools from its` Baltic partners during the economic crisis. Second, the goal to join Eurozone was seen as a priority for any cost and fulfilling the Maastricht criteria seemed possible only through austerity and budget cuts strategy. Third, there was both political and social consensus that additional costs and loans will not be a part of the solution, rather they would destabilize the situation. Fourth, Estonia was able to choose austerity as having no pressure of long term governmental debt, no tradition of budget deficit and low cost-level for social services. During the financial crisis Estonia continued its previous practice as hard-liner in terms of social security, but added to it image of committed follower of European solidarity

Estonia and in many aspects all three Baltic states offer also a valuable example of economic recovery from very high GDP decline (in 2009 GDP decline topped with -17,7% in Latvia, -14,8% in Lithuania and -14,1% in Estonia) without devaluation, bail-out or additional loans (Raudla and Kattel 2013, 733).

Especially in financial and legal terms Estonia followed more the decisions and debates of Finland (than its Baltic neighbours), which is the only Eurozone member next to Estonia among Nordic and Baltic countries. There is also another similarity: Finland and Estonia were the only states next to Luxembourg actually fulfilling Maastricht criteria in 2010 and 2011. Second, main partner and source for Estonia of inspiration in the way towards austerity was Germany. Cooperation and relations between Baltic States however remained as formal as they were before.

When looking at the cost of austerity, then two problems have grown, which will slow Estonian development in upcoming years, first, the growth of unemployment and especially structural unemployment; second, missing investments in energy sector which have resulted in the highest energy costs per person (form GDP) in the EU.

When looking back to crisis years and Estonian government´s later comments to crisis experience, then no lesson was learned or even seen necessary. On the contrary, according to the opinion of Prime Minister (Andrus Ansip) and Minister of Finance (Jürgen Ligi), Estonia was one of the most decisive, moral and successful member states in solving problems during the crisis and the other member states should learn from Estonia. The only admitted lesson from crisis was that buffers - governmental stability funds, need to be bigger because of possibility of unexpected pressure, but no changes are needed in terms of government revenues and taxes. The philosophical debate on pro-

Thatcherism and the opposite classical welfare state model was also used to support the government's argument that austerity is the one and only strategically acceptable solution to the crisis.

Can Estonia´s austerity experience serve as an example for other CEE new-comers in Eurozone? It is possible only for the countries that have no high level of governmental debt needing renewing systematically and no tradition of budget deficit. Among the Eurozone members only Finland and Luxembourg meet these central pre-conditions. Important question to answer before following Estonia's way of austerity, is whether the measures taken supported a long term economic and social stability and growth or lowered competitiveness and social security.

Abstract

The development of modern business technology provides an opportunity for future virtual entrepreneurs to start-up a product and build their very own empires at a very low cost and no border interactivity with the consumer because the information is easily accessible. The generation with the most potential to become future virtual entrepreneurs is the Nexus generation This paper aims to present reviews of Nexus generation behaviour and analyze the reasons why the Nexus generation has the potential to become virtual entrepreneurs. Today is the era of technological advancement. Many researchers in the Social Sciences claim that Nexus is the first generation of this era of technological growth. They are well educated, confident, achievers who take advantage of opportunities and are highly technologically savvy. The stumbling blocks are the unemployment rate among the Nexus generation and the lack of opportunitiesto become entrepreneurs. Therefore, the purpose of this study is to investigate the entrepreneurial potential of the present Nexus generation graduate and to determine the qualities which contribute to them becoming virtual entrepreneurs. This study is significant because it will contribute to the development of Malaysia's growth in line with the National Strategic 2015 set by the Government.

Keywords: Nexus generation, virtual entrepreneur, graduates, Malaysia.

Introduction

Every developing country has its own vision of becoming a developed country. Malaysia is no exception. Malaysia's Vision 2020, launched in 1991, envisages Malaysia as a fully developed country economically, politically, socially, spiritually, psychologically and culturally by 2020 (By, Prime, The, & Rakyat, 2016; Yunus, 2006). In order to achieve this vision, the government has implemented several initiatives such as the National Blue Ocean Strategy (NBOS) (Economic Planning Unit, 2015). The National Blue Ocean Strategy (NBOS) involves strategic planning and operations for positive, high impact programs and services for the public. They are to be low cost to assemble and should be able to be executed quickly in order to assist the nation's growth (Economic Planning Unit, 2015; Laird, 2015).

The National Blue Ocean Strategy is divided into many strategies including creating more jobs for Nexus generation graduates. Aligned with this, the Ministry of Human Resources has provided an automated online job matching service called JobsMalaysia (United Nations, 2002). JobsMalaysia was previously known as the Job Clearing System, an electronic labour exchange (ELX). Through JobsMalaysia, the job seekers are able to search for suitable job vacancies publicly for free through the facilities of the Ministry of Human Resources (Laird, 2015). However, even though it acts as a one-stop centre for labour market information, the objective of the system is to improve and ensure manpower utilization. It optimises opportunities for job seekers but it does not apply to fresh graduates, especially from the Nexus

generation (Laird, 2015; Zulkifli, Omar, & Rajoo, 2016). Research has found that there are several reasons why companies do not hire fresh graduates. Below, Figure 1 has been adapted from http://hk.jobsdb.com/hk/en/staticcontent/hiring-survey/2013/Q2-hiring-index/fresh-graduate-employment.htm (Zulkifli et al.,2016).

Reason for NOT hiring fresh graduates	% of company
No vacancies suitable for fresh graduates	76%
Lack of experience	52%
Not stable	32%
Unable to work independently	27%
Having too high expectation on salary	18%
Unable to face difficulties with a positive mind	6%
Lack of teamwork skills	3%
Others	6%

Figure 1: Fresh Graduate Employment

Source: jobsDB, 2013
(http://hk.jobsdb.com/hk/en/staticcontent/hiring-survey/2013/Q2-hiring-index/fresh-graduate-employment.htm)

The reason that received the highest percentage for not hiring fresh graduates was because no vacancies were available (32%) (Fresh Graduate Employment, 2013). Because of these reasons, many Nexus generation graduates are unemployed. Department of Statistics Malaysia reveals that, of the total unemployed labour force, 16.7% of 65,500 graduates were unemployed (Zulkifli et al., 2016). The number of unemployed graduates increases throughout the year. Unemployment among local university graduates has become a big problem in Malaysia. Figure 2 shows the unemployment rate in Malaysia from April 2016 until Jan 2017.

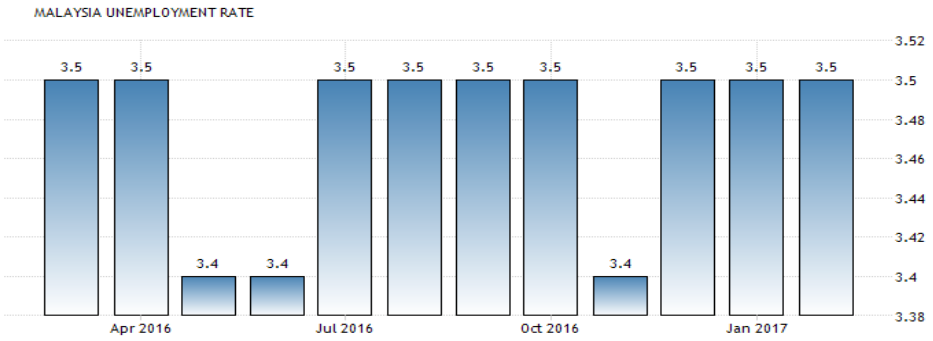

Figure 2: Unemployment Rate in Malaysia Source: Department Statistic Malaysia, 2017 (http://www.tradingeconomics.com/malaysia/unemployment-rate)

The asymmetrical growth of job opportunities and youth population presents a great challenge to many nations. At the same time, driven by the growth of high Internet usage and the disposable income in recent years, digital businesses are also becoming a hot topic among globally. Empowering youth through entrepreneurship initiatives is seen as a feasible option to ensure the development of a balanced and stable economy. Hence, the Malaysian government support for young entrepreneurs' development is very encouraging. Various services such as the business advisory, loans and funding have been offered to stimulate the interest of these young people and to encourage them to establish their own start ups (http://www.cedar.my/publications-store/64-new-gen-entrepreneur-in-malaysia-a-vibrant-economic-force.html).

Objectives

Towards 2020, The National Youth Policy, is part of the Government's policy for greater democratic participation and impartial economic and social progress for all (Secretariat, 2015). The Government aims to support youth who form the Nexus generation and is steadfast in its aim to execute the new policy for youth over the five-year time frame 2015-2020 (By et al., 2016; Laird, 2015). Hence, the main objectives of this conceptual paper are:

i. To identify the Government plan to develop job creators among the Nexus generation.
ii. To explore the characteristics and behaviours that make Nexus generation the best choice over other generations to become future virtual entrepreneurs.
iii. To identify the reasons for unemployment in the Nexus generation.

Job Creators

Nowadays, all developing countries have the issue of unemployment among fresh graduates. This makes it hard for the government to sustain the nation's economy (Yunus, 2006). The era of globalisation has made the labour market more vibrant with rapid changes in technology and the changing needs of companies (Lenhart, Purcell, Smith, &Zickuhr, 2010; Zulkifli et al., 2016). The economy of a developing country like Malaysia is directly connected to the rate of unemployment. The Malaysian economic recession in 1997 led to a massive downsizing of companies. It is a lesson that needs to be kept in mind (Zulkifli et al., 2016). The unemployment rate increased rapidly and individuals were left high and dry. During that period, entrepreneurship managed to sustain the economic lives of some of these individuals by providing an alternative source of income (Petkova, 2009; Zulkifli et al., 2016). Entrepreneurship is still needed to create new jobs as large firms are no longer creating jobs as they once did (M. Hoppe, E. Union, 2016). Large organisations are downsizing to cut costs in order to remain competitive in the market. In August 2013, the unemployment rate increased by 3.1% a month compared with previous months - 3.0% in July and in August 2012 only 2.7% (Yunus, 2006; Zulkifli et al., 2016).

Due to the issue of unemployment among local university graduates in Malaysia, the government would like to see the youth sector becoming self-employed as entrepreneurs. The Government addressed this issue by changing the position of "job seeker" into "job creator" through the National Blue Ocean Strategy (NBOS) (Laird, 2015; By et al., 2016). The Government's plan is a final five-year strategic development through the Eleventh Malaysia Plan to ultimately achieve Vision 2020 (Economic Planning Unit, 2015). The strategic development plan consists of six strategic thrusts. One of the main focuses of the six strategies is for youth, who are the nation's hope for the future as well as being an important asset. By implementing the new National Youth Policy, the Malaysian government hopes to encourage the Nexus generation through capacity building, education, skills training, entrepreneurship, sports and volunteerism (Secretariat, 2015; United Nations, 2002).

Through the National Youth Policy, the government and the Malaysian Global Innovation and Creativity Centre (MaGIC) established a one-stop centre that provides a comprehensive ecosystem for entrepreneurs

to develop the businesses and services required by entrepreneurs (New Straits Times, MaGIC Empowers Nation's Economy, 2015). Entrepreneurship is needed to create new businesses while simultaneously creating new jobs (M. Hoppe, E. Union, 2016). The Malaysian Global Innovation and Creativity Centre (MaGIC) encourages start-ups by entrepreneurs to market their products abroad using online technologies such as websites, social media and mobile applications (New Straits Times, MaGIC Empowers Nation's Economy, 2015).

In addition, the Government implemented entrepreneurship education because of the relationship between regional trade and industry development through new ventures and job creation (Entrepreneurship, 2016). The strong emphasis on economic success and job creation has indeed moved entrepreneurial education into a top position at the higher education level (Entrepreneurship, 2016; Secretariat, 2015). Malaysia's Higher Education Minister Datuk Seri Idris Jusoh stated that future graduates of institutes of higher learning will no longer need to depend on government or private sector jobs but will be able to create jobs for themselves and others (News Malaysia, 2015). This statement came as a reply to a question regarding the future of the country's higher education system, quality of graduates, lecturers and researchers at universities (News Malaysia, 2015; Secretariat, 2015).

The introduction of this policy shows the government's emphasis on the importance of integrating entrepreneurial values and cultures among Higher Education Institutions' (HEIs) graduates. At a launch in April, 2010 by the Ministry of Education (MOE), Higher Education Entrepreneurship, it became apparent that the Development Policy is the current policy concerning entrepreneurship education. The aim of this policy is to boost the development of more holistic and well organizes entrepreneurship programs (S. Shamsudin, A. Mamun, N. Nawi et al., 2016). Following the launch of the policy, the MOE as well as the HEIs gave taken a number of initiatives to implement entrepreneurial education and development to increase the number of entrepreneurs among Malaysia's younger generation.

Meanwhile, by endorsing the implementation of entrepreneurial education in the Malaysian Higher Education, as well as ensuring the aim of the Higher Education Entrepreneurship Development Policy is achieved, the Strategic Plan on Entrepreneurship Development in Higher Education (2013-2015) was launched on April, 2013 (Kementerian Pengajian Tinggi Malaysia, 2013). Specifically, the implementation of the policy aims to produce graduates from HEIs with thinking and entrepreneurial attributes as well as to increase the number or entrepreneurs among graduates who are engaged in business. This will serve as a catalyst for the achievement of an economic transformation in the country. Hence, entrepreneurship education particularly is one of the best solutions to reduce the dependency of graduates on being employed. With this in mind, it is also essential to investigate how generation evolution plays a role in stimulating job creators.

Generation Evolution

A generation can be considered a group of the population who has shared experiences and has a history that influences their thinking and behaviour (O'Keeffee, Thomson, & Dainty, 2013; William J. Schroer Principal). Each generation shares the same experiences and they remain with them as they grow up through different stages of life even though not every individual in a generation has identical personal experiences (Lifestyle, 2011).

Researchers have referenced **Jane Holroyd's Study of Generation Evolution. Baby Boomers are a generation** now approaching retirement age. The Baby Boomers are those born roughly between the years 1946 and 1964 (aged 53-71) (Lifestyle, 2015). This is the generation which has had it all, raised by parents who experienced the Great Depression but then the prosperous post-war era (http://socialmarketing.org/archives/generations-xy-z-and-the-others). Many benefited from free tertiary education and relatively low housing costs. Generally speaking, some range from being self-obsessed to "stuck in their ways". Baby Boomers' life experiences were completely different from other generations

in their attitudes, behaviors and society (http://socialmarketing.org/archives/generations-xy-z-and-the-others).

Meanwhile, **Generation X are** those who were born between 1965-1980 and are now aged 52 to 37 (Lifestyle, 2011). Generation X is a smaller population group than the previous Baby Boomer generation. Generation X is often labeled as the slacker generation and sometimes referred to as the lost generation (Moorthy, 2014; William J. Schroer Principal). This was the first generation that had lots of day care and experienced divorced parents which led them to being uncommitted and distracted. Generation X job hops several times. It is also known as the "why me?" generation (Lifestyle, 2011). While their parents grew up in the era of the Civil Rights movement, Generation X is considered as the generation that quit without trying to identify the problems or care about the social issues around them. They more likely want to keep their heads down rather than change the world. Generation X is the generation with the lowest rate of selection for participation in research compared to others generation (William J. Schroer Principal; Lifestyle, 2011; Sally Kane, 2017).

Lastly, the **Nexus generation** or **Generation Y** comprises those born between 1980s and 2000s. Nexus members are considered to be very sophisticated technology stars, resistant to most traditional marketing and sales trends because they have grown up, seen it and been exposed to it all,since early childhood (Lenhart et al., 2010; O'Keefee et al., 2013; Sally Kane, 2017). Nexus members are more ethnically different, much more segmented and have grown up quickly with Cable TV channels, satellite radio, the internet and so forth (Howe et al., 2013). The Nexus generation is not brand loyal and the rapidity of the Internet has led the group to be correspondingly flexible by varying in fashion and up to date styles and their modes of communication (Hargittai&Hinnant, 2008; O'Keeffee et al., 2013)

Nexus Generation

The Nexus generation is a group of people that was born between 1980 and 2000 and is commonly referred as Generation Y, the Millennials, eco-boomers or dot.com generation (San, Omar, &Thurasamy, 2015). Nonetheless, there is much divergence and argument concerning the age range of the Nexus generation.

In 2010, Malaysia's the Nexus generation was 40% of Malaysia's population (Barford& Hester, 2011; Howe et al., 2013; Zulkifli et al., 2016). Compared with other generations, the Nexus generation formed the major part of Malaysia's population. Malaysia's internet usage, as a percentage of the population, based on age, revealed that 38% were 15-24 years old, 26% were 26-35 years old, 23% were aged between 36-44 years old, 9% were from the age of 45-54 and 5% were aged 55 and above (San et al., 2015). Based on those statistics, the majority of the Internet population in Malaysia was the Nexus generation with 49% (San et al., 2015).

Past studies have explored the organizational needs of the Nexus generation because 66% of Nexus will lead the way in the future (Barford& Hester, 2011). As a result, the organizational expectations and needs of the generation have now been well explained. The Nexus generation tends to be self-reliant, independent and require freedom and flexibility to complete tasks at their own pace and in their own way (Howe et al., 2013; Sally Kane, 2017). They are the most technologically savvy and educated generation to enter industry (Hargittai&Hinnant, 2008; Lenhart et al., 2010; O'Keeffee et al., 2013). The Nexus generation tends to think in a short term mode and expecting direct feedback (Sally Kane, 2017). This generation is very responsible and sees work as a chance to show their skills and their significance within the organization. It is a generation that has grown up in rapidly changing surroundings in a more globalized and mobilized world and experienced technological advances such as the Internet and mobile phones (Hargittai&Hinnant, 2008; Lenhart et al., 2010; O'Keeffee et al., 2013).

Though there has been some research done on the Nexus generation around the globe, not as much research has been done on the Malaysian Nexus generation especially research that looks into their characteristics and their learning methods (Majid et al., 2016). Some recent research includes the investigation of cultural values and career goals of the Malaysian Millennials (Maimunah & Hoo, 2014), and employer rewards and Malaysian Millennials (Maznah et al., 2014). However, it is interesting to note that the few of the findings in these studies confirm that the Malaysian Nexus generation is particularly technologically savvy and that the use of web technologies is a common part of their daily routines (Majid et al., 2016).These findings confirm that the Nexus generation in Malaysia is no different from their Western counterparts in relation to technology and the use of web technologies.

Key Aspects of Nexus Generation

For the purpose of the study, the Nexus generation is considered to consist of individuals born in the 1980s and early 2000s, and are currently aged between 17 and 37 years (San, Omar, & Thurasamy, 2015). The general definition differentiates them from the generations before them such as the Baby Boomers, Generation X and the following generation referred to as Generation Z (Sally Kane, 2017). The Nexus generation made up the largest growth sector in the labour force in the 2010s with numbers estimated as high as 80 million or more and therefore, companies cannot simply ignore their needs, requirements and attitudes. Based on the previous cohort, the Nexus generation has come to be defined by the characteristics formed mainly by the world and the culture in which they grew up (William J. Schroer Principal; Paper, Fitri, & Universiti, 2016; Sally Kane, 2017).

There are a few common key aspects of the Nexus generation. However, that does not mean that all these key aspects can be found in all Millennials. The broad statements are based on an average statistical perspective. The Nexus generation is technology savvy (Lenhart et al., 2010). It grew up with technology and relies on it to perform its jobs. Growing up with smartphones, laptops and other gadgets, this generation is plugged in 24 hours a day, 7 days a week (Lenhart et al., 2010; O'Keeffee et al., 2013). It likes to communicate through email and text messaging rather than face-to-face contact and prefers webinars and online technology to traditional lecture-based presentations (Sally Kane, 2017). They were born into an interconnected world, and presume that people can and should be connected at all times (Hargittai & Hinnant, 2008). The Millennial generation grew with strong virtual friendships and communication. A great variety of social networks, such as Facebook, Twitter and other platforms are used by them to make communications easier (Hargittai & Hinnant, 2008; Howe et al., 2013; Sally Kane, 2017). The Millennials understand how to use internet technology and social media and try to show the value of these modes to their parents and older members in the workplace.

The Nexus generation is family-centric (Moorthy, 2014). Nexus members are willing to trade high pay for shorter working hours and flexible time schedules to better their work-life-balances (Moorthy, 2014; Paper et al., 2016). Other generations may view this attitude as a lack of commitment or discipline, but Nexus members of the legal profession for example have a different vision of workplace expectations. They often value family upper most and it "comes first" before work (Sally Kane, 2017). The Nexus generation sees nothing wrong with taking off early or finishing important tasks at the office rather than taking them home. In an always-connected world, Millennials do not feel the need for rigid office hours to be productive (Barford & Hester, 2011). For the Millennials, salary is in general, of secondary importance. They consider work as fun and a hobby and gaining extra free time is more important (Moorthy, 2014).

Another characteristic of the Nexus generation is that it is achievement and team oriented (Hargittai & Hinnant, 2008; Zulkifli et al., 2016). Having been nurtured and pampered by parents who didn't want to make the same mistakes as their parents, Millennials are more confident, ambitious and achievement-oriented (Solnet, Kralj, & Kandampully, 2012). They have high expectations of their job tasks. They seek

new challenges and are not afraid to question authority (San et al., 2015).The Nexus generation desires significant work and a solid learning curve (Yunus, 2006). On the other hand, Nexus members value teamwork and seek the input and commitment of others. They are loyal and committed members. They want to be included and involved in any task. They try to avoid competition and prefer situations where there is no winner or loser, but rather a good compromise (Howe et al., 2013; Yunus, 2006).

Lastly, they crave attention and continuous development for a better future (Sally Kane, 2017). Nexus members need constructive criticism and supervision. They value being kept in a group and often need repeated commendations and encouragement (W.Horsaengchai, 2011). Millennials appreciate a mentor who can help lead and expand their talents. The disadvantage of Nexus employees is that they are always looking for something fresh and better. Their way of learning is going far beyond traditional methods. Millennials are searching for new opportunities for self development and it is not uncommon for a Millennial to stay with a firm for only two to three years before moving on to a better position perceived to be better elsewhere (Hargittai & Hinnant, 2008; Yunus, 2006; Lifestyle, 2011). They are not afraid to change their place of employment several times, which is a clear difference between them and people of the older generations. On the positive side, working for several firms provides them with a lot of experiences (Sally Kane, 2017). The Nexus generation is constantly learning and is a better educated generation. Overall, when it comes to work values, the Nexus generation is seen as appreciating flexibility, leisure, innovation, more emphasis on a participatory management style, a balance between work and personal life and social value.

Nexus Generation as Virtual Entrepreneur

An entrepreneur is one who plays a major role in the economic development of a nation (Entrepreneurship, 2016; M. Hoppe, E. Union, 2016). Basically, an entrepreneur can be regarded as a person who has the initiative, the ability to express his/her ideas and implement their skills, and the motivation to set up a business or an enterprise of their own (Uyar & Deniz, 2012). An entrepreneur always looks for significant accomplishments of his own or in collaboration with a team. An entrepreneur is conduit for social change and works for the common good. Entrepreneurs will look for opportunities, identify them and seize them mainly for economic profit (Uyar & Deniz, 2012). Entrepreneurship research defines entrepreneurs as individuals who discover, evaluate, and exploit profitable opportunities (M. Hoppe, E. Union, 2016). Thus, entrepreneurs often need a new idea or knowledge, not just in a useful or tested form, but more creatively (Petkova, 2009). The characteristic of looking for opportunities, taking risks and having the courage to develop a plan through to reality, combine into a special entity that can be defined as an entrepreneur (Petkova, 2009; Uyar & Deniz, 2012).

For anyone considering starting a business, ongoing development of entrepreneurial learning is essential to ensure he/she is being exposed to the realities of entrepreneurship and is equipped with the skills to support them when he/she starts a business (New Straits Times, MaGIC Empowers Nation's Economy, 2015; Secretariat, 2015). Entrepreneurship is a dynamic and social process wherein individuals, alone or cooperatively, identify opportunities and if necessary redesign the ideas to be practical, targeted activities in social, cultural or economical contexts (M. Hoppe, E. Union, 2016). Figure 3 sets out the five levels of learning related to entrepreneurial skills and illustrates that entrepreneurship education has five levels of skills that can be developed when studying entrepreneurship (Petkova, 2009). First is the “know why” referring to attitudes, values and motivation, “know how” is identifying abilities, while “know who” are the short and long term social abilities. The “know when” refers to long-term social skills and finally the “know what” relates to knowledge of the market place and goods (Petkova, 2009).

Levels of learning	Individual	Context
Know why	Self-confidence, motivated to achieve, perseverance, acceptance of risk	Entrepreneurial spirit, sponsors, models
Know how	Technical abilities	Complex structures on both career and business levels
Know who	Ability to develop networks	Production and social networks
Know when	Experience and intuition	Industrial traditions
Know what	Encyclopaedism, institutional facts	Information networks, technical traini diversified cultural life

Figure 3: Five Levels Of Learning of Entrepreneurial Skills Source : Johannison. B, 1991)

However, few studies have been carried out on the traits of Nexus members as entrepreneurs (W. Horsaengchai, 2011). The unique situation for Nexus members as entrepreneurs is that they are the first generation to grow up with entrepreneurial role models (O'Keeffee et al., 2013; Yunus, 2006) such as Steve Jobs who developed the Apple company and Mark Zuckerberg, the social media sensation who developed Facebook. These role models have been enough to inspire them to join their ranks.

Next, the Nexus member is highly collaborative and team oriented (Hargittai & Hinnant, 2008). Nexus members will pitch ideas, gain feedback from peers and display everything for the world to see and respond to. They work better in a team rather than alone (W. Horsaengchai, 2011). The main feature of the Nexus generation is that they are highly technologically savvy (Sally Kane, 2017). They came of age at the peak of the digital revolution. The Nexus members developed a unique understanding of the inner workings of the new devices which they tried to figure out through trial and error to gain knowledge (Howe et al., 2013).

Lastly, the Nexus generation member is the type who is motivated by purpose and thinking outside the box (Barford & Hester, 2011). The Nexus member is very passionate about work but not solely about money. Nexus members are blessed with many characteristics that are unique when compared to older generations. They like thinking outside the square to learn how to do things in new and creative ways (Uyar & Deniz, 2012) Nexus members tend to be thrilled about their jobs and they will attempt to do the job efficiently. They will not easily give up and they always learn from failure (Petkova, 2009).

Meanwhile, the virtual entrepreneur or online entrepreneur is being accepted and emerging in Malaysia (San et al., 2015). A virtual entrepreneur is a technology user with the capability of filling the world with virtual objects of their own design, with the freedom to direct their virtual experiences throughout the world (Lenhart et al., 2010; San et al., 2015). A virtual economy evolves through a user's collective efforts or contributions to create virtual objects or goods. The rise of Internet dispersion in Malaysia has created new virtual entrepreneurs among the Nexus generation (San et al., 2015; New Straits Times, MaGIC Empowers Nation's Economy, 2015). The Internet has become a platform for businesses and service providers to communicate information and deliver products and services to consumers (New Straits Times, MaGIC Empowers Nation's Economy, 2015). According to Turban, et al. (2009), the Internet is a useful tool to convey information to consumers as it is flexible, open, informal, and interactive. The internet had changed the way businesses operate and the way consumers purchase goods and services (Lenhart et al., 2010). Of all the generations, Nexus is the first generation to be raised in the era of technology and social media (W. Horsaengchai, 2011; Sally Kane, 2017). Hence, the Government really needs to support the Nexus generation in becoming future entrepreneurs (Secretariat, 2015; New Straits Times, MaGIC Empowers Nation's Economy, 2015; Entrepreneurship, 2016).

Conclusion

The youth population plays an important role in this nation, so it is essential to develop and prepare our young people with attitudes, knowledge and skills necessary for Malaysia's development and economy. Furthermore, nowadays, businesses must adapt to the new realities and understand the work value of the new generation that is entering the workplace. At the same time, the digital technologies offer tremendous growth opportunities but require entrepreneurs to fully unlock their economic potential as the bases of new businesses.

To summarize, this research contributes to Malaysia's economic growth by investigating the development of job creators among Nexus members. There is growing evidence from previous studies that globally, the Nexus generation faces increasing difficulties when entering the workforce. Without the right guidance from the start, our youth will be less proficient at making choices that will improve their career scenarios and their future. The resulting effect of inadequate education, low-productivity, unemployment and the increasing poverty from one generation to the next must be identified in the Government's plan to overcome these problems (Secretariat, 2015). Hence, there is a necessity for the Malaysian government to develop strategies aimed to give young people a chance to make the most of their productive potential.

Leveraging Big Data to Improve Customer Experience

Rdouan Faizi, ENSIAS, Mohammed V University in Rabat, Morocco, r.faizi@um5s.net.ma

Sanaa El Fkihi, ENSIAS, Mohammed V University in Rabat, Morocco, s.elfkihi@ um5s.net.ma

Abdellatif El Afia, ENSIAS, Mohammed V University in Rabat, Morocco, a.elafia@ um5s.net.ma

Abstract

In today's marketplace, businesses are increasingly realizing that a true competitive advantage lies in building a strong customer experience. Since customers have endless choices and, hence, more demanding, neither low prices nor smart advertising are enough to win their business. Nowadays, customers expect outstanding experiences more than ever before. As such, companies hoping to maintain a competitive edge should adopt innovative strategies to enhance interactions with their customers. The objective of this article is, therefore, to explore the way big data can improve customer experience. In this respect it was revealed that this data revolution can enable businesses to gain an in-depth understanding of their customers and of their needs. Big data can also allow businesses to transform customer feedback into actionable insight and customer satisfaction in real-time. Moreover, it can provide every individual customer with a customized customer experience that meets his needs and behavioral patterns. Given these opportunities, we strongly believe that big data can help companies deliver engaging customer experiences and, thus, stand out in an increasingly competitive advantage.

Keywords: big data, customer experience, customer retention, competitive advantage

Introduction

In an increasingly competitive marketplace, it is no longer sufficient to propose a reliable product or a competitive price. With modern technologies, today consumers are highly connected, well informed and digitally empowered. Accordingly, they have higher expectations and are more demanding than ever (Newman 2017). In fact, they are longing for an astounding customer experience, which many businesses ultimately fail to provide.

In that past, customer experience was a journey that had a clear beginning, middle and an end. As such, nearly all customers followed the same path. Nowadays, customer experience is non-linear and unpredictable. It is a journey that does not solely take place in a brick-and-mortar store, on an e-commerce website or when calling a support line. Rather, it encompasses instances of knowledge sharing and discussions that occur beyond a business' owned channels (Lemon & Verhoef 2016). In fact, there are massive amounts of data or big data that are generated at a rapid pace by customers and other users on social media platforms. This valuable data could be beneficially used to improve customer experience and, hence, help companies compete in an increasingly complex consumer marketplace (Newman 2015). Thus, instead of relying primarily on transactional and demographic data for strategic marketing information, businesses could extract value from these huge amounts of data (Faizi et al. 2017).

Therefore, the objective of this paper is to examine how big data could be leveraged to enhance customer experience. The remainder of the present article is organized as follows. Section Two provides a brief overview of customer experience. Section Three discusses how big data can be used to improve customer experience. Section Four concludes this paper.

Customer Experience: A Brief Overview

Customer experience refers to the sum of all interactions and experiences that a customer has with a company's products, services, people and processes throughout their business relationship. These interactions and experiences can include awareness, discovery, cultivation, advocacy, purchase and service (Singh 2016). Though customer experience can encompass a lot of constituents, it can briefly be defined as the perception the customer has of a given brand.

A customer experience can take place in a physical store, online or when communicating with a contact centre. It happens while visiting a store or a website, interacting with an employee and while receiving a shipped order. According to Richard Owen, vice president of Dell Online Worldwide, customer experience goes from the instant a customer sees an advertisement to the moment he or she accepts the delivery of a product, and beyond (Roumeliotis 2012).

Given that 21st century consumers have more power and choice than ever before, they are a mouse-click away from competitors. For this reason, customer experience has become an important and powerful part of a business strategy. Today, offering an amazing customer experience will not only help businesses build long-term relationships with their customers, but it will also create a competitive advantage and increase revenue and sales. Therefore, every organization's brand heavily relies on the customer experience it delivers.

According to a survey conducted by Gartner in 2014, 89% of the surveyed companies expected to compete mostly on the basis of customer experience by 2016 versus only 36% in 2010 (Sorofman 2014). Gartner also predicts that by the year 2018, more than 50% of businesses will implement major business model changes to enhance customer experience (Gartner 2016).

Within the same context, a study published by Walker, a customer intelligence consulting firm, stipulates that by 2020, customer experience will overtake product and price as the primary brand differentiator. For illustration consider the following figure.

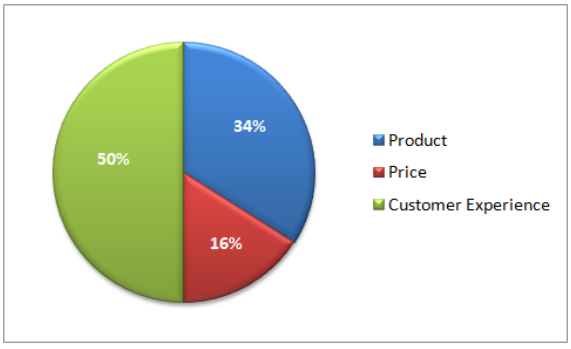

Fig. 1: Companies' ratings as to the most important Element to their business strategy by 2020

When companies that were surveyed were inquired about how important are experience, price and product are to their business strategy, the figure clearly shows that more emphasis is on the experiences that a company delivers to create a competitive advantage. This means that customer experience will be the main factor that will distinguish one company from another.

A more recent survey carried out by Econsultancy in association with Adobe also confirmed the continued dominance of customer experience in terms of the focus of marketers. In fact, 91% of the surveyed B2B brands continue to make customer experience a strategic priority in 2017 (Econsultancy 2017).

As is clear from the evidence above, customer experience continues to grow as a priority for companies in every industry. Since no business can exist without customers, companies across all industries are focusing on how to attain higher customer satisfaction rates and more importantly on how to reduce customer churn.

How Can Big Data Enhance Customer Experience?

The rapid growth in the quantity of information that has been generated in the last couple years has resulted in the emergence of a new concept termed 'Big Data' (Bakillah et al. 2014). Big data is currently one of the hottest technology trends that is used in a variety of fields for various purposes. This data revolution is expected to transform not only how companies and industries use and process data but will also reshape the face of our world (Schmarzo 2013). This data can, for instance, help in a political campaign, prevent disasters or boost a company's revenue. Big data can, thus, open up many new avenues and opportunities. Given the potential value that can be derived from big data, our purpose in this section is to examine the ways in which it can improve customer experience.

First, big data can enable businesses gain a better understanding of their customers (Marr 2016, Wang 2014). Thanks to big data technologies, companies can have access to tremendous quantities of valuable information about their customers. In fact, many businesses are not longer confined to collecting demographic information (age, gender, marital status, ethnic group, etc.) of their customers or their transactional data, namely how much, how often and which products or services they spend their money on. In addition to this traditional data, companies can better understand their customers by leveraging data generated on social media. Today, a customer's journey is not solely taking place in a physical store or on an e-commerce website. Rather, it mainly consists of instances of knowledge-sharing and discussions that are happening beyond the channels of a business. With the hundreds of various social media networks that are available, there are billions of data points that a business could tap into to get its customers' insights. On Facebook or Twitter, for instance, big data can enable businesses to get valuable information on their customers' latent interests, preferences and needs. More importantly, they can help get the customers' attitudes and perceptions towards a given brand (Voulgaris 2014). Shortly after trying a brand, a customer can hop up on Facebook or YouTube and spread the news. Never before have businesses been able to listen to what customers say to friends or to other people about a product or service. Fortunately, with big data, it is possible to quickly capture and process every comment or post that an individual makes on these social media networks. Massive amounts of data captured from Internet of Things devices can also reveal much information on how customers use products, when they use them and for how long they make use of them.

Second, big data can also help businesses convert customer feedback into actionable insights and customer delight in real-time. In fact, by retrieving the mixture of data sets that are generated from various streams and then analyzing them, businesses can identify in real-time problems that their customers are encountering with their products or services (Nasir 2015). They can, thus, see what is working and what is not and can identify patterns in their customer engagement strategies that need improvement (Newman 2017). Armed with this pertinent information, businesses can fix the problems that have been detected or at least provide customers with the immediate feedback that they usually demand. In the past, collecting and processing data before passing it to the right person to make actionable decisions or adjustments often took months. By contrast, big data can allow businesses to act as quickly as possible not only to resolve problems that customers have detected but also to fix problems

before they even happen. By being proactive, a business is able to remain in control of the user's or customer's experience at all times. Moreover, these real-time or instant interactions or feedback will ultimately drive customer satisfaction and provide a greater customer experience (Lane 2011). The faster businesses respond to requests and complaints, the better they are likely to cater to meet the needs of their customers.

Third, big data can also be used to offer a personalized customer experience (Montaño & Pal 2014). Today, customers want neither a one size fits all approach, which provides all customers with the same offers, nor any goods or services that work. They aspire to have customized offers that both save them time and take into consideration their interests or preferences. Henceforth, a customized customer experience is no longer merely wanted, but highly expected. However, if a consumer's data is stuck in silos or scattered among different departments or teams, no business will be capable of taking full advantage of this data because no one will have a total view of its customers.

However, by embracing big data technologies, businesses can aggregate all customers' data, be it structured, semi-structured or unstructured. As such, they can gain a 360-degree view of every individual customer and, thus, get deep insights into what is important to the customer (Lopez 2014). Therefore, instead of 'spamming' a customer with one needless offer after another, businesses can via big data technologies recommend goods and services that go in line with a customer's interests and preferences. In addition, big data can allow businesses to get engaged with their customers on the right channel with the right message and at the right time.

From the discussion above, it quite clear that leveraging the power of big data captured from diverse internal and external data sources can enable businesses to craft a seamless customer experience that will help them attract and retain customers and increase revenues.

Conclusion

The purpose of this paper was to examine the ways big data technologies can improve customer experience. In this vein, it was clearly shown that this valuable data can provide companies with a better understanding of their customers and can help them convert customer feedback into actionable insights in real-time. It was also demonstrated that big data can be used to personalize customer experience following customers' needs and preferences. Taking all these potentials into account, we think that big data provides businesses with an ideal opportunity to deliver strong customer experiences that will significantly increase revenue.

MOOCs: An Upcoming Trend for Corporate Training and Development

Rdouan Faizi, ENSIAS, Mohammed V University in Rabat, Morocco, r.faizi@um5s.net.ma

Sanaa El Fkihi, ENSIAS, Mohammed V University in Rabat, Morocco, s.elfkihi@um5s.net.ma

Abstract

Massive Open Online Courses (MOOCs) have gained popularity in the last couple of years as they enable learners to access world class education from leading universities and colleges at a low cost or even for free. MOOCs are, therefore, expected to significantly alter the traditional modes of learning. However, these online video courses will not only impact the way education is delivered in academic institutions, but will also disrupt how corporate learning is conducted. In fact, given the limitations and requirements of in-house training, MOOCs can be learning assets in the workplace. The objective of this paper is, thus, to explore the potential benefits of using MOOCs for corporate training and development. In this respect, it was revealed that MOOCs can allow employees to learn at their own pace and can help businesses reduce instruction time and, hence, boost productivity. Moreover, the use of these online learning resources can cut down training costs, improve employees' retention rates and allow employers to monitor and evaluate the learning performance of their workforce. Accordingly, they should be incorporated in all corporate training initiatives.

Keywords: MOOC, human resources, corporate training, professional development

Introduction

Massive Open Online Courses (MOOCs) have quickly grown in popularity in the last couple of years and become a favored way of interactive online learning. In fact, learners all over the world are currently opting for these online video courses to complete higher education studies from a variety of universities or colleges, or to enhance their personal and professional skills. Since no physical attendance is required, courses can be accessed by anyone at any time and from anywhere in the world just with an Internet connection.

As opposed to traditional modes of distance learning, which have basically been used for distributing text-based educational resources, a MOOC focuses more on multimedia materials such as videos and animations and uses quizzes for assessment and immediate feedback. In addition, MOOCS foster interaction amongst a varied global learning community.

Today, a large number of MOOCs taught by professionals in the field are offered by many leading universities in the world either as an additional resources or reference materials of a course or even as an independent module. Given this valuable opportunity, students and learners in general resort to these video educational resources to enhance their learning in different subjects and to explore academic topics of interest. However, the popularity of MOOCs is not only confined to educational institutions but is also extended to the business world given the growing awareness in the role MOOCs might play in workforce training.

Therefore, the objective of this paper is to explore the potential opportunities of using MOOCS in business contexts. The rest of the present article is structured as follows. Section Two gives a brief overview of MOOCs. Section Three details the reasons why MOOCs should be used in the workplace. Section Four concludes this paper.

MOOCs: A Brief Overview

Since their introduction in 2008, MOOCs have drawn a considerable amount of interest within higher education and corporate learning. These educational video resources, actually, have the potential to widen access to world class universities and to offer new and alternative routes to education and to corporate learning and development. MOOCS are, thus, likely to disrupt many of the sectors' traditional approaches and assumptions.

The MOOC acronym – massive, open, online and course – has been interpreted in distinct and sometimes conflicting ways. However, all interpretations more or less converge on defining a MOOC as a model for delivering educational content online to an unlimited number of students or participants from anywhere in the world for free or nearly free. Accordingly, MOOCs can be seen as a way to democratize and re-visualize education so that all learners, anywhere, regardless of their social status or income can have access to education (Kanani 2014).

Most MOOCs provide the usual traditional classroom material in the form of video lectures, which are often sliced into 10 or 15-minute segments. Learners enrolled in a MOOC can also read assigned materials, complete quizzes and tests and interact with instructors and other learners in online forums.

Though different types of MOOCs have emerged in the last few years, MOOCs can generally be divided up into two major categories: cMOOCs and xMOOCs (Haber 2014, Rhoads 2015).

A cMOOC is based on the learning theory of Connectivism which emphasizes the power of connecting with other learners. In a cMOOC, learning occurs through the interaction of learners with learning materials and with each other (Daniel 2012). According to George Siemens, one of the MOOCs pioneers, cMOOCs rely on the idea that learning happens within a network, where learners use social media platforms to make connections with content, learning communities and other learners to co-create and share their collective knowledge (Siemens 2012). Given that the participants in a cMOOC co-produce and share information with each other and get engaged in joint experiences and discussions, they assume the dual role of both the instructor and the learner.

Unlike cMOOCs which emphasize knowledge creation and generation, xMOOCsrely on knowledge duplication and are modeled on more traditional learning theories and teaching methods where the professor is the expert and learners are consumers of knowledge (Hai-Jew 2014, Jemni & Khribi 2016). These MOOCs are a combination of pre-recorded video lectures and assessments that are centered around a teacher rather than around a community of learners. Currently, hundreds of xMOOCs are offered to the general public via platforms such as Coursera, EdX, and Udacity. As such, they are the most common type of MOOCs.

Despite their common goal of offering open and free or relatively free education and training to learners, both categories of MOOCs have distinct structures and qualities. Each MOOC category establishes a different type of learning environment that suits specific modes of knowledge acquisition.

Why use MOOCs to Enhance Corporate Training?

When new employees are hired, they are generally offered onboarding training which enables them to acquire the skills, knowledge and behaviors needed so as to become valuable contributors to an organization. However, given that company policies, processes and product specs change over time, it is of utmost important to provide all employees with continual training so that they could stay up-to-date with the requisite skills, professional knowledge and industry trends that might benefit them at work. It is, thus, essential that employees be given access to new training courses on a regular basis. Nevertheless, given the constraints and limitations of on-site training sessions, an increasing number of employers have started incorporating MOOCs to help further train their employees. Rather than being restricted to traditional training programs (face-to-face or online), employers resort to MOOCs as a new corporate training mode for the numerous benefits that they provide (Carson 2014, Hamori 2017, Wang et al. 2017, Radford et al. 2014).

The first potential benefit of using MOOCs for corporate training is that they offer a flexible learning experience. On a 24/7 basis, employees can access training at the time and place that suit them. In fact, rather than being required to attend a three-day or a one-week training session which is oftentimes exhausting, or being obliged to wait for a scheduled session that takes into consideration all employees' needs, preferences and constraints, any individual employee can learn at his own pace and in moments that do not conflict with his own work responsibilities or personal life. As such, all staff members are likely to take full advantage of these video learning materials.

The second potential benefit of incorporating MOOCS in training is that they can help businesses reduce instruction time and, thus, boost productivity. Given that MOOCs can be accessed by any employee irrespective of time and place, the wasted time and costs associated with the employees not being at their desks during a face-to-face training session are, thus, saved (Nielson 2014). In this respect, some studies have demonstrated that the shift from on-site to e-learning training has proven to decrease the instruction time by up to 60% (Ferriman 2014) Though a lot of evidence is not yet available, the use of MOOCs can contribute to more training time savings and, thus, lead to more productivity. Before McAffe, the American global computer security software company, renewed its hiring strategy, the latter was more than 80 hours long and was composed of about 40 hours of pre-work, 5 days of on-site instruction as well as post-work to be completed at home. However, the incorporation of MOOCs as new training model enabled McAffe to save both time and generate more lucrative sales (Meister 2013).

An additional advantage of using MOOCs is that they reduce the costs related to employee training and development as they are usually offered for free or at a minimal cost (Ong & Jambulingam 2016). Following a study conducted by Bersin by Deloitte in 2014, corporate training is a $70 billion industry in the United States and a $130 billion industry worldwide (Bersin 2014). These expenses are even expected to increase in the future. However, while these are good signs that business is booming, not all companies have extra money to spend on training their employees. Therefore, one way to cut down training costs is to have recourse to MOOCs (Dodson et al. 2015). The latter do, in fact, enable businesses to deliver high-quality training at a low cost. Instead of having to pay for an on-site instructor or expert or spending money on travel, accommodation, logistics, and resource-related expenses, the incorporation of MOOCs can save an organization a lot of money. Moreover, once a MOOC is online, the course can be delivered to as many employees as possible. This means that once the first group of employees has been trained, there are no marginal costs related to the training of additional employees.

A further advantage of using MOOCs for corporate training is that they help improve employees' retention rates. Retaining employees in this competitive talent marketplace has, actually, been found out to be one of the biggest priorities and concerns for business leaders (Schawbel 2016). Given this fact, the constant access to learning materials that MOOCs can always guarantee can keep employees well

informed and can enhance their engagement. Indeed, as long as employees are enriched with the education and skills they need to carry out different daily work duties, they are more likely to thrive in the organization. In this context, A recent survey by Udemy revealed that 46% of US employees noted that limited or lack of learning opportunities is the major reason why they are bored or disengaged in their roles (Wiechers 2016). MOOCs for corporate training and development can help companies not only with retention, but also with developing their future leaders. MOOCs can make employees feel they are growing professionally and expanding their understanding of work processes. This provides the personnel with the energy and power to deal with the different challenges they might face while at work and make them feel a sense of personal satisfaction.

In addition to the above-mentioned benefits, MOOCs can also help businesses track employees' learning performance and assess the knowledge retention for corporate training efforts. Thanks to big data technologies, an employer can know which skills or information have been taught to which employees. It is also possible to identify employees who completed a specific course and how long it took them to complete it. Just by analyzing an employee's interaction behavior towards a MOOC, an employer or manager can spot which course or part of a course is easy or hard to understand and also to identify motivated employees who have acquired the desired skill sets (Faizi et al. 2017). In this way, every individual employee can be assigned a customized training experience. However, not only can MOOCs enable an organization to detect motivated employees internally, but also to find prospective employees who have the skills and experience that the company is looking for. When a company offers its MOOCs externally, it can reach out valuable candidates that might not have been found otherwise (Castellano 2014). In this respect, many companies such as Eurotunnel, SNCF and Orange have started using MOOCs not only for training purposes but for hiring decisions as well.

Conclusion

Our purpose in this article was to examine the potential role that MOOCs may play in corporate training and development. In this vein, it was found out that these online video courses can allow employees to learn at their own pace given that they can be accessed irrespective of time and place. Therefore, unlike in-house training, MOOCs can also reduce training time and, thus, boost productivity. In addition, the use of these online video courses can cut training costs, enhance employee retention rates and can help employers track and assess the learning performance of every individual employee. Given all these benefits, we believe that MOOCs are potentially an excellent solution that businesses should incorporate in their training initiatives.

Preparation for Providing Crisis Communication During Blackout Occurrence

Alena Oulehlová, Department of Emergency Management, Faculty of Military Leadership, University of Defence, Brno, Czech Republic, alena.oulehlova@unob.cz

Štěpán Kavan, Fire Rescue Services of South Bohemia Region, České Budějovice, Czech Republic, stepan.kavan@jck.izscr.cz

Abstract

Due to the increasing threat of long-term blackout and its impact on all sectors of human activity, it is necessary to increase crisis preparedness of the public administration for such possibility. It is necessary to map the capabilities of all entities for the crisis management purposes and to check their ability to respond to the situation for the purpose of the operational processing of crisis managements plans in the crisis preparedness phase. Checking the ability to respond is carried out using risk analysis, processing planning documentation and subsequently carrying out exercises of responsible crisis management authorities. Working groups have been set up to analyze impacts on the life and health of the population, its property and environment with regards to ensure the functionality of all key stakeholders as a part of the Blackout 2017 exercise preparation in the selected region of the Czech Republic. The article focuses on the results obtained by a working communication group, with the emphasize put on providing communication between responsible authorities and providing information to the population about the situation development. Article puts emphasizes on the analysis of the mobile networks functionality as the most widely used communication and information tool.

Keywords: communication, mobile operators, area analysis, blackout

Introduction

This section should follow keywords. This section should provide background of the study and highlight research motivation. Information and communication technologies (hardware, software, netware and telecommunication) have contributed significantly to the development of globalization. Current society is going through digital age which is based on the use of the latest scientific knowledge in the field of information and communication technologies. Besides its positive consequences, such as facilitating communication, economic benefits, data archiving, etc., it also brings a negative impact in the form of latent risks such as the possibility of data misuse, cyber-terrorism and pathological addictions.

Providing timely and relevant information on the development, course and way of dealing with the crisis situation is vital to the population affected by a disaster. In the case of blackout, communication through ordinary telecommunication means is highly limited or almost impossible. Communication via mobile phones, in particular, is very vulnerable. Mobile transceivers are usually nonfunctional during disasters. For example, during hurricane Katrina, more than 70 % of mobile transceivers were malfunctioned (Nicholas, 2017). On that account, it is necessary to re-evaluate the use of mobile phones in the event of disaster. It is possible to use portable devices with battery power - Citizen Band radio, satellite phones, General Mobile Radio Service radio, Amateur radio (Nicholas, 2017). These devices have its advantages and disadvantages (such as affordability, reach, popularity among the population). In the Czech Republic,

these communication tools are not very spread among the population and the crisis management authorities. In relation to the crisis preparedness of the crisis management bodies as well as the population, it is necessary to become ready for such situation since the lack of information and the absence of communication can give rise to negative impacts, losses or damage. Negative impacts can be minimized even before the actual crisis situation occurrence by a thorough analysis of the field that maps out potential responses in the area affected. Adaptation and mitigation measures have been subsequently proposed based on the results of the analysis.

The objective of the article is to present the results of implemented analysis aimed at functioning of communication and information technologies in the South Bohemian Region serving for the needs of the exercise Blackout 2017. Based on the results of the analysis, there are identified problems areas ready for solutions. There will be proposed a way of communication between the crisis management authorities and the affected population. The results will serve to change and supplement the crisis documentation of the South Bohemian Region.

Current Situation

Crisis communication

Crisis communication is an interactive information process, verbal, visual or written between the organization and the stakeholders (Feam-Banks, 2010). Crisis communication plays crucial role in the crisis management (Zhao, 2007).

The term “crisis communication” is generally used in two ways:

- It describes communication activities of an organization or agency facing a crisis. It needs to communicate concerning the crisis within the organization, with various partners and the public.
- The term “crisis communication” is associated more often with emergency management and the need to inform and alert the public about an emergency. In this case, crisis communication might refer to the community leaders’ efforts to inform the public (Center for Disease Control and Prevention, 2014).

The second way of communication is being dealt with in the presented article. The underlying thread in both forms of crisis communication is that an unexpected and threatening emergency requires an immediate response. The content, form and timing of the communication can help reduce, sustain the harm or make the situation even worse (Center for Disease Control and Prevention, 2014).

There are currently several topics dominating the area of crisis communication:

- Characteristics of crisis communication in the social media (Sakasi et al, 2010, Muralidharan et al, 2011, Lotan et al, 2011).
- The role of media in the crisis communication (Lotan et al, 2011, Utz et al, 2013, Starbird et al, 2015).
- Organization or crisis response strategy (Yates and Paquette, 2011, Sutton et al, 2013, Rutset et al, 2014).
- Communication behaviour in the times of crisis (Xie et al, 2017, Esworthy et al, 2015).

Focusing attention on crisis communication through mass media and social media arises from their position and role in contemporary society. All these communication means require electrical power for

their operation. During the research into this topic, it was found out that, no research which would deal with the issue of providing communication in the case of blackout, has been carried out in the area of crisis communication. The authors of the article were unable to obtain information on the way in which the analysis of the area was carried out from the point of view of communication possibilities in other states. From the point of view of dealing with the crisis communication with the population affected by blackout that happened abroad, a network of amateur radios was used in Japan in 2011. Japanese radio amateurs powered their stations with car batteries or portable generators and transmitted rescue requests, information on refugee centres and availability of supplies. Similarly, the network is used in the USA during hurricanes and other natural disasters (Nollet and Ohto, 2013).

Czech Republic

The territory of the Czech Republic (CR) has not been affected by a large-scale and long-term blackout yet. The high stability of electricity supply in the Czech Republic is also evidenced by the distribution continuity indicators (Dušek, 2016). The average duration of one interruption of electricity supply for the customers in the previous year was 116.96 minutes, with an average of 2.21 interruptions (Energy Regulatory Office, 2017). Short-term local outages in the period 2000-2016 were predominantly related to natural disasters (floods, storms, snow calamities and icing) and anthropogenic dangers (transformer stations fires, unintentional damage to the facilities) caused by human factor failure. Electricity supplies to all locations were restored within 48 hours at the latest. In the context of crisis preparedness, it is necessary to take into account all aspects of life, eg. Preparedness of the population, social and healthcare facilities in relation to communication skills (Brehovska et al, 2015).

In the case of the threat analysis for the Czech Republic (Government of the Czech Republic, 2016), the risk of large-scale disruption of power supply (45.73 points out of 100) and the risk of disturbing the functionality of major electronic communications systems (32 out of 100) was assessed as an unacceptable risk. For unacceptable risks, the competent authorities of the central state administration have to create type plans. During the implementation of threat analysis for the area of regions, the risk of large-scale disruption of power supplies was identified as unacceptable risk in 13 of 14 regions of the Czech Republic (Šindlerová, 2017). On the basis of the created type plan, crisis management authorities are obliged to incorporate ways of addressing the crisis situation into the crisis plans of regions and municipalities with extended powers. Emergency communication and connection also form part of the crisis documentation, however, they are of limited use for addressing the danger of blackout.

In spite of the above mentioned facts about the supply stability, considering the increasing vulnerability of the population to crisis situations, crisis management bodies prepare themselves for the risk of long-term blackout by the form of exercises in individual regions. Exercises with blackout topic took place in the Czech Republic in 2014 in Prague, in 2015 in the South Moravian, the Olomouc and the Hradec Králové Regions and in 2016 in the Vysočina Region. In 2017 it will take place in the South Bohemian Region. Each region has approached the organization and scope of the exercise in a different way. Even one of the regions practised as if all communication channels were working, which is in fact unrealistic. The benefits of such type of exercise are highly limited.

Aim and Methodology

The aim of the paper is to carry out research into the possible ways of communication in the case of a long-term power outage in the territory of the South Bohemian Region in the Czech Republic. Partial goals are exploration of communication through mobile operators and radio communication. The basic issue addressed is thus connection and passing information between the population, crisis management bodies and integrated rescue services. The basic research method is analysis, where the analysis of the

individual communication possibilities and impacts during a long-term blackout has been performed. The information was obtained by research into the information sources and literature and in particular, by a semi-structured interview and a questionnaire given to the representatives of individual entities that provide one of the connection services. The final information has been compiled and using the deduction method, the final conclusions have been drawn while coming from assumptions to conclusions.

Results and Discussion

As a part of a preparation of the Blackout exercise in the South Bohemian Region (Czech Republic) which will be held in November 2017, 13 working groups have been created. Working groups have dealt with the key areas influenced by blackout (e.g. food, healthcare, drinking water, fuel and transport). The task of each working group has been:

1. Identify elements belonging to the topic area.
2. Determine the impacts of power failure.
3. Identify the preserved activities.
4. Decide what is necessary for emergency provision in the set area.
5. Determine how to address impacts in the affected area.
6. Select the entities for the provision of basic functions for priority electricity supplies in the affected area.

The article deals with the analysis of the area in terms of ensuring the functionality of the information and communication technologies in case of a large-scale blackout in the region. Emphasis was put on mobile operators as the number of used mobile devices is growing. The analysis of the area was carried out by the Regional Fire Brigade in cooperation with experts from the individual organizations responsible for traffic operation, postal services and telecommunications.

Identify Elements Belonging To the Topic Area

The following elements were identified in the area of communication, postal services and telecommunications within the region:

- Digital Radio Network of the Ministry of the Interior of the Czech Republic – PEGAS.
- Analogue Radio Network of the Fire Rescue Service of the Czech Republic.
- Mobile operators.
- Fixed line operators.
- Satellite telephones.
- Radio broadcasting,
- Television broadcasting,
- Internet,
- Local information systems,
- Unified system of warning and notification,
- Postal Services.

These elements are used not only by crisis management bodies and components of the Integrated Rescue System, but also by the population whose security needs to be ensured during blackout.

It was found out as a part of element identification that some entities owning such elements are part of the critical infrastructure - VI Information and Communication Systems Area under the Government Regulation of the Criteria for Determination of the Critical Infrastructure Element (Government

Regulation, 2014). Components of the Integrated Rescue System, in particular the Operational and Information Centers are dependent on receiving information to provide protection to the population. They are also components of the critical infrastructure elements.

For the elements included in the critical infrastructure, it is essential that the functionality is maintained even in the event of a large-scale, long-term power outage since the disruption may have implications for state security, economy and providing the basic living needs of the population as well as their health and property.

Determine the Impacts of Power Failure

After identifying potentially endangered elements, impacts have been identified with regard to the preparedness for dealing with crisis situations and protection of the population. The most significant problem is the limitation or complete disruption of communication between citizens, crisis management authorities, administrations authorities and business entities. Communication interruption will arise from the congested base transceiver station (BTS), discharged users‘ mobile phones, failure of mobile operators BTS which are not backed up with back-up sources). Disruption of communication on the part of the citizens affects the provision of assistance to the citizens who will not be able to reach the emergency lines for help. In addition, population will not be provided by a long-term warning via the Unified system of warning and notification (sirens) and local information systems. The provision of information to the population will be as well limited by television and local radio. This disturbs the standard communication channels used during other types of crisis situations. This may lead to increased damage to human health, the impossibility of providing pre-hospital emergency care or even the death of persons. In addition to the above-mentioned impacts on human health, the failure of communication and information technologies will have significant social impacts on the population (making access to funds through electronic banking impossible, limitation of purchases via credit cards, transport, etc.).

In the case of crisis management bodies and the components of the integrated rescue system, their telephone numbers at mobile operators can be given priority. For telephone numbers with priority calling, unlike normal phone numbers, call priority is set. Priority levels are 1+, 1, 2, and 0 depending on the particular participant in the crisis communication. In addition to the priority calls which depend on the BTS functionality time as well, components of the Integrated Rescue System can still use radio stations for making emergency communication.

Identify the Preserved Activities

A key step in the whole analysis of the territory was to identify the preserved information and communication technologies. The step was based on interviews with liaison security officers or experts of the entity, about the extent to which they are able to provide crisis communication. From the point of view of population protection, the most important is the mobile operators’ network and systems providing information for the population; this is the reason why attention is focused on them.

There are three major mobile operators in the Czech Republic - O2 Czech Republic, T-Mobile and Vodafone. Currently, O2 Czech Republic and T-Mobile share networks including the infrastructure excluding core exchanges. If the T-Mobile network is available, there is a high probability that the O2 Czech Republic network will also function. To ensure communication, it is necessary to have the whole structure of the infrastructure running from the mobile phone via the base stations, the controllers to the core exchange. The keystone for crisis communication during the blackout is BTS power. The other elements are sufficiently ensured during blackout and are described in the text below. All operators

declare their readiness to provide priority calls in the case of request for activation during an emergency or crisis situations.

O2 Czech Republic

Mobile services are made up of two core exchanges within the Czech Republic and other infrastructure (backbone network, transport network, access network, BTS). About half is backed up by batteries. Backbone networks are backed up for 4 hours and BTS for 2 hours. BTSs are not backed up in marginal locations. The operator is able to provide about 2 pieces of mobile BTS for the needs of crisis management authorities. The operator also runs fixed lines. Their use is, due to the need to power elements of data transmission and reception, most likely improbable.

T-Mobile

Mobile services are made up of four core exchanges within the Czech Republic. They are located in objects with their own motor generator and fuel for a period of min. of 24 hours. If the refuelling is provided, the operation of the core exchanges will be unlimited. Similarly, other infrastructure to the level of BTS controllers is resolved. Both operators have about 10,000 BTS in the Czech Republic area. BTS are backed up by batteries. In places with good accessibility there is a backup for about 2 hours, with poor accessibility up to 8 hours. If the BTS is located in a building with motor generator, it is usually connected to it and its functionality is maintained as long as it runs. Assuming that the way to the controllers and exchanges is maintained, the system will be functional.

Vodafone

Mobile services are made up of three core exchanges within the Czech Republic. They are located in the buildings with their own motor generator and fuel supply for min. of 24 hours. When refuelling, the operation will not be interrupted. Similarly, additional infrastructure to the level of BTS controllers is resolved. BTSs are backed up by batteries with a capacity from 2 hours to 24 hours.

It was found out during analyzing mobile operators, that a single company - HUAWEI contractually maintains the network functionality for all three mobile operators. The relationship between mobile operators is shown in Figure 1.

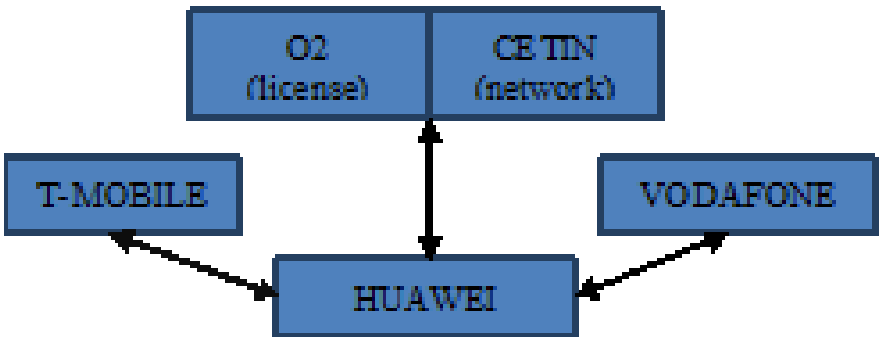

Fig 1. Maintaining the mobile operators network functionality in the Czech Republic [author‘s own source]

The production and transmission by national TV and radio broadcast providers will be maintained. The problem here is on the household side, i.e. the receivers. TV sets without a back-up power source will not work. Radios will work in passenger cars or radios with charged batteries. It is advisable to use emergency radio, which uses manual recharging or solar power. However, among the Czech population it is not a well-known product.

The created questionnaires were sent to the entities after the interviews were finished to check, complete and update the information.

The functioning of a Unified system of warning and notification, serving to alert the population in the case of emergency and crisis situations, depends on the siren type. In the case of installed rotary sirens, their dysfunction is obvious as they are permanently dependent on the power supply. Electronic sirens have backup batteries with a maximum operating time of 72 hours.

The digital radio network of the Ministry of the Interior of the Czech Republic - Pegas, the Tetrapol system, is used for the needs of the components of the Integrated Rescue System (the Czech Police, the Medical Rescue Service, the Fire Rescue Service of the Czech Republic and selected units of the Volunteer Fire Brigades of the Municipalities). On the territory of the South Bohemian Region, backup batteries for approximately 10 hours are on the 22 base stations and 10 points of radio links. For longer run, 6 base stations have a backup motor generator. However, only 2 base stations will fully provide services in two parts of districts. The remaining 4 base stations will be minimally functional, only for users who have been logged in under this cell prior to disconnection.

The fire rescue service of the South Bohemian Region and the volunteer fire brigade units of the municipality included in the coverage can moreover use the analogue radio network. It consists of transceivers, repeaters, radio controlled radio stations, base stations, receiving radio stations integrated into the operating and information centre via ErcLink, data links (IP MPLS-KI element) and base stations. There are 16 basic elements (transceivers, repeaters); most of them are backed up by batteries for about 6-24 hours. For longer maintenance of run, 5 elements have their own backup motor generator. They provide full connections for the majority of the region's territory and are connected to the Regional Operational and Information Centre. During battery backup, it is possible to communicate under the transceivers/repeaters without linking to the Operations and Information Centre. Elements that do not have their own motor generators can be connected to power generators with power consumption up to 0.3 kW.

The operation of Internet services from various providers cannot be guaranteed.

Decide what is necessary for emergency provision in the set area

From the results of the territory analysis, it is clear that in order to ensure the functionality of the information and communication technologies, the supply of electrical energy to the elements of the critical infrastructure and other important elements must be provided. These are mainly BTS, transmitters, receivers, transceivers and exchanges. Based on the survey results, a list of priority locations was created. For priority locations, power supplies should be provided mainly from back-up power sources that form part of the elements or are installed on a one-time basis. The supply of fuel and lubricants must be provided by the operator of the facility, the crisis management authorities and the components of the Integrated Rescue System to the back-up power sources. Currently, the calculation of the quantity and frequency of fuel supplies to the priority points takes place since the first deliveries will have to be realized no later than 6 to 24 hours after the blackout has occurred. Indispensable condition for refuelling the motor generators is to enable access to these elements by their owners.

Determine how to address impacts in the affected area

From the perspective of providing basic functions in the affected area and the basic needs of the population, it is necessary to thoroughly address the following issues:

- List the essential transmitters/receivers to maintain basic connections.
- Verify the possibilities of connection of a backup power source and accessibility of the location throughout all seasons.
- Provide backup power supply for transmitters/receivers and their transport to a location as well as a specialist to connect the back-up source.
- Provide fuel and lubricants for the backup power sources.
- Determine people for priority calls.
- Map the possibility of using mobile base stations which are used for commercial use.
- Use of radios in cars and possibly in mobile phones.
- Create mobile phone charging points.

Select the entities for the provision of basic functions for priority electricity supplies in the affected area

In determining bodies for ensuring basic functions in the affected area, entities have been identified in each area that play a key role in providing communication between stakeholders or providing information to the public. These were mobile operators, fixed line operators and radio and television broadcasters. In addition to individual operators, it is necessary to include entities which provide operation of these technologies. Most of these entities are privately owned, which makes implementation of preventive and mitigation measures more difficult.

Conclusion

Crisis communication between stakeholders has to be ensured regardless of the type and extent of the crisis situation.

The results of the analysis of the functionality of the information and communication technologies have shown that without the secured connection between the crisis management authorities and the components of the Integrated Rescue System, the management and dealing with the crisis situation of a long-term blackout will be limited or almost impossible. The main contribution of the article is creation of the overview of the functionality of communication and information systems on the territory of the South Bohemian Region in case of long-term electric power supply failure (blackout). This makes it much easier for the crisis management authorities to prepare for this situation by modifying the documentation and activities of the components of Integrated Rescue System. Dealing with the issue during the real blackout would reduce the operational capacity of the intervening units and assistance to the affected population. For this purpose, it will be necessary to establish "connection system islands" which will provide a basic exchange of information between crisis management bodies, components of the Integrated Rescue System, business entities and the affected population. The "connection system islands“ will only be able to be used for crisis management purposes and for the protection of life, health and property.

The article proposes six steps of how to perform the area analysis used for the preparation of blackout exercises. It presents range of relevant issues for securing communication between affected population and responsible authorities. The analysis of the territory from the point of view of communication was very time consuming.

An important problem encountered by the working group was the different willingness to provide information from owners and operators of information and communication networks. Most owners and operators are private companies and the willingness towards volunteer co-operation is low. At the same time, there is a limited range of legislation that can be used for mandatory co-operation in the area of crisis preparedness. It is obvious that this problem is not appropriate to solve from the regional level, but it is necessary to solved them from the national level. Work on creating of mitigation measures will require communication with owners and operators of information and communication networks and also funds. Co-operation with these subjects will be absolutely crucial in the real blackout occurrence.

For the reasons of information protection, it was not possible to present all the obtained information in detail, such as a specific list of priority points. To ensure communication, it is necessary to finalize the conditions for the priority calls and the lists of persons who can use such system; provide fuel and backup motor generators; create a network of charging points for mobile devices and a system for exchanging information with the affected population.

The preliminary calculation of fuel amount shows a high demand on the amount of fuel needed, its transport and a large number of motor generators for the operation of information and communication network elements which are not currently available. Other problematic area seems to be lack of a sufficient number of experts (authorized persons) who are able connect backup power sources to the required object. Similar requirements for increased supply of fuel, motor generators and experts have also come from other working groups. Furthermore, there is a high economic burden on the entities that will buy and maintain motor generators and eventually provide their delivery.

Acknowledgment

Results presented in this article were obtained as a part of the solution to the project by Technology Agency of the Czech Republic with the topic Research and Development of Simulation Instruments for Interoperability Training of Crisis Management Participants and Subjects of Critical Infrastructure (research project No. TA04021582).

Theory and Practice of Design Thinking: Systems Approach

Eva Svirakova, Tomas Bata University in Zlín, Faculty of Multimedia Communications, Stefanikova 2431, 760 01 Zlín, Czech Republic, svirakova@utb.cz,

Abstract

The article describes the practical use of system thinking in product design. The aim of the article is to propose a set of qualitative research methods that can be used to get information about a creative project as a system and use it in practice. The article shows the gradual use of methods on a project that originated at a university in its creative workshops. The data are collected through questionnaires and interviews. The grounded theory method identifies issues from the acquired data and is further solved by the mental mapping technique. Missing parts of the system are added using the backward mapping method. The resulting model is built up using System Thinking Language and is published as a Causal Loop Diagram. This approach enabled both the visible and invisible side of the design process to be displayed. The mental model of the entire design process is very extensive, so the published model solves only one selected category. This category is "project assignment," which is the first phase of the design process. This article is intended for students of creative disciplines at the university who are ready to use systems thinking as well as design thinking. The originality of the article is that it seeks systemic solution to problems that does not have a negative retrospective effect on another part of the design process in the studio.

Keywords: backward mapping, causal loop diagram, design process, grounded theory

Introduction

The project, as designer's deliberate efforts to design a new product innovation, is a system. The visible and invisible elements of this system are interconnected by the design process activities. According to various authors (Ambrose and Harris, 2011; Hanek, 2013; Knapp, J. Zeratsky, J., Kowitz, B., 2016), there is a different number of phases, but one aspect is always common to the design process. It includes design thinking, which is a way of thinking that is customer focused. In the design process, we often create models or prototypes to verify with the customer whether the designer's ideas about the product are the same as the customer's expectations and whether they will purchase the product. We are thinking of a project that results in product innovation as a system of interconnected parts, so we are in the process of systems thinking. The article connects both types of thinking and creates a new model. Our model is mental; we cannot produce it as a three-dimensional (unlike the designer in the fashion design studio - it is a model that is the product of system design thinking). The mental model solves problems and challenges that are hidden in a particular design process and which we have systematically identified through qualitative research. The aim of the article is (1) to propose solutions to the problems we have identified and (2) to publish research methods that allow system thinking to be translated into usable practice. The article is intended for all who read the Fifth Discipline (Senge, 2006) and want to bring the knowledge about systems thinking into life. We do not claim that our mental models are the only correct ones. However, we claim that we have reached them on the basis of data collection, which we have subjected to carefully aligned research methods of analysis and synthesis. The user of the article needs to judge themselves whether our approach to mental modeling meets their expectations.

Literature Review

As Soukalová (2016) specified, an important part in the process of technology transfer, innovation and competitiveness development in the economic and social system is played by universities, particularly by their research and development centers and departments. Universities guarantee independent research and freedom of knowledge that has its rational and ethical dimension, morals and conscience shared by an independent community of teachers and students. Implementing results of research and development, thoughts and individual creativity in practice is a predisposition of continuous innovative activity and of increasing the competitiveness of national economies. Strážnický (in Soukalová, 2016), however, points out certain pitfalls of transfer of creative innovations. He claims that the basic precondition of technology transfer is (1) knowledge that relates to the functionality of the transferred solution, (2) its applicability in the market and (3) willingness of the authors to disclose supporting information when negotiating with business partners. Strážnický remarks that it is still true that design sells. That is due to the fact that most technical solutions repeat and a new design is a significant added value of a product that manufacturing companies are interested in.

Design thinking is a style of thinking that uses the ability to combine three components. (1) empathy in responding to customer needs, (2) creativity in the creation of new solutions, (3) rationality in analysis (Hanek, 2013). The design process is a combination of design thinking and system approach. At each stage of the design process, problems and challenges may arise that accelerate or slow down the design process. Ambrose and Harris (2011) define seven stages of the design process that are in line with the proposed procedures for creative project management: (1) define, (2) research, (3) ideate, (4) prototype, (5) select, (6) implement, (7) learn. The objective of this paper is to find barriers and advantages in the design process at the university and propose solution that will facilitate transfer of innovations. We consider transfer of innovations to be successful in the following cases: (1) Transfer of a product or service to the market using transfer or the relevant license to a commercial company that incorporates the product or service in its market portfolio. (2) Transfer of a product or service to the market when at least one customer buys the product or service.

We can also consider innovation to be potentially successful when the product is displayed at an exhibition, in a catalogue or presented in some other relevant ways. This definition of successful innovation is based on educational and creative mission of universities. We cannot expect every product made by students to be intended for the market. The objective of creation in studios is to make a product that is potentially innovative, interesting and valuable in its field. Such products also include models, mock-ups and prototypes. Nevertheless, for the purposes of this article, we primarily focus on the students´ outcome that has been successful in the market (if only partially).

Materials and Methods

For the analysis of the design process and design thinking, we chose to use qualitative research. We started collecting data through questionnaires in November 2016. With respect to the fact that our target group was rather peculiar, i.e. students of art studios, we used a specific graphic form. We presumed that students would find this way of expressing familiar and we would get relevant data in a more efficient way. The questionnaires did not contain any questions, but were in the form of a calendar. There were three milestones on a timeline, the first of them concerned the initiation of their common project at the faculty and the other two were check points of the project. We addressed 85 visual art students and received back 65 filled questionnaires from the following studios: graphic design, spatial design, industrial design, product and digital design, fashion and shoe design. Work of the students from these studios is capped at the end of each term by handing over a specific innovative product in 2D visualization or as a 3D mock-up, model or prototype, which is the third milestone in the calendar-like questionnaire. In our survey, we assumed that the students´ goal is to carry out the assignment of the supervisor, pass the studio exam, and receive the credit hours. We asked, for instance, the following

questions: What barriers and advantages do you see in your studio? Did you set your product target at the very start? Do you have an idea at what stage of the design process you currently are? Do you have a schedule for your further activity? How did the project assignment form suit you?

We analyzed the data from the questionnaires using Grounded Theory and open coding process. Grounded theory is a qualitative research method that is typically used as a means of developing theoretic and conceptual understanding of social and interpersonal phenomena. We classified the answers received in the questionnaires by topics. Each topic represented a certain problem or challenge. For each challenge, we grouped the relevant phrases and pieces of sentences. After completing the analysis, we selected a questionnaire filled by a student who was successful in innovation transfer and we proceeded to the second part of the survey: an interview with a selected author of a product. We decided to conduct the interview with the author of a specific design of a fashion collection. We recorded the interview and then transcribed it word for word. We analyzed the sentences from the interview in the same manner as we did with sentences in the questionnaire: we grouped them using the open coding process by topics. During the analysis of the questionnaire and interview we dealt with every single sentence, which is in line with recommended processes of Grounded Theory. We asked: What is the gist expressed with this sentence? (Corbin and Strauss, 1990). After dividing the sentences into categories, we assessed the relation between them. We wrote down the results using the mental modelling technique during which we assessed the relation between two elements: A causes B. The relation between these two elements is also expressed with the polarity of the relation. Generally, we can say: If A happens, then B is greater; or if A happens, then B decreases. We marked the polarity using the (+) or (-) sign next to the arrow.

However, events around us are more complicated. Oftentimes, they have many reasons and simplified explanation using the cause and effect is insufficient. Such thinking is referred to as linear thinking. The mental model we recorded on the basis of the assessment of primary data is imperfect. The lack of feedback suggests we need to consider wider context. However, primary data did not allow us to do so, since the student only dealt with the problems or advantages in the design process from her own perspective. Yet, this poses no problem for the survey, quite on the contrary: opinions and experience of the students were a valuable basis that we intended to gather. We continued with the analysis by applying another research method: backward mapping (Glaser and Strauss, 1967).

The backward mapping method is a strategy for the analysis of policies and their implementation that starts with the description of the desired behaviour on the lowest level of intervention, in this case with the designer or in the studio (Elmore, 1980). The analysis may continue by defining the policies, resources and support that is necessary from the highest level if the analysed problem is to be solved. Backward mapping presumes that the closer a participant is to the source of the problem, the greater his/her ability to influence it. Therefore, backward mapping method asserts that the ability to solve problems of complex systems does not depend on the hierarchical structure and system control, but rather on whether we delegate maximum powers to act at the moment when the problem occurs. Using the backward mapping method, we extended the mental model of linear thinking and “closed its loops”. With this step we arrived at a better mental model that corresponds with the technique of systems thinking (Senge, 2006). Summary of the ascertained conclusions resulting from the questionnaire and interviews was written using the Causal Loop Diagram (CLD), which contains, besides polarities, also specification of the loops (reinforcing, balancing). All the research methods we used are shown in the chart below (Figure 1).

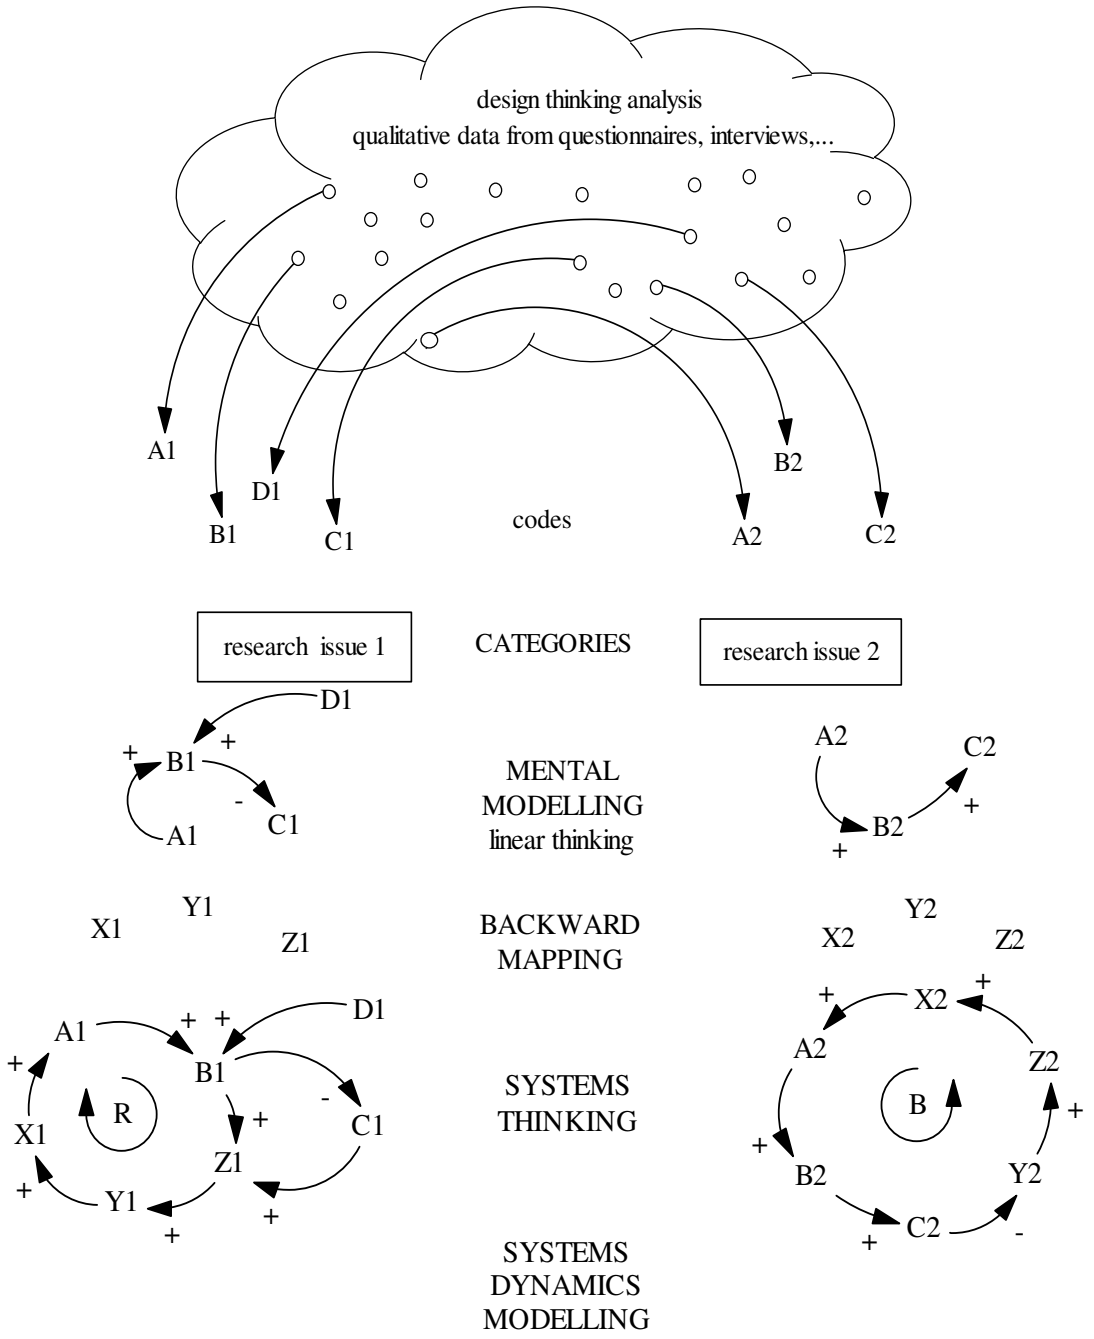

Fig. 1:Research methods, inspired by Simonsen & Friberg, 2010 (own resource, 2017)

Case study from Fashion Design Studio

Using the case study from the Water for All Project we show the possibilities of design thinking in the working process of authors creating a new innovative design. "Water for All" is a project by the Faculty of Multimedia Communication, Tomas Bata University in Zlín, which is based on the environment of cultural and creative industries. All studios under the faculty participated in it. Twelve studios, in a joint effort, dealt with "Water" as a topic of their creation from the beginning of the academic year (September 2016). Outcomes of the project are exhibitions, fashion shows, websites, a catalogue, Facebook campaign, conference and scientific publication. A partial outcome of the fashion show is a collection of dresses inspired by the problem of the Aral Sea (see Fig 2. below).

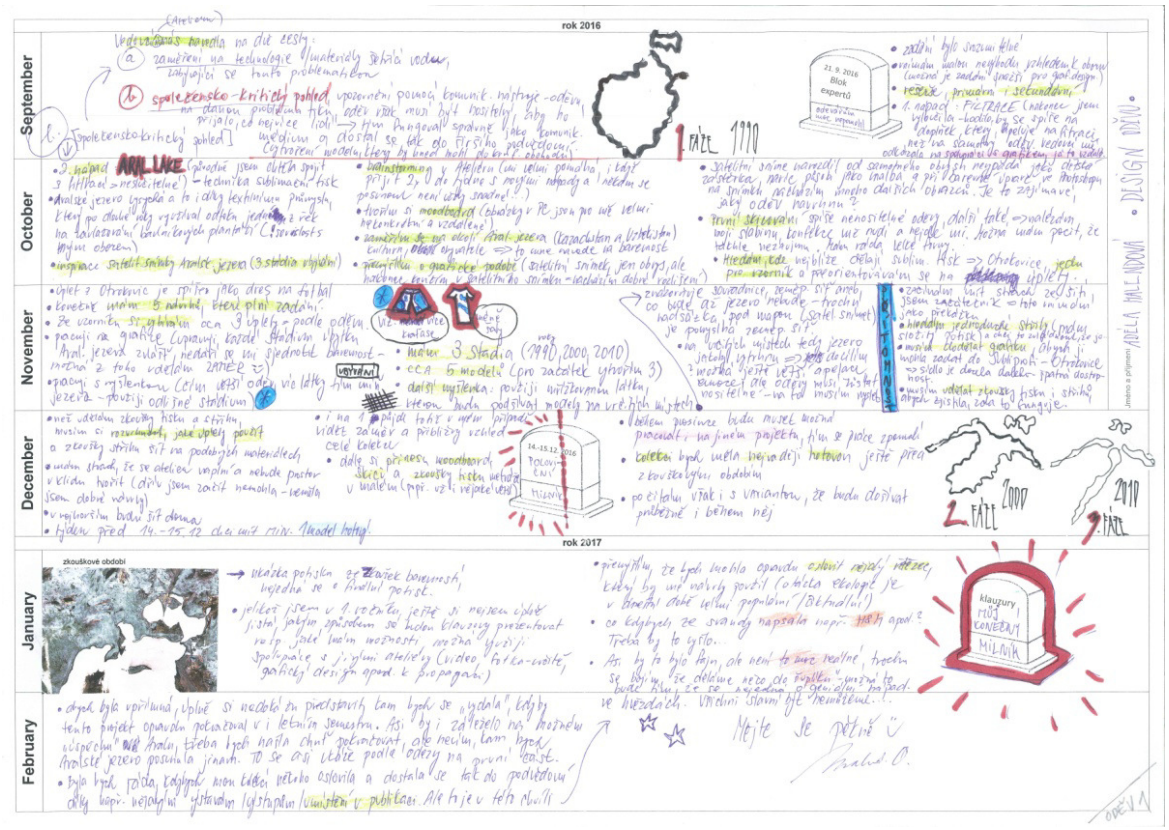

Fig. 2: Questionnaire. Aral Sea. (Adela Malendova, student, 2016)

Results and Discussion

From the primary data we identified several research problems using coding and formulated research questions. The research problems are as follows: (1) Innovations are not interesting to customers, (2) Problematic transfer of innovation to the market, (3) Negative assessment by the student of the studio. For further analysis, using the backward mapping method we selected the first of the above defined research problems. Following the experience of IDEO a design agency (Knapp, Zeratsky, Kowitz, 2016) we reformulated the problem so that is sounded rather open and optimistic. It is a good predisposition so that we do not get overwhelmed by problems that sound negativistic right at the beginning. That is why we formulated the research question in the following way: How might we get a potentially successful innovation? As it showed, the answer to this question is not obvious at first sight. Introducing a product to

the market was simplified to that extent that in our case, it is the moment when the first customer buys the product and there is demand of other customers for the same or similar product made by the same designer. If we were to solve all the research problems, our systems model would become far too extensive. We divided designers´ answers into chosen segments and grouped them under headings, as you can see below.

Quality of Assignment from the Studio

"The assignment was understandable. The leader has shown us two paths. I see a small disadvantage with regard to the field, perhaps it is easier for graphic design. The block of experts did not help the garment industry much. The supervisor asked me to work with the graphic artist, I gave up. I am a beginner. Brainstorming in the studio helps me a lot, even if coming up twice a week with new ideas and get somewhere is not always easy. "[Questionnaire - AM]

In order to compile a mental model, we need to paraphrase sentences and interviews. Paraphase: The manager of the studio increases the clarity of the assignment. An experienced designer will work better with other studios. Brainstorming increases the number of new ideas. Brainstorming also increases the quality of the assignment from the studio (supported by the studio). Against the usability of ideas, the designer's new ideas are being put under pressure by the studio's management.

Consistency Of The Idea With The Vision Of The Designer

"Clothing must be wearable. In order (for the clothing) to be accepted by as many people as possible and therefore to function properly, as a communication medium, to gain a wider awareness. To create a model that could fit into the off-the-rack shop. I think I could really reach out to a retail chain that would use my ideas. What if I wrote for fun, for example, to H&M, maybe it would be happen? Perhaps it would be nice, but it is not very real. I am a little afraid that I am doing something that will never happen, probably it's not a brilliant idea. I would love to address somebody with my collections and made my mark, for example, by exhibitions, by being in a publication. Time will tell. Not everyone can be famous. "[Questionaire - AM]
Paraphrase: The author has a vision that is customer focused and serial production for business. The better the vision, the higher the potential for success of the product. The designer doubts her ability to get the product to the customer. Doubts have a negative impact on her motivation. The designer's motivation is to be known about through her products. The more successful the product, the greater the motivation of the designer.

Record of parts from the interview, which took place four months after submitting the questionnaire (June, 2017), are next. This section talks about the past because the student has already completed her collection and evaluated her design thinking.

Designer Experience

"... I wanted to get it into the store. It did not work out. The initial enthusiasm is somewhere else, yes, I wanted to send it to some shops, but the problem is that a lot of those stores are foreign and for me it means more complications, they want to work with more familiar names." [Interview - AM]
"I'm beginning to be afraid of sewing. I'm a beginner, I see this as an obstacle. [AM - Questionnaire]
I certainly had a great graphics problem, and I could not make much choice, I needed a great resolution. So it was a problem to find an image that could then be graphically converted to be high resolution." [AM - interview]
Paraphrase: The designer's experience with communication with clothing stores is missing. An experienced designer is one who has had success with their products, the more successful the products,

the more experienced the designer. Experienced designer has a greater opportunity to acquire special abilities to communicate with clothing stores. The designer needs to increase the potential for success of their product by working with other studios.

Motivation of the Designer

"But it was certainly interesting because the dean opened the exhibition in the dress. That's the best thing that can happen. This is how we transfer something about us and something about our thinking." [Interview - AM]

Paraphrase: The higher the potential for product success, the higher we can expect the designer's motivation. The closer the product captures the original assignment, the more usable the idea and the higher the potential for success. Success is when a product purchased by a customer. If the customer is a dean of the faculty, then the product is in line with the intention of the faculty. Success is when the product is presented. When the product is (potentially) successful, it is also presented.

The mental map (Fig 3.) was made on the basis of the rephrasing of the designer´s statements. The polarity of relations between most of selected elements is positive, (+) symbol. It means that the following element has the same growth (and also decrease) tendency as compared with the preceding element. If there is the (-) symbol next to the arrow pointing at the following variable, it means that the following element has the opposite growth tendency when compared with the preceding element. Most of the elements in the figure below (Fig 3.) are linearly dependent, that means they simplify the relation between cause and effect. This mental model (Fig 3.) is only partially acceptable from the system point of view (Šusta, 2015). The model is largely open because most of the elements lack feedback loops, so it is based on linear thinking.

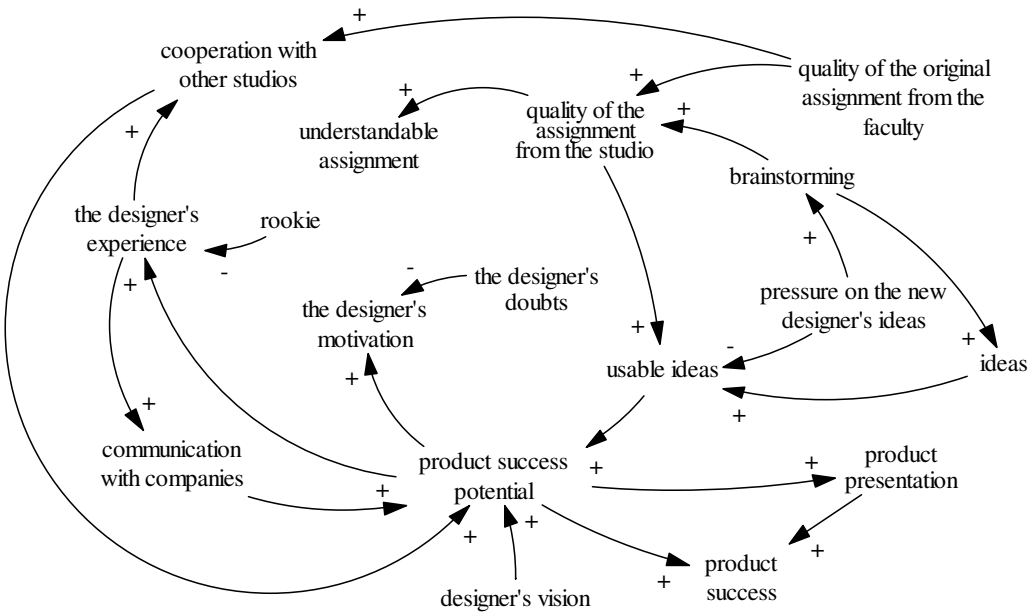

Fig. 3: Mind model according questionnaire and interview (own resource, 2017)

All the mentioned relations between elements (Fig 3.) are strictly based on the records of the questionnaire and interview with the designer. However, these opinions do not give us, for the time being, the answer to our research question: How might we get a potentially successful innovation? Systems

thinking (in another mental model Fig 4.) is comprehensive and describes more aspects of reality. Using backward mapping, we suggested the solution to the problem that is addressed by the research question. We investigated which elements and links (left-hand side of Table 1) we can include in the design process in the implementation stage and which ones we cannot (Table 1 see below right-hand side Table 1). The elements from right-hand side Table 1 we did not include in the model but they cannot solve our problem and they are beyond the possibilities of our solution implementation.

Table 1: Backward mapping method (own resource, 2017)

Activities and resources needed to gain potentially successful innovation	
Such variables we discussed and placed in the model (blue color in Fig 4). The development of variables is directly related to the findings of the research.	Such variables that we discussed but did not place in the model or left it as an explicit variable (red color in Fig 4.)
• Sorting ideas and usability of ideas and links between them • The link between the potential of a successful product and the pressure on new designer ideas • The link between the clarity of the assignment and the doubts of the designer • Link between the sorting of ideas and ideas	• Quality of the original assignment from the faculty • Designer's vision • The link between the quality of the original assignment from the faculty and the vision of the designer • Product presentation • Product success

The above-mentioned new variables and their relationships (Table 1) have helped us to close the loops and to promote the mental model to the systemic causal loop diagram. On the basis of all the findings stated above and of the backward mapping method we prepared a back-loop diagram that is shown in the figure below. All conclusions resulting from the backward mapping method were recorded into the mental model that we can call systemic, as it contains closed back-loops, see Figure 4 below. Blue dashed arrow marks added relations between elements we identified using the Backward mapping method.

We know that the Causal Loop Diagram can hardly be marked as complete at any stage. We also cannot say for certain that ours is right. Everyone has their mental model that they project into their thinking. However, the published Causal Loop Diagram (Fig 4.) is compiled according to the answers to the questionnaire and the interview. We try to analyze each sentence of primary data in order to find a suitable management policy that supports potentially successful innovations. According to Peter Senge (2006), the behavior of the system is influenced by its structure. The structure of the system is partially invisible. Using system language thinking, we reveal the structure of the system so that we could answer the research question: How can we get a potentially successful innovation?

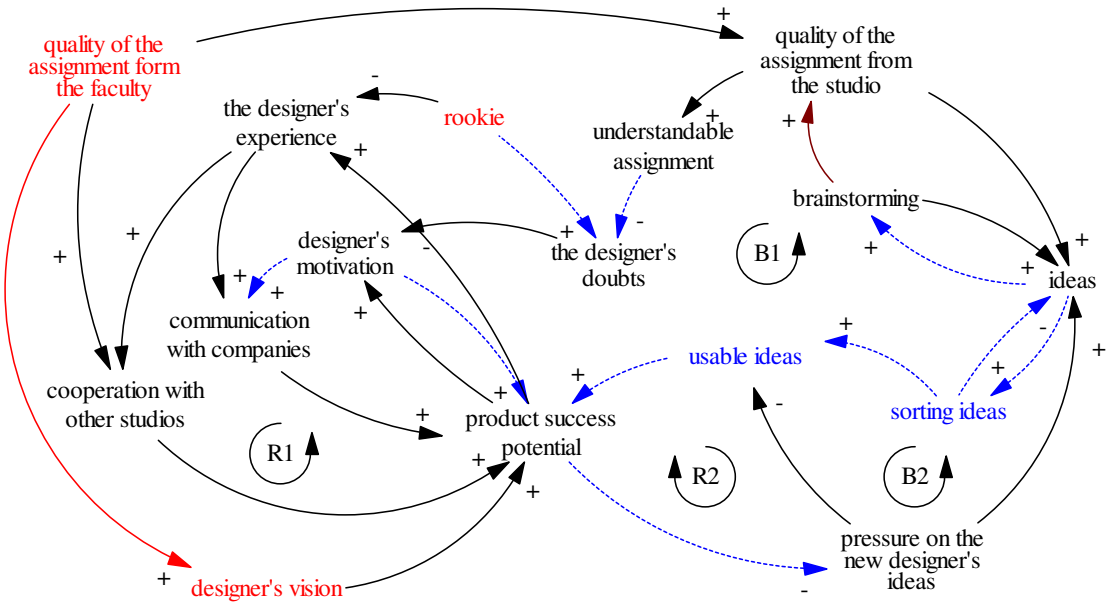

Fig. 4: Causal Loop Diagram as a new mental model (Own resource, 2017)

In accordance with the systems thinking method (Senge, 2006) and in order to make the back-loop diagram easy to understand, we marked all closed loops with two symbols: (1) with R for reinforcing, which means that with every new circulation through the loop all the elements within have the tendency to grow or to fall; (2) with B for balancing, which means that the Loop has a balancing task, or – to be precise - rather counteracting, and it contains an odd number of minuses. As these are back-loops, it does not matter from which element we start telling their story. A systematic creative project does not have any explicitly defined beginning or end.

Loop R1. If the number of potentially successful designer products increases over time, this will increase the designer's experience as it expands their portfolios. If their experience is greater, he or she can start communicating with retail chain stores, and this again increases the potential for their success in the design market. Experienced designer will also work better with other studios and this collaboration will also increase the number of potentially successful products.
Loop R2. Once a designer reaches an idea that has a high potential for success, he or she will be under the decreasing pressure of new ideas, and their ideas will be more usable as they can develop and think more. *("... even if coming up twice a week with new ideas and get somewhere is not always easy...").*
Loop B1. Increasing pressure on new ideas of a designer increases the number of new ideas that come up thanks to brainstorming technique. Brainstorming enhances the quality of the assignment from the studio, helping to make the assignments more comprehensible. The high clarity of the assignment reduces the designer's doubts and increases his / her motivation, which again will contribute to the higher product success potential.
Loop B2. Decreasing pressure on new ideas reduces the number of new ideas, which also reduces the need to sort them, and this affects fewer usable ideas, which will again reduce the potential for product success. The lower potential of product success will increase the pressure on new designer ideas.

Archetype Limits to Grow

The structure of the archetype is composed of one reinforcing loop and one balancing loop. To simplify the description of the archetype, let us assume that it consists only of loops R1 and B1. **Reinforcing loop R1**: The ongoing process is strengthening itself by creating opportunities for increased growth. A condition that must be fulfilled is that the increasing variable has the potential for success of the product. As it grows, the designer's experience is also increasing. Experienced designer is better able to work with other studios, which increases the product's success potential. **Balancing loop B1**: The slowdown occurs as a result of the balancing process that will begin to apply when the "limit" is reached. This limit is in our case the part of the system that acts on the variable pressure on the new ideas of the designer. For example, it may be the capacity of a studio that is unable to develop other designer ideas. Focusing on lots of new ideas consumes both financial and human resources and thus opposes the brainstorming. Once the brainstorming variable is reduced, the quality of the input from the studio is also reduced. When the studio does not give an explanation of the assignment, its clarity will be reduced, the designer's motivation will be reduced and the product's potential for success will be reduced.

How Might We Increase The Potential For Product Success?

It remains to answer the research question: How might we increase the potential for product success? We are looking for a solution that is given by the structure of the system. Given the fact that we have discovered the Limits to Grow archetype in the mental model (Fig 4.), we will focus on the use of the guiding principle by Peter Senge (2006). We must solve the negative effects of this archetype. We cannot see only the growth loop and the growth process. It is also necessary in the process of completing the idea to strengthen the capacity of the atelier, which is oriented towards new ideas and their appropriate sorting. As is clear from the feedback chart, the potential for product success not only increases the number of usable ideas, but also the intelligibility of the assignment and the designer's motivation. The clarity of the input increases not only the implicit variable quality of the input from the workshop but also the brainstorming.

Conclusion

An analyzed problem may be described as a system structure, which means interlinking all the components of the system. (Šusta, 2015). The only demonstration of the structure that we are able to capture using our senses are events. Qualitative research is based on the analysis of events, as we ask about what happened and we get answers. Research Question: How might we get a potentially successful innovation? We have found one strategy that we have described in the article and justified on the basis of design thinking in the language of systems thinking. Behavior that threatens our goal is to quietly reduce the product's product potential through low pressure on new designer ideas and lowering the quality of the assignment from the studio. This danger corresponds to the Limits to Growth Archetype. We will prevent it from negatively impacting the capacity of the studio to create new ideas and stay in a brainstorming process that improves the quality of the assignment from the studio. We do not give up new ideas, even if we do not implement them all, their search process increases the clarity of the designer's assignment. New ideas also deal with the choice of new communication and research approaches to design thinking. That is how we can better understand the customer, the assignment becomes clearer, and we get closer to our model, model or prototype to a successful innovation.

Acknowledgements

I would like to thank the author of the fashion collection Adéla Malendová for exemplary filling of the questionnaire and for the interview. The article was supported by Project No. 4/2017/FSR, which was financed from the strategic development fund of Tomas Bata University in Zlín.

Abstract

This paper investigates the effect of green supply chain practices on environmental development. There is a growing need to study the effects of green supply chain practices towards environmental development in the manufacturing industry due to the large environmental impact and the growing pressure for companies to go green. A survey was sent to 621 Malaysian ISO 14001 certified manufacturing companies. With a total of 146 usable questionnaires, the response rate was 23.51%. This study identified that green purchasing and eco-design has a positive effect towards environmental development. These results present empirical evidence of the relationship between green supply chain practices and environmental development. The adoption of green supply chain practices by manufacturing firms would be justified, not just by merely moral grounds, but also the positive effect companies gain in their performance.

Keywords: environmental development**,** green purchasing, eco-design, reverse logistics

Introduction

In recent years, the issue of sustainability and the environment has become a key managerial concern. Presently, businesses, societies and governments are giving more attention to the issue as there are escalating challenges revolving around balancing between environmental and business requirements. In view of the challenges faced by organisations, green supply chain practices has emerged as an approach that extends the environmental responsibility of organizations throughout their entire supply chain. There is a growing need to study the effects of green supply chain practices towards corporate sustainable development in the manufacturing industry due to the large environmental impact and the growing pressure for companies to go green.

Although green practices are well founded in developed nations, however, they are not well established in developing countries (Gonzales et al., 2010). Little is known about the potential of green supply chain practices towards corporate sustainable development in the Malaysian context. The increasing number of ISO 14001 certification shows that Malaysian corporations aim to endure in the current highly-competitive contemporary business setting (Rahman, 2012). Hence, this paper seeks to investigate the effect of green supply chain practices (green purchasing, eco-design, reverse logistics) towards environmental development.

Literature Review

Corporate Sustainable Development

The WCED defined sustainable development as development that meets the requirements of present-days without conceding with the abilities of the forthcoming generations to meet their essentials which is concerning the integration of economic, environmental and social impacts of development (WCED, 1987). There are various viewpoints of analysis in studies on Corporate Sustainable Development (CSD). CSD is recognised as an extensive notion because it comprises of an entire set of normative concerns associated with both the function of businesses in society and the natural setting (Sharma and Ruud 2003).

The main purpose of CSD ought to be for the achievement of a firm's economic performance at the same time considering the societal wellbeing and environmental constraints (Sharma 2002; Osterle et al., 2010). Yet, the most vital and vigorous debate related to sustainable development is the method and utility of assessment for future needs and desires by an organisation (Saaty, 2008). The requirements of upcoming generations are an attached component of the sustainable development idea (Orlitzky, 2008). Thus, the primary worry to CSD is concerning the decision for forthcoming generations' essentials, where sustainability decisions must have more than a superficial assessment of upcoming necessities, because intergenerational fairness is a difficult, vital and emotional notion that is important for corporate sustainable development dimensions (Yam, 2012).

One of the broadly recognised CSD frameworks explains the paradigms of CSD through three linked dimensions, identified as environmental, economic and social developments (Erol et al., 2009). These three extents of CSD are recognised respectively, environmental development through cooperate environmental management for refining the ecosystem, economic progress through firm value creation by refining the efficiency and effectiveness of services and products, finally, social development through corporate social responsibility in terms of increasing social wellbeing and encouraging better societies (Bansal 2005). This study adapts the works of Chow and Chen (2012) and defines CSD as the extent to which firms are willing to adopt environmental, economic and social development in their operations. This paper presents findings on the effect on environmental development.

Environmental Development

In general, the complexity in measuring environmental development is evident through the assortment of information utilized, from subjective indications, case studies, and surveys to proprietary information sources (Montabon, Sroufe and Narasimhan, 2007). Numerous researches have resolute to environmental development by utilizing a survey due to its extensive and merely perceptual view (Montabon, Sroufe and Narasimhan, 2007). But countless studies have identified a list of items to measure environmental development, such as decreasing water usage (Erol et al. 2009), recycling waste, reversing logistics and redesigning products (Prahinski and Kocabasoglu, 2006) and making green purchases (Diabat and Govindan, 2011).

This study identified the characteristics of present dimensions and measured environmental development from a rather broad and fundamental view. Numerous taxonomies depict environmental development, extending from reactive to proactive advances (Pradeep, 2012). In a majority of cases, the reactive advancement entails activities that could reduce the environmental effect of products and services through

proper waste disposal (Schianetz and Kavanagh, 2008). On the other hand, the proactive advancement entails alternate fabrication procedures that reduce waste and emissions (Bansal, 2005). Alternative processes includes, utilizing minimum conventional fuels and reducing negative effects towards animals and the natural environments (Lindgreen et al., 2009). Also, they are practices that reduce procurement of non-renewable resources, chemicals, components and decrease energy utilization (Baumgartner and Ebner, 2010).

Green Supply Chain Practices

In the 21st century, Green Supply Chain (GSC) has appeared as a significant element of the environmental and supply chain approaches in many companies. GSC practices can be defined as applied organisational activities motivated to allocate and circulate environmental management, in specific progressive environmental managing practices, through the whole supply chain, by extending relationships between large-sized buying organisations and their suppliers (Lee, 2008). In this context, supply chains attempt to preserve internal wellbeing and environmental sustainability by the ability to self-regulate based on data from the external environment (Vachon and Klassen, 2006).

As establishments that form a supply chain become conscious of customer requirements for goods and services delivered without harming the environment, administrators will make choices that support the incorporation and organisation of GSC practices along the supply chain (Vachon and Klassen, 2008). It is commonly thought that supply chains and establishments can achieve competitive advantage by being the pioneers to embrace environmental sustainability and adopt GSC practices (Green et al., 2012). This study adopts the green supply chain practices that were identified by Eltayeb (2009). They conducted a study by reviewing twenty one literatures on green supply chain practices and determined that the green supply chain practices can be categorised into three main practices, namely (1) green purchasing, (2) eco-design and (3) reverse logistics.

Green Purchasing

Green products purchasing is one of the responses towards addressing environmental concerns. As green goods are somewhat new for Malaysian industries, there are limited recognized studies about green consumers, green marketing and green product in Malaysia (Shahnaei, 2012). Previous literatures in Malaysian identified, cost reductions, marketing prospects and financial earnings from the trade of green goods, to be the key reasons organisations are implementing green practices (Eltayeb, Zailani and Jayaraman, 2009). As of current, companies are gradually dealing with their environmental performance to ensure the supplies and machinery utilized by them are environmentally-friendly and are fashioned from environmentally-friendly procedures.

Largely, green purchasing concentrates on assisting organisations attain savings in the long run by keeping them from any possible losses to their brand value (Shi et al., 2012). In a wider context, green purchasing guarantees the commitment of supply chain managers towards sustainable development by obtaining or purchasing environmental friendly inputs to address the general environmental concerns (Kumar et al., 2009). Subsequently, when the virtuous of the company overlaps with the benefit of the society in which it functions, there is a synergistic consequence. Therefore, the company would benefit from improved operations management combined with increased sales as the society shifts toward sustainability and consciousness for greener products.

In addition, green purchasing specifically addresses the environmental concerns of manufacturing firms and are intended to significantly influence environmental management (Diabat and Govindan, 2011). Also, a study by Green et al. (2012) identified that green purchasing provides enhanced economic and environmental management, this leading to enriched operating and organizational outcomes. Owing to this, businesses are aiming for green purchasing among their consumers and implementations of environmental management concepts in their manufacturing processes for sustainable development (Hajli and Hajli, 2013).

Eco-Design

Eco-design includes activities that change the resources and materials utilized throughout the manufacturing procedures to be less harmful and more environmentally friendly. The main purpose of eco-design is to reduce an item's environmental effect throughout its entire life cycle. The eco-design practise assimilates environmental features into the product designing processes, keeping in mind the complete movement of the product in its supply chain (Handfield et al., 2002).

Eco-friendly or ecological design places importance on investment recapture and is identified to positively affect environmental outcomes. This has been proven in a study by Cheng and Shiu (2012) where they identified, in the manufacturing industry, teamwork with retailers and suppliers' resulted in better environmental performance. Therefore, eco-design facilitates corporations to increase environmental performance and to close the supply chain by managing product practicality while decreasing the environmental effects of product life-cycle (Zhu et al., 2008). Hence, environmentally accountable design or eco-design is a crucial GSC practice that assists firms towards realizing their goals such as replacing harmful and hazardous materials with environmentally friendly substances, decreasing resource usage, and increasing organizational obligation towards their products.

Due to standards and consumers' increasing consciousness of environmental concerns, firms must change their daily actions from design to eco-design to remain competitive. According to Lauring and Thomsen (2009), the only manner to enhance corporate sustainable development is to improvise. That is, to move to more sophisticated types such as product differentiation and innovation through eco-design. However, a substantial reduce in environmental effect is not attained by merely including a 'green' limitation but then again environmental effect is reflected from the designing stage.

Reverse Logistics

The concept of reverse logistics has been discussed in many past literatures and was initially defined as "the function of logistics in product recovery is to decrease resources, reuse, substitute resources, recycle materials, discard waste, restore, remanufacture and amend" (Lee, 2008). This decrease in resources take account of both the reduction of resources utilized in goods and the reduction of waste and energy attained through the design of environmentally-friendly goods (Gupta et al., 2013). Previously, when the alternative of decreasing resource has been used extensively, the subsequent intention was to recycle materials, and the reusing of discards through reverse logistics. Yet in organizations, reverse logistics was typically the last option employed (Gupta et al., 2013).

Through the changes of time, in the existing business setting, companies are not solely competing on a producer to producer basis, but also on supply chain to supply chain basis. Somewhat, the real competitive encounter is between supply chains (Gupta et al., 2013). Hence, establishments globally have

started understanding the significance of reverse logistics towards corporate sustainable development. Thus, companies are required to deal with the reverted goods in an efficient fashion to gain consumer's relationship and reduce the related expenses (Yacob et al., 2012). Consequently, the encouraging findings of reverse logistics among businesses through waste management provides hope to commercialize this idea and are increase practical executed. In a quantifiable manner, reverse logistics is beneficial for the enhancement of sustainable development both at the individual businesses and supply chains level (Starostka-Patyk and Grabara, 2010).

Research Design and Methodology

A survey was sent to 621 Malaysian ISO 14001 certified manufacturing companies from the Federation of Malaysian Manufacturers (FMM) directory 2014 of Malaysian Industries (FMM, 2014). This research was carried out using a 7-point Likert scale for environmental development. The scales are from 1= a small extent to 7= a large extent. The items were adopted from Chow and Chen (2012). For green purchasing, eco-design and reverse logistics, this study uses a 5-point Likert scale. The scales are from 1= not at all to 5= very high extent. The items were adopted from Eltayeb (2009).

The questionnaires were e-mailed to the respondents. After three reminder emails, two postal mails and in-person surveys, 146 completed questionnaires were received. With a total of 146 usable questionnaires, the response rate was 23.51%. The response rate is considered adequate given the low levels of reply from mail and electronic mail surveys (Sekaran and Bougie, 2013) and generally low response rate for this sort of correlational study in Malaysia. The response rate of this study is also recognised to be satisfactory in relation to similar studies in Malaysia, such as Eltayeb (2009) whose research on green supply chain initiatives stated a 23.9% response rate and Vachon and Klassen (2006) whose research on green supply chain initiatives attained a response rate of 23%.

SPSS (Statistical Package for Social Science) software for Windows release 21.0 was used to analyse the data. The profile of responding firms are shown in Table 1. The table indicates that most organisations (32.9%) are from the electrical and electronics industry and the second highest being from the wood and furniture industry at 17.1%. The remaining percentages were distributed between the metal and machinery, chemicals, food and beverage, rubber and plastic, paper, textile and apparels and finally the other industries. From the table, it can also be observed that there are only a few newly started up organisations (5.5%) and most of the firms are well established and have been functional for more than 15 years (83.6%). Likewise, most organisations are noticeably large firms with exceeding 250 employees (75.3%).

Table 1: Profile of Responding Firms

Variable	Categories	Frequency	Percentage
Type of Industry	Electrical & Electronics	48	32.9
	Chemicals	11	7.5
	Food & Beverage	8	5.5
	Rubber & Plastic	3	2.1
	Textile & Apparels	1	0.7
	Paper	2	1.4
	Wood & Furniture	25	17.1
	Metals & Machinery	15	10.3
	Others	33	22.6
Age of Firm	Less than 5 years	8	5.5
	5 – 9 years	5	3.4
	10 – 15 years	11	7.5
	More than 15 years	122	83.6
Number of	Less than 100	14	9.6
Employees	100 – 250	22	15.1
	251 – 500	40	27.4
	501 – 1000	40	27.4
	More than 1000	30	20.5

Results and Discussion

A study by Chiarini (2013) reported that, components of social influence, environmental concern, green product knowledge, and environmental labeling are significantly related toward green purchase behavior by organizations. Therefore, towards pursuing sustainable development goals and preserving the environment, implementing green purchasing practices in organizations is essential (Su et al., 2008). Thus this study hypothesizes that:

H1. Green purchasing has a positive effect towards environmental development.

This design for "green" is sometimes referred to or defined as design for the environment. Whereby, the purpose of eco-design is to reduce products' environmental effect without causing an undesirable trade-off with other design standards, such as prices and utility for sustainability. Thus, eco- design emphasises investment recovery and will positively influence the sustainable development of organisations by decreasing the environmental effect of designs (Green et al., 2012). Thus this study hypothesizes that:

H2. Eco-design has a positive effect towards environmental development.

The concept of reverse logistics has been defined as "the part played by logistics in merchandise returns, decreasing sources, recovering, materials replacement, reuse of materials, waste removal and restoring, mending, and remanufacturing" (Lee, 2008). It is essential for manufacturers to handle the reimbursed

merchandises in an optimal manner to improve customer's relationship and reduce the related charges (Yacob et al., 2012). Reverse logistics aids the practical application of sustainable development both at individual business and supply chain levels (Starostka-Patyk and Grabara, 2010). Thus this study hypothesizes that:

H3. Green purchasing has a positive effect towards environmental development.

Regression analysis was conducted to test the hypotheses. Results of the regression analysis of green supply chain practices on environmental development are shown in Table 2.

Table 2: Multiple Regression Result: Effect of Green Supply Chain Practices on Environmental Development

Variables	DV: Environmental Development		
	Standard Beta	t-value	p-value
Green purchasing	0.215*	2.531	0.012
Eco-design	0.264**	3.070	0.003
Reverse logistics	-0.038	-0.453	0.651
F value	4.476**		
R^2	0.140		
Adjusted R^2	0.109		
R^2 change	0.127		
F change	6.721**		

Significant levels: *p<0.05, **p<0.01

Referring to Table 2, green purchasing (β= 0.215, p<0.05) showed a significant effect on environmental development. By implementing green supply chain practices, firms generally gain a competitive advantage by adapting their internal and external aspects of their firm. In this study, it has been identified that green purchasing does not only provide internal benefits to the firm but also external benefits to their suppliers. In other words, green purchasing practices in firms reflects on their suppliers, besides the focal firm. This view is supported by Rao (2006), where he stated that generally, green purchasing encourages effectiveness and cooperation amongst business partners and their main companies. In addition, green purchasing also has a significant effect on the company's commitment to the society, environmental development, decreasing waste and attaining cost savings.

This study also identified that eco-design (β= 0.264, p<0.01) has a significant effect on environmental development. Results from this study identified a significant effect between eco-design and environmental development. Eco-design, in contrary to green purchasing and reverse logistics, is an internally-focused type of green supply chain practice. This means, firms try to improvise the environmental qualities of its goods internally, with some collaboration or interface from external groups, such as suppliers and consumers. Therefore, the impact is directly linked to the internal productivity and gains to the company. A past study by Green Jr et al. (2012) recognized that effective adoption of green supply chain practices like eco-design, would lead to better environmental and social outcomes which includes enhanced operational and organizational productivity. Green Jr et al. (2012) also further stated, that eco-design targets to meet the requirements of consumers for eco-friendly products and services fashioned from green design.

The results of this study also identified that there were no significant relationships between reverse logistics towards environmental development. This finding can be explained through the fact that the government does not play the central role of a facilitator to provide structured responsibilities and obligations for the diverse components involved for environmental conservation and a better social living standard. Therefore, firms are not embracing reverse logistics wholly, instead, reverse logistics is viewed as an optional practice in firms. This finding is supported in past literature by Kersten (2008), where most firms do not embrace reverse logistics whole-heartedly because there is no strong government enforcement for reverse logistics to be practiced in all firms. Therefore, the ultimate potential of reverse logistics for the environment, society and the nation is yet to be achieved.

Conclusion

This study identified that there exists a statistically significant positive effect of green purchasing and eco-design towards environmental development. The findings of this study is supported by past literature by Chiou et al. (2011), where they determined that greening the supply chain within firms lead to noticeable benefits towards the social standpoint, environmental outcomes and added advantages to the corporation. Firms with green supply chain practices can position themselves to gain opportunities and influence the effect of environmental development by concentrating on green purchasing and eco-design, in order to meet environmental requirements encouraged by the government. Also in this research, the Natural Resource Based View theory was used to shed light concerning the current business environment and how firms seek to attain competitive advantage by implementing green supply chain practices for competence in forthcoming years. The findings of this research indicate that managers in Malaysian manufacturing companies have to comprehend that green supply chain practices have significant gains, in terms of satisfying the increasing demands of customers for greener products which can be directly reflected on environmental development. In line with this finding, managers in the Malaysian manufacturing industry are encouraged to amplify their implementation of green supply chain practices so as to lead towards corporate sustainable development.

Development of Agricultural Location Theory

Artem Golovin, Southwest State University, Kursk, Russia, cool.golovin2011@yandex.ru

Alexey Golovin, Southwest State University, Kursk, Russia, dr.golovin2013@yandex.ru

Marina Parkhomchuk, Southwest State University, Kursk, Russia, marinaanatollevna@yandex.ru

Abstract

Having studied the location theories developed by world scholars it was concluded that the attention paid to the location theory of agriculture was insufficient. J.Thünen is one of the few scholars who considered the issues of farming location. However, economic environment has changed significantly, transportation costs are no more the main ones, and production gravitates towards market outlets and resources. Agricultural resources include financial (the most mobile), human (less mobile) and land (not mobile) resources. Therefore, in present-day conditions there is a need for the development of the theory of location considering human resources and market outlets. Labor input in the sphere of crop farming and livestock breeding was analyzed, and on this basis, levels of farming location were offered. Implementation of the developed approach to agricultural location can ensure sustainable development of rural areas through conservation and development of human resources in rural areas and increase of efficiency due to heavy, large-size production location close to agricultural product processing centers.

Keywords: location theory, agriculture, human resources, labor cost, efficiency, Russian Federation.

Introduction

Since first theories of location appeared, significant changes have taken place both in production and people's life on the whole. Most theories were focused on a transportation constituent, which was caused by inferiority of roads, vehicles and methods of products preservation. Modern production is provided with good hard-surfaced roads, efficient freight transport and products processing providing commodities transportation over long distances. There is an adverse trend of rural depopulation in Russia. The reasons of the depopulation are rural unemployment, low level of infrastructure development, insufficient efficiency of farming and demographic problems. Development of a modern theory of agricultural location, relevant for current conditions of the economic environment, will ensure efficient use of human resources, increase efficiency of farming and provide stable conditions of the economy.

The purpose of the studies is to develop a theory of agricultural location meeting the current requirements of national economy performance.

To achieve the goal it is necessary to accomplish the following tasks:

– to study existing theories of location;

– to reveal specific features of the theory of location;

– to substantiate the choice of production location based on labor costs;

– to estimate labor costs for main branches of farming in the Russian Federation;

– to develop the location scheme of the regional farming.

The object of the research is social and economical processes mediating location of agricultural production branches.

The subject of the research is economic relations in the field of agricultural location.

Working hypothesis is in a scientific guess supposing that reasonable farming location based on labor costs will even and sustain living standards for the population of the region and provide efficient location.

Theoretical and methodological basis of the research includes some theoretical propositions, methodological approaches and philosophy, results of the research of Russian and foreign scholars in the field of production location.

The following methods were applied: abstract-logical, comparative methods, methods of grouping and case study, statistic analysis and system analysis methods. Tabulated graphical forms were used for material presentation, systematization and scientifically grounded interpretation of the empirical data.

The information - empirical base of the research includes scientific papers devoted to the problem under study, materials of the Federal Service for National Statistics of the Russian Federation, data from financial and economic reports on Russian Federation agricultural producers, results of research of regional scientific research institutions, monographic and economic research data, printed media and Internet materials.

Results and Discussion

The founder of the theory of location was J.Thünen. In his paper "The Isolated State with Respect to Agriculture and Political Economy" some patterns of agricultural location were defined (Thünen, 1826).

J.Thünen studied agricultural production location on the basis of an abstract model of the isolated state with a city in its centre which is the only market outlet and an industrial products supplier. The difference between prices for both farming and industrial products is the difference between transport costs for products transportation to the market outlet. On the basis of difference in transport costs per product unit, J. Thünen highlighted the best areas for the location of production of certain types of products. In this way J. Thünen proved the fact that the higher the productivity is, the closer to the market the production shall be located and, correspondingly, vice versa, the lower the production intensity is, the farther from the market outlet it is located.

J. Thünen developed a model of six concentric rings or areas. In the centre there is a central city, the consumer of farming and industrial products.

The first level is for a free farmstead located in the suburban area. Gardening and stabled cattle-breeding are the basis of the area. This level is characterized by high-technological and intensive production. To support soil fertility organic fertilizers are used, there are no fallows at all. It should be mentioned that there are no organized crop rotation in its pure form.

The second level is for forestry. Its proximity to the centre is accounted for by high production volumes and consequently, heavy transport costs. Large volume of consumed at that time wood was due to great demand for fire wood and timber for construction.

The third level is for crop rotation farming. The number of crops includes grain, tilled crops and perennial grass in equal proportions. Livestock is kept stabled. There are no fallows, and soil fertility is supported by organics and perennial grass in crops rotation.

The fourth level is for ranching, the land is used less intensively. More than 40% of the used land is for cattle grazing, and in the rest part of the area grain crops are grown and a considerable area is provided for fallows. Grains, livestock for slaughter, and animal products (butter, fat etc.) are transported to the market.

The fifth level is for a three-course farming system where shares for fallows, winter and spring crops are equal. The major specialization is grain farming and cattle-breeding for farmer's own needs. There are small meadows and pastures to provide animals with fodder.

The sixth level is for cattle and sheep-breeding. Farming is extensive. The most part of land is range lands and hay meadows, grains are grown for farmer's own needs. The main products are meat, wool, skins and other animal products.

Some drawbacks of Thünen's model are its abstract character, a limited number of factors, and a large number of restrictions. Nevertheless, J.Thünen laid the foundation of agricultural location and application of abstract mathematical models in economics.

W. Launhardt was another scientist who studied the issues of the theory of location. Location of an industrial plant was the main subject of his concern. He like Thünen, was focused on transportation costs. He proceeded from the abstract model where production costs are similar through the whole territory and the point of optimal location is closely connected with the weight of transported products and transport costs. As a result, he developed a location triangle (Launhardt, 1882).

Launhardt's weight or location triangle is the first model aimed at the solution of the problem of optimal location of production. The positive aspect of Launhardt's model is a great number of points of sources of raw materials in case a convex polygon is formed, and the negative aspect is the fact that only transportation costs are taken into consideration as a factor of industrial location.

The next scientist who significantly contributed to the theory of industrial location was A.Weber. In his work "Über den Standort der Industrie (Theory of the Location of Industries) (Weber, 1909) he developed J.Thünen's and Launhardt's theories.

He introduced new factors of industrial location, set a task to minimize all production costs, and classified the factors of industrial location according to the extent of their influence on production cost reduction. The following factors impacting industrial location were identified: raw material cost, labor cost and transportation cost. A. Weber excluded raw material cost from the analysis as taken into account in transportation costs. He called other factors impacting industrial location, "united agglomeration", which was the third factor of production location. Each factor was analyzed to find the optimal location for an enterprise.

To find the optimal point of transportation Launhardt's location triangle is used. Production with a significant material index is located closer to sources of raw materials; production with a low index is located closer to consumption centers.

At the next stage, location of labor is taken into consideration. A settlement attracts production to it, and production moves to it from the transportation point if labor cost saving exceeds transport cost saving.

To consider a joint impact of transport and labor orientation A.Weber offered to use isodapanes. Transport costs increase caused by the relocation of the production to the point of human resources is even in all directions. Due to this there are points with similar growth of transport costs and lines connecting these points are called isopadanes.

At the final stage of production location, agglomeration orientation of an enterprise is defined. To estimate agglomeration changes A.Weber used a saving index based on cost savings and increase in production output.

Analysis of the influence of agglomeration factors assumes exclusion of other factors impact except for transport costs. On the basis of transportation orientation, production alterations in transport points caused by the influence of agglomeration factors are found. These changes are efficient if the effect of agglomeration is higher than costs for relocation.

Location of agglomeration production takes place on the bases of drawing isodapanes around transportation points. Some isodapanes are critical ones, i.e. transportation cost over-expenditure is equal to the effect of production agglomeration. According to A.Weber, production relocation from transportation points is feasible if these producing units are not beyond their critical isodapanes connected in one place.

An indispensable condition of production location is availability of close market outlets which are concentrated mostly in settlements. Theory of industrial location with consideration for settlements availability was developed by W.Christaller. Christaller did not rely on the study of the existing system and location regularities but proceeded from the concept of ideal production location.

In his work "Central places in Southern Germany" W.Christaller proceeded from the idea of ideal conditions of location, i.e. is a valley with equally fertile soils and even distribution of population. Specialization, growth of commodity production and product range cause a gap between production centers and centers of consumption (Christaller, 1933).

Central places according to W. Christaller are production centers, providing themselves and some areas with commodities. According to the theory of central places, production distribution areas are formed as regular hexagons, which cover all the settled territory. W. Christaller explained why basic necessities shall be realized in all settlements, such goods as clothes, household goods etc. shall be disposed in middle-sized settlements and luxury goods only in large cities.

Each central place does not only provide its area (hexagon) with required products but also areas of settlements of the lower level. Therefore, a central place has a production distribution area in proportion to its rank.

W. Christaller's theory drawbacks are the abstract character of the model and difficulty of its implementation due to the fact that influence of climate and environment conditions, raw material locations, etc. is not taken into consideration. At the same time this theory should be regarded ideal, and in comparison with it recommendations for the improvement of the existing production location can be developed.

Location theory was further developed by A. Lösch. Using J.Thünen's, W. Launhardt's, A. Weber's ideas A. Lösch built his own theory of industrial location based on profit maximization. A. Lösch found out that location of enterprises in case of free competition is determined not only by profit maximization, but by the growth of the number of firms and coverage of all available territory. The optimal location of an enterprise is at the top of the regular hexagon of the "Christaller's grid".

An economic region according to August Lösch should be described as a market with boundaries determined by inter-regional competition. A. Lösch studied market areas defined by the radius of efficient production distribution, and an economic landscape, which is the highest level of the region which unites market areas (Lösch, 1940).

Lösch's significant contribution to the location theory is in the development of the theory of spatial economic equilibrium. Besides, he gave a mathematical description of the process of operation of the system of consumers and manufacturers, where each business entity is attached to a certain point in space. Functions of cost and demand are the components of the equilibrium model. Equilibrium is characterized by the following conditions:

1) market areas are of a minimum size and have the form of a regular hexagon;

2) enterprise location provides full coverage of the whole possible area;

3) stable equilibrium is provided by the going of the boundaries of market areas along indifference curves;

4) lack of surplus revenue;

5) location of every enterprise provides maximization of advantages both for consumers and manufacturers.

A. Lösch's significant contribution into the development of the location theory is in the developed by him mathematical tool, determining the location of the equilibrium point of the enterprise considering demand in a certain market area and production costs. Profit maximization and coverage of the whole area are the defining moments in the location of an enterprise. The abstract character of the theory and imperfection of the mathematical tool are the drawbacks of Lösch's theory. These drawbacks do not derogate his contribution into the spatial location theory.

The location theory was further developed in "Spatial Economy: Cities, Regions and International Trade" by Paul Krugman. He managed to formalize in the form of an economic model the idea of enterprise gravitation towards market outlets and materials suppliers, which leads to the concentration of production attracting a great number of enterprises (Fujita, Krugman, Venables, 2001).

Cumulative expansion of a region economy is possible only when it reaches a certain big size, then it starts growing on its own bases.

Stratification of regions according to the level of their development is explained by P. Krugman's "centre-periphery" theory. The center attracts labor, financial and material resources which are used for innovations.

Kruman's agglomeration model takes into consideration two types of goods: manufactured (M) and agricultural (A). Agricultural enterprises produce similar range of products and industrial enterprises produce different products. Production of manufactured goods is characterized by the economy of scale, and agriculture on the contrary is characterized by the absence of the economy scale.

P. Krugman defined two groups of factors important for taking the competitive advantages of regions. Natural resources and geographical location, i.e. factors independent of human activities belong to the first group. Some regions have significant natural resources - mineral, wood and land resources and some regions have favorable climatic conditions or are located on the international trade routes.

Factors of the second group are the result of human activity; high level of human capital assets development, economy of scale (agglomeration) and institutions providing economic development belong to this group.

It should be mentioned that a number of scientists criticize this Krugman's work, accusing him of the development of the theory on the basis of integration of other scientists achievements. However, in spite of the criticism P. Krugman's work is worthy of noticing.

On the basis of the studies of the theories of industrial location we see that only J. Thünen paid considerable attention to farming. Farming location was not the main subject of other academic economists' research.

Imperfection of the approaches to farming location and some gaps in the theories are the reasons for further development of this issue.

Recourses, processing centers and market outlets impact agricultural location. On this basis a number of assumptions for use of labor costs as a location index were defined.

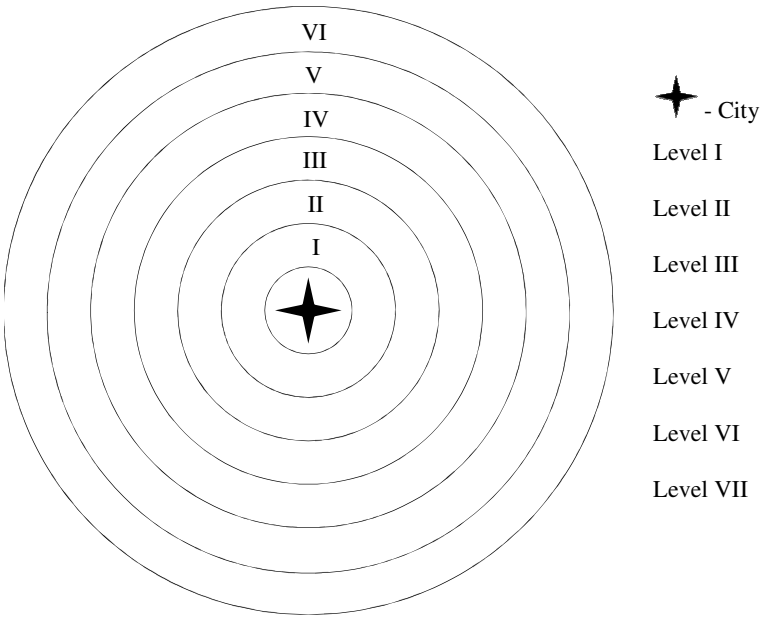
Firstly, growth of transportation costs impacts labor costs for production of specific products as it is impossible to transport freights without any personnel.

Secondly, land resources are not mobile while financial resources are very mobile; therefore, production should be located considering human resources.

Thirdly, raw materials are hardly used in farming, so, production location gravitates to processing centers and market outlets related to settlements, which are sources of human resources.

Table 1 shows farming labor costs estimate and their further grouping according to the levels of location.

Table 1: Labor cost estimate and levels of location of branches of farming in the Russian Federation



Parameter	Man-hour costs per 1 ha/1 animal unit	Level of location
Greenhouse vegetables *	25440.98	Level I
Horse-breeding	192.00	Level II
Dairy breeding	104.17	
Potato	65.24	Level III
Feeding roots and melons and gourds	44.78	
Apiculture **	33.33	Level IV
Fruit and berry crops	32.06	
Beef cattle breeding	31.23	
Field vegetables	25.20	Level V
Sugar beet	23.30	
Grain legume crops	15.65	Level VI
Maize for silage and green fodder	15.42	
Grain maize	11.01	
Soya bean	10.71	
Silage crops	10.00	
Winter cereals	9.51	Level VII
Spring cereals	9.34	
Perennial grass	8.00	
Rape	7.83	
Grain Sunflower	7.63	
Sheep and goat breeding (meat-producing)	6.88	
Grassland and pastures	5.61	
Annual grass	5.04	
Swine breeding	3.66	
Eggs	0.36	
Poultry husbandry	0.05	

Source: calculated by authors using statistical data

* – greenhouse area is represented in ha, not sq.m for relevant comparison;

** – bee-families;

Based on the conducted analysis of labor costs in farming in the Russian Federation (Table 1) there were obtained some groups; on their basis levels of agricultural location are represented in Figure 1.

Source: development of the author

Fig.1: Levels of location of farming branches

The first level is represented by greenhouse facilities and aquaculture. It is advisable to locate these types of farming production within urban territories due to the considerable labor costs. Lack of necessary information about labor costs of aquaculture facilities and difficulty of comparison of scopes of work did not allow us to include this type of activity in our research.

The second level of location is for horse-breeding and dairy breeding. It is advisable to locate these types of facilities in the suburban areas as labor costs for these activities are more than 100 man-hours per cattle. At the same time beside labor costs, dairy breeding location depends on low transportability of fresh products and high degree of processing of products.

The third level includes potato, feeding roots and cultivation of melons and gourds; high level of labor costs is caused by heavy weight of products which increases transport cost and labor cost for both cultivation and transportation.

Apiculture, beef-farming and fruit and berry crops cultivation have a high level of labor costs (31.23-33.33 man-hours, which allows us to include these types of production into the fourth level of location.

Labor costs for field vegetables and sugar beet are 25.2 and 13.3 man-hours per 1 ha of the harvested acreage respectively. They comprise the fifth level of location. It should be noted that vegetable, sugar beet and fruit and berry crops should be located in close proximity to vegetable stores, cannery and sugar plants.

The sixth level of location is for grain legume crops and feeding and industrial crops. Labor costs for these crops are 10.00-15.65 man-hours.

The seventh level is composed by crops and animal breeding which have the lowest labor costs. Grains, natural hay meadows, pastures, perennial and annual grasses, used for hay-harvesting, rape and sunflower for grains belong to the branch of plant cultivation in the seventh level of farming

location. Animal-breeding belonging to this level is sheep-, goat and swine - breeding and poultry and eggs production.

The formation of levels should be based on cluster technologies and creation of food internal regional clusters, which ensures efficiency improvement of farming due to the agglomeration effect.

Therefore, it is recommended to locate the most labor-consuming production in close proximity to settlements, which will provide rational use of human resources, including minimum migration and minimization of transport costs for population for commuting and products transportation to the centers for products realization and processing.

Conclusions

For the last century, technologies, forms and methods of farming have changed considerably; significant human resources are not required any more. These processes have led to rural population migration, reduction of the number of rural settlements, considerable part of which is by less than 60 % inhabited compared with the level of 1989, and some settlements ceased to exist. The proposed system of farming location will enable efficient use of human resources on the basis of their concentration. High concentration of population will in its turn enable decrease of migration processes and costs of state authorities for the support of underpopulated and dying out settlements. Rational peripheral farming location will provide local population with working places and decrease over-population of the regional centers.

Beside the use of labor cost in the proposed model it is necessary to apply environmental standards, soil, climate and natural conditions and take into account the state of the market.

Theoretical relevance of the research is in the development of the theory, methodological support and substantiation of measures for rational location of farming considering labor costs.

The results of academic and research work devoted to rational region farming location can be used to substantiate the trends of the development and increase of the efficiency of the farming sector of the region or the country as well as to achieve sustainable development of rural areas.

An analysis of innovation framework conditions between Poland and the other Moderate Innovators countries

Aleksandra Zygmunt, Opole University of Technology, Opole, Poland, a.zygmunt@po.opole.pl

Abstract

Innovation stimulate economic growth. Regarding the role of innovation in adaptation of countries, regions and firms to dynamic environment and enhancing their competitiveness, it is important to explore how innovation framework conditions in Poland differ from the other the EU countries with a similar to Poland level of innovation. Thus, the particular emphasis was put on Moderate Innovators countries. Hence, the aim of this paper is to investigate how innovation framework conditions in Poland differ from the other the EU countries with a similar to Poland level of innovation. To study multivariate analysis and the zero unitarization methods were applied. These methods allowed to divide Moderate Innovators countries into four groups and to multivariate analysis of the main drivers of innovation performance external to the firm. The time period was 2009–2015 and was limited by data availability. The study was based on data from the European Innovation Scoreboard 2017 related to innovation framework conditions dimensions: human resources, attractive research systems and innovation-friendly environment. This paper contributes to the existing literature by providing new insight on understanding the issues in regard to innovation framework conditions. The analysis revealed, among others, the necessity to strengthen in Poland actions to enhance main drivers of innovation performance external to the firm. It is assumed that the obtained results may be useful for country, regions and firms in fostering competitiveness.

Keywords: innovation framework conditions, Moderate Innovators countries, the European Union.

Introduction

The circumstances of rapid changes impact on countries, regions and firms. Keeping up with changes, it seems necessary to maintain and foster the capacity to competitive advantage. In this regard, a fundamental driver of competitiveness and economic growth is innovation. The importance of innovation to enhance competiveness of countries, regions and firms has been widely argued in the economic literature (see, e.g., Huggins & Thompson, 2015, 103-128; Fagerberg *et al*., 2012, pp. 1121-1131), especially in endogenous growth theory and knowledge spillovers theory. In particular, above theories put emphasis on the linkage between competiveness of countries, regions and firms (see, e.g., Asheim *et al*., 2011, pp. 1133-1139; Huggins & Williams, 2011, pp. 909-910). When considering this issue, the essential for economic growth is create appropriate conditions for innovation (Asheim *et al*., 2016, pp. 1-19). Against this background, the particular emphasis should be put on drivers of innovation performance. Regarding the significance of the country and regional policy to support competitiveness enhancing, the crucial are innovation drivers external to the firm.

Concerning the above, it is very important to explore how the main drivers of innovation performance external to the firm differ between countries with a similar level of innovation. Hence, the aim of this paper is to investigate innovation framework conditions in Poland against the other Moderate Innovators countries.

The study was carried out under theoretical and empirical analysis of the problem based on a related literature review and data from the European Innovation Scoreboard (EIS) related to Moderate Innovators

countries (the EU countries with innovation performance below that of the EU average). The time period is 2009–2015 and is limited by data availability.

The paper is organized as follows: First part presents a short overview of the literature on innovation framework conditions. Second part provides methods of the research. Next part presents the findings. Last part concludes the paper.

This paper contributes to the existing literature by providing new insight on understanding the issues related to innovation framework conditions. In order to understand the differences between Moderate Innovators countries in context of the main drivers of innovation performance external to the firm, the zero unitarization method and multivariate analysis were applied. These methods enabled to division of Moderate Innovators countries into four groups related to the level of indicators of innovation framework conditions.

Theoretical Background and Hypothesis Development

There is a widespread agreement in the academic literature that innovation is a key factor of development of country, regions and firms (see, e.g., Asheim *et al*., 2011, pp. 1133-1139; Huggins & Thompson, 2015, 103-128). With this regard, particularly salient is cooperation between regions and firms. Hence, achieved cooperation will enhance the competitive advantage of country, regions and firms. However, for such cooperation, suitable framework conditions for stimulation innovation are required. In this context, since early to current state of literature on innovation a strong emphasis is put on innovation drivers (see, e.g., Grillitsch & Nilsson, 2015, pp. 299-321; Florida *et al*., 2008, pp. 615-649) and the importance of combination of exogenous and endogenous drivers of regional development in shaping conditions for fostering the competitiveness of country, regions and firms (Barca, 2009, pp. 1-244). As regards firm capabilities in increasing innovation performance the special attention is put, among others, on leadership practices, development of individual knowledge, employees' skills and innovativeness, support culture (Lawson & Samson, 2001, pp. 377-400), investment, innovation activity (Zygmunt A., 2015, pp. 89-92) and project and firms' management (Maj, 2016, pp. 123-130; Bębenek, 2017).

On the other hand, the circumstances of dynamic environment enhance also the role of drivers of innovation performance external to the firm. In this respect, the contribution of the national and regional innovation systems in foresting innovation and increasing competitiveness, is crucial and connected with innovation-friendly environment, attractive research systems and human resources. From this point of view, such contribution is essential for creation network between, among others, research organisations, institutional environment, universities and firm (see, e.g., Asheim *et al*., 2016, pp. 1-19). Hence, the key role played knowledge spillovers and knowledge bases. Thus, human capital as an important driver of innovation performance external to the firm, is highlighted. According to a number of theoretical and empirical studies, human capital "operates by increasing regional income and wealth" (Florida *et al*., 2008, pp. 615-649) and become "a meaningful determinant for generating business growth" (Zygmunt J., 2017, pp. 226-236). In this context, the significance is put on the quality of human capital (see, e.g., Asheim *et al*., 2016, pp. 1-19), measured, among others, by the percentage of adults in the population with a bachelor's degree and above (Lee *et al*., 2004, pp. 879-891). A wide body of empirical literature assessing also the role of attractive research system as the essential driver of innovation performance external to the firm. The argument put forward here is that research system generates knowledge necessary for stimulation innovation performance (see, e.g., Asheim *et al*., 2011, pp. 1133-1139). This requires, among others, scientific research inputs for firms (Tödtling *et al*., 2006, pp. 1133-1139) and conferences and specialized journals (Fagerberg *et al*., 2012, pp. 1121-1131). Innovation performance external to the firm depends also on innovation-friendly environment. This highlights, among others, the growing importance of opportunity-driven entrepreneurship, as the core to "access and exploit knowledge and generate innovation" (Huggins & Thompson, 2015, 103-128).

An increasing rank of drivers of innovation performance external to the firm in foresting innovation and competitiveness, requires undertake studies how the main drivers of innovation performance external to the firm differ between countries with a similar level of innovation. Hence, the following hypothesis was posed: despite Poland belongs to the group of the EU countries with a similar level of innovation, innovation framework conditions in Poland differ from the other Moderate Innovators countries.

Methods of the Research

The data of this study were extracted from the last report of the European Innovation Scoreboard (European Commission, 2017) and refers to the main drivers of innovation performance external to the firm. In this respect, the EIS contains three dimensions regarding to human resources, attractive research systems and innovation-friendly environment. These dimensions and their eight specific indicators are consistent with endogenous growth theory and knowledge spillovers theory. The study uses data concerning Moderate Innovators countries, such as: Croatia, Cyprus, Czech Republic, Estonia, Greece, Hungary, Italy, Latvia, Lithuania, Malta, Poland, Portugal, Slovakia, and Spain. The time period was 2009–2015 and was limited by data availability. The descriptive statistics of diagnostic variables (mean, standard deviation, minimum, maximum) are presented in Table 1.

Table 1: Descriptive statistics of diagnostic variables

Variables			Mean	St. Dev.	Min.	Max.
Human resources	x_{1t}	New doctorate graduates	1.24	0.67	0.30	2.69
	x_{2t}	Percentage population aged 25-34 having completed tertiary education	34.05	9.01	22.41	51.46
	x_{3t}	Percentage population aged 25-64 participating in lifelong learning	6.90	2.90	3.00	12.04
Attractive research systems	x_{4t}	International scientific co-publications per million population	451.71	166.24	201.42	763.67
	x_{5t}	Top 10% most cited publications	7.06	1.98	3.81	9.79
	x_{6t}	Foreign doctorate students	8.75	5.47	1.06	20.98
Innovation-friendly environment	x_{7t}	Broadband penetration	8.03	4.76	0.14	16.71
	x_{8t}	Opportunity-driven entrepreneurship	2.15	0.97	0.78	4.18

Source: own calculations based on data from the European Innovation Scoreboard 2017 (European Commission, 2017).

All diagnostic variables distinguish sufficient variability (coefficient of variation is higher than 0.1).

In order to investigate how innovation framework conditions in Poland differ from the other Moderate Innovators countries, the zero unitarization method and multivariate analysis were applied. These methods provides a basis for an analysis the differences between the European Union countries (Balcerzak, 2015, pp. 190-205) and "enable comparing the values of synthetic index for all years" (Balcerzak, 2015, pp. 191). Thus, four classes of Moderate Innovators countries were grouping: (i) the countries with the very high level of indicators of innovation framework conditions, (ii) the countries with the high level of indicators of innovation framework conditions, (iii) the countries with the average level of indicators of innovation framework conditions, (iv) the countries with the low level of indicators of innovation framework conditions. Such grouping was done with regard to each of the EIS innovation

dimensions related to the main drivers of innovation performance external to the firm: human resources, attractive research systems and innovation-friendly environment.

At first, the normalisation of diagnostic variables was conducted. In this regard a constant reference point (the range of the normalized variable) was calculated, according to the zero unitarization method (Kukuła & Bogocz, 2014, pp. 7):

$$R(X_{jt}) = \max_{it} x_{ijt} - \min_{it} x_{ijt} \qquad (1)$$

In order to normalise diagnostic variables the following formula was used (all diagnostic variables are the stimulants) (Kukuła & Bogocz, 2014, pp. 7):

$$z_{ijt} = \frac{x_{ijt} - \min_{it} x_{ijt}}{\max_{it} x_{ijt} - \min_{it} x_{ijt}} \qquad (2)$$

, where $z_{ijt} \in [0,1]; (i = 1,2,\dots,n); (j = 1,2,\dots,m); (t = 1,2,\dots,l)$

Subsequently, the synthetic measure was calculated in compliance with the following formula (Balcerzak, 2015, pp. 196):

$$SM_{it} = \frac{1}{m}\sum_{j=1}^{m} z_{ijt} \qquad (3)$$

, where $z_{ijt} \in [0,1]; SM_{it} \in [0,1]; (i = 1,2,\dots,n); (j = 1,2,\dots,m); (t = 1,2,\dots,l)$

Next, on the basis of the synthetic measure and assumptions for grouping the EU countries proposed by Balcerzak (Balcerzak, 2015, pp. 196), the division of Moderate Innovators countries into four groups was made:

(i) the countries with the very high level of indicators of innovation framework conditions:

$$SM_{it} \geq \overline{SM_{it}} + S(SM_{it}) \qquad (4)$$

, where $(i = 1,2,\dots,n); (t = 1,2,\dots,l)$

(ii) the countries with the high level of indicators of innovation framework conditions:

$$\overline{SM_{it}} \leq SM_{it} < \overline{SM_{it}} + S(SM_{it}) \qquad (5)$$

, where $(i = 1,2,\dots,n); (t = 1,2,\dots,l)$

(iii) the countries with the average level of indicators of innovation framework conditions:

$$\overline{SM_{it}} - S(SM_{it}) \leq SM_{it} < \overline{SM_{it}} \quad (6)$$

, where $(i = 1,2, \dots, n)$; $(t = 1,2, \dots, l)$

(iv) the countries with the low level of indicators of innovation framework conditions:

$$SM_{it} < \overline{SM_{it}} - S(SM_{it}) \quad (7)$$

, where $(i = 1,2, \dots, n)$; $(t = 1,2, \dots, l)$

Where (Balcerzak, 2015, pp. 196):

$$\overline{SM_{it}} = \frac{1}{n}\sum_{j=1}^{n} SM_{it} \quad (8)$$

, where $(i = 1,2, \dots, n)$; $(t = 1,2, \dots, l)$

$$S(SM_{it}) = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(SM_{it} - \overline{SM_{it}})^2} \quad (9)$$

, where $(i = 1,2, \dots, n)$; $(t = 1,2, \dots, l)$

Above procedure allowed to investigate how innovation framework conditions in Poland differ from the other Moderate Innovators countries.

Findings

Tables 2 to 4 depict the results of multivariate analysis of innovation framework conditions between Moderate Innovators countries (in appendix). In compliance with the obtained results, the main drivers of innovation performance external to the firm differed in Poland from the EU countries with a similar to Poland level of innovation (in 2009-2015). Regarding human resources dimension, the results distinguished relatively high diversity between Moderate Innovators countries, in level of new doctorate graduates, percentage population aged 25-34 having completed tertiary education and percentage population aged 25-64 participating in lifelong learning (Table 2). Among these countries, Poland rank predominantly with average level of innovation framework conditions in the field of human resources. In this regard, Poland highlighted high similarity with such countries as Hungary and Italy. On the other hand, the results indicate in Poland decreasing level of new doctorate graduates, percentage population aged 25-34 having completed tertiary education and percentage population aged 25-64 participating in lifelong learning. This situation should be treated as negative in relation to build a competitive advantage of country, regions and firms. The results also reveal the highest diversity between Poland and Estonia,

Portugal and Spain - countries with the highest level of indicators connected with human resources dimension.

Concerning attractive research systems dimension, the results indicate location of Poland in the last place between Moderate Innovators countries (Table 3). This situation was seen in the period 2009-2015 and should be treated as negative in regard to maintain and enhance the capacity to competitive advantage of country, regions and firms. Based on the results, the high distance between Poland the other Moderate Innovators countries appeared with respect to Estonia, Portugal, Cyprus, Italy and Spain. According to the obtained results, similar to Poland, low level of international scientific co-publications per million population, top 10% most cited publications and foreign doctorate students, distinguished such countries as Malta (in 2011) and Lithuania (in 2012-2015).

Regarding innovation-friendly environment dimension, the obtained results highlight a relatively high distance between Poland and the other countries with a similar level of innovation (Table 4). Among Moderate Innovators countries, Polish firms ranked into average group (in 2009, 2013-2015) and low group of countries (in 2010-2012). This situation, in relation to relatively lack of enhancement of broadband penetration and opportunity-driven entrepreneurship should be treated relatively negative, especially in the context of enhancing competitiveness of country, regions and firms. With respect to innovation framework conditions in the field of innovation-friendly environment, Poland differed significantly from especially such Moderate Innovators countries as: Portugal, Lithuania, Italy and Estonia.

Conclusions

The results confirm that in terms of the main drivers of innovation performance external to the firm, Poland differed (in 2009-2015) from the other Moderate Innovators countries. With respect to innovation framework conditions, Poland outstand the most from the group of the EU countries with a similar level of innovation, in terms of attractive research systems dimension. In particular, Poland characterised the lowest level of international scientific co-publications per million population, top 10% most cited publications and foreign doctorate students. Such situation, against the background of decreasing level of new doctorate graduates, percentage population aged 25-34 having completed tertiary education, percentage population aged 25-64 participating in lifelong learning, and relatively low level of specific indicators depicted innovation-friendly environment, may cause an limited innovation abilities to foster competiveness of countries, regions and firms.

These findings have practical and policy implications. In this respect, the findings imply the necessity to strengthen actions to enhance main drivers of innovation performance external to the firm. This can contribute to foster country, regions' and firms' capabilities to adaptation to rapid changes and uncertainty in the environment. The findings call also for strengthening the network between universities, institutional environment, research organisations and firms.

This study is not without limitations. This paper based on indicators of innovation framework conditions and data from the European Innovation Scoreboard. It would be interesting to whether the obtained results also hold for another drivers of innovation performance external to the firm.

The complexity of innovation framework conditions requires further studies. In terms of future research, it seems important, among others, to focus on the causes of differences between Poland and the other Moderate Innovators countries in terms of main drivers of innovation performance external to the firm.

Evaluation of the Effectiveness of Marketing Communications in Russian Business Using the Example of St. Petersburg Enterprises

Anastasii I. Klimin, Peter the Great Saint Petersburg Polytechnic University, Saint Petersburg, Russian Federation, klimin@kafedrapik.ru

Dmitrii V. Tikhonov, Peter the Great Saint Petersburg Polytechnic University, Saint Petersburg, Russian Federation, tikhonov@kafedrapik.ru

Aleksei M. Efimov, Peter the Great Saint Petersburg Polytechnic University, Saint Petersburg, Russian Federation, efimov@kafedrapik.ru

Abstract

The proposed study is devoted to the actualization of information on the use of various tools and methods of marketing communications, the metrics used to measure marketing communications effectiveness, share of advertising expenditures from revenue at Russian enterprises. The submitted article presents the results of a survey of Russian enterprises from St. Petersburg on this topic. During the study, it was found that respondents consider the most effective advertising on the Internet and social networks, advertising at the point of sale, participation in exhibitions, sales promotions activities and direct contacts with customers via e-mail and telephone. The main problem in measuring the effectiveness of marketing communications, the participants of the study considered setting up at the enterprise a system for collecting and analyzing information on the results of advertising campaigns.

Keywords: Effectiveness of marketing communications, tools and methods of advertising.

Introduction

The problem of measuring the effectiveness of marketing communications has been and remains an actual task for strategic and operational management levels. The range of tools and methods of marketing communications is expanding, new possibilities of measuring effectiveness appear. The volume of information available to analyze the results of marketing communications is increased. The objectives of the study are to understand what means and methods of marketing communications are now considered to be the most effective at Russian enterprises, what indicators are used to evaluate the effectiveness of marketing communications, what are the ways and methods to measure effectiveness, what are the problems of measuring the effectiveness of marketing communications at Russian enterprises. The proposed study was focused on the operative level of management, associated primarily with the increase in sales volumes.

Literature Review

The effectiveness of marketing communications is a wide concept. As noted in the article by McAlister, Srinivasan, Jindal, and Cannella, (2016), the effectiveness of marketing communications relates both to the operative and to the strategic levels of organization management. The effectiveness of marketing communications includes measurements of the effectiveness of the use of advertising media (Klimin, (2011)), the effectiveness of the content of advertisements (Kutlaliev, Popov, (2006)), the impact of media planning indicators on the effectiveness of communication (Tikhonov, (2012)), the cost effectiveness of marketing communications in terms of generating additional profits (Dubolazov, Klimin, Tikhonov, (2014)). In articles of Klimin, Tikhonov (2016), Klimin, Tikhonov, Orlov (2017), Glukhov, Ilin (2014) consider impact of various social, psychological and cultural aspects of advertising slogans and illustrations on communication effectiveness.

Trofimova, Zelenina, (2015), Glukhov, Ilin, Koposov, Levina (2014), Bril, Kalinina, Ilin (2017) discuss the importance of the campaign in the organization's activities, considers the methods to assess its effectiveness, as well as models used in the calculation of the advertising budget.

Article by Novoselsky, Mozgovaya (2015) deals with methods of evaluating the effectiveness of advertising campaigns. Evaluation of the effectiveness of advertising takes into account the complex current market conditions and factors that promote or inhibit the solution of commercial problems of the enterprise.

In contemporary marketing communications much attention is paid to SMM and measuring its effectiveness (CMO survey by the Duke University, (2014)). Marketing through Social Media nowadays represents one of the most effective ways to introduce the company and its products on the market. Beqiri Gonxhe (2016) make an overview on Social Media and its impact in marketing strategy, he gives an example of marketing social media strategy.

The article of Belogorodsky (2006) focuses on measuring the effectiveness of marketing communications based on media planning indicators, such as frequency, reach, number of advertising contacts.

Advertisers, advertising agencies, research firms, Internet companies are engaged in advertising effectiveness measurement. The largest volume of statistical information is owned by firms TNS, Nielsen, Google, Facebook. This allows them to make a long-term and in-depth analysis of the effectiveness of marketing communications in various media (Wood, Poltrack, (2015)).

Research Design and Methodology

The research was conducted in the period January-May 2017 using the Internet service for surveys. The base for the survey was the Alumni Club of the Institute of Industrial Management, Economics and Trade of the Peter the Great Saint Petersburg Polytechnic University (Graduate School of Business Technologies) and the St. Petersburg International Business Association (SPIBA). 80% of respondents specifically responsible for marketing and sales in their organizations.

For the convenience of understanding figures and tables with the distribution of answers to the questions of the questionnaire, it is presented in Appendix A. The questionnaire presents classification questions (questions 1-5) and questions for the realization of the research objectives. The number of correctly completed questionnaires that were obtained during the study (120 pcs) in the most cases does not allow the division of enterprises into groups according to the classification and perform a comparative analysis of the answers to questions for the implementation of the study objectives by groups because of a significant sampling error.

In Fig. 1 shows the distribution of classification into business types of the organizations surveyed. In Fig. 2 shows the distribution of organizations by revenue size.

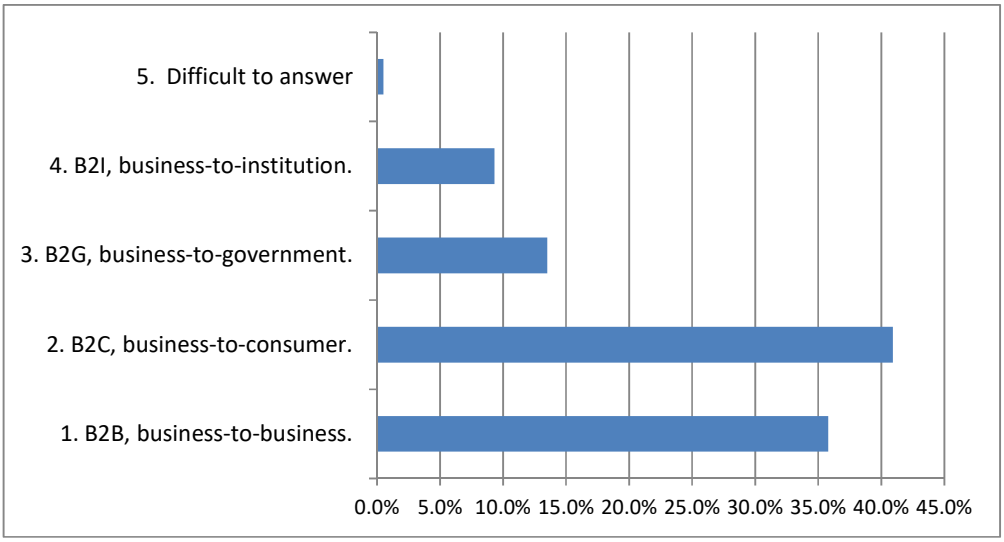

Fig. 1: Business type of organization, share of respondents, %

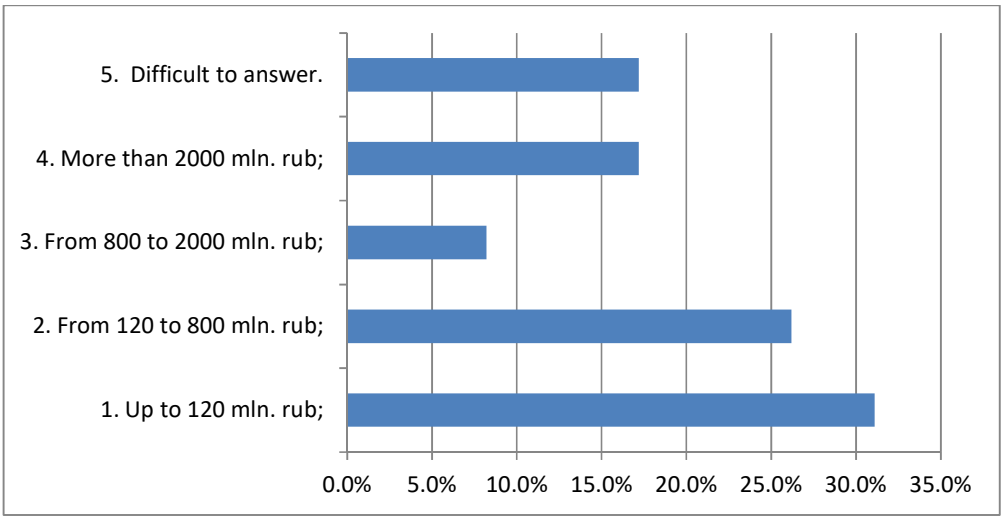

Fig. 2: Approximate turnover of organization over the last year, share of respondents, %

Results of the Study

Below is an analysis of the answers to the most interesting questions of the questionnaire about effectiveness of marketing communications. One of the important questions in the questionnaire was question 7. "Specify what percentage, in Your opinion, of the total turnover is spent on advertising in Your organization?" (Fig. 3)

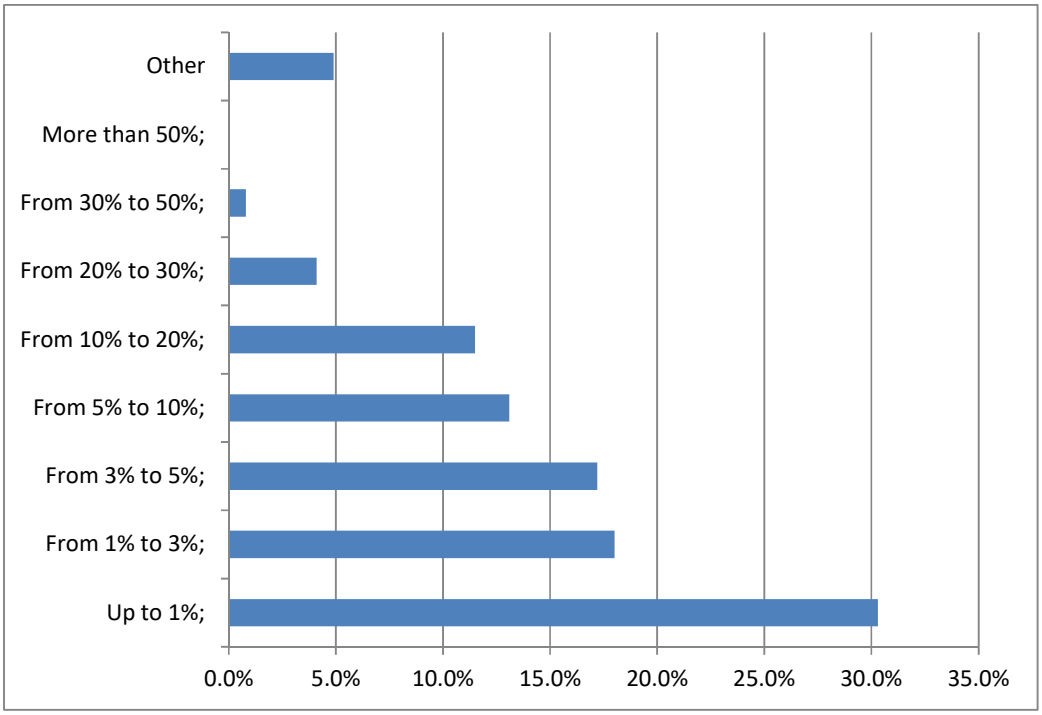

Fig. 3: Share of advertising expenditures from revenue, share of respondents, %

Table 1 presents data on the share of advertising expenditures from revenue for B2C and B2B of organizations, as well as for enterprises with different revenue per year.

Table 1: Share of advertising expenditures from revenue, share of respondents, %

Share of advertising expenditures from revenue	Type of market of organization		Volume of revenue of organization, million rubles in year			
	B2C	B2B	Up to 120	120-800	800-2000	More than 20000
Up to 1%	20	42	32	38	62	29
From 1% to 3%	24	20	16	38	12	7
From 3% to 5%	16	12	24	9	13	7
From 5% to 10%	22	12	12	5	13	43
From 10% to 20%	12	12	16	5	13	7
From 20% to 30%	4	2	0	5	0	7
From 30% to 50%	2	0	0	0	0	0
More than 50%	0	0	0	0	0	0
Weighted average	6,4	4,2	4,7	3,5	3,9	6,6

Companies with revenues of more than 2,000 million rubles a year are approaching the expenditures of advertising at a rate of 10% of revenue, as is typical for large American and European companies (CMO survey by the American Marketing Association and Duke University, (2014)).
The average score of the answer to question 9. “Rate the effectiveness of Your company's advertising media” are shown in Fig.4. Was made a calculation of the weighted indicators where the respondents

evaluated the effectiveness of the following methods of advertising on a scale from 1 to 5. The most effective means of advertising based on these results are online advertising, social media marketing, sales promotions and POSM.

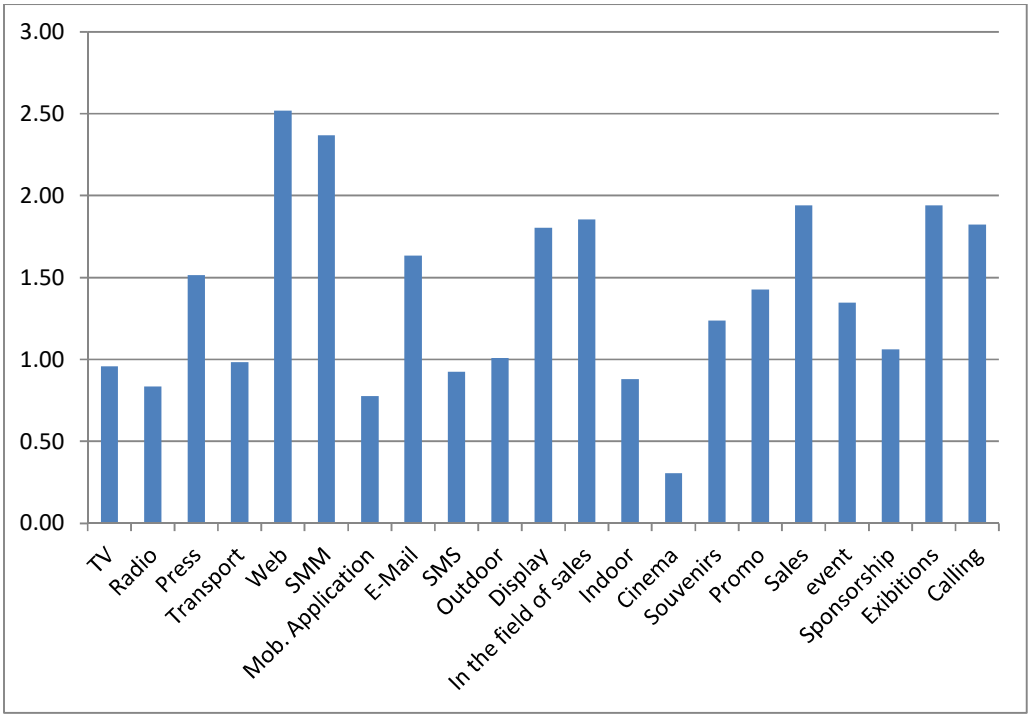

Fig.4: Effectiveness of advertising channels, points

Also presented is an analysis of what methods of advertising on the opinion of B2B and B2C companies are the most effective. (Fig. 5)

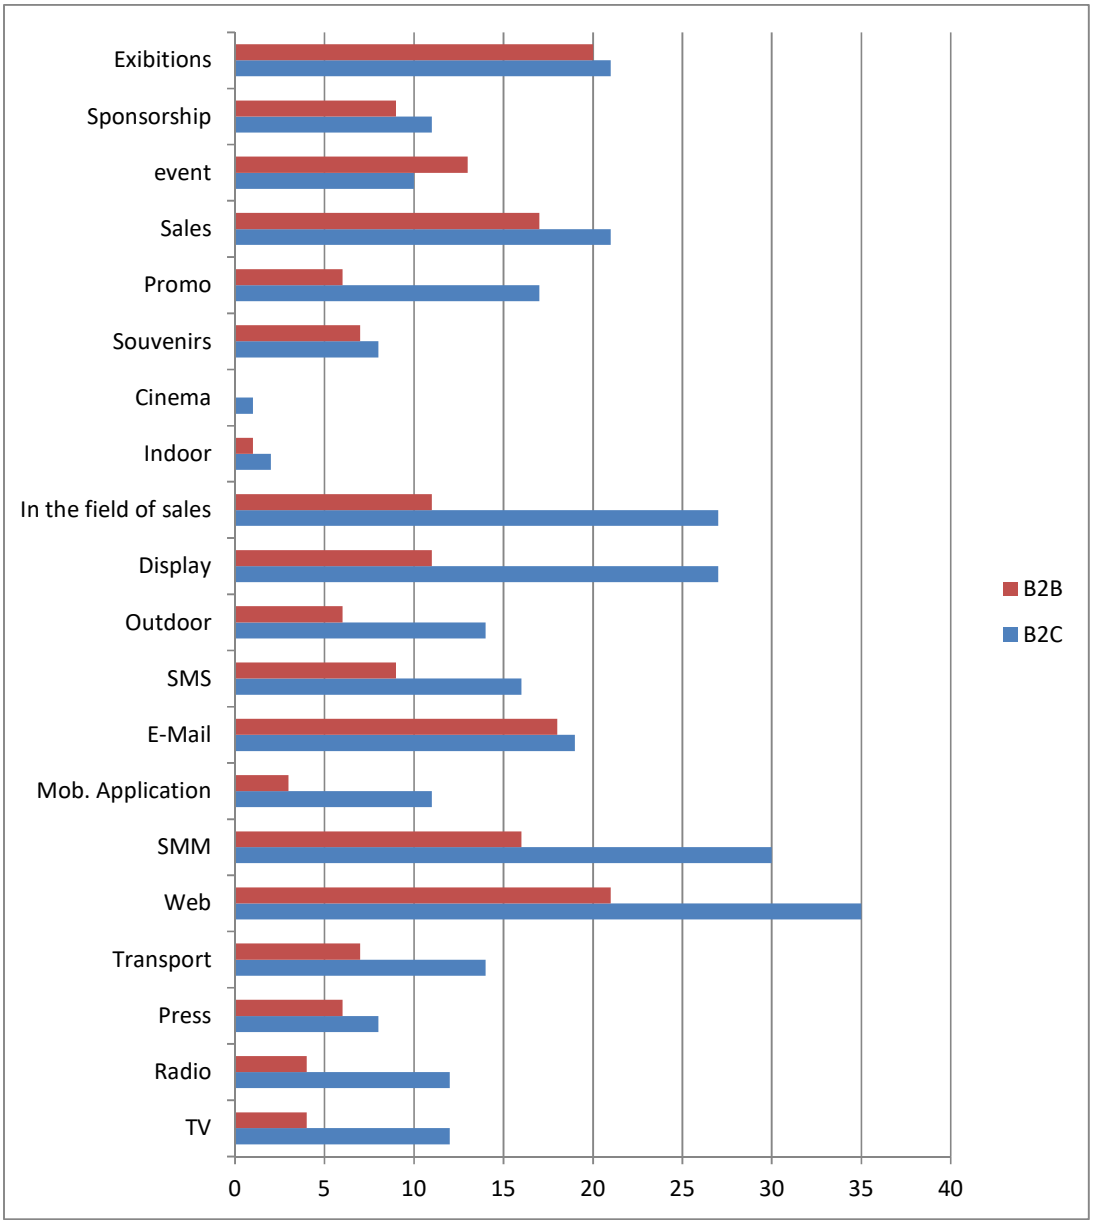

Fig. 5: Effectiveness of advertising channels among B2B and B2C, share of respondents, %

Social media has an significant impact in marketing, especially in communication and connection of businesses with their customers. There is a question 8 in the survey about using social media among Russian companies (Fig. 6). The Russian companies allocate three leaders according of SMM, it's Vk.com, Facebook and Instagram. Among the messengers has no clear leader.

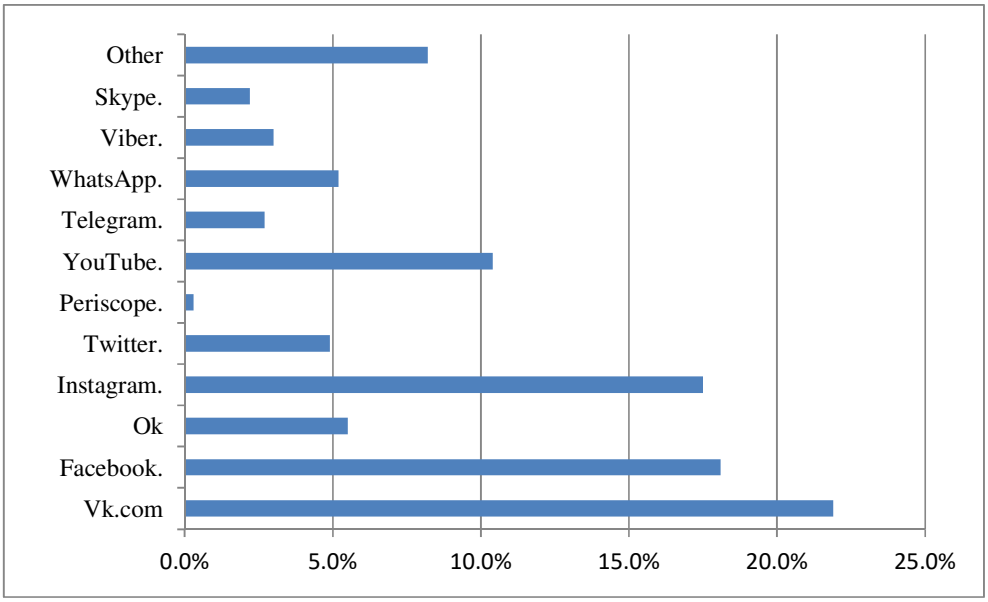

Fig. 6: Popularity of SMM platforms, share of respondents, %

In Fig. 7 are the answers to the question 10. "What are some ways Your organization evaluated the preliminary effectiveness of planned advertising and marketing activities, advertising media, advertising materials?"

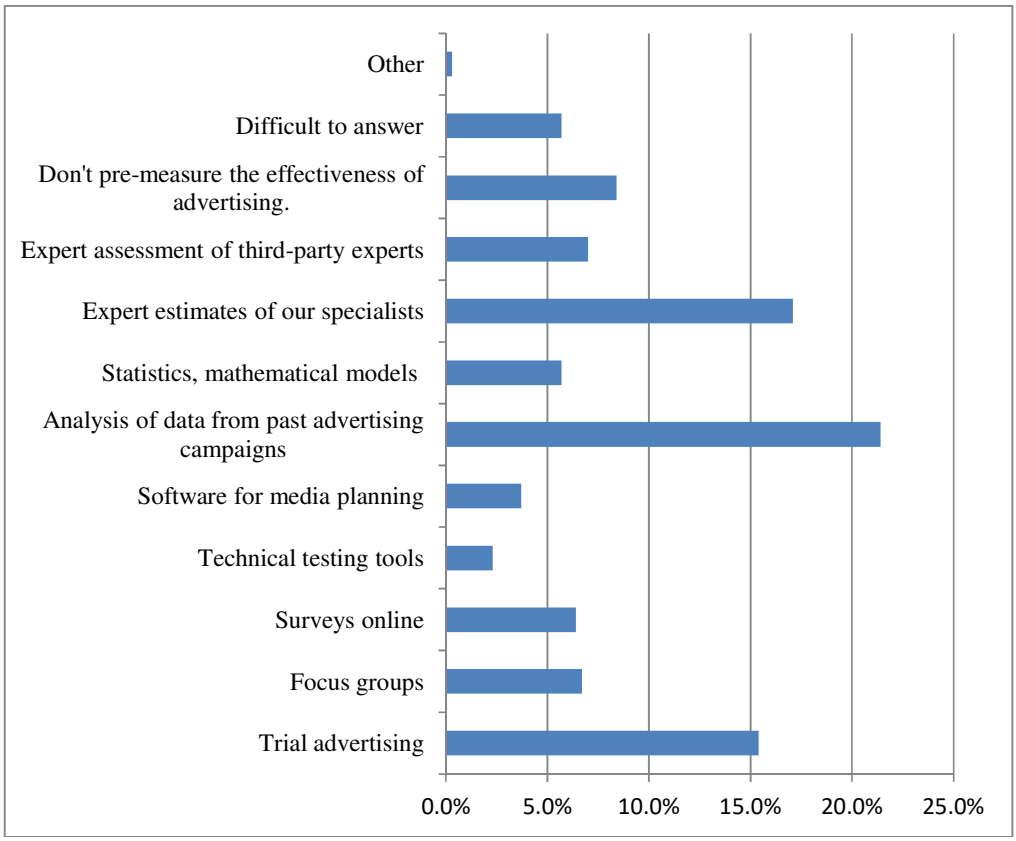

Fig. 7: Methods of the preliminary analysis of effectiveness, share of respondents, %

In Fig. 8 are the answers to the question 11. “In what ways does your organization determine the final effectiveness of advertising?”

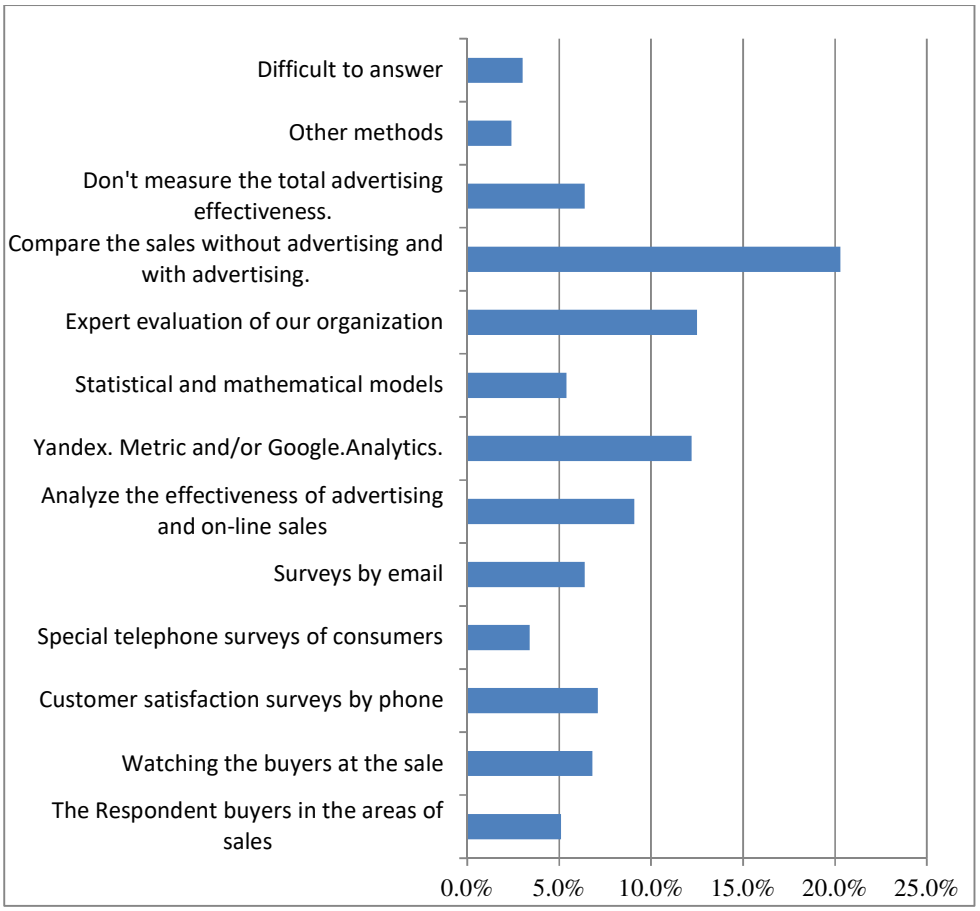

Fig. 8: Methods of the final analysis of effectiveness, share of respondents, %

In Fig. 9 are the answers to the question 12. “What are the indicators of advertising effectiveness are measured in Your organization?”

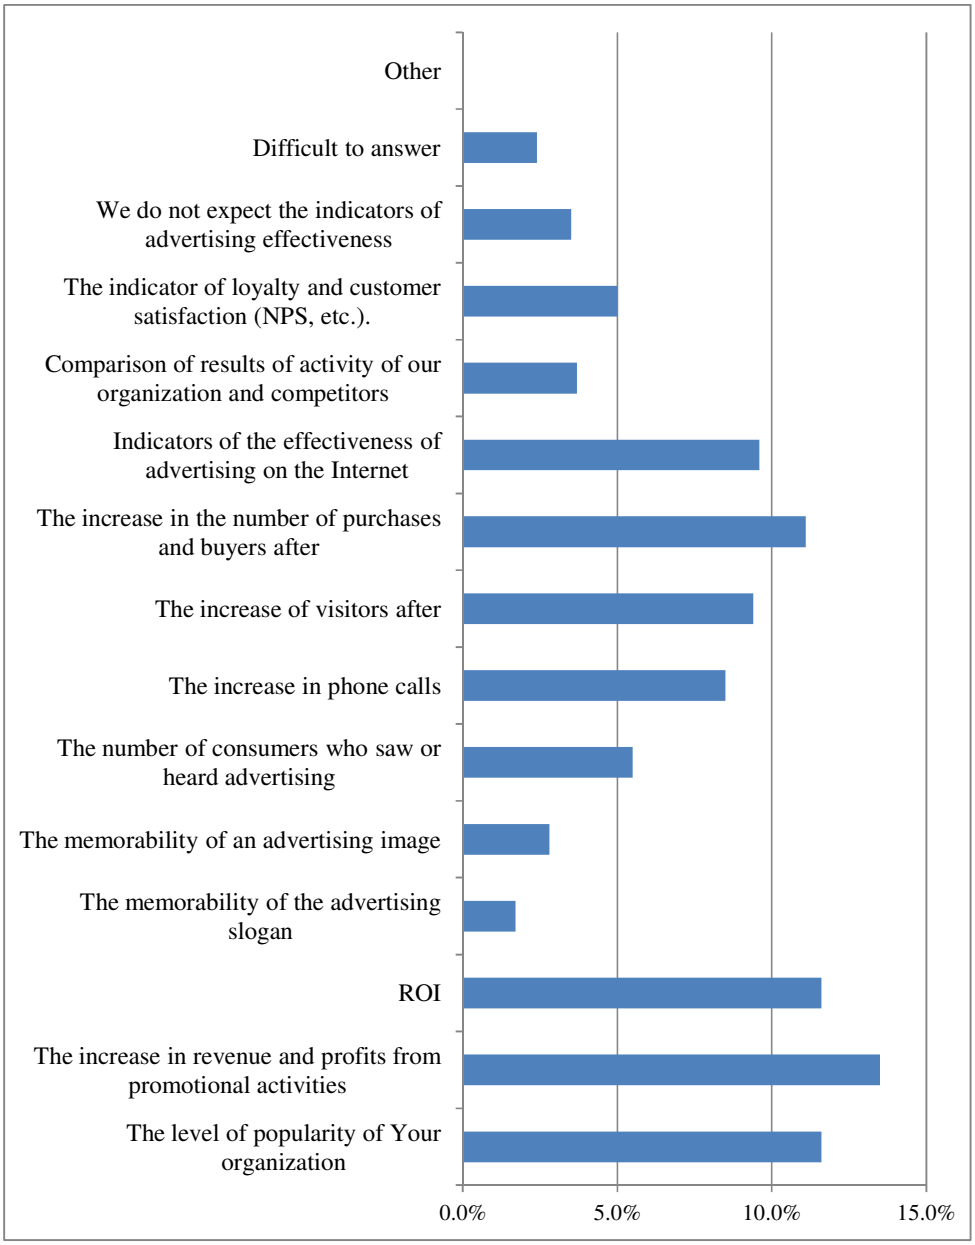

Fig. 9: Effectiveness indicators, share of respondents, %

The most popular results among the respondents are the increase of revenues and profits from promotional events, brand and organization awareness, as well as the profitability of advertising costs, that is, the ratio of profit from advertising to the advertising expenditures (ROI).

It is important that the process of performance measurement is regular, it is necessary not only to determine the timing of the advertising, but also to know the deadlines of measuring results of advertising. In Fig. 10 are the answers to the question 13. “How often do you measure the effectiveness of advertising in Your organization?”.

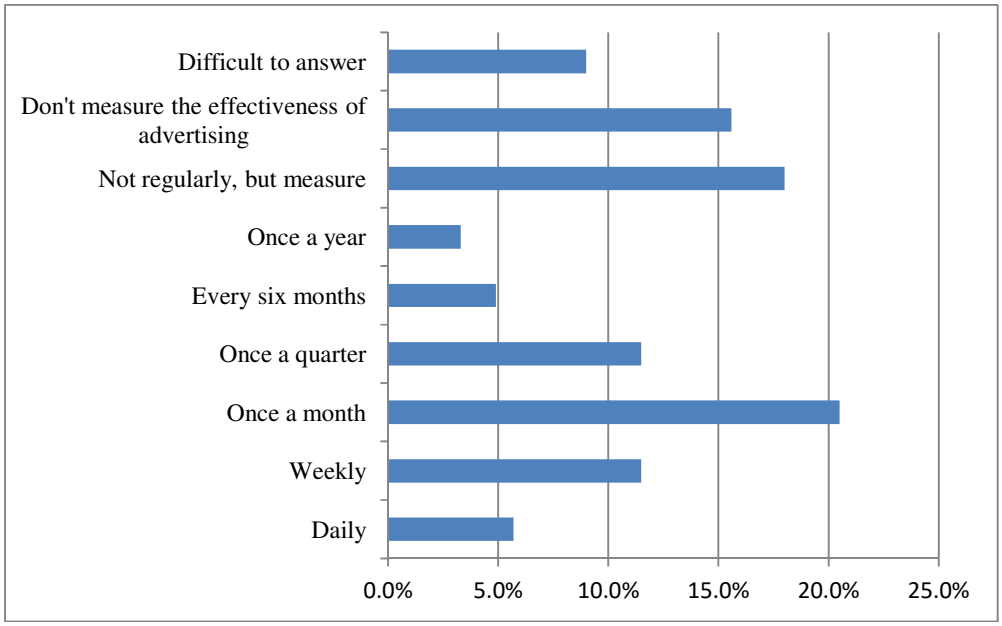

Fig. 10: Frequency of measuring, share of respondents, %

Top 3 popular answers: either not measured at all or there is no clear regularity, either measured once a month. The top 3 includes more than half of the companies participating in the survey. Only 9% of companies measure the effectiveness of weekly and 5 % daily. This indicator is very important, as it allows to evaluate an advertising campaign in the dynamics.

In Fig. 11 are the weighted answers in score to the question 14. "How often Your organization uses is in the following subjects, topics of advertising?"

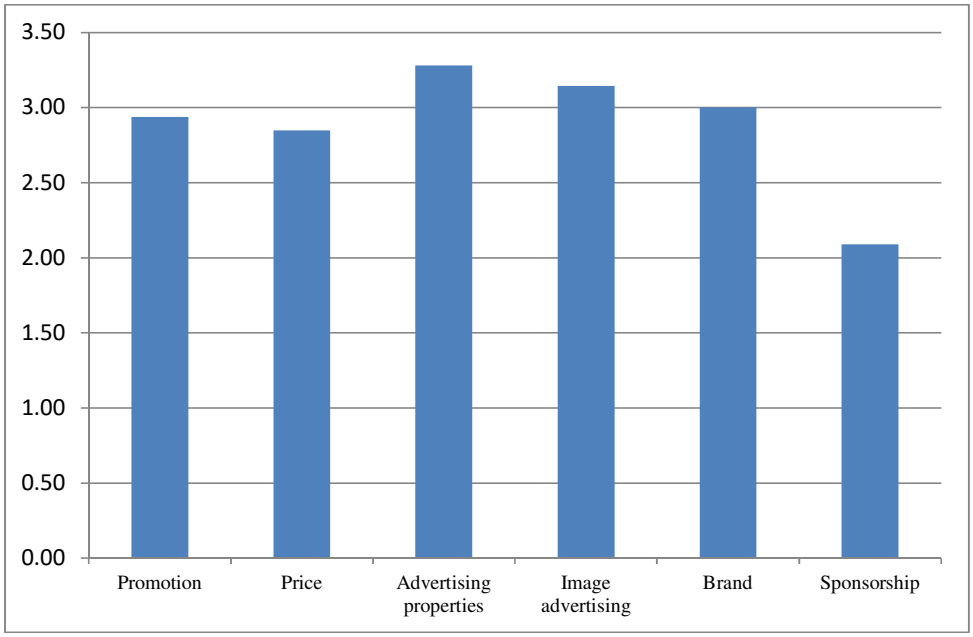

Fig. 11: Subjects, topics of advertising, points

In Fig. 12 are the answers to the question 16. “What are the challenges of measuring the effectiveness of advertising You encounter in Your organization?”

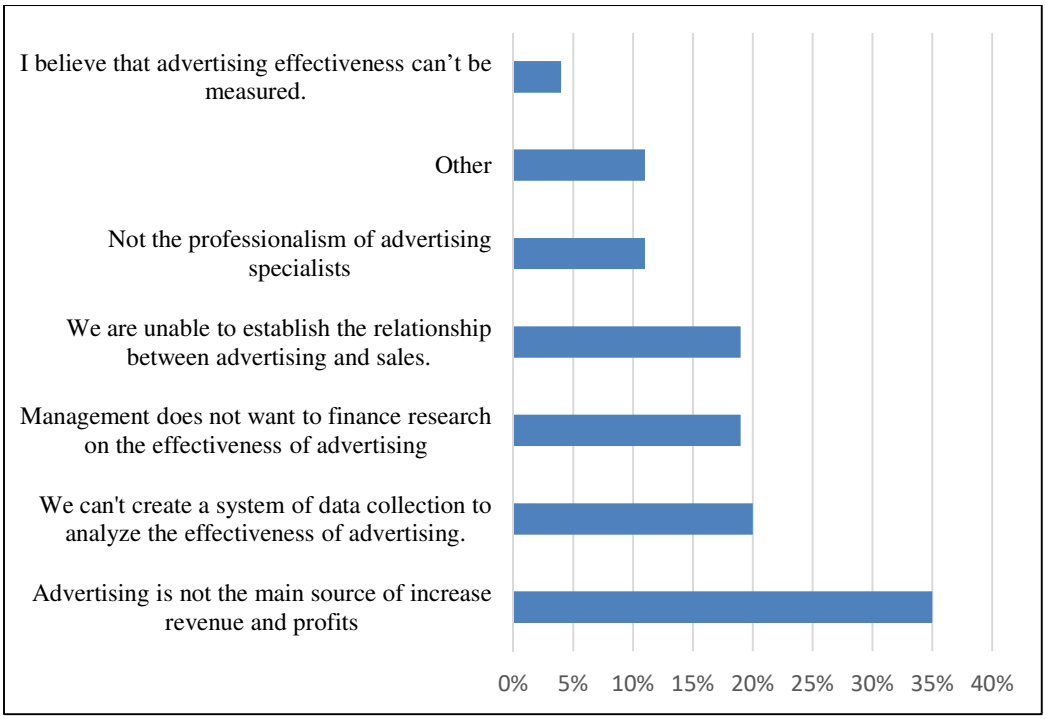

Fig. 12: Challenges of measuring the effectiveness of advertising, share of respondents, %

Discussions and Conclusions

Discussion of the results will begin with the question 16. The main problem for assessing the effectiveness of advertising (excluding answer “Advertising is not the main source of increase revenue and profits …”, which is typical for small businesses where the receipt of orders primarily associated with personal selling, personal connections and recommendations) is the establishment of a system for collecting and analyzing the necessary information, for which professionals are needed, and money, which is not inclined to allocate management for these purposes. The problem of establishing a connection between advertising and sales is also informational in nature. In this regard, the importance of creating integrated information systems for the collection and analysis of marketing information on various indicators of the effectiveness of marketing communications is increasing. The construction of integrated information and communication systems is one of the conditions for the innovative development of the enterprise as a whole. (Silkina G.Yu., (2017)). These systems should include data from call centers, CRM systems, analytical tools for Internet advertising, consumer surveys, data from social networks. For such data, the regularity of their collection and processing is important. However, according to the answers to question 13. "Only how many do you measure the effectiveness of advertising in Your organization?" only 5% of respondents said that their organization collects daily data, 9% of organizations collect data weekly.

During the study, the differences in the share of advertising costs from the revenue between B2C and B2B (weighted average 4,2%) companies, as well as between companies with different revenue levels, were confirmed. 38% of B2C companies spend on advertising from 3% to 10% of revenue, weighted average 6,4%. 62% of companies in B2B markets spend on advertising from 0 to 3% of revenue, weighted average 4,2%. For B2B market, this indicator is more stable, most of the companies have about the same indicator. Unfortunately, in Russia there is no organization that would regularly monitor the share of advertising costs in revenue for a large number of companies,

as, for example, the American journal Advertising Age (Ad Age Datacenter, (2017)). Data from the Internet in Russia on this indicator from various sites are very fragmentary and not representative.

The most effective among the means of advertising in the opinion of the respondents are advertising in the Internet and social networks, advertising at the point of sale, exhibitions, sales promotion activities and direct contact with consumers via e-mail and telephone. Thus, it can be concluded that advertising efforts are increasingly shifting to direct advertising, direct contacts with individual consumers in various ways. This corresponds to the trend of growth in the cost of Internet advertising in Russia in the first half of 2017 (Association of Communication Agencies of Russia, (2017), Table 2).

Table 2: The volume of advertising costs in Russia in the first half of 2017, billion rubles

Advertising media	The volume of advertising costs in Russia in the first half of 2017, billion rubles.	Increase in comparison with the previous half-year,%
TV	77,5-78,0	12
Radio	6,7-6,9	3
Press	8,3-8,5	-14
Out of Home (Outdoor advertising, Transit advertising, Indoore advertising, Advertising in cinemas)	20,8-21,2	10
Internet	74,0-75,0	23
Total	190,0-192,0	14

More than 85% of companies from survey use social media. Doing a bit of analysis we found that 61% of B2C companies use as a tool SMM the social network Vk.com. Probably, this is because this service is created in Russia and more people-oriented, not organization. B2B companies are using Facebook more than Vk.com (69% of the companies). 57% of B2B companies use Facebook and Vk.com together. The following were highlighted as important components of the use of social networks is to communicate to the target audience the necessary information about the company's products and to communicate, to get feedback about the product in real time from real buyers. The main question of using social media: for what purposes do we need them? This question was not asked in the study and we plan to use it in the future. Increasing sales through social networks is not the main purpose of their use. According to the study of Statista (2015), only 10% of online retailers in Germany indicated that increasing sales through social networks is the main goal of their use. 30% of respondents indicated that they use social networks to create a marketing platform, 28% - to establish a closer relationship with the client, 24% - to increase the level of recognition.

For preliminary analysis of effectiveness the majority of respondents analyze data past advertising campaigns, use an expert assessment of specialists in advertising and marketing, and conduct a trial placement of advertising in selected media. Comparison of sales volumes without advertising and with advertising is the main indicator of the final evaluation of the advertising effectiveness. This emphasizes the operational level of perception of the effectiveness of advertising by respondents in this study.

Advertisers know and apply the ROI metric in measuring the effectiveness of advertising. This suggests that accounting for the growth in sales and profits from marketing communications, as well as accounting for advertising costs in Russian enterprises in some form is being conducted.

The general conclusion: the popularity of methods and means of advertising which can show a real connection between their use and sales growth is growing.

In the future, our research team plans to continue research in the field of research methods for evaluating the effectiveness of advertising used in Russian enterprises in accordance with the questionnaire in Appendix A to track changes in the opinions of respondents.

Our research was focused on the study of indicators, ways of measuring the effectiveness of advertising at the operative level, which is primarily connected with the increase in sales volumes. In the future, we plan to expand the field of study and explore the impact of advertising on the performance of the firm at a strategic level.

Appendix A. Questionnaire

1. What is the type of businesses of Your organization? (multiple possible answers)
1. The manufacturer of the goods.
2. Services (except wholesale and retail trade).
3. Wholesale trade organization (agent).
4. Retail trade organization.
5. Public, non-profit organization.
6. Other_____

2. In which markets of goods and services does your organization operate? (multiple choice are allowed)
1. Products/services for businesses (B2B, business-to-business).
2. Products/services for citizens (B2C, business-to-consumer).
3. Goods/services for government organizations (B2G, business-to-government).
4. Products/services for public, non-profit organizations (B2I, business-to-institution).
5. Other_____

3. What does your organization do, write in your own words: _____

4. The approximate turnover of Your organization over the past year:
1. Up to 120 million rubles.
2. From 120 to 800 million rubles.
3. From 800 to 2000 million.
4. More than 2000 million.
5. It's difficult to answer.

5. Approximately, how many employees work in your organization?
1. Up to 20 people.

2. From 20 to 100 people.
3. From 100 to 500 people.
4. More than 500 people.

6. Does Your organization have on-line sales (via website, mobile app, social networks, etc.) and what share of turnover they bring you?
1. We have no on-line sales.
2. We have no on-line sales, but we are planning to organize.
3. The proportion of turnover on-line sales to 25%.
4. The proportion of turnover on-line sales from 25 to 50%.
5. The proportion of turnover on-line sales of 50 to 75%.
6. The proportion of turnover on-line sales from 75 to 100%.
7. There are on-line sale, but the share of turnover is difficult to determine.

7. Specify what percentage, in Your opinion, of the total turnover is spent on advertising in Your organization?
1. Up to 1%.
2. From 1% to 3%.
3. From 3% to 5%.
4. From 5% to 10%.
5. From 10% to 20%.
6. From 20% to 30%.
7. From 30% to 50%.
8. More than 50%.
9. Other_____/I find it difficult to answer

8. In which social networks, messengers (short message services) does your organization (not you personally) have accounts, groups, pages for communicating with potential and existing customers?
1. Vkontakte (Vk).
2. Facebook.
3. Odnoklassniki.(OK).
4. Instagram.
5. Twitter.
6. Periscope.
7. YouTube.
8. Telegram.
9. WhatsApp.
10. Viber.
11. Skype.
12. Other _____

9. Rate the effectiveness of Your company's advertising media on the proposed scale: 1 - minimal effect, 5 - maximum effect.
1. TV.
2. Radio.
3. Press.
4. Advertising on transport, including the subway.
5. Advertising in the Internet, except social networks and mobile applications.

6. Advertising in social networks
7. Mobile app.
8. Mailings by e-mail.
9. SMS sending, send via instant messenger Telegram, WhatsApp, etc.
10. Outdoor advertising on billboards.
11. Signs, shop window decoration at point of sale.
12. Internal advertising at points of sale (posters in the trading room, etc.).
13. Internal advertising in shopping malls, business center and other public places.
14. Advertising before movies in cinemas
15. Souvenirs.
16. Promotions: tastings, product presentations, etc.
17. Promotions: discounts, sales, gifts, contests, sweepstakes, etc.
18. Event marketing (event): festivals, performances, schools for buyers, press conferences, etc.
19. Sponsorship.
20. Participation in exhibitions.
21. Telephoning potential customers.

10. What are some ways Your organization evaluated the preliminary effectiveness of planned advertising and marketing activities, advertising media, advertising materials? (multiple choice are allowed)
1. Carry out a trial placement of the advertisement in the selected advertising media with the subsequent control of effectiveness.
2. Tested advertising materials in focus groups or personal interviews with consumers.
3. Test advertising materials to consumers via surveys online, via e-mail.
4. Use technical means testing of promotional materials (eye tracker, magnetic resonance scanner, polygraph, preview of videos with a joystick "like/dislike" etc.).
5. For selecting advertising media we use a special software for media planning, the services of advertising agencies or advertising media having such programs.
6. Analyzed data from past advertising campaigns.
7. Build statistical, mathematical models of the impact of planned advertising and marketing activities on the performance of the organization.
8. Use expert judgment of our experts in marketing and advertising.
9. Use expert judgment of outside experts in marketing and advertising.
10. Other methods _____
11. We do not pre-measure the effectiveness of advertising.
12. It's difficult to answer.

11. In what ways does your organization determine the final effectiveness of advertising? (multiple choice are allowed)
1. The respondent buyers in the area of sales (Consumer surveys at points of sale).
2. Watching the buyers at the point of sale.
3. Customer satisfaction surveys by phone.
4. We conduct special telephone surveys of consumers.
5. Conduct consumer surveys on your website or by e-mail.
6. We analyze the effectiveness of advertising on the Internet through on-line sales data.
7. Analyze the effectiveness of advertising on the Internet through Yandex.Metrics and / or Google.Analytics.
8. We apply statistical and mathematical models to determine the dependence of sales volumes on advertising costs.

9. We use expert estimates of employees of our organization.
10. Compare the sales volumes without advertising and with advertising.
11. We do not measure the final effectiveness of advertising.
12. Other methods (please specify) _____
13. I find it difficult to answer

12. What are the indicators of advertising effectiveness are measured in Your organization? (multiple choice are allowed)
1. The level of publicity Your organization and brand.
2. The increase in revenue and profits from promotional activities.
3. The profitability of advertising expenditures (the ratio of profit from advertising to the expenditures of advertising).
4. The memorability of the advertising slogan.
5. The memorability of advertising illustration, advertising image.
6. The number of consumers who saw or heard advertising of Your organization.
7. The increase in the number of telephone calls to the organization after advertising.
8. The increase in the number of visitors after advertising.
9. The increase in the number of purchases and buyers after advertising.
10. Indicators of the effectiveness of advertising on the Internet (site traffic, number of purchases via the Internet, etc.).
11. Comparison of results of activity of our organization and competitors with a simultaneous comparison of advertising activity of our organization and competitors.
12. The indicator of loyalty and customer satisfaction (NPS, etc.).
13. Other indicators (to add so):_____
14. We do not calculate any indicators of advertising effectiveness.
15. I find it difficult to answer

13. How often do you measure the effectiveness of advertising in Your organization (independently or through outside organizations)?
1. On a daily basis.
2. On a weekly basis.
3. Once a month.
4. Once in a quarter.
5. Once in six months.
6. Once a year.
7. Not regularly, but we do.
8. Don't measure the effectiveness of advertising.
9. I find it difficult to answer

14. How often Your organization uses is in the following subjects, topics of advertising? Rate scale: 1 - do not use advertising at all, 5 – always use.
1. Sales promotions (discounts, gifts, contests, sweepstakes, etc.).
2.The prices of goods.
3. Advertising properties, features, advantages of the product.
4. Branding with beautiful illustrations.
5. Brand is: a name, logo, corporate motto.
6. Advertising sponsorship, philanthropy, the organization's involvement in socially significant activities, events.

7. More _____

15. On what area in Russia appears to be promoting Your organization?
1. One or several closely located settlements (local advertising).
2. In different regions, Federal districts of Russia (regional advertising).
3. In most regions of Russia (national advertising).

16. What are the challenges of measuring the effectiveness of advertising You encounter in Your organization? Choose no more than three basic problems.
1. Specialists in advertising and marketing (including research companies and advertising agencies) do not know how and what to measure, do not own methods, do not know the indicators of effect and campaign effectiveness.
2. We are unable to establish the relationship between advertising and sales.
3. We can't create a system of data collection to analyze the effectiveness of advertising.
4. Advertising is not the main source of increase revenue and profits, so the problem of measuring its effectiveness, we were not particularly interested in.
5. Management does not want to finance research on the effectiveness of advertising, does not see in this sense, does not believe in such an opportunity, does not allocate money, workers, other resources.
6. I believe that advertising effectiveness can't be measured.
7. Other (enter)_____

17. Who do you work for in your organization?
1.Senior Executive management (Director, Deputy Director, senior Manager).
2.Head of middle management (head of Department).
3.Specialist.

18. Do you work in advertising, marketing, sales?
1.Yes, these are my main job responsibilities.
2. I am related to this, but this is not my main job description.
3. No, I have nothing to do with this.

Regional Dimension of Entrepreneurship in a Developing Economy An Analysis of Polish Północno-Zachodni Region

Justyna Zygmunt, Opole University of Technology, Opole, Poland, j.zygmunt@po.opole.pl

Abstract

The aim of the paper is to investigate regional dimension of entrepreneurship in a developing economy, with a focus on Północno-Zachodni Region which represents one of NUTS-1 regions in Poland. Concentration on this region may provide a valuable insight since it embodies not only developing, but at the same time transition economy. Regional dimension of entrepreneurship in Północno-Zachodni Region was studied with fixed effects panel regression. Welch F was used to test estimated results. Panel data includes 315 observations for the 2000-2014 period. Data sources were EUROSTAT and Central Statistical Office of Poland. The main finding is that substantial for entrepreneurial activity in a developing economy is the share of high-skilled people in relation to total employment. Evidence have been provided that together with human capital growth the increase of entrepreneurial attitudes is observed. The results indicate also that a developing economy tends to follow the path of developed countries in a positive relationship between unemployment rate and the share of self-employed within total workforce. The findings may be interesting for policymakers, especially in terms of supporting entrepreneurial attitudes among high-skilled people.

Keywords: entrepreneurial activity, developing economy, regional dimension, Poland.

Introduction

A considerable amount of literature deals with the influence of various factors on entrepreneurship. It has been found that regional entrepreneurial activity is influenced by business conditions (e.g. Gries and Naudé, 2009), demographic attributes (e.g. Bosma and Schutjens, 2011), amount of human capital (e.g. Huggins *et al*., 2017). The evidence have been also provided that entrepreneurial activity in regions may be dependent inter alia on informal institution, such as entrepreneurship culture (e.g. Fritsch *et al*., 2014). But for all that, the debate on regional dimension of entrepreneurship, in particular with regard to developing economies is still incomplete.

The aim of this paper is to investigate regional dimension of entrepreneurship in a developing economy, with an emphasis on Północno-Zachodni Region which represents one of NUTS-1 regions in Poland. The focus on this region may provide revealing findings since it represents both developing and transition economy. To test for regional dimension of entrepreneurship fixed effects panel regression has been employed.

This paper contributes to the existing literature by presenting an analysis of regional dimension of entrepreneurship in a developing and at the same time transition economy. The findings may be supportive in establishing successful entrepreneurial policy in economy in question.

The remainder of the paper proceeds as follows. First section presents the theoretical background leading to the hypotheses of this paper. Second section includes method of the research. This is followed by sample and variables description. The findings are presented in fourth section. Conclusions are included in the final section.

Theoretical Background and Hypotheses Development

Regional economic development depends on heterogeneous factors. They involve inter alia innovation activity (e.g. Zygmunt A., 2015; Bębenek, 2017), companies competitiveness (e.g. Maj, 2016). Essential determinant of regional development is entrepreneurship. However, regions differ in entrepreneurial activity. Various dimensions are accountable for it. One of them is a regional economy structure. It is claimed that the structure of regional industries substantially determines entrepreneurial activity since, as emphasises Wyrwich, it impacts on "the demand for entrepreneurs, as well as the supply of entrepreneurs […]" (2012, p. 425). According to Reynolds *et al*. high share of services is accompanied with high startup rates (1995).

In entrepreneurship literature economy structure is generally measured as a share of employment in respective industries to total employment in a region/country (e.g. Fritsch and Falck, 2007). The differences in regional economies may also be assessed with Krugman specialization index. However, the effect of economy structure on entrepreneurial activity in developing regions may be ambiguous. Therefore, in this paper no clear assumption on relationship between Krugman specialisation index and entrepreneurial activity is provided. This approach is in line with other studies (e.g. Wyrwich, 2012).

Entrepreneurial activity is also determined by unemployment rate. Numerous studies provide evidence that entrepreneurship increases with the growth in unemployment rate (e.g. Wagner and Sternberg, 2004). However, this relationship seems to be intricate. For example Audretsch and Fritsch emphasise that high unemployment rate may reflect "slack growth" (1995, p. 360) which drives to dissipating of entrepreneurial attitudes, and at the same time may encourage new firm creation since "the pool of potential resources available to new entrants will tend to be higher" (1995, p. 360). It is also claimed that relationship between high unemployment rate and entrepreneurial activity represents the "refugee" effect which embodies in diminishing unemployment in subsequent periods (Thurik *et al*., 2008).

Significant for entrepreneurial activity is also knowledge. It has been found that inadequate knowledge inhibits entrepreneurship (Storey, 2016). However, relation between entrepreneurship and knowledge seems to be bidirectional, since as argue Acs *et al.*, entrepreneurial activity constitutes "important spillover mechanism[…]" (2005, p. 14) for new knowledge. Some studies have identified also that impact of knowledge creation on entrepreneurial intensions does occurs, however this linkage is not direct (Stuetzer *et al.*, 2014).

Entrepreneurial activity is associated with the amount and structure of human capital (Zygmunt J., 2017). Positive impact of human capital for entrepreneurial activity has been identified in many studies (e.g. Gries and Naudé, 2009; Storey, 2016; Huggins *et al.,* 2017). It has been observed that e.g. an enhancement of management education may be significant for nascent entrepreneurship growth (Wennekers *et al.*, 2005).

In view of the foregoing, in this paper the following hypotheses are tested:

H1 Unemployment positively affects entrepreneurial activity in a developing economy

H2 Together with growth in knowledge inflows, entrepreneurial activity in a developing economy increases

H3 Entrepreneurial activity in a developing economy is positively influenced by human capital

Method of the Research

To analyse regional dimension of entrepreneurship in Polish Północno-Zachodni Region, a panel regression was employed. The panel had one time dimension t, with t= 2000, 2005,…, 2014, and one cross-section dimension r for the regions which comprise Północno-Zachodni Region, with r = Wielkopolskie Voivodeship, Zachodniopomorskie Voivodeship, Lubuskie Voivodeship.

To test hypotheses, the estimated model was described as:

$$E_{rt} = K_{rt}\beta_1 + U_{rt}\beta_2 + R\&D_{rt}\beta_3 + HC_{rt}\beta_4 + INC_{rt}\beta_5 + GDP_{rt}\beta_6 + \alpha_r + \varepsilon_{rt} \quad (1)$$

where,
E_{rt} – entrepreneurial activity,
other variables – as defined in table 1.

F test was used to check for joint significance of differing group mean and to determine the usage of fixed effects estimation. Model's statistical significance was verified with Welch F test. To control for the autocorrelation and the heteroscedasticity, Durbin-Watson and Wald statistic were employed respectively. Lagged influence of variables was considered (with t-1, and t-2 lag). High level of collinearity[1] between variables was identified with Pearson's correlation coefficient.

Sample and Variables

For this research, Polish Północno-Zachodni Region (NUTS-1 level, PL4) was analysed. This region is one of six NUTS-1 regions in Poland. Północno-Zachodni Region consists of three NUTS-2 regions: Wielkopolskie Voivodeship (PL41), Zachodniopomorskie Voivodeship (PL42), Lubuskie Voivodeship (PL43). It represents 21% of Polish territory and 16% of Polish population[2].

The analysis of regional dimension of entrepreneurship in Polish Północno-Zachodni Region were conducted for the 2000-2014 period. Data source were EUROSTAT and Central Statistical Office of Poland. Panel data comprises of 315 observations.

Dependent variable (entrepreneurial activity) was measured as the share of self-employed within total workforce for region r and year t (E_{rt}). This approach is consistent with e.g. Gries and Naudé, 2009; Wyrwich, 2012; Fritsch *et al*., 2014.

Explanatory variables were as follows: Krugman specialization index, unemployment, inflows of knowledge, human capital. Differences in the economic size of regions were taken into account and most of the indicators of variables in question were expressed per inhabitant or to total employment in respective regions.

The control variables were included in the estimation (incomes of households and output region growth) to account for regional differences. Income of households embodies regional demand (Wagner and Sternberg, 2004) and impacts positively on entrepreneurial activity (Reynolds *et al*., 1995). Thereby, it is expected that together with income growth a tendency to self-employment increases. Output region growth is claimed to be interrelated with entrepreneurial activity (Bosma and Schutjens, 2011). Hence, it is anticipated that the enhancement of output region growth in a developed economy is followed by the rising in entrepreneurial activity.

The definitions of explanatory variables and data sources are shown in table 1.

Table 1: Definitions of explanatory variables and data sources

Variable	Definition	Data source
Krugman specialization index (K_{rt})	$$K_{rt} = \sum_{i=1}^{I} \left\| b_{irt} - \bar{b}_{it} \right\| \times 100$$ where: I – the number of economy sectors b_{irt} – the share of employment in a sector i in total employment in a region r in time t $\bar{b}_{it}$ – the share of employment in a sector i in total employment in Poland in time t	own calculation based on data from Central Statistical Office of Poland
Unemployment (U_{rt})	Unemployment rate (in %) in region r in time t	EUROSTAT
Inflows of knowledge $(R\&D_{rt})$	Intramural R&D expenditure in euro per inhabitant in region r in time t	EUROSTAT
Human capital (HC_{rt})	Share of population with tertiary education degrees in relation to total employment (in %) in region r in time t	EUROSTAT
Incomes of households (INC_{rt})	Log of income of households in euro per inhabitant in region r in time t	EUROSTAT
Output region growth (GDP_{rt})	Log of gross domestic product in euro per inhabitant in region r in time t	EUROSTAT

Source: own study based on Krugman, 1991; Bosma and Schutjens, 2011; Wyrwich, 2012; Huggins *et al.*, 2017.

Descriptive statistics of variables is presented in table 2.

Table 2: Definitions of explanatory variables and data sources

Variable	Obs.	Min	Max	SD	Mean
E_{rt}	45	13.1893	23.4715	2.4667	16.8309
K_{rt}	45	6.6000	23.0000	4.0931	12.8622
U_{rt}	45	6.0000	26.3000	6.2526	14.1444
$R\&D_{rt}$	45	4.8000	94.8000	21.0668	24.8733
HC_{rt}	45	9.8000	24.6000	4.4162	16.7089
INC_{rt}	45	8.0709	8.7796	0.2168	8.4506
GDP_{rt}	45	8.2523	9.2350	0.2799	8.7307

Source: Own estimation.

High level of collinearity between some variables was identified. Therefore, the variable GDP_{rt} was excluded from the data set and from further studies in this paper. Correlation matrix is shown in Appendix (table 3).

Findings

Table 4 reports the estimate of equation 1 with the share of self-employed within total workforce in the 2000-2014 period as dependent variable.

Heteroscedasticity and autocorrelation consistent. Standard errors in parenthesis. Level of statistical significance: $***p \leq 0.01$; $** p \leq 0.05$; $*p \leq 0.10$. Source: Own estimation.

The analysis does not reveal any significant relationships between Krugman specialization index and the share of self-employed within total workforce. Indeed, the results indicate that some cross-region heterogeneity in the degree of sectoral specialisation does not influence entrepreneurial activity in developing, transition regions. The results are consistent with the observation of Wyrwich, who for the former German Democratic Republic did not found any statistically significant connection between Krugman specialization index and startup rate (2012).

According to research expectations, the direct link between unemployment rate and the share of self-employed within total workforce has been found. The coefficient of the estimation confirms the anticipated contribution of unemployment on entrepreneurial activity in developing regions. The results support Hypothesis 1 and indicate the relevancy of necessity entrepreneurship. The findings confirm previous studies that have identified that the growth of unemployment leads to the enhancement of "out of need" entrepreneurship (e.g. Audretsch and Fritsch, 1994; Fritsch *et al*., 2014; Storey, 2016).

Contrary to research expectations, an attempt to identify an increasing effect of knowledge inflows on entrepreneurial activity in developing regions has not lead to any significant results. Indeed, the evidence that together with a rise in intramural R&D expenditure the growth in the share of self-employed within total workforce is observed, has not been found. These results do not correspond to Hypothesis 2, however they are in line with some of studies for developed regions, which emphasize a lack of direct relationship between regional knowledge and startup activity (e.g. Stuetzer *et al.,* 2014).

The results indicate that the contribution of human capital to entrepreneurial activity in developing regions is statistically significant. The coefficient of the estimation confirms the expected effect of the share of population with tertiary education degrees in relation to total employment on the share of self-employed within total workforce. Hypothesis 3 is supported. It is particularly interesting that the positive impact of human capital is also lagged (t-1 lag), however with significance at the 0.1% level. The results are in line with e.g. Gries and Naudé, 2009.

Unexpectedly, the results for control variable are not statistically significant. It indicates that findings corresponding to the positive impact of demand on entrepreneurial activity have not been found. The analysis does not reveal any significant relationships between income of households and the share of self-employed within total workforce. Hence, the results do not provide any support for explanations that

demand determines entrepreneurial activity, and then are not consistent with previous studies (e.g. Reynolds *et al.,* 1995).

Conclusions

This paper investigated regional dimension of entrepreneurship in a developing economy, with regard to Polish Północno-Zachodni Region. The results indicate that unemployment has positive effect on entrepreneurial activity in developing regions, which suggest its relevant consequence for nascence of entrepreneurial behaviours in these regions. However, these observations are not exclusive only for developing economies, since significant positive relationships between unemployment and entrepreneurship have been found also in developed countries (e.g. Thurik *et al.*, 2008). The findings suggest also that the focus on human capital in developing economies may contribute to an increase of entrepreneurial activity. The evidence of a positive effect of tertiary education on the share of self-employed within total workforce should encourage policymakers to establish and intensify schemes for encouraging entrepreneurial attitudes among high-skilled people.

Various shortcomings of the study presented here should be acknowledged that provide directions for further research. First, although dependent variable was proxy in line with literature, a limitation of this research is the lack of information on the self-employment in the agricultural sector in respective NUTS-2 regions, which makes impossible to learn whether dependent variable should be corrected for high employment in question (with regard e.g. to Acs *et al*., 2005). Second, despite analyzing regional dimension of entrepreneurship with a focus on principal variables, this paper does not control for regional: migration rate, foreign direct investment, density. These dimensions may reflect the level of human capital, knowledge inflows and demand for goods and services (e.g. Reynolds *et al.*, 1995; Wyrwich, 2012), therefore it seems interesting to test to what extent these factors determine entrepreneurial activity in Północno-Zachodni Region. Third, whereas this study allows to observe relationships for one of NUTS-1 regions in Poland, future discussion on entrepreneurship issues in a developing, transition economy should involve all Polish regions.

Abstract

Definition of exploitation strategy for water distribution system is determined by many factors which have different functions in the socio-economic system. The paper presents characteristics of external environment of water distribution system, which potentially influence definition exploitation policy. The research includes analysis of exploitation strategy for a small water distribution system located in the poorly urbanized area (small municipality) and comparison of importance of decision criteria considered with the criteria considered for typical urban water distribution system. The basic research question is: Do the size and character of a water distribution system strongly influence decisions on implemented water distribution system exploitation strategy?

Keywords: water distribution system, structural analysis, exploitation strategy.

Introduction

Water distribution systems constitute part of the basic elements of contemporary technical infrastructure of urban and rural areas. It is a complex engineering system composed of transmission networks and auxiliary equipment (e.g. controllers, checkouts etc.), scattered territorially over a large area. Simplified structure of a water distribution system and its functions are presented in the figure below (Fig. 1).

Acquiring and collecting	Processing	Distributing
- acquiring water from sources - transporting and collecting water in a well or a tank	- bringing water to a treatment facility - conducting required biological and physiochemical processes	- bringing water to the supply area - distributing water in the supply area

Fig. 1: Structure and functions of water distribution system

From the water distribution system operation point of view, its basic features are: functional variability and territorial dispersion. Functional variability results from the need to adjust the system

to temporary fluctuations in demand for water. Territorial dispersion on one hand allows for the realization of the basic goal of supplying water to consumers; while on the other is a serious impediment to maintenance work (inspections, repairs, etc.) as it implies the need to move people and equipment necessary to carry out the work and to ensure proper communication. It is important to note that water distribution networks are usually large assets, of the value significantly higher than the income of its operator. There is therefore no financial or technical capacity to reproduce a significant part of the network in a short period of time. Hence, it is important to adopt exploitation policy striving for maintaining the system and adjusting it to growing requirements (increasing number of customers, increase in the length of the water distribution network, changes in legal requirements, etc.), by systematic but not extensive actions (compared to the size and value of the facility being used).

The basic research question is: Does the size and character of the water distribution system significantly affect the adopted exploitation strategy? Such a question has shaped the goal of research and the method of their implementation. The paper analyzes the exploitation strategy of a small water distribution system in poorly urbanized areas (small municipality) and compares the importance of the criteria under consideration for this system and the typical urban system (Loska, 2016). The article consists of four chapters. The chapter 2 describes the STEEPVL (Social, Technological, Economic, Ecological, Political, Value and Legal) method, defining the goal of the method and the steps to its implementation. The next chapter presents the research structure. This chapter characterizes the research object and analyzes factors influencing the exploitation strategy of the water distribution system exploited by the small municipality. The MICMAC analysis (Matrice d'Impacts croises-multiplication appliquée anclassment) has been carried out, allowing for the assessment of the influence and dependence of the features and the visualization of the results. A comparative analysis of the results obtained for the large city water distribution system with the results obtained for the water distribution system exploited by the small municipality was also carried out. The last chapter is a summary and definition of directions for further research.

Assumptions of Structural Analysis

Structural analysis is a tool that enables structuring and analyzing sets including large number of factors (variables) influencing each other (Grzybowska, 2012). The first stage of its implementation is to identify the type of interaction between the pair of factors. Applying structural analysis to each pair of A and B factors will yield answers to the following questions: (i) does the A factor have a direct impact on the B factor? (ii) If so, is this impact small, medium, or crucial? For this purpose, it is necessary to determine whether it is direct and what is its strength (low, medium, high or potential). The impact is assessed in three points scale, that offers also opportunity to identify potential impact and is defined as follows:

- „0” – no impact;
- „1” – small impact;
- „2” – medium impact (crucial, but not essential);
- „3” – crucial’ P – potential impact.

The structural analysis matrix can be processed with tools such as the MICMAC, based on the algebraic Boollean logic. Application of the MICMAC program enables analysis and comparison of hierarchy of individual variables, taking into account their direct and indirect impacts, which is a rich source of information about the system being analyzed. The strength of structural analysis is in particular its ability to identify relations between variables when mutual influences are not obvious and may remain unrecognized even by experts in the field. The fundamental limitation of the method is the necessity of limiting the number of variables considered in such a way as to allow experts to determine, within a reasonable time, their mutual relations. The algorithm used in the MICMAC software is based on three fundamental stages (Ahmed et al., 2009):

- Stage 1: Determining factors that have influence on the given occurrence

- Stage 2: Describing relations between factors by building matrix and drawing direct and indirect impact graph
- Stage 3: Identifying groups of factors including crucial factors and drawing the influence-dependence chart

Structural analysis with MCMAC software enables identification of factors influencing a given research area (fig.2):

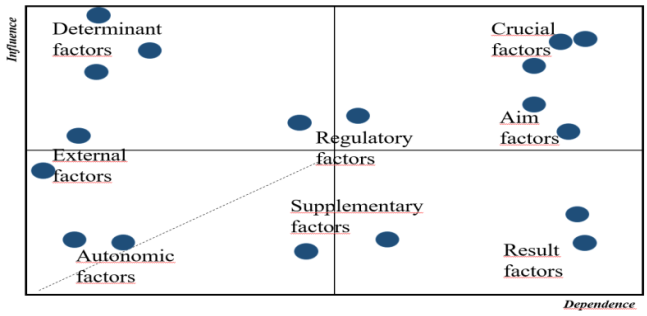

Fig. 2: Example of structure of factors influencing a given research area

(based on Nazarko et al., 2017)

The groups of factors presented in the figure 2 can be characterized as follows (Nazarko et al., 2017):

- crucial factors, which are characterized by large-scale impact and a high degree of dependency on other factors- due to high instability, these factors require critical scrutiny
- aim factors, are dependent on other factors and tend to be influenced by such factors rather than vice versa;
- result factors, are characterized by low impact and high dependency on other factors and are especially susceptible to changes in crucial factors;
- determinant factors (motorbikes, brakes) have a strong impact on the system, are characterized by a low level of dependency on other factors, and can be regarded as a driving or breaking force;
- regulatory and supplementary factors are characterized by minimal impact on the system and can prove to be beneficial in achieving strategic goals;
- autonomic factors are characterized by exerting the least impact on changes taking place in the system as a whole unit;
- external factors are characterized by having a relatively smaller impact on the system than determinant factors, but a greater impact than autonomic factors, and are not impacted upon by other variables.

Methodology

Introduction of the Object of the Research

The object of the research is a water distribution network supplying the small municipality. It is a rural municipality located in Wielkopolska (Greatpoland) region in Poland. The first plans for construction of the aqueduct were made in 1911. Currently the water distribution network extends over a total area of 185.5 km2, of which 134.3 km^2 is the rural area and 51.2 km^2 is urban area.

Currently, the company manages a system of about 190 km. Over 60% of the system are installations that were made more than 20 years ago, 20% are installations that are between 11 and 20 years old, and the remaining 20% are installations less than 10 years old. The system consists of cement-asbestos pipes (18%), PVC pipes (65%), cast iron pipes (15%) and PE pipes (2%).

The goal of the enterprise is to supply water to the consumers, providing:

- quantitative parameters, taking into account needs of customers varying in time and space,
- quality parameters, taking into account the need to adjust and maintain the water characteristics at the level defined by legal requirements.

In pursuit of such goals, the network's performance is crucial for the company, including:

- operation aspect - providing organizational and economic conditions for the efficient use of all network elements (sale of water produced to end users)
- maintenance aspect - providing technical capabilities for effective operation and efficient use of the network, by monitoring and maintaining parameters at the required level, e.g. water pressure in the network, carrying out scheduled inspections, maintenance and repairs and performing unscheduled work resulting from emergency events.

It is important for network managers to consider what external factors should be taken into account when determining the exploitation policy for water distribution network, and which of them will have the greatest impact both on the performance of the customer response and on the company's own efficiency.

Selection of factors

The research was to identify, select and organize a set of features describing the impact of the external environment on the water distribution network's exploitation policy. Due to the objective of the research, the external environment features developed by A. Loska (Loska, 2017) for the large water distribution system were used for further consideration. The identification of the external environment was carried out in the research with an expert method (involving researchers and employees of the company) using the STEEPVL model. This model includes seven criterion classes, each of which determines the selected aspect of the external environment: Social, Technological, Economic, Ecological, Political, Value, Legal. The factors can be defined as follows (Nazarko & Kuźmicz, 2017):

- **Social factors** include culture, health consciousness, population rate, age distribution and importance of safety. Trends in social factors affect the demand for products and how enterprises operate,
- **Technological factors** cover technological aspects such as R&D activity, technology incentives and the rate of technological change. They can determine barriers to entry, minimum efficient production level and influence outsourcing decisions. Technological shifts may affect costs, quality, and lead to innovation,
- **Economic factors** can relate to economic growth, interest rates or exchange rates. They have major impact on how enterprises operate and make decisions Environmental factors cover ecological and environmental aspects, which may influence enterprises. Growing awareness of the potential impact on environment affects business activity, technologies involved and final products,
- **Political factors** mean to what degree the government intervenes in the economy. They include areas such as tax policy, labour law, trade restrictions and political stability,
- **Legal factors** include different national and international regulations on different levels of government and mechanisms to monitor and ensure compliance with these laws.

The identified features for each of the criteria classes are shown in the Table1.

Table 1: The list of the factors, as a result of the analysis using the STEEPVL model (Loska, 2017)

Classes of factors	Factors
Social	(1) Level of request and consumption of water in the activity area of the enterprise. (2) Staff potential of the enterprise. (3) Staff potential of the maintenance department of the enterprise
Technological	(4) Level of modernity of the water supply system (5) Access to innovative exploitation solutions on the water supply system. (6) Level of the use of innovative methods and tools in the exploitation of the water supply
Economic	(7) Dynamics of changes in the price (cost) of water supply to consumers. (8) Expenditures for development and modernization of the water supply system. (9) Expenditures for activities of the maintenance department.
Ecological	(10) Influence of the water supply system on the environment. (11) Impact of exploitation activities for the water supply system on the environment.
Political	(12) State and region policy in the field of water management. (13) Enterprise policy for ensuring supply of water to customers. (14) Importance of the maintenance activity for the enterprise.
Value	(15) Life style and consumption patterns of the local community. (16) Level of acceptance of maintenance works of the water supply system by the local community.
Legal	(17) Legislation in the supply of water to consumers. (18) Legal requirements and standards for the exploitation of the water supply system.

The criteria and features presented in the table 1 were the subject of further research conducted by the team of experts.

Research framework

The analysis of external factors influencing the selection of the exploitation strategy of the water distribution system in a small municipality was carried out in accordance with the steps outlined in Chapter 2. The first step was to determine the relationship between the factors.For developing contextual relationships among variables, the opinion of five experts, (three from industry and two from academia) was taken. For expressing the relationship between different critical factors, four symbols have been used to denote the direction of relationship between the parameters i and j:

- V is used for the relation from enabler i to enabler j (i.e. if enabler i influences or reaches to enabler j).
- A is used for the relation from enabler j to enabler i (i.e. if enabler j reaches to enabler i).
- X is used for both direction relations (i.e. if enablers i and j reach to each other).
- O is used for no relation between two enablers (i.e. if enablers i and j are unrelated).

Based on this contextual relationship, the SSIM has been developed. To obtain consensus, the SSIM was discussed in a group of enterprise experts and based on their responses, SSIM has been finalized and is presented in table 2.

Table 2: Structural self-interactive matrix (SSIM)

Factor p_i	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18
1		V	V	0	0	V	V	0	0	0	0	X	V	V	A	V	0	V
2			X	0	0	A	A	X	0	0	0	0	A	A	0	0	0	0
3				0	0	X	0	0	V	0	0	0	A	X	0	X	0	0
4					A	A	0	X	0	V	0	0	A	V	0	V	0	0
5						V	0	0	A	0	0	0	V	A	0	0	0	V
6							V	X	X	0	X	0	0	A	0	X	0	A
7								A	A	A	A	A	A	0	X	V	A	0
8									V	X	V	A	X	X	0	0	A	A
9										V	X	0	A	X	0	A	0	A
10											V	0	0	0	0	0	A	0
11												0	0	1	0	0	0	0
12													V	0	0	0	V	0
13														V	A	0	0	A
14															0	X	0	A
15																V	A	0
16																	0	0
17																		0

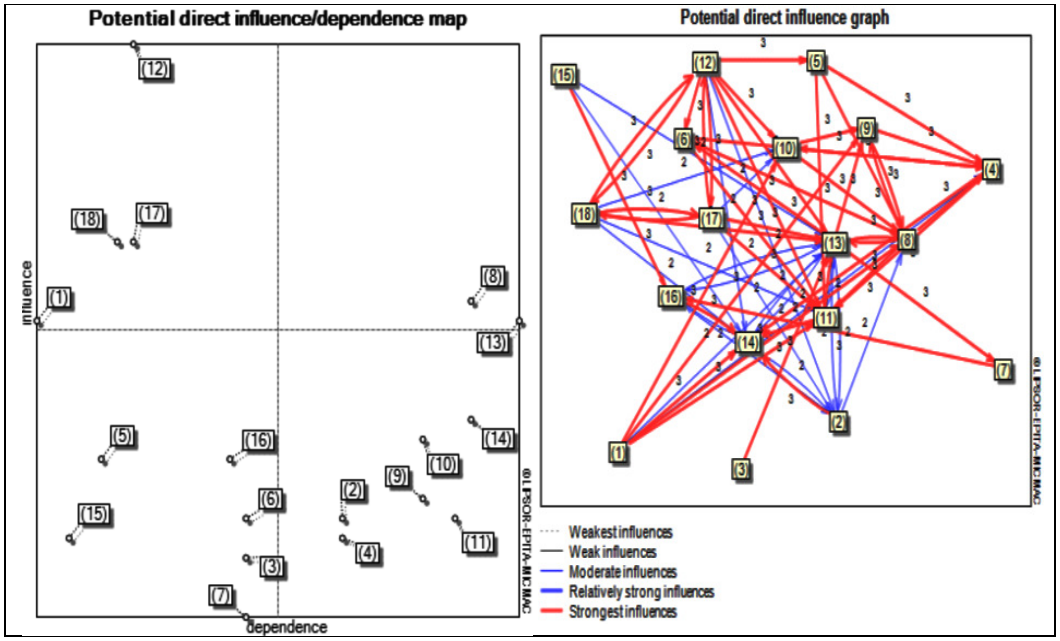
The SSIM is transformed into a reachability matrix format by transforming the information in each entry of the SSIM into 1s and 0s in the reachability matrix. The substitution of 1s and 0s are as per the following rules (Attri et al., 2014):

- If the (i, j) entry in the SSIM is V, the (i, j) entry in the reachability matrix becomes 1 and the (j, i) entry becomes 0.
- If the (i, j) entry in the SSIM is A, the (i, j) entry in the reachability matrix becomes 0 and the (j, i) entry becomes 1.
- If the (i, j) entry in the SSIM is X, the (i, j) entry in the reachability matrix becomes 1 and the (j, i) entry also becomes 1.
- If the (i, j) entry in the SSIM is O, the (i, j) entry in the reachability matrix becomes 0 and the (j, i) entry also becomes 0.

Following the above rules, the initial reachability matrix is developed. In the next step, the team re-examined and verified the impact of each factor. As a result of the analysis, a new, verified matrix was developed, which was further analyzed (Table 3).

Table 3: Matrix after verification by experts

Factor p_i	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18
1	0	1	0	1	0	0	0	1	1	1	1	1	1	1	0	1	0	0
2	0	0	1	1	0	0	0	1	0	0	0	0	1	1	1	0	0	0
3	0	1	0	0	0	1	0	0	0	1	0	0	1	0	1	0	0	0
4	0	0	1	0	0	0	0	0	0	1	1	0	0	1	0	0	0	0
5	0	0	1	1	0	0	0	1	1	1	1	0	0	0	0	0	0	0
6	0	1	0	1	0	0	0	1	0	1	1	0	0	0	0	0	0	0
7	0	0	0	1	0	0	0	0	0	1	1	0	1	1	0	1	0	0
8	0	1	0	1	1	1	0	0	1	1	1	0	1	1	0	0	0	0
9	0	0	1	1	1	0	0	1	0	1	1	0	0	0	0	0	0	0
10	0	0	0	0	0	0	1	1	1	0	0	1	1	1	0	1	1	0
11	0	0	0	0	0	0	1	0	1	1	0	0	1	1	0	0	1	0
12	0	1	1	1	1	1	1	1	1	1	1	0	1	1	1	1	1	1
13	0	1	0	1	0	1	1	1	1	0	1	0	0	1	0	1	0	0
14	0	1	1	0	0	1	1	1	1	1	1	0	1	0	1	1	0	0
15	1	1	1	0	0	0	0	0	0	0	0	1	1	1	0	1	0	0
16	0	1	0	0	0	0	1	1	1	0	0	1	1	1	1	0	0	1
17	0	1	0	1	0	1	1	1	1	1	1	1	1	0	0	0	0	1
18	0	1	1	0	0	0	1	1	1	1	1	1	1	1	0	1	1	0



In the next step, the team assessed the impact between factors using the scale presented in the second chapter („0" – no impact; „1" – small impact; „2" – medium impact (crucial, but not essential); „3" – crucial'impact) and developed conical matrix. Conical matrix is developed by clustering factors in the same level across the rows and columns of the final reachability matrix. The drive power of a factor is derived by summing up the number of ones in the rows and its dependence power by summing up the number of ones in the columns. Next, drive power and dependence power ranks are calculated by giving highest ranks to the factors that have the maximum number of ones in the rows and columns, respectively (Table 4).

Table 4: Conical matrix

Factor p_i	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	Drivers power

Matrice d'Impacts croises-multiplication appliqu´e anclassment (cross-impact matrix multiplication applied to classification) is abbreviated as MICMAC (Arcade et al., 1994). The purpose of MICMAC analysis is to analyze the drive power and dependence power of enablers. MICMAC principle is based on multiplication properties of matrices. It is done to identify the key enablers that drive the system in various categories. The direct and indirect drive power - dependence power diagram is drawn as shown in Fig. 3. This figures was prepared with MICMAC software (http://en.laprospective.fr

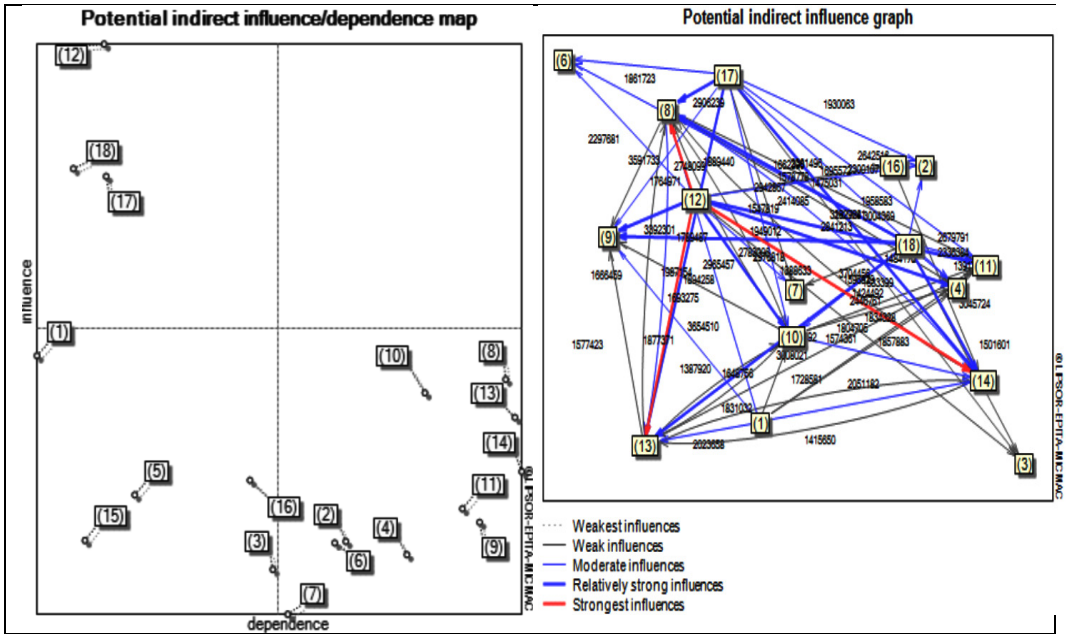

Fig. 3: MICMAC graph for water distribution system exploited by a small municipality (This figures was prepared with MICMAC software (http://en.laprospective.fr)

To answer the question: Does the size and character of the water distribution system significantly affect the adopted exploitation strategy? The results of the research should be compared with the results obtained for the large urban water distribution system located in Dolnośląskie (Silesia) region in Poland (Loska, 2016). Direct influence/dependence maps of compared waer distribution systems were presented on Fig.4 and the division of the factors of the structural analysis, based on direct impacts was presented in Table 2.

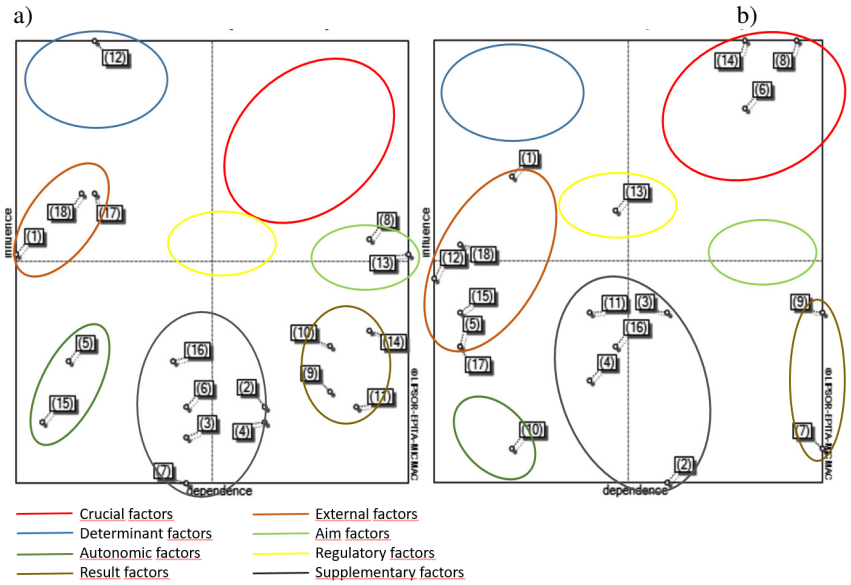

Fig. 4 :MICMAC direct influence/dependence map a) small municipality water distribution system b) large city water distribution system

Table 2: The division of the factors of the structural analysis, based on direct impacts

Groups of factors	Small municipality water distribution system	Large city water distribution system (Loska, 2016)
Crucial factors	None	(6) Level of the use of innovative methods and tools in the exploitation of the water supply (8) Expenditures for development and modernization of the water supply system. (14) Importance of the maintenance activity for the enterprise.
Determinant factors	(12) State and region policy in the field of water management.	None
Autonomic factors	(5) Access to innovative exploitation solutions on the water supply system (15) Life style and consumption patterns of the local community.	(10) Influence of the water supply system on the environment.
Result factors	(9) Expenditures for activities of the maintenance department. (10) Influence of the water supply system on the environment. (11) Impact of exploitation activities for the water supply system on the environment. (14) Importance of the maintenance activity for the enterprise.	(7) Dynamics of changes in the price (cost) of water supply to consumers. (9) Expenditures for activities of the maintenance department.
External factors	(1) Level of request and consumption of water in the activity area of the enterprise. (17) Legislation in the supply of water to consumers. (18) Legal requirements and standards for the exploitation of the water supply system.	(5) Access to innovative exploitation solutions on the water supply system (12) State and region policy in the field of water management. (15) Life style and consumption patterns of the local community. (17) Legislation in the supply of water to consumers. (18) Legal requirements and standards for the exploitation of the water supply system.
Aim factors	(8) Expenditures for development and modernization of the water supply system (13) Enterprise policy for ensuring supply of water to customers.	None
Regulatory factors	None	(13) Enterprise policy for ensuring supply of water to customers.
Supplementary factors	(2) Staff potential of the enterprise. (3) Staff potential of the maintenance department of the enterprise (4) Level of modernity of the water supply system. (6) Level of the use of innovative methods and tools in the exploitation of the water supply (7) Dynamics of changes in the price (cost) of water supply to consumers.	(2) Staff potential of the enterprise. (3) Staff potential of the maintenance department of the enterprise (4) Level of modernity of the water supply system. (11) Impact of exploitation activities for the water supply system on the environment. (16) Level of acceptance of maintenance works of the water supply

	(16) Level of acceptance of maintenance works of the water supply system by the local community.	system by the local community.

A comparison of the impact of selected indicators for both water distribution systems shows distinct differences. First of all, for the small system (Fig. 4a, Table 2 - left), crucial factors have not been distinguished, with a significant impact and a high degree of dependence on other factors. For large systems (Fig. 4b), factors (6), (8), (14), related to increasing the innovativeness of operations in the enterprise and associated financial outlays were pointed out. At the same time, on the opposite side - autonomic factors that have the least effect on the changes occurring in the system as a whole are indicated respectively (5) and (15) for the small water distribution system and (10) for the large water distribution system. This shows that for a small system, a client, a relatively small, slowly changing municipality, does not generate / enforce compliance with changing conditions because the changes are very slow and invisible. The policy pursues the preservation of the existing substance (property) in good condition, and the main external factor influencing it (determinant factors) are legal changes and regional policy. This corresponds to the placement of "expenditures for the development and modernization of the water supply system" (13) in the focus groups, i.e. those that are rather the result of activities other than the cause and represent possible corporate goals. In the result index, for a large enterprise, it is important to place an "environmental impact" in a group of autonomous factors with a low impact on the system. It seems, however, that this is not a lack of concern for the environment, but with a greater focus on the price of water sold (7) and an active policy (9) aimed at reducing its start-up - more attention is paid to maintaining this price on acceptable level by "taking care of the environment by preventing the waste of this resource.

Conclusion

The STEEPVL-based model has been developed to analyze interactions among different factors of the external environment in shaping the exploitation policy of a small municipal water distribution network. This model has been developed on the basis of consensus of experts from industry and authors of this paper.

On the basis of a comparative analysis of external factors influencing the selection of exploitation strategies in the small municipal water distribution system and in the large municipal water distribution system, significant differences in exploitation strategy formulation can be observed. Managers of small water distribution system are less interested in innovations, but they recognize the importance of innovation as a possible future goal. In addition, they consciously acknowledge the essence of shaping the activities of their own organizational units and the way water is used in relation to the environment. In contrast, in a large urban area, innovations are important and environmental elements are treated as an element of preventing excessive consumption and wastage of natural resources such as water.

Irrespective of the difference in approach to the development of exploitation policies for water distribution systems by business managers, the added value for both companies is to draw attention to the fact that strategy development requires a broad spectrum of social, economic and environmental factors. Each of these factors reflects the nature of the impact of the decisions made both on the company and its stakeholders.

Abstract

This article describes research findings aimed at identifying the customer's perception of the quality of the visual processing of marketing information media in relation to the perceived quality of the offered services in the search for SMEs. The basic population for the purpose of the survey is the population of the East Slovakian region. 1055 respondents were surveyed and it was possible to include 987 respondents' answers based on the criterion of completeness of completed questionnaires. Data collection was conducted through simple random sampling in October and November 2016. To verify the hypotheses we used the StatSoft STATISTICA software. Due to the nature of the analyzed variables we used correlation analysis. Based on the research findings, respondents who prefer internet communication media to traditional ones, tend to think that a high-quality, visually-executed information carrier guarantees the quality of service. In general, there is a tendency for a visually produced information carrier to guarantee a well-served service. At the same time, we can say that there is a statistically significant dependence between the opinion on the equality of information media quality and the quality of the service provision. Also, our survey revealed that there is a statistically significant dependence on the relevance of interventional information carriers to the quality of visual processing of these information carriers. The results of our research are relevant to SMEs, which focus on the quality of the visual processing of marketing information media. Research results should help SMEs in the quality of their customer service.

Keywords: marketing communication, visual processing, marketing information carriers, quality of services.

Introduction

From a commercial perspective, success in the online environment depends in large part on company familiarity with the size, characteristics, and demands of the Internet user market. Thus, better understanding of who is using the Internet, what they demand from it and how they behave in an online context is crucial for businesses, looking to establish an effective online presence (Perju-Mitran et al. 2014). Marketing strategy and communication is not the privilege of large companies; it also plays a significant role in small and medium-sized enterprises (SMEs) (Kašík & Šnapka 2017). Companies use marketing communication to advertise various products they sell to increase their prestige and image, moreover to attract more customers and increase their profitability (Jirák & Köpplová 2009; Gavurová & Šoltés 2016). In order to succeed in the current hyper-competitive environment, the SMEs carry out

marketing communications activities (Štefko et al. 2010; Šnapka & Kašík 2012). Kotler (2007) emphasizes that for small and medium sized businesses the problem is not the communication itself but how to say it, to whom and how often. The answer to these questions is just marketing communication (Gay et al. 2007; Gburová & Matušíková 2016). In addition to the use of marketing communication tools, the quality of the visual processing of marketing information carriers is also important, which is one of these tools (Edmiston - Strasser 2009). In general, it can be said that with the Internet a new space has been opened to promote its products, services or brands. Specifically, it is a new dimension in the level of creating direct and effective relationships with the customers (Frankovský & Birknerová 2016; Svec et al. 2015; Grncay et al. 2015). Investing in marketing activities in the online environment is incomparably lower compared to the cost of other forms of promotion (Janouch 2010; Scott 2010).

Expenses on online promotion in the UK, according to the eMarketer survey (2016), amounted to 9.64 billion pounds (10.51 billion euros) in 2016. This year, these expenses are at 10.60 billion pounds (11.56 billion €). The forecast for 2020 predicts an average year-on-year rate of 2.2%. In 2020, the estimated cost of digital advertising is 13.11 billion pounds (14.30 billion euros). Based on the Marketo survey (2013), we note that 90% of the information transmitted to the brain is visual and visual information is processed 60.000 times faster than texts. There is an 85% chance that viewers or potential customers will rather buy the product after looking at a video about the product. 46.1% of the respondents said that the quality of the visual processing of marketing information carriers affects the credibility of the company.

Several authors in various disciplines, such as Klabiková Rabová (2015) in the study "Marketing communication of SMEs specialized in cosmetic industry", as well as Hwang and Lee (2017) in their study "Using an Eye-Tracking Approach to Explore Gender Differences in Visual Attention and Shopping Attitudes in an Online Shopping Environment". Another study responding to the problem is "Business information visualization intellectual contributions: An integrative framework of visualization capabilities and dimensions of visual intelligence" by Bačić and Fadlalla (2016).

Methodology

Based on the above described facts, the main goal of the research was to analyze customer perceptions of the quality of visual processing of offline and online marketing information media in relation to the perceived quality of offered services when searching for SMEs. The main objective consisted of two research questions:

- Is there a significant dependence on the visual quality of the information media and the quality of the services provided?

- Is there a significant dependence on the relevance of information media to the quality of visual processing of information carriers?

For the purposes of our survey, we proceeded from material obtained from primary sources. The basis of primary sources was based on data obtained through the realization of the survey in a questionnaire form. The basic set of respondents consists of inhabitants of the Eastern Slovak region, which can be identified as the main target group for the SMEs, operating within the region. In the survey, 1055 respondents were interviewed, and it was possible to include 987 respondents' answers based on the criterion of the fully completed questionnaires. Data was also collected electronically, using online form creation and data collection tools (the online Google Form tools). The online version of the questionnaire was sent to the respondents via the available email addresses. Data collection for the main research was conducted in October - November 2016.

Based on the questions, we identified the attitudes and preferences of the respondents in relation to the analyzed problem of our research. Specifically, the aim was to identify the relationship between the quality of the visual processing of the traditional (offline) forms of the marketing information media (i.e. the traditional information sources - Advertising Billboards, Advertising News, Advertising Leaflets, TV Advertising, Radio Advertising, Daily Press) and online forms of marketing information carriers (i.e., Online information sources - Internet sites, Online catalogs of companies, Online advertising, Community discussions, Business blogs, Social networking profiles) and perceived quality of services offered by SMEs.

Subsequently, with the use of other mathematical-statistical methods to solve the problem, a 5 and 10 degree interval scale, also referred to as the Likert scale, was used in the questionnaire. Our hypotheses have been confirmed through the StatSoft STATISTICA statistical program. Based on the size of the file and the characteristics of the primary data and the analyzed variables, the correlation coefficient Phi and Gamma was used.

48.53% of women and 51.47% of men participated in the questionnaire survey. The largest group of the respondents surveyed was a group of respondents from the age 18 to 25 with a share of 21.28%. The second most frequent group was the group of respondents from the age 26 to 30, representing a share of 13.78%. On the basis of a deeper perspective, respondents from the age 18 to 35 represent a share of 46.61%. For all other age categories surveyed, the proportion of respondents did not exceed 12%. Regarding the highest level of education, the biggest group was the ones with secondary education without a school leaving examination and their share of 31.51%. The share of respondents with a secondary education with a school leaving examination was 28.37%. The share of graduates of the first level of higher education represented 20.77%. The share of respondents who achieved the second level of higher education represented 19.35%.

Results

The first part of our research focused on detecting the extent to which traditional (offline) or online sources of information preferred by respondents believe that quality visual processing of information carriers guarantees the quality of the services provided. We used the correlation coefficient Phi to analyze this area. All of the respondents' answers were in the survey, none of them were omitted. Based on the formulated research problem, the following hypothesis was formulated:

H1: We assume a statistically significant dependence of the opinion on the equality of the quality of the information carriers and the quality of the provided services on the preference for obtaining information.

Table 1 : Crosstabulation – H1

Preferred sources of information on products and services	Allegation: Generally well-processed information carrier = quality services provided		Total
	Yes	No	
Through the Internet	558	157	715
Traditionally, without the use of the Internet	180	92	272

Based on the findings in Table 1, respondents who prefer Online communication carriers to traditional ones tend to think that a high-quality visual information carrier guarantees the quality of the service. In general, there is a tendency for a visually produced information carrier to guarantee a well-served service.

The following Table 2 gives us the exact output of the correlation analysis, and thus the extent to which the preferred channel (traditional or online) influences the view of equality of quality of services and quality of visual processing of information carriers.

To confirm or refute the above hypothesis, it is necessary to formulate partial hypotheses for testing the individual components of the files in the question:

- H0: We assume that there is a statistically significant dependence between the view of the equality of the quality of the information carriers and the quality of the provision of the services on the preferences of obtaining the information.

- H1: We assume that there is no statistically significant dependence between the view of the equality of the quality of the information carriers and the quality of the provision of services on the preferences of obtaining information.

Table 21 Symmetric Measures – H_1

Variables		Value	Approximate Significance
Nominal by Nominal	Phi	0.122	0.000
	Cramer's V	0.122	0.000
N of Valid Cases		987	

The correlation coefficient π with an output value of 0.122 tells us about the weakness of the analyzed elements. Tests depending on the dimension of the set "p" at the nominal data level and at the correlation coefficient p are not studied under standard circumstances. We consider the statistically significant dependence on an output value of 0.20, which is understood as the medium-term dependence at this coefficient. Therefore, the output of p value equals to 0.000, which suggests to accept the H0 and reject the original H1 hypothesis. Therefore, we accept a position implying our hypothesis. Moreover there is statistically significant dependence between the analyzed elements.

The second part of our research focused on the extent to which respondents perceive the relevance of traditional and Online information carriers as being dependent on the quality of the visual processing of information media. We analyzed 100% of the file data 987 respondents answered. We used the Gamma correlation coefficient with respect to the ordinal level. Based on the formulated research problem, the following hypothesis was determined:

- **H2:** We assume a statistically significant dependence of the relevance of the traditional information carriers on the quality of the visual processing of these carriers.

- **H3:** We assume a statistically significant dependence of the relevance of online information carriers on the quality of the visual processing of these carriers.

For the final evaluation of the H2 hypothesis, the following partial hypotheses are required:

- H0: We assume a statistically significant dependence of the relevance of the traditional information carriers on the quality of the visual processing of these carriers.

- H1: We do not expect a statistically significant dependence of the relevance of traditional information channels on the quality of the visual processing of these information carriers.

Table 32 : the degree of relevance of traditional information carriers

Variables		What importance do you attach to the quality of visual processing of the following types of information carriers - Traditional information carriers?					Total
		Minimal importance	Less important	I can not judge	More important	Maximum importance	
The degree of relevance of traditional information carriers	Strongly irrelevant	15	0	16	149	0	180
	Slightly irrelevant	7	48	35	144	261	495
	I can not judge	8	10	5	42	2	67
	Slightly relevant	18	20	3	29	31	101
	Strongly relevant	16	31	7	65	25	144
Total		64	109	66	429	319	987

Table 4: Symmetric Measures – H_2

Variables	Value	Asymptotic Standardized Error[a]	Approximate T[b]	Approximate Significance
Ordinal by Ordinal - Gamma	-0.109	0.034	-3.117	0.002
N of Valid Cases	987			
a. Not assuming the null hypothesis.				
b. Using the asymptotic standard error assuming the null hypothesis.				

From Table 4, with a negative correlation output value, it can be assumed that this is a negative correlation between the relevance of the traditional information carriers on the quality of the visual processing of these information carriers. The absolute value of output equals to 0.109, which is a weak correlation. Based on the above, we accept the H0 and reject the alternative of this hypothesis. Therefore, we agree with the standpoint, that the importance of visual processing of traditional information media is low to the extent that it is capable of inducing a less perceptible relevance of these information carriers.

For the final evaluation of the H3 hypothesis, the following hypotheses are formulated:

- H0: We assume a statistically significant dependence of the relevance of online information carriers on the quality of the visual processing of these carriers.
- H1: We do not expect a statistically significant dependence of the relevance of online information carriers on the quality of visual processing of these carriers.

Table 53 : The relevance of Online information carriers

Variables		What importance do you attach to the quality of visual processing of the following types of information carriers - Online information carriers?					Total
		Minimal importance	Less important	I can not judge	More important	Maximum importance	
The relevance of Online information carriers	Strongly irrelevant	3	4	8	7	2	24
	Slightly irrelevant	39	8	27	44	5	123
	I can not judge	8	17	10	24	19	78
	Slightly relevant	13	33	41	171	93	351
	Strongly relevant	8	40	29	143	191	411
Total		64	71	102	115	389	310

Table 6 : Symmetric Measures – H_3

Variables	Value	Asymptotic Standardized Error[a]	Approximate T[b]	Approximate Significance
Ordinal by Ordinal - Gamma	0.430	0.033	11.842	0.000
N of Valid Cases	987			
a. Not assuming the null hypothesis; b. Using the asymptotic standard error assuming the null hypothesis				

It can be seen from the above Table 6 that among the elements of the attributed importance of the quality of the visual processing of Online information carriers to the degree of relevance of these information

carriers is a strong dependence, as evidenced by the output value being equal to 0.430. Thus, we receive an opinion implying our partial H0 hypothesis and dismiss its alterative, the H1. There is a statistically significant dependence on the relevance of interventional information carriers to the quality of visual processing of these information carriers.

Conclusion

In a competitive environment communicating with customers is undoubtedly an important factor in the success of SMEs. Based on a well-chosen marketing communication and the quality of marketing information carriers, the company informs consumers of their products and services. Due to the development of the Internet and scientific and technological progress, the customer purchase cycle has become more complex. The development of communication media gives customers a broad access to information. This choice of the customers makes it difficult for companies to select individual communication media and compose a communication mix in line with the customer's path.

Based on the above-mentioned analyzes we can state that apart from the chosen communication media, the quality of the visual processing of these media and the individual marketing information carriers are also important. Customers who prefer Internet communication media instead of traditional ones tend to think that a high-quality, visually-executed information carrier guarantees the quality of the services. In general, there is a tendency for a visually produced information carrier to guarantee a well-served service. Our survey also confirmed that there is a statistically significant dependence on the relevance of interventional information carriers on the quality of visual processing of these information media. This dependence, however, has not been confirmed in the case of traditional information media, which, in terms of promotional activities, is considered to be a significant point of view.

The popularity of the online environment for marketing communication activities is also reflected in the advertising spending. An example for this is an eMarketer (2016) analysis of the UK market, which estimates that by 2020 we can expect an average increase in digital advertising spending of 2.2%. In particular, we can speak about an increase from the current value of 10.60 billion £ (€ 11.56 billion) to 13.11 billion £ (€ 14.30 billion) in 2020.

Based on the results of our survey, the SMEs should certainly take care of the quality of the visual processing of marketing information media. Research results should help the SMEs to provide the quality of their customer service. Implementing and correctly understanding the quality of online marketing information carriers in the context of marketing and the SME strategies over the long term, which represents an indisputable competitive advantage while improving the quality of the services offered by the SMEs. Specifically, it is to grasp current trends and practices in marketing communication with what makes easier the implementation of the future innovations.

Abstract

The aim of this article is to identify customers' perceived usefulness of offline communication tools when searching for SMEs. The aim of this paper is to help clarify the impact the selected offline communication tools have when reaching target audiences of SMEs. The basic set for the purpose of the survey is the population of the Eastern part of Slovakia. 1055 respondents were addressed, and it was possible to include 987 respondents' answers based on the criterion of completeness of the completed questionnaires. The aim was to identify the attitudes and preferences of respondents in relation to traditional (offline) forms of marketing communication focusing on SMEs. Specifically, we focused on offline communication tools such as Advertising newspapers, Advertising billboards, Advertising leaflets, TV advertising, Radio advertising, and last but not least, an advertisement in the Daily press was analysed. Data collection was conducted through simple random sampling in October and November 2016. To verify the hypotheses we used the software StatSoft STATISTICA. Due to the nature of the analysed variables we used correlation analysis. Based on research findings, it can be noted that a total of 27.56% of respondents prefer traditional offline communication tools to get information about SMEs. Given the existence of a statistically significant dependence on the impact of online communication tools when searching for SMEs, the strongest dependency identified for Advertising leaflets and Advertising newspapers. The weakest dependency was identified in the case of Billboards. The research results are intended to assist SMEs in deciding on the strategic direction of their marketing communications.

Keywords: Marketing communication, Offline environment, Consumer behaviour.

Introduction

Communication plays a very important role among humans and it is an indispensable part of their lives. The situation is the same in the business world, where enterprises and especially small and medium-sized enterprises (SMEs) implement marketing communication activities to succeed in the current hyper-competitive environment (Lajčin et al. 2014; Šoltés & Gavurová 2010). Despite the fact that nowadays online marketing communication is undeniably important, traditional (offline) marketing communication also has its place and meaning in corporate communication (Matušíková & Gburová 2016; Fedorko et al. 2015). Kotler (2007) emphasizes that not the communication is what matters for small and medium-sized businesses but rather that what to say, how to say, to whom and how often. The answer to these questions is the marketing communication. Marketing communication with its communication methods presents the company and ultimately helps to satisfy the needs of consumers (Zamazalová 2009; Hradiská 2010; Šnapka & Kašík 2013). Nowadays, social changes as well as constant innovations in the field of

communication technologies strongly influence the marketing development as well as the marketing communication (Gerrikagoitia et al. 2015, Štefko et al. 2010, Gavurova et al. 2017). Přikrylová (2010), emphasises that one group of companies can not adapt to the rapid development of the technologies or to the market reality itself, which in most cases results in a decrease in the sale or the disappearance of the company. The second group presents companies which are open to new opportunities, which are not afraid to experiment with the new strategies and thus to reach out to target groups more effectively and flexibly (Constantinides 2014; Kašík y Šnapka 2015). The global expenditures of eMarketer advertising spending (2016a) was amounted to 571.36 billion € in 2016. A significant increase in the percentages (6%) is expected for 2017. According to foresight, these expenditures will increase by an average 5.83% year-on-year by 2019. Of the total ad spending, digital advertising spending for 2016 was 67.12 billion €, representing 35.8%. Traditional offline advertising in printed form (newspapers, magazines) is represented by 13.9%. Other traditional ad forms for people away from their homes had a 3.9% share, and ads addressed directly to potential customers had a 2.2% share of total ad spend. It is worth mentioning that on the one hand the eMarketer (2016b) predictions for traditional or offline advertising will decrease in 2017-2020, on the other hand digital advertising spending will increase year-on-year by 2.28% on average. In 2017, digital advertising spending will increase compared to television advertising in the amount of € 77.17 billion to € 67.73 billion (eMarketer 2016c). According to the foresight of the Marketing Charts portal (2017) for the period 2017-2012, the hardest hit of the media types examined, newspaper advertising is the only market expected to see a decline in revenues between this year ($16.8 billion) and 2021 ($12.2 billion). Based on the distribution of expenditure by region, our region falling under Central and Eastern Europe is at the level of spending 12.74 billion €. The eMarketer portal (2016d) predicts this year's increase of 13.09 billion, representing a 2.7% year-on-year increase.

Several authors from different industries, such as author Klabikova Rabová (2015) in the study "Marketing communication of SMEs specializing in cosmetic industry", as well as authors Khoshnodifar, Ghonji, Mazloumzadeh and Abdollahi (2016) in their study "Effect of Communication channels on the success rate of entrepreneurial SMEs in the agricultural sector ". Another study responding to the issue is the "SME practice towards integrated marketing communications" by Balboni and Gabrielli (2010).

Based on the above described facts, the main purpose of this article is to find out how customers perceive offline communication channels service providers use to communicate with their target audience in online and offline environments alike and how such communication affects behaviour of their consumers.

Methodology

For the purpose of solving the aim of our survey, we proceeded from the material obtained from primary sources. The basis of primary sources consists of the data obtained through the realization of the research in a form of questionnaire. The basic set consists of the inhabitants of the Eastern Slovak region. These respondents can be identified as the main target group of SMEs operating within the region. 1055 respondents were interviewed. Subsequently, based on the criterion of completeness of the completed questionnaires, 987 respondents' answers could be included in the analysis. Data collection was done in electronic form. Online forms for creating and collecting data were used in a questionnaire form (the online Google Forms tool). The online version of the questionnaire was sent with the consent of the respondents via the available email addresses. Data collection for the research was conducted in October - November 2016.

The aim of the questionnaire was to identify the attitudes and preferences of the respondents in relation to the analysed problem of our research. In particular, the aim was to identify the respondents' attitudes and preferences in relation to traditional (offline) forms of marketing communication (i.e., traditional information sources - Advertising billboards, Advertising newspapers, Advertising leaflets, TV advertising, Radio advertising, Daily press).

Regarding to the mathematical and statistical solution of the issue, the questionnaire questions used a 5 and 10 degree interval scale, also referred to as the Likert scale. Verification of our hypotheses was carried out through the statistical program StatSoft STATISTICA. Based on the size of the file and the characteristics of the primary data and the analysed variables, the Wilcoxon double-choice test was used.

Based on the results of the questionnaire survey, 48.53% of respondents were women and 51.47% were men. The age structure of the surveyed respondents was dominated by a group of respondents in the range of 18-25 years with a share of 21.28%. The second largest group is the age group of respondents from the age 26 to 30, representing a share of 13.78%. Within broader intentions, respondents from the age 18 to 35 represent a 46.61% share. In all other age categories in the survey, the proportion of respondents did not exceed 12%. Regarding to the highest level of education, respondents with secondary education without maturity (31.51%) dominated. The proportion of respondents with secondary education with a school leaving examination was represented by 28.37%. The share of graduates of the first level of higher education represented 20.77%. The share of respondents who achieved the second level of higher education represented 19.35%.

Results

The first part of our research focused on detecting the extent to which traditional (offline) or online sources of information preferred by respondents believe that quality visual processing of information carriers guarantees the quality of the services provided. We used the correlation coefficient Phi to analyze this area. All of the respondents' answers were in the survey, none of them were omitted. Based on the formulated research problem, the following hypothesis was formulated:

H1: We assume a statistically significant dependence of the opinion on the equality of the quality of the information carriers and the quality of the provided services on the preference for obtaining information.

Table 1: 1 Crosstabulation – H_1

Preferred sources of information on products and services	Allegation: Generally well-processed information carrier = quality services provided		Total
	Yes	No	
Through the Internet	558	157	715
Traditionally, without the use of the Internet	180	92	272

Based on the findings in Table 1, respondents who prefer Online communication carriers to traditional ones tend to think that a high-quality visual information carrier guarantees the quality of the service. In general, there is a tendency for a visually produced information carrier to guarantee a well-served service.

The following Table 2 gives us the exact output of the correlation analysis, and thus the extent to which the preferred channel (traditional or online) influences the view of equality of quality of services and quality of visual processing of information carriers.

To confirm or refute the above hypothesis, it is necessary to formulate partial hypotheses for testing the individual components of the files in the question:

- H0: We assume that there is a statistically significant dependence between the view of the equality of the quality of the information carriers and the quality of the provision of the services on the preferences of obtaining the information.

- H1: We assume that there is no statistically significant dependence between the view of the equality of the quality of the information carriers and the quality of the provision of services on the preferences of obtaining information.

Table 2: 2 Symmetric Measures – H_1

Variables		Value	Approximate Significance
Nominal by Nominal	Phi	0.122	0.000
	Cramer's V	0.122	0.000
N of Valid Cases		987	

The correlation coefficient π with an output value of 0.122 tells us about the weakness of the analyzed elements. Tests depending on the dimension of the set "p" at the nominal data level and at the correlation coefficient p are not studied under standard circumstances. We consider the statistically significant dependence on an output value of 0.20, which is understood as the medium-term dependence at this coefficient. Therefore, the output of p value equals to 0.000, which suggests to accept the H0 and reject the original H1 hypothesis. Therefore, we accept a position implying our hypothesis. Moreover there is statistically significant dependence between the analyzed elements.

The second part of our research focused on the extent to which respondents perceive the relevance of traditional and Online information carriers as being dependent on the quality of the visual processing of information media. We analyzed 100% of the file data, 987 respondents answered. We used the Gamma correlation coefficient with respect to the ordinal level. Based on the formulated research problem, the following hypothesis was determined:

- **H2:** We assume a statistically significant dependence of the relevance of the traditional information carriers on the quality of the visual processing of these carriers.

- **H3:** We assume a statistically significant dependence of the relevance of online information carriers on the quality of the visual processing of these carriers.

For the final evaluation of the H2 hypothesis, the following partial hypotheses are required:

- H0: We assume a statistically significant dependence of the relevance of the traditional information carriers on the quality of the visual processing of these carriers.

- H1: We do not expect a statistically significant dependence of the relevance of traditional information channels on the quality of the visual processing of these information carriers.

Table 3: 3 The degree of relevance of traditional information carriers

Variables		What importance do you attach to the quality of visual processing of the following types of information carriers - Traditional information carriers?					Total
		Minimal importance	Less important	I can not judge	More important	Maximum importance	
The degree of relevance of traditional information carriers	Strongly irrelevant	15	0	16	149	0	180
	Slightly irrelevant	7	48	35	144	261	495
	I can not judge	8	10	5	42	2	67
	Slightly relevant	18	20	3	29	31	101
	Strongly relevant	16	31	7	65	25	144
Total		64	109	66	429	319	987

Table 4 Symmetric Measures – H_2

Variables	Value	Asymptotic Standardized Error[a]	Approximate T[b]	Approximate Significance
Ordinal by Ordinal - Gamma	-0.109	0.034	-3.117	0.002
N of Valid Cases	987			
a. Not assuming the null hypothesis.				
b. Using the asymptotic standard error assuming the null hypothesis.				

From Table 4, with a negative correlation output value, it can be assumed that this is a negative correlation between the relevance of the traditional information carriers on the quality of the visual processing of these information carriers. The absolute value of output equals to 0.109, which is a weak correlation. Based on the above, we accept the H0 and reject the alternative of this hypothesis. Therefore, we agree with the standpoint, that the importance of visual processing of traditional information media is low to the extent that it is capable of inducing a less perceptible relevance of these information carriers.

For the final evaluation of the H3 hypothesis, the following hypotheses are formulated:

- H0: We assume a statistically significant dependence of the relevance of online information carriers on the quality of the visual processing of these carriers.

- H1: We do not expect a statistically significant dependence of the relevance of online information carriers on the quality of visual processing of these carriers.

Table 54 : The relevance of online information carriers

Variables		What importance do you attach to the quality of visual processing of the following types of information carriers - Online information carriers?					Total
		Minimal importance	Less important	I can not judge	More important	Maximum importance	
The relevance of Online information carriers	Strongly irrelevant	3	4	8	7	2	24
	Slightly irrelevant	39	8	27	44	5	123
	I can not judge	8	17	10	24	19	78
	Slightly relevant	13	33	41	171	93	351
	Strongly relevant	8	40	29	143	191	411
Total		64	71	102	115	389	310

Table 6: Symmetric Measures – H_3

Variables	Value	Asymptotic Standardized Error[a]	Approximate T[b]	Approximate Significance
Ordinal by Ordinal - Gamma	0.430	0.033	11.842	0.000
N of Valid Cases	987			
a. Not assuming the null hypothesis; b. Using the asymptotic standard error assuming the null hypothesis				

It can be seen from the above Table 6 that among the elements of the attributed importance of the quality of the visual processing of Online information carriers to the degree of relevance of these information carriers is a strong dependence, as evidenced by the output value being equal to 0.430. Thus, we receive

an opinion implying our partial H0 hypothesis and dismiss its alterative, the H1. There is a statistically significant dependence on the relevance of interventional information carriers to the quality of visual processing of these information carriers.

Conclusion

SMEs marketing communication is an important area of knowledge based on the current strong competitive environment, both domestically and globally. It should be noted that under the influence of the rapid development of information technologies, it is possible to identify changes in the target audience - customer preferences in what way they seek information about products and services. On the other hand, it is the overwhelming amount of advertising content that consumes these target audiences on a daily basis.

The current status shows that the total ad spending per year is growing and this trend will continue for the future. Digital advertising has already exceeded TV advertising in terms of spending, and even though advertising costs are rising year on year, digital advertising spends grow at a much faster rate year on year. The region of Central and Eastern Europe, which includes Slovakia, but also the neighbouring Czech Republic, estimates a share of total advertising spending worth 13.09 billion €, which is just 2%. Even though the importance of online marketing promotion is growing, we believe that traditional or offline marketing communication continues to be an importance and position in the marketing communications of SMEs and businesses in general.

The offline environment is linked to the online environment, and on the basis of advertising spending trends, online advertising costs can be expected to rise and advertising spending in daily press sharply declines in the next period, up to 2021 (Marketing Charts 2017). Based on the results of our survey, we can conclude that with regard to traditional (offline) promotion tools, people prefer to search for information via advertising leaflets and advertising newspapers. On the contrary, the least-used information sources for people in the offline environment are Advertising billboards.

The results of our research are relevant for SMEs, which are sceptical about the offline environment from the perspective of marketing communications. The research results are intended to assist SMEs in deciding on the strategic direction of their marketing communications. It is important to implement and understand offline marketing tools within SMEs marketing activities and strategies. Finally, it must be emphasized that from a long-term perspective, the proper understanding of the promotion instruments in general is a necessity in the current market environment.

Abstract

The aim of this paper is to describe the necessity of scientific background for governmental industrial policy. Existing separately, any industrial policy may lose connection between governmental aims and reality. Scientific approach represents a great number of models of isolated economic systems, which may predict economic behavior or give us an opportunity to make forecasts for the future. It seems evident, that the industrial policy of the Russian Federation needs to be based on the scientific theory. Nowadays, the idea of improving endogenous regional development via the increase of agglomeration and urbanization effects is being widely negotiated. The main idea of the growth poles theory has an evident similarity with the theories based on industrial localization. In fact, this theory is widely used in French regional planning experience and has already shown its potential. The concept of this theory is focused on estimation of leading components of the theory and benefits which can be obtained by applying it to the Russian economy.

Keywords: agglomeration, network effects, industrial policy.

Introduction

The main aim of Strategic Development for the Russian Federation is to create strong and competitive economy, which is supposed to be based on innovations and modern technologies. Nowadays, we can find out a lot of factors which need to be improved, but we have to admit that industry sector is an absolutely significant one. Coming up with ideas of industrial renovation, government may be extremely awkward in its desire of total supervision. Improving economic reality should have efficient cooperation between aims and rules. On the one hand, the government is able to use as many resources as it has, but on the other hand, it should clearly understand the market rules and take in account the location, resources and strategical development of each company. Such point of view may persuade the government to place company´s strategies and aims into the center of industrial development as a starting point. Undoubtedly, we see the growth poles theory as a necessity for implementation in the regional industry sector with the following adaptation for the whole country. Nevertheless, we have to pay attention to the drawbacks of the theory, such as a decreasing level of creativity in conditions of increasing industrial location.

Theoretical Background

According to the benchmarking analysis of the factors and institutions that determine long-term growth and prosperity, which was made in The Global Competitiveness Report 2016-2017, innovations are named as the most important factor for finding new growth engines, but laying the foundations for long-term, sustainable growth requires working on all factors and institutions identified in the Global Competitiveness Index. Leveraging the opportunities of the Fourth Industrial Revolution will require not

only businesses willing and ability to innovate, but also sound institutions, both public and private; basic infrastructure, health, and education; macroeconomic stability; and well-functioning labor, financial, and human capital markets.

Undoubtedly, innovations as a key point are vital today, but they may be just a single step to change the economic system, but not to form the structural base. To find out the routs of modern economical processes we have to explore the theoretical background and its evolution. So, a brief mentioning of the founders of economic space theories will be suitable in the frames of this article.

The content of theories of spatial development deserves a special interest, especially the study of the interrelations between the "first" generation of French economists such as of F. Perrouxand (Perrouxand, 1967) and J. Boudeville (Boudeville, 1966) and an activity of the "Association of Regional Science" (Association de Science Régionale de Langue Française (ASRDLF)), which was founded in 1961.

The data of the theory created the essential theoretical basis for M. Porter's theory of clusters (Porter, 2003). Additionally, M. Porter (Porter, 2003), in particular, refers to the fact that he relied on the ideas of A. Marshall (Marshall, 1879), representatives of the "German" and "California" schools and the Italian "school" of industrial districts, etc. One of the most curious facts is that global spreading of the Porter theory (Porter, 2003) in France led to the state program to develop the poles of competitiveness. That is why it was included into the research.

There are also Russians scientists such as: M.K. Bandman (Bandman, 2014), A.G. Granberg (Granberg, 2011), V.V. Leontief (Leontief, 1990), O.A. Lomovtseva (Lomovtseva, 2015), O.S. Pchelintsev (Pchelintsev et all, 1998), A.A. Taubaev (Taubaev et all, 2002), R.I. Shniper (Shniper et all, 1991), who have contributed a lot into the issue of research.

The matter and content of economic and social transformation were studied by A.V. Buzgalin (Buzgalin et all, 2016), P. Drucker (Drucker, 1994), K.A. Khubiyev (Khubiyev et all, 2004), and others.

Materials and Methods

The theory of spatial and industrial policy stems from the range of theories on regional development. For example, endogenous regional development theory along with the theory of production force location were also studied in our research. Research methodology deals with general approaches. It provides the principles for organizing, planning and conducting research. In carrying out the economic research, we used quantitative methods (statistics and econometrics), data analysis techniques, and training in research methods. The aim of described theories is to determine the causes of inequalities in space location for manufacturers, distributors, markets and differences in demographic processes. The vast majority of models was based on the interconnection of transport costs – time deadlines-money expenses, but globalization has changed not only described factors, but also added a number of modern ones (communication, virtual space, integration into the global economy, acceleration of economic growth). Expansion of global markets leads to dramatic differences in regional development and inspired scientists to clarify a "coordinating" infrastructure as a key point in a regional economic development. The diversification theory of regional production and formation of industrial potential is based on the growth poles theory, and was first put forth systematically by F. Perrouxand (Perrouxand, 1967) improved by J. Boudeville (Boudeville, 1966). The main idea of the growth poles theory is that economic development, or growth, concentrates in a specific pole, which may take place on the territory of one or several regions. The so-called pole moderates industrial development in a wide variety of sectors, mainly through direct and indirect effects. Direct effects are produced by dealing with suppliers and customers (upstream linked industries & downstream linked industries). Indirect effects take place when employees operate as a customer and expand economic activities in the other sectors. An agglomeration effect has an impact on

spreading new technologies, labor movements, investments and, therefore, may lead to unbalanced regional development. By dividing “poles” into two groups: global supply chain and local industrial companies, the theory shows us the correlation between the size of the company and value of infrastructure (transportation process).

For a global supply chain there are no limits in outsourcing of its activities and production in any location. The only one factor, which is really matters, is the location of resources.

Availability of resources, which is necessary for industrial development and growth, allows an industry to generate the growth in cooperating sectors and to spread the growth impulses. The impulse can be horizontal or vertical, the first contributes to the development of a new type of activity and stagnation of non-flexible industries (conservative), the second introduces innovations in the industry and creates the deformation of the related industries. The growth poles are the targeted points for launching the region's economic development, attracting investments and generating agglomeration effects, as well as expanding sales markets. At the regional level a pole is located in the urban zone or generates it by itself, at once, creating an agglomeration effect of attraction, development and expansion of coordinated industries. Boudeville (J. Boudeville, 1966) showed the transformation of processes from the macro (country) to micro (region, territory, and city) levels, in the form of a matrix of sectoral balance, investment resources, infrastructure – in his description of the pole structure.

Nowadays, the most famous theory which proves the benefits of agglomeration effect and spatial localization is a cluster approach theory. The first scientific steps to create it were taken by A. Marshall, later it was transformed into the cluster theory by M. Porter (Porter, 2003). The key factors of production which may give firms competitive advantages in the regions, according to this theory, are capital, labor and natural resources.

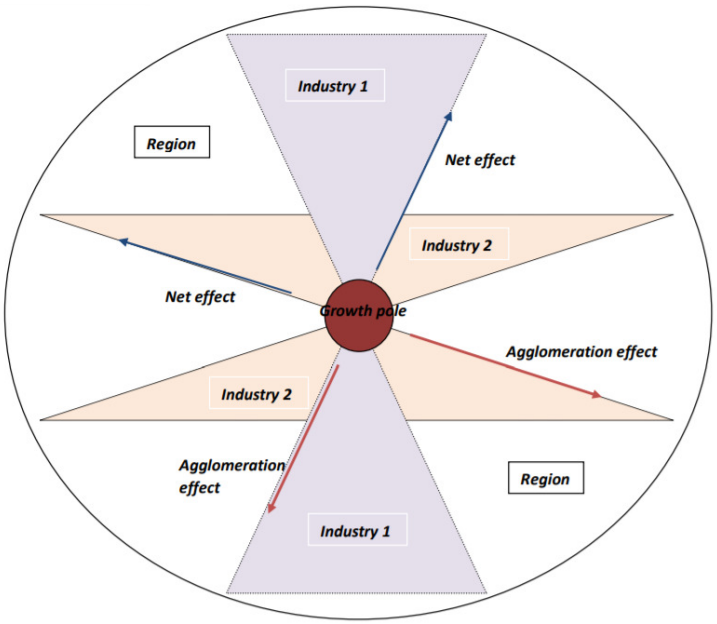
The cluster associations mean a group of companies which have a strong presence within the territory and occupy the related market niche in production of a similar type of goods (services). On the regional level of clusters M. Porter (Porter, 2003) identified potentially competing forces that affect the regional economy: convergence and agglomeration.

As for convergence, it leads to a decrease in the growth rate of the industry, even despite stability or the increase in economic activities. Agglomeration itself enlarges the returns on activities either from one industry (localization), or from the diversity at the regional level (urbanization) (Kudryavtseva, Rodionov, Kravchenko, Maryta, 2016), (Russian cluster observatory, 2017). It must be mentioned, that strong cluster links stimulate active growth rate of employment, the number of firms and patents in the region of the cluster location, but also in the geographically adjacent territories (Shabunina, Shchelkina, Rodionov, 2017).

Therefore, regional economy is definitely affected by both competitive forces. The cluster approach has influenced the process of development of regional strategies in European countries, as well as the regional governance in the Russian economy (Rodionov, Kudryavtseva, 2016). The new research is aimed to study the agglomeration effect as a key factor for global cities, for economic clusters and industrial complexes, as well as for international trade. It seems to be relevant as modern economic activity is increasingly concentrated in super-dense urban spaces (Ukrainskyi, 2011). E. Glaser, R. Florida, P. Krugman (Glaeser E.L.et all, 2000). It has to be mentioned, that as a result of the agglomeration effect, the world is becoming increasingly "hilly": the main national and regional locomotives of economic growth are concentrated on the sites of global and large cities, which are limited.

A significant attention is paid to the role of the agglomeration effect in the process of new knowledge creation and the innovation process, as the high-dense environment of modern large cities creates lots of talents with different knowledge, which leads to the birth of innovations. (Ukrainskyi, 2011).

The spatial expansion of the agglomeration is affected by a comparative decrease in the costs of goods transportation. This phenomenon is convincingly described by E. Glaser (Glaeser E.L. et all, 2000), on the basis of the American economy.



However, we must mention the less studied network effect, which is considered a controversial force of agglomeration effect. According to Ukrainskyi (Ukrainskyi, 2011) there aren't enough economists in this scientific field. An interesting conclusion of this idea is that in the future cities may just disappear, and all human activities will be dispersed in a huge number of free spaces, which would create a new era of global information networks and computer technologies.

Results and Discussions

Today, the modern economy world is under the influence of agglomeration and network effects. It is evident enough, that the agglomeration leads to the concentration of the population in the city, and causes huge problems for villages and small, medium-sized towns. It's not so obvious in small countries, but in Russia we can easily estimate the net profit which comes from using large territories.

The agglomeration creates competition, the network effect generates the creative forces and recourses for new means of communication and development of business environment in the world.

Additionally, the agglomeration effect increases productivity of any industry, as well as cuts the expenses, but there are additional challenges or obstacles for the development and industrial breakthroughs. The necessity for sustainable economic development shows that agglomeration tools and net effects can be implemented on the country's territory, taking into consideration the degree of influence in every region.

Picture 1 – Region model of growth poles

– Net effect
– Agglomeration effect

The network effect is the study of local communities and lands as a part of united network taking into account: firstly – migrants, trade and money exchange, secondly – human, natural, financial resources on a vast territory.

Conclusion

To sum up, a starting point for sustainable development and diversification of the domestic economy is the collaboration between business and governmental institutions, which would contribute to modernization processes and stimulate innovative activities of economic entities. These goals are directly related to the development of innovative territorial clusters. It would lead to the growth and localization of the leading industries that would have interaction with each other, as well as with scientific and educational organizations. The promotion of the clusters development involves the following tools: industrial, scientific, technical, educational and regional policies, which, therefore, were named as the crucial elements of the innovation state policy. The clustered regional innovation systems would lead to increasing cooperation between business entities and government, e.g. by creating forums and special web-sites, such as “windows of communications and feedbacks”.

As a result, the investment attractiveness and competitiveness of companies and regions would increase. The framework of cluster policy in Russia is established in the Concept of Long-Term Social and Economic Development of the Russian Federation. However, developing a regional industrial policy should be focused on the agglomeration and net effects. All these aspects are parts of economic process which have an enormous impact not only on individual region, but also on the country's economy. Developing strategies, the government should take into account the balance between localization processes and keeping distance. Otherwise, in the future we may have overdeveloped and overestimated urban industrial zones and with total absence of commonly needed services in distant areas.

In conclusion, as a summary of our research we should identify the following issues:
- the creation of industrial policy should be based on collaboration between business, government and other social institutes , which constitute economic environment;
- main targets of industrial policy should have scientific background and be based on location, variety of energy resources, market demand, manufacturing costs;
- the potential of industrial transformation and natural forces (such as net & agglomeration effects) should be in the equilibrium position.
-net effect should be considered within the regional policies of development and a social criteria system should be created, which will allow to maintain the balance between agglomeration and net effects.

IT Governance Inhibitors: An Empirical Study in Slovak Republic

Anita Romanová, Department of Information Management, Faculty of Business Management, University of Economics in Bratislava, Bratislava, Slovak Republic, anita.romanova@euba.sk

Vladimír Bolek, Department of Information Management, Faculty of Business Management, University of Economics in Bratislava, Bratislava, Slovak Republic, vladimir.bolek@euba.sk

Michal Zelina, Department of Information Management, Faculty of Business Management, University of Economics in Bratislava, Bratislava, Slovak Republic, michal.zelina@euba.sk

Abstract

IT Governance is a set of rules, relationships, and processes that help manage your organization so that the IT supports the organization's strategic goals to the maximum. It defines how IT/ IS supports business and covers risks. There are a number of factors affecting IT Governance and its successful implementation and management, inhibitors that inhibit its successful implementation and subsequent management. A survey carried out in the Slovak Republic shows that the most significant ones are considered to be the non-existing system of IS/IT metrics and the unclearly defined responsibilities of the company departments. The implementation of IT Governance has a positive impact on increasing the competitiveness of the organization and strengthening its market position.

Keywords: Information Technology, Information Systems, Governance, IT Governance, IT Management

Introduction

Today information systems supported by information technologies (IS/IT) can help businesses succeed in the competition, strengthen the market position, streamline work, take advantage of opportunities offered as well as identify potential threats. In today's rapidly changing business environment, leaders are deciding in conditions of uncertainty. In turbulent environments, the decision based on 80 percent of information supplemented by pervasive intuition is often better than waiting for a 100 percent of information (Ljudvigová, 2014). Zagoršek (2012) identified a high level of informatization. Based on his research he claims that information technologies impacted the product as well as organizational structure. By creating partnerships with individual stakeholder groups, businesses overcome the constraints resulting from the complexity of the business environment and the range of information technologies needed to produce a product that often goes beyond the capabilities of one enterprise. The creation of these important relationships makes it possible to share the unique capabilities of individual companies together, and also contributes to the transfer of knowledge among the partners (Gubová et al., 2017). Černý (2014) notes that the competition struggles in recent years have forced businesses to implement, as much as possible, innovative software solutions in practice or improve the existing ISs. The value of IS/IT for businesses and its implications is reflected in the increasing sensitivity of organizations to IS/IT risks, especially with regards to the size of IS/IT investments. Errors in IS/IT security and their malfunctions increase the company's dependency on IS/IT functions. IT Governance is the way to mitigate this risk. IT Governance includes a set of rules, relationships and processes that help manage your organization so that the IT supports the organization's strategic goals to the maximum. IT Governance, similar as Corporate Governance, is one of the more recently areas addressed. Over the last 10 to 12 years many definitions and approaches occurred in this area in terms of terminology. The concept of IT governance has been enforced by ISACA (Information Systems Audit and Control Association - the international association focused on the areas of audit, management, control and security of information systems) since the mid-1990s.

The main objective of the research presented in this scientific paper was to deepen and expand the knowledge of inhibitors and critical factors of IT Governance, based on foreign and domestic literature,

in order to identify the current state of knowledge in this field, to compare and synthesize the acquired knowledge based on data and information obtained through a questionnaire survey in companies in Slovakia.

Literature Review

Attention is drawn in this chapter to a critical comparison of inhibitors and critical success factors in IT Governance. We present several views of the authors on this issue, which coincide in many points but also differ in different partial views. Conformities and differences depend on the chosen angle of view as well as the degree of detailed elaboration or the level of generalization chosen.

IT Governance is a concept that emerged in the 1990s and one of the first authors who used it were Henderson & Venkatraman (1993), Venkatraman & Loh (1993) to describe a comprehensive set of intra-company relations involved in achieving the strategic linking of business activities with IS/IT.
Administration of the IS/IT area, referred to as IT Governance, is one of the basic functional governance models. IT Governance inspired by Corporate Governance aims to ensure the effective use of IS/IT with a focus on strategic alignment of IS/IT with business activities, risk management, resource management, value management and performance measurement (ITGI, 2003). The definition of IT Governance, which was conceived up by Rose and Weil, is accepted by most authors and considered to be the starting point in their work. They define IT governance as "a decision-making framework of rights and responsibilities to encourage desirable behaviour in the use of IS/IT." (Weill and Ross, 2004) The increasing amount of work on IT Governance points out that there is no single agreed definition of IT governance, but that the stated definitions differ in various aspects. Webb, Pollard and Ridley use content analysis to integrate the diversity that is reflected in many definitions of IT Governance and define it as follows: IT Governance represents strategic alignment of IS/IT with business in order to achieve the maximum value through development and maintaining an effective control, accountability, performance management and risk management in the area of IS/IT. (Webb, Pollard and Ridley, 2006). Similarly, R. Butler and M.J. Butler originated from the definition of Weil and Ross in constructing a framework for IT Governance, which considers the following three elements to be the most important: processes, structures and relational mechanisms that also appear in the works of other authors (Symons, 2005; Larsen et al., 2006; De Haes and Van Grembergen, 2008; Butler and Butler, 2010). According to Wilson and Pollard (2009) the elements of IT Governance are: structures and processes, supplemented by control frameworks, which they regard as essential tools for application, implementation and development of IT Governance.

IT Governance architectures typically focus on finding rational solutions to problems, decision-making at different levels or on other variables. By aligning decisions to address these issues, prioritizing resources and staffing capabilities, investing in strategic objectives of the company, the management of this framework can help reduce costs, streamline processes, and achieve an added value. These effects ultimately lead to increased organizational competitiveness and strengthening the company's market position. Achieving such improvements should therefore be a reason for businesses to formulate and effectively implement IT Governance (Lee et al., 2008). Ensuring consistency between IT Governance and organisation, emphasised by Gottschalk (1999), requires understanding of organizations themselves and their processes. At the same time, it emphasizes the importance of the funds allocated to the project, its adequacy and the provision of qualified human resources within the required time horizon.

Multiple factors have a significant impact on IT Governance. Some of these include the socio-technical factors, to which only limited attention is devoted in IT Governance literature. Most research focuses on IT Governance as a structure or process (Musson & Jordan, 2005). Peterson et al. (2002) and Kingsford et al. (2003) are one of the few authors to address the implications of IT Governance outside the IT Governance mechanisms and structures. Willson & Pollard (2009), with reference to Peterson et al. Indicate that focusing on tools and structures is not a sufficient guarantee of efficient IT Governance and, like Muson & Jordan (2005), they also claim that success in IT governance is dependent both on organizational and social factors as well as on the efficiency of IT Governance processes, structures and mechanisms. Bai & Lee (2003), in their study to examine the organizational factors affecting IS/IT

and the strategic planning process, suggest that a common factor that can influence the company's performance is the complexity of communication between groups of managers and stakeholders. De Haes & Van Grembergen (2005) also supported the importance of good communication strategies for IT Governance. McLeod & Smith (1996) identified two key preconditions for the effective direction of IT Governance and the IS/IT strategy: IT Governance trainings, which are perceived in terms of staff training within an IS/IT project, and external support in the form of external consultants and suppliers, which will enable to acquire the expertise required to implement internal IT Governance.

Research Objectives and Methodology

In designing a research model concept for a part of inhibitors and critical factors in IS/IT administration and management, we used the current state of knowledge. In this scientific paper we focus on the partial part of the research model, which is the issue of IT Governance inhibitors.

The research applied the general theoretical methods including analysis, synthesis, induction, deduction, comparison, analogy, generalisation; the specific methods including questionnaire survey, mathematical-statistical and analytical-logical methods; the empirical methods, in particular observation.

A questionnaire survey was selected as the basic research tool for obtaining data from company practice in Slovakia. The survey has been conducted between companies in the Slovak Republic. These are companies that are included in the extensive database of our University and cooperate with us on different surveys. The research sample included 363 enterprises with the largest share of small and medium-sized enterprises, while the small enterprises had a share of 31.40% and the medium 29.48%. The share of large enterprises was 22.87% and micro-enterprises 16.25%. In terms of sectoral coverage, the biggest shares had: industrial production 14.33%, information and communication 13.50%; wholesale and retail; repair of motor vehicles and motorcycles 12.12%. The share of the enterprises in terms of geography: the highest share solely in the Slovak Republic 37.47% and 23.14% in Europe; the lowest share only in Slovakia and the Czech Republic, namely 9.92%; and only in a certain region of the SR 10.74%. The structure of the surveyed sample according to the IS/IT customer or the IS/IT contractor is the following: 71% IS/IT customers from the business field, 23% suppliers of IS/IT products and services.

Results and Discussion

In this section, we present the views of respondents on the extent to which individual IT Governance inhibitors are considered to be more or less important. The starting point was an approach towards increasing the organization's performance, the motivation and the interest in its further enhancement. The results tell us that only 21.55% of enterprises have no motivation and interest in improving performance, of which only 3.03% with a clear opinion and 24.52% a with partial one (tab. 1). In 71.35% of organizations, we identified the existence of the motivation and the interest in increasing performance, but up to 47.38% of organizations with only a partial confirmation.

Table 1: There is no motivation and interest in increasing the organization's performance

Opinion	Micro	Small	Medium	Big	Total
a) I totally approve	0.28 %	1.10 %	0.83 %	0.83 %	3.03 %
b) I rather approve	3.03 %	8.82 %	6.89 %	5.79 %	24.52 %
c) I rather disapprove	7.71 %	14.05 %	14.33 %	11.29 %	47.38 %
d) I totally disapprove	4.96 %	7.16 %	6.89 %	4.96 %	23.97 %
e) Other	0.28 %	0.28 %	0.55 %	0.00 %	1.10 %
Total	31.40 %	16.25 %	29.48 %	22.87 %	100.00 %

The lack of an effective IS/IT management and a management model are considered to be an issue by a total of 41.60% enterprises, of which only 12.12% of enterprises expressed their full approval and 29.48% partial approval. The lack of an efficient model is not considered to be an issue by as many as 55.93% of enterprises, with a partial approval 41.05% and a complete approval 14.88% (tab. 2).

Table 2: There is no effective model, or an IS/IT governance and management methodology

Opinion	Micro	Small	Medium	Big	Total
a) I totally agree	3.58 %	4.68 %	2.48 %	1.38 %	12.12 %
b) I rather agree	11.02 %	4.13 %	8.82 %	5.51 %	29.48 %

More than half of businesses (51.52%) consider to be an issue the unclear definition of responsibilities of IS/IT and other units for achievement of IS/IT benefits. Even in this case, however, most of the answers are found in the opinions of partial approval or partial disapproval. A clear approval of this factor was confirmed by only 12.40% of the enterprises, partially by 39.12%. A clear disapproval of this statement was confirmed by almost the same percentage of businesses as was the case with the clear approval, namely 13.50%, a partial disapproval was expressed by 32.78% (tab. 3).

Table 3: There is no clear definition of the responsibility of IT and other departments for achieving the benefits from IS/IT

Opinion	Micro	Small	Medium	Big	Total
a) I totally approve	3.03 %	1.65 %	5.51 %	2.20 %	12.40 %
b) I rather disapprove	5.51 %	14.60 %	11.29 %	7.71 %	39.12 %
c) I rather disapprove	3.31 %	12.12 %	8.82 %	8.54 %	32.78 %
d) I totally disapprove	3.31 %	2.75 %	3.31 %	4.13 %	13.50 %

The cooperation of IS/IT units with other user units is not considered by the respondents to be an inhibitor in IS/IT Governance. Only 26.72% of enterprises have confirmed bad cooperation; 67.49% of enterprises do not have such a problem.

As a result of the previous findings, it can again be positively stated that most businesses have no problem with the willingness of the IS/IT units, which was confirmed 77.41%; of which with a full approval 31.13% and a partial approval 46.28%. The reluctance on the part of IS/IT departments was identified by a total of 14.60% of the enterprises as a problem, of which only completely 2.48% and partially 12.12% (tab. 5).

The poor quality of business and SLA contracts for identifying IS/IT service management issues between the provider and the customer was identified as a problem by only 4.46% of enterprises. Similarly, a low share of approving responses was also found when responding to the question of whether the quality of these contracts was problematic. Only 2.48% of enterprises clearly identified it as a problem, 19.83% of enterprises partially considered it to be a problem. Most of the responses were

reflected in the opposing positions, with a partial disapproval of 54.82% and a complete disapproval of 20.11%.

Up to 65.10% of enterprise inclined towards the opinion that a non-existing system of IS/IT management metrics is a problem. A clearly approving opinion was expressed by 14.60% of enterprises, partially by 40.50%. As many as 43.25% do not consider the non-existent system of IS/ IT metrics a problem, of which partially 33.06% and completely 10.19% (tab. 4).

Table 4: Non-existent system of metrics for IS/IT Governance and their processing system

Opinion	Micro	Small	Medium	Big	Total
a) I totally approve	4.96 %	4.96 %	2.20 %	2.48 %	14.60 %
b) I rather approve	5.23 %	12.95 %	13.22 %	9.09 %	40.50 %
c) I rather disapprove	4.13 %	11.02 %	10.74 %	7.16 %	33.06 %
d) I totally disapprove	1.93 %	2.20 %	2.48 %	3.58 %	10.19 %

Source: Authors' calculations

The poor quality of services of IS/ IT suppliers was clearly confirmed by only 2.48% of enterprises, a partial issue with the service quality was identified by 14.05%. Overall, there are 82.65% of enterprises with no IS/IT service quality issues, of which completely 23.42% and partially 59.23%.

The problem of inadequate work capacities of IS/IT units was confirmed by 11.29% of enterprises. Larger shares were recorded in this question with partial answers, whether agreeing or disagreeing. A partially agreeing opinion was expressed by 35.54 % of enterprises and a partially disagreeing by 33.61 %. The share of 15.70% of enterprises does not consider this factor as an inhibitor that would affect IS/IT management.

The issue of IS/IT literacy, both on the side of users and IS/IT service providers, was also monitored in the part mapping the level of IS/IT alignment with business activities. The level of preparation on the user side was also incorporated into the question by which we explored the basic IS/IT management problem areas, and precisely in this answer we recorded the highest share of all problem areas identified by enterprises, up to 27.58%. Compared to this finding, it can be considered a surprising result in assessing the lack of user preparation for applications, where only the total of 5.79% of enterprises confirmed a completely approving opinion that could be considered problematic. In this statement, the bulk of the responses concentrated into partially approving 35.54% and partially disapproving opinions 46.56%. As a clear issue it was ruled out by 11.57% of enterprises (tab. 5).

Table 5: Insufficient qualification preparation of users in relation to applications

Opinion	Micro	Small	Medium	Big	Total
a) I totally approve	1.10 %	1.93 %	1.38 %	1.38 %	5.79 %
b) I rather approve	6.06 %	11.29 %	9.37 %	8.82 %	35.54 %
c) I rather disapprove	6.34 %	15.15 %	15.98 %	9.09 %	46.56 %
d) I totally disapprove	2.75 %	2.75 %	2.48 %	3.58 %	11.57 %
e) Other	0.00 %	0.00 %	0.00 %	0.00 %	0.00 %
f) They did not state	0.00 %	0.28 %	0.28 %	0.00 %	0.55 %

In the summary of this subchapter, our focus will be on the overall evaluation of the obtained results of the individual surveyed parameters on the basis of a summarizing view in which we have included answers to the individual questions in the approving opinions of the respondent, where they have expressed a completely and partially approving opinion. The results summarised by individual survey areas and a share of the approving opinion are shown in tab. 6.

Table 6: Summary of the approving opinion of the variables examined

Variable	Share of the approving opinion
1. Lacking motivation and interest in increasing the organization's performance	28 %
2. There is no effective IS/IT governance and management methodology	42 %
3. There is no clear responsibility of individual units	**52 %**
4. Bad cooperation of IS/IT units and user units	27 %
5. Reluctance of IS/IT units	15 %
6. Poor quality of commercial contracts and SLAs	22 %
7. Non-existing system of IS/IT metrics	**55 %**
8. Low-quality services of IS/IT suppliers	17 %
9. Insufficient working capacity of IS/IT unit	47 %
10. Insufficient qualification preparation of users	41 %

Source: Authors' calculations

The most significant IT Governance inhibitors were considered: a non-existent system of IS/IT metrics (55%) and an unclearly defined corporate responsibility (52%). Only these two variables recorded a share of over 50%, others had lower shares. The lowest shares of up to 20% were achieved by: the reluctance of IS/IT units (15%).

Conclusion

IT Governance identifies the approach and way of managing the whole IS/IT area in an organization, aligning IS/IT with the business activities and the strategy of the whole organization. Mutual compliance has a positive impact on enhancing the organization's competitiveness and strengthening the company's market position. The results of several researches proclaim that a good structure of IT Governance can positively affect the performance of companies, increase their competitiveness or strengthen their market position. According to research by Lee et al. (2008), some of the leading companies even reported an increase of almost 40% in ROA by applying the IT Governance concept that changed structures and redistributed tasks between individual business units and IS/IT units. There are a number of inhibitors affecting IT Governance, which can slow down the final effect of this approach. A research carried out in the Slovak Republic shows that the most significant ones include a non-existing system of IS/IT metrics and unclearly defined responsibilities of the company units.

IT Governance is gradually becoming an integral part of the management concept of any modern organization and is the responsibility of the top management. However, the implementation and sustainable development of IT Governance penetrates through all levels of organization management, constantly refining and achieving the benefits of this concept.

Acknowledgments

The paper was elaborated within VEGA 1/0436/17 Conceptual Frameworks of IT Governance and their impact on the competitiveness of companies in the Slovak Republic.

Impact of the CO2 Emissions Cost On Electricity Production Profitability

Anna Hnydiuk-Stefan, Opole University of Technology, Faculty of Production Engineering and Logistics, Department of Power Engineering Management, Opole, Poland, a.hnydiuk-stefan@po.opole.pl

Abstract

The paper presents the most important issues related to environmental costs in a electricity production company under the current III period of the EU Emissions Trading Scheme. In the current stage of EU ETS a clear distinction has been made with respect to free allocation of CO2 allowances for electricity generation producers and other industries. In some countries it is possible to receive free EUAs by the energy sector, however, under strict exemption from the obligation to buy the EUA at auctions, under the so-called derogation. For the purposes of this article an example of the management of CO2 emissions in the modern power unit is discussed. As part of the discussions, the possibility of receiving a free allocation of CO2 allowances (EUAs) for the installation under derogation following investment under the National Investment Plans and management of the purchase of EUA for production was analyzed. Based on the mathematical model, the costs associated with the purchase of the EUA were calculated over the years, and then the sensitivity of the level of purchase of CO2 emissions to the cost of electricity production was analyzed.

Keywords: emissions, EU ETS, CO2, electricity

1. Introduction

European Union Emissions Trading Scheme (EU ETS) operates in 31 countries which are 28 European Union members plus Iceland, Liechtenstein and Norway, from almost 12 years. However, legislative and regulatory changes are still being implemented, causing increased uncertainty, which significantly affect the costs incurred by installations that are obliged to participate in it. From the all sectors which the EU ETS covers, the electricity sector is particularly exposed to the significant costs involved in CO2 emission permissions (European Union Allowances – EUA) purchase. It is due to the large amount of CO2 by-products and the differing regulations on free allocation of CO2 allowances, as described in this article. Since the launch of the system in 2005, the installations covered by it, had to comply with a number of environmental requirements, with the biggest changes occurring at the I-II and II-III interim periods, in 2008 and 2013 years. The EU ETS is now in its third phase – significantly different from phases 1 and 2. The main changes compare to the previous phases includes, according to European Comission, a single, EU-wide cap on emissions applies in place of the previous system of national caps. Auctioning is now the default method for allocating allowances in phase 3, and it is instead of free allocation which had place in 1st and 2nd phase. Harmonized allocation rules apply to the allowances still given away for free. 300 million allowances is set aside in the NER 300 (New Entrants Reserve) to fund the deployment of innovative renewable energy technologies and carbon capture and storage through the program.

The current period, which began in 2013 year, made a clear division of the free allowances for CO2 emissions for electricity generation producers and other industries. The original premise was to completely eliminate the free allocation to all electricity generators and the rule to purchase all the EUA needed at auctions. However, exception from this rule is derogation mechanism which allow to electrical installations to receive some amount of free allocation.

Withdrawing the governmental allocation of CO2 allowances (EUAs) that had previously been granted to installations free of charge and substantially covered actual emissions, meant that the cost of participating in the system was not so significant. Moreover, the installation was not so much exposed to the risk of extremely high variability of rules in the CO2 market community.

Currently, the only way to obtain a free allocation to the power sector is derogation mechanism, which applies only to some countries in the EU ETS. Derogation mechanism means the investment in construction of a new or upgrading of an existing power plant. However, even in these privileged countries, starting from a year 2020, energy sector will not receive a free allowances even with a derogation mechanism. The auction system introduced in the third period is intended to provide an access to the primary EUA market without using exchanges or brokers. However, as the practice shows, the purchase prices of EUA units at auctions are very close to those of the secondary market. A detailed assessment of the impact of environmental costs, including mainly the purchase cost of the EUA, as these cost is the most variable and much higher than other environmental costs.

The paper presents a model of environmental cost management in an electricity generation companies. These costs have a significant impact on the cost of generating electricity and due to the large variability they should be taken into account and calculated on a continuous basis. Excessive EUA price levels may lead to unprofitable generation of electricity due to the impossibility of concluding contracts for sale at the desired price, when taking into account the cost of environmental charges. The analysis takes into account the possibility of receiving free EUA allocations that affect the cost-effectiveness of electricity production and significantly reduce the cost sensitivity associated with the compulsory purchase of EUAs.

2. Emissions Management on the Example of Coal Power Plant

Emissions management in the installation includes both the aspect of choosing the best moment to purchase EUAs, which mean at the lowest possible price and with the longest possible payment at the same time. All available market mechanisms should be used to reduce the cost of generating electricity.

2.1. Using the Derogation Mechanism

An important mechanism in the EU ETS, which is to encourage energy companies to modernize existing electricity sources or build new ones, is the mechanism for allocating free CO2 emission allowances, so called derogation mechanism. The result of that is the reduction of the obligation to pay for each tone of CO2 emitted. This voluntary mechanism was introduced in Poland, the Czech Republic, Hungary, Estonia, Lithuania, Latvia, Bulgaria and Romania. Obviously, in order to obtain such a disposable European Union Allowance EUA, significant financial resources should be invested in the modernization of electricity sources in order to reduce CO2 emissions or to build new high-efficiency sources of electricity. The CO2 emissions trading market is in the process of continuous development, where increasingly stringent CO2 emission limits are being established. In the third period of this trading system, i.e. in the years 2013-2020, consisting in particular of the purchase of CO2 emission permits through government auctions, the above mentioned derogation mechanism was introduced, which included the possibility of derogating from the purchase of CO2 emission allowances at auctions for power sector.

To estimate the best choice for managing CO2 emissions, a cost management model was developed for the actual coal-fired power station which is mandatory covered by the CO2 emissions trading scheme. The 460 MW block is classified for the derogation mechanism, so that in the first year of operation it will

receive 70% of CO2 allowances needs and in the last year of the third phase, 2020 will not receive free EUAs. This block has a high net efficiency of 43%. It should also be emphasized that the fluidized bed boiler used in the installation is currently the largest boiler in the world and technically suitable for the use of oxy-combustion process, which could be an alternative to reducing future CO2 emissions in the case of a high EUA price increase of € 52 / EUA, according to Hnydiuk-Stefan and Składzień (2017). Cost-free to operate on CO2 emissions would require an annual average of free allocation 3,000,000 CO2 emissions (EUA) per year, according to data from Community Independent Transaction. This would almost equal the allocation of real-level emissions so that the installation owner would not have to buy additional permissions in the free market. With the accession of the third period, from 2013 onwards, the power units, will not receive a free allocation of CO2 allowances like in the first and second phases of EU ETS. The only form of obtaining additional free allowances is the derogation mechanism, however, provided the investment is implemented as planned in the national investment plans. Detailed rules are set out in Article 10 (c) of Directive 2009/29 / EC concerning the possibility of transitional allocation of free allowances for the modernization of electricity generation units. Under the derogation, analyzed installation will be able to receive the free EUA quoted in Table 1.

Table 1: Maximum annual amount of free CO2 emission allowances received under the derogation mechanism

Year	Free allocation under derogation for the analyzed investment (kEUA)	CO2 emission allowances shortage (kEUA)
2013	2100	900
2014	1950	1050
2015	1800	1200
2016	1620	1380
2017	1410	1590
2018	1170	1830
2019	870	2130
2020	0	3000

Source: Own calculations based on European Transactions Log [11] and EU ETS Directive

The declining free allocation that the installation is able to obtain through investments covered by the National Investment Plan increases the EUAs shortfall, and the remaining amount is estimated in Table 1. The exact cost of the environmental fees that will be incurred by the owner of the electricity generating plant is difficult to predict as it depends on the purchase time of the EUAs. Factors influencing the EUA price levels are described in research study by Hnydiuk-Stefan (2017). For the purposes of this article, it was assumed that the cost of purchasing 1 Mg of CO2 emissions in the EU ETS market is between 5 EUR/EUA - 8 EUR/ EUA, so the cost of covering the shortage is as follows [Table 2]:

Table 2: Annual costs cover the shortage of emissions for discussed installation

Year	Cost of covering CO2 shortage at assumed CO2 price [euro]			
	5 euro/EUA	**6 euro/EUA**	**7 euro/EUA**	**8 euro/EUA**
2013	4 500 000.00	5 400 000.00	6 300 000.00	7 200 000.00
2014	5 250 000.00	6 300 000.00	7 350 000.00	8 400 000.00
2015	6 000 000.00	7 200 000.00	8 400 000.00	9 600 000.00
2016	6 900 000.00	8 280 000.00	9 660 000.00	11 040 000.00
2017	7 950 000.00	9 540 000.00	11 130 000.00	12 720 000.00
2018	9 150 000.00	10 980 000.00	12 810 000.00	14 640 000.00
2019	10 650 000.00	12 780 000.00	14 910 000.00	17 040 000.00
2020	15 000 000.00	18 000 000.00	21 000 000.00	24 000 000.00

2.2.Methodology for estimating the impact of environmental costs on the specific cost of electricity production

The cost of the environmental charges significantly affects the profitability of electricity production. It is therefore reasonable to estimate the environmental cost each time during contracting the sale of electricity. The difference between the contracted electricity sales price and the cost of generating it will set the amount of profit or loss for the installation. The average specific cost of electricity generation can be calculated in each case using the formulas from the book by Bartnik and Hnydiuk-Stefan (2016):

$$k_{el,av} = \left\{ (1+x_{sw,m,was}) \frac{e_{fuel}^{t=0}}{a_{fuel}-r} [\mathrm{e}^{(a_{fuell}-r)T} - 1] + K_{env} + (1-u) \frac{\rho_{CO_2} e_{CO_2}^{t=0}}{b_{CO_2}-r} [\mathrm{e}^{(b_{CO_2}-r)T} - 1] + \right.$$
$$\left. + \frac{\eta_{el}}{rt_A} \left[(1+x_{sal,t,ins}) i (1-\mathrm{e}^{-rT}) \delta_{serv} + riz \left(\frac{1-\mathrm{e}^{-rT}}{T} + 1 \right) \right] \right\} \frac{r}{\eta_{el}(1-\varepsilon_{el})(1-\mathrm{e}^{-rT})} \rightarrow \min. \quad (1)$$

where:

$$K_{env} = \frac{\rho_{CO_2} p_{CO_2}^{t=0}}{a_{CO_2} - r}[e^{(a_{CO_2}-r)T} - 1] + \frac{\rho_{CO}\ p_{CO}^{t=0}}{a_{CO} - r}[e^{(a_{CO}\ -r)T} - 1] +$$
$$+ \frac{\rho_{NO_X} p_{NO_X}^{t=0}}{a_{NO_X} - r}[e^{(a_{NO_X}-r)T} - 1] + \frac{\rho_{SO_2} p_{SO_2}^{t=0}}{a_{SO_2} - r}[e^{(a_{SO_2}-r)T} - 1] + \quad (2)$$
$$+ \frac{\rho_{dust} p_{dust}^{t=0}}{a_{dust} - r}[e^{(a_{dustt}-r)T} - 1]$$

where:

a_{el}, a_{fuel}, a_{CO_2}, a_{CO}, a_{SO_2}, a_{NO_X}, a_{dust}, b_{CO_2} – controls,

δ_{serv} – annual rate of constant cost regardless of the value of investment (cost of maintenance of overhaul of equipment),

ε_{el} – internal electric load of the power plant (its value is relative to the technology applied in electric power generation),

η_{el} – gross electric power efficiency (its value is relative to the technology applied in the electric power generation),

u – ratio of the chemical energy of the fuel in its total annual use for which the purchase of additional CO_2 allowances is not required,

p_{CO_2}, p_{CO}, p_{NO_x} p_{SO_2}, p_{dust} – specific rates per emissions of CO_2, CO, NO_x, SO_2, particulate matter, PLN/kg,

ρ_{CO_2}, ρ_{CO}, ρ_{NO_x}, ρ_{SO_2}, ρ_{dust} – emission of CO_2, CO, NO_x, SO_2, per unit of the chemical energy of fuel, kg/GJ (relative to the type of fuel).

r – discount rate,

t_A – annual operating time,

T – calculated exploitation period of a power plant expressed in years (depreciation rate),

$x_{sw,m,was}$ – coefficient used to account for the cost of supplementing water, use of auxiliary materials and waste disposal,

$x_{sal,t,ins}$ – coefficient used to account for the cost of remuneration, taxes, insurance, etc.

z – coefficient expressing immobilization of capital.

3. Results of calculation examples

From the economic perspective, the most beneficial technology is the one in which the cost of power generation $k_{el,av}$ is the lowest. It is relative to: specific cost of investment i, internal electric load of the

power plant ε_{el}, its annual operating time t_A, fuel prices and their variability in time, ratio u of the chemical energy of the fuel in its total annual use, for which the purchase of additional CO2 allowances and tariff rates on the use of the environment is not required.

Table 3: Data used for specific cost of electricity production calculations

Coal fired power plant
Estimated investment i, mln EURO/MW =1.55
Annual operating time $t_{R,}$ h/year=7500
Internal electrical load: $\varepsilon_{el,}$ % =7.6
Construction period b, years =5
Specific fuel price, EURO/GJ =2.7
Exploitation period: T = 20 years
Annual rate of maintenance and overhaul δ_{serv} = 3%.
Coefficients: $x_{sal,t,ins}$ = 0.25; $x_{sw,m,was}$ = 0.02.
Discount rate r = 8%
Tariff charges on emissions: p_{CO2}=0,07 euro/Mg_{CO2}, p_{CO}=26 euro/Mg_{CO}, p_{NOx}=126 euro/Mg_{NOx}, p_{SO2}=126 euro/Mg_{SO2}, p_{dust}=83 euro/Mg_{dust}
Emission from coal combustion: ρ_{CO2}=95 kg/GJ, ρ_{CO}=0,01 kg/GJ, ρ_{NOx}=0.164 kg/GJ, ρ_{SO2}=0.056 kg/GJ, ρ_{dust}= 0.007 kg/GJ

Using the formulas (1, 2) and data in Table 3, the following calculation results are presented in Figures 1 and 2.

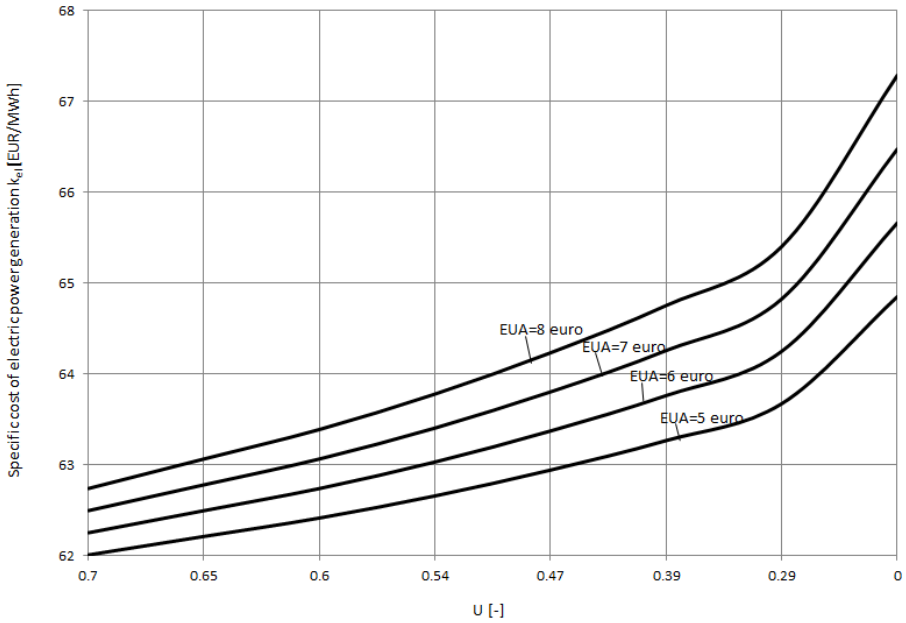

Fig 1. Impact of EUA prices and derogation mechanism based on the ratio of the chemical energy of the fuel in its total annual use for which the purchase of additional CO_2 allowances is not required U, on the

specific cost of electric power generation k_{el} for a coal-fired power plant during the pay-back period and after depreciation period.

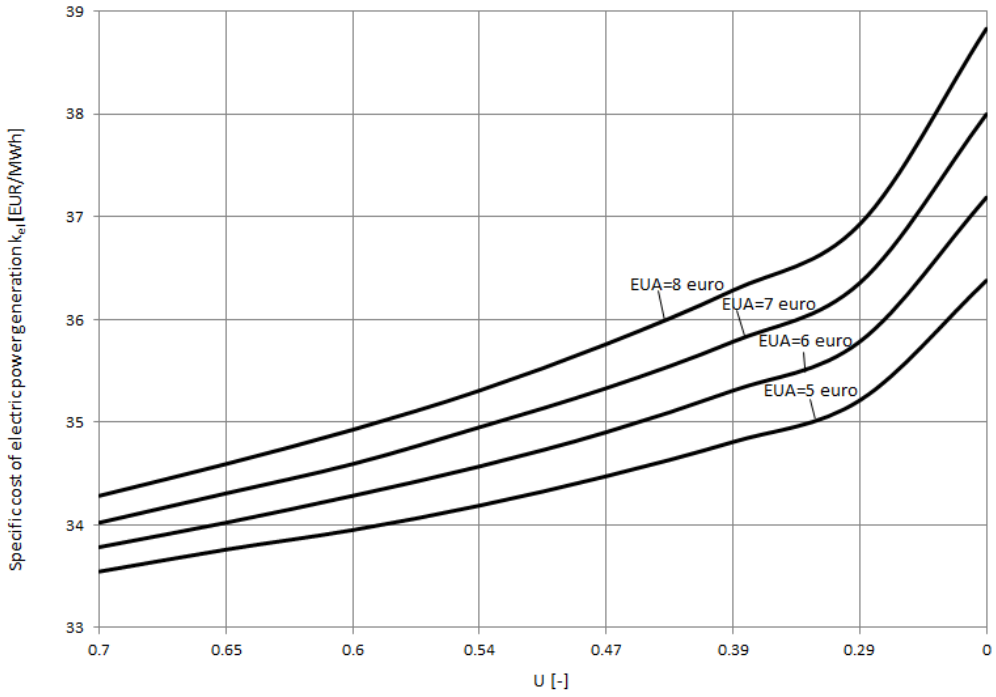

Fig 2. Impact of EUA prices and derogation mechanism based on the ratio of the chemical energy of the fuel in its total annual use for which the purchase of additional CO_2 allowances is not required U, on the specific cost of electric power generation k_{el} for a coal-fired power plant after depreciation period.

As Figures 1 and 2 presents, both factors like this related to the level of amount which is required to supplement the shortage of EUAs as well as the price of their purchase are relevant. Obtaining free EUAs in a quantity that secures even part of the production needs is important for the cost of generating electricity, as it sets different acceptable price levels for EUA purchases.

The cost of producing electricity with a 50% free allocation for one year of production and the purchase price of the rest CO2 emissions needs at 8 EUR/EUA is the same for the company as the cost of purchasing the full amount of allowances for one year at a maximum of 5 EUR/EUA. On the other hand, if the EUA is to be purchased without free allocation, which will occur in 2020 year, at a price of 8 EUR/EUA, then the electricity cost per 1 MWh will be 2.5 EUR higher compared to CO2 emissions purchase price of 5 EUR/EUA.

It is therefore appropriate to use financial instruments such as forward contracts or options to secure the future purchase price, thus eliminating the risk of EUA price increases that could lead to financial losses for the installation. However, due to the constant volatility of the EUA price levels, it is justified to keep track of market prices and to contract EUAs at a price acceptable to the company. The acceptable price means the EUA price level at which the contract price of the electricity sales is higher than the specific cost of electricity production.

4. Summary and conclusions

The analysis points to the significant environmental costs of the coal-fired power plant, mainly related to the purchase of additional CO2 emissions, which are required to keep compatibility under EU ETS. Even in the case of the construction of modern coal blocks for supercritical parameters, which are characterized by one of the lowest emission factor in using hard coal as a fuel, environmental costs are significant and can affect the cost-effectiveness of electricity generation. It is extremely important to properly plan the mandatory purchase of EUAs in order to balance the real emissions in a given year with the amount of surrender EUAs under EU ETS. The increasing level of EUA shortage should be consistently included in the price of electricity.

In order to guarantee specific prices when purchasing the EUA shortfall, the installation should use market mechanisms such as post-delivery contracts or options when an acceptable level of EUA purchase occurs on the market. With currently available financial instruments offered by the stock exchanges, the plant owner can take one of the available possibilities for CO2 buying or diversify the cost of CO2 emissions purchasing by combining all available strategies.

Contracts for the sale of electricity in futures without taking into account the cost associated with the purchase of a sufficient number of EUAs units can cause significant losses for the company due to high volatility of EUA prices. The model indicated in the paper can serve to assess current environmental costs associated with the purchase of CO2 allowances and other environmental costs such as supplemental water prices, waste disposal and charges for the other emissions to the atmosphere such as NOx, SO2, CO.

Abstract

Nowadays, questions related to citizens' financial literacy, their abilities to plan for future and to make sound financial decisions are considered to be critically important, because of strong relationship between the level of personal financial knowledge and skills and households' well-being. The aim of the current research is to evaluate financial knowledge of Latvian young population. The paper reflects the results of the pilot study conducted among 17-19-years-old citizens. A preliminary evaluation of their knowledge in macroeconomics was performed, using data from annual financial competition, organized by the University College of Economics and Culture. Last year students of Latvian secondary and vocational schools performed tasks and answered the questions in the field of macroeconomics and personal budgeting. The results of 94 participants were analyzed. The obvious conclusion was that the level of students' knowledge in macroeconomics is higher than the level of knowledge in personal budgeting.

Keywords: financial literacy, Latvia, youth, macroeconomics, personal budget.

Introduction

The interest to the issues related to financial knowledge and skills of citizens, as well as to the consistency between study programmes in schools and HEI and emerged needs for financial education, are prioritized at the government level of many countries, including Latvia. According to the OECD report (2015), 34 countries have been implemented first or even second (revised) National strategy for financial literacy, whereas in 25 countries a National strategy "is being actively designed". It is logically to assume that till 2017 this number has been increased.

In Latvia the National Strategy for Financial Literacy was implemented in 2014. It has been coordinated by the Financial and Capital Market Commission (FCMC) – a regulatory authority of the Latvian financial sector. The Strategy was drawn up in cooperation with strategic partners – the Ministry of Education and Science, National Centre for Education, Consumer Rights Protection Centre, BA School of Business and Finance, as well as the Association of Commercial Banks of Latvia and Latvian Insurers Association. Since 2014 many other organizations have been engaged in various kinds of activities aimed to enhance awareness of the importance of financial knowledge in the society and to increase the level of citizens' financial literacy, including the University College of Economics and Culture.

One of the projects towards promotion financial literacy in Latvia is an annual competition for last year students from Latvian secondary and vocational schools named "Financial ABC" which is organized by the University College of Economics and Culture since 2016.

This paper reflects the results of 2017 competition – achievements of students in performing financial tasks. The authors stated the hypothesis, based on the OECD report on PISA (Programme for International Student Assessment) 2012 results (OECD, 2014). Unfortunately, Latvia did not participate in PISA 2015 - financial literacy assessment of 15-year-olds' ability to apply their

accumulated financial knowledge and skills to real-life situations involving financial issues and decisions. Latvian results in PISA 2012 was 501 score (not statistically significantly different from the OECD average). The authors assumed that students will demonstrate average-level results in competition "Financial ABC 2017". To evaluate the level of knowledge, results were assigned to the Evaluation criteria for study results, i.e. to the school grades. Besides, the authors predicted that the students' knowledge in macroeconomics will be better than their knowledge in personal budgeting, because of the content of educational programmes in Latvian schools. Thus, the stated hypotheses were the following:

H1: Most of Latvian students' demonstrate average level of financial knowledge

H2: The level of students' knowledge in macroeconomics is higher than the level of knowledge in personal budgeting

Multiple-choice test data was analyzed, applying such methods, as ranking and analysis of frequencies. The received results allowed making preliminary conclusions on students' knowledge in specific financial questions. The testes hypotheses were confirmed, indicating the lack of focus on personal budgeting issues in financial education programmes realized in Latvian schools. To receive more reliable results, database should be enlarged. Considering that the project "Financial ABC" is planned to be organized on the regular basis, it is possible to continue the research.

Financial literacy

As a starting point for a comprehensive investigation of financial literacy issues was a programme initiated by OECD in 2003. Since that time the importance of financial education, and consequently, the level of citizens' financial literacy level has been recognized by many countries. Financial literacy of citizens was recognized as one of the prior task in development of the national educational programmes. High level of financial literacy allows people to succeed in their planning (Lusardi and Mitchell, 2011), to participate in financial markets and perform better on their portfolio choice (van Rooij *et al*. 2011; Chu *et al*. 2017), making sound financial decisions (Fraczek, B. and Klimontowicz, 2015), and, consequently, to improve their and their families' well-being (Behrman *et al*. 2012; van Rooij *et al*. 2012).

Since 2008 an interest to financial literacy issues extremely increased, considering a global negative impact of the financial crisis. It becomes obvious, analyzing the statistics from academic data bases. The authors made a search for scientific publications in EBSCOhost Business Search Complete, ScienceDirect and Scopus in the period 2008-2017, using the key words "financial literacy". We found 10844, 9523 and 10887 results respectively.

Financial literacy referred to (1) financial knowledge, (2) financial skills, (3) financial behaviour or a certain combination of elements (ASIC 2011; Kozup, Hogarth 2008; Atkinson, Messy 2011; Hung *et al*. 2009; PISA/OECD 2012; Widdowson, Kim 2007). The most commonly used definition was offered by the OECD: [Financial literacy is a] „combination of awareness, knowledge, skills, attitude, and behaviors necessary to make sound financial decisions and ultimately achieve individual financial wellbeing" (Atkinson and Messy, 2011).

Definitions of financial literacy, provided by various researchers and organizations, are quite different that can be explained by the multidimensionality and the comprehensive structure of the concept. Financial literacy has a number of elements, including:

- basic numeracy skills, such as the ability to calculate rates of return on investments, the interest rate on debt, and basic arithmetic ability;
- an understanding of the benefits and risks associated with particular financial decisions, including spending, borrowing, leverage and investing;

- the ability to understand basic financial concepts, including the tradeoff between risk and return, the main attributes of different types of investments and other financial products, the benefits of diversification, and the time value of money;

- the capacity to know when to seek professional advice and what to ask, and the ability to understand the advice given by professional advisers (Widdowson, 2007).

Some examples of the proposed definitions of the term "financial literacy" are summarized in the Table 1.

Table 1: Definitions of Financial literacy

Source	Definitions of the term "financial literacy"
PISA –Programme for International Student Assessment (2012)	„Financial literacy is knowledge and understanding of financial concepts and risks, and the skills, motivation and confidence to apply such knowledge and understanding in order to make effective decisions across a range of financial contexts, to improve the financial well-being of individuals and society, and to enable participation in economic life".
Kozup and Hogarth (2008)	"…a set of critical thinking skills to weigh and assess the pros and cons of a particular decision relative to one's own needs, values, and goals"
Mandel (2007)	" …ability to evaluate the new and complex financial instruments and make informed judgments in both choice of instruments and extent of use that would be in their own best long-run interests"
Atkinson and Messy (2011)	"…combination of awareness, knowledge, skills, attitude and behaviours necessary to make sound financial decisions and ultimately achieve individual financial wellbeing".
Remund (2010)	"Financial literacy is a measure of the degree to which one understands key financial concepts and possesses the ability and confidence to manage personal finances through appropriate, short-term decision-making and sound, long-range financial planning, while mindful of life events and changing economic conditions".
Worthington (2006)	"Financial literacy means different things to different people, and this is reflected most clearly in the many definitions used in the literature. For some it is quite a broad concept, encompassing an understanding of economics and how household decisions are affected by economic conditions and circumstances. For others, it focuses quite narrowly on basic money management: budgeting, saving, investing and insuring".
Hastings *et al.* (2013)	"…it [financial literacy] has been used to refer to knowledge of financial products (e.g., what is a stock vs. a bond; the difference between a fixed vs. an adjustable rate mortgage), knowledge of financial concepts (inflation, compounding, diversification, credit scores), having the mathematical skills or numeracy necessary for effective financial decision making, and being engaged in certain activities such as financial planning."

Source: Authors' compilation of the definitions

In the current paper the authors focus on financial knowledge as an integral part of financial literacy concept, because the process of data collection (multiple-choice and practical tasks for students) did not assume the assessment of other components, such as attitude and behavior. Students knowledge was measured, mainly focusing on such financial literacy elements, as numeracy, knowledge of basic financial concepts and awareness of different types of risks.

Measuring of financial literacy level is a complicated process, because the development of the measurement instrument should be performed considering all the elements. Besides, financial literacy is not only about financial knowledge, but also about skills to apply knowledge and attitude to

financial issues, i.e., readiness and willingness to solve financial questions. In assessment of the financial literacy level the experts frequently use OECD measurement scale (Hung *et al.* 2009; Krizek and Hradil, 2012), instrument applied in DNB Household Survey (van Rooij *et al.,* 2012) or American Life Panel (Heinberg *et al.,* 2010) and others.

Data about financial literacy level of Latvian citizens are available in the report from OECD/INFE International Survey of Adult Financial Literacy Competencies (OECD, 2016). First survey of financial literacy in Latvia was conducted by the FCMC and carried out in cooperation with the research centre SKDS in Q3 2014. In total, 1009 respondents aged 18 to 79 years were surveyed. The questions developed by the FCMC experts the questions from OECD base questionnaire have been included in the questionnaire for the survey. The data of the study was used for development of a new FCMC measurement system – *Financial Literacy Index.* The second stage of the survey was realized in 2015. The evaluation of financial knowledge of Latvian citizens is planned to be made on a regular basis. Besides, individual researchers conducted survey among Latvian citizens to evaluate their financial knowledge (Titko *et al.* 2015).

Methodology

Data analyzed in the current research was received from participants of the annual financial competition organized by the University College of Economics and Culture in collaboration with the educational vortal "Customer School" (*Klientu skola*) developed by the Financial and Capital Market Commission – FCMC (klientuskola.lv) and the educational portal "Money School" (*Naudas skola*) developed by the Bank of Latvia (naudasskola.lv). In 2017 107 pupils representing last year classes of 39 Latvian secondary schools and vocational schools participated in this competition.

To be representative sample size should be approximately 380 participants, considering population statistics as of 2016 in the age group 15-19 years (Central Statistical Bureau, 2017). The authors had data only from 94 participants provided qualitative responses to all the questions.

55% of participants were girls, and 45% were boys. 48% of the total number of participants represented schools of Riga (capital of Latvia).

Tasks for 2017 year competition were developed covering such fields as financial sector participants, regulation of the financial sector, factors affecting economic development and national well-being, banks and other financial services providers, investments, e-services and e-security, financial risks and insurance, personal budget, planning and others. All the tasks and questions were grouped into two content blocks: A) Macroeconomics, and B) Personal budgeting.

This paper reflects the results of the analysis of participants' answers to seventeen multiple-choice questions from the first block (A) and sixteen questions from the second block (B). To improve a visibility of the results, each question was labeled (Table 2, Table 3).

Table 2: Multiple-choice questions from block A and block B; content and labels

Block A			Block B		
Q	**Content**	**Label**	**Q**	**Content**	**Label**
1	Factors affecting the size of wages and salaries in market economy	Salary	1	Private person's liabilities	Liabilities
2	Relationship between the consumer price index and the inflation rate	Consumer price index	2	Private person's assets	Assets
3	The indicators of the standard of living in a country	Standard of living	3	Statements about deposits	Deposits
4	Purchasing power of the pension	Pension	4	Risk of investments	Investments
5	The institution regulating the activities of financial institutions	FCMC	5	Statements about loans	Loans

6	Factors affecting the lending interest rates in euro	EIRIBOR	6	Statements about the II level of pension	II level of pension
7	Factors affecting money supply	Money supply	7	Private pension funds	PPF
8	Nominal lending interest rate	Nominal interest rate	8	Statements about insurance	Insurance
9	Relationship between the nominal lending interest rate and the real lending interest rate	Real interest rate	9	Credit limit for account	Credit limit

17	The rule of 70 - inflation level	Rule of 70			

Source: Authors' contribution

For every correctly answered question (Q1-Q17) participants received 1 point. Consequently, a maximal number of points possible to receive was equal to 17, and a minimal number of points was 0. For easier interpretation of the results, points were assigned to the Latvian grading system (Ministry of Education and Science, 2017) assuming that the educational achievements are assessed in a ten-point system. Dividing 17 points into 10 equal figure diapasons, marginal grades were received to estimate participants' "grades" (Table 3).

Table 3: Interconnection between number of points and grading system

Number of points	Grade in 10-point system	Number of points	Grade in 10-point system
0 – 1,7 points	1 (very very weak)	8,6 – 10,2 points	6 (almost good)
1,8 – 3,4 points	2 (very weak)	10,3 – 11,9 points	7 (good)
3,5 – 5,1 points	3 (weak)	12 – 13,6 points	8 (very good)
5,2 – 6,8 points	4 (almost satisfactory)	13,7 – 15,3 points	9 (excellent)
6,9 – 8,5 points	5 (satisfactory)	15,4 – 17 points	10 (with distinction)

Source: Authors' contribution, based on Ministry of Education and Science (2017)

Results

First stage of the data analysis was to determine a number of participants provided correct answers, analysing the responses regarding each task separately. This number as a percentage of total number of participants is reflected in Fig. 1.

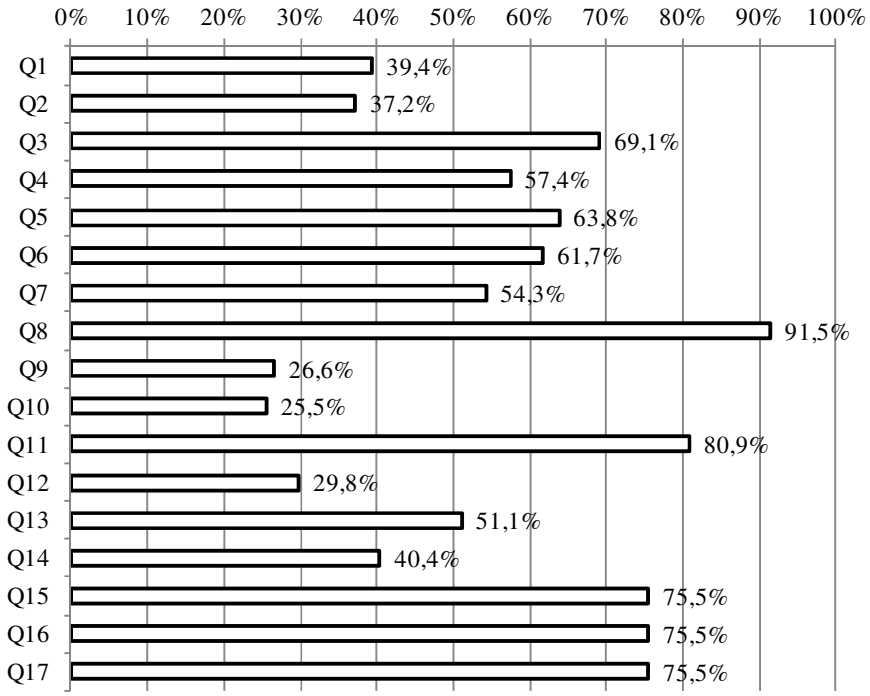

Fig. 1: Number of participants (% of total number)

correctly answered questions (block A tasks)

Source: authors' compilation of results

The authors provisionally determined 30% as a lower threshold of knowledge, whereas 70% - as a higher threshold in order to interpret results of participants. The best results the students demonstrated answering the questions Q8, Q11, Q15, Q16 and Q17 (more than 75% of participants answered correctly).

- Q8. Commercial banks set the nominal lending interest rate: (4 answer variants)
- Q11. After Latvia has joined the Eurozone, the key tasks of The Bank of Latvia are the following: (4 answer variants)
- Q15. Progressive tax rates are set by: (4 answer variants)
- Q16. On the condition that other circumstances do not change, the real wages and salaries will increase if: (4 answer variants)
- Q17. Based on "the rule of 70", how long it will take for prices to double, considering that the inflation level is equal to 5%: (4 answer variants)

The worst results the students demonstrated answering the questions Q9, Q10 and Q12 (less than 30% of participants answered correctly).

- Q9. If the nominal annual lending interest rate is 16% and the estimated inflation rate 18%, the real lending interest rate is:
- Q10. If the Central Bank sells big amount of state securities on open financial market, then its purpose is to:
- Q12. What does The Bank of Latvia do with damaged euro banknotes?

It is interesting that the most of students (57 of 94 participants or 61%) as a answer to Q12 selected the variant „sends to the European Central Bank to replace with new banknotes".

W can judge about students' awareness of Latvian financial sector, analyzing the answers on Q5 "Which institution regulates and supervises the activities of the Bank of Latvia, savings and loan associations, insurance agencies and insurance brokers, participants of financial instrument market, private pension funds, payment institutions and electronic money institutions?" The correct answer is "Financial and Capital Market Commission". However, 25% of participants answered "Ministry of Finance". It points to the fact that some questions are not highlighted within the economic subject in Latvian school. FCMC regulates the financial sector since 2001, and this information should be delivered to students.

Analyzing differences between results provided by boys and girls, the conclusion is that they are not significant. Besides, the number of participants-girls was higher that, in turn, could affect the results. Results provided by boys and girls are reflected in Fig. 2.

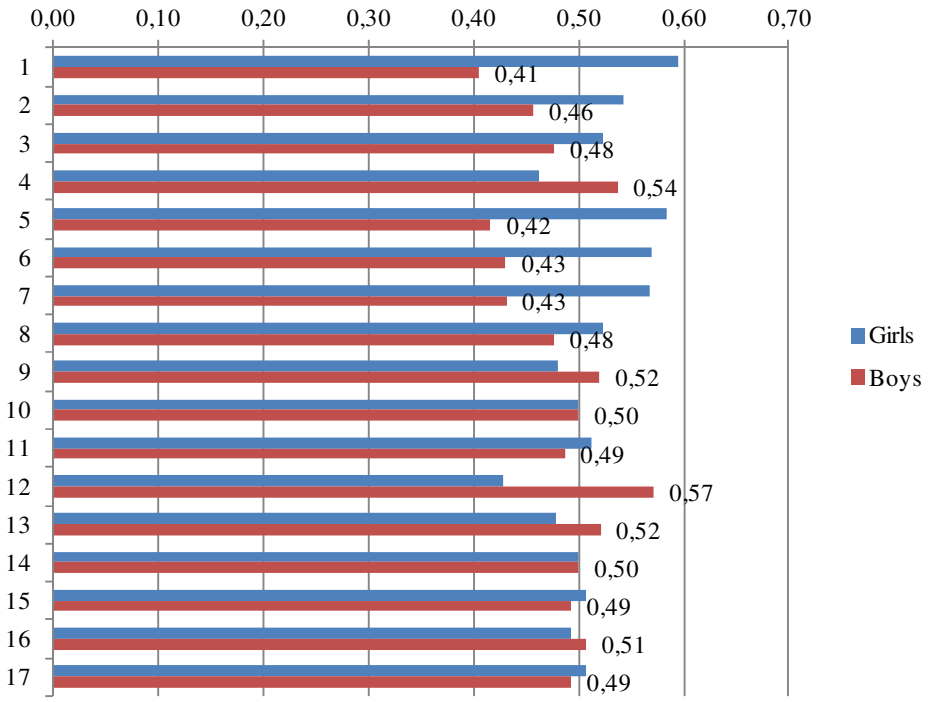

Fig. 2: Number of correct answers provided by boys and girls as a percentage of the total number of correct answers (block A)

Source: authors' compilation of results

A number of participants providing correct answers to multiple-choice questions from block B "Personal budgeting" is reflected in Fig. 3.

Best results the students demonstrated answering the questions Q11 and Q12 – 96% and 88% of correct answers respectively. The questions were aimed to check the ability of students to calculate the interest with deposits. However, it could not indicate a high level of numeracy, because the results of Q14 (calculation of monthly payment for mortgage loan) were relatively low (40% of correct answers).

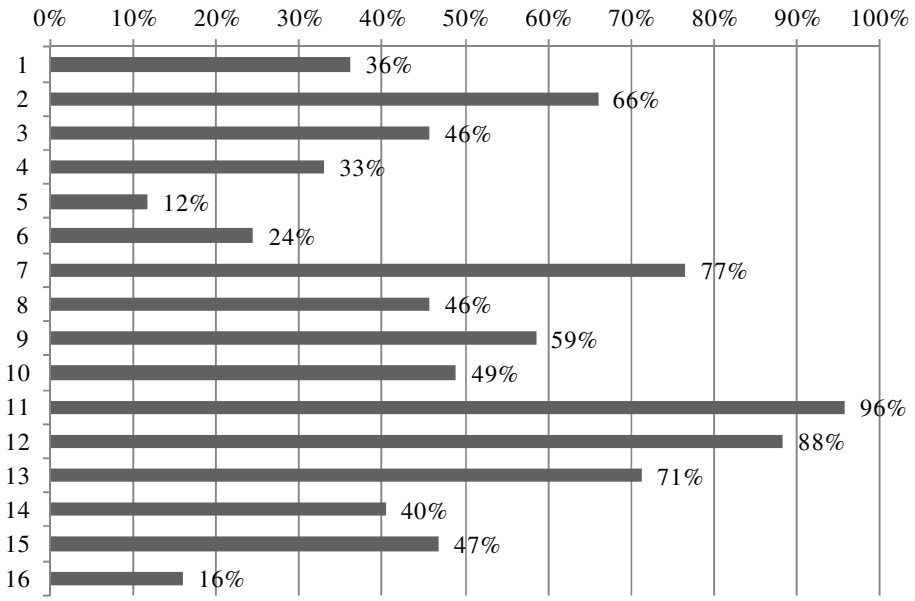

Fig. 3: Number of participants (% of total number) correctly answered questions (block B tasks)

Source: authors' compilation of results

The worst results were in Q5 and Q16 – questions about lending practices and Latvian Credit register. Students also demonstrated low level of knowledge, answering the question Q6 about the 2nd level of Latvian pension system. However, analyzing the responses of boys and girls separately, it is seen that the girls provided considerably more correct answers to questions Q5 and Q6 (Fig. 4).

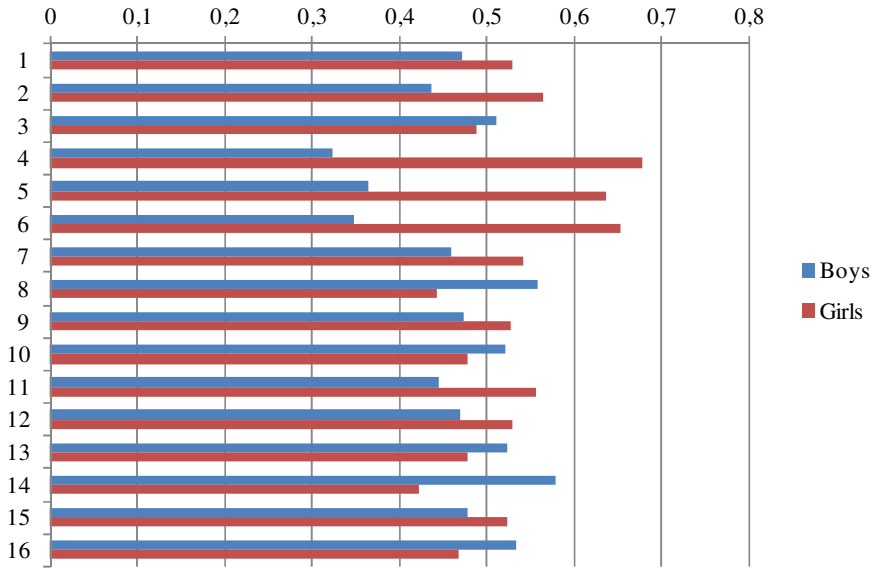

Fig. 4: Number of correct answers provided by boys and girls as a percentage of the total number of correct answers (block B)

Source: authors' compilation of results

Analyzing the results from both stages of the competition, it is obvious that the first hypothesis is confirmed. The most frequent "grade" received by the participants was 5 ("satisfactory"). About 50% of participants performed 50%-60% of tasks correctly. About 10% of students demonstrated very low knowledge (less than 30% of correctly performed tasks). The same number of students demonstrated upper level – more than 70% of correctly performed tasks.

As for the second hypothesis, it also has been confirmed. 61% of participants, answering macroeconomic questions, received high "grades" ("almost good" and better). In turn, answering the questions related to personal budgeting issues, the number of good and excellent students was quite lower (only 31%). Students "grades" are summarized in Fig. 5.

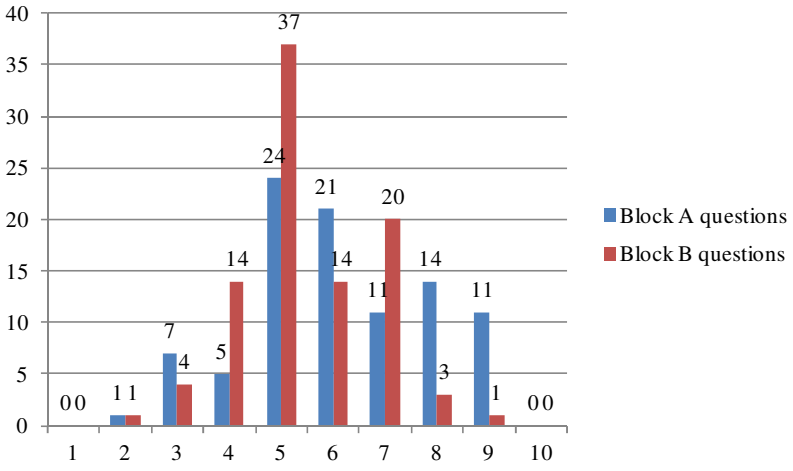

Fig. 5: Students achievements assigned to 10-point grading system

Discussion and conclusions

The given paper reflected the results of the competition "Financial ABC" between the representatives of Latvian secondary and vocational schools that was organized in 2017 by the University College of Economics and Culture in cooperation with the educational vortal "Customer School" developed by the Financial and Capital Market Commission and the educational portal "Money School" developed by the Bank of Latvia.

Two hypotheses were stated by the authors:

H1: Most of Latvian students' demonstrate average level of financial knowledge – Confirmed

Most of students performed at "5" (almost good), answering the questions related to macroeconomics and personal budgeting (Fig. 5).

H2: The level of students' knowledge in macroeconomics is higher than the level of knowledge in personal budgeting - Confirmed

Answering the questions from the block A "Macroeconomics" the students demonstrated better results. It can be explained by the content of the educational programme in Latvian schools. „Economics" is one of the obligatory courses. However, the programme is oriented to teaching such topics as money, demand and supply, employment and other macroeconomic issues. Questions in the field of consumer financial behaviour (personal budget, investments, loans and etc.) are not prioritized. Actually, such topics should be discussed within the separate course or the number of teaching hours for "Economics" should be increased.

Considering the limited number of participants of the competition, received results cannot be used as a basis for making conclusion about financial literacy level of all young citizens in Latvia. Thus, it is necessary to continue the research. The competition is panned to be organized on a regular basis and it is possible to provide a large volume of information for further analysis.

The authors of the given paper contribute to the informational base with the data about financial knowledge of Latvian young citizens. Considering that FCMC survey respondents are adults in the age of 18-79, but participation of Latvia in OECD survey among 15-years-old students is not regular, such kind of data from individual researchers and organizations allow understanding the problems in financial education in Latvia and making some steps to improving the situation.

In the future studies, the authors plan also to provide expert evaluation of the questions in order to determine their complexity. In this case, students can receive more points answering correctly more difficult questions.

Abstract

Corporate social responsibility (CSR) issues are still on the agenda due to the growing social needs, emerging issues faced by a global society, as well as under the pressure of local authorities and newly implemented CSR-oriented management practices. The aim of the study was get an insight into and an understanding of CSR and Sustainability, perceived by middle-sized and large Baltic companies. The current paper reflects the results of the survey conducted in 2015, and is limited to only Latvian sample data analysis. Latvian sample consisted of 59 business sector representatives. Latvian business sector representatives see CSR primarily as a corporate image driver. However, they are aware of the CSR role in improving of employee and customer satisfaction. Perceived importance of CSR is predicted to be increased in the future, but the relevant investments will not increase so much.

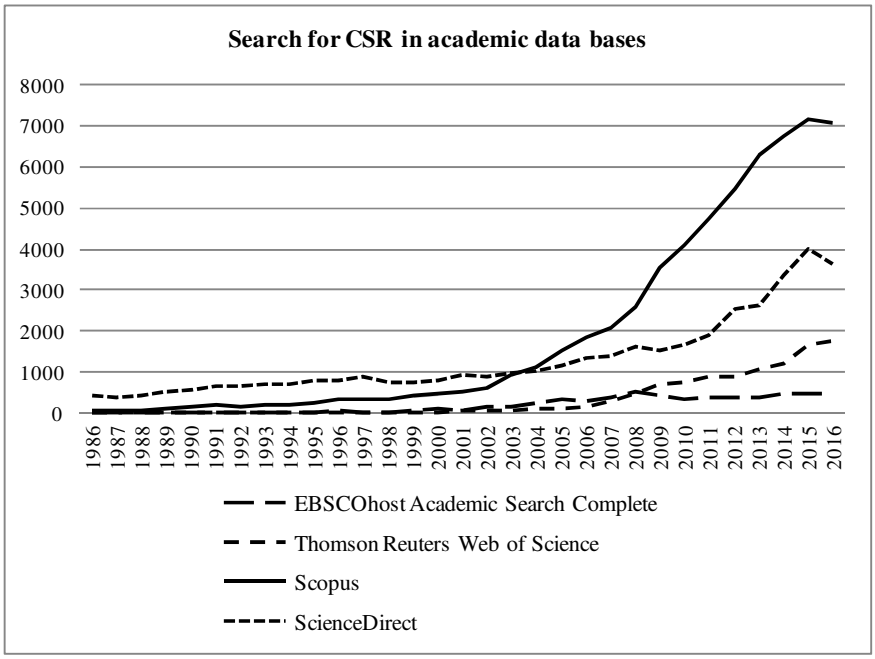
Keywords: corporate social responsibility, Latvia, large and middle-sized companies.

Introduction

Corporate social responsibility (CSR) and related issues are frequent topic for debates in the academic and business environment. There is an empirical evidence of the academicians' interest to CSR: search for the keywords "corporate social responsibility" in the academic data bases yielded 40185 results in ScienceDirect, 10469 results in Thomson Reuters Web of Science, and 59710 results in Scopus, applying the limitation of 30 years for publishing period, which is 1986-2016 (results of the authors' made analysis).

Modern history of corporate scandals that was started in 2001 with Enron Corporation contributed to the transformation of corporate social responsibility from theoretical concept to practical aspect of any business activities.

Companies operating in the Baltic States, as well as in other countries of the European Union, are "forced" to pay attention to the corporate social responsibility issues under the pressure of the European authorities, which is the implementation of the Directive 2014/95/EU of the European Parliament and of the Council regarding non-financial data reporting by large companies (European Parliament, 2014).



Current paper reflects the results of the large-scale study on corporate social responsibility that was conducted within the framework of the project "Comparing state of CSR in Baltics and Finland". The aim of the research was get an insight into and an understanding of CSR and Sustainability, perceived by middle-sized and large Baltic companies. The representatives of 172 companies were surveyed, using the specially designed questionnaire. Research period covered August-October of 2015. The only Latvian sample results are reflected in the given paper. Latvian sample consisted of 59 business sector representatives.

The authors of the given paper analyzed the respondents' answers on questions grouped into three main categories: (1) awareness of CSR significance, (2) CSR in practice, (3) Issues of CSR implementation and management. The data was processed with the application of descriptive statistics methods.

The results of the survey were promising. Most of respondents recognize the importance of corporate social responsibility and expect an increase of it in their companies in the next 5 years. However, the awareness of the importance of responsible business does not always result in the appropriate investments into CSR-oriented activities.

Theoretical Aspects of Corporate Social Responsibility

The interest of academicians and practitioners to the issues regarding corporate social responsibility has not been decreased over the years, but, conversely, it is still increasing. To illustrate this statement, the authors analyzed the statistics generated by the academic data bases EBSCOhost Academic Search Complete, Thomson Reuters Web of Science, Scopus and ScienceDirect. We looked for the number of published papers in each particular year in the period of 30 years (1986-2016), searching for the key words "corporate social responsibility". The results are reflected in the Figure 1.

Source: Authors' compilation based n data from EBSCOhost, WoS, Scopus, ScienceDirect

Fig. 1: Search for "Corporate Social Responsibility" in Academic Data Base

The breaking point (Figure 1) could be assigned to the Year 2001 (Enron corporate scandal). The graph of the number of the published papers devoted to CSR (at least in Scopus) demonstrates the exponential growth.

The concept emerged in 1950-s; it was introduced by Bowen in 1953. A comprehensive overview of the evolution of CSR definitions has been made by Carroll (1999), Dahlsrud (2008), who performed of a content analysis of previously developed definitions and by Ismail (2009), who focused on analysis of CSR concept through prism of management theories. Several definitions of the concept are summarized in the Table 1.

Table 1: Definitions of Corporate Social Responsibility

Source	CSR definitions
European Commission (2017)	CSR refers to companies taking responsibility for their impact on society
Chin, 2014	CSR is far from a cost, a constraint, or a charitable act, but a source of opportunities, innovation and competitive advantages. Implementations of good social responsibility make the corporation obtain more materials and human resources to gain a favourable social image and realize the corporation's long-term interests.
Crowther & Aras (2008)	[CSR] definition is concerned with the relationship between a corporation and the local society in which it resides or operates.
Ismail, 2009	[CSR] is a concept whereby business organizations consider the interest of society by taking responsibility for the impact of their activities on customers, suppliers, employees, shareholders, communities and other stakeholders as well as their environment.
Frederick et a. 1992	[CSR] a principle stating that Social corporations should be accountable for the Environmental effects of any of their actions on their community and environment
Jones, 1980	[CSR is] the notion that corporations have an obligation to constituent groups in society other than stockholders and beyond that prescribed by law or union contract, indicating that a stake may go beyond mere ownership

Analysing the concept of corporate social responsibility, different scholars and practitioners emphasize the role of various CSR components. For instance, Caramela (2016) named such SCR aspects, as (1) environmental efforts, (2) philanthropy, (3) ethical labour practices, and (4) volunteering. Mandina *et al* (2014) described SCR as (1) philanthropic project, (2) employing locals, (3) investment incentives, (4) Environmental management, and (5) adherence to the legal systems of the country- indigenization act. In turn, The World Business Council for Sustainable Development defines CSR components as "commitments and activities pertaining to:

- corporate governance and ethics;
- health and safety;
- environmental stewardship;
- human rights (including core labour rights);
- sustainable development;
- conditions of work (including safety and health, hours of work, wages);
- industrial relations;
- community involvement, development and investment;
- involvement of and respect for diverse cultures and disadvantaged peoples;
- corporate philanthropy and employee volunteering;
- customer satisfaction and adherence to principles of fair competition;
- anti-bribery and anti-corruption measures;
- accountability, transparency and performance reporting;
- supplier relations, for both domestic and international supply chains." (Hohnen and Potts, 2007)

Many researchers focused their attention on studying the motives for companies to be socially responsible (Campbell, 2007), specifically, on the investigation of the impact of CSR-oriented business activities on company's financial performance. CSR and company's performance has been studied for more than 30 years (McGuire *et al*, 1988; Pava and Krausz, 1996; Van de Velde *et al*, 2005; Nelling and Webb, 2009; Palmer, 2012).

Meta-analysis of 52 studies over 30 years allowed concluding that business social performance is positively correlated with business financial performance (Orlitzky *et al*, 2003). Palmer (2012) analyzed performance of 333 companies included in the S&P 500 in the period of 2001-2005. The conclusion was that CSR performance (expressed by MSCI ESF (Environmental, Social, and Governance) index) leads to increase in a company's gross margin. Zhang and Gu (2012) analyzed the relationship between financial performance expressed by Tobin's Q and seven CSR indices, using the sample of US companies in 2010-2011. The study revealed a positive relationship between CSR on employees and a corporate performance. Rajput *et al* (2012) conducted their analysis in the Indian market: analysis of 500 Indian companies in 2008-2009 and 2009-2010 led to the conclusion that CSR expenditure by the firm results in improved financial performance. Pan *et al* (2014) studied the link between CSR and corporate financial performance in China, using data of 228 listed companies in the period 2010-2013. General findings substantiated the impact of CSR on ROA, ROE, and EPS.

In turn, a range of studies revealed no statistically significant relationship between CSR scores and financial results of companies. Hirigoyen and Poulain-Rehm (2015), studying 329 listed companies in the United States, Europe and the Asia-Pacific region for the years 2009 and 2010, concluded that overall social responsibility score had no statistically significant impact on accounting measures of financial performance. Johansson *et al* (2015) examined 311 Swedish companies in the period 2006-2009, and found no statistically significant relationship between CSR and financial performance.

Different results are explained by the specifics of analyzed companies, diversity of the regions, and the difference of measures used as CSR proxies. Issues of measuring corporate social responsibility are studied as a separate research topic (Saveanu *et al*, 2014; Wood, 2010).

The given paper focused not on measuring corporate social responsibility in Latvian companies, but on investigation of the overall attitude to CSR demonstrated by business sector representatives. Despite the huge amount of studies on assessment of organizational attitudes towards CSR (Dzansi and Okyere, 2015; Bluhm and Trappmann, 2015; Echevarria-Cruz *et al*, 2015; Brown, 2001; Abdul and Ibrahim, 2002; Mazurkiewicz *et al*, 2006), there is a limited number of researches based on Baltic sample data.

Methodology

For large-scale survey companies were selected mainly, based on the criteria described in the Directive 2014/95/EU. Non-financial information should be disclosed by the "large public-interest entities (listed companies, banks, insurance undertakings and other companies that are so designated by Member States) with more than 500 employees" (European Commission, 2016). One thousand companies were selected in each country. Latvian sample involved also 250 largest companies in terms of turnover and number of employees. Small companies also participated in the survey. However, the response rate was rather low – only 59 companies provided full and qualitative responses.

As for companies' size, which representatives participated in the survey, the distribution in terms of the number of employees and turnover is reflected in the Table 2. National companies were represented by 45% of respondents, but Baltic and international companies – by 13% and 33%, respectively. Representatives of the companies were owners (5%) and board members (18%), as well as held the position of a middle-level manager (49%) and others (27%).

Table 2: Research sample distribution

Number of employees	Respondents	Turnover	Respondents
1	4%	0 – 0,99 mln EUR	18%
2 – 49	29%	1 – 9,99 mln EUR	20%
50 – 249	18%	10 – 49,99 mln EUR	24%
250 – 999	22%	50 – 99,99 mln EUR	13%
Over 1000	27%	Over 100 mln EUR	25%

Source: Authors' compilation of the survey results

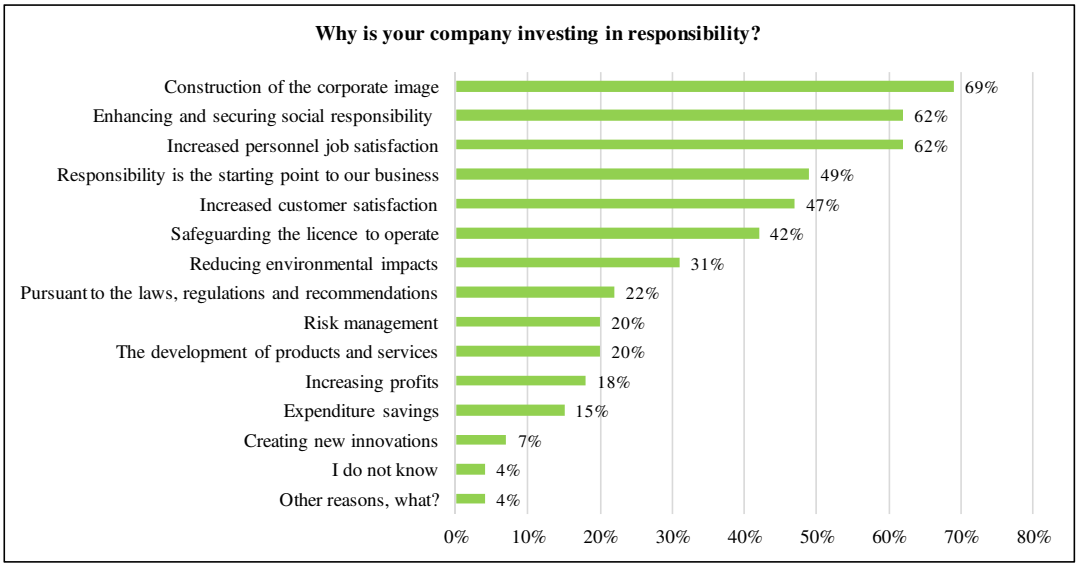
Respondents were offered to answer 16 multiple-choice questions (Table 3) from the large-scale project „Comparing state of CSR in Baltics and Finland" questionnaire, developed by the project participants. The questions were designed, based on ISO 26000 framework, as well as on experience of the participants representing Latvian Corporate Social Responsibility Platform – CSR Latvia, Responsible Business Association of Lithuania – LAVA, Responsible Business Forum Estonia – RBF Estonia and Finland Corporate Responsibility network - FIBS. Data was collected electronically through TNS-Gallup platform.

Table 3: Survey questions

Questions	Content
Q1	How relevant is the corporate responsibility theme in your company at present?
Q2	Why is your company investing in responsibility?
Q3 Q4	Who are the driving forces behind your business, and influence most in how committed your company is in responsibility? Has your company deployed the following responsibility management practices?
Q5	Which corporate responsibility issues do you consider relevant in your company?
Q6	What measures have you taken to enhance the relevant corporate responsibility themes?
Q7	What kind of cooperation does your company practice with non-profit organisations at present?
Q8	Does your company comply with some of the following international guidelines or operational principles?
Q9	How does your company benefit from corporate responsibility?
Q10	Through which features do you follow the fulfilling of your corporate responsibility objectives?
Q11	What are the challenges to your management of corporate responsibility at present?
Q12	What do you see as the most challenging corporate responsibility theme at present?
Q13	With which stakeholder group are you having the biggest challenges in communicating/sharing your CSR values?
Q14	How would you see the significance of corporate responsibility changing in your company within the next 5 years?
Q15	How would you see the amount of your company's corporate responsibility resources to develop within the next 5 years?
Q16	Do you plan to report about CSR under EU non-financial information disclosure directive?

Source: Authors' compilation of the survey results

The authors of the given paper focused their attention on respondents' viewpoint about CSR significance, CSR-related practices in respondents' represented companies, as well as on respondent's evaluation of the issues in the process of CSR implementation and management.

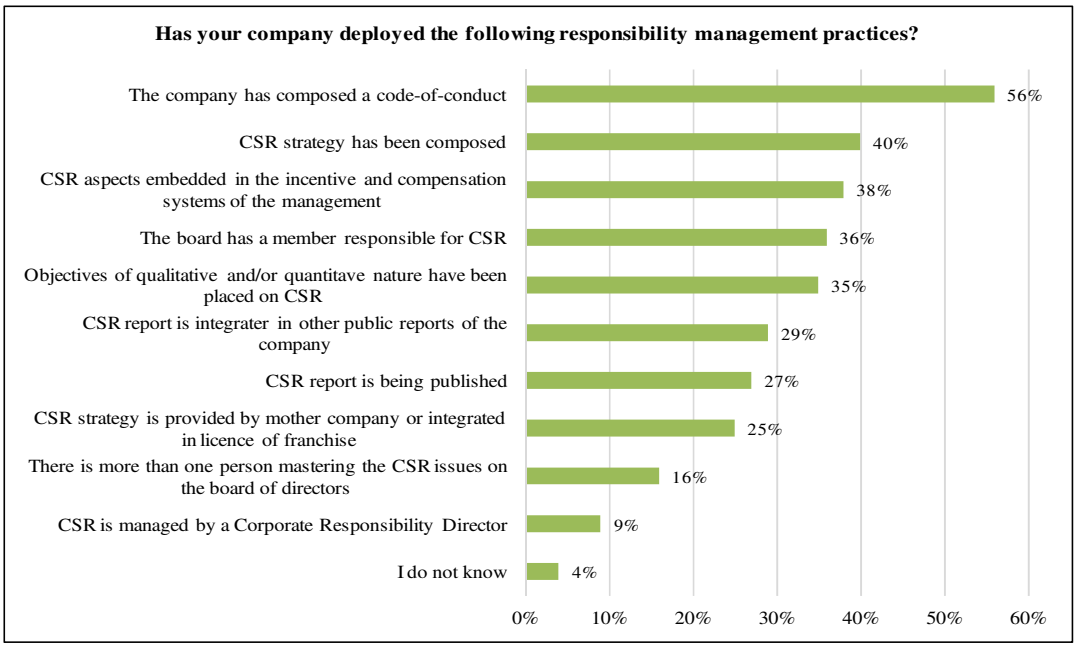


Results

Respondents were asked about the relevance of CSR activities in their companies at the current moment, as well as their vision of the CSR future importance in 5 years. 51% of companies consider CSR to be very important topic for their company at the moment. Only 11% of the respondents selected the answer "not relevant". The only 5% of the respondents assumed that CSR significance will decrease in the future. 38% of the respondents selected the answer "the significance will remain stable", whereas 55% are waiting for increasing importance of CSR in their companies.

And, accordingly, there should be a link between the change of SCR significance and amount of CSR-related investments. However, the number of respondents considering that the importance of CSR will increase in 5 next years is larger than the number of respondents predicting increase in investments (35%). 44% of the respondents stetd that "investments will remain stable", and only 7% predicted decrease in this type of investments.

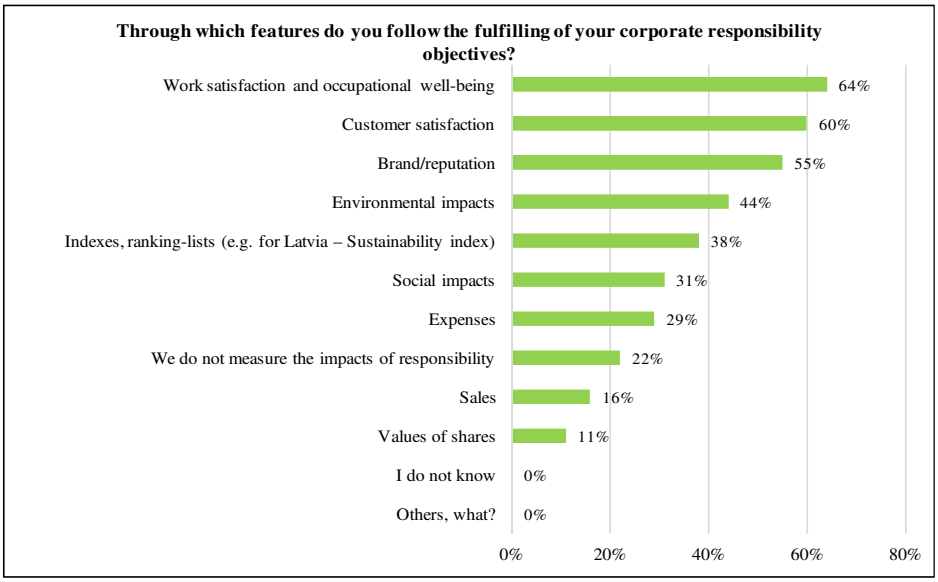
As for perceived benefits from CSR-oriented business practices, most of the respondents (76%) stated that CSR "facilitates the development of sustainable corporate image". Other frequently selected statements about benefits from CSR were "aids in streamlining operations" (25%), "accommodates innovation of new products and/or services" (20%) and "aids in saving expenses" (20%).



Respondents were offered to mark the reasons for investment into responsibility in their companies. Several options were possible to select. The results are reflected in Figure 2.

Source: authors' compilation of survey results

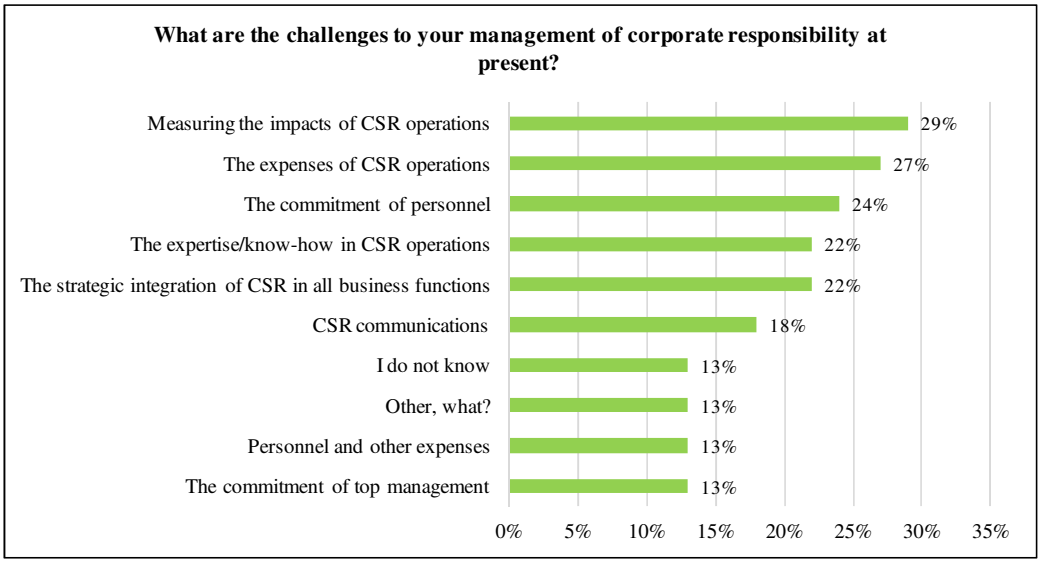
Fig. 2: Reasons for CSR investments



Respondents were also asked about responsible management practices in their companies. The most popular answer was "a company has composed a code of conduct" (56%). The results are summarized in the Figure 3.

Source: authors' compilation of survey results

Fig.3: CSR management practices



Evaluation of the process of achievement CSR objectives in the respondents' represented companies is made mostly through evaluation of "work satisfaction and occupational well-being" (64%) and "customer satisfaction" (60%). The full list of responses is provided in the Figure 4.

Source: authors' compilation of survey results

Fig. 4: Evaluation of the fulfilling SCR objectives

Most of the respondents treat measuring of the impact of CSR activities as the most challenging process on the way towards responsible business. The second place takes financial issue – "the expenses of CSR operations". Respondents' answers are summarized in the Figure 5.

Source: authors' compilation of survey results

Fig. 5: CSR management issues

Evaluating most challenging CSR-related issues for the companies at present, the respondents prioritised "fair competition and compliance to the law" (31%), as well as "managing supply chains" (29%) and "operations against corruption and bribery" (22%).

The results of the given study provide an insight into CSR perceptions in Latvian business environment, that, in turn, allow founding a basis for the following investigation of CSR practices in Latvian and Baltic companies. The survey should be iterated in the nearest future with a larger number of participants. Probably, the interest to CSR will increase with the necessity to disclose non-financial information in accordance to the Directive 2014/95/EU. At the moment, 44% of the respondents still "have no information about the directive requirements".

Discussion and conclusions

The current paper reflected the results of the survey that was conducted within the framework of the project "Comparing state of CSR in Baltics and Finland". Representatives of the business sectors of Baltic countries participated in the survey; the given paper reflects the results received within the Latvian sample.

Respondents demonstrated the awareness of CSR significance; however, they link it mostly with the construction of the corporate image. On the other hand, companies are enhancing and securing their responsibility in society, as well working to increase their reputation as good employer by increasing employees' satisfaction (62%). The tendency is promising - 49% of respondents see CSR as starting point or core for their business.

It is obvious that conclusions about companies' re-orientation towards corporate responsibility should be made not only based on declarations, but on the real situation.

The most popular responsible management practice used by the companies is the code of conduct (56% of respondents). There is an evidence that almost half (40%) of companies has at least some kind of strategy on CSR. Only one third (38%) says that the responsibility aspects are embedded in the incentive and compensation systems of the management. Only 35% of the respondents measure the CSR objectives and results, and only 27% report on results publicly. Good indicator of management involvement in strategic approach on CSR is fact that about one third of the respondents have someone responsible for CSR issues on companies' board level.

Regarding the issues in the field of corporate responsibility, management is concerned about methods to measure CSR feedback and return on investment, and how to manage the expenses on CSR operations and raise the commitment of personnel. Companies are struggling with CSR issues – such as raising the part of fair competition in industry, mapping supply chain and sharing company's values to mitigate the risks of company's corporate interests, as well as introducing the corruption and anti-bribery programs in company's operations. The biggest challenge for stakeholders is to create a common understanding and cooperation related to CSR issues with supply chain partners, shareholders and customers.

Based on the respondents' viewpoint, the importance of CSR will increase in the following 5 years; investment on the other hand – not that much.

Reliability of the research results was limited by the relatively low sample. It was assumed to be 1000 companies, including 250 large companies. However, the response rate was unexpectedly low – only 59 respondents provided full and qualitative responses. This,, in turn, predetermined the way of data processing. For example, the idea to make a correlation analysis to see any relationships between the answers and respondents' profile data was rejected, because of limited amount of data.

It is assumed by the authors that corporate responsibility topics will increase their relevance in Europe in the nearest future in any case, since the Directive of the European Parliament on non-financial information disclosure entered into force on January 1, 2017. Thus, the first reports should be prepared by large companies in 2018. It means that the survey should be repeated in 2018-2019 to see the progress and to evaluate the change in the attitude to CSR activities among business sector representatives.

The prospective further research areas could be referred to certain aspects of corporate social responsibility. For instance, tax governance as a part of CSR or CSR investments.

Acknowledgment

Hysteresis of Gender Inequality in the Duration of Unemployment: Evidence from the European Union, Spain and Switzerland

Marina Faďoš, Comenius University in Bratislava, Faculty of Management, Bratislava, Slovakia, marina.fados@fm.uniba.sk
Mária Bohdalová, Comenius University in Bratislava, Faculty of Management, Bratislava, Slovakia, maria.bohdalova@fm.uniba.sk

Abstract

The paper examines hysteresis of gender inequality in durations of unemployment. Spain, Switzerland and the European Union were compared and we found out that women tend to stay longer in unemployment than men, which causes higher inequality with rising durations of unemployment in Spain and the European Union, while in Switzerland gender inequality didn't exist. Analysed series were computed with our new method of gender inequality calculation and were tested for hysteresis with linear univariate unit root tests, both without structural break and with structural break. Cross dependence was tested with Pesaran CD test and hysteresis in full panel was tested with IPS, LLC and Moon Perron test. Stationarity was proven in all series of Switzerland, while some series of Spain and the European Union were non-stationary, meaning that gender inequality there depended on time.

Keywords: duration of unemployment, gender, inequality, unemployment

Introduction

Gender inequality on the labour market has been a major concern of policy makers during the last decades. Women are still unemployed more than men. Women also tend to be unemployed longer than men, while we have almost equality among those who are unemployed for less than three months, with increasing of time inequality is occurring in disadvantage of women (Eurostat, 2017). In this paper, we introduce new method of gender inequality in unemployment calculation and check for hysteresis in gender inequality in durations of unemployment. Paper is valuable because compares gender inequality in durations of unemployment in Spain, Switzerland and the European Union and explains differences between them. Spain is country with turbulent unemployment rates, who were both very high and low in various times, while Switzerland is a country with very low unemployment rates. Our motivation is to discover how time influences changes of gender inequality in unemployment.

Paper is structured as follows. First, we introduce a literature review of gender inequality research during the last years. Afterwards, new method of gender inequality in unemployment calculation was described and methods of unit root testing were listed. In section Results, gender inequality in unemployment series of Spain, Switzerland and the European Union were presented. Results from linearity test and univariate tests of the series were presented next. Afterwards, the results of cross dependence and unit root tests in territories panel were presented. Finally, we give our conclusions.

Literature Review

Gender inequality was researched since recently, after 2000. Azmat, Gűell and Manning (2004) and Queneau and Sen (2007) were the first one who were devoted to gender inequality investigation. They

calculated gender gap as the difference between the unemployment rate of females and males and as a ratio of unemployment rates of women to men. Koutentakis (2015) analysed gender inequality by constructing a steady state of the gender gap from job finding rates and job separating rates. Others, such as Ollikainen (2006), Theodossiou and Zangelidis (2009), Gokulsing and Tandrayen-Ragoobur (2014) and Baussola, Mussida, Jenkins and Penfold (2015), implemented probability analysis to outflows and inflows to unemployment, in order to discover how unemployment by genders behaves.

Stationarity of unemployment rates was analysed by many authors, among them are Ayala, Cunado and Gil-Alana (2012), Camarero, Carrion-i-Silvestre and Tamarit (2008), Garcia-Cintado, Romero-Avila and Usabiaga (2015), Fallahi and Rodriguez (2015) and Marques, Lima and Troster (2017). While there is still a lack of stationarity analysis of gender inequality in unemployment. Queneau and Sen analysed gender inequality in unemployment using augmented Dickey Fuller (ADF) test (2007) and using Phillips Perron test (2009), which lead them to conclude that gender inequality is disappearing with time but is still persistent. Bakas and Papapetrou (2014) confirmed that gender gaps are persistent using the ILT unit root test. Sahin, Song and Hobijn (2010), Peiro, Belaire-Franch and Gonzalo (2012) and De la Rica and Rebollo-Sanz (2017) discovered that in times of crisis, unemployment rate of men is increasing faster than the unemployment rate of women, which decreases gender inequality, but this is only a temporary effect which disappeared quickly after the crisis.

Women are usually longer in unemployment than men, according to Pašic, Kavkler and Boršič (2011). Economic crisis prolongs duration of unemployment, according to Bachmann and Sinning (2016). Flek, Hála and Mysíková (2015) discovered that the duration of unemployment is higher among youth. They also discovered that the probability of finding a job is decreasing for the people unemployed for more than one year. Böheim, Horvath and Winter-Ebmer (2011) discovered that people who are long term unemployed have a misleading perception of wages on labour market, which leads them to expect higher wages and reject wage which don't meet their expectations, which prolongs their duration in unemployment. Duration of unemployment can be decreased through training programmes which are designed to help unemployed to find jobs faster, it was also discovered that women who finish this training find jobs faster than men (Arellano, 2010).

We contribute to literature of gender inequality researching, by proposing a new method of gender inequality calculation from quantitative data of the duration in unemployment. Gender inequality series were then tested for stationarity, cross dependence and stationarity in full panel.

Data and Methodology

We have used annual data about the duration of unemployment (thousands) from the Eurostat database (2017), of Spain, Switzerland and the European Union for the sample period 1996-2016. These time series were then modified as follows.

Let $P_m^* = (d^*/D^T) \times 100$ resp. $P_f^* = (d^*/D^T) \times 100$, where P_m^*, P_f^* is proportion of men resp. women unemployed in each duration category (d^*) from the total unemployed people (D^T). Then we multiply P_m^*, resp. P_f^* by unemployment rate of men (u_m) resp. women (u_f) to obtain weighted proportions p_m^* resp. p_f^*. Weighted unemployment gender inequality rate (u_t^{wi}) was subsequently calculated as

$$u_t^{wi} = u_t^i \times \frac{u_t}{100}, \tag{1}$$

where u_t is the average unemployment rate and u_t^{wi} was calculated as

$$p_m^* = p_f^* \Longrightarrow u_t^i = 0, \tag{2}$$

$$p_m^* > 0 \ \wedge \ p_f^* = 0 \Longrightarrow \ u_t^i = -1, \tag{3}$$

$$p_f^* > 0 \ \wedge \ p_m^* = 0 \Longrightarrow \ u_t^i = 1, \tag{4}$$

$$p_f^* < p_m^* \Longrightarrow \ u_t^i = \left(\left(p_f^*/p_m^*\right) - 1\right) \times (-1), \tag{5}$$

$$p_m^* < p_f^* \Longrightarrow \ u_t^i = \left(p_m^*/p_f^*\right) - 1. \tag{6}$$

Finally, series of gender inequality rate u_t^{inq}, denoted as

$$u_t^{inq} = u_t^{wi} \times 100, \tag{7}$$

were computed and analyzed in this paper.

To prove, that gender inequality doesn't depend on time and don't follow the random walk we need to prove that the computed series are stationary, resp. that series' characteristics such as mean, variance, auto-correlations doesn't change over time, that is, they are constant (Lyócsa, et al., 2011). In this paper, we employ both individual and full panel–linear univariate unit root and stationarity tests. We test stationarity of each series using individual unit root test for each country.

We decide to analyze the stationarity of our series using Philips-Perron Unit Root test (PP), Augmented Dickey Fuller test (ADF) and Kwiatkowski Phillips Schmidt Shin test (KPSS). We also employ Phillips-Perron Unit Root test with the presence of one structural break to obtain better results.

Note, that the series may appear as non-stationary in the PP test if the structural break is present in the series (Queneau & Sen, 2007).

Stationarity was tested on Dickey Fuller type regressions (Dickey & Fuller, 1979):

With trend and intercept: $$\Delta y_t = \hat{\alpha} y_{t-1} + \hat{\beta} t + \hat{\mu} + \sum_{j=1}^{k^*} \hat{c}_j \Delta y_{t-j} + \hat{e}_t \tag{8}$$

With intercept: $$\Delta y_t = \hat{\alpha} y_{t-1} + \hat{\mu} + \sum_{j=1}^{k^*} \hat{c}_j \Delta y_{t-j} + \hat{e}_t, \tag{9}$$

where Δy_t stands for the first difference of y_t denoted as $\Delta y_t = y_t - y_{t-1}$. $\sum_{j=1}^{k^*} \hat{c}_j \Delta y_{t-j}$ stands for an additional correlation in the time series, $\hat{e}_t$ stands for estimated error of regression. Number of lags *k* was determined by Newey-West method.

The stationarity was tested by:

1) Perron's modified *t-statistic* (Phillips & Perron, 1988):

$$Z_t = \left(\frac{\hat{\sigma}^2}{\hat{\lambda}^2}\right)^{1/2} \cdot t_{\alpha=0} - \frac{1}{2}\left(\frac{\hat{\lambda}^2 - \hat{\sigma}^2}{\hat{\lambda}^2}\right) \cdot \left(\frac{T \cdot SE(\hat{\alpha})}{\hat{\sigma}^2}\right). \tag{10}$$

2) Augmented Dickey-Fuller *t-statistic* (Dickey & Fuller, 1979):

$$t_\alpha = \frac{\hat{\alpha}}{SE(\hat{\alpha})}. \tag{11}$$

3) Kwiatkowski Phillips Schmidt Shin *LM-statistic* (Kwiatkowski, et al., 1992):

$$LM = \sum_t S_t^2 / \hat{\sigma}_\varepsilon^2 \tag{12}$$

In stationarity, statistics $\hat{\sigma}^2$ and $\hat{\lambda}^2$ are consistent estimates of the variance parameters $\sigma^2 = \lim_{T\to\infty} T^{-1} \sum_{t=1}^{T} E[u_t^2]$ and $\lambda^2 = \lim_{T\to\infty} \sum_{t=1}^{T} E[T^{-1} S_T^2]$ where $S_T = \sum_{t-1}^{T} u_t$ and $u_t = y_t - y_{t-1}$, $SE(\hat{\alpha})$ is a coefficient standard error, t_α is *t*-ratio of α.

To test stationarity of the computed series when structural break is included, we employ Phillips-Perron unit root test (Perron, 1997) with break-point for the regression:

$$\Delta y_t = \hat{\mu} + \hat{\theta} DU(T_b)_t + \hat{\beta} t + \hat{\gamma} DT(T_b)_t + \hat{\delta} D(T_b)_t + \hat{\alpha} y_{t-1} + \sum_{i=1}^{k^*} \hat{c}_i \Delta y_{t-1} + \hat{e}_t, \tag{13}$$

where DU_t stands for intercept-break dummy, and it is equal to one if $t > T_b$, zero otherwise. DT_t stands for slope-break dummy and equals to one if $t = T_b$ and $t - T_b + 1$ if $t > T_b$, zero otherwise. D_t stands for dummy variable which equals to one for $t = T_b$ and zero otherwise. T_b $(1 < T_b < t)$ stands for break-date. Only one break-date is allowed in this test. k regressors in $\{\Delta y_{t-j}\}_{j=1}^{k^*}$ stand for additional correlation in the time series according to Queneau and Sen (2009). Break date T_b has been chosen as the date that minimizes Dickey-Fuller *t-statistic*.

Cross-dependence, for the null hypothesis that series are independent, was tested using Pesaran CD test (Bakas & Papapetrou, 2014)

$$CD = \sqrt{\frac{2T}{N(N-1)} \left(\sum_{i=1}^{N-1} \sum_{j=i+1}^{N} \hat{\rho}_{ij} \right)}, \tag{14}$$

where $\hat{\rho}_{ij}$ is the average of the pairwise correlation coefficients from the ADF regressions residuals.

Stationarity of highly dependent panel data was tested using Moon Perron test (Moon & Perron, 2004) for the AR(1) model

$$y_{i,t} = (1 - \lambda_i)\mu_i + \lambda_i y_{i,t-1} + u_{i,t} \tag{15}$$

$$u_{i,t} = \delta_i' F_t + e_{i,t}, \tag{16}$$

where δ_i' is a vector of coefficients corresponding to the common factors F_t $(k \times 1)$, $e_{i,t}$ is cross-sectional uncorrelated idiosyncratic error term.

Two statistics t_a^* and t_b^* were considered as

$$t_a^* = \frac{\sqrt{N}T(\hat{\lambda}^* - 1)}{\sqrt{\frac{2\hat{\varphi}_e^4}{\hat{\omega}_e^4}}} \xrightarrow[T,N\to\infty]{} N(0,1) \tag{17}$$

and

$$t_b^* = \sqrt{N}T\left(\hat{\lambda}^* - 1\right) \sqrt{\frac{1}{NT^2} tr(Y_{t-1} Q_{\hat{\Delta}} Y_{t-1}')} \left(\frac{\hat{\omega}_e}{\hat{\varphi}_e^2}\right) \xrightarrow[T,N\to\infty]{} N(0,1) \tag{18}$$

where $\hat{\lambda}^*$ is pooled least squares estimate of λ, $\lambda = 1$ for the null unit root hypothesis, $\hat{\varphi}_e^4$ is a cross-sectional average of $\hat{\omega}_e^4$, $\hat{\omega}_e^4 = \hat{\varphi}_e^4$, $\hat{\omega}_e^4$ is the long run variance of e_{it} (Khraief, et al., 2015).

Stationarity of independent panel data was tested using:

1) Levin, Lin and Chu (LLC) test, where the null hypothesis is that panels contain unit roots ($\rho = 0$) against the alternative hypothesis that all panels are stationary. Following *t* statistic was used

$$t_\rho^* = \frac{t_\rho}{\sigma_T^*} - NT\hat{S}_N \left(\frac{\hat{\sigma}_{\hat{\rho}}}{\hat{\sigma}_{\hat{\varepsilon}}^2}\right)\left(\frac{\mu_T^*}{\sigma_T^*}\right), \tag{19}$$

where $\hat{S}_N$ is average of long-run toward short-run variances individual ratio, $\hat{\sigma}_{\hat{\rho}}$ is the standard deviation of slope coefficient, $\hat{\sigma}_{\hat{\varepsilon}}^2$ is the standard deviation of the error term, μ_T^* and σ_T^* are tabulated values of the test for time *T* (Khraief, et al., 2015).

2) Im, Pesaran and Shin (IPS) test, which presume that all panels contain unit roots (null hypothesis) against the alternative hypothesis that some panels are stationary.

$$Z_{t\ bar}(p;\beta) = \frac{\sqrt{N}[t_bar_{NT} - E(t_{iT})]}{\sqrt{V(t_{iT})}}, \tag{20}$$

where t_bar_{NT} is the standardized statistic of individual ADF statistic limiting distribution (Khraief, et al., 2015).

Results

In Spain and the European Union, gender inequality was decreasing in all series. While in Switzerland, women and men were equally represented in the unemployment duration categories, or inequality was low. Highest inequality was among those who were unemployed for more than 18 months, in disadvantage of women. While the lowest inequality was among those who were unemployed for less than three months. From this we can conclude, that women tend to be unemployed longer than men. If women don't find job within 6 months, it is very probable that they would stay unemployed longer than men. Crisis in 2008 caused an increase of the number of men in long-term unemployment, both in Spain and the European Union. Which resulted in shifting all series towards equality, and suddenly men were unemployed longer than women in the European Union and Spain (Figure 1).

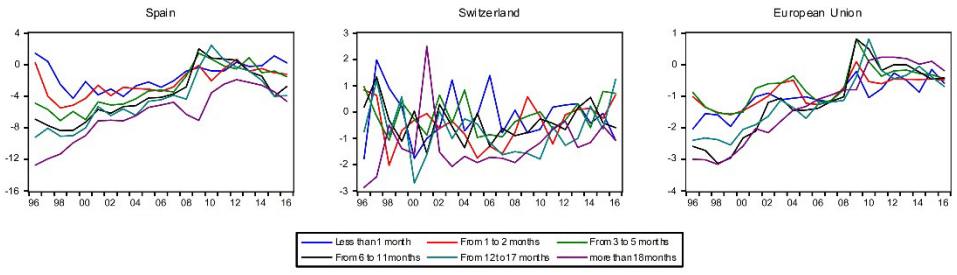

Fig 1: Inequality among genders in selected unemployment durations during period 1996-2016

Source: Own calculations

Before we checked if gender inequality depends on time, or there are other factors who influence it, we check for linearity of data. According to results from linearity test, we found all series being linear (Table 1).

Table 1: Linearity test results

Source: Own calculations

We used stationarity tests (10), (11) and (12) for linear data. All series of Switzerland were stationary, while only gender inequality among those unemployed for less than 3 months in Spain and less than one month in the European Union, were stationary (Table 2). Non-stationarity in Spain and the European Union could be caused by neglecting the influence of structural breaks. The series could be stationary, but because structural breaks were not included, false non-stationarity was concluded.

To discover, if series of the European Union and Spain were non-stationary, we performed stationarity test (13) with one break. Obtained results were better. All series of Switzerland were also stationary. By including a structural break in the analysis of stationarity, all series of Spain, except those who were unemployed for more than 18 months, were stationary. Stationarity was also proven in inequality series of the European Union, among those who were unemployed for less than 1 month and from 6 to 18 months. Structural breaks had only a temporary effect on gender inequality, and the consequences from it, quickly disappeared (Table 3).

The null hypothesis of cross-dependence test (14) was rejected for Spain and the European Union, meaning they are highly dependent, while for Switzerland couldn't be rejected, no dependence was proven (Table 4).

Since data of Spain and the European Union were highly dependent, stationarity in them was tested using Moon-Perron test (17) and (18), which couldn't be used for data of Switzerland, because they were independent. Stationarity in panel data of Switzerland were therefore tested using LLC (19) and IPS test (20). Stationarity in panel data was proven for all three territories (Table 5).

Conclusion

Women were unemployed longer than men, with increasing of time in unemployment gender inequality is increasing in disadvantage of women. We introduce a new method of gender inequality in unemployment calculation, which consist of a ratio between the unemployment rate of women and men and is weighted with an average unemployment rate. Series computed with this method were then tested for linearity and since they were all linear we used linear univariate unit root tests to check for hysteresis in them. To obtain better results we used three methods which we compared. Only gender inequality series of Switzerland were stationary in all cases. Number of a stationary series increased in Spain and the European Union when a structural break was included, but there were still some inequality series that depended strictly on time. Structural breaks had only a temporary effect on gender inequality series, and consequences from them disappeared very quickly. When analysing for dependence on territory panel, only Switzerland series were independent. When testing for hysteresis on territory panel, we used proper tests depending on results from the cross-dependence test, and according to tests used, all series were stationary in territory panels. Even when it looks that gender inequality in durations in unemployment is disappearing, it is still persistent and further analysis is needed.

Abstract

Social networks are one of the current modern methods of employee recruitment. For every person, finding and getting an adequate job is an important life step. Equally, it is also very important for an enterprise to get the right candidates. Therefore, in the process of employee recruitment, enterprises use different ways that depend on many factors. In addition to the classic methods used by businesses in the process of recruiting and selecting employees, modern methods have gradually evolved. These methods allow faster contact between the employer and the potential job seeker. One of these options is the use of social networks. The aim of paper is to define the perspective and usability of social networks for employers of small and medium-sized enterprises within recruiting employees. The survey was focused on students and graduates from Slovak and Italian universities. Research has shown that respondents have been using social networks to search for work only exceptionally, but they see the benefits and potential for them in the future. In order to attract potential job seekers, we recommend employers to publish job offers also with the help of modern technologies.

Keywords: employee recruitment, social networking, employee search, HRM.

Introduction

Nowadays, information technologies have a significant impact on all areas of our society, its development and the overall development of society (Vetráková, Smerek, 2016). Thanks to this trend, businesses have become more interested in modern technology (Hada, Gairola, 2015). Different types of people use modern technology, which means that businesses have an impact on a large number of potential job seekers. The innovations and development in field of internet and social networks require new trends as well as an adequate approach to human resource management (Pozo-Rico, Gilar, Castejon, 2016). In today's job search, social networks are a very effective channel of communication, which is also declared by research of Topolovec-Vranic and Natarajan (2016) or Amadoru and Gamage (2016). These authors share the view that the use of social networks has grown over the last 10 years. Social networks provide access to information about potential job seekers, can quickly disseminate job offers and provide feedback (Jere, et al. 2017). Services, provided by social networks within the Internet, represent an expanding social phenomenon. Today, especially students perceive social networks as a space for expressing their own personality.

The main goal of the recruiting process is to obtain the right employees at the lowest possible cost with adequate quality of the job potential of the candidates at the optimum time. We understand employees' work potential as knowledge, experience, skills, talent or some specific personality characteristics needed to meet the desired goals and missions of a particular business (Kachňáková, Nachtmannová, Joniaková, 2008). Factors from the outside environment of the organization may also affect the process of recruiting employees. These include, for example, demographic, economic, technological and legal conditions. These factors cannot be influenced but should be taken into account when deciding on concrete steps in the process of recruiting.

Material and Methods

Different methods are used to recruit employees. With rapidly changing times and trends, the methods are changing, too. Print media has been in use since the 17th century, when the first newspapers began to appear in Europe, later in the 18th century in America. Newspapers had an impact on almost every household, which caused the later boom of print media. Therefore, the company, the company that used this resource to advertise the job, had the highest chance of reaching as many potential candidates as possible. After the arrival of television and radio, some companies have also started to use these methods to offer a job. We have observed the greatest change in the use of different methods since the onset of the internet phenomenon. Companies follow trends in the use of different media by their potential candidates. Without costly studies, they noticed that the internet and especially today's popular social networks were the best place to attract potential employees. There are two main social networking functions in the labour market. The first one is to provide information on job offers and the second one is to present information on employee productivity and quality. In this way, both employed and unemployed people receive job vacancy information and each individual is in touch with others. Employees do not use job offers for themselves but they inform their unemployed friends. Therefore, the number of working friends determines the amount of available job vacancy information and increases the possibility of finding a job (Cappellari, Tatsiramos, 2015).

Nowadays, there are many social networks and they include Twitter, Facebook, LinkedIn, Instagram, WhatsApp, Google+, YouTube, Skype, Pokec and ICQ and others. They offer solutions not only for students and graduates but also for all who are looking for a job. Data from social networks can help many job seekers. On the other hand, social media are helpful to companies in finding a suitable employee. Using large data social networking options is the biggest opportunity for students. More and more businesses and businesses agree that processing large volumes of social data is an opportunity for both students and businesses. Students who succeed are not the ones who have the most to put on the Internet. Successful students know best to use these data. Social networks provide a stepping stone in finding jobs and obtaining information easier that could contain unique and valuable employment information (Fieseler, Meckel, Müller, 2014).

The job search process begins by creating profiles on Twitter, LinkedIn, Google+ and Facebook. Social media and websites allow them to connect with potential companies or other employers (Batagan, Boja, 2015). Through the social media, it is easier to get the full background of a candidate with detailed references that staffers need. Most companies have their own web portal. In most cases, these companies also have their profiles on social networks. Specialized personnel agencies have found that internet communication or communication using social networks was much more effective than regular ads for specific professions or groups of people. The main reason for lower printed media preference is that young people less read daily press and spend more time on social networks. Another advantage is that the information spreads very quickly and has an impact on many people in a very short time (Potkány, Hajdukova, 2015). The research of Melanthiou et al. (2015) also points to the many benefits provided by social networks. Social media allow users to present themselves in different ways. For example, one of the options is through participation in expert groups or in groups that are connected with companies interested in job seekers. Nowadays, most people agree that the job search process can be a long and time-consuming process (Nikolaou, 2014). The combination of formal and informal job searching is the most successful way to find a job.

Table 1: Composition of the research sample

Data to identify respondents		Italy		Slovakia	
		Absolute frequency	Relative frequency	Absolute frequency	Relative frequency
Gender	Male	51	48	103	41
	Female	56	52	186	59
Age	Up to 20 years	9	8	11	3
	21 – 25 years	64	60	232	73
	26 – 29 years	34	32	55	17
	30 years and more	0	0	18	6
Completed education	Secondary education	46	43	163	52
	Higher education of I. degree	32	30	103	33
	Higher education of II. degree	29	27	47	15
	Higher education of III. degree	0	0	3	1

Source: authors

We have used the descriptive statistics and the chi-square test of the good match based on the contingency table for producing the results. The contingency table presents the frequency distribution of the two categorical variables simultaneously. It claims that the expected and observed frequencies are equal, which means that the nominal variables are independent. The rejection of the zero hypothesis means that the difference between the observed and expected frequencies in the table is so great that it cannot only be random and therefore there is a relationship between the nominal variables. We determined the statistical significance of the difference between the respondents using the level of significance p on the sample of Italian and Slovak students and graduates ($p > 0.05$ among countries is not statistically significant difference; $0.01< p <0.05$ between countries is a small statistically significant difference; $0.001< p <0.01$ among countries is a statistically significant difference; $p < 0.001$ between countries is a very significant statistical difference) (Rimarčík, 2007).

In research, there was a questionnaire used by Potkány, Hajduková (2015). The aim of the questionnaire survey, which we conducted in 2017, was to define the perspective and usability of social networks in recruiting employees for small and medium-sized enterprises. The survey was designed for students and graduates of Italian and Slovak universities. In total, 423 respondents were involved (107 from Italy and 316 from Slovakia) in the structure according to Table 1.

Results and Discussion

Based on the results of analysis of the use of different types of social networks, we can state that most respondents from Italy use the social network WhatsApp (89.72%). Facebook is used by 83.18% of Italian respondents. Instagram and YouTube are represented similarly to Italian and Slovak respondents. 57.94% of respondents use Instagram and 41.12% of respondents prefer YouTube. Also, 99.37% of respondents from Slovakia have a profile created on the social network Facebook. More than half of respondents say they use the Instagram social network (53.16%). YouTube is the third most common social network, which is used by 42.72% of respondents.

Italian respondents use social networking to find employment in 49 cases from the total of 107 respondents. Slovak respondents are most often connected to social networks anywhere via mobile devices (exactly 190 out of 316 respondents). The answer “at home” was the second most frequent answer selected by 119 respondents out of a total of 316. Slovak respondents use Social Networks to find employment in 146 cases out of a total of 316 respondents.

Italian respondents most prefer the option to look for work over the Internet, up to 87.85% of respondents. The second most common answer was to find a job with personal contact. More than half (57.94%) of Italian respondents chose this option. The way of looking for work through the Office of Social Affairs and Family was preferred by 38.32% of respondents and 35.51% of Italian respondents chose to work through social networks. The Internet as a way of seeking employment holds a dominant position among Slovak respondents (76.58%). The second most frequent response was with the known (64.56%) and 46.84% of the respondents choosing the option through social networks. The way of looking for work through the Office of Labour of Social Affairs and Family is used by 37.97% of the Slovaks interviewed.

Consequently, we determined how many respondents use social networks to find employment. The respondents had a choice of more options and the main question was whether they use or not use social networks for that purpose. The observed results do not indicate any statistically significant difference. The participants in both surveys said they were using social networks as a tool for finding employment. This option was marked by 91.59% of Italian respondents and 89.24% of Slovak respondents.

Table 2 Comparison of differences within job search

	Chi-squared	Degrees of freedom	p-level
Pearson's chi-squared	0.4826791	df=1	p=0.48721
M-V chi-squared	0.5008238	df=1	p=0.47914

Source: own research

Furthermore, we investigated what kind of social network respondents used. Italian respondents are seeking job most through specific social networking sites of enterprises (67.29%). The looking for employment through special applications on social networks is the second most common option for them (for exactly 40.19% of respondents surveyed by Italy). Most of the Slovak respondents use social networks to find employment through friends' recommendations (67.41%). On the other hand, 42.72% of Slovak respondents are looking for employment on specific pages of enterprises within social networks.

There is a statistically significant difference in the view of respondents in terms of social perceptions as a credible tool for finding a job (Table 2). 30.84% of Italian respondents see social networks as an untrustworthy way of seeking employment, while Slovak respondents perceive social networks as a trusted tool (up to 50% of the respondents identified this possibility).

Table 3 Comparison of differences in assessing the reliability of social networks

	Chi-squared	Degrees of freedom	p-level
Pearson's chi-squared	86.41233	df=3	p=0.0000
M-V chi-squared	77.03946	df=3	p=0.0000

Source: own research

In the context of analysing the benefits of social networks in finding employment, the statistically significant difference was not confirmed by the opinions of Italian and Slovak respondents. In both cases, respondents indicate that social networking services have benefits in finding a job. This view is presented by 90.65% of respondents from Italy and 90.19% of respondents from Slovakia (Table 3).

Table 4 Comparing differences in benefits of social networks

	Chi-squared	Degrees of freedom	p-level
Pearson's chi-squared	0.0196889	df=1	p=0.88841
M-V chi-squared	0.0198306	df=1	p=0.88801

Source: own research

Italian respondents argue that the greatest benefit of social networks in finding a job is a large amount of information in one place (58.88%). The benefit of rapid feedback is also very significant for Italian respondents (51.40% of respondents indicated this possibility). The "comfort" option was marked by 49.53% of respondents from Italy. More than half of Slovak respondents see the biggest advantage in time-consuming social networks (53.80%). The second significant advantage for Slovak respondents is a large amount of information on social networks. Italian respondents (79%) see potential in the social networks for looking for employment, in the future. In contrast, 21% of Italian respondents claim that social networks have no potential for the future. In Slovakia, 67% of respondents see the potential to job seeking in the future. Another 24% of respondents do not see the potential for the future.

Social media and the Internet are widely used in the recruitment process by both human resources and job seekers. Personnel managers use social and Internet technology to access a large amount of information about job seekers. Their aim is to avoid negligence in hiring and discover the real person of the applicant. Personalists continue using social media in the process of recruiting even though they are still considered socially irresponsible and violating privacy. This can lead to negative impacts on company reputation and disputes between job seekers and companies. Also, the reliability and validity of information obtained from social media are debatable. On the other hand, job seekers know that their social media profiles are likely to be checked by potential employers. Many of them even believe that employers have the right to control the profiles of applicants for social media. In spite of this, many jobs seekers do the so-called "posting paradox" when they publish and share content that is inappropriate to be seen by their potential employer. This paradoxical behaviour opens a key question about the factors that predict the behaviour of potential job seekers in the social media, (irrespective of suitability or inappropriateness, especially with regard to their awareness of potential employers) (Ouirdi *et al.*, 2015b).

In addition to psychological openness, employers expect to find some other personality features that are considered important when deciding to be recruited in relation to the use of social media. For example, how candidates use social media, their dependence on social media and possibly low self-control. When using social media to a greater extent, it is expected that shared content could potentially be detrimental to their career or job search. We can observe this fact among Facebook-dependent people and frequent Facebook users with a clear negative impact on their work or study. People with a greater need to be more frequent on the Internet are more likely to share potentially problematic material. It is also assumed that people with low self-control would disagree with the use of social media when deciding employers to take up employment (Drouin et al., 2015).

Employers control several things related to the personal lives of employees or potential employees that could endanger the business or the enterprise itself. It is very easy to harm a business by someone who has undesirable behaviour. Multi-national or multicultural societies are oriented towards extremists or employees with racist views that could be expressed on social networks and could endanger the enterprise. According to the Eurocom Worldwide Global PR Network survey, two of the five technology companies (nearly 40 percent) view profiles of potential employees on social networks such as Facebook or LinkedIn. This is just another example of the fact that very personal photos or information published on social media websites may seem like a good idea but can affect the future career of an employee (Bawaba, 2011).

Study results of Ouirdi et al. (2015a) demonstrate the sensitivity of younger users to social impacts. The reason could be that younger users are more sensitive to pressure from friends and are using social media in general. This could also be transferred to the workplace. Younger people show a stronger interest in relationships with other people, including co-workers. In comparison with older workers, younger workers have stronger motives for growth in terms of new learning, education and development. Therefore, they could be more sensitive to the perception of social impact on the workplace and to accept innovation and progress in their careers. Highly educated people are more motivated by community interests, inclusion in society and reputation. It is possible that highly educated people are increasingly exposed to social influence in the profession and are more vulnerable to this pressure.

Based on the research results, we have come to the conclusion that Slovak personnel should focus on social networks such as Facebook, Google +, YouTube and Instagram, in search of potential employees. They should include these networks in the classic way of looking for job seekers, because they are among the most used in Slovakia. Volkova et al. (2017) present similar facts. The results of their research claim that Facebook is the most successful tool used in the recruitment process. Searching for potential employees also depends on the type of user on social networks. The survey showed that most respondents actively use social networks. These two studies show that the place, where respondents are joining social networks, has changed significantly. Nowadays, there is no problem connecting to the Internet, almost anywhere. Operator coverage increases each year and almost everybody has the internet on the phone. Our respondents are most often connected using mobile devices. Methods used by potential job seekers in finding an employment are equally important.

The survey found that Slovak respondents mostly use the Internet, personal acquaintances, and social networks to find employment. The possibility to look for employment through social networks is more often used than the results from previous years according to the above-mentioned surveys it is important to take into account factors such as basic salary, working environment and the possibility of career growth (these factors are a priority for Slovak respondents) so that job seeker is interested in the job offer. If respondents choose to use social networks to find employment, they will follow the recommendations of their friends.

The level of trustworthiness of social networks has improved from the point of view of Slovak respondents. In research of Bartaková, Brtková, Gubiniová and Hitka (2017), which was carried out on a sample of 211 students and university graduates from Slovakia and 181 from abroad, social networks were evaluated as a less trusted tool for finding employment. In our research, Slovak respondents have already perceived social networks as a credible tool for finding employment.

Further, we investigated what social networks had benefits for potential employees. The Slovak respondents see their advantages, especially in the timelessness. We can conclude that the use of social networks, as a modern job search tool, has seen an increase in Slovakia. The respondents see the potential in this modern method, and they will use it more in the future, given the current trend of growth. Therefore, it is very important for employers to have their profiles on social networks with attractive job offers attractive to potential job seekers.

Conclusion

The reality of the present affirms us how quickly the world around us changes. Competitive struggle is a very important factor that significantly shapes the environment around us and affects the competitiveness of the business on the market, at the same time (Stacho et al., 2015; Potkány, Stachová, 2015; Nedeliaková et al., 2017; Smerek 2017; Smolková et al., 2016; Urbancová, Urbanec, 2012). Therefore, in the field of human resource management, there is a great deal of attention devoted to the emerging generation, especially today's university students. They bring a different view of the world, other habits and ideas about the working environment and often have their own innovative views (Kucharčíková et al. 2016). The survey's priority (which we have addressed to students and university graduates in the form of questionnaires) was to find out if they are using

social networks when looking for jobs in Italy and Slovakia and what will be the trend of social networks in recruiting employees in the next period. From our survey, we estimate that social networks, as a modern job search tool, have great potential in the future and have the opportunity to become a full-fledged way of looking for an employment. Authors Gelinas et al. (2017) share the same view.

Generation Y in Parent´s Business – Their Motivation

Ondřej Hradský, University of Economics, Prague, Czech Republic, ondrej.hradsky@vse.cz

Tomáš Sadílek, University of Economics, Prague, Czech Republic, tomas.sadilek@vse.cz; sadt00@vse.cz Department of Retailing and Commercial Communication, Faculty of International Relations, University of Economics, Prague, Czech Republic

Abstract

The goal of this article is to identify how working expectations and motivations of generation Y working in parent's businesses varies from the working expectations and motivations of whole generation Y. We proceeded a qualitative research design to gain opinions of generation Y members working in parent's businesses. Three main dimensions of the working motivation were surveyed: (1) Reasons for entering a family business, (2) What does work in a family business mean? and (3) Their general working motivation. Main findings of the article are the importance of work-life balance, flexibility, possibility of career development and own will to continue his or her family tradition for generation Y members working in parent's businesses.

Keywords*:* Motivation, Generation Y, Succession, Family Firms

Introduction

Family businesses are important actors of the Czech economy. In the Czech Republic was the tradition of family business restored after the collapse of the totalitarian regime. These regimes did not allow free enterprise; therefore, family business was not even the subject of scientific research. However, nowadays the issue of family business in the Czech Republic is receiving more attention. According to Machek (2017), it is a young, but popular and rapidly developing science discipline in management. Similarity can be found with topic of youth employment, especially with theme of generation Y-members and their work motivation.

Generation Y are the individuals born from 1980 to 1995 (McCrindle, 2014). This term includes people who are currently completing their university studies or are economically active for a relatively short period of time. Statistically, this represents 21% of citizens of the Czech Republic (CSO, 2016). Thanks to historical events, they have a different view on the world than previous generations. Therefore, it can be expected that their access to family businesses have specific features than previous generations. Members of the Y generation enter the labor market and at the same time enter these individuals into family businesses. This contribution focuses on those whose parents are doing business and they can become their potential successors. The aim of this article is to find out whether the work expectations of members of the generation Y whose family are owning business differ from the motivation of the whole generation Y. The article should help to understand motivation and preference for young people to enter into companies owned by their family.

Due to lack of statistical data, the research was carried out using the method of qualitative research. The article is structured in the following way. In the first part Literature review are presented the work motivation and preference of the Y generation. Then the way of data acquisition is explained. Finally is presented a summary.

Literature Review

Generation Y is characterized by certain specificities. Compared to previous generations, it is characterized by a high degree of individualism, openness, willingness to experiment and liveliness for the thing (Twenge, Campbell, 2012). It is referred to as the most technically skilled, having the best access to education and more individualistic than the previous generation (Eisner, 2005). This is due to continuous contact with state-of-the-art technologies, which the most important is the Internet. Attempting to achieve their personal and work goal is leading members of this generation to find

meaningful work in a working group that is similarly set up. This generation differs with access to money, which it does not perceive as the most important criterion for choosing a profession. Important features in deciding about profession gives gen Y to character of work, the opportunity to work, while enjoying life and contributing to the creation of a satisfied human society (Allen, 2004).

A typical characteristic of generation Y is multitasking. This feature brings many benefits, such as the ability to work on multiple different tasks at once. Lewis (2003), on the other hand, states that they often use technology not only to fulfill their tasks but also to personal issues (such as watching videos, sending messages or reading on forums) at the workplace.

The examined generation Y is often perceived as one of the first globally interconnected generations. Therefore, it is being researched worldwide regardless of nationality. Due to this fact, the Czech environment was examined (Šilerová, Flodrová, 2011), which did not show significant differences of motivation from the results of obtained by global surveys. Differences can be seen in cultural affairs. However, cultural topic is not explored in this text. Generation Y seeks a job position from which it can develop and grow. And it has much greater emphasis on flexibility and self-development than previous generations. It also wants to step up in the career ladder if they are offered that opportunity. Otherwise, members of this generation set up their own business (Sheahan, 2005, Twenge, 2010). Consultancy company's surveys focused on defining gen´s Y work motivations and preferences in choosing a profession can be used. They are up-to-date and applicable for the purposes of this research.

Characteristics of the generation Y are influenced by factors and criteria by which its members decide while choosing a future profession. The propensity for individualism to some extent explains the importance of a work-life balance that is rated as key factor. Other key criteria for choosing a job are flexibility, development and career growth, meaningful work, financial rewards (Deloitte, 2017, Universum Global, 2014, Pwc, 2016, Harward Business Review, 2016, Manpower, 2016).

The work-life balance is one of the most important criteria for generating Y to decide on accepting a job offer. Leisure, family, and career development even favor this generation before financial rewards. Up to 34% of respondents from the global survey with more than 16,000 respondents said the managerial role was not attractive to them, as they were worried that they would take too many hours a day and would not have enough time for their free-time activities. (Universum, 2014)

Another incentive factor is flexibility. Like the previous work-life balance, it stems from individualism and openness. (Twenge, Campbell, 2012) Flexibility is reflected in adapting to working life. Typical is the optional working time, the freedom to decide on working conditions and associated possibility of home office. (Deilotte, 2017) Generation Y members want to create their individual surroundings and timetable for their work to suit their lifestyle. (Kubátová, 2004)

Willingness to learn new things to support own personal growth, is another typical stimulating feature of the generation under studies. Education contributes to personal development, which leads to self-worth, and consequently helps to achieve own goals. This is supported by the already mentioned individualism. This is another factor of motivation - career growth. Generation Y is entering the labor market and expects to rise rapidly in career rankings and is generally not willing to stay at the same job for too long period. (Universum, 2014)

Surveys were conducted among members of the generation Y, but notwithstanding their preferences regarding the type of ownership of the company. Due to the differences between family and non-family businesses, these research questions arise:

1) What motivates members of the Y generation to work in their parents' businesses?
2) Do these reasons differ from the results of the whole generation?

Methodology and data

Selected statistical databases focus on issues of generation Y and factors affecting career choices. However, there is no diversion between the companies that are selected by the Y generation, following their form of ownership. The absence of a wider statistical database leads to the creation of

this qualitative article. Its empirical part is created based on in-depth unstructured interviews with twenty representatives of gen Y.

These interviews were conducted in the first half of year 2017 at neutral public places so the interviewees were not exposed to any environmental pressures and their ideas could be fully demonstrated. Each interview lasted about two hours. Respondents were selected based on several criteria. They had to be members of generation Y, people born between 1980 and 1995. Their parents must have a family business and be active in both statutory and executive positions for at least 5 years. The family business has a turnover more than 20 million crowns and employs between 12 and 250 employees. Business ownership is only in the hands of the family or wider family. Important condition was the active working participation of the interviewee within the family business.

Eight women and eleven men were interviewed. Examined family businesses operate in following areas: food (6), engineering (5), services (4), agriculture (2), textile (2) and construction (1). These companies are owned by either one of the parents or parents and someone else from the family (most often the founder).

Interviews were based on a pre-prepared scenario. To verify the reliability of the statements, questions were raised on each topic several times, but each time at a different time and with other words. The aim was to answer the above questions. That is why the interviews concerned the following topics:

- Reason for entering a family business.
- Work duration in a family business.
- What does the work for their family mean?
- Overall work motivation.

Reasons for entering family business

The first part of the interview was conducted to find out the real reason for entering a family business. From the nature of the defined goal, the answers will differ from the answers of people who do not have the opportunity to enter their parents' family business. However, it is important to get better understanding of the possible differences of Y generation representatives in family businesses than others. Responses can be divided into three types.

Typical reason for ongoing family businesses is tradition. The continuation of the family tradition as a reason to enter the family business has given a corresponding part. Another respondent admitted that she had no choice but to get into a family business after they had finished their education. From such responses, it can be concluded that parents in these cases developed some pressure and that their child was not exposed to a choice.

The third type of answers showed the fact that respondents was given the opportunity to arbitrarily decide. They entered the family business at their own discretion. Most respondents were in the third category of responses. They decided on their own, based on experience or discretion. These interviewees also reported different length of time in the family business. For the first two types of responses, interviewees engage in family business either during their training or immediately after their termination. Also, the subject in which the interviewee was educated informed him whether he was preparing for work in a family business or not. No respondent who entered family business because of tradition or necessity was educated in another field.

Respondents admit that they are dealing with the resistance of parents and workers who prevent changes in the processes involved. They see this as a frustrating factor, but also on the other hand as a challenge that makes them work harder and do more.

What does the work for their family mean?

In third part interviewees were asked to find out what the work for their family mean. Focus was made to capture mainly different responses than the generation Y, which does not work in family businesses. Relationships with parents have been mentioned in a different form. One praised that

relations with parents had improved with their entry into the family business. Communication has improved, clarification has been made of the relationship and way of working in the company's hierarchy.

On the other hand, the involvement of offspring can also lead to a deterioration of family relationships. For example, three respondents said they sometimes feel that their parents would rather see someone else's place at their work place.
Per respondents is also more difficult to distinguish working hours from their free time. Most of them said often think about work at weekends and does not even know when they work and when they do not work. They also admit that they try not to think about working by relaxation, but it is not easy.

An interesting insight brought answers to the field of work with modern technologies. Respondents mostly talked about technologies as something quite common to them, but not as common to others. There was complete agreement among respondents on the use of modern technologies. They marked themselves as advanced users and maybe the most active on the Internet from the whole family business.

Overall work motivation

Main part of the interviews was conducted to identify the factors that led respondents to enter and continue working in their parents' family business. From the interviews of all interviewees, it can be stated that the crucial role of continuing their work is to meet the need to combine working life with personal.

The interviewees said that their work in a family business allows them to organize time per themselves. That was, per most of the respondents, one of the key factors that motivated them to enter the family business. This is associated with another often-mentioned benefit - flexibility. Organization of work per their selves, but also the possibility of switching to another job and the opportunity to try everything. Without bureaucratic impediments and internal regulations, it is easier for them to quote.

Another reason was the possibility of self-development. Respondents recognize that they are educated in their fields. In their words, they have access to less information, so they are more actively searching for them. Their parents are more easily allowed to learn more than they would in a non-family business.

Like the previous stimulus, career growth has been mentioned. Answers on this subject depended on the job position the examiner found when entering the company, compared to his current situation. Everyone who saw a certain career shift mentioned this thing as important for staying in a family business.

Another reason for joining the family was the effort to maintain a family tradition. The responses all agreed that they have a big emotional attitude to the company and want to act at least if their parents. Tradition is, per their words, unrelated to the organization of their business affairs, but it motivates them to stay in the company.

Conclusion

By comparing the results of the surveys and the actual examination, many conclusions can be drawn. Studies show that for members of the generation Y are particularly important in their working life work-life balance, flexibility, personal development and career growth, meaningful work, and financial rewards. Within the investigation, itself, these factors have also emerged as important. Other factors that decide to enter or work in a family business are their own will to continue family tradition.
Per the survey, work-life balance is achieved. The organization of working time by one's own person leads to the fulfillment of both work-life balance and flexibility. Career growth is not planned in more

detail in the surveyed companies, but one can see a gradual approach to the target position. The meaningfulness of Y's work is that their work is beneficial to the environment and the people their parents employ. These factors coincide with the results of generational surveys. Financial reward is an important aspect, but its weight has not been sufficiently verified. Therefore, it can not be stated whether it can be categorically included among the main motivational factors.

The limitation of this research is that it can not be determined whether the present generation entering the labor market is significantly different from other generations. The result of this investigation can only be applied to a limited part of the population and there is no possibility of comparison with past generations. Further research could therefore be dealt with by other generations and their reasons.

In conclusion, generations Y enter their parents' businesses on the same criteria as non-family companies, but with the added incentive to maintain tradition. It has been shown for gens Y are particularly important in their working life to combine work and private life, flexibility, personal development and career growth, meaningful work, and a continuation of family tradition. This motivation factor distinguishes the investigated person from the rest of their peers. It should therefore be considered in any further work with the Y generation in family businesses.

Is Growth In The European Union Countries Green?

Armand Kasztelan, University of Life Sciences, Department of Economics and Agribusiness, Lublin, Poland, armand.kasztelan@up.lublin.pl

Abstract

The aim of this paper is to analyze the level of 'greening' growth in European Union countries. Research was carried out based on the taxonomic linear ordering method, which enabled multidimensional comparative analysis of multi-featured objects. It is based on indicators related to economic, social, and environmental issues, according to the OECD methodology. The adopted method made it possible to evaluate the studied phenomenon as a whole, providing grounds for assigning the 21 selected countries into five groups, characterized by similar levels of green growth. The conducted analysis shows that Germany was characterized by the highest level of 'greening' growth, while Poland received the lowest rating. Generalizing the results of the study, it can be stated that the degree of greening the economic growth of EU countries is insufficient, especially in the context of pursuing the long-term goal which is the entrance to the path of sustainable development.

Keywords: green growth; sustainable development; taxonomic linear ordering method.

Introduction

In the past decade governments of EU member states have been under pressure to present a credible exit strategy to address the financial and economic crisis (2007-2008). Paradoxically, the crisis also provided a chance to revive activities aiming at a low-emission economy. It contributed to verification and reforms of such sector policies which so far had been both costly and harmful to the environment. (Huhtanen, 2010, s. 91–92; OECD, 2009b)

In the age of 'bootstrapping', the recommendations of OECD concerning resolution of both climatic issues and other environmental challenges at minimum cost seem current and adequate. Many countries use the crisis as an opportunity to implement the ecological tax reform which, as a source of additional budget receipts, at the same time will reduce labour tax burdens (OECD, 2009a, p.2). Mechanisms such as environmental taxes and tradable allowances systems help relieve tax burdens (or at least a part of such burdens) from corporate and personal income tax and social insurance contributions. Taxes on energy and CO2 emissions can also become a natural element of a broader budget consolidation package providing an attractive alternative to increasing taxes on payroll or revenues from economic activity and to cutting down on public expenses (OECD, 2011b, s.4).

The implementation of reforms in OECD countries commenced in the first place under the so-called green growth strategy. Recently, the term 'green growth' has rapidly encroached on the international public debate. The concept was rolled out in 2005 by the United Nations Economic and Social Commission for Asia and the Pacific (UNESCAP) as a way of finding options for introducing a low-

emission model of sustainable development for fast developing Asian countries (Satbyul, Ho, Yeora, 2014, s. 37–38; ESCAP, 2005).

As a consequence of the last financial crisis interest in green growth has increased among politicians and scientists. The term that was rarely used before 2008 is now a leading discussion point for many international institutions. The World Bank together with five other multilateral development banks agreed to implement the concept of green growth (The World Bank, 2012; OECD, 2012). In turn, the Organization for Economic Cooperation and Development (OECD) developed the assumptions of Green Growth Strategy (the Strategy) consisting of four documents: Towards Green Growth, Towards Green Growth: Monitoring Progress – OECD Indicators, Tools for Delivering on Green Growth and Towards Green Growth: A summary for policy makers (OECD 2011a, b, c, d). In addition, a new international body – the Global Green Growth Institute, supported by many governments, was set up. Its mission is providing respective countries with advice related to the implementation of the assumptions of the concept. Moreover, a decision to organize cyclic meetings at the highest level and to create a cooperation network was made (Global Green Growth Forum, Green Growth Leaders). During G-20 summits in France and Mexico in 2011 and 2012 the world's largest economies made a commitment to promote the idea of green growth (Jacobs, 2012, s. 4).

In 2012, under Mexican presidency, the G20 forum introduced a term 'inclusive green growth', that is, green growth fostering social inclusion as a cross-section priority of the G20 development agenda. During the meeting in Seoul on 19–20 March 2012 the necessity to concentrate activities for the sake of inclusive green growth was emphasized, indicating that it was the key element of achieving long-term sustainable development (OECD, 2015).

Generally, two main conditions that determine the dynamic development of the green growth concept can be identified. First, there is a growing fear of environmental instability of conventional paths of economic growth and the related risk of irreversible change in the fundamental environmental base required to maintain the achieved level of economic welfare. The increasing awareness of imminent climatic crisis brought attention to the fact that environment and economy cannot be treated separately any longer. The existing hazards point to the need for considerable modification of consumer behaviour, structure of industry and technologies in use.

Secondly, the financial and economic crisis created a field for formulating agendas encouraging reconstruction of growth on more ecological and socially sustainable grounds. The high level of economic stagnation means that the alternative cost of 'green' investments is temporarily limited, so the fiscal stimulus packages introduced by governments in response to the crisis contain many measures oriented in particular at 'green' growth. Emphasis was put on the necessity for a strategic approach in order to ensure that upon exit from the crisis and at the following stage the implemented policies are most adequate in terms of economic efficiency, environmental integrity and social justice and are consistent both at a national and international level (OECD, 2010, s. 13; Reilly, 2012, s. S86).

Also, a third reason is given (although not officially) for increased interest in the green growth concept, namely the recently decreasing impact of the sustainable development concept on the development of economic policy. Immediately after the Earth Summit in 1992 the principle of sustainable development was commonly adopted by governments and in many countries it had a significant impact on priority treatment of environmental goals. In the 1990s a sudden 'abundance' of regulations concerning environmental protection, and in the business sector – procedures related to implementation of

environmental management – could be observed. However, at the beginning of the new millennium the global trend towards sustainable development slowed down significantly. What is more, it turned out that practical measures undertaken by states in that respect were not sufficient enough to prevent global changes in the environment. Sustainable development became just one of many obligations of governments. Simultaneously, they realized that in a world where the increase in GDP (and the employment it generates) remains the main driving force for voters and businesses and a priority of government policy, it would be a mistake to focus environmental discussion only on the existing barriers and costs and the related need for restraining economic growth. This is particularly significant with reference to issues of climatic changes where the main care point is the economic costs of mitigating climatic changes and international negotiations concerning the global distribution of associated burdens. Therefore, the fundamental assumption of the green growth concept is departing from the negative and politically unattractive perception of environmental issues in economy (Stern, 2007; Jacobs, 2012, s. 6).

It should be also remembered that green growth, despite being a separate category, is not in opposition to the assumptions of sustainable development. According to a manual prepared by the European Commission, the concept of green growth was developed in order to supplement the concept of sustainable development (European Commission, 2012). With regard to the position of UNO, it can be stated that green growth is seen as an efficient tool to ensure long-term sustainable development. In addition, taking into account the goal we should be aiming at, that is, a 'green' economy built on solid grounds, the following definition of green growth can be proposed: economic growth which takes into account rational utilisation of natural capital, prevents and reduces pollution, and creates chances to improve the overall social welfare by building a 'green' economy, making long-term sustainable development possible. Such a treatment makes it possible to emphasize the integrity of the trio: green growth – green economy – sustainable development (Kasztelan, 2015b; 2017a).

Literature most often quotes the definition proposed by OECD, being the institution most involved in promoting this concept throughout the world. According to the report of the OECD (2017), 'green growth is about fostering and development, while ensuring that natural assets continue to provide the resources and environmental service on which our well-being relies'. Green growth strategies developed at the national level are to encourage businesses and consumers in environmentally friendly behaviours, to improve the optimal reallocation of jobs, capital, and technology toward greener activities, and to provide motivation for the development of eco-innovation (OECD, 2011a; Kijek, 2013; Kijek and Kasztelan, 2013).

The OECD proposed a set of indicators for defining and tracking changes towards green growth. In 2011, the first OECD report was published, showing the conceptual framework, the initial proposal of a set of 30 key indicators of green growth and the results for selected indicators from the OECD database. (OECD, 2011b). In 2014 the second version of the report was published, based on the national sets of green growth indicators ((Federal Statistical Office, 2013; Havranek and Sidorov, 2011; Hak et al., 2014; Statistics Korea, 2012; Statistics Netherlands, 2011 and 2013). A new report proposed 41 core indicators grouped around four main objectives: establishing a low carbon, resource-efficient economy; maintaining the natural asset base; improving people's quality of life; and implementing appropriate policy measures and realizing the economic opportunities that green growth provides. In addition, in order to facilitate communication with decision makers, media, and society, it was decided to develop a representative set of six key indicators. They will allow monitoring several key elements of the concept of green growth,

that is, carbon and material productivity, environmentally adjusted multifactor productivity, a natural resource index, changes in land use and cover, and population exposure to air pollution (OECD, 2014).

The latest report was published in June 2017. It updates but also extends the set of indicators presented in the previous editions of the document. In comparison to 2014, methodological changes include: indicators taking into account in economic efficiency measures the degree of natural resources consumption and the scale of pollutant emissions; revised indicators of technological innovativeness and the level of environmentally harmful subsidies used; improved indicators of human exposure to air pollution and related economic costs (OECD, 2017).

In the updated OECD database, 99 detailed green growth indicators can be extracted, based on the experiences of the member states. However, there is no one synthetic metric that would allow one to evaluate and compare the phenomenon at an international level. Green growth of a given country can be measured but expressing it with one universal meter requires application of a proper method. This amounts to the formation of an aggregate indicator, also called a synthetic variable, which is the basis for structuring examined objects by the level of multi-feature phenomena.

Related surveys carried out so far covered, among other things, an evaluation of green growth in 21 selected OECD countries and were based on Hellwig's model. Analyses involved 33 indicators of green growth for the years 2010-2014 (Kasztelan, 2017b). In addition, in South Korea surveys aimed at utilising 12 OECD framework indicators for comparing green growth strategies implemented in 30 countries. (Satbyul, Ho, Yeora, 2014).

The main goal of this paper is to evaluate the green growth of selected EU countries, based on the set of OECD indicators and taxonomic linear ordering method enabling multidimensional comparative analysis of multi-featured objects. This type of analysis provides answers to the following questions: (1) At what stage are the individual countries placed in terms of implementing the green growth assumptions? (2) What is the overall situation of EU countries according to the studied phenomenon? (3) What are the weak points of greening growth in the analyzed countries? For the purposes of implementing the main research objective, the article utilises the literature method, comparative method, and deductive reasoning. The article concludes with a summary identifying the areas for further research.

Research Methodology

The assessment of the degree of "greening" the economic growth has been carried out based on the taxonomic linear ordering method (taxonomic classification) (Hellwig 1968). Taxonomic procedures are used in the study of complex phenomena that cannot be measured directly (e.g. green growth of countries). For this purpose synthetic measures are constructed. Each of the multidimensional spatial objects (e.g. country) is assigned a metric value that allows for their linear ordering (Kijek, A. 2013). Taxonomic analysis provides an estimate of the level of diversity of objects (e.g., countries) described by a set of statistical characteristics (e.g., indicators). Linear ordering is used to establish a hierarchy of individual objects based on their distance from a reference (e.g., the country for which a particular index is a reference). In a linear hierarchy the maximum degree is 1 (Łogwiniuk, 2011).
Evaluation of the green growth of the EU countries was conducted based on five groups of indicators (table 1). The reference years 2011–2015 were chosen due to the rule of the last available year. Diagnostic variables defining the level of green growth for particular countries were adjusted in an

attempt to meet two criteria: substantive and formal. Substantive indicators selection was based on literature studies, first of all strategic documents of the OECD (2011 b, c, d; 2014) and review of OECD databases. On this basis, 27 countries (EU members, no data for Cyprus) and 99 diagnostic variables were chosen.

The next step was to check if they meet formal criteria, that is, whether they are measurable, complete, and ensure comparability. Firstly, from the database minor and difficult comparable indicators were eliminated. At this stage, the number of indicators was reduced to 73. In the next step, after analyzing the initial data matrix, the following countries were eliminated due to large information gaps: Bulgaria, Croatia, Malta, Romania, Latvia and Lithuania. Furthermore, given the lack of data for the individual indicators, their number was limited to 50.

Ultimately, 21 countries and 50 diagnostic variables were selected for the green growth analysis (table 1). Among the selected variables, twelve were considered to be smaller-the-better (de-stimulants) reducing the synthetic measure of green growth, whereas the rest were regarded as larger-the-better (stimulants) characteristics having a positive influence on the measure.

Stimulants (selected indicators) are explanatory (independent) variables whose increased values cause an increased value in the dependent variable (green growth of countries), while de-stimulants are explanatory variables whose increased values induce a decrease in the value of the dependent variable. Since the set of independent variables (metrics) contains variables that cannot be aggregated directly using appropriate standardization, normalization formulas were applied. Among the normalization formulas, unitarization methods were selected based on the interval of a normalized variable. This was dictated by the fact that it can be used for three types of variables: stimulants, de-stimulants, and nominants. The zero unitarization method was used as follows (Kijek A., 2013; Kukuła, 2000):

– For stimulants:

$$z_{ik}^{t} = \frac{x_{ik}^{t} - \min\limits_{t}\min\limits_{i}\{x_{ik}^{t}\}}{\max\limits_{t}\max\limits_{i}\{x_{ik}^{t}\} - \min\limits_{t}\min\limits_{i}\{x_{ik}^{t}\}} \tag{1}$$

– For de-stimulants:

$$z_{ik}^{t} = \frac{\max\limits_{t}\max\limits_{i}\{x_{ik}^{t}\} - x_{ik}^{t}}{\max\limits_{t}\max\limits_{i}\{x_{ik}^{t}\} - \min\limits_{t}\min\limits_{i}\{x_{ik}^{t}\}} \tag{2}$$

where:

z_{ik}^{t} is the normalized value of the *k*th characteristic in the *i*th object in the *t* period (t = 1, 2, ..., T)

x_{ik}^{t} is the initial value of the *k*th characteristic in the *i*th object in *t* period

Diagnostic features normalized in the abovementioned way take the value from the interval [0; 1]. The closer the value to unity, the better the situation in terms of the investigated feature, and the closer the value to zero, the worse the situation.

Among the methods for creating synthetic metrics, a non-reference method with the system of constant weights was selected, which was influenced by the previously used normalization method of the investigated features. Taxonomic metrics of green growth for the respective periods were built as follows:

$$z_i^t = \frac{1}{k}\sum_{k=1}^{m} z_{ik}^t \tag{3}$$

Table 1: Selected indicators of green growth

Indicators group	Indicators sub-group	Indicator symbol	Indicator name
ENVIRONMENTAL AND RESOURCE PRODUCTIVITY	CO_2 productivity	x_1	Production-based CO_2 productivity, GDP per unit of energy-related CO_2 emissions (US dollars per kilogram, 2010)
		x_2	Production-based CO_2 emissions, Index 2000=100
		x_3	Demand-based CO2 productivity, GDP per unit of energy-related CO2 emissions (US dollars per kilogram, 2010)
		x_4	Demand-based CO2 emissions, Index 2000=100
	Energy productivity	x_5	Energy productivity, GDP per unit of TPES (US Dollar, 2010)
		x_6	Energy intensity, TPES per capita (Tonnes of oil equivalent)
		x_7	Total primary energy supply, Index 2000=100
		x_8	Renewable energy supply, % TPES (Percentage)
		x_9	Renewable electricity, % total electricity generation (Percentage)
	Non-energy material productivity	x_{10}	Non-energy material productivity, GDP per unit of DMC (US dollars per kilogram, 2010)
		x_{11}	Biomass, % of DMC (Percentage)
		x_{12}	Municipal waste generated, kg per capita (Kilograms per capita)
		x_{13}	Municipal waste recycled or composted, % treated waste (Percentage)
	Environmentally adjusted multifactor productivity	x_{14}	Environmentally adjusted multifactor productivity growth (Percentage points)
		x_{15}	Contribution of natural capital (Percentage points)
NATURAL ASSET BASE	Freshwater resources	x_{16}	Total renewable freshwater per capita (Cubic metres per capita)
	Land resources	x_{17}	Forest, % total land area (Percentage)
	Forest resources	x_{18}	Forests under sustainable management certification, % total forest area (Percentage)
ENVIRONMENTAL DIMENSION OF QUALITY OF LIFE	Exposure to air pollution	x_{19}	Mean population exposure to PM2.5 (Micrograms per cubic metre)
		x_{20}	Percentage of population exposed to more than 10 micrograms/m3
		x_{21}	Mortality from exposure to PM2.5 (Per 1 000 000 inhabitants)
	Access to sewage treatment and drinking water	x_{22}	Population connected to public sewerage, % total population (Percentage)
		x_{23}	Population with access to improved sanitation, % total population (Percentage)
		x_{24}	Population with access to improved drinking water sources, % total population (Percentage)
ECONOMIC OPPORTUNITIES AND POLICY RESPONSES	Technology and innovation: Patents	x_{25}	Development of environment-related technologies, % all technologies (Percentage)
		x_{26}	Relative advantage in environment-related technology (Ratio)
		x_{27}	Development of environment-related technologies, % inventions worldwide (Percentage)
		x_{28}	Development of environment-related technologies, inventions per capita

	Technology and innovation: R&D	x_{29}	Environmentally related government R&D budget, % total government R&D (Percentage)
	International financial flows: Official Development Assistance	x_{30}	Environmentally related ODA, % total ODA
		x_{31}	ODA - all sectors - biodiversity, % total ODA
		x_{32}	ODA - all sectors - climate change mitigation, % total ODA
		x_{33}	ODA - all sectors - climate change adaptation, % total ODA
		x_{34}	ODA - all sectors - desertification, % total ODA
		x_{35}	ODA - renewable energy sector, % total allocable ODA
		x_{36}	ODA - water supply and sanitation sector, % total allocable ODA
		x_{37}	ODA - environment sector, % total allocable ODA
		x_{38}	Net ODA provided, % GNI
	Environmental taxes and transfers	x_{39}	Environmentally related taxes, % GDP
		x_{40}	Environmentally related taxes, % total tax revenue
		x_{41}	Petrol tax, USD per litre, 2010
		x_{42}	Petrol tax, % end-user price
		x_{43}	Diesel tax, USD per litre, 2010
		x_{44}	Diesel tax, % end-user price
		x_{45}	Total fossil fuel support, % of total tax revenue
SOCIO-ECONOMIC CONTEXT		x_{46}	Real GDP, Index 2000=100
		x_{47}	Real GDP per capita (US Dollar, 2010)
		x_{48}	Population density, inhabitants per km^2
		x_{49}	Labour tax revenue, % GDP
		x_{50}	Labour tax revenue, % total tax revenue

Source: own elaboration based on OECD database.

The procedure chosen for evaluating the green growth provided multidimensional comparative analysis, allowing comparison of multi-featured objects. Taxonomic meters were applied, which replaced research description using a set of diagnostic features with one aggregate volume that is a synthetic variable. It allowed a comparison between selected member states of the EU providing grounds for classifying them into uniform groups characterized by similar levels of green growth. According to the values of the z_i indicator the EU countries were assigned to one of the five groups with regard to their level of green growth. Group I consisted of member states with the highest while group V was with the lowest level of green growth.

Results

The level of green growth in the selected 21 European Union countries was evaluated based on 50 variables, and the outcomes of the analysis were presented in Table 2. The conducted analysis shows that Germany was characterized by the highest level of 'greening' growth. The taxonomic metric of this country was estimated at 0.4873. Five classes of countries were distinguished that differ in the level of green growth. Besides Germany, Group I included: Denmark, Great Britain, Sweden and France. The lowest evaluation of the studied phenomenon among all 21 member states was Poland for which zi indicator amounted to a mere 0.2906. It is worth noting that none of the examined countries recorded at least an average level (0.5000) of a synthetic green growth meter.

Table 2: Classification of 21 EU member states according to the value of the synthetic measure describing the level of green growth

Group number	The number of countries in the group	The level of green growth	OECD countries
I	5	above 0,4501	Germany (0.4873), Denmark (0.4866), United Kingdom (0.4865), Sweden (0.4796), France (0.4769)
II	4	from 0,4001 to 0,4500	Finland (0.4272), Italy (0.4082), Ireland (0.4076), Belgium (0.4075)
III	7	from 0,3501 to 0,4000	Spain (0.3978), Portugal (0.3836), Luxembourg (0.3758), Hungary (0.3754), the Netherlands (0.3729), Austria (0.3635), Slovak Republic (0.3539)
IV	4	from 0,3001 to 0,3500	Slovenia (0.3375), Czech Republic (0.3303), Estonia (0.3294), Greece (0.3173)
V	1	below 0,3000	Poland (0.2906)

Source: author's calculation.

An extended analysis of respective indicators showed that in all studied countries only 14 (28%) indicators presented outstanding (higher than 0.5000) standardized average values. The worst case recorded was the development of environmental technologies (0.1080) and certain indicators referring to international financing cash flows for the benefit of environment protection: % of total allocable ODA on environment sector (0.1529), % of total allocable ODA on renewable energy sector (0.1808) and % of total ODA on biodiversity (0.1862).

Foreign sources of funding, both public and private, may be particularly useful for those countries that have problems acquiring the national funds. Official development assistance (ODA) is an important source of government-funded international financial flows. It can help catalyze investment for pro-environmental projects and technologies, thus realizing also general development goals. It is also an important factor for the flow international know-how (OECD, 2017).

The results of surveys also indicate that the EU member states have low environmental taxes, including in the first place fuel taxes. This is testified by the values of standardized average taxes on diesel (0.1714) and petrol (0.1750) calculated as USD/litre, as well as the low share of environmental taxes in overall tax revenues (0.2059). In comparison to regulation instruments such as emission limits or mandatory technology norms, application of environmental taxes contributes to achieving environmental goals by polluters at minimum cost. In addition, revenues from ecological taxes foster financial consolidation and reduction of other burdens (e.g. taxes on labour and capital).

On the other hand, if we wish to identify areas with reference to which high standardized average values of synthetic indicator measures were recorded, without any doubt we should mention indicators describing the percentage of population having access to wastewater treatment plants and good quality drinking water (more than 0.8000). Other standardized and averaged values of synthetic measures of the indicators did not exceed 0.7000 and ranged from 0.2241 to 0.6804.

Conclusion

The proposed activities which put economic development and environmental quality together as alternatives can lead to considerable controversies. On the other hand, progress towards green growth offers a chance of a wider consensus and acceptance in that respect. At the time when many governments face increasing environmental hazards, apart from constant pressure to generate economic development, the green growth policy provides societies with chances to achieve the maximum return on investment in economic and environmental progress.

The results of the study show that much still remains to be done in sustainable greening of the economic growth in EU countries. The results of the research presented in this article were based on green growth indicators selected from the OECD database. The use of the taxonomic linear ordering method in the research, which belongs to the group of multidimensional taxonomic methods, allowed the classification of the selected EU countries into one of five groups identified based on their green growth level. Taking into account the adopted research methodology it can be stated that none of the countries surveyed is even half way to achieving fully green growth.

The obtained results support the usefulness of synthetic metrics for evaluating the level of green growth at the national level. It should be stressed, however, that the research was based on 50 out of 99 indicators included in the OECD database. There is, therefore, a significant information gap with regard to specific indicators. Due to better data availability, it would be possible to expand the set of indicators for the analysis, as well as the number of countries, which in turn would lead to more comprehensive evaluation of green growth.

Abstract

In conventional insurance, the basis of the contract is not mutual help where each of the policy holders contribute money to help one another when they face difficulties; rather the insured transfers their risks onto the insurer, who in return transfers the same risks onto the reinsurance operators. Hence, the contractual relationship in conventional insurance is not based on risk sharing where each and every one supports and helps the other, but instead on risk transfer which fosters an atmosphere of selfishness in protecting each individual party. Furthermore, the conventional insurance practice is embedded with unethical elements, which include but are not limited to: investment in *Shari'ah* non-complaint elements, gambling, uncertainty, and usury. In essence, it is some of the practices related to insurance that are against *Shari'ah*, not the concept of insurance itself. When something is not in conformity with *Shari'ah*, unethical consequences arise. In an effort to avoid the unethical and *Shari'ah* non-complaint issues in insurance practices, one practical solution is to replace conventional insurance with a *Shari'ah* compliant version known as Takaful. To ensure the preservation of a harmonious society, *Shari'ah* aims to mould our conducts in all aspects of our rituals and daily life activities. Takaful operators need not to be anxious of loss of profits since *Shari'ah* compliance does not equate to financial loss because Islam actually encourages business activities and trade where transactions are also compliant within the boundaries of *Shari'ah*. With Takaful functioning as an alternative counterpart to conventional insurance, solutions will be drawn up for many problems. For instance, major prohibited elements which include uncertainty, usury, and gambling will be eradicated. Additionally, prohibited business activities are steered away from Takaful scheme. What makes Takaful contracts totally unique compared to conventional insurance contracts is that the latter is based on the exchange of risk whereas the former is based on the concept of risk sharing. Setting aside the financial gains, moral and societal gains are also expected from Takaful where solidarity among the society is promoted with the concept of mutual cooperation put into action throughout the community.

Keywords: Risk Sharing, Solidarity, Takaful & Insurance

Introduction

Conventional insurance is based purely on the element of interest, whether it is life or general insurance (Salman, 2014; Salman & Htay, 2014; Ali et al., 2014; Kasim et al., 2015). The main objective of the insurance company is to generate interest income by investing its funds in traditional investment instruments. The policyholders have to pay surcharges if they fail to pay their premium on time. Moreover, when life insurance policy reaches its maturity or death claim, the amount payable under such policy is much more than the amount received by way of premium. Both in general and life insurance, the insurance funds are invested in instruments which are interest based (Qaiser, 2014).

Conventional insurance is based on the uncertainty whether it is life or general insurance (Htay & Salman, 2014; Kasim et al., 2015), whereby the policyholders pay the premium with the expectation that they will be able to claim in the case of misfortune and future loss. In this situation, it is not clear for what the policyholders are paying. The future loss is not sure, and hence, there exist uncertainty of the substance for which the policyholders are spending their money (El- Gamal, 2000; Kasim et al., 2015). Insurance involves gambling because it is the game of gain or loss. If the policyholders make the claims, it will be the loss for the insurance companies, and if there is no claim, the insurance companies make a profit and the policyholders will get nothing and lose their premium (Salman & Htay, 2014). Also, Actuaries use the statistical method to estimate the probability of gain for the insurance companies, and then the underwriting process and premium is determined. Hence, it is trying to ensure that insurance companies are in the upper hand to benefit more from the game (Kasim et al., 2016). When the insurance operator receives the premium, it will be invested in income-generating activities such as investment in short-term deposit or companies by buying the shares. The investment revenue is generated out of prohibited activities such as investing in the interest-bearing loan or liquor business. Conventional insurance operators are not currently restricted on where they can invest. They can invest anywhere regardless of Shari'ah compliance (Salman, 2014).

The practice of insurance involves interest, uncertainty, gambling and involvement in prohibited elements. Thus, Shari'ah scholars unanimously agreed on the prohibition of insurance and the Muslim scholars introduced *Takaful* to replace the conventional insurance. Therefore, this paper shows how Takaful is free from prohibited elements and based on risk sharing and solidarity.

What is Takaful: A Brief Introduction

If the history of takaful is examined, it can be traced back to Prophet Muhammad (PBUH). The concept of Al-Aqīlah was established by the Prophet (PBUH) in the decision given in a dispute among two women from the tribe of Huzail (Hassan, 2011; Salman et al., 2015 Salman et al., 2015). Al-Aqilah is a concept of mutual assistance by the members in the society whereby they jointly contribute for the payment of compensation the in the event that any of the member committed murder and has to pay compensation to deceased family. The notion and concept of takaful initiated from the idea and concept of Aqīlah and it has been experienced since the Prophet's (PBUH) through to the present day (Htay & Salman, 2013; Salman et al., 2017; Salman et al., 2017).

It is obvious that nowadays insurance has become a necessity rather than a luxury. Overall, the growth of the insurance industry is tremendous due to employment and regulatory requirements, which force us to buy it (Salman et al., 2017). The concept of insurance is against Islamic principles and also with ethical perspective (Htay & Salman, 2014). In Islam, something is not in line with Shari'ah, it will incur unethical consequences from the Islamic perspective. The objective of Shari'ah is to moul our conducts in all aspects of our ritual and daily life activities in order to ensure that we can stay in the harmonious environment and society.

For insurance to be a perfect tool, it should be transformed into Takaful. Since Takaful has been introduced as an alternative to conventional insurance. Takaful is an insurance product which is free from prohibited elements.

Takaful is based on the principle of *Taʿāwun* (cooperation) and *Tabarru* (mutual help) where the risk is shared collectively by members of a policy (Billah, 2002; Maysami & Williams, 2006; Usmani, 2007; Htay & Salman, 2013; Faruk & Rahaman, 2015; Htay & Salman, 2015).

The contract used in Takaful differs completely from conventional insurance because the former is based on risk sharing while the latter is based on the exchange of risk. The policyholders in Takaful are helping one another by mutually giving the protection in the event that anyone of them have met with a misfortune. With that, Takaful will be able to promote the solidarity and brotherhood among the society as well as practice of mutual and cooperative concept in the community.

Moreover, Takaful is based on mutual-cooperation which can bring the society together, inject the harmonized atmosphere, consider the needs of society for the long-term success and sustainability of the insurance operators. Consequently, unfairness and unethical practices can be minimized to some extent.

Regarding surplus distribution, surplus is profit in insurance and the insurance operators take it without sharing with the policy holders. However, in Takaful, the surplus is shared among the participants, and so it is a good and unique practice. Takaful contribution is structured in such as a way that some portion of the contribution is allocated to the risk sharing fund from which the claims are paid. This fund is based on the concept of risk sharing among the participants under the supervision of Takaful operators to help the financial needs of the participants according to the terms and conditions of Takaful contract. It can be assumed to be the unique features of Takaful because, in the conventional insurance, the policy holders pay the premium and consequently, it will be the revenue for the operators, and when there is any claim, it is recognised as expenses for the operators. Thus, in the later practice, there is no concept of risk sharing.

Takaful is not a religious product, but rather, it is a commercial product. It is suitable for anyone, regardless of religion. Its importance and significant role in the finance industry is tremendous. It can be remarked that takaful has a more value-added substance than insurance and it is the ultimate solution for anyone who is seeking financial protection for their potential misfortune.

Conclusion

Like insurance, takaful can provide financial assistance while remaining free from the prohibited elements involved in the insurance practices. In addition, Takaful is known as ethical insurance. It is based on the concept of mutual help and cooperation and it fosters solidarity and brotherhood among the participants.

Abstract

Whether it relates to personal life or business transactions, one of the main factors that make human being unsafe is misfortune. It has become custom that people who wish to transfer or mitigate the consequences of misfortune do so through the purchase of insurance premiums, which serve to compensate misfortune with financial aid when the conditions of such insurance coverage occur. There is no doubt that insurance is part and parcel of practices in all types of human societies as witnessed all over the globe. However, some negative elements, such as the uncertainty, usury and gambling, are often included into the practices of conventional insurance. Due to the unfair ethical nature of these aforementioned practices, conventional insurance is sometimes rejected since these practices are against the teachings of Islam. In order to benefit from insurance and steer away from such practices, an alternative form of insurance known as Takaful has been recommended by experts in Islamic finance. Since its introduction, Takaful seems to have gained momentum not just in Muslim majority lands but also in the non-Muslim countries. Hence, this study aims to discover to what extent has Takaful been accepted in the countries where Takaful products are presently offered, and to what extent is it potentially possible to introduce Takaful in non-Muslim countries. The sample countries included in this paper are Singapore, India, Canada, the USA, and Australia. By looking at the literature review, it was revealed that the availability of Islamic Banks in the non-Muslim countries is quite limited compared to those in Muslim majority countries. Furthermore, there is a huge potential to introduce and disseminate Takaful throughout India which is home to a Muslim population of 180 million people. By looking back at the existing and potential development of Takaful, the presence of significant numbers in the Muslim communities is one main factor that facilitates the potential expansion of Takaful into future market. Furthermore, it can be said that Takaful has the huge potential for growth with the existing Islamic banks in non-Muslim countries serving as jump boards for future Takaful products. Thus, the findings conclude that there is higher level of acceptability and possibility of Takaful in the conventional systems of Singapore, India, Canada, the USA, and Australia.

Keywords: Acceptability, Possibility, Takaful, Conventional Insurance

Introduction

Human activities and transactions are always vulnerable to error and mistake, which makes them exposed to risks. Risks may be minor, but all too often these risks may affect property, business transactions, and even lives in the form of hurdles and wounds. With such risks arising, the question on how to assist such unfortunate people is posed; with one of the solutions to tackle such situations is through insurance policies. The most sublime form of insurance aims at distributing liability among the concerned parties through understanding and mutual co-operation; hence potential victims can have peace of mind from such dangers and unforeseen risks can be steered away from.

Albeit beneficial, elements such as gambling, usury and uncertainty are entwined into the fabric of conventional insurance, which are deemed as unethical and prohibited under certain belief systems, including Islam. As noted by Billah (2007), specialists in Islamic finance proposed an alternative unconventional insurance, known as Takaful and based on ethics and fairness, mainly due to the fact that contemporary scholars of Islam concluded that conventional insurance is Islamically prohibited.

Takaful is based on the concept of Tabarru' and Taʿāwun (cooperation) where each and every member of the insurance policy collectively share the risk (Billah, 2002; Maysami & Williams, 2006; Usmani, 2007; Htay & Salman, 2013; Faruk & Rahaman, 2015; Htay & Salman, 2015).

Acknowledging its great benefits, Takaful is not exclusively for the Muslims. In addition to offering the assurance and protection that conventional insurance does, Takaful includes additional attractive features particularly the fact that Takaful is free from uncertainty, usury, and gambling. This makes Takaful more attractive compared to conventional insurance. Furthermore, Takaful opens the door to potential Muslim customers because some Muslims steer away from conventional insurance due to the prohibited elements, whereas Takaful is halal-certified, making it acceptable in Islam. Another unique feature of Takaful as compared to conventional insurance is that when there is a surplus then all parties, including the insured, are expected to share it with the Takaful operators. Htay and Salman (2013) reckoned that this additional benefit serves as a criterion between Takaful and conventional insurance.

The Milliman Research Report (2017) informs of a 13% to 14% growth per annum in the total contributions of the overall global Takaful market for the period of 2012-2015. Despite its strong growth, compared with the global insurance the market share of Takaful is comparatively low. However, this can be justified by acknowledging the fact that the Takaful industry is relatively new with only 35 years of presence in the market as compared to conventional insurance which dates back to more than a millennium.

The researchers are motivated to observe to what extent Takaful is accepted and possible to be introduced into conventional environment markets with ethics being a central part of Takaful. This study aims to examine the acceptability and possibility of introducing Takaful in Singapore, India, Canada, the USA, and Australia, as case studies to carry out this research.

Case studies of Takaful in Non-Muslim Countries

Singapore

The year 1995 marked the first time when Takaful products were first offered in Singapore where the Monetary Authority of Singapore (MAS) spearheads the role of regulating Takaful under the same framework as conventional insurance. Lian (2008) stated that this is the case because supervisory oversight and prudential concerns are largely common to both forms of insurance. To ensure a level playing field between conventional insurance and Takaful, MAS works closely with industry players to make sure that regulatory and tax incentives for both conventional products and *Shari'ah* compliant products are treated alike. This leads Muslim respondents in Singapore who observe Shari'ah compliance in financial products to be aware of the existence of Takaful (Maysami & Williams, 2006).

India

India offers a multitude of factors that attract the introduction of Takaful products. As observed by the IRDA Annual report (2010-2016) there is a decline in life insurance offices with a low life insurance penetration rate, serving as evidence for a diminishing demand for life insurance policies among Muslims in India. Surprisingly, India's investment in the Saudi Arabian market has been a success with Takaful

investment in the form of the Saudi Indian Company for Cooperative Insurance (SICCI), which is owned by an Indian public company called the LIC. This success ought to encourage the Indian government to consider and encourage the introduction of Takaful throughout India. Another factor found by Htay and Salman (2013) is related to demographics in India, whereby the second highest Muslim population in the world are based in India[i]. Most Muslims are reluctant to participate in forms of insurance which are prohibited in Islam given there is no Takaful alternatives in India. Adding to this argument, Salman et al. (2015) states that not only is India home to the second largest Muslim population in the world after China, India is also the second most populous country in the world with a population of 1.27 billion people[ii] providing huge potential to Takaful provider.

Canada

Many factors make Canada a fertile place for Takaful schemes, with some of these being: the highest growing rate in Canada being within the Muslim population, the acceptance of mutual insurance, favourable GDP growth in Canada, and the current existence of concept and faith based insurance practices, with the potential to integrate the concept of Takaful into the practice of Christian faith based insurance companies in addition to commercialized insurance companies (Htay & Salman, 2015). Ethics are enshrined in Takaful which makes it favourable in Canada, keeping in mind the diversity of Canada in its religious and cultural backgrounds. To curb the current moral hazard and adverse selection in some insurance policies, as revealed by Htay and Salman (2015), Takaful products serve as a good venture to consider, giving Canada much potential to serve as a hub for Islamic finance in North America.

The USA

Two elements that make the USA attractive to Takaful schemes is the potential for increased demand in the US and the stability of Islamic investments. Being a country of immigration, Takaful offers yet another opportunity for American Muslims to assimilate in the fabric of society at their own terms, acknowledging the need for a comprehensive policy on regulating the Takaful industry therein and encouraging future growth in the US market. The sense of second generation American Muslim's identity has dissolved into the American fabric but is retained in the form of religious adherence. While the US market has traditionally focused on three separate sectors of securities, banks, and insurance, Hashmi (2016), observed that the global growth of Islamic finance in these three areas has also occurred, where the researcher found that securities insurance policies in the form of Takaful in the form of Sukuk are among the fastest growing sectors and the US market can benefit greatly from these two.

Australia

Despite the small percentage of Muslims in Australia compared to other developed nations, Islamic financial services are growing and on the rise in the Australian market, which includes Takaful. Although the industry consisted of mutual operators in Muslim majority countries, the relative success of these schemes has lead these Islamic financial services to be introduced into developed non-Muslim countries with a growing involvement in the market. Despite this penetration, Australia poses certain challenges to Takaful providers. Jamie Reid (2008), predicts that if the Muslim population of Australia continues to grow then the viability of introducing Islamic financial services in Australia will become viable, both to mutual and profit financial institutions. Jalaluddin (2015) took the stance that Takaful services have the potential to create jobs for all Australians, Muslims and non-Muslims, and hold a high ability to generate profits since Australian Muslims are a segment of society that require ethical alternatives in insurance services to protect their properties and belongings.

Conclusion

In this paper, a few developed countries have been selected as case studies to project the potential of the Takaful industry as an alternative form of insurance. Bearing in mind that Takaful is suitable for both Muslim customers and non-Muslim due to ethical issues conventional insurance is steered away from by Muslims, Takaful appeals to a wider range of customers promising excellent potential and high rapid growth due to this wider coverage. Furthermore, the distribution of surplus among all the parties in a Takaful scheme, including the insured, makes it more attractive compared to conventional insurance. Parallel to Takaful, the increasing growth rate of Islamic banking also offers a field for Takaful operators because Islamic banks need protection for their depositors. Another opportunity for Takaful industrial players to penetrate the market is considering societies with a high growth of Muslims. As is the case of India and Singapore, countries with high Muslim populations where Islam is not the official religion and that they are the minority, offers a potential mass market for Takaful schemes, serving to saturate the urgent need of Muslims in these countries in the form of Islamic compliant financial products, particularly Takaful services. With high demand and low supply, more Islamic financial institution should be set up in these countries due to the limited number of Islamic financial institution therein, serving as a call to the major Takaful operators to take the initiative to explore these virgin markets that are yet to be given their full potential.

An Analysis of Local Search Engines in Europe With a Focus on the Czech Market

David Prantl, author, Plzeň, Czech Republic, prantld@kmo.zcu.cz

Abstract

There are numerous search engines on the Internet, thanks to which users can quickly access information from all over the world. One of the world's best-known search engines is Google; however, in Europe it has two local competitors – Yandex and Seznam.cz. This paper focuses on the Czech search engine, Seznam.cz, and an evaluation of its position in the Czech market as well as, on a wider scale, the European market. The analysis of the economic performance of Seznam.cz revealed that the company has excellent financial results. The two main search engines used by Czech Internet users are Seznam.cz and Google. Market research has indicated that while in the past the most widely used search engine was Seznam.cz, in recent years its share has been rapidly dropping, and since 2016 the majority of Czech Internet users have been using Google. The Seznam.cz Company has recently been transforming into a media empire and news server. With respect to the wide range of its services, the company can be expected to grow despite a decrease in its search engine market share.

Keywords: search, engines, Seznam.cz, local

Introduction

Search engines are a type of Internet website (Kotler, 2007). Tonkin (2016) considers Google to be the most successful one in the world. It uses very advanced algorithms for sorting websites, which can offer relevant results even for complex key phrases. Developing such an algorithm is very difficult. Google is one of the most valuable companies in the world (Levy, 2012). Search services sort information and are essential in today's society. It is very difficult to compete with such a large and valuable company. Despite this fact, several local search engines are faring well. In the article, we will focus on the search engine of the Seznam.cz Company, which for years has surpassed Google in the Czech market.

The Analysis of Search Services in European Countries

Google clearly dominates among web search services in the European market. The only exception is Russia, where the Yandex search engine is used more frequently. This is confirmed by statistics provided by the Alexa.com tool, which has been recommended as a suitable tool for evaluating website traffic by a number of studies (Bruce, Sedhain, 2006, Vaughan, Yang, 2013, Fishkin, 2015). The Yandex search engine also has a strong position in Ukraine, Belarus and Kazakhstan, although according to Alexa.com (2016), Google is the most widely used search engine in all these countries. However, according to Similarweb.com (2016), the most frequently used search engine in Kazakhstan and Belarus is Yandex. The Yandex Company also operates in the Turkish market, although its position there is the weakest among the countries mentioned above.

In most European countries, Google is not only the most widely used web search service, but also the most visited Internet website in general. According to Alexa.com (2016), only in Albania, Russia and Malta does a the most frequently visited website differ. In Russia, the top website is the social media site VK. In Albania, according to Alexa.com (2016), the most visited websites are local news servers. However, these statistics are not confirmed by Similarweb.com (2016), which names Google as the market leader in these countries.

Google's dominant position is strongest in Western European countries, where the second most frequently visited Internet website is often YouTube.com, also owned by Google. Third on the list is

Facebook.com. The most visited websites in Western Europe also include Amazon.com. Mainly in smaller European countries, local news websites and e-auction portals also rank high. This is due to the fact that in these countries global companies are not interested in having a strong market share (no local representation exists).

The prominent web search engines used in European countries are Google, Yandex and Seznam.cz (Table 1). The last of these has a strong position in the Czech market. No other web search service has made it to the top 5 most frequently visited websites in any European country (Alexa.com, 2016). According to Alexa.com (2016), the Seznam.cz search engine is the third most frequently visited website in the Czech market. The first two places are held by Google.com and the video portal YouTube.com. The same position of the Seznam.cz search engine in the Czech market is also confirmed by the service Similarweb.com (2016).

Table 1: List of European countries where Google is threatened by a local search engine

Country	Local search engine	Estimated total number of visits in September 2016 to the local search engine	Estimated total number of visits in September 2016 to Google
Russia	Yandex.ru	**2,415 million**	1,419 million
Ukraine	Yandex.ua	237 million	**421 million**
Czech Republic	Seznam.cz	178 million	**192 million**
Belarus	Yandex.by	**81 million**	69 million
Kazakhstan	Yandex.kz	**50 million**	35 million

Source: Similarweb.com (2016)

Apart from the Google search engine and the local search engines mentioned above, also operating in the European market is Microsoft's global search engine, Bing, as well as the Yahoo search engine. However, both of these search engines have a rather low market share in European countries (Rosoff, 2014).

According to a study (Paananen, 2012), Yandex's higher position compared to Google is attributed to the more advanced use of the Russian language (better knowledge of synonyms, declination, etc.) However, since 2012 Google has significantly improved its algorithms for foreign languages and thus a new study is needed. A study (Raddad, 2013) from 2013 already prefers Google to Yandex. The study conducted by Bihun (2017) compared the speed of the Google and Yandex search engines. Google displayed the results faster and thus received a higher rating. The main reason for the dominant position of Yandex over Google in Russia lies in the marketing activities of Yandex and the overall advantage of the fact that it operates on home turf (users tend to prefer local services).

No scientific study comparing Seznam.cz and Google has been conducted. Technical literature has not dealt with this search engine. The author of this paper will be one of the first researchers to focus on the Seznam.cz Company and its search engine in the following text.

Brief information about ICT in the Czech Republic

The Czech Republic is a country in the Central Europe with population of 10.56 million. The gross domestic product is USD 192,9 billion, inflation 0,7 % and unemployment 5,5 % (CSO, 2017). ICT has played an increasingly important role in economics growth.

The table no 1 presents the basic data about households, individuals and enterprises and ICT.

Table 1: Households, individuals, enterprises and ICT in the Czech Republic

Items	Percent (2016)
Households with a computer in the Czech Republic	75,6
Households with Internet access in the Czech Republic	76,1
Mobile phones in households	98 (2015)
Individuals in the Czech Rep. using the Internet	76,5
Individuals in the Czech Rep. using Internet banking	47,4
Individuals in the Czech Republic purchasing over the Internet	26,7
Individuals in the Czech Republic reading on-line news	62,2
Enterprises in the Czech Rep. with the Internet	93,6
Enterprises in the Czech Republic with a Website	82,2

Resource: CSO (2017)

In the behavior of the population groups, however, are differences. For example: Individuals in the CZ using the Internet, age group 16 – 24 group = 96,3 %, Individuals in the CZ using Internet banking, age group 35 – 44 = 71 % and Individuals in the CZ purchasing over the Internet, age group 25 – 34 = 72 % (in the last 12 months).

For the purpose of our article, it is also worth mentioning that in the Czech Republic it is a good level of information technology education at schools (Eger, 2015, Rambousek, Štípek, Wildová, 2015) and ICT is used also in company training and lifelong learning (Eger, Egerová, 2013).

The Networked Readiness Index, that comprises four components which measures the environment for ICT, the readiness of a society to use ICT, the actual usage of all main stakeholders and the impact that ICT generate in the economy and in society, was 4,7, rank 36 (World Economic Forum, 2016).

The Czech Republic has one of the most dynamic ICT markets among Central European Countries. The ICT development index 2016 for the CZ was 7,20, rank 32 (LTU, 2017). The Czech Republic is one of Europe' s top locations for ICT investments. The list of successful investors in the country involves Microsoft, Skype, DHL, Tieto, Red Hat, SolarWinds, IBM etc. Two of the world's few antivirus-software providers, AVAST and AVG, grew out of this environment. Of all the countries where the Latin alphabet is used, the Czech Republic is the only one whose domestic web search provider, Seznam.cz, is challenging Google on the local market (CzechInvest, 2015).

The history of the Seznam.cz Company

The Czech portal Seznam.cz was first presented on April 30, 1996, by its founder, Ivo Lukačovič (Peterka, 2016). At that time, the Czech Internet had only recently been established and had few users. It was often available only to the academic sphere, where it was used by students to create websites aimed at providing entertainment. Then student Ivo Lukačovič was no exception when in 1995 he created a fun website about Jára Cimrman (a fictitious figure of a Czech genius, created as a practical joke by Jiří Šebánek and Zdeněk Svěrák and now a prominent phenomenon in Czech culture). With his website dedicated to Jára Cimrman, Ivo Lukačovič realized the major problem of a website not being indexed by a search engine, which made it very difficult to find on the Internet (Peterka, 2016). There was no search engine on the Czech Internet and for the small number of Czech websites, it would have been quite useless and very difficult to create. Moreover, the authors of Jára Cimrman's character forbade Lukačovič to continue developing his seemingly official website about the fictitious figure (Seznam.cz, 2017).

Instead of the fun website, Ivo Lukačovič decided to create a sort of website catalogue, Seznam.cz, which was to contain, in an organized fashion, references to all websites on the Czech Internet and be a kind of portal for Czech users of the Internet (Peterka, 2005). He modeled Seznam.cz on the American website Yahoo and his website received a favorable response. A year later, Ivo Lukačovič added the site's own search engine to Seznam.cz (originally, users of full text search were redirected

to the AltaVista website), which searched and indexed Czech websites. Seznam.cz quickly continued to add further services, following the model of Yahoo. These included, for example, email and an entertainment site.

At the beginning, Seznam.cz was not very profitable (Zeman, 2004). Advertisers purchased advertising on Seznam.cz out of friendship and as financial support. At the time, there were very few Internet users and companies did not yet understand this medium. Advertising on the Seznam.cz homepage cost a mere CZK 4,800 per month (Zeman, 2004). Ivo Lukačovič created custom websites for others and used any profits to further develop Seznam.cz. A major improvement in the financial situation came with the arrival of other people in the company, who helped to build up a business plan. Seznam.cz launched sites dedicated to the sale of cars or real estate over the Internet and intensified the effort to explain to companies the advantages of online advertising. Already in 1998, the 100,000 visits a day mark was exceeded, and in the same year Seznam.cz became the most visited Czech website (Seznam.cz, 2017).

In 2000, Seznam.cz became a joint-stock company and the Swedish company Spray Ventures bought 30% of the company's shares for USD 2 million (Seznam.cz, 2017). This major investment helped the Seznam.cz Company to achieve major growth. In 2001, due to large investments in new services, Seznam.cz found itself in the red, though in 2002 the investments resulted in further growth. In 2002, Seznam.cz generated a profit of CZK 27 million and defended its position as the market leader of the Czech Internet. A substantial part of the revenue came from targeted advertising displayed with search results. Conventional banner advertising made up only 25% of the revenue.

In late 2003, the monthly traffic on the Seznam.cz homepage was, according to iAudit statistics, 2,265,566 actual users (Seznam.cz, 2017). What helped to increase the website traffic was the newly added news section of the portal. At that time, Seznam.cz had 146 employees, which represented a year-on-year increase of almost 200%. In 2004, the revenue doubled to more than CZK 500 million, and the number of users also grew. At the end of that year, the monthly traffic approached 3 million actual users. In 2005, Seznam.cz invested substantial resources in the development of new full-text web search (until then, the company depended on other companies, for a short period of time in 2002 also on Google). With its own web search service and advertising in it, in 2006 Seznam.cz achieved a revenue of over CZK 1 billion. In the coming years, Seznam.cz continued to grow thanks to acquisitions of other companies, adding new services and improving existing ones. In 2007, the company became an investor in the Stream.cz video-sharing website, a competitor to YouTube in the Czech market. As of 2010, Seznam.cz modified its websites to give them a responsive design (the design of a large number of services underwent a complete overhaul).

In 2016, Seznam.cz launched its own news portal called Seznam Zprávy (Seznam.cz, 2017). This news site focuses primarily on video news coverage and the editorial office is made up of prominent Czech journalists (Lupa.cz, 2016). Seznam.cz is thus becoming more of a media empire and responds to the drop in its search engine's market share compared to its competitor, Google.

Financial Results

The development of financial indicators between 2006 and 2015, according to Justice.cz (2017), is summarized in Figure 1. The revenue from sales of the company's products and services grew from CZK 1 billion in 2006 to nearly CZK 3.5 billion. The graph clearly shows that since 2011 the growth has not been as substantial as between 2006 and 2011. The company was profitable the entire time. In 2015, the company achieved its largest pretax profit of CZK 1 billion.

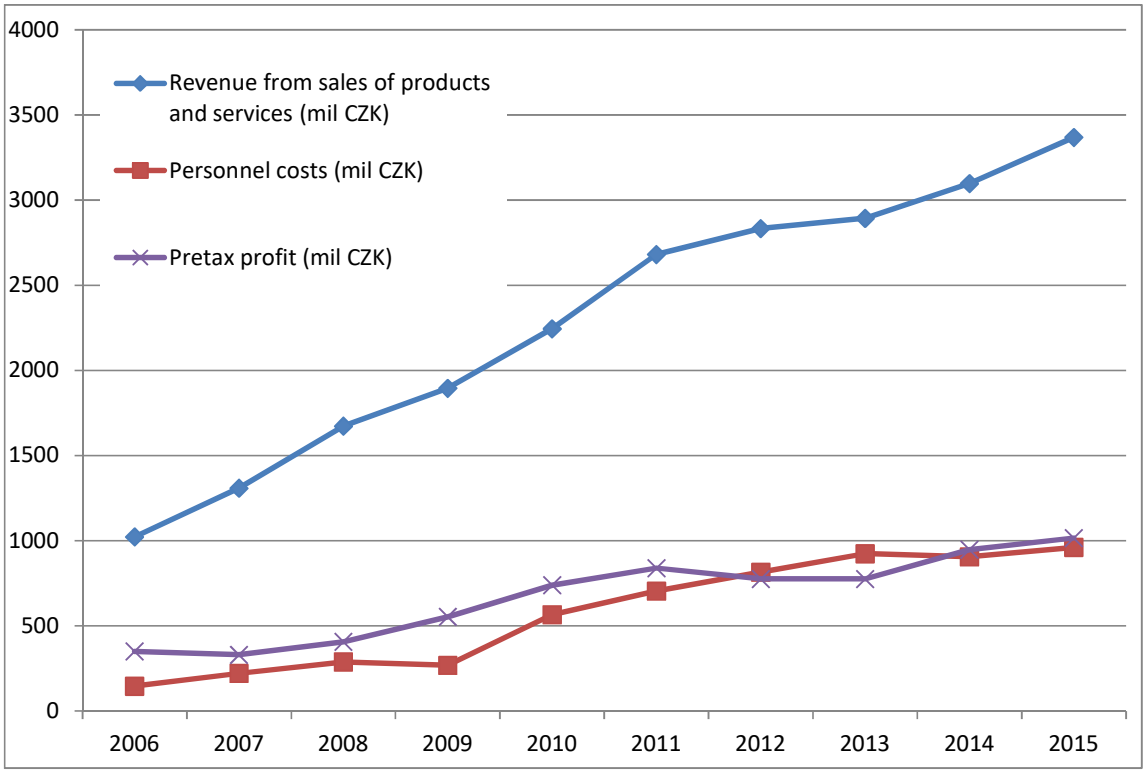

Figure 1: Selected financial indicators of Seznam.cz between 2006 and 2015

Source: Justice.cz (2017)

The development of the number of staff from 2006 to 2015 is shown in Figure 2. The substantial increase between the years 2009 and 2010 was caused by the merger of the sales department with the entire Seznam.cz Company. Since 2012, the company has had more than 1,000 people on staff and the number continued to grow gradually until 2014. In 2015, the number of employees slightly dropped.

Website Traffic to Seznam.Cz Sites

Apart from the search engine, the Seznam.cz domain currently encompasses several other services. These include e-mail, weather information, a TV guide and a dictionary. According to Netmonitor (2016), in September 2016 the Seznam.cz domain registered 385 million visits. The number of actual users that month was 6 million. Most users visit the Seznam.cz homepage, while approximately 35% of visitors use the webmail service. The weather information site is displayed by about 4% of the visitors, the TV guide by fewer than 2% and the dictionary is used by 1% of visitors.

The Seznam.cz Company is one of the co-owners of the popular news server Novinky.cz, which in September 2016 registered 107 million visits. Also popular is the online tabloid magazine Super.cz, with 80 million visits in September 2016. Another widely-read site is the sports news service Sport.cz, with website traffic of 41 million visits. Other essential services for Seznam.cz include the companies register at Firmy.cz and the maps at the Mapy.cz domain. These two services combined had website traffic of 30 million visits in September 2016. The last major website run by Seznam.cz is the video sharing portal Stream.cz, with website traffic of around 14 million visits. Unprofitable services of the Seznam.cz Company include the social media sites Lide.cz and Spoluzaci.cz. The traffic to these websites, which enjoyed a prominent position in the market between 2006 and 2010, i.e., before the arrival of Facebook, has been dropping continually.

Table 2: List of the most visited websites owned by Seznam.cz, source: Netmonitor (2016)

Website	Visits in September 2006 (millions)	Visits in September 2016 (millions)	Change between 2016 and 2006
Seznam.cz	126	386	306 %
Novinky.cz	33	107	324 %
Super.cz	23	79	343 %
Lide.cz	15	5	-300 %
Spoluzaci.cz	7	1	-700 %
Sport.cz	7	41	586 %
Mapy.cz	6	18	300 %
Firmy.cz	x	12	x
Stream.cz	x	14	x

A Comparison between the Seznam.Cz and Google Search Engines in the Market

Neither Seznam.cz nor Google provide exact statistics about the number of search queries or statistics regarding visitor traffic to the websites with their search engines. This makes it difficult to compare the two services, and the exact values of the market shares of these two search engines vary. Moreover, their market shares change over time, so it is necessary to conduct research regularly.

For the purpose of this article, its author chose two data sources to assess the market shares of the Seznam.cz and Google search engines in the Czech market. The first source is the visitor traffic to the popular weather portal www.in-pocasi.cz, which does not have a narrowly defined target group and thus can capture the situation in the entire market. The other source is the statistics of the Toplist.cz (2016) portal, which collects data from hundreds of different (mostly small) websites in the Czech Republic. Subject to the assessment was the traffic directed to the target websites from the two search engines, which is their primary function, and which will conveniently illustrate the overall visitor traffic to (and popularity of) the search engines tested.

The research data from the Czech weather portal www.in-pocasi.cz are summarized in Table 3. A total of 71 million visits between the years 2007 and 2017 were included in the research. From 2007 to 2010, is Seznam.cz has a clearly dominant position in terms of visitor traffic directed to the weather site from this search engine (in 2007 it was approximately seven times as much compared to Google). Between 2011 and 2014, there is a noticeable stagnation, with more or less stable market shares. However, since 2015 the market share of the Seznam.cz search engine has been dropping constantly, with Google taking over the dominant position. This is related to the current efforts of the Seznam.cz portal to transform itself into a media service.

Table 3: Development of the shares of the Google and Seznam.cz search engines in the overall organic traffic to the Czech weather portal

Year	Google's share	Seznam.cz's share
2007	12%	88%
2008	16%	84%
2009	24%	76%
2010	35%	65%
2011	45%	65%
2012	40%	60%
2013	40%	60%
2014	44%	56%
2015	48%	52%
2016	55%	45%
2017*	60%	40%

* Statistics available only for the first half of the year

Source: Google Analytics (2017)

Table 4 summarizes the situation in the Czech market based on data from Toplist.cz (2017), which provides search engine share statistics for the past two years. These statistics also confirm the current dominant position of Google in the Czech market, roughly to the same extent as the previous analysis.

Table 4: Development of the share of traffic from the Google and Seznam.cz search engines, according to Toplist.cz statistics

Year	Google's share	Seznam.cz's share
2016	60%	40%
2017*	65%	35%

* Statistics only for the first half of the year

Source: Toplist.cz (2017)

Conclusion

The major local search engines in Europe are Yandex and Seznam.cz. Seznam.cz ranks among the most prominent companies in the Czech market. Over the past twenty years, it has grown from a one-man project to a company with over 1,000 employees. The Seznam.cz portal currently offers a wide range of services, from its search engine, entertainment and news sites, to a classifieds site. Such a wide range of services allows the portal to dominate the Internet and generate a pretax profit of around CZK 1 billion. The revenue from sales of the company's own products and services grew from CZK 1 billion in 2006 to almost CZK 3.5 billion in 2015. Based on the analysis of the company's economic results, Seznam.cz is considered a financially sound and strong company. The position of Seznam.cz in the European market is unique. Over the past 10 years, Seznam.cz and Yandex have been the only companies in Europe that have managed to outperform Google in terms of market share.

The portal's main source of income is the advertisements displayed with search results. Between 2000 and 2010, Seznam.cz was the most widely used search engine in the Czech Republic and was way ahead of its competitors (particularly Google). Thanks to Google's investments in the Czech market and its higher-quality web search technology, the primacy of Seznam.cz has gradually decreased over the years. Since 2015, the most frequently used search engine in the Czech market is undoubtedly Google. The market share of Seznam.cz has significantly dropped to approx. 35-40%. The remaining 60-65% share is that of Google. No other search engine has a share of more than 1% in the Czech market. In recent years, Seznam.cz has been transforming itself into a media empire. Seznam.cz makes up for the decrease in income from its web search services by developing other services, and despite the expectation of a further drop in revenues from advertising associated with the search engine, the company's future is not threatened.

Abstract

The significant growth in biological data has driven computer scientists to create fast, efficient and accurate algorithms for searching databases at the fastest possible search responses, in order to assist the biologists to retrieve the existing information quickly from any biological database. Furthermore, the trends in parallel programming models have also encouraged the computer researchers to improve the searching approaches to cope with this exponential increase. This research provides a comprehensive summary of some searching methods, as well as the state-of-the-art for the Parallel Boyer-Moore-Quick Search Algorithm (P-BM-QS). The results of the literature review show that the hybrid technique of P-BM-QS will improve the searching speedup in comparison with one direction algorithms. It could be concluded from the literature review that the proposed P-BM-QS is appropriate for large data sets, in terms of searching time.

Keywords: String Matching, Boyer-Moore Algorithm, Quick Search Algorithm, Bidirectional Algorithm, Parallel Computing, OpenMP, Windows Thread.

Introduction

The tremendous increasing in the amount of Biological data draws the attention of the researchers to investigate the best approaches to reduce the search response time in order to extract meaningful information from the biological sequence in an accurate way. One of these approaches is to develop efficient and speed string matching algorithms. A string matching algorithm can be defined as: a class of string algorithms that attempts to find the occurrence(s) of a string Pattern (P) within a Text (T) over some alphabet ($\sum$) where T is longer than P (Al-Mahasneh, 2014). Such algorithms are considered as one of the most significant studied area in computer science. They are widely used in many applications including information retrieval, web search engines, library systems, DNA sequencing, signal processing, error correction, pattern recognition and in many other fields (Naser et al., 2012).

Despite the fact that the development of processors technology and other advances have reduced search responses to negligible times, string matching problem still remains a useful area of research and development for a number of reasons. Firstly, as the size of data continues to grow, sequence searches will become increasingly taxing on search engines. Secondly, pattern matching still remains an integral part of faster matching algorithms, typically comprising the final part of a search. Lastly, researchers have to understand the classical methods of pattern matching to develop new efficient algorithms. With the developments of new string matching techniques, efficiency and speed are the main factors in deciding among different options available for each application area. Each application

area has certain special features that can be used by string matching technique which is suited for that area (Kouzinopoulos and Margaritis, 2010).

Accordingly, one of the areas that can be combined with string matching algorithms in order to speed them up is parallel computing. Parallel computing can be defined as: multiple processors that work simultaneously in order to accomplish one task. Parallel computing can be classified into two basic architectures depending on the way the communication between the processing elements occurs: the distributed memory architecture and the shared memory architecture (Hussain et al., 2010a). The most widely used Application Programming Interface (API) for shared memory parallel processing is Open Multi-Processing (OpenMP) which is set of directives, runtime library routines and environmental variables that is supported on a wide range of multicore systems, shared memory processors, clusters and compilers. OpenMP consists of a set of specifications for parallelizing programs on shared memory parallel computer systems without the explicit need for threads management. To parallelize an existing algorithm, the parallel parts it contains must be identified; the speed-up to the execution will then be proportional to the level of the algorithm's parallelism (Rao et al., 2013).

In this paper we merged one of the most two popular matching algorithms; Boyer-Moore and the Quick Search Algorithm, in addition to utilizing parallel computing in order to obtain a fast string matching algorithm that is called Parallel Boyer-Moore-Quick Search Algorithm (P-BM-QS). The proposed algorithm can reduce the number of comparisons performed by using the idea of searching from both sides (from right to left by using Boyer-Moore and from left to right by Quick Search algorithm) to combine them in one algorithm.

This paper is organized as follows. Section 2 presents the background of the Boyer-Moore and Quick search algorithms, in addition to the related works of matching algorithms. While Section 3 presents our proposed algorithm. Section 4 provides the conclusion remarks along with the future works.

Related Works

In this section a basic description of the Boyer-Moore algorithm and Quick search algorithm is presented. Furthermore, we introduce some of the related works that used Boyer-Moore algorithm and quick search and other algorithms to tackle the problem of string matching.

The Boyer-Moore algorithm is a fast exact pattern matching algorithm that was published by Boyer and Moor in 1977 (Sheik et al., 2004 ; Jaber et al., 2013; Al-Mahasneh, 2014). This algorithm with its variations is based on comparing a pattern from its rightmost end. In addition, it jumps along the text instead of searching every single character in that text. Additionally, it allows for larger shifts which can be pre-computed from the pattern. The best-case complexity of this algorithm is: O (n / m), this is due to the reason that a pattern of length (m) can be aligned (n / m) times with a text of length (n). If there is no match between P and T, (n / m) is the amount of comparisons necessary to determine that P does not occur in T (Cantone and Faro, 2003). This algorithm is based on three basic concepts; the right to left scan, the bad character shift rule and the good suffix shift rule. Together, these concepts lead to a method that typically examines fewer than (m + n) characters (an expected sublinear-time method) Hussain et al. (2010a).

On the other hand, Quick Search Algorithm (QS) is an algorithm that scans the pattern (P) from left to right, when a mismatch character is encountered; the pattern is always shifted to the right by at least one character, but never by more than (m) characters. Additionally, this algorithm is considered to be simple and practical. Also, it can be coded, debugged and executed quickly. It is very easy to implement and scans the pattern in the most natural forward order (Hussain et al. 2010b). The Quick Search is an efficient algorithm when using large alphabets with a short pattern during the text search Hussain et al. (2010b), but show less efficient behavior for small alphabets with a long pattern Naser et al. (2012).

One of the researches that compared Boyor-Moore algorithm with other matching algorithms is the work done by Diwate and Alaspurkar (2013). This work discussed the techniques, complexity and

efficiency of pattern matching algorithms. Also, they presented an analysis and made a comparison among four different pattern matching algorithms; Naive, Rabin Karp Algorithm, Boyor-Moor and Kunth-Morris Pratt They concluded that Boyor-Moore and Kunth- Morris Pratt algorithms are the most effective for searching, where Knuth-Morris Pratt algorithms having less time complexity and Boyor-Moore algorithms has less preprocessing time complexity.

Another work by Al-Mahasneh (2014) presented a new string matching algorithm to improve the pattern matching technique. The algorithm scans the text from two sides simultaneously using two windows. All the processing of this algorithm depends on the pre-processing phase in Boyor Moore and the Quick search algorithms on the left and right windows respectively on the text. They concluded that the performance of the proposed algorithm is much better than that of the traditional algorithms including Boyer-Moore algorithm because it reduced the number of comparisons needed.

Based on two factors, the number of comparisons performed, and the search time needed; a comparison between Boyor-Moore and its improved versions in order to investigate which one is better was presented by Choudhary et al. (2012). This work explained the Boyer-Moore(BM) algorithm and then explained its improvement as Boyer-Moore-Horspool (BMH), Boyer-Moore-Horspool-Sundays(BMHS), Boyer-Moore Horspool-Sundays2(BMHS2), improved Boyer Moore-Horspool-Sundays (improved BMHS), Boyer-Moore improvement (BMI) and composite Boyer-Moore(CBM). They concluded that; in terms of the number of comparison performed, the performance of BM, BMH and BMHS are almost the same. Furthermore, the improved BMHS outperformed BMHS as number of comparison decreased. BMI and BMHS2 performed even better than Improved BMHS. On the other hand, in terms of search time, BM and BMH performed almost the same but BMHS search time increased, Improved BMHS search time is less than that of BM, BMH and BMHS. In BMI searching is faster than the above four algorithms and BMHS2 search time is even less than BMI. According to this, BMHS2 is the best among all six algorithms as search time and number of comparison both are less than all other algorithms.

Additionally, there have been many works to improve Bidirectional algorithms. One of these works is the one presented by Hussain et al. (2013) where it improved a Bidirectional exact pattern matching algorithm to solve the problem of exact pattern matching. The researchers solved this problem by comparing the character of a pattern to selected text window (STW) from two sides (right and left). The improved algorithm time complexity of preprocessing phase is O(2m), and O(mn/2) for the searching phase. According to the researchers, there is one drawback for the proposed algorithm which is the need to improve the shift decision of the preprocessing phase of exact pattern matching problems, to move pattern to the right of selected text window with long distance.

Cantone and Faro (2003) presented a variant algorithm for Boyor-Moore string matching algorithm called Forward-Fast search algorithm. This algorithm achieved good results when dealing with very short or small alphabets. The improved algorithm applied repeatedly the bad-character rule until the last character of the pattern is matched correctly at the end of matching phase. Also, it computed the shift advancement as a function of the matched suffix pattern, and the first character of the text past the current window (forward good suffix rule), the space complexity of this improved algorithm is O $(m.|\sum|)$ and time complexity O $(m.max(m.|\sum|))$.

Quick search algorithm plays a significant role in real-time applications, therefore Hnaif, et al. (2009) presented a parallel Quick search algorithm to speed the packet content filtering for Network Intrusion Detection System (NIDS). This work parallelized the Quick search algorithm using OPEN/MP and Pthread. The improved algorithm was used in NIDS to enhance the speed of matching process between incoming packets contents and snort rule sets. The process of packet filtering is speeded up by 40% using the proposed method.

Rao et al. (2013) presented an evaluation study for string matching problems with parallel approaches. Their work was based on the recent developments of parallel string matching, and the main idea of each algorithm and its complexity. In this study, they investigated the problem of sequential and parallel approaches in the context of string matching. This works presented the performance of the different algorithms and their effectiveness. Additionally, they developed a

parallel string matching with JAVA Multi-threading with multi core processing, and performed a comparative study on Knuth Morris Pratt, Boyer-Moore and Brute force string matching algorithms based on the running time. This study showed that the Boyer-Moore string matching algorithm is the most efficient one among the three string matching algorithms with multicore processing in comparison with earlier versions of these algorithms.

Parallel Boyer-Moore-Quick Search Algorithm (P-BM-QS) Framework

This section presents the Parallel Boyer-Moore–Quick Search Algorithm (P-BM-QS) framework. All of the literature reviews that were discussed in the previous section have one main objective which is to reduce the computation time for the searching algorithm. In this section, the proposed method that is used to achieve this objective is discussed.

To clarify the problem area, Figure 1 shows the main steps and the framework of the proposed P-BM-QS method.

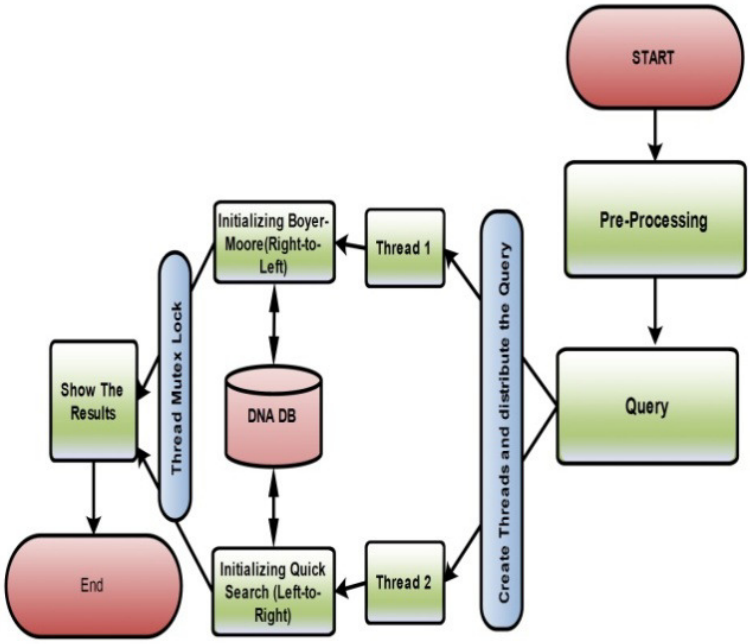

Fig.1:The proposed P-BM-QS method

The proposed method contains four main phases, each phases is described in details as follows:

1) Pre-Processing the DNA datasets: The aim of this phase is to prepare the representation of the data sets that will be stored in the databases. This phase is carried out in one step. In this step the data is retrieved from a text file by opening the file, then reading the data line by line. Each line that has been read is cleaned by removing the wild-card characters such as N and X, accession number (ID), family name and so on.

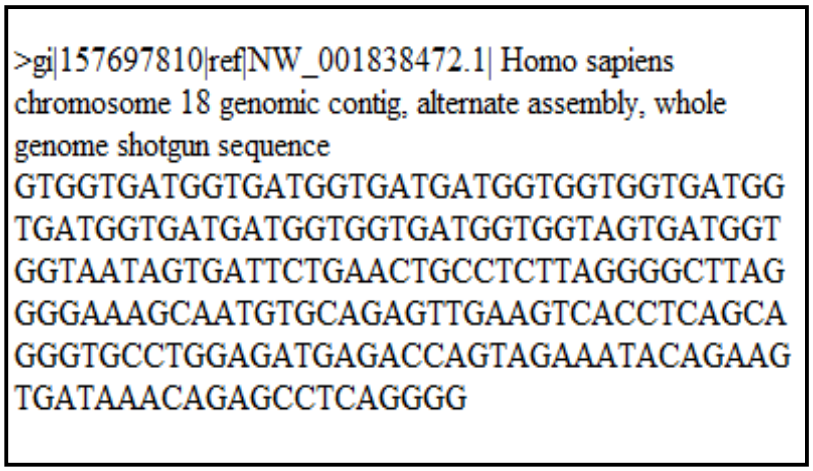

Fig.2: An Example of DNA Sequence

2) Search Queries in Data Sets: The second phase of this framework involves the searching process. The searching process of this work could be:

- **a.** Enter the query (Q) or queries.
- **b.** Search the query in the DNA Database (Figure 2 shows an example of a DNA sequence in the DNA database).

3) Initializing the Windows Threads API: The P-BM-QS was implemented using Windows Threads or shared memory programming model. Threads are light weight processes; it is quite easier to write threaded programs because the applications which are threaded and run on a single machine can also run on multiple machines without major changes. The master thread will create one thread for Boyer-Moore algorithm which is working from left to right. After this, another thread is created for the quick search algorithm. However, the two threads are working simultaneously.

4) Joining the results: Finally, synchronization is needed before the results are combined and all threads are terminated. To accomplish synchronization, the thread lock is used between the threads to obtain the final results and terminate all threads. However, it waits for all threads to be completed and then detaches the threads. Afterwards, it joins all the final results.

Conclusion

In this paper, we highlighted the problem of the high computational demands of searching algorithms. We conducted a review of many published state-of-the-art approaches, which hope to form the direction of future research in the area. We also proposed in this paper, the parallel Boyer-Moore–Quick Search Algorithm (P-BM-QS). The need for further investigations in utilizing parallel computing methods to solve this problem is still needed. Future efforts can be possibly directed to the implementation of parallel techniques such as hybridization between distributed and shared memory models, hybridization between GPU and CPU methods.

Abstract

Ensuring the sustainable development of economic entities of all levels is a priority task of their management, both at the state, and at the regional and corporate levels. The diversity of existing approaches to the definition of the term "sustainable development entity" and the numerous approaches to determining the sign of such development complicate the evaluation of the phenomenon. The aim of the research is the development of a universal tool that allows us to identify and assess the level of sustainable development of such economic entities as a region, enterprise, individual entrepreneur; this tool should be based on the criteria predetermined by the logic of economic processes. A balanced scorecard was chosen as a tool for achieving the goal. Research methods include comparison, financial and economic analysis, and expert method. The results of the research allow firstly to identify the uniformity of the criteria of sustainable development for economic entities, meso-, micro - and nanolevel, and secondly, the admissibility of usage to assess the level of sustainable development of static and dynamic indicators that reflect the income and resources of the final results of the operation to the original, receipts, payments, commitments to their own resources, thirdly, to develop options for the development strategy of economic entities depending on the combination of the results obtained and the type of business entity.

Keywords: sustainable development, business entity, balanced system of indicators, development strategy.

Introduction

Functioning of economic entities of macro-, meso-, micro - and nanolevel (whether integrated Union of countries, region, industry, holdings, enterprise and even individual entrepreneur) is carried out on the basis of such economic principles as self-sufficiency and self-financing.

First, the business entity needs resources to ensure the purpose of its functioning, these resources are characterized by a certain value and are not always their own. This circumstance requires the provision of such operating results that would be able to cover (recoup) the costs spent for achieving the purpose of the business entity resources. The principle of self-repayment mainly characterizes the operational (current) level of management of business entities.

Self-financing characterizes an ability of a business entity to provide self-development from its own sources of financing. The principle of self-financing concerns mainly the strategic level of management of the business entity.

Nevertheless, the analysis of the correspondence of the operational results of functioning of economic entities to their strategies often reveals their complete inconsistency.

The objectives of functioning of economic entities are formed under the influence of the interests of a wide range of stakeholders. Thus the purposes can have both economic and noneconomic nature. All mentioned above predetermined the relevance of the study of sustainable development of subjects at different levels of management and the development of a methodological tool for assessing the level of their sustainable development.

Approaches of the Defining the Term “Sustainable Development” And Its Criteria of A Business Entity

In 1987 the Brundtland Commission published its report "Our common future" to link the problems of economic development and environmental stability, in which the term “sustainable development” was presented as "development that meets the needs of the population without compromising the ability of future generations to meet their own needs" (Report, 1987). As early as the beginning of the twentieth century, A. Pigu considered the approach of his predecessors in the development of Welfare theory as insufficient due to "market failures" or non-market ties, as well as the existence of monopoly and monopolistic competition, which inevitably cause a gap between public and private interests (Pigou, 1920). Thus, the precondition for the emergence of the concept of sustainable development, firstly, is the welfare theory, and secondly, the stakeholder theory. There are many approaches to defining the essence of sustainable development.

So the definition given in analyzed literature (Cerin, 2017; Dernbach, 1998; Dernbach, 2003) is a broad definition, which does not limit the volume of stability. The definition reflects the need to preserve resources for future generations, defining it as one of the main features that distinguish sustainable development from traditional environmental policies. The overall goal of sustainable development is the long-term stability of the economy and the environment; this would be achievable through integration and solution of economic, environmental, and social problems during the decision-making process. In applying this definition of sustainable development, one aspect concerns the sustainability of capital (Emas, 2017). The author believes that there are several types of capital: social, natural, and artificial, which predetermines two approaches to the definition of sustainable development. The "weak" definition of sustainable development implies that artificial or manufactured capital can become an alternative to natural capital. The "strong" definition of sustainability reflects the exceptional characteristics of natural resources that cannot be replaced by manufactured capital. Most ecologists and environmentalists are supporters of a strong definition of sustainability (Stoddart, 2011). An important step in promoting the concept of sustainable development was the declaration on environment and development (Rio Declaration, 1992), which consolidated the general principles of this concept: long-term sustainability; the principle of compensation payments for environmental pollution; precautionary principle; principle of common and differentiated responsibility.

In Russian economic science the most common formulation of sustainable developmentis the development that meets the needs of the present, but it does not put at risk the ability of future generations to meet their own needs (Mazunina, 2009).

R. Kolmanovsky and N.N. Renkas emphasize that the most important criterion of sustainable development is achievement of strategic balance between human activity and the maintenance of reproducing possibilities of the biosphere, which is especially important for regional development (Kormanovskaya, 2006).

Principles of sustainable development, according to the approach of A.P. Zakharov, include:
1) improving the quality of life;
2) guaranteed health of people;

3) satisfaction of the basic life needs of both the population and future generations;
4) fight against poverty;
5) rational patterns of production and consumption;
6) rational environmental management;
7) conservation of ecosystems, protection of the climate and ozone layer;
8) ensuring environmental safety;
9) elimination of all forms of violence against man and nature (prevention of wars, terrorism and ecocide);
10) global partnership (Zaharov, 2011).

We are of the opinion that sustainable development of business entity is the state of permanent efficiency and stability of development, strict implementation of all commitments, under the condition of independence in decision-making.

Balanced Scorecard as a Tool for Assessing the Level of Sustainable Development of a Business Entity

Since we have identified four principal components in the definition of sustainable development, it was logical to use such a tool as a balanced system of indicators for the purposes of assessing the level of sustainable development. A balanced system of indicators was proposed for the wide use by D.P. Norton and R.S. Kaplan (Kaplan, 1992; Kaplan, 1993; Kaplan, 1996). A balanced system of indicators can be used to manage the activities of economic entities, both state and municipal (Rohm, n.d.), and also corporate levels (Epstein, 1997; Hahn, 2001).

Traditionally, a balanced scorecard consists of four key prospects – "Finance", "Customers", "Internal business processes" and "Learning and growth". However, this basic set of perspectives can be adapted to the specifics of a particular industry, enterprise or economic phenomenon, in particular, the "sustainable development of the entity".

Stacey Barr notes that high-performance organizations gain a higher return on initiatives and improvements (Barr, n.d.). And as factors providing a higher yield, she noted factors such as: "leverage of influence", "understanding problems", "knowledge", "truth". Each factor has its own evaluation instruments: for the factor "leverage of influence" such instruments are the ability and the efficiency of their use, for the factor "understanding the problems" they are reports, for the factor "knowledge" they are results of analysis of the situation; for a factor of "truth" it is the speed and accuracy of the data.

Assessment of the level of sustainable development of industrial enterprises and small business enterprises (manufacturing) is proposed to carry out with using a balanced scorecard (BSC) that includes the following components:

1) evaluation of the effectiveness of the operation;
2) assessment of the stability of development;
3) assessment of the degree of fulfillment of obligations;
4) evaluation of independence in decision-making.

The functioning of the economic system (enterprise) is the process of refining (converting) the enterprise of natural resources in manufacturing products, satisfying social needs in material goods (products, services). In the categories of a particular economy, functioning of the economy is a process of transforming resources (through their spending) into the results of activities, characterized by a certain level of efficiency. Resources and efficiency are considered as means of achieving a goal – the result.

Obligations of enterprises, from an economic point of view, are related to the definition of financial solvency – the capacity to repay loans and payables in time and in full volume. Independence in decision-

making is largely determined by the capital structure and the specifics of building relationships with contractors of the enterprise. Assessment of the processes and phenomena is proposed to be carried out using the following groups of indicators.

The assessment of the performance of activities is based on the DuPont equation for economic and financial profitability.

The DuPont formula for economic profitability shows the relationship between indicators of economic profitability (Rk), net profit ratio (Rt) and the coefficient of business activity (turnover capital) (Ktc):

$$\mathrm{R\kappa} = \mathrm{Rt} \times \mathrm{Ktc}, \quad (1)$$

where $\mathrm{R\kappa} = \frac{\mathrm{Qs}}{\mathrm{K}} \times 100\%$ – economic profitability – the ratio of profit from sales (Qs) to the average capital of a company (K), expressed as a percentage;

$\mathrm{Rt} = \frac{\mathrm{Qs}}{\mathrm{Qr}} \times 100\%$ – net profit ratio (sales) – the ratio of profit from sales (Qs) to revenue (Qr), expressed as a percentage;

$\mathrm{Ktc} = \frac{\mathrm{Qr}}{\mathrm{K}}$ – coefficient of business activity – the ratio of revenue (Qr) to the average capital of enterprises (K).

The formula reflects the efficiency of using company's capital. All the components of the DuPont formula should have a positive growing trend; growth indexes should be greater than one.

The DuPont formula for financial profitability shows the dependence between the indicators of financial profitability (Rfp), rate of return (Nrr), the coefficient of the business activity (capital turnover) (Ktc) and financial leverage (FL):

$$\mathrm{Rfp} = \mathrm{Nrr} \times \mathrm{Ktc} \times \mathrm{FL}, \quad (2)$$

where $\mathrm{Rfp} = \frac{Qs\ clear}{OC} \times 100\%$ – financial profitability - net profit ratio (Qs clear) to the company's average annual net worth (OC), expressed as a percentage;

$\mathrm{Nrr} = \frac{\mathrm{Qs\ clear}}{\mathrm{Qr}} \times 100\%$ – profit ratio (profit margin) is the ratio of net profit to revenue, expressed as a percentage;

$\mathrm{FL} = \frac{\mathrm{K}}{\mathrm{OC}}$ – financial leverage – the ratio of the average of the company's capital to the average annual equity.

All the components of the DuPont formula for financial profitability should also have a positive trend. Estimation of stability of development is based on mapping the dynamics of capital and financial results with the "Golden rule of business":

$$\mathrm{IQ_{s\ clear}} > I\ \mathrm{Q_s} > I\mathrm{Q_r} > IK > 1.0 \quad (3)$$

Decoding of this rule is more reasonable to start from the right:

I – indicator of index growth;

IK > 1.0 – the constant growth of capital invested in the activities of the enterprise, which should ensure the development of its business;

IQr > IK > 1.0 – a growing business should generate a significant increase in financial results at the enterprise, the growth rates of which should exceed the growth rate of investments;

IQs > IQr > IK > 1.0 – the company should ensure the priority in the growth rates of the final financial result (profit) compared to the growth of the economic result (sales revenue);

IQs clear > IQs > IQr > IK > 1.0 – the growth rate of net profit exceeding the growth rate of gross profit should be provided by an increase in other revenues and a decrease in other expenses of the enterprise.

Estimation of the degree of fulfillment of obligations can be realized on the basis of the "Golden Financing Rule":

$$\mathrm{Ivc} > \mathrm{Ici} > Ip > 1.0, \quad (4)$$

The value of capital can be determined by the formula [19]:

$$VC = \sum_{t=o}^{N}(CI_t - P_t) \times q^{-1}, \quad (5)$$

where VC – value of capital – the difference between discounted receipts (CI) and payments (P) over a number of periods [8, p. 77];
CIt – cash inflow in the period t
Pt – payments in the period t;
N – number of periods;
t – current period index (t = 0, ..., N);
q – discount factor (1 + i);
i – interest rate expressed in decimal fractions ir ⁄ 100;
ir – interest rate, %.

The "golden rule of self-financing" is fulfilled under conditions 1 and 2:
Condition 1: IQr > IQoc, at which revenue should grow faster than the total cost of the enterprise (Qoc).
Condition 2: IQr < IQoc, at which revenue grows slower than the total costs of the enterprise, but accounts receivables grow slower than creditor indebtedness.

The lack of efficiency in the formation of financial results and costs can be compensated by improving the efficiency of working capital management of the enterprise.

The assessment of independence in decision-making is primarily assessed by indicators of financial and market stability, which can also be grouped in the Golden Rule of sustainability:

$$\mathrm{I_{wc}} > \mathrm{I_{Cfi}} > \mathrm{I_{Lpc}} > 1.000, \quad (6)$$

where WC – working capital (the difference between permanent capital and non-current assets);
Cfi – coefficient of financial independence shows how much equity owns in the entire capital of the enterprise;
Lpc –level of permanent capital of the enterprise, which shows the share of its own financial resources in the composition (asset) of the liability. The higher the indicator, the higher the financial and market stability of the enterprise will be.

For the integral evaluation of the level of sustainable development of the enterprise these indicators should be estimated on the basis of a system of criteria and endowed with weight. The use of integral indicator of sustainability assessment will allow comparative analysis of both enterprises and holding structures.

The stages of formation of the balanced scorecard are:
1) determination of the composition of indicators and their evaluation, for example, on a three-point scale;
2) weighting of the indicators within each component. In this case, the sum of the weights of the component indices must be equal to 100%.
3) selection of four evaluation indicators (one for each component);

4) determination of the weight of each component, the sum of the weights of all components being 100%;
5) conducting a final assessment of the level of economic sustainability of an enterprise on the basis of an integral indicator.

The use of the balanced scorecard, as well as their scoring, allows you to give a set of indicators to a single system of assessment, integrate them into the overall criterion of sustainable development, according to which there is a possibility of comparative analysis of the level of sustainable development of enterprises.

Criteria for scoring of indicators and linkages methods for the assessment of the level of sustainable development for the industrial enterprises and small business enterprises are presented in Table 1.

Table 1: criteria for scoring indicators and interrelations of methods for assessing the level of sustainable development of an enterprise

Indicators	Criteria for scoring indicators, ballpoints		
	1	2	3
Assessment of efficiency of functioning			
Economic profitability	<0	0-d, I>1, I<1	>cr, I>1
Net profit ratio	<0	>0, I<1	>0, I>1, when a positive value appears
Activity ratio	I<1	I=1	I>1
Dynamics of DuPont equation for economic profitability $I_{R\kappa} > I_{Rt} > I_{Ktc} > 1.000$	Not performed	Partially performed	Performed
Financial profitability	<0	0-d, I>1,<1	>dep, I>1
Rate of return	<0	>0, I<1	>0, I>1
Finance leverage	>2	<2, I>1	<2, I<1
Dynamics of DuPont equation for financial profitability $I_{Rfp} > I_{Nrr} > I_{Ktc} > I_{FL} > 1.000$	Not performed	Partially performed	Performed
Stability evaluation			
Net profit	<0	>0,I<1	>0, I>1, when a positive value appears
Sales profit			
Revenues from sales	I<0,5	I<1	I>1
Capital in the mid-annual measurement	I<1	I>1	I=1
The Golden Rule of Business $I_{Qs\ clear} > I_{Qs} > I_{Qr} > I_K > 1.0$	Not performed	Partially performed	Performed
Assessment of the degree of fulfillment of obligations			
Value of capital	<0	>0, I<1	>0, I>1
Cash inflow	I<0.5	I<1	I>1
Payments			
The Golden Rule of Financing $I_{vc} > I_{ci} > I_p > 1.0$	Not performed	Partially performed	Performed
Evaluation of independence in decision-making			
Working capital	<0	>0, I<1	>0, I>1

Coefficient of financial independence (equity ratio)	<0.5	>0.5, I<1	>0.5, I>1
Level of permanent capital of the enterprise	<0.6	>0.6, I<1	>0.6, I>1
The Golden Rule of Sustainability $I_{wc} > I_{Cfi} > I_{Lpc} > 1.000$	Not performed	Partially performed	Performed

An assessment of the level of sustainable development of a meso-level entity – region management is carried out using the static values of indicators, as well as their growth indices.

The evaluation of the effectiveness of the functioning will be estimated by DuPont's formula for economic profitability, determined by the indicators of the total number of enterprises in the region [21].

Evaluation of stability of development analogous to the "Golden Business Rule" built for the regional level on the basis of a comparison of the indexes of growth in profits, revenue and assets of a set of enterprises in the region (The central database, n.d.).

Assessment of the degree of fulfillment of obligations should be based on the volume of revenues and expenditures of the consolidated budgets of the regions (Russian regions, 2010-2014).

Evaluation of independence in decision-making should be carried out in terms of the level of absolute value and indices of growth of own circulating assets and the autonomy ratio of the aggregate of enterprises of the region (Russian regions, 2010-2014). The criteria for scoring indicators are presented in Table 2.

Table 2: criteria for scoring of indicators and linkages methods for the assessment of the level of sustainable development of the region

Indicators	Criteria for scoring indicators, ballpoints		
	1	2	3
Assessment of efficiency of functioning			
The economic profitability of the enterprise population of the region	<0	0-d, I>1, I<1	>cr, I>1
The profitability of turnover (sales) of the enterprise population of the region	<0	>0, I<1	>0, I>1, when a positive value appears
The coefficient of business activity of the enterprise population of the region	I<1	I=1	I>1
Dynamics of DuPont equation for financial profitability of the enterprise population of the region $IR_К > IRt > IKtc > 1.000$	Not performed	Partially performed	Performed
Stability evaluation			
Sales profit of the enterprise population of the region	<0, I<0.5	>0, I<1, I<1	>0, I>1, when a positive value appears I>1

Revenues from sales of the enterprise population of the region			
Assets of the enterprise population of the region	I<1	I>1	I=1
The golden rule of business of the enterprise population of the region IQs clear > IQs > IQr > IK > 1.0	Not performed	Partially performed	Performed
Assessment of the degree of fulfillment of obligations			
Surplus (+) / Deficit (-) of income and expenses	<0, I>1	<0, I<1	>0, I>1, I<1
Incomes of the consolidated budgets of the region	I<1, I<1	I≥1, I≥ $(1+t_{inf})$	I≥$(1+t_{inf})$, I≥1
Expenses of consolidated budgets of the region			
The golden rule of financing Ivc > Ici > Ip > 1.0	Not performed	Partially performed	Performed
Evaluation of independence in decision-making			
Working capital of the enterprise population of the region	<0	>0, I<1	>0,I>1
Coefficient of financial independence of the enterprise population of the region, %	<50.0	>50.0, I<1	>50.0, I>1
The golden rule of sustainability Iwc > ICfi > ILpc > 1.000	Not performed	Partially performed	Performed

The Testing Of the Proposed Methodical Approaches to Assessment of the Level of Sustainable Development of Economic Entities of Different Levels

Approbation of author's method of assessing the level of sustainable development of business entities is conducted at the meso-level – as an example Chelyabinsk region was taken (Table 5), the micro-level on the example of machine-building enterprises of the Chelyabinsk region, PAO "Chelyabinsk forging plant" (Table 3) at the nanoscale – for example, small business and trading company LLC Verevkin Chelyabinsk (Table 4).

Table 3: the results of the assessment of the level of sustainability of the development of the industrial enterprise of PAO "CHKPZ" during 2014-2016

Indicators	Indicator value			Growth index		Weight of indicators, %	Evaluation score, ballpoints		Weighted estimate	
	2014	2015	2016	2015/2014	2016/2015		2015	2016	2015	2016
Economic profitability, %	8.9	8.9	10.5	1.004	1.178	3.571	2	3	0.071	0.107

Integral assessment of the level of sustainable development of the enterprise						100			2.252	2.320

Increasing the level of sustainability of development in 2016 compared with 2014-2015 is due to the strengthening of assessments on the components: efficiency of functioning (+0.143 points), independence in decision-making (+0.125 points), stability of development (+0.05 points).

It is obvious that a state order for products is the driving factor in ensuring and improving the sustainability of development of the industrial machinery business in the conditions of crisis trends in the economy.

Implementation of the golden rule of sustainability						8.33	1	1	0.083	0.083
Evaluation of independence in decision-making						25			0.417	0.333
Integral assessment of the level of sustainable development of the region						100			1.854	2.021

Increasing the level of sustainability in 2015 compared to 2014-2013 is due to the strengthening of unit assessments: effective functioning (+0.187 points), assess the stability of development (+0.063 points). Dynamics of assessments of these components reflects the high dependence of the region's indicators on those of large industrial enterprises.

Nevertheless, there are significant trends in the level of sustainable development at both the meso- and micro- and nanoscale levels.

Conclusion

In this study the author's definition of the sustainable development of the business entity is formulated as a state of permanent efficiency of functioning, ensuring the stability of development, rigorous fulfillment of all obligations, subject to independence in decision-making.

An approach is proposed for assessing the level of sustainable development of the economic entity of the meso-, micro- and nano-level using a balanced system of indicators adapted to the level of management.

The approbation of the author's method of evaluation in relation to the region, and industrial engineering enterprises and small trade business was carried out based on the development of the scoring criteria for the components of the BSC and the analysis of financial and economic indicators of business entities.

The results of the approbation made it possible to identify the level of sustainable development of the business entity and determine the reasons for its positive dynamics. At the same time, the factors specific for economic entities of each level, which have a predominant influence on the level of their development stability, have been identified, which makes it possible to develop management decisions of a strategic nature aimed at strengthening the positive influence of these factors and weakening, if any, their negative influence in the long term.

Abstract

The article presents the results of the analysis of the influence of the industry factor on the dynamics of tax revenues in the subsidized regions of the North Caucasus Federal District. It is proved that the low level of tax revenues is determined by the deformed structure of the economy with simultaneous heterogeneity of the actual sectoral tax burden. Based on the results of the study, tactical and strategic measures of economic policy aimed at increasing the fiscal efficiency of subsidized regions are revealed.

Keywords: tax revenues, sectoral structure, gross regional product, tax burden, sectoral disproportions.

Introduction

One of the attributive features of Russia's current tax system is the growing imbalances in the dynamics of the formation of tax revenues by individual regions (Dzhurbina, 2016), which in turn neutralizes the positive effects of fiscal federalism and contributes to the preservation of the depressed economic state of some subjects of the federation. Analysis of the industry specific tax revenues in the context of extremely low activity of subsidized regions to develop their own tax base will allow developing concrete proposals for improving economic and fiscal policy.

Literature Review

In international practice, the problem of sufficiency of tax revenues is investigated in relation to developing countries. In particular, in the work of economists of the World Bank it is proved that the level of the tax burden of states with low per capita GDP is usually lower than the potential one, which creates difficulties in adequately financing the needs of society and slows economic growth. (Minh Le et al., 2011). This statement can also be projected onto the regional level of large federal states, whose territorial subjects are quite differentiated both in terms of socio-economic development indicators and in terms of the level of their own tax opportunities.

The traditional quantitative approach to the comparison of regions and countries in terms of average per capita tax revenues or the tax burden (as a percentage of GDP/GRP), in our opinion, is not sufficiently correct, since it does not take into account the structural features of the economy, as well as the institutional characteristics of the tax system. (Alfirman, 2003) In order to assess the influence of structural factors in the process of econometric modeling of tax revenues, additional explanatory

variables are used, such as: the share of the industrial sector (Eltony, 2002), the share of agriculture in GDP (Gupta, 2007), the share of the natural resource sector (Botlhole et al, 2012), etc.

Empirical studies show that this group of factors refers to a universal characteristic of the sectoral structure of the economy that corrects the aggregate tax potential of a region or state, calculated on the basis of a basic macroeconomic indicator, for example, GDP/GRP. For example, the materials of the scientific work carried out on the actual data of Turkey confirm the positive influence of increasing the share of industry and the negative - of agriculture, on the dynamics of tax revenues, and this statement is valid for a long time interval. (K. Karagoz, 2013).

At the same time, the use of the regression approach does not allow analyzing tax receipts in the context of the entire variety of economic sectors due to the multicollinearity between the regressor factors, as well as a significant increase in the requirements for the number of initial observations. That is why in the modern studies of tax systems, the industry approach finds limited application. However, its application in the framework of traditional statistical procedures, in our opinion, opens additional opportunities for analyzing the fiscal opportunities of taxpayers, as well as the scientific justification of the priorities of the structural economic policy of the regions, aimed at reducing the subsidy of their budgets.

Comparative Structural Analysis of Tax Revenues in Subsidized Regions

It is advisable to start studying the branch specificity of tax revenues in subsidized regions from a comparative structural analysis in the context of the most important sectors of the regional economy. This makes it possible to quantify the actual proportions of the economic complex of a particular region and to specify the initial factual basis for their "decomposition" into determinants of a more particular order.

The sectoral structure of aggregated tax revenues in the subjects of the North Caucasus Federal District and Russia as a whole, calculated on the basis of official statistics for 2015, is presented in Table 1.

Table 1: sectoral structure of gross tax revenues in the regions of the North Caucasus Federal District in 2015, %*

Region	Branch of national economy										
	A**	B	C	D	E	F	G	H	I	J	K

* Source: calculated by the authors according to (Finances of Russia, 2016).

** Legend (hereafter in the tables): A - agriculture, hunting, forestry, fishing, fish farming, B - mining, C - processing industries, D - electricity, gas and water production and distribution, E - construction, F - wholesale and retail trade; repair of vehicles, motorcycles, household products, G - transport and communications, H - real estate transactions, rental and provision of services, I - public administration and military security; social insurance, J - education, health and social services, K - other activities.

According to the data in Table 1, the composition of tax revenues in the whole country is characterized by a rather low sectoral diversity. In particular, the sectors "Extraction of minerals" and "Processing

industries" generate more than 50% of tax revenues; trade, household services and real estate transactions provide about 20% more.

The sectoral proportions of the formation of tax revenues in the regions of the North Caucasus Federal District differ significantly from the Russian Federation as a whole. This statement, first of all, is true for extractive industries, whose role in the formation of tax revenues is extremely low and varies from 0.2% in the Kabardino-Balkar Republic to 10.5% in the Republic of Ingushetia. Only in the Chechen Republic, the share of the natural resource sector in fiscal payments is at the level of average Russian indicators. The exceptionally low contribution of processing industries to tax revenues takes place in the poorly industrialized economies of the Chechen Republic and the Republic of Ingushetia (1.2% and 1.6% respectively).

A distinctive feature of the sectoral disproportions of tax revenues in the regions of the North Caucasus Federal District is the expressed priority of the sphere of tertiary non-market services. For example, the sector "Public Administration and Ensuring Military Security" generates 6.9% of total tax revenues in the Stavropol Territory to 36.3% in the Chechen Republic (with an average for Russia of 2.9%). At the same time, in four regions of the okrug this type of activity absolutely dominates the structure of tax revenues. If we take into account its aggregate fiscal "contribution" taking into account the spheres of education and healthcare, the share of the tertiary non-market sector exceeds 30% of the total fiscal revenues in the Karachay-Cherkessia and Kabardino-Balkar republics, 52.2% and 56.0% in the Chechen Republic and republic of Ingushetia respectively.

It is symptomatic that the aggregate share of the tertiary market sector (transport and communications, real estate transactions, financial activities, hotels and restaurants) is significantly lower than the corresponding average Russian indicators. This is due both to the insignificant role of these activities in the structure of regional added value (as will be further emphasized) and to their transition to the "shadow" sector.

Thus, the structure of tax revenues by sector is determined by the territorial features of distribution and the level of development of the productive forces of each region. It will be further shown that the sectoral heterogeneity of the fiscal productivity of the regions can be explained by the complex and non-linear influence of economic, administrative and territorial factors creating a unique structure and dynamics of tax revenues.

Disproportions of Regional Economy and Decrease in Its Tax Capacity

The determining factors of differentiation of subjects of the federation according to the criterion of generated tax revenues are of an objective nature and are determined by the unequal potential of certain sectors of the economy to the formation of fiscal obligations. For their characterization it is expedient to analyze the structure of gross added value in the regional context (Table 2).

Table 1: sectoral composition of the gross regional product in the regions of the North Caucasus Federal District in 2015, %*

* Source: calculated by the authors according to (Finances of Russia, 2016).

These tables give grounds for stating that there are significant differences in the GRP structure of the subsidized subjects of the NCFD from the average Russian proportions, which is determined by historically established approaches to the location of the productive forces and by the lack of valuable minerals produced on an industrial scale.

Characterizing the features of the development of the economic complex in the subjects of the North Caucasus Federal District, one should emphasize negative deindustrialization processes that were accompanied by the replacement of released niches by trade, mainly by "shadow" agriculture, including private households, as well as public sector hypertrophy (education, healthcare , public administration).

The prevalence of agriculture observed in most of the regions of the okrug, whose share varies from 6.4% in the Republic of Ingushetia to 19.2% in the Karachay-Cherkess Republic (with an average Russian value of 5% GRP), appears to be the most important factor in reducing tax revenues due to a lowered level Tax burden in this area. The significant role of agriculture in the structure of the economic complex is an indirect indicator of weak urbanization, which in turn initiates negative effects for effective implementation of fiscal procedures and rules: low level of wages and incomes of the population, labor migration, high share of the informal sector.

Negative impact on the taxability of the constituent entities of the district is provided by the extremely low level of development of the manufacturing industry, which on the national scale ranks second in the generation of fiscal revenues, but in the regions under consideration it forms between 2.7% and 14.2% of the gross value added (at an average Russian rate of 17, 4% GRP). The actual replacement of the manufacturing industry with the service sector and trade, on the one hand, is in line with current trends in the strengthening of the role of the tertiary sector, but on the other hand it leads to an expansion of the horizons of informal economic activity and a reduction in the tax capacity of the subsidized regions.

Analysis of the structure of value added across the regions of the Russian Federation allows us to come to the conclusion that the subjects forming tax revenues within the national average are characterized by a diverse composition of GRP, in which the shares of processing industries and trade are approximately at the same level. In general, the existing sectoral disproportions determine the low volume of fiscal revenues generated by the economy, and also substantially limit the strategic opportunities for their increase without a purposeful financial "recharge" from the federal center.

Sectoral Tax Burden and Its Impact on the Aggregate Fiscal Productivity of Regions

The Russian tax system, declaratively establishing the principle of fairness of taxation, actually contributes to the uneven distribution of fiscal pressure on various sectors of the economy. The reasons for the heterogeneity of the sectoral tax burden are determined by the existence of an objective diversity in the structure of operating expenses, differentiation of the level of profitability, and also by different initial possibilities for legal and illegal minimization of fiscal obligations. The listed reasons are exceptionally bright in the regional context, contributing to the strengthening of the territorial heterogeneity of sectoral fiscal pressures (Table 3).

Table 3: share of tax payments in value added industries (tax burden) in the regions of the North Caucasus Federal District, 2015, %

Region	Branch of national economy										
	A*	B	C	D	E	F	G	H	I	J	K
Republic of Dagestan	-0,04	63,0	27,7	15,1	1,3	1,3	5,8	5,3	14,4	8,1	5,3
Republic of Ingushetia	0,52	37,8	1,2	7,1	4,3	1,4	4,4	6,2	9,5	8,0	7,4
Kabardino-Balkar Republic	1,02	21,7	25,4	14,9	3,4	3,8	6,9	18,4	15,1	9,6	13,1
Karachay-Cherkess Republic	0,91	30,9	13,2	12,9	4,9	12,1	10,1	8,6	11,7	8,4	8,5
Republic of North Ossetia	0,38	13,4	17,4	13,2	6,9	4,2	4,4	23,0	12,3	7,9	9,8
Chechen Republic	0,35	141,2	4,3	-13,5	0,8	1,3	6,3	4,8	14,1	5,6	6,6
Stavropol Territory	4,22	134,2	18,1	18,9	11,8	11,2	12,7	19,1	9,7	11,1	10,6
Russian Federation (by the sum of regions)	2,31	60,3	22,3	16,9	14,7	11,9	14,3	18,8	10,7	11,3	20,0

The tax load indicators presented in Table 3 show its pronounced sectoral heterogeneity: the maximum burden - more than 60% of the value added - "carries" the mining sector, at the other extreme (about 2%) is the agricultural sector characterized by an unstable financial situation.

Regional indicators of the tax burden of the subjects of the North Caucasus Federal District in most cases "lag" behind the average Russian values. For example, payments of the extractive sector outstrip the national average in only three constituents of the region where oil and gas are extracted and transported, while in other regions the tax burden is relatively small.

The effectiveness of taxation of agriculture is also extremely low, both due to the traditionally low profitability of activities, and because of the production of a substantial part of the output on personal farmsteads, in fact excluded from controlled economic turnover.

Attention is drawn to the tax burden in the construction sector, fiscal obligations of which range from 0.8% in the Chechen Republic to 11.8% in the Stavropol Territory (the average Russian value is 14.7%). This is due to the high share of the shadow economy in this sector, as well as the use of budgetary resources to finance socially important facilities.

The tertiary sector of public services (health, education, public administration) objectively has a limited fiscal capacity, represented primarily by the personal income tax. The revenues of this tax, in turn, are determined by extremely inertial determinants of wages and the number of employed in the public sector.

A comparative analysis of the data in Table 3 allows us to conclude that the public sector demonstrates a higher level of fiscal discipline compared to commercial economic entities. This statement is especially true for such areas as wholesale and retail trade, construction, production and distribution of electricity, gas and water. It is necessary to emphasize that the current situation should not be unambiguously interpreted only from the point of view of informal activity, since the financial results and profitability of the above sectors lag behind the average Russian values.

In general, in all regions of the region (with the exception of the Stavropol Territory), the lower sectoral tax burden has a negative impact on the dynamics of budget revenues. Unused reserves for increasing fiscal discipline are observed in the wholesale and retail trade sectors (from 0.2% to 2.0% of the produced added value), processing industries (from 0.7% to 3.7%), and construction (from 2, 9% to 13.9%).

Discussion of Results and Findings

The sectoral aspect of regional differentiation of tax revenues is determined by the different ability of certain sectors of the economy to form and execute tax obligations, which in turn are formed under the influence of two most important factors.

First, the subjects of the federation are diverse in the branch structure of the gross regional product: in the subsidized regions, it is shifted in favor of agriculture, administration and trade. At the same time, the "donor" regions specialize in the extraction of minerals, industrial production and financial intermediation.

Secondly, the indicators of the actual tax burden of the economic sectors indicate that the maximum share (about 60%) is generated by the "Mining" industry, while agriculture is widely represented in the subsidized subjects of the Russian Federation (due to unstable financial condition) and trade (Due to the presence of a large informal sector) generate tax payments of 2.3% and 11.9% of value added, respectively. The current situation is determined by the unique structure of expenditures, the heterogeneous level of profitability, and the initiation of opportunities (including illegitimate ones) to minimize fiscal obligations.

The study of tax revenues of the subsidized regions of the North Caucasus Federal District from the point of view of the sectoral approach makes it possible to conclude that the insufficient fiscal efficiency of these entities is determined both by structural imbalances in the produced added value and by pronounced fluctuations in the actual sectoral tax burden, Factors is highly differentiated.

Thus, the influence of the low sectoral tax burden, which itself is an indicator of the unstable financial state of taxpayers, as well as the presence of "failures" in the implementation of administrative procedures, is most clearly manifested in the republics of Ingushetia, North Ossetia, Kabardino-Balkaria and Karachaяu-Cherkessia In order of decreasing importance of this factor). In the Stavropol Territory, on the contrary, actual seizures in the sectors "Mining" and "Agriculture" are much higher than the average Russian values, however their positive effect is offset by the presence of other sectoral imbalances.

The negative impact of the structural factor, primarily due to the low level of industrialization with simultaneous activation of the non-profit sector of the tertiary sector (public administration, security) is most pronounced in the Chechen Republic. The deformity of the regional economy is also the reason for the extremely low tax efforts of the Republic of Dagestan, whose basic sectors (trade, construction, agriculture) are traditionally characterized by a significant "shadow" component.

Conclusion

The reasons for the insufficient fiscal performance of the subsidized entities of the North Caucasus Federal District are concluded both in an objective sectoral imbalance of the regional economy whose dominant sectors are immanently low in tax capacity and in weak administration of tax revenues.

Sectoral variations in the tax burden, acting in concert with the heterogeneous geographical distribution of the branches of the national economy, contribute to the non-linear strengthening of regional inequality by the criterion of fiscal productivity.

Current measures to increase tax revenues should be oriented towards "pulling" the level of tax burden in agriculture, construction and manufacturing to the average Russian level. This implies not only a tactical intensification of the control activities of the tax authorities, but also a set of measures of an institutional nature to remove "from the shadow" of the agricultural, construction and industrial sectors.

The system economic policy of the regions should take into account the fiscal component, the priorities of which at the initial stage are the structural reorganization of the economic complex of regions in favor of the "tax-intensive" sectors: secondary (manufacturing industry) and commercial tertiary (financial activities, transport and communications). Undoubtedly, this will require considerable financial support from the federal center both through the mechanism of conditional transfers, and through the tools of program-targeted and project financing.

Integrated Organizational Management Model In Overcoming Challenges of Sustainability

Dalia Susnienė, Kaunas University of Technology, Lithuania, dalia.susniene@ktu.lt

Daiva Žostautienė, Kaunas University of Technology, Lithuania, daiva.zostautiene@ktu.lt

Abstract

Diminishing natural resources, environmental pollution and persistent social inequalities in many countries clearly indicate that the current economic model is increasingly inconsistent with public expectations. Corporate interests are increasingly determining economic globalization, and the development of the private business interests are increasingly at odds with the public ones. Due to the negative effects of economic development on social and environmental aspects private business successfully exploit free-market ideology. In order to change the destructive direction of established practice, it is necessary to involve business into the decision process of the world's most pressing issues, and work together to create a sustainable future of the world. The paper aims to develop a conceptual integrated organizational management model expanding it upon the relationships among organizational management system and stakeholder management in pursue of sustainability. This paper makes several contributions: extends discussions on the development of stakeholder management issues and enhances theoretical foundation disclosing interdependencies among organisational sustainability, social responsibility and stakeholder management. As a result an organizational management model is presented that offers guidelines how to integrate these three important issues in management practice. The discussions on conceptual level have been stimulated and reasoned from theory on stakeholders and their relationships management, corporate social responsibility and sustainability by revealing these interfaces in organizational management.

Keywords: sustainability; stakeholder management; social responsibility; organizational management; integrated management system

Introduction

New trends in economic development, the usage of information technologies and globalization of the world economy present new challenges not only for business community in different countries and governments, but also for the humanity as the whole. Unprecedented global environmental, social and economic issues require innovative solutions from different world-view and perspective. Diminishing natural resources, environmental pollution and persistent social inequalities in many countries clearly indicates that the current economic model is increasingly inconsistent with public expectations.

Macro issues consist of aggregate micro problems. Due to the negative effects of economic development on social and environmental aspects, private businesses are given a particular attention, especially large global corporations which gained more power by successfully exploiting free-market ideology. Corporate interests are increasingly determining economic globalization, and the development of the private business interests are increasingly at odds with the public ones. In order to change the destructive direction of established practice, it is necessary to involve business into the decision process of the world's most pressing issues, and work together to create a sustainable future of the world, based on ecological sustainability, social justice, peace, human rights, democracy, prosperity, consciousness and similar values.

Long-term organizational success depends on how they are able to integrate sustainability aspects into the organizational environment and feel the mood and expectations of stakeholders in order to meet their needs and create socially responsible cooperation.

Management system exists in every organization, which includes the environmental management system, occupational health and safety, and financial management as well as quality management system if the organization has developed and implemented it. Organization management system includes organization's business policies together with goal setting and their achievement system, and is a way of managing organizations. In order to implement social responsibility initiatives, the most important consideration should be given to the organization's internal systems integration.

In pursuit to ***answer the guiding research question, the objective of the article*** is to introduce the modern attempts in the development and validation of the scientific and practical problem presenting a conceptual integrated organizational management model with the focus on the relationships among organizational management system, social responsibility and stakeholder management in pursue of sustainability.

The goal pursued allows highlighting the ***scientific problem of the paper***: how to integrate corporate social responsibility (CSR) principles into the organizational management model adjusting the interests of stakeholders and enterprise in a more effective way.

The ***methods of the research include*** comparative structural analysis and synthesis of scientific literature. The theoretical arguments possess intuitive appeal based on systematic comparative and logical exploration of empirical studies as well as scholarly insights.

The scientific novelty of the research lies in the presentation of research disclosing wider perspective and incorporating stakeholder management issues and disclosing a systematic and proactive approach to organization where these three components can be managed and the problems envisaged. Since the very idea of trying to view social responsibility and sustainability as complementing each other is not new, however framing the former into the enterprise value-based change principles promoting CSR through specific action points is a new standpoint for the academic research. In result, the relations among organizational sustainability, social responsibility and stakeholder management are emphasized and an all-embracive organizational management model is presented. A model takes into consideration theoretical aspects of social responsibility, stakeholder relationships management and sustainability disclosing interfaces and how these three dimensions can be incorporated and managed as a system. The benefits of the model of an integrated management system in organization are reasoned and it might be used to explain actual behavior of organizations regarding their aspirations for sustainability. The chapter also contributes to the expansion of knowledge about stakeholder management.

Considerations on Social Aspect of Sustainability

Previous theories on business and its place usually concentrated on its economic role whereas sustainable development ideas gave emphasis on business environmental dimension from the perspective of politics, research and practice. Today the modern understanding of sustainable development became wider and encompassed one more important aspect - social dimension. (Dagiliene *et al*., 2014). Sustainable enterprise aims at minimizing trades and maximizing synergies between economic, social and environmental aspects. All economic activities must create enough value in everybody's life do not harm our ecological system and insure the survival of future generations without exposing to danger global sustainability. Issues of global sustainability and organizations activities are interdependent and must be important to all types of organizations (Garvare & Johannson, 2010; Scherer & Palazzo, 2007).

The analysis of academic literature has shown that in understanding the relations among three spheres of sustainable development, social actions are more consistent with the concept of sustainable development than others.

Early definitions of sustainable actions emphasized the importance of relating business responsibility to power, more recently the importance of balancing the multiplicity of interests represented by internal and external groups emerged. Consequently, businesses found that they disregard their responsibilities because consumers, employees, national government bodies, international organizations (such as European Union) demand business to act in more socially responsible manner (Fairbrass, *et al*., 2005).

In recent years, scientists studying the implementation of the principles of sustainable development, in most cases relate it with social responsibility of organizations (Ebner & Baumgarther, 2006; Engel, 1997; Rego & Cunha, 2008; Garvare & Johansson, 2010). In response to numerous demands for corporations to play a more active role in the overall welfare of society, many businesses have paid considerable attention to the social impact of their economic activities in recent years (Hingley, 2010; Wildes, 2008).

Corporate social responsibility may be defined in different ways regarding expected obligations or other ethical behavior. While earlier understanding of CSR often had a local, person orientated philanthropic focus, modern notion of CSR is comprehensive and diverse integrating social and environmental interests in business and in its relationships with the stakeholders on a voluntary basis (González-Rodríguez *et al*., 2013; Wettstein, 2012 b; Wood, 2010). Other authors (cf. Wettstein, 2012 a, b; Scherer & Palazzo, 2007, Crane *et al*., 2008) refer to CSR as an "umbrella term" because business responsibilities and its role in society include subfields such as business and society, business ethics, or stakeholder theory. With regard to the terms "business social responsibility" and "corporate social responsibility", they are often treated as synonymous ones; however, the concept of corporate social responsibility is narrowed to a specific enterprise-level by integrating social responsibility principles into its activities.

Thus, CSR can be treated as a companies' commitment to take into account wider social impacts of their activities regarding different stakeholders. Often companies must use their resources to bring benefit to the society by demonstrating their commitment and participating in the community life as well as contributing to its initiatives, independent of direct firm profits. From this scenario, it follows that any company not only displays a range of negative and positive impacts on society through its profit-seeking activities but also meets certain obligations to contribute to the management of those impacts, wherever they levy external costs or harms on others (González-Rodríguez *et al*., 2013; Daszynska-Zygadlo *et al*., 2016). It is obvious that stakeholder management and corporate social responsibility share relevant and potential synergies, but this topic is underdeveloped in scientific works.

Stakeholder Paradigm in Socially Responsible Corporate Management

It is difficult to imagine business without stakeholders and relationships with them. The only issue is how purposely, ethically and considerately these relations are managed. All businesses have wide range of different stakeholders and their groups (owners, shareholders, customers, employees, suppliers, partners, communities, etc.) and companies need to satisfy their needs and balance their and organizational interests. Therefore, communication and relationships with stakeholders should always be on a daily agenda. The question is whether all businesses, or in other words their leaders and managers, have a planned strategy to guide these relationships? Do they have a set of values to guide and maximise the potential of these relationships? Or is this managed in an ad-hoc basis when there is a threat? Or do they take actions without having clear strategy and only from economic self-interest?

Changes in economic development, national or local security, and expectations of society influence how social performance is defined and how it involves stakeholders and thus the performance of a corporation. It is evident that the pressure for corporate accountability is increasing (Beurden & Gossling, 2008; Orlitzky *et al*., 2015; Zaharia & Grundey, 2011). Considering company's operation on micro level, it involves understanding of stakeholder needs and expectations with the intention of achieving medium and long-range success, and thereby demonstrating sustainability.

Two very clearly expressed respects emerged associated to stakeholders in the beginning of 21st century. First - the aim to respond to the demands by the interest groups – employees, suppliers, dealers, local communities and even nations. The second – attention to broad and complex issues as unemployment, racial discrimination, pollution, and poverty - commonly defined as actions that aim to social betterment (Holmqvist, 2009). The notion of 'stakeholder management' for organizational sustainability has been described as an organization behaving in such a way as to satisfy the needs and expectations of its stakeholders. According to Garvare (2010) and Habisch (2011), the aim of organizational sustainability will be accomplished if organizations act to maximize the quality of their products to customers, subject

to meeting the wants and expectations of non-customer stakeholders. This viewpoint reflects a new paradigm in the conventional understanding of organization purpose; furthermore, it offers an important improvement in the quality of organization management.

Stakeholder management from corporate social responsibility and sustainability approach has demonstrated to business its strategic opportunities, i.e. a company that knows or anticipates legitimate expectations of stakeholders and is ready to satisfy or balance those expectations, in the course of time will gain a competitive advantage over its rivals in the market.

Benefits of Stakeholder Relationships for Organization

Organizations and namely top management are well aware that organizations have their stakeholders though how to deal with the interdependent network of these relations between organization and stakeholders it is not always clear. Stakeholders and their groups are unique in every organization. Stakeholders can be internal or external and their interests are closely interrelated with organization's wealth as they face a common risk as well as probable benefits or losses depending on organization's performance. It is not enough to acknowledge the importance of stakeholders and their interests in organization management but it is often difficult and not clear how to implement effective stakeholder relationships. Very often business give preference to the focus on profit, results not paying enough attention on people and their relationship management. But current trends in the global business world manifest the significance of people in striving for success.

Value of stakeholder relationships should not be ignored and must be regarded as being developing, and mutually defined (Figure 1).

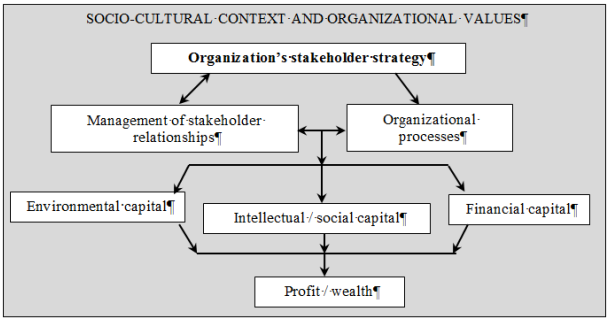

Fig. 1: Value of stakeholder relationships for organization (source: the Authors)

A collaborative model of stakeholder relationships can be a source of opportunity and competitive advantage (Buchanan, 2013; Ebner & Baumgarther, 2006; Fairbrass *et al.*, 2005; Post, 2013). The benefits of the relationships are evident in turbulent and very competitive business environment and can offer stability to certain extent, possibility of influencing circumstances, capacity expansion in addition to increased organizational effectiveness. Such holistic approach creates synergies as effective relationships with one stakeholder or group can bring benefit to another stakeholder or group, e.g. sustainable relations with local community has positive effect on customers as well.

This encompasses all activities in an organization starting from research and strategy development alongside of creation and implementation of business processes and demonstrates how stakeholders and relationships have impact on organization's activity. The relationship model discloses systematic approach to organization in a society where companies can have or experience both active and passive interrelationships with their stakeholders. Organization-stakeholder relationships reveal a multidimensional nature of the phenomenon and are under permanent development, mutual dependence and should be controlled by direct and indirect agreements. These agreements are often tacit, subjected to ongoing negotiation and indicate the expectations of both parties from their relationships as well as possible gains in return. . Therefore, organizational wealth as final output of its performance and stakeholder strategy is given emphasis over the profit. The modern approach focuses on wealth maximization rather than profit maximization. This gives a longer term horizon for assessment, making

way for sustainable performance by businesses. Finally, according to Adam Smith – a businessmen in order to fulfil their profit motive in turn benefits the society as well. Maximization of wealth is more modern approach and is treated as more advanced to profit maximization. Profit maximization represents a short-term perspective as compared to wealth maximization. Wealth maximization entails corporate benefit while profit maximization entails shareholders' benefit. Wealth maximization therefore ensures a more stable, larger market share, greater financial market performance in terms of value of stocks, more long-term financial benefits for stockholders this therefore makes wealth maximization of greater benefits compared to profit maximization. Wealth maximization also maximizes the achievement of other objectives. Wealth can be derived in many different ways by creation of employment, payment of wages and salaries, and purchasing products because the new products create new jobs. People prosper when they get profit from their investments; they have wealth when they use their achieved profit for creating value for themselves, families, community.

It is claimed that stakeholder relationships can be seen as being the vital spark of the organization. It is just as if we people live in an interdependent and synergetic relationship with the environment, not excepting organizations. Relationships with the stakeholders are source of energy and information, assets and supplies that are vital to the existence. These relationships provide companies with social, intellectual, environmental, and financial capital that assures company sustainable development in a long-term perspective. The numerous researchers (cf. Marrewijk, 2003; Mattingly & Berman, 2006; Porter & Kramer, 2006; Godfrey & Hatch, 2007; Juscius & Snieska, 2008; Garcia-Castro *et al*., 2008; Matten, & Moon; 2008; Dahlsrud, 2008; Juscius, & Jonikas, 2013; Rangan *et al*., 2015) claim that CSR is beneficial to organizations in creating consistent social networks and social capacity. Corporate activity that plays important and positive role in the community life can generate social participation and positive attitudes towards the business, and can be a significant factor in economic success and sustainable development (Silberhorn & Warren, 2007). Most of the carried research (Wood, 2010; Saeed and Arshad, 2012; Porter & Kramer, 2006; Aupperle, *et al*.,1985; Griffin & Mahon, 1997; Orlitzky *et al*., 2003; McWilliams & Siegel, 2000; Waddock & Graves, 1997) link CSR to profitability and conclude that CSR investments bring better financial gains to organizations, both in marketing and accounting actions (Boutelle, 2004) and finally assures mutual value (Figure 2)

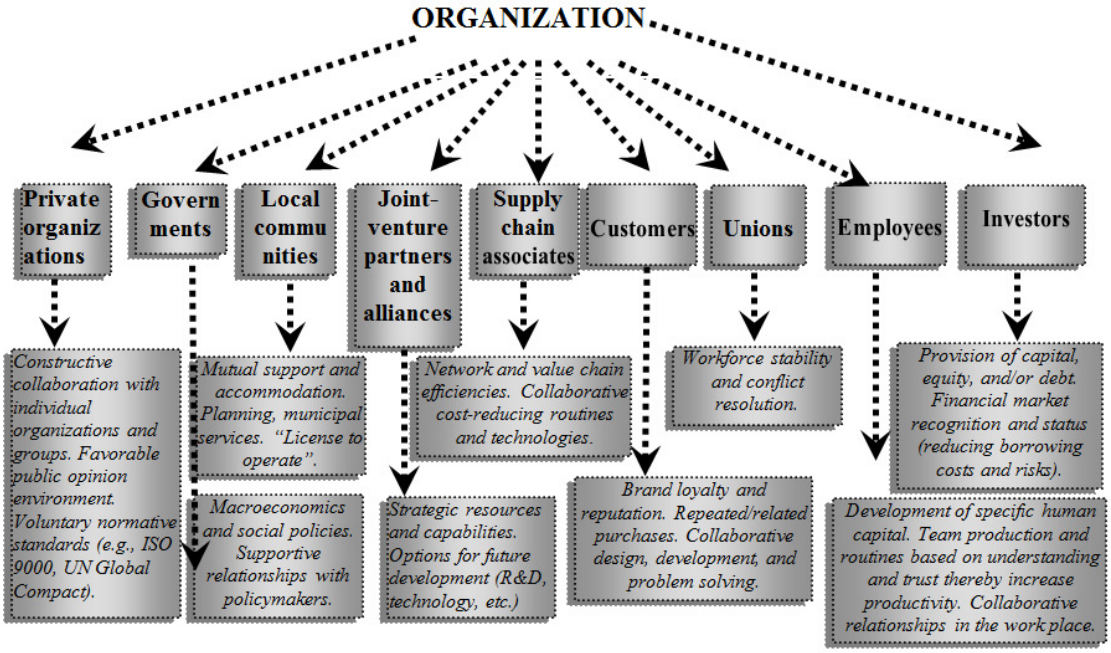

Fig. 2: Contribution of stakeholders to value creation

(source: the Authors)

Considering stakeholder influence to organization, the organization is seen as a relationship network where different individuals or groups and their interests meet and, depending on the achievement of organization's goals, everyone can contribute and/or get benefit. Reciprocal relationships help to achieve competitive advantage and provide exclusive attributes and elements to organization that are impossible to copy. It is hardly possible to imitate relationship model as it is very sophisticated, distinct and exclusive process. The organizational advantages can be achieved in the long run are as follows:

- Enduring recognition.
- Cost reduction.
- Positive image.
- Employee job satisfaction and positive motivation.
- Synergy from stakeholder relationships.
- Greater competitiveness, and
- Increased trust.

The analysis of stakeholders relationships in organization reveal different beneficial aspects not only to organizations operations but also to organizations' wealth where combination of tangible and intangible factors (economical, technological and social) make organization balanced and sustainable. Therefore, stakeholder approach offers better understanding and wider perspective of the organization.

Theoretical Framework of Integration of Social Responsibility and Stakeholder Issues in Organizational Management

There is growing understanding that there is a need for transformation in order to reduce harmful environmental and societal impacts created by our currently unsustainable business practices. Therefore, sustainable development deals with the diverse social, environment, and economic issues and raises a number of important questions on balancing present material needs against those of the future ones or the ways of balancing environmental protection with poverty relief. Economic sustainability is a foundation for corporate success, without financial success it won't survive. Social sustainability express philanthropic and people orientated business context encompassing very important issues as education, health care, poverty, income and gender inequality, human rights, people with special needs. This approach focuses more on external stakeholder needs such as harmonization of community and business interests in a mutually beneficial way, philanthropy and voluntary participation in community and society initiatives. Environmental sustainability in business reflects its influence on environmental issues, natural resources or global warming. It emphasizes the importance of knowledge on the environmental laws and their enforcement, effective and responsible use of enterprise resources, reduction of pollution, brownfield revitalization, "green" products (suitable for processing that consume fewer resources during the manufacturing process to promote more economical use of energy and other resources), etc. The same key issues are highlighted in the United Nations Global Compact which is an important document identifying the milestones for global corporate social responsibility and consist of ten principles that cover such topics as labor, human rights, environmental protection, and anti-corruption. These vital themes could not be handled without including 21st-century corporations and setting for them new values, strategy and responsibility. Generalizing in a sentence and summarizing what was said above it might be concluded that the term sustainability must be used involving careful analysis that goes far away beyond a single enterprise entity: integrating public expectations and enterprise value-based change CSR is promoted through five principles and five so called corresponding interactive action points (Idowu, 2016, p. 307):

- principle of resource perpetuation;
- principle of worthy contribution - both correspond to defining scope of influence and catalyst;
- principle of benefit stacking;
- principle of qualitative management – both above transform into motivation;
- principle of strategic satisfaction – review of the process.

"Nowadays business orientation to socially responsible business is determined by common tendency when both individual persons and participators of collective activity realize their responsibility for all those people who are influenced by results of their activity " (Bernatonytė& Simanavičienė, 2008, p. 502). Stakeholders evaluate how well the organization has met their expectations and/or how organizational strategy has affected the groups and organizations in the external business environment (Holmqvist, 2009; Aggerholm et al., 2011). Managers can both lead and serve by practicing CSR in the everyday workplace and in the boardroom as well (Wildes, 2008). Employees are no longer defined within a Tayloristic notion of humans as raw materials, but recognized as meaning-making corporate citizens. Communication is no longer merely understood as a tool in solving a specific problem but recognized as constitutive of the organization in terms of dialogical processes, complex discursive formations and interpretation of meaning among the organizational stakeholders (Alvesson, 2002; Aggerholm *et al*., 2011; Stuart, 2011).

It is difficult to imagine corporate social initiatives not involving employees in them. Different surveys on CSR indicated that employees were inseparable and one of the most important stakeholder groups in organization, and management should start exercising their social responsibility in a company from them. It is more than evident that organizations both depend on a high degree of employee commitment to their corporate moral brands and expect a high degree of employee commitment because of their corporate moral brands (Morsing, 2006). Consequently, matching expectations and involving employees in CSR initiatives increases production, stimulates improvements in services, and enhanced performance (Dahlrsud, 2008). Furthermore, employees feel loyal to companies that take their interests into account and treat them well. This results in lower employee turnover and helps to save intangible cost of training and development. The efficient and responsible management of the company reflects the ability to maintain profitability, contribution of business operations to sustainable economic development, socially responsible marketing, financial risk management, financial reporting, etc.

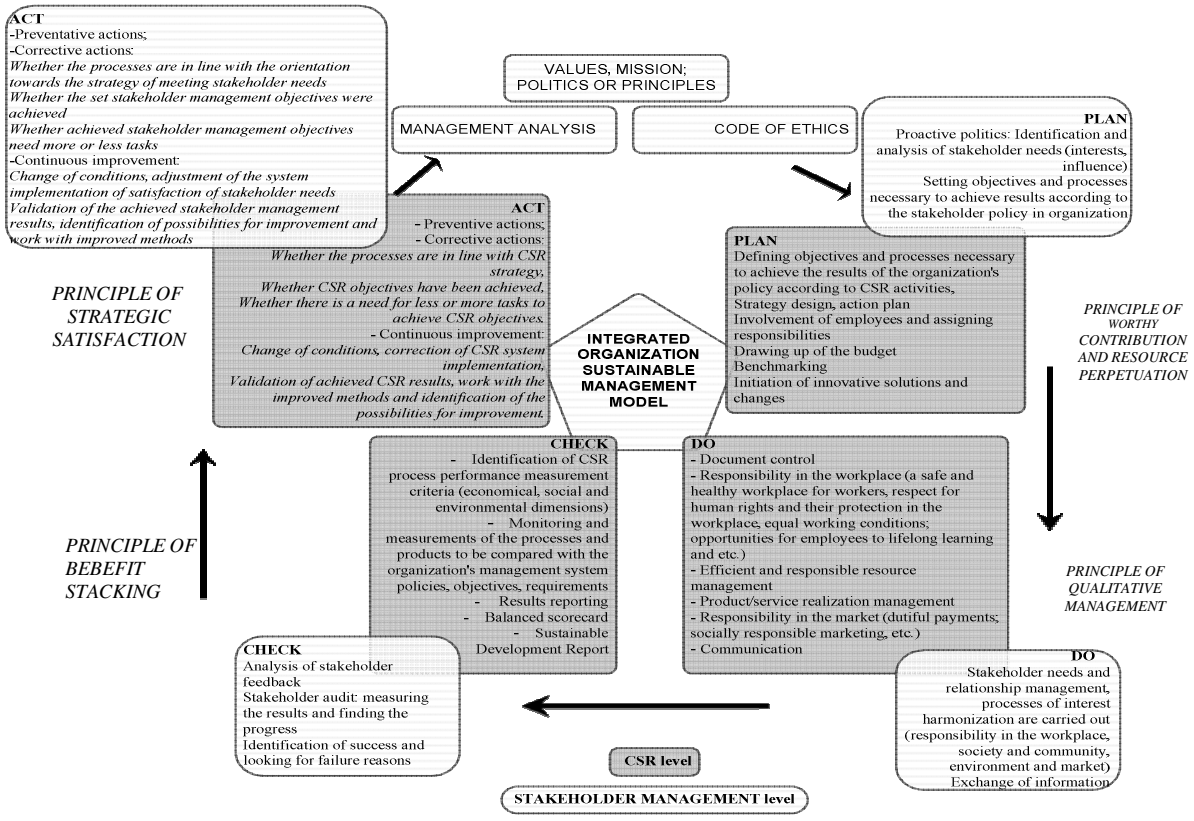

Fig. 3: Integrated management model for CSR and stakeholder management

(source: the Authors)

In order to implement social responsibility initiatives, the most important consideration should be given to the integration of internal systems in organization. Other authors provide the integration of management systems as a way to achieve operational excellence. Integrated management system is a term denoting a management system that can meet the requirements of many standards and other specific objectives of the organization. The organization must be an integrated system in which the responsible persons harmonizes the relations between the individual elements and integrates the objectives of the whole. It can be argued that an organization has implemented an integrated management system (including quality management, environmental management, social responsibility management, occupational safety and health at work and other management systems) that meets the requirements of international standards, and it can be treated as one of the alternative measures facilitating the integration of social responsibility and management system (Figure 3).

Integrated social responsibility management system can be a tool to manage social responsibility issues. After the development and implementation of an integrated management system, the organization is run as interrelated and interacting processes system, in which each process is controlled as system of interrelated and interacting processes operated by P - D - C – A cycle approach. Empirical studies have demonstrated that in many cases the CSR programs are treated favorably as their necessity is understood, but only part of them aims to make social responsibility an integral part of organization's values (Hingley, 2010). Organizations, in assessing the social responsibility with the same criteria as they use for evaluation of its performance and strategic perspectives, can make sure that the CSR is not the additional costs or charitable behavior; it naturally might be considered as opportunities for innovation and competitive advantage.

Results and Concluding Remarks

Diminishing natural resources, environmental pollution and persistent social inequalities clearly indicate that the current economic development model of nations in general is increasingly inconsistent with public expectations.

Naturally, the social and economic issues require innovative solutions from different perspectives ensuring that development take into account the needs of the present generation but at the same time does not hinder future generations from the ability of to meet their own needs. This is what sustainability is "about". Therefore, long-term organizational success depends on how they are able to integrate sustainability aspects into the organizational environment and management. We argued that application of effective management system creates the prerequisites for sustainable and successful operation of the company. From this perspective, the paper developed and validated the scientific and practical problem presenting a conceptual integrated organizational management model and expanded upon the relationships in organizational management system, social responsibility and stakeholder management in pursue of sustainability. Thereby special emphasis on the social dimension comes into play as a very important aspect for company sustainable development and strengthening company's strategic position on the market. Furthermore, majority of scholars agree that inclusion of social responsibility activities in organization strategy creates intangible assets and can even increase the firm's profitability and competitiveness. This viewpoint can be reasoned and approved as the construction of CSR integration model helps to understand the importance of the relations with stakeholders and rationalize their potential influence in the process of CSR implementation. Productive relationships with stakeholders can provide different benefits in a form of tangible and intangible resources and information necessary to survival. In that way relationships help to generate social, intellectual, environmental, and financial capital. The organizations get benefits not only in growth and long-term sustainability but assure mutual value as well disclosing mutual interdependence where everyone can provide and have benefit depending how successful the organization is in the achievement of its goals. This approach offers new perspective for corporate purpose together with more up-to-date quality criteria for management.

This paper makes several contributions: extends the existing understanding and discussions on the development of social responsibility and stakeholder management issues. The theoretical discussions have been inspired and deducted from theory on stakeholders and their relationships management, corporate social responsibility and sustainability by revealing these interfaces in organizational management.

Secondly – it enhances theoretical foundation in analysis of relations between organisational sustainability and stakeholder management. As a result an organizational management model is presented. The standpoint is evident and implies that, with the intention to meet the needs of all stakeholders and create value, the company must manage these processes in an efficient way. Therefore, guidelines and model of integrating these three very important elements -stakeholder relationships management, sustainability and social responsibility - can generate fluent implementation of these issues starting from strategic level and ending at tactical one. This encompasses various and different organizational processes: from research and strategy development to the design and implementation. Furthermore, the view of organization as a system closely related to society and engaged in array of different rapport with stakeholders reveals the perspective for generating wealth from these interrelationships.

The research suggests practical implications as well. As far as integration and implementation of stakeholder management, social responsibility is a multidimensional process; the issue is treated from organizational aspect and is limited to organizational management processes. Integrated social responsibility management system can be a practical tool to manage social responsibility issues. After the development and implementation of an integrated management system, the organization is run as interrelated and interacting processes system, in which each process is controlled as system of interrelated and interacting processes operated by P (plan) - D (do) – C (check) – A (act) cycle approach. The benefits of the model of an integrated management system in organization are reasoned and it might be used to explain actual behaviour of organizations regarding their aspirations for sustainability. Organizations, in assessing the social responsibility with the same criteria as they use for evaluation of its performance and strategic perspectives, can verify that the CSR is a competitive advantage rather than additional costs or charitable behaviour.

Although this study makes several contributions, it also has several limitations that provide perspectives for future theoretical and empirical refinement. We view this as the starting point for more detailed and empirical research agenda, which can be refined from different aspects. Owing to the study's exploratory character, the findings of our study stress the need for additional theoretical and empirical research in the area of management by upgrading the model with the expert and practitioners opinion and then testing it on real data taken from empirical research.

Abstract

The relevance of the topic of the article is due to the acceleration of the pace of changes occurring in the external environment of the enterprise and the need to ensure the functioning and development of enterprises under these conditions. At the same time, the applied scientific and methodological base is not sufficiently focused on raising the level and dynamics of the enterprise's viability, taking into account the dynamic nature of the environment. The purpose of the article is to substantiate the necessity of priority development of organizational and economic relations between the subjects of the enterprise in order to ensure its viability. The approach outlined in the article is based on a comparison of the level and dynamics of labor productivity in different countries, a comparative analysis of the essence of viability in various sciences, an analysis of the economic performance of domestic enterprises, a generalization of the practical activity of enterprises in the development of organizational and economic relations. The viability of an organization is understood as the ability to function independently and develop under the influence of unfavorable external factors on the basis of self-organization. It is proved that successfully developing enterprises in modern conditions achieve sustainable economic indicators mainly due to the transformation of organizational and economic relations, which are understood as a complex system of relations arising in the process of production and labor activity between employees and employers regarding the definition, establishment and performance of functionals, and also the allocation of resources for their implementation. Progressive and balanced types of organizational-economic relations are distinguished. Under the progressive one, it is suggested to understand the organizational and economic relations that are oriented and ensure the readiness of the subjects of these relations to achieve results that exceed the requirements of the market environment. Under the balanced one - organizational and economic relations, characterized by mutual satisfaction of the interests of employers and employees. The conditions are determined, observance of which allows forming progressive and balanced organizational and economic relations.

Keywords: organizational and economic relations, enterprise viability.

Introduction

In modern conditions, the acceleration of changes, increasing their depth and scale, makes enterprises more sensitive to the emergence of new challenges, increasing the risk of loss of viability. These changes are caused by political, economic, social, technical and technological, institutional, organizational and other factors. The acceleration of changes is manifested at all levels of the economy - from the economy of the household to the economy of the country. At the household level, an example of accelerating change may be a reduction in the average life span of household appliances - in 10 years since 2004, the overall level of replacement has almost doubled.

At the microeconomic level, there is also an increase in dynamism and instability. So, from 1982 to 2001, the share of executive directors on the Fortune 300 list, which occupy this post for more than six years, has almost halved, since 1935. By 2016, the average life span of companies in the S&P500 rating has decreased 6-fold (from 90 to 14 years) (Meyer, 2003; Anthony, 2016). An increasing number of enterprises are becoming unviable, that is, they are not able to function independently and develop in a dynamically changing, unstable competitive environment.

The dynamics of the environment at the level of macroeconomics can be traced through economic cycles, price fluctuations, etc. For example, according to analysts' estimates in early 2000, the economic situation in Russia is characterized by significant positive changes: since 1998, the GDP has grown by an average of 7% per year, and the country has moved from 72 to 53 in the world in terms of well-being; following the rapid increase in wages, the growth of disposable income of the population reached the level of 26% per year (Smirnov, 2009). However, under the influence of the global financial crisis that began in 2008, positive trends have been replaced by significant negative results - by 2017, according to various sources, Russia ranks 57-60 in the ranking of countries in terms of living standards. This shows that the Russian economy as a whole and individual economic entities are not sufficiently stable. According to experts, economic growth until 2008 was mainly associated with the loading of available free capacities. In the current conditions of aggravation of competition in the labor and capital markets, the need to increase the efficiency of the use of resources and labor productivity as the most important condition for the viability of the enterprise becomes more evident.

Globalization has a significant impact on the acceleration of change. Obviously, domestic economic entities compete not only among themselves, but also with foreign enterprises. At the same time, the pace of development of foreign enterprises, and, consequently, their viability, is much higher. According to the Organization for Economic Co-operation and Development (OECD), labor productivity per working hour in Russia in comparison with the economically developed countries of 1995 was more than 4 times lower. By 2015, the gap has narrowed somewhat, but still remains very significant - about 3.5 times (Figure 1).

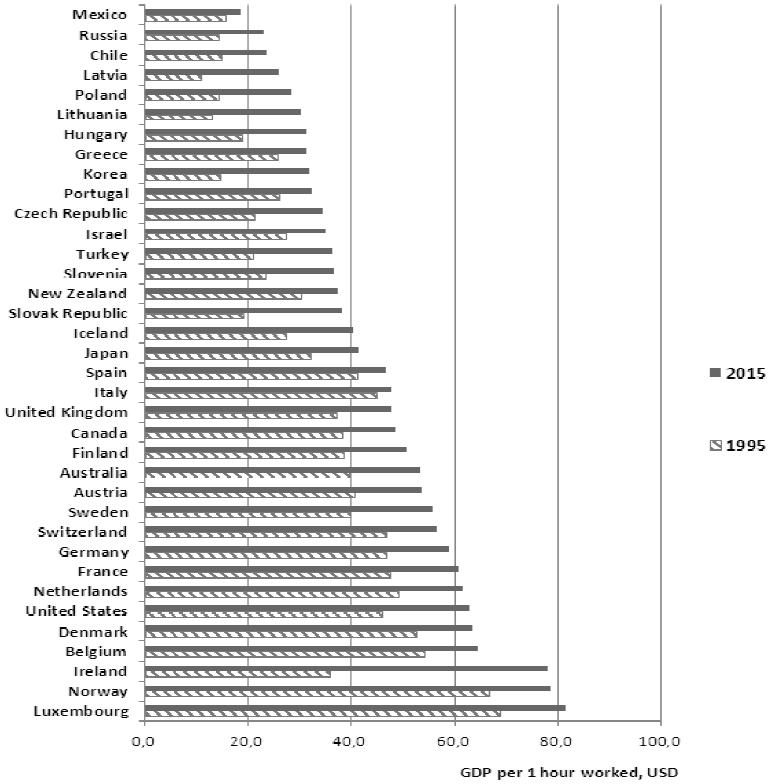

Fig.1. Labor productivity in different countries of the world (GDP per 1 worked hour, USD, 1995-2015) (calculated according to [4])

A comparison of the dynamics of labor productivity over the past 10 years between countries shows that the highest growth rates - more than 2 times - are shown by countries such as Ireland, Korea, Lithuania and Latvia. The lowest growth rates in Italy - about 6%. In Russia for the years 1995-2015 the labor productivity increased 1.6 times, which is somewhat higher than the average for the countries in question (47%) (Figure 2).

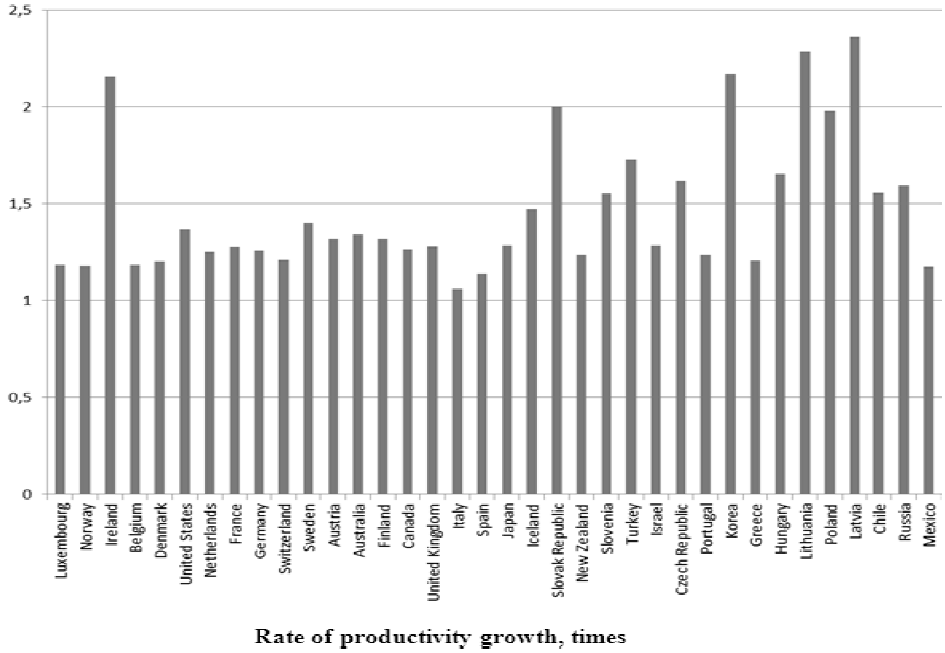

Fig. 2: Dynamics of labor productivity in different countries of the world for 1995-2015. Calculated by (Organization, 2017; Economist, 2013).

Acceleration of the processes of change, and as a result of the high turbulence of the external and internal environment of the enterprise, exacerbates the need to study the factors and conditions for ensuring the viability of the enterprise.

What is viability?

The term "viability" is the subject of study of the biological, sociological, psychological and economic sciences. In biology, viability is understood as the ability of an individual or population to maintain its existence under changing conditions. Regarding social systems, viability is seen as the ability to work together to overcome conflicts and unfavorable internal factors. In psychology, a person who is able to adapt, realize self-regulation and development, constructing a constructive relationship is considered to be viable. Applied to organizations, this concept is used relatively recently - from the end of the 20th century, and in recent years the interest of both Russian and foreign researchers to this phenomenon has been increasing (Bhamra, 2012; Gittell, 2006; Kerr, 2017; Lengnick-Hall, 2011; Richtner, 2014; Blagutin, 2014; Makarov, 1997). Summarizing different points of view, under the viability of the enterprise we will understand its ability to independently function and develop under the influence of unfavorable external factors on the basis of self-organization.

Self-organization means the process of ordering the structure of a dynamic system, taking place without external organizational influences. Self-organization is based on certain relations between the subjects of

the system. Within the framework of the enterprise, such relations are organizational and economic - it is a complex system of relations that arise in the process of production and labor activity between employees and employers (or owners of the enterprise) regarding the definition, establishment and performance of functionals, and the allocation of resources for their implementation.

Role of Organizational-Economic Relations in Ensuring the Viability of an Enterprise

A comparative analysis of the performance of a number of mining enterprises showed that the change in labor productivity in the period 1990-2000. It is primarily due to an increase in the capacity of the main equipment (Figure 3).

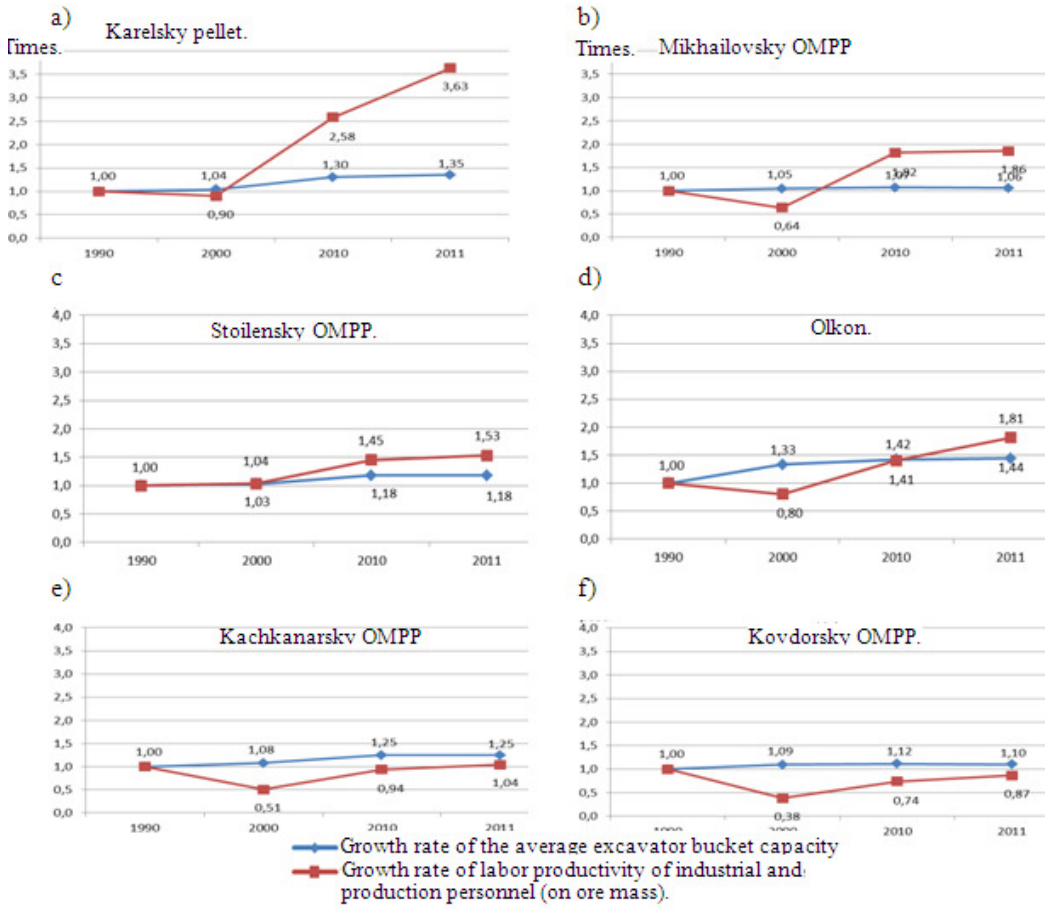

Fig. 3: Dynamics of labor productivity and excavator capacity at Russian mining enterprises for 1990-2011. Calculated by (Technical, 2012)

The increase in labor productivity in the subsequent stage (2000-2010) is associated with successfully developing enterprises (Figures 3 a, b, c), mainly with the implementation of organizational transformations and the transformation of organizational and economic relations, including a reduction in the number through the outsourcing of services (works), optimization of the number of auxiliary and maintenance personnel.

Other enterprises (Figures 3 d, e, f) retain the orientation toward increasing the capacity of the equipment while increasing labor productivity. The conducted researches show that the workers of the above-

mentioned enterprises have mastered and reproduce this way of increasing labor productivity, without seeking to change the system of organizational and economic relations. This is confirmed by the results of the questionnaire survey - the majority of respondents connect the prospects for the development of production with technical re-equipment, and not with improving the organization of labor, production and improving the state of jobs.

The conducted time-keeping observations and subsequent calculations revealed that 20-60% of working time losses is caused by uncoordinated interaction and insufficiently high level of development of organizational-economic relations. These losses of working time lead to a rise in the cost of a unit of labor, which is unprofitable both for the employer and for the employee, because the profit and the stimulating role of wages are declining.

The dependent position of the personnel in relation to the increase in labor productivity is maintained by the institutions operating at the enterprises (rules, regulations, instructions) regulating the procedure for rationing, organization and payment of labor. This is manifested in the lag in the rates of growth of labor productivity from the wages of the average worker, which can reach 2-3 times during the years.

The quality of organizational and economic relations determines the coordination of interaction between employees and the readiness for self-organization of the collective. The basis of any relations of subjects, including organizational and economic, is exchange as an act of mutual satisfaction of needs or a process of obtaining mutual benefits. Proceeding from this, the sustainable viability of the enterprise can only be achieved if the interests and responsibilities of employees and employers are balanced (Figure 4).

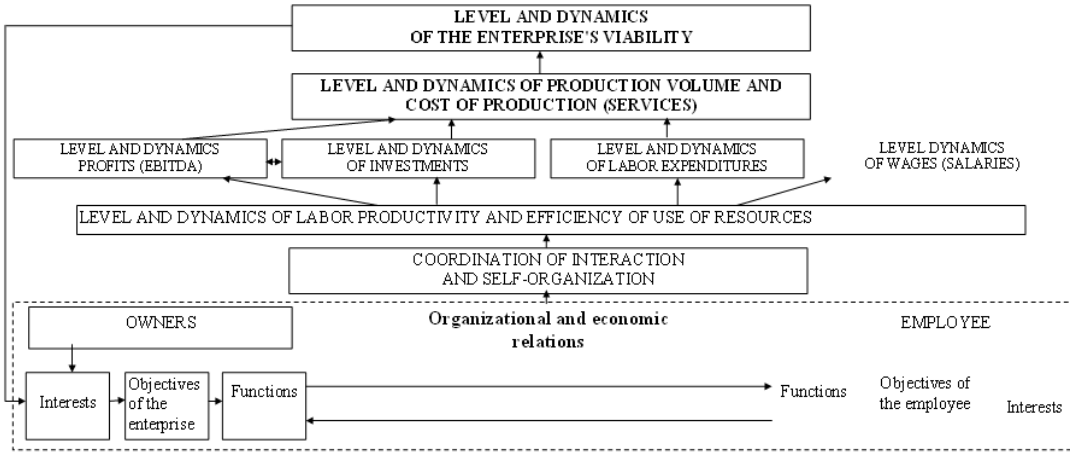

Fig. 4: Influence of organizational-economic relations on the viability of an enterprise

The main economic interest of the owner of the enterprise is the receipt of profit, the employee - pay for the function performed. Therefore, in order to balance the interests and responsibilities of business entities in the context of ensuring its viability, certain conditions must be met: 1) the volume of investments does not exceed the amount of EBITDA received; 2) the level of efficiency of the use of resources and wages is not lower than the industry standard; 3) the growth of labor productivity must outpace the growth of wages.

Ensuring the viability of the enterprise is impossible without the development of production, which is achieved on the basis of investment. The inflow of investments is determined by the attractiveness of the enterprise and is achieved on the basis of increasing the efficiency of the use of labor. The investment attractiveness of an enterprise depends on how much its employees have effectively worked in the past period. This is confirmed by the results of a correlation analysis of the efficiency of labor utilization expressed by the specific volume of profit before deduction of interest expenses, taxes and accrued

depreciation per employee (EBITDA) and the specific volume of investments with a time lag of one calendar year that showed a high degree of tightness of communication These indicators - the coefficient of pair correlation was 0.67-0.8 (Figure 5).

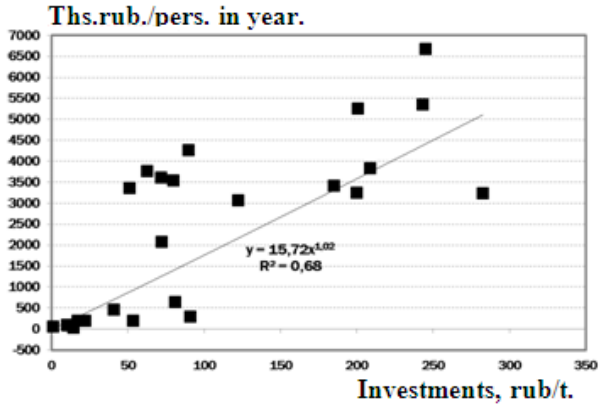

Fig.5: Connection between investments and EBITDA in Russian coal-mining enterprises (2003-2015).

Types of Organizational and Economic Relations

Compliance with the above conditions makes it possible to form progressive and balanced organizational and economic relations. By progressive understand organizational and economic relations, oriented and ensuring the readiness of the subjects of these relations to achieve results that exceed the requirements of the market environment. Balanced organizational and economic relations are characterized by mutual satisfaction of the interests of owners (employers) and employees (Table).

Table 1 : interrelation of organizational and economic relations of personnel and the viability of an enterprise

Type of organizational-economic relations	Level of viability	Characteristics of the viability level
Progressive and balanced	High - changes in the internal environment are ahead of changes in the external requirements (conditions)	The growth rate of labor productivity outstrips the growth rate of wages; Labor productivity, wages and efficiency of resource use are higher than the industry benchmark; Income (EBITDA) exceeds investment
Either progressive, or balanced	Medium - changes in the internal environment are comparable with changes in the external requirements (conditions)	Any one of the ratios is violated: the growth rate of labor productivity outstrips the growth rate of wages; Labor productivity, wages and efficiency of resource use are higher than the industry benchmark; Income (EBITDA) exceeds investment
Neither progressive, nor balanced	Low - changes in the internal environment lag behind changes in the external requirements (conditions)	Two or more ratios are violated: the growth rate of labor productivity outstrips the growth rate of wages; Labor productivity, wages and efficiency of resource use are higher than the industry benchmark; Income (EBITDA) exceeds investment

Conclusion

It should be noted some commonality in the mechanism for ensuring the viability of various systems, namely one of the basic elements of such a mechanism are the relationships within the system and with the external environment.

In economic systems, the development of organizational and economic relations should go in the direction of achieving a balance of interests and responsibility of business entities, as well as results exceeding the requirements of the market environment. The formation of progressive and balanced organizational and economic relations allows enterprises, in conditions of accelerating the dynamics of the environment, to update and achieve the goal at a faster rate, that is, to remain viable.

Abstract

Data and information quality (DIQ) is a critical issue for effective asset management in modern higher education (HE) sectors. Managing DIQ is essential to any asset management program. Problems with data quality can result in a number of unpredictable negative consequences. Several studies have provided strong evidence to indicate that most of HE institutions have DIQ problems. DIQ has recently been brought to the forefront and has become a pressing issue. This is particularly important in an environment where HE institutions begin to share their information systems with their stakeholders such as suppliers and business partners. Moreover Universities have millions of digital assets, thousands of users, hundreds of policies, many departments and stakeholders, and just one goal that is easy, affordable digital asset management that works the way everyone expects it to work. In such an environment, knowledge on how to manage the quality of the information asset has become very crucial in order to support the HE development. This paper describes a study, which explores DIQ problems with existing HE's asset management system, and identifies key factors that impact on DIQ. The study applies a DIQ issues for asset management in a preliminary case study of a large HE institution in Makassar, Indonesia. The findings of the study suggest that the importance of DIQ issues for effective asset management in HE needs to be widely understood. The paper also provides recommendations that may be useful to HE managers/practitioners.

Keywords: (DIQ), (HE)

Introduction

Assets management is an important part of university management, so the assets management has significant impacts on universities' teaching and scientific research. With the deepening university reform, assets management has become a vulnerable link in university management and badly harmed the harmonious development of higher education (HE). To understand the current conditions and shortcomings of university assets management and to enhance the efficiency of university assets

management will be meaningful for the benefits of university assets (Wang, 2015). Data quality issues are at the heart of effective asset management. Managing data quality is essential to any asset management program as there are enormous benefits to be gained from ensuring the quality of data, e.g. information integration, interoperability, reduced costs, quality decision support, institutional integration, process innovation, knowledge management, and ability to reuse data. There is a growing need to address the issue of DIQ of asset management systems of HE institutions, by analyzing existing practices and providing current DIQ problems and its solutions to assist engineering enterprises to capture, process and deliver quality data and information. It is essential to ensure quality of data in monitoring systems, control systems, maintenance systems, procurement systems, logistics systems, and range of mission support applications to facilitate asset availability, readiness, reliability, effectiveness, and management. Therefore, when enterprises are managing their valuable engineering assets, it is critical that DIQ issues are placed in high priority.

In managing physical assets through the entire asset life cycle, large amounts of data is needed for long term performance and reliability prediction, as well as informing the decision making process on how and when to retire an asset. Although very large amounts of data are being generated from condition monitoring systems, little thought has been given to the quality of such generated data. Thus the quality of data from such systems may suffer from severe quality limitations (Saunders 2004). This paper aims to explore DIQ problems with existing asset management systems in HE sectors, to identify the issues that are particularly relevant in the asset management domain, and to understand what differences may exist in the data quality critical factors that exist in the management of physical assets.

Data and Information Quality in Higher Education

Asset management in Indonesian HE institution is not considered as a core business activity therefore they depend on the traditional organizational information sources to manage engineering assets. These traditional sources represent tacit and implicit knowledge of engineers, operators, and information contained in information systems, which have been primarily designed to increase productivity rather than improving efficiency of the processes involved in production. A unified and modern assets management system has not been established. Therefore, university assets management is still in a dispersed state, without realizing the centralized management, which harms the assets management and the long-term development of universities. An imperfect management system will inevitably cause the misty of responsibilities. Although some Indonesian top universities try to reform the assets management system, the phenomena of unclear responsibilities are still common and tend to be severe. In many universities, the assets are usually jointly managed by different agencies. For instance, university dormitories, canteens, cafes and other real estate are chiefly managed by the logistics, while the monetary assets by financial department. University assets are respectively managed by different agencies. This assets management mode seems accomplishing the specialized management. However, it usually results in the unclear of responsibilities. Wang (2015) emphasize that once there is a problem raised, it is not easy to determine who is responsible.

At the same time, a variety of operational and administrative systems exist in asset management, which not only control and manage the operation of asset equipment but also provide maintenance and administrative support throughout the entire asset lifecycle. In practice, data is collected both electronically and manually, in a variety of formats, processed in isolation, stored in a variety of customized and off the shelf legacy systems, shared among an assortment of operational and administrative systems across faculties, study programs and other departments, communicated through a range of sources and to an array of business partners and sub contractors. Data captured and processed by these systems is not comprehensive and is process dependent, making it difficult to be reused for any other process or process innovation (Syafar et al., 2015).

Most importantly, there has always been a degree to which data has been obtainable, sometimes due to

lacking data acquisition standards (Syafar & Gao 2013, Syafar et al., 2014), sometimes due to university culture, and sometimes due to the inability of a head of asset manager to judge what data is important. One such example is that of out door devices, which have mainly been used to monitor the condition of asset equipment (Syafar et al., 2013, Syafar et al., 2014a). Whereas, such information could provide the engineering asset manager with vital failure and maintenance trends (Syafar et al., 2014; 2014a), and coupled with financial information it could provide decision support for budgetary constraints, asset improvement, and planning and scheduling to support academic and students activities.

Research Method

For this research, two large Australian Institutions were selected as case sites. Case study research is used to study the contemporary phenomenon in its real-life context (Yin, 1994) and it can be used where the research and theory are at their early, formative stages (Benbasat *et ul.,* 1987). As data quality for asset management has received little attention in the research community, there is a need to examine whether the data quality is a critical issue to any asset management program and what the key factors are to ensure data quality in managing assets. Therefore, case study research appeared to be appropriate for this study.

In data quality studies, four types of stakeholders have been identified by Strong et al. (1997); Wang (1998):

1. data producers;
2. data custodians;
3. data consumers; and
4. data managers.

To apply this stakeholder's concept into an asset management environment:

1. Data producers are those who create or collect data for asset management system.
2. Data custodians are those who design, develop and operate the asset management system.
3. Data consumers are those who use the asset information in their work activities.
4. Data managers are those who are responsible for managing data quality for asset management systems.

Data was collected using semi-structured interviews with key stakeholders of asset management systems. Each interview included questions about the background of the organization, as well as its asset management practice, the participants' roles, and their views about data quality issues in managing assets. Additional information was obtained from secondary data including reports and internal and external documents. The purpose of the case study was to investigate what was actually happening in real-world Institutions in relation to data quality issues associated with engineering asset management within engineering enterprises.

Preliminary Research Findings

Selected case study of HE institution (mentioned as institution A in this paper) is a nationally recognized of public (government) university that has 887 university lecturers, 720 administrative staffs and provides services to approximately 31.000 students within 11 faculties and more than 100 study programs.

DQ problems

Institution A used multiple systems to process various functions of asset management. It used MainPac only for electrical and mechanical assets management, and PC Works for work management that had a lot of checks and validation rules built into the system. The main focus was about quality rather efficiency. To improve the speed and efficiency, Institution A decided to use Maximo to replace some of its legacy systems. The current Maximo is actually help educational institutions thrive the asset management

solution with:

- Visibility to respond faster and make better decisions. Complete, real-time visibility improves responsiveness and supports high-level, integrated use of information technology for effective, adaptive and mobile operational capability.
- Control to maximize return on investments and reduce risk. Built on a cost-effective, robust, secure and agile foundation, the solution delivers higher-quality services for improved customer satisfaction.
- Automation to streamline processes, accelerate growth and build greater agility into business operations. This reduces operational cost, risk and complexity by integrating business and IT services across the enterprise.

However, the change of system has caused several problems. Users of the Maximo package do not find it easy: the work management tool used for work scheduling is perceived as inappropriate for recording, as well as accessing the detailed information for assets, for example time and location. It is perceived as tedious to do combination for job allocation for different people in work planner. Consequently it appears that people are becoming less diligent in recording information. As one interviewee commented ***"Now we are worse off particularly from the data quality point of view".*** It was indicated that a trial period should have been taken place before the adoption of the new system, so that difficult issues are resolved. In addition the User Interface needed to be much easier and simpler to use by the workers.

Field people communication

Out door person within Institution A can produce unreliable data. In this Institution, the task of collecting the data is accomplished under adverse environmental conditions by a variety of personnel skill levels. The format for data collection vary considerably, as there is no set method for the accomplishment of such, and the data desired may be different for each system. One of the causes for data errors overtime has been due to the lag between out door data collection and entry into the computer. The longer the time lag, the less the chance there is for cleaning up the data to make it useful. Therefore, the earlier the data is recorded, the earlier it can be validated for possible future analysis. Possible reasons for this lag are laziness and a lack of awareness of the importance of the data on the part of those who collect the data. Another cause for data errors is the use of paper based collection technique. The need to write things down means, that the out door workers are less interested and motivated in recording the data. The lack of information feedback subsystem for data collection also proves to be another cause of error. Overtime, out door workers realized that the whole process was simply pointless as they perceived that no follow ups were made and hence lost interest and motivation. The data collection subsystem must not only incorporate the forms for recording the right type of data, but must consider the personnel factors (skill levels, motivation, etc.) involved in the data recording process. The person who must complete the appropriate data form(s) must understand the system and the purposes for which the data are being collected. If the person is not properly motivated to do a good thorough job in recording events, the resulting data will of course be highly suspect.

Data Collection Technology

To better aid the out door people in data collection, data recording technology should be improved such that it will not discourage the collection process. Ways of achieving this include better interface design and the replacement of paper based techniques. Several ideas have been thought in order to improve the quality of the collected data in Institution A. The Institution has identified a need for developing a wireless mobile device system to assist the out door workers for receiving real-time job details and making job entries at the place where the job is conducted. This application will use smart phone with GPS based data for locating a particular asset and allow the users to update the asset location data using

location identification feature.

Discussion

DQ Problems

There are often different types of operational and administrative systems in engineering enterprises, which not only control and manage the operation of asset equipment but also provide maintenance and administrative support throughout the asset life cycle (Syafar et al., 2013, Syafar et al., 2014a). In practice, data is captured both electronically and manually, in a variety of formats, distributed over large and complex communication networks, shared among an assortment of off the shelf and customized operational and administrative systems, communicated through a range of sources and to an array of business stakeholders. The problem of data quality becomes crucial when huge amounts of data are exchanged and distributed in such an intensive way as in these contexts. What is more, more often these assets operate in unstable environments and consequently generate maintenance demands hitherto unseen. In such circumstances, incomplete and historic information hampers the ability of a plant manager to make far-reaching decisions on asset operation; maintenance scheduling, planning and execution; and asset disposal (Syafar et al., 2015).

Wang et al. (1994), Tayi and Ballou (1998), and Orr (1998), term data quality as 'fitness for use'. The brevity of this definition covers most important aspects of data usage. Orr (1998) argues that the issue of data quality is intertwined with how users actually use the data in the system, since the users are the ultimate judges of the quality of the data produced for them. In engineering asset management, the issue of data quality has it roots in multiplicity of data acquisition tools and methodologies, and the exchange of the data thus captured within an assortment of systems. Therefore, according to Syafar and Gao (2013a) conforming to user requirements is extremely difficult.

Integration of Asset Management Systems

Most HE institutions today purchase specialized systems from difference suppliers. The asset management systems used to not only for controlling and managing the operation of asset equipment but also to provide maintenance and administrative support throughout the asset life cycle. Some of these systems include: reliability assessment systems, operational data historians, enterprise asset maintenance systems, asset capacity forecasting systems, and physical asset data warehouse systems. Normally these systems are bought from multiple vendors and each is specialized to accomplish its task. Such disparate systems can often lead to an extremely difficult integration job for the end-user. However, to be effective to all levels of decision-makers in an university, physical asset management systems need to be integrated. Integration is required in order in implementing condition-based maintenance (CBM), since CBM-enabled enterprise asset maintenance systems rely on condition monitoring systems to notify them of the need for maintenance.

Data Exchange

There is a need for data exchange between asset management applications for seamless access to information across heterogeneous systems and different departments/study programs within a university. The life cycle performance data of the various assets are kept in individual uncoordinated databases. The numerous information systems and databases for todays engineering asset management in HE institutions run with little or no interaction. However, there is a lot of information that must be communicated across departments/study programs and among different users, and the existing systems do not offer this functionality. Therefore, providing the enterprise personnel (service and operation, back-office, management) with the seamless access to information is crucial to academic success.

There exist IT systems that support to some extent the institutional goal to optimally manage their assets, such as condition monitoring applications and computerized maintenance management systems. The former focus on an asset and its process data; they are usually closed systems, physically linked to an asset, and providing no interface to other asset systems; finally, their output is usually convenient and understandable for equipment specialists only. The latter are typically back-office applications, having no verification data link to the out door (i.e., asset themselves).

Data Cleaning

Data cleaning is a labor-intense, complex, and costly task. Data quality problems that are addressed by data cleaning can roughly be divided into two categories, such as single source and multi source problems, each of these two categories is further divided into two sections, i.e., schema and instance related problems (Rahm & Do, 2000). Schema level problems may replicate in instances, and can be resolved at the schema level by an improved schema design, schema translation and schema integration. Instance level issues signify data errors and inconsistencies not visible at the schema level. Generally, the most common examples of dirty data (Hurwicz 1997; Jake et.al. 2003) are: format differences, information hidden in free-form text, violation of integrity rules (e.g., in the case of redundancy), missing values, schema differences. There will be a need for data cleaning in HE asset management to develop.

Training

From a data and information quality perspective, training in real world cases has not been addressed enough. Managing assets requires all aspects of training as well as appropriate documentation of the system. It was found that selected university tended to focus more on the 'hardware' part of the systems' development process, putting less effort on the 'soft' part, that is, the training of how to operate, manages the system. The people's skills, people's abilities to use the system efficiently are very critical to ensure data quality in asset management system. If people do not have the skills and knowledge to control the system, then even the perfect system would not be able to produce high quality information. Lack of training can cause serious damage and have an adverse impact on information quality. It is easy for Institutions to find reasons/excuses for avoiding adequate training for the staff and management. According to Syafar et al. (2015) education and training is vital for everyone who will use the new system. It's because the system does not just about know the minimum necessary to access data and information, but the system will improve business process, achieve operational efficiencies and increase collaborative-shared information in real-time. Therefore, effective and quality training should aim to improve the critical mode of knowledge held by different data roles (data collector, data custodian, data consumer) in a data production process work with more focus on enhancing data collector's know-why knowledge for high data quality.

Conclusions

This case study provided a better understanding of data and information quality issues for HE asset management as well as providing useful practitioner findings from real-world practice. Key data quality issues discussed should help HE institutions obtain a better understanding of data quality issues throughout the process leading to activities which will help ensure information quality. Although the university may not have controls on those factors, this HE institution can actively manage those changes. Institutions could use external pressures to accelerate a whole of internal academic information quality management.

University has not established complete assets evaluation mechanism, which causes confused assets management, resulting in serious losses of assets. Currently, the phenomenon of "emphasis on purchase over management" is common in Indonesia university assets management. The lack of regulations makes multiple aspects of management out of control. Many universities are even not clear about their assets, let

alone the complete assets management. In addition, the losses of university assets caused by changes of original utility of assets have become increasingly prominent. Interests drive human, which is the classical theory of economy. University assets managers are no exception. According to the university assets management conditions, we hope that they can increase DIQ in order to ensure the normal teaching and scientific research, and the assets managers' awareness of assets appreciation can be enhanced significantly.

Life-cycle Risk Management Methodology of European-Funded Projects

Nicoleta Daniela Ignat, University POLITEHNICA of Bucharest, Bucharest, Romania,
nicoleta_ignat@yahoo.com,

Abstract

The purpose of this paper is to create a unitary risk management framework for projects funded from European non-reimbursable funds in Academia as beneficiary in order to ensure a reduction in exposure to losses.The paper briefly presents a risks management methodology developed by analyzing a range of 40 projects focused on the development of human capital and implemented in Academia.There are methodologies to approach and manage the risks occurring at Beneficiaries but different notions and concepts are applied. Moreover, it should be noted that they are developed with the organization as starting point, the elements directly affect the organization and universities are public institutions in which a wider range of activities (both didactic and research activities) are carried out, thus a risk approach is required at the project level.Following the analysis of the projects implemented in Academia over the last five years, it was found that project managers in Academia do not have project management expertise, therefore guidance to properly manage projects is needed.
In this paper, a qualitative risk analysis was proposed by using the risk matrix. Exposure to risk is directly related to the probability of materializing the risk. Using the proposed methodology, a qualitative risk analysis can be carried out from internal or external factors that directly or indirectly affect the achievement of the objectives assumed at each project level. This methodology can be transposed and correlated with existing risk management methodologies in Academia.
The risks management methodology also includes a risks register.

Keywords: Risks, risk management methodology, projects funded by European funds

1. Introduction

In terms of innovation, but also due to the challenges of globalization, projects are constantly subject to constraints (Alhawari, et al., 2012; PMI 2013) and risk management is of interest for Academia.

Practices in project management are increasingly needed as a thorough identification and management of risks can be provided.

Also, using project management practices can ensure better communication between project partners, thus facilitating decision making and prioritization to achieve the objectives (Marcelino-Sádaba et al., 2013).

Risks are classified according to one of their characteristics, without taking into account the interactions that may arise between the risks that may occur concurrently. In fact, the project manager often faces risks from different groups / categories that occur at the same time (Marle, F., 2011; Vidal et al., 2009).

To manage the risks, there are project management models, but management models that are tailored to project types and organizations are required because not all of these models can be transposed into different types of projects (Turner et al., 2010).

Uncertainty represents an event with unknown probability which is not susceptible to analysis (Kolisch, 2010). Throughout the life cycle of the project, project managers must identify risks and uncertainties that can not be evaluated (Ward and Chapman, 2003).

2. Risk Management - Approach to Projects

Risk management is a complex process of identifying, analyzing, and responding to possible risks that may arise over the life cycle of a project. Thus, the risks can occur at the project design stage, in the implementation phase and in the sustainability period.

Thus, by monitoring the implementation of projects (internal control), risk management is directly ensured.

Achieving a coherent risk management involves:

- preliminary analysis of all risk exposures, the identification of risk sources being fundamental and determinant in the proper assessment of risks;
- identifying significant / strategic risks that may affect the effectiveness and efficiency of activities related to specific objectives,
- defining the degree of tolerance / acceptable level of exposure to risks;
- assessing the likelihood that the risk materializes, the impact assessment and its exposure;
- establishing the strategy (control measures) for the management and monitoring of risks.

The key word in terms of risk management is the term "systematic". We do not have to deal with the consequences of any events that have occurred, because this does not improve the causes. Therefore, a proactive management style must be adopted, which means that it is necessary to design and implement measures aimed at identifying possible risks before they materialize and produce unfavorable consequences on the set objectives.

Throughout the lifecycle of the projects, especially during their implementation, universities interact with other entities (partners, authorities, public institutions, etc.). In this environment there are threats and opportunities that can condition / endanger / promote the achievement of the objectives assumed by the projects and implicitly at the level of the university. Interaction of public institutions with the external environment is inherently one that assumes the acceptance of uncertainty as a standard variable of management activity.

If uncertainty is a daily reality, then the reaction to it must be a permanent practice.

Risk management involves addressing a proactive management style:

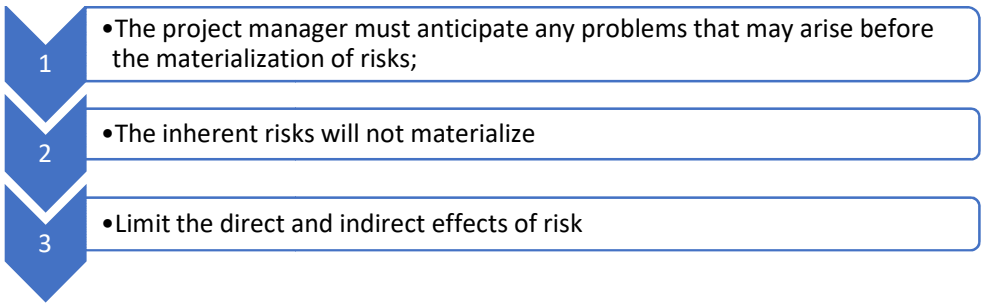

Fig 1: Risk management involves addressing a proactive management style

Risk management provides an efficient and effective organizational framework for achieving the goals assumed at the Academia.

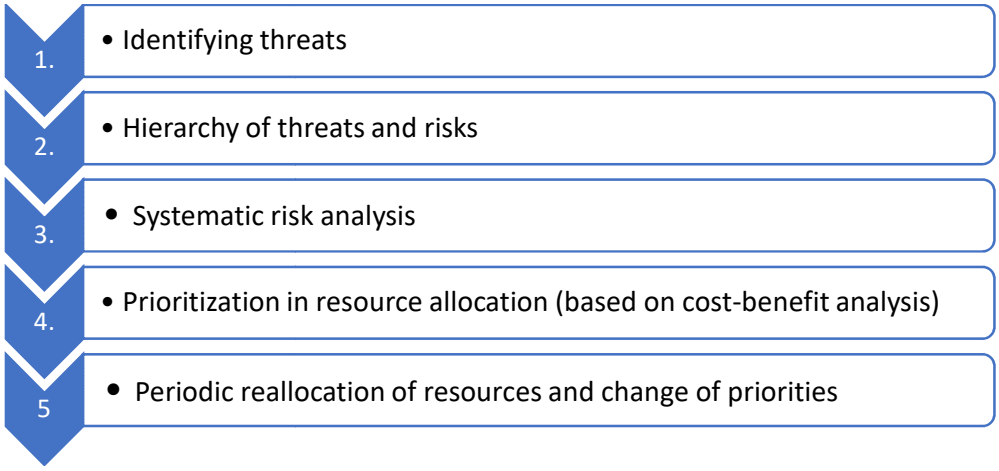

Fig. 2: Risk Management - Organizational Framework in Achieving Objectives

3. Risks management methodology at projects level

In the first stage, each project should identify the risks that might arise over the life cycle of the project. In the second step for each identified risk, a more detailed description must be made, identifying at the same time the causes that have favored their emergence.

Therefore, the risks management methodology is the basis for identifying and assessing risks; the establishment of control measures, in order to diminish the possibility of their defense, as well as to mitigate the consequences of the products as a result of their materialization.

3.1 Identifying the risks that may arise over the life cycle of projects

These can be identified by looking at both internal factors - the vulnerabilities of the project and the external ones that can lead to unwanted effects having a direct impact on project objectives and indirectly on the Academia.

In order to identify the factors that can lead to risks, the project and their documents will be analyzed in detail. Risk factors identified by the analysis will be quantified in a risks register.

Table 1: Risks register

Objectives /Activities	Risk	Causes for risk	Inherent risk			Suggested solution	Residual risk		
			Probability	Impact	Exposure		Probability	Impact	Exposure

3.2 Risks description and risk exposure assessment

Exposure to risk is a probabilistic concept, being directly related to the probability of materializing the risk. It is the significance just before the occurrence of the risk. Exposure to risk operates with an implicit hierarchy of identified risks.

For risks assessment, in this methodology, the risk is mathematically expressed according to the following formula:

Risk = Impact x The probability of occurrence of an event

The formula used presents the risk calculated as a product between impact and probability.

Exposure to risk is a combination of probability and impact, being a two-dimensional, matrix type indicator.

A matrix for exposure to risk can consider the levels: very low (VL), low (L), moderate (M), high (H), very high (VH) for both impact and probability, which results in risk such as VL -VL, L - VL, M -VL, etc.

Considering that this analysis will be done step by step, we propose the use of a 5-step staircase to obtain a risk exposure matrix. These values can be both qualitative and quantitative.

In order to be able to apply the methodology presented at the level of the project management team, a high managerial capacity at the project level is required which is quantified as follows: Each risk will be classified at the level of the analyzed project using a subjective scale for probability and impact. This creates a risk matrix in which color codes will provide a way to assess the risks in terms of impact on the project.

Table 2: Risk matrix - exemplary with a degree of tolerance matrix defined in according to the project parteners

Impact					
0.8	0.08	0.24	0.40	0.56	0.72
0.4	0.04	0.12	0.20	0.28	0.36
0.2	0.02	0.06	0.10	0.14	0.18
0.1	0.01	0.03	0.05	0.07	0.09
0.05	0.01	0.02	0.03	0.04	0.05
	0.1	0.3	0.5	0.7	0.9

Probability

Table3: Color code contrains and Relation between the project risk impact

Color Code Constrains		**Project impact**
Between: 0.00 and 0.05		Low
Between: 0.06 and 0.14		Moderate
Between: 0.15 and 1		High

All risks that have an exposure level above the accepted risk tolerance limit require control measures to make these risks residual.

Establishing the risk tolerance limit is an act of managerial accountability, as it has important implications for the costs associated with control measures and the costs of exposure to risk.

Conclusions

The methodology will be a working tool that will be used to implement projects at Academia. Taking into account the fact that the development of projects proposals, their implementation and ensuring sustainability are done by the project teams with the administrative support of the Academia, it is

necessary to have a risks management methodology at the level of the projects that can be made available to the project teams and adapted to each project proposal.

The role of this methodology was to provide a unitary risks management framework for projects funded by European funds (proposed and implemented by Academia).

At the same time, the methodology will also be useful in the reporting process at the level of the Beneficiaries who will apply it at institutional level.

The reasons behind the development of this methodology are:

- at the level of Beneficiary, the risks are managed by the management team of each project on the basis of the experience of the project manager / without a unitary approach as to how to identify, evaluate and manage the risks that occur at the level of the projects;
- substantial terminological differences in the methodologies used at national level in the management of different types of risks;
- substantial differences in establishing the criteria on the basis of which the impact of different types of risks is assessed;
- differences at national level regarding the assessment of the impact of certain risks.

New Method of Monitoring a Creative Project and its Use in Practice

Eva Svirakova, Tomas Bata University in Zlín, Faculty of Multimedia Communications, Stefanikova 2431, 760 01 Zlín, Czech Republic, svirakova@utb.cz,

Abstract

The objective of this paper is to design new methods of creative project management and verify whether they are practically applicable by the means of Water for All Project, a case study of product innovation. Our effort is based on the method of Earned Value Management, which we modify so that it can be used in a creative environment and we use a universal unit for measuring the planned as well as implemented value. This unit comprises difficulty points assigned to the project products. Through our own procedure we define an exact reference mode of the project so that we can complement it with a simulated process using dynamic modelling. This allows us to compare on the model the planned and actual development of the project with the simulated development that also contains forecast of the further advancement of the project. The simulation includes elements such as fatigue during the project, team members´ motivation and quality of the work done. We describe the use of new methods step by step on the case study of the Water for All Project.

Keywords: Culture and creative industries, system dynamics, systems thinking, creative project management

Introduction

Monitoring the progress of a certain project is a challenging managerial task. Unless it is defined what the project wants to achieve before it actually starts, it is impossible to assess the degree of deviating from the original intentions and whether the project has been successful or not. In the project portfolio in the field of cultural and creative industries we keep facing the same problem over and over again: cultural creativists often don´t have an idea how their project will advance and how many resources they are going to need in order to implement it. This means that project managers in this environment don´t have relevant plans for their projects. They manage their creative projects intuitively and underestimate the importance of planning. This implies that they are not able to monitor its actual implementation. Their argument for such an attitude to planning is that traditional methods are not practically applicable. The reason is as follows: a creative process is hard to predict, which means that during the project implementation many unexpected situations that cannot be planned will arise. However, sponsors and customers who order this type of projects require objectively verifiable information to be able to conclude whether their assignment has been fulfilled and whether the project achieved the goals expected. Therefore, managers in cultural and creative industries have to know at what stage of a project they are at a given moment so that they could inform the sponsor accordingly. Managers of creative projects need to know the reasons why projects get into trouble, how such problems can be prevented and how they can improve their project management. If we offer them suitable methods of monitoring project development so that they could use them without any administrative obstacles, we will increase the efficiency of their decision-making when managing projects. The objective of this paper is to design new methods of creative project management and verify whether they are practically applicable by the means of Water for All Project, a case study of product innovation.

Literature Review

We design new methods for cultural and creative industries. We first had to define clearly the environment. According to Guntern (in Steiger and Lippmann, 2012; Bačuvčík 2012), a creative product is a product that meets four criteria: it has to be original, unique, valuable for users in terms of its functions (a product must function as it is supposed to) and formally perfect (in other words, a product must be beautiful). Creative project management is a method of creating a new value which is based on the unique talent of the creator aspiring to create a high-quality product within pre-defined limits. The way of creating new value consists in setting relevant processes for creative project management. In addition to the processes of project management, a project manager of a creative project also needs to take into account the talent of the creator and uncertainty of future achievements that are based on the invention of the author of the design. A creative project is a temporary organization that is formed with the view to deliver original and formally perfect products that contain intellectual property and are delivered in accordance with the objective and within limits that have been mutually agreed in advance (Svirakova, 2014).

Bartoška (2011), Lacko (2004) and Rehacek (2015) note that in management of actual projects, regardless of the industry, we can find a lot of incorrect approaches that are the root cause of not adhering to the budget, not meeting deadlines or failing to deliver the scope of the project and its objectives. Wrong decisions made by managers resulting from incorrect assessment of the situation in a project result in losses. An unsuccessful project is a result of managers´ insufficient knowledge of the actual development of the project as compared with its plan. Taraba (2015) points out that the appropriate use of project management methods under the supervision of a competent project manager can be one of the key success factors of the company. Simon Collyer and Clive M. J. Warren (2008) focus on the issue of projects in a dynamic environment. They claim that an appropriate approach to monitoring the scope of a project is to divide it into stages that are easier to plan and manage. Other authors deal with project monitoring using the tools of system dynamics: several significant studies on project management were written on this topic by Cooper (1980), Richardson and Pugh (1981), Morecroft and Abdel-Hamid (1983), Abdel-Hamid (1984), Ford and Sterman (1998), Lyneis et al., (2001), Park and Pena-More (2003), more recently by Bérard (2010) and Ghaffarzadegan, Lyneis and Richardson (2010), Cosenz (2017). These authors focus, among others, on simulated monitoring of the currently earned value according to the EVM method (Earned Value Management). They compare the value created with the plan in relation to the approaching scheduled date of completion and point out the rising level of stress. Their models simulate a situation when a project is behind schedule while the deadline is approaching.

The value-added method, which is often used in the Czech environment by its English equivalent Earned Value Management, as well as its abbreviation (EVM), is an important part of the International Project Management Institute (PMBoK, 2013). The EVM method can be characterized as a systematic project process for finding deviations in a project based on a comparison of the work done and the planned work. However, as stated in Skalický (2016), the EVM method, although it has the word "management" in the name, does not control the project but only supervises it. Project control is based on calculated indices - deviations and performance. Therefore, it is questionable whether we can use the EVM method to track the actual course of a project if we want to manage the project as a system (Skalický, 2016).

This article comes up with new methods for monitoring the development of a project in a cultural and creative environment. It uses the Earned Value Management method by applying its principle and then modifies it, which leads to the creation of a new method called CREA TRACK, which is the first stage of a more advanced method CREA TRACK PLUS. Results of CREA TRACK can be presented with MS Excel, which is common software. CREA TRACK PLUS enables its users to predict the development of a project: the prediction is based on system dynamics modelling and it requires simulation software (e.g. Vensim, iThink, Stella etc.). It allows for including some system elements for future project development that would be omitted in CREA TRACK such as: the quality of the project team, lack of time for completing the project in the entire scope and lack of communication within the project.

Materials and Methods

The objective of the research is to verify whether the new methods, i.e. CREA TRACK and CREA TRACK PLUS, are applicable to projects in the creative environment. We verified the use of the methods on the Water for All Case Study. At the beginning of the research, the following two research questions (RQ) were asked:

RQ1: Can we alternatively apply the Earned Value Management (EVM) method using the assignment of points to the difficulty of outcomes so that the objective of the research is met?

RQ2: Can we use the system dynamics model for quantifying the problematic behaviour of a project and predict its future development?

So that the research is complete and provides the framework necessary for defining the problem and relevant solution, we used two methodologies:

1. Quantitative research – project content analysis based on predicting the difficulty as an alternative to Earned Value Management (EVM). The indicators that we measure by data quantification are the following: (1) The planned value (PV) of the project, which corresponds to PV under the EVM method, when we quantify the effort that is planned to be expended over a given time in order to ensure the desired outputs of the project. (2) The actually earned value (EV) of the project, which corresponds to EV under the EVM method, is quantification of the actually achieved value of the output at a given moment. (3) The actual costs (AC) of the project, which corresponds to AC under the EVM method, the units are difficulty points calculated from the budget in the given currency. (4) Planned costs (PC) of the project – a new indicator that is modified and prepared in accordance with the planned budget of the project, the units are difficulty points converted from the budget in monetary units at a given time. The indicator is abbreviated as PC meaning Planned Costs of the project at a certain moment.

2. Qualitative research – interview as input information for system dynamics modelling. Managers/members of the management team who participated in the project preparation and implementation were interviewed. The key elements that are the cause of a problematic behaviour of a project are determined on the basis of an interview with the project manager and members of his/her team. Questions for the interview are formulated in advance so that the researcher has the opportunity to be initiative. It is a semi-structured interview with narrative elements: the interviewer adjusts to the project type and knowledge of the interviewee during the interview. Such interviews give the interviewer the possibility to be initiative and explore in a detail issues that may arise during the interview. The interview is recorded with the consent of the interviewee. The recording is then transferred in a written form for the purpose of further analysis.

Case study Water for All Projects

Using the case study from the Water for All Project we show the possibilities of design thinking in the working process of authors creating a new innovative design. Water for All is a project by the Faculty of Multimedia Communication, Tomas Bata University in Zlín, which is based on the environment of cultural and creative industries. All studios under the faculty participated in it. Twelve studios, in a joint effort, dealt with “Water” as a topic of their creation from the beginning of the academic year (September 2016). The Water for All Project has two main objectives. The first one is systematic work with the general public. Students came up with a warning that concerned the gradual depletion of water on the Earth. They accentuated that the problems does not only concern developing countries, but also the Czech Republic and it needs to be addressed. The second objective is to instigate cooperation not only between the studios, but also between the faculty and companies that can help students implement their design drafts that concern the “Water” issue. Outcomes of the project are exhibitions, fashion shows, websites, a catalogue, Facebook campaign, conference and scientific publication.

Formulation of dynamic hypotheses

We see correct formulation of dynamic hypotheses by the model creator as a part of the methodology for system dynamics modelling. When formulating them, so-called thought mapping is used, in particular its effective tool, causal loop diagrams. These diagrams allow for clear description of the system elements and their mutual bounds. In the preparatory phase, we focus not only on hard data that can be obtained from the content analysis of the project, see the first part of the research methodology (quantitative research), but also on soft data that can be classified as behavioural information about the project. The concept of system thinking (Senge, 2006) is a suitable method of expressing dynamic hypotheses. The tool for displaying this type of thinking is the feedback loop diagram thanks to which we can display relations between causes and consequences in the systems researched as well as feedback impacts of various decisions on the future development of variables that we could include in the model.

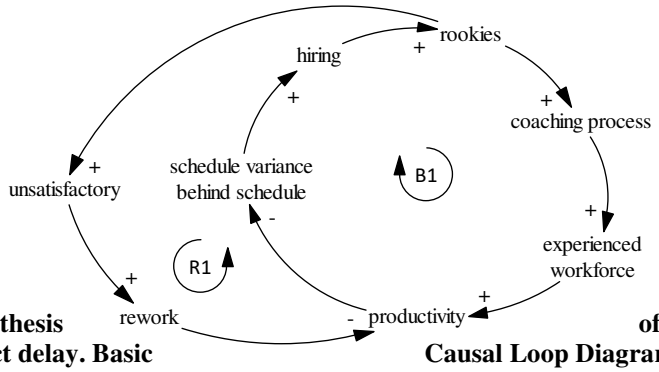

Fig. 1.: Main hypothesis of the project problem: Decrease project delay. Basic Causal Loop Diagram - CLD. (Svirakova, 2017).

The main hypothesis of the problem we want to solve by modeling corresponds to the System Archetype Limits to Growth (Senge, 2006). The problem is the delay in delivery of the project products compared to the plan. We deal with the delay by extending the project team to new members. We need newcomers (rookies) in the team, but at the same time they cause another delay in the project, because their performance is not first-rate and they cause a greater need for reworking of the project's partial products. The following solutions are offered: Training rookies faster so that they could be swiftly relocated to experienced team members who make fewer mistakes. Strengthening the coaching process is one of the scenarios to improve project productivity and reduce the delay over the plan.

System Dynamics Project Model

On the basis of dynamic hypothesis H1 that is shown in the picture above (Fig. 1.) we compiled a basic system dynamics model that contains a cycle of reworking unapproved (low-quality) outputs of the project. This model (Fig. 2.) was complemented by data from the reference mode, which is the data obtained in quantitative research of the project.

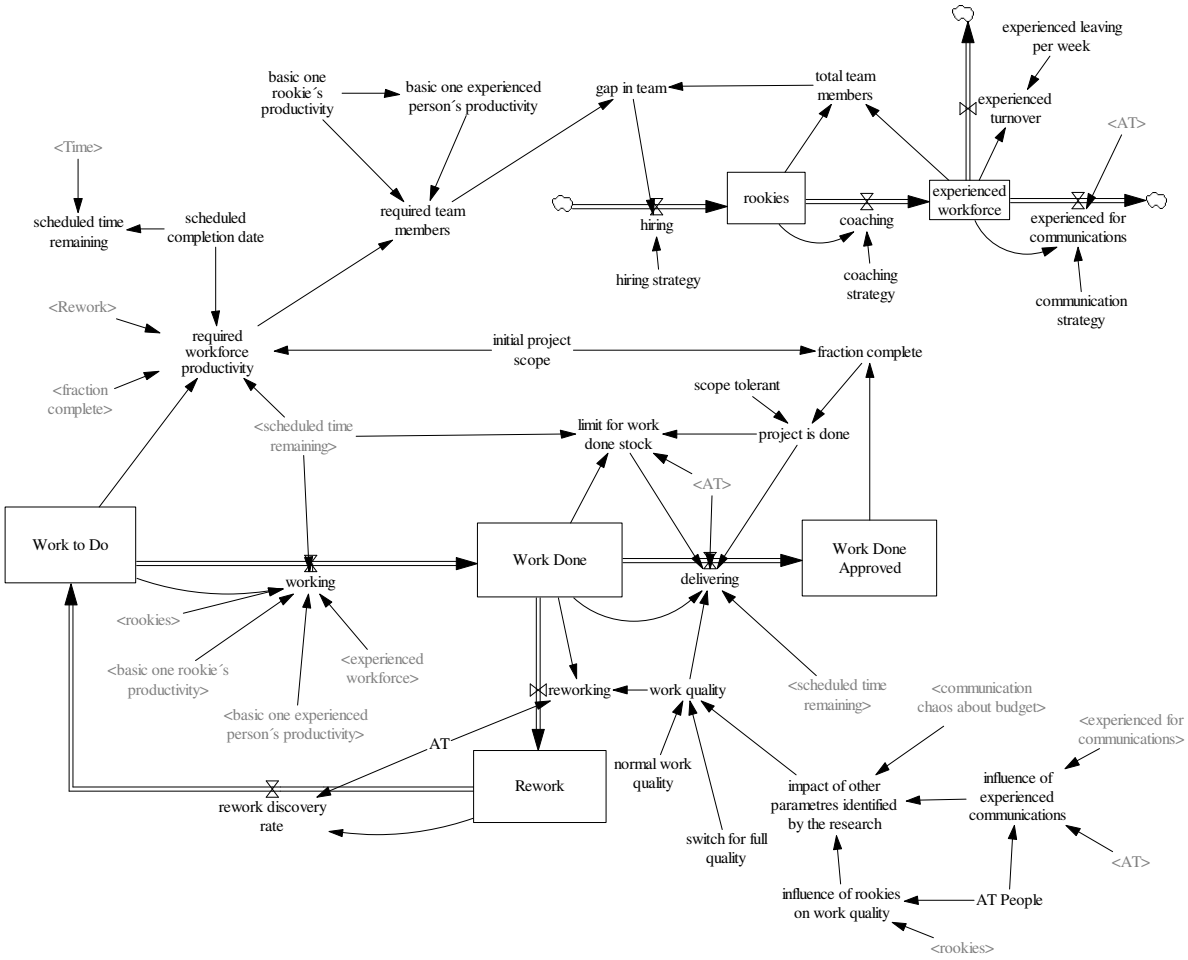

Fig. 2. Basic model – Stock and Flow Diagram - SFD: rework cycle. (Svirakova, 2017).

Analysis of conversation and causality search

Qualitative research aims to use its results to refine the system-dynamic model. Its basic elements are set according to the dynamic hypothesis, in which the basic project cycle of reprocessing of non-approved project products is displayed (see Fig. 1, Fig. 2). In addition, part of the interview with the project manager and its analysis is recorded. Relationships between selected elements of the system are briefly characterized by the language of system thinking.

Report of a part of the interview with Project Manager Water for All Project Project Manager: *"The main problem of the project ... for sure communication and distribution of information, both to each other and to the head of the studio, and of course also to the students of the project. ... I know there is a delayed realization and, in general, the whole organization mainly of websites that were to be ready by the end of December and will be ready by the end of January. The only thing I have (to track the actual course of the project, note: the interviewer) is a schedule that we put together at the beginning of the project, in which we have set deadlines for fulfillment, but I have never implemented them ... I mostly use my head and my diary. Interviewer: "Do you think the problem can be avoided and in what way?" Project Manager: "I think the problem can be partially avoided. I think, for example, setting reserve in terms of time is an effective helper. Another prevision should be personal meetings of the team and mutual motivation, support of other members, such "psyching up" to work. And especially COMMUNICATION. COMMUNICATION. COMMUNICATION. Let each other know when something goes wrong and find the cause. Ask for help. Talk about problems and slips within deadlines. Speak. Speak. Share it. I think that is crucial: when the problem is known, it can be solved."*

Paraphrased in the language of system thinking and the new hypothesis: A less experienced team manager means a reduced continuous check of the implementation of the project timetable (+>), the communication of monitoring progress in the project is reduced (+>) leading to a longer delay of the project than the plan (->).

In addition, the elements and links between them follow the main dynamic hypothesis: the more emphasis on the recruitment of new members to the team (+>), the more newcomers in the team (+>) and after a certain coaching process, the more experienced members of the team (+>). The odd number of arrows is changed by the negative polarity in the loop. The loop is counterpart. New Hypothesis 1 (NH1): More experienced team members lead to a better ongoing control of the timetable, which leads to a reduction in project delay compared to the plan.

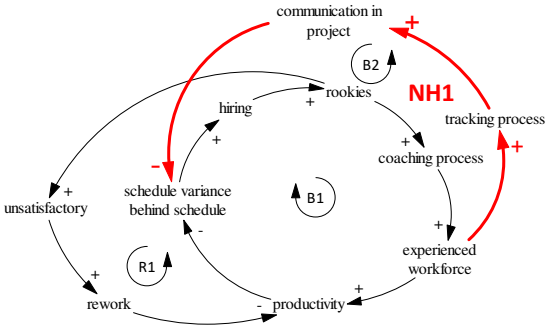

Fig. 3: Incorporation of the new NH1 hypothesis into the basic feedback loop diagram. (Source: own processing, 2017)

Based on an analysis of the interview with the project manager Water for All Project, we first extended the main dynamic hypothesis in the feedback loop diagram against Figure 1 (Fig. 1 Formulation of Dynamic Hypotheses). The result of this extension is the structure shown above (Fig. 3). According to the concept of the whole model, elements that represent new dynamic NH1 hypotheses are added to the main

hypothesis. These new elements are linked by feedback loops with relevant elements of the Basic CLD for the Water for All Project (Fig. 1, Fig. 3). The base model uses black thin arrows. Added loops are highlighted in color and highlighted by a stronger line.

Results and Discussion

The project started in July 2016, its duration scheduled for the end of 2017, i.e. the planned duration of the project is 72 weeks. The graph (see below) is set to 75 weeks for the duration of the project, leaving 3 weeks as a time reserve. In the initial weeks of the project, its actual course (EV - red dotted curve, Fig. 4) is the same as planned, and approximately until the 18th week (PV - blue full curve, Fig. 4, Fig. 5). After this period, the project actually begins to delay the plan, and at the end of the period under review, which is the 52th week of the project, the plan is worth 1335 points of difficulty (EV - red dotted curve). The chart also includes the development of planned cost values (PC - green intermittent curve) and actual cost over time (AC - Gray curve). Values were determined by quantitative research, data analysis of the project and evaluated using difficulty points, a modification of the EVM method we named as the CREA TRACK method. The values in the table are the reference framework of the system (project) with which we work in system dynamics models. This is how we find out what interests us most in the project: whether the project is behind schedule, whether the project is actually more expensive than we planned. The unit for comparison is the difficulty points. Problems in the project that may contribute to deviation from the plan have been identified by qualitative research and are simulated in the project model. The project reference frame is embedded in a system-dynamic model, although MS Excel can also be used for its graphical expression. The aim of our article is not only the use of the modified EVM method, the CREA TRACK method, but also the full implementation of the CREA TRACK PLUS method, so we only use Vensim outputs rather than MS Excel (see Figure 4 below). We can now comment on whether the proposed methodology has met the research goal of verifying the practicality and usability of system dynamics modeling for projects in a creative environment.

Research Question 1 (RQ1): Can an universal "point of difficulty" unit for project scope determination be used as part of project tracking and use the modified EVM as a reference framework for a system dynamics model

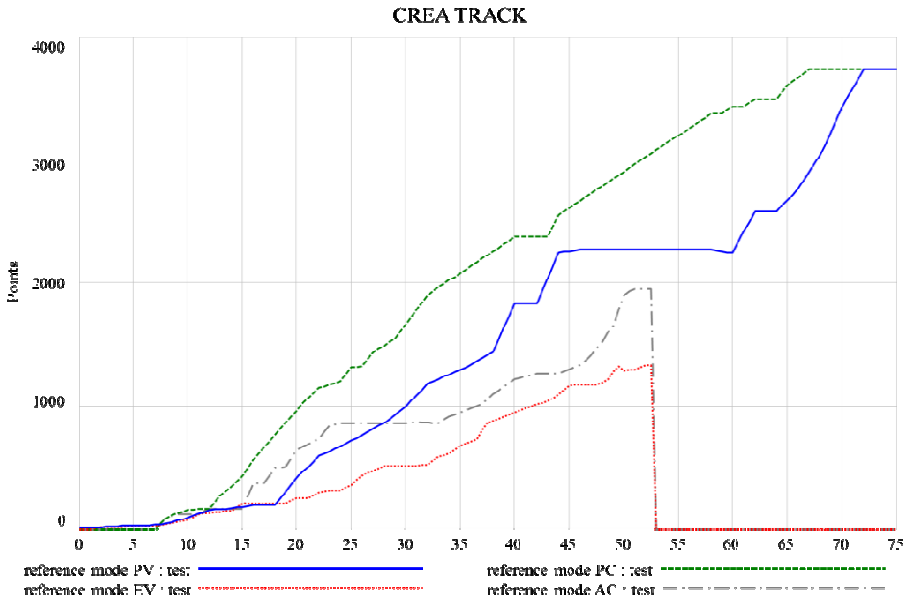

Fig. 4: Comparison of all four measured values from the CREA TRACK method. Source (own processing, 2017).

The answer is: Yes, we have applied the project reference frame in the system dynamics model, see the research result (Fig. 5.) above in all four project performance parameters: planned PV value, generated EV value, planned PC costs and actual costs at a given time AC. All of these curves are ready to be compared with the simulated course of a project in a system dynamics model because we have been placed in the Vensim software using the graph function. The graph shows the state of the project at the 52th week: the material extent is behind the plan, but the cost is higher. So we actually created fewer outputs for more money. Planned costs are not exceeded, even until the 52th week of the project, the planned project financing has a higher dynamics at the beginning of the project, so a slower cost drawdown is planned in the last approximately 10 weeks of the project.

Research Question 2 (RQ2): Can we use the system-dynamic model to quantify the problematic behavior of the project and estimate its future development?

The answer is: Yes, the problematic behavior has been described and it is demonstrable that the problems in the project exist, see the report from the interview with the project manager as a output of qualitative research. The parts of the interview were analyzed, translated and paraphrased by system thinking, and we processed the results of the analysis into an extended causal loop diagram (Fig. 3). Through qualitative research, we have identified the need to add new variables that have not yet been included in the basic model: the quality of tracking process quality, communication in project. We have quantified these variables for system dynamics modeling. An increasing tendency in the number of experienced workforce, that is, the Experienced Workforce variable, causes the interest in controlling the implementation of the project schedule to be increased, and the measured delay in the project is more communicated in the team, thus reducing the project delay compared to the plan, which confirms the new NH1 hypothesis. The model shows the advantage of a computer simulation: a managerial decision is without risk, the organization does not bear the negative consequences of its incorrect assessment of the situation. However, it is important to note that the implementation of management decisions is not easy and will probably bring with it another negative backward impact on the development of the project. For example, if we decide to shorten the time for adapting newcomers to the team, we need to hire new coaches and not burden experienced team members with these processes, which would lead to further delays in the project. Efficiency of scenarios can also be judged by their economic impact or the financial advantage of deploying the chosen strategy.

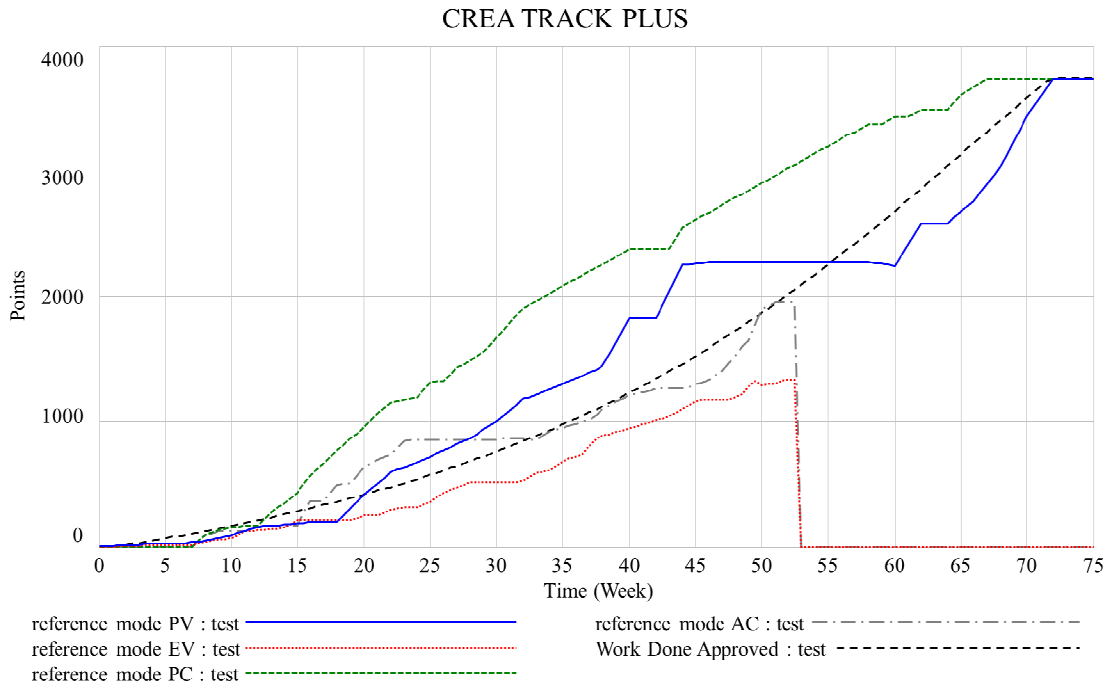

Fig. 5: CREA TRACK PLUS - comparison of the reference frame and dynamic simulation of the Water for All Project. Source (own processing, 2017)

Conclusion

The data for CREA TRACK were processed by the EVM method under the standard A Guide to the Project Management Body of Knowledge (PMI, 2013). However, the method differs from the EVM methodology (as it is actually applied), with its units that make reports and work with project monitoring that is part of control process significantly simpler. Thanks to the reference mode that we used when applying the CREA TRACK method we know where exactly we are in the project implementation and how much we have deviated from the plan. We focus our research on the actual project development and we want to find out what are the reasons that result in schedule variance. We processed these causes in a system dynamics model so that we could predict further development of the project and what the chances are it will meet its goals. The fact we used CREA TRACK had one positive side-effect: it made us naturally prepare background documents for the final report on the fly.

With CREA TRACK we contribute to emphasising the importance of planning in a creative environment and we offer an easily accessible method for monitoring the actual development of project implementation without ineffective use of project team members´ labour costs as a unit. Labour costs (planned and consumed) are measured by the PC indicator as Planned Costs and by the AC indicator as Actual Costs and we can process them and show the project development in a graph following the same principles on which the CREA TRACK method is based.

We called the other method based on dynamic simulation of the project CREA TRACK PLUS, because it is an extended version of the CREA TRACK method. We extended the model that simulates the probable course of project development by adding other variables that either slowed down or accelerated the work on the project outputs. For this step, we first obtained relevant data from our research. We could compare

the simulated development of the project with its actual development thanks to the reference mode of the achieved value of the project.

Both methods, CREA TRACK and CREA TRACK PLUS, are in line with the new requirements that concern project management, i.e. going beyond the boundaries of technical and engineering disciplines and create a procedure that will be in line with transdisciplinary and integration approach (Saynisch, 2010). Cultural and any other creative or scientific projects of the 21st century cannot be based on intuitive management or on bureaucratic processes that leave very little space for changes to the plan. A creative environment must remain dynamic and it has to keep offering new challenges including the integrated possibility of making changes to the planning process. The advantage of CREA TRACK consists in simplifying the units of measure through which we can quantify the progress of the project plan and its implementation. The advantage of CREA TRACK PLUS is the prediction of further development of the project, testing of various scenarios and policies for decision making of managers. However, this method can only be implemented if there is an experienced project supervisor who can use software for system dynamics modelling.

The objective of the research, i.e. verifying whether the CREA TRACK and CREA TRACK PLUS methods are suitable for monitoring project implementation and thus for increasing the effectiveness of project managers´ decision making, has been met. Both methods can be practically applied, which has been proved by the research of the Water for All Project Case Study.

Acknowledgements

I would like to thank project manager Eva Gartnerová for providing an interview on the issue of managing the Water for All Project. The article was supported by Project No. 4/2017/FSR, which was financed from the strategic development fund of Tomas Bata University in Zlín.

Assessment of the Suitability of the Use of Foreign Exchange Interventions by the Czech National Bank for the Fulfillment of Monetary Policy Objectives

Ing. Martin Pernica, Ph.D.
Institute of Finance, Faculty of Business and Management, Brno University of Technology, Brno, Czech Republic, martin.pernica@gmail.com

Ing. Helena Hanušová, CSc.
Institute of Finance, Faculty of Business and Management, Brno University of Technology, Brno, Czech Republic, hanusova@fbm.vutbr.cz

Abstract

The Czech National Bank adopted a foreign exchange rate commitment to keep the exchange rate of the Czech crown at 27 CZK to € 1 in November 2013. The purpose of weakening the Czech currency was to avoid the risks of deflation and to support the competitiveness of the Czech exports by making goods cheaper on foreign markets. Higher demand for Czech goods should lead to a drop in unemployment and stimulate the Czech economy. The main goal of the article is to compare selected instruments of the monetary policy of the Czech National Bank in achieving the inflation target – open market operations, minimum reserve requirements, forward guidance, quantitative easing, negative interest rates and foreign exchange interventions. An evaluation of the economic development of the Czech Republic is performed at the end. The main interest rates of the Czech National Bank reached a level of technical zero. The potential of conventional instruments of monetary policy has ran out. The usage of negative interest rates faces legislative barriers and would lead to erosion of the profitability of the banking sector. Foreign exchange intervention helped to increase exports. Prolonged weakening of the Czech currency leads to an increase in the difference between the artificially weakened Czech currency and its real market potential which represents a risk to the entire economy.

Keywords Foreign Exchange Interventions, Forward Guidance, Negative Interest Rates, Quantitative Easing

1 Introduction

The last two decades of the 20th century were characterized by a gradual reduction of inflation and reduction of price fluctuations in most important world economies. This development has created conditions to reduce interest rates and to support an economic growth. A monetary policy began to be very important. Central banks affect the liquidity of the banking sector through short-term interest rates. This economically very successful period, which is known as the Great Moderation, resulted in the emergence of the crisis on the US mortgage market in 2007 (Stock & Watson, 2002). The global financial and economic crisis has changed monetary policy. The interest rates were close to technical zero (zero lower bound, ZLB) and could not fall (Swanson & Williams, 2014). Transmission mechanism, which has been supplying liquidity to banks, collapsed (Svensson, 2013). Central banks, including the Czech National Bank, had to use untested monetary policy instruments.

In early November 2013, the Czech National Bank (CNB) began to intervene in the foreign exchange market to weaken the exchange rate of the Czech crown to the level 27, - CZK per 1 €. The importance of this action was to meet the inflation target at 2 %, which the bank has set and a support the competitiveness of the Czech export. A weaker Czech crown leads to cheaper domestic production on foreign markets, which creates a presumption for increasing sales. Higher sales lead to the growth of production by companies that focus on exports and thus contribute to the growth of real output and employment. Depreciation of the Czech crown, on the other hand, brings an increase of prices of imported goods, which reduces household consumption and is leading to higher prices of

inputs, on which the Czech economy depends, as it has a minimum of natural resources. CNB faces to considerable criticism. Some legal experts assess foreign exchange intervention as illegal (Lazarevič, 2013). The economists criticize foreign exchange intervention because they threaten the consumer demand (Brožka et al., 2013).

Status and activities of the Czech National Bank regulates the constitutional act no. 1/1993 coll., Constitution of the Czech Republic, and act no. 6/1993 Coll., on the Czech National Bank. Under Article 98 of the Constitution of the Czech Republic and in line with EU primary law, the primary objective of the CNB is to maintain price stability. Achieving and maintaining price stability, i.e. creating a low-inflation environment in the economy, is the central bank's ongoing contribution to the creation of conditions for sustainable economic growth. (Czech National Bank, 2017a) The Czech legislation does not specify conditions for achieving this goal. The European Central Bank, which defines "quantitative definition of price stability", defined price stability as follows: "*Price stability is defined as a year-on-year Increase in the Harmonised Index of Consumer Prices (HICP) for the euro area of below 2%.*" (European Central Bank, 2016)

The inflation target at 2 % is consistent with the characteristics of price stability of the European Central Bank (Czech National Bank, 2013).

2 Theoretical Solutions

2.1 Open Market Operations

The most commonly used tool of conventional monetary policy are open market operations and automatic facilities, i.e. the deposit facility and the marginal lending facility.
The figure 1 demonstrates the development of the two-week repo operations - 2W repo rate, the deposit facility - discount rate and the marginal lending facility - Lombard rate of the CNB in the period 2008-2017.

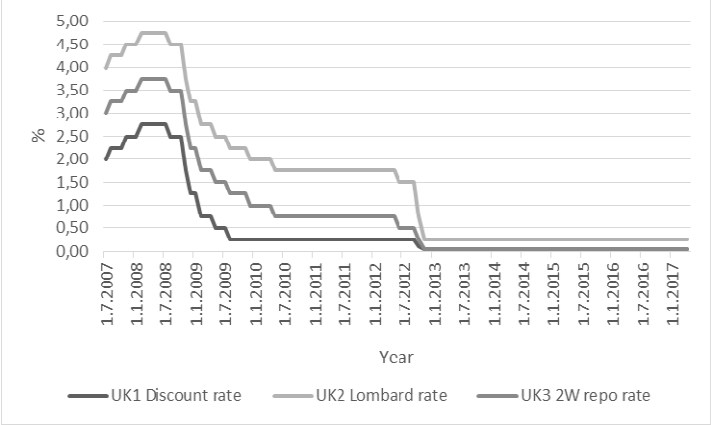

Fig. 1 – Development of the two-week repo operations - 2W repo rate, the deposit facility - discount rate and marginal lending facility - Lombard rate of the CNB in the period 2008-2017. Source: Authors' interpretation based on the data of Czech National Bank, 2017b

The potential of most frequently used monetary policy tools ran out, as both main rate - the 2W repo rate and the discount rate reached in November 2012 the zero lower bound. The Lombard rate reached a level of 0.25 %. Banks in the Czech Republic have too much liquidity. The usage of the marginal lending facility is rather exceptional.

The last possible standard instrument by which the central bank influences the volume of free resources in the banking system are Minimum reserves. Minimum reserves were previously used as

an instrument for covering waves of deposit withdrawals by commercial bank clients. It is unlikely that there will be a sudden outflow of deposits from banks, unless the CNB reports negative rates. The Minimum reserves are currently used to smooth over interbank payments.

2.2 Forward Guidance

Forward guidance (FG) is the central bank's communication strategy, which consists of publishing information about monetary policy (Klíma & Komárek, 2014). The opportunity to influence the exchange rate in a situation ZLB first appears in the record of the meeting of Bank Board dated 19. 12. 2012 (Czech National Bank, 2012). The determination of the CNB to influence the exchange rate of the Czech currency is apparent from other records of the meetings of CNB Bank Board on 28 3. 2013, then on 2. 5. 2013 and on 27. 6. 2013. The record of the meeting of CNB Bank Board on 1. 8. 2013 shows that the CNB Board accepted to initiate foreign exchange intervention as the instrument for further easing of monetary conditions and finally decided not to use this instrument (Czech National Bank, 2013). The initiation of foreign exchange interventions dated 7. 11. 2013 surprised political representation, entrepreneurs and the ordinary people. Raiffeisenbank analyst Michal Brožka commented on this: *"We did not count with the beginning of foreign exchange interventions in view of the ongoing revival of the Czech economy."* (Brožka, 2013) CNB did not manage forward guidance at all.

2.3 Negative interest rates

Negative deposit rate affects the commercial banks for holding an excess of liquidity. It stimulates them to a higher economic activity – such as investment money lending, offering mortgages, etc. Negative interest rates were used in 2009 by the Swedish National Bank for the first time (Severiges Riksbank, 2009). Sveriges Riksbank was later followed by the Bank of Japan and the European Central Bank.

The usage of negative nominal interest rates in the Czech Republic is a legal and economic problem. In terms of economic theory, the interest is a form of reward for lending money. E.g. Jurečka defines this idea as follows: "*Interest is income for depositing money in a bank, is expressed in monetary units*" (Jurečka, 2010). In the Czech legislation, there is no precise definition of the concept of interest. General business conditions of commercial banks reflect the economic concept of interest on which Czech legislation is based.

The balance sheet of the Czech banking sector reached by the bank statistics at the end of March 2017 the amount of 7,106,000 million CZK. The most important item of the asset side are loans provided to residents. Their volume amounted to 5,104,000 million CZK. The volume of deposits of residents, which constitutes the most significant item of liabilities of banking sector amounted to 4,043 ,000 million CZK (Czech National Bank, 2017c).

The figure no. 2 and no. 3 of the development of the assets and liabilities of commercial banks in the period 2008-2016 is below.

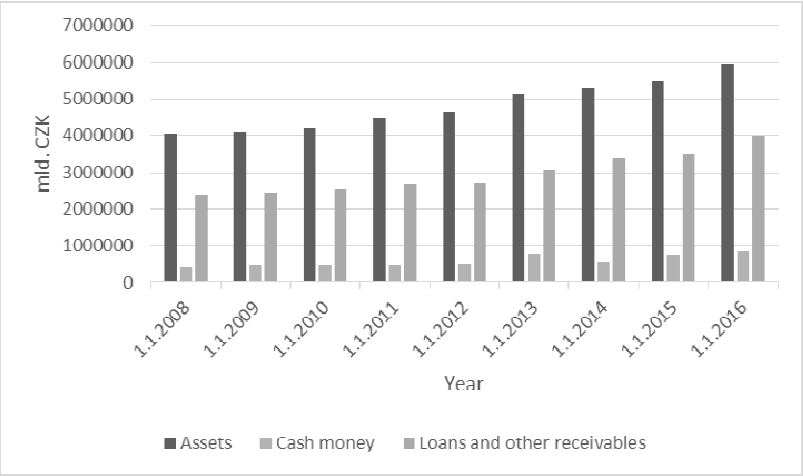

Fig. 2: Development of assets of commercial banks in the period 2008-2016. Source: Czech National Bank, 2017c

With regard to the policy of interest rates of commercial banks in the Czech Republic, it is not convenient for households to leave the money "appreciate" in the form of deposits in savings accounts, even though the central bank still did not use negative interest rates.

Fig. 3 : Development of liabilities of commercial banks in the period 2008-2016. Source: Czech National Bank, 2017c

With regard to the interest rate policy of commercial banks in the Czech Republic, which reflects their over-capitalization, it is not very convenient for households to "capitalize" on money in the form of deposits on savings accounts or on time deposits. This despite the fact that neither the central bank nor the commercial banks have used negative rates.

2.4 Quantitative easing

Through quantitative easing, the amount of money in the economy increases. This arises from the fact that the central bank purchases securities in the financial market. Most of them are the least risky assets. These are, above all, government bonds, which reduce their profitability. More money in the economy leads to a decrease of interest rates. Low interest rates lead both to rising inflation and to

increasing liquidity (money supply) of commercial banks, which contributes lower interest rates and leads to higher demand for corporate loans (Rejnuš, 2015).
Quantitative easing was used for the first time by the Japanese Central Bank at the turn of the millennium. Later, during the financial crisis in 2008-2012, it was also used by other central banks - the US Fed, the Central Bank of England and the European Central Bank.

2.5 Foreign exchange intervention

When the Czech National Bank decided to use foreign exchange intervention, it used the study by Professor McCallum (Tomšík & Vlček, 2015). McCallum´s model is based on Hicks' IS-LM model, which shows the interaction of real output, interest rates and money (Hicks, 1980). This model proves that an open economy with a low inflation rate in the situation ZLB can support inflation by weakening the exchange rate of foreign ex-change intervention. McCallum´s model of monetary policy in a situation ZLB is based on Taylor´s rule and can be expressed as follows (McCallum, 2015).

The rule of monetary policy in the ZLB:

$$s_t - s_{t-1} = \mu_0 - \mu_1(\Delta p_t - \pi^*) - \mu_2 E_{t-1}\tilde{y}_t + e_t$$

where

$s_t - s_{t-1}$ the change of the nominal exchange rate

Δp_t the change of prices

π^* the targeted inflation rate

μ_n constant

$E_{t-1}\tilde{y}_t$ the product gap

e_t the white noise - uncorrelated random variables with zero mean and constant variance

The model assumes a very open, export-oriented economy and very low inflation rate. The foreign exchange interventions devalue currency exchange rate. The central bank buys foreign assets - foreign currency and sells domestic assets - the local currency. The central bank as the issuer of the domestic currency may carry out foreign exchange intervention indefinitely. Inflation expectations lead to a real increase of prices, which performs additional inflationary expectations. The depreciation of the real exchange rate of the domestic currency increases the demand for "cheaper" domestic goods in foreign markets and brings a fall of demand of "expensive" foreign goods. The context can be expressed as follows.

The relationship of the real exchange rate:

$$R_{D/F} = E_{D/F} \times P_F / P_D$$

where

$R_{D/F}$ represents the share of price level in abroad and domestic price level

$E_{D/F}$ represents the number of units of domestic currency, for which you can buy foreign currency unit (e.g. 27 CZK/€)

P_F is the price level of foreign currency

P_D is the price level of the domestic currency

The drop of real exchange rate lasts until the nominal exchange rate reflects the influence of interventions on the domestic market.

3 Objectives And Methodology

The aim of this article is to assess the suitability of using various instruments of the monetary policy to achieve the inflation target. Another objective of this article is to evaluate the economic development of the Czech Republic in the period before the start of CNB interventions and to evaluate the success in fulfilling the inflation target, which CNB has set before the intervention started. Key foreign studies were presented for the purpose of assessing foreign exchange intervention – "Theoretical analysis regarding a ZLB on nominal interest rates" by McCallum and Svensson's "bulletproof" monetary policy recommendation at zero interest rates. Logical methods are used to process the paper. In particular, induction and deduction, analysis, synthesis, and comparison. In order to assess the dynamics of the economic development of the Czech Republic in the period before and after the start Czech National Banks´ foreign exchange interventions, the time series prepared for the period 2008 - 2016 will be used. Economic growth dynamics will be assessed through macroeconomic policy objectives – development of Gross Domestic Product, Foreign Trade, Unemployment and Inflation Rate. The article was prepared using data from the Czech Statistical Office, the European Statistical Office and the Ministry of Labour and Social Affairs of the Czech Republic.

4 Results

Analysis of the economic situation of the Czech Republic in the period before and after the weakening of the Czech crown is described in following chapters.

4.1 The Development Of Gross Domestic Product

In the days before start of CNB interventions, Czech economy faced to the economic downturn, stagnation of foreign trade, high unemployment and zero growth in consumer prices - inflation.
Below is an overview of the development of GDP in the period 2008 – 2016.

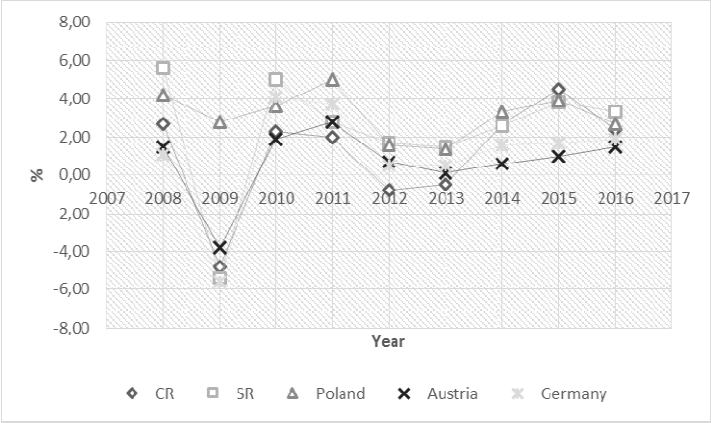

Fig. 4 : Development of GDP in the period 2008-2016. Source: Authors' interpretation based on the data of Eurostat, 2017

Development of the Czech economy follows the economic development of the entire Eurozone. In the last ten years, there were two falls. The first fall was caused by the global financial and economic crisis, in the years 2008 and 2009. The second fall in the years 2013 and 2014 was caused mostly by the Eurozone debt crisis, which was escalated by problems of public budgets of some indebted countries – especially Greece and Spain. The GDP of the Czech Republic reached to -0.8 % in 2012 and in the year 2013, it reached to -0.5 %. The GDP of Slovak Republic was +1.7 % in 2012 and +1.5

% in 2013. The slump of the Czech economy at that time was deeper in comparison with other countries of Central Europe. Any other economy had negative economic growth in 2012 and 2013. The reason was mostly restrictive government policy, which significantly weakened domestic demand, consumer and business confidence in the Czech economy.

There were elections in the Czech Republic in 2013. The new government conducted a number of changes to support the economic growth. The Czech Republic obtain more grants from the EU Structural Funds. The Czech government increased the minimum wage and reduce some taxes. The Czech economy reached economic growth of +2.7 % in 2014 and +4.5 % in 2015.

4.2 Competitiveness Of Foreign Trade

The Czech economy has a positive trade balance since 2005. The Czech Republic has only a small internal market and it is fully dependent on imports of raw materials. For the successful development of the Czech economy in the long-term, it is crucial to increase the volume of exports, especially the difference of export and import.

The development of Czech foreign trade of goods in the period 2008 - 2016 is illustrated in Figure 5.

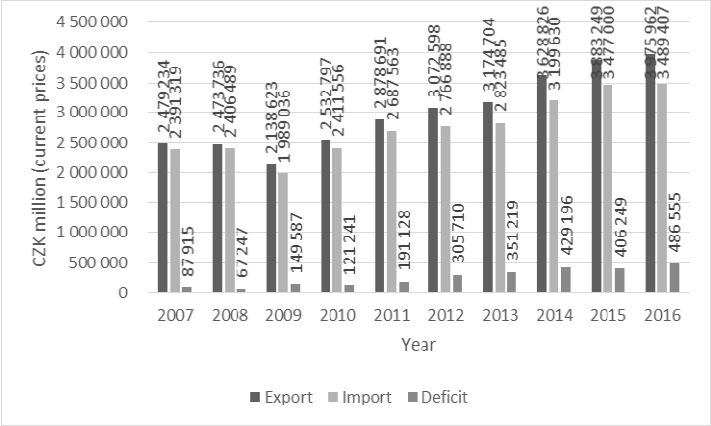

Fig. 5: Development of Czech foreign trade of goods in the period 2008-2016. Source: Authors' interpretation based on the data of Eurostat, 2017

In the years, 2012 and 2013 there was a rise in exports only about 102,106 million CZK. The trade balance during the same period increased by only 45,509 million CZK.

Foreign exchange intervention helped particularly to firms that export to foreign markets and are not dependent on manufacturing inputs procured in Euros. A significant increase in Czech exports occurred immediately after the initiation of foreign exchange intervention. Czech exports in 2014 rose by about 500,000 million CZK compared to 2013. In 2015, export growth was not significant, because traders already had enough time to adjust prices in response to the strong Euro currency. Foreign exchange interventions of the Czech National Bank helped to increase the competitiveness of Czech goods in foreign markets through its lower price. In 2014, exports increased by 13% and imports by 12%. In 2015, exports grew by 6.7% and imports by 7.8%. The competitiveness of our economy, measured by exports, has not diminished and imports have not slowed down.

4.3 Development of unemployment

There was a significant rise of unemployment in the Czech economy since 2008. Unemployment reached a peak in 2010 and 2013. The number of job seekers registered by the Labor Office in those years approached the limit of 600,000 (Ministry of Labor and Social Affairs, 2015).

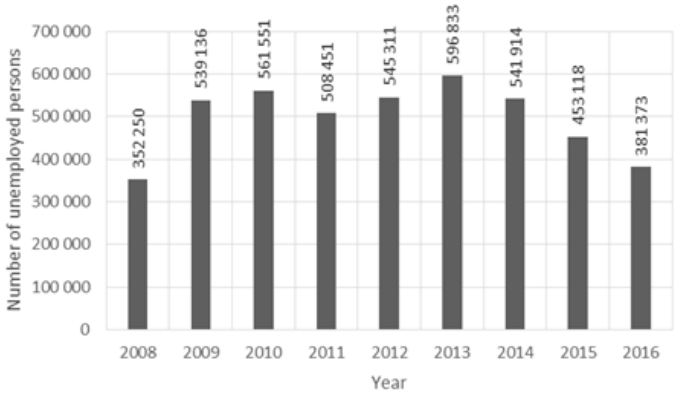

Fig. 6 : Development of the number of registered unemployed persons by the Labor in the period 2008-2016. Source: Ministry of Labor and Social Affairs, 2017

In 2013, the number of unemployed persons registered by the Czech Labor Office was two times higher compared to the state of the year 2008.

Since 2013, the number of unemployed persons is steadily declining.

4.4 Inflation

CNB's monetary policy reacts to monetary policy inflation, which is based on general inflation but it does not include the impact of indirect taxes.

The development of consumer price and monetary policy inflation in the period 2008 – 2016 is illustrated in Figure 7.
The limited growth of prices in 2012 and 2013 was caused primarily by the decline of the Czech economy.

There was a reduction in household consumption and investment. In 2013 there was a significant fall of fuel prices. Conversely, there was an increase in food prices and regulated prices due to the increase of contributions to renewable energy sources. Inflationary impact had also the fiscal government policy.

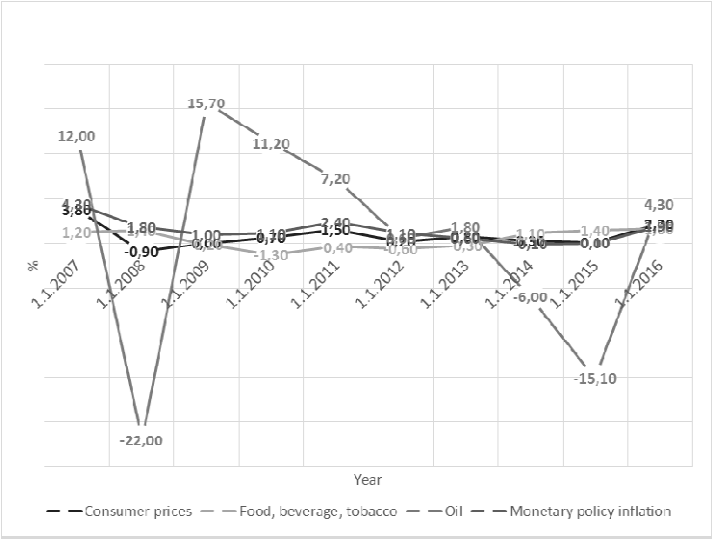

Fig. 7 : The development of consumer price inflation and monetary policy in the period 2008 - 2016. Source: Czech National Bank, 2017d

The low growth of prices in 2012 and 2013 was due to a decline of the Czech economy, a decrease in household consumption and investments. Fuel prices fell significantly in 2013. On the contrary, food prices and regulated prices increased as a result of the increase renewable energy sources. On the contrary, the government supported inflation by increasing indirect taxes.

5 Discussion

All of the main CNB interest rates reached the zero lower bound. The potential of the most commonly used conventional instruments of monetary policy ran out.

The central bank discussed badly its monetary policy that was based on foreign exchange interventions. Forward Guidance has not been managed well. CNB even after more than three years did not achieve the inflation target. CNB forecast of 17. 12. 2013 expected the end of interventions at the beginning of 2015.

The negative nominal interest rates are connected with economic risks. Probably the most significant is the loss in profitability of commercial banks. Commercial banks in the Czech Republic have enough money in the form of deposits in savings accounts, therefore the interests on deposit accounts are close to zero. Negative interest rate used by commercial banks could cause an outflow of deposits.

The Czech economy does not suffer from lack of money, using of "quantitative easing" to maximum extent does not seem appropriate.

6 Conclusion

The effect of foreign exchange interventions reduces several facts. In the ZLB situation (zero interest rate) does not operate the transmission channel of interventions to the exchange rate. The revenues from short-term domestic bonds, that are in the case of CNB especially treasury bills and revenues from deposit money are almost the same. These assets can be considered as substitutes. Interventions

will not affect the nominal interest rate and monetary supply. Interest rate channel, which is very important, therefore, cannot be considered. The effect of interventions on the exchange rate must be carried out through other channels - signaling channel, channel portfolio balance and coordination channel. McCallum´s study does not specify how to calculate the volume of interventions, that would weaken the currency. Since the launch of interventions regime in November 2013 to September 2016, the CNB intervened in the range of approximately 900,000 million CZK. This is significantly more than CNB expected at the beginning of the intervention.

The Czech economy is closely linked with the economies of the Eurozone countries. Czech government managed to restore consumer and business confidence in the Czech economy, which had a positive impact on economic growth. CNB in the form of foreign exchange interventions applied a little-tested instrument of monetary policy. A weakening of domestic currency is a simple step. Closing intervention regime could be much harder. CNB since mid-2015 was forced to intervene more frequently and in larger volumes of money to defend the exchange rate commitment before foreign exchange speculators. The use of interventions over a longer period would increase the difference among artificially weakening domestic currency and its real market potential, which carries a risk to the entire economy. Despite all the negatives mentioned above, the intervention regime was better solution than the use of negative interest rates. The competitiveness of our economy, measured by exports, has not diminished and imports have not slowed down. The Czech economy has a long-term positive trade balance. Foreign exchange interventions have increased the competitiveness of Czech products by cheapening them on foreign markets. In the long run, however, it is not possible to establish the competitiveness of Czech goods on foreign markets, mainly on its price.

The Importance of Information Security Management System in Slovak E-business

František Korček, Department of Information Management, Faculty of Business Management, University of Economics in Bratislava, Bratislava, Slovak Republic, frantisek.korcek@euba.sk

Mojmír Kokles, Department of Information Management, Faculty of Business Management, University of Economics in Bratislava, Bratislava, Slovak Republic, mojmir.kokles@euba.sk

Anita Romanová, Department of Information Management, Faculty of Business Management, University of Economics in Bratislava, Bratislava, Slovak Republic, anita.romanova@euba.sk

Abstract

Information security management is still very little known and definitely underused in the conditions of enterprises which are active in the electronic market. There is a lack of adequate security awareness against IT security threats that relate to the growth of ICT. In terms of business size, it is generally assumed that the smaller the enterprise is, the less the enterprise is concerned with information security. However, vulnerable information assets need to be secured in any enterprise that sells products and services electronically, as the consequences of risks could be existential. The paper presents the results of a survey focusing on the current state of information security management in Slovak e-business and evaluates a correlation between the costs incurred for information security and the level of information security in the examined enterprises.

Keywords: Information security, e-business, assets, threats

Introduction

Information is a central concept of today's society, which we acquire through efficient data-linking using information and communication technologies (ICT). Because information is too large, it needs to be processed, sorted, analyzed, compared, but especially selected and saved. If we assign meaning to information, we gain knowledge that is of great importance to society as it brings a certain advantage to its owner. As this benefit is visible in the society, there are always enemies who want to get it for themselves. The owner's job is to protect crucial information and knowledge. Enterprises also overlap with information through all stages of their life cycle and a transformation process. Protecting important knowledge, confidential information and other information assets is their duty. If an enterprise acquires knowledge, it gains a competitive advantage and can overtake its opponents. On the other side, the opponents are trying to gain such advantage by performing various information security attacks. Information security management system (ISMS) helps businesses successfully address threats and protect confidential information and knowledge at an appropriate level.

The introduction and active use of e-commerce is undoubtedly a modern way of offering goods and services and one of the fastest growing spheres of the economy (Skitsko & Ignatova, 2016). Securing business environment, devices, business processes, business secrets and supplier relationships against information security threats can be rapidly obsolete because of the constant and rapid development of ICT (Bolek, 2015). If the business processes are supported by ICT, new information security risks and the possibility of leakage or loss of confidential information will still arise. This leakage or loss causes disclosure of business secrets, investigation, lost working time, additional time to repair vulnerabilities, additional financial costs, loss of competitive advantage, opportunities, reputation, reduction in work efficiency, existential problems and many others. It is essential to protect enterprises against threats, ideally by suitably applied information security management system. This system introduces a procedural approach to information security, thus ensuring constant improvement of the quality protection of enterprises's information assets. This paper is a partial output of the survey focused on the current state of ISMS in Slovak e-business.

Literature Review

Computerization encourages businesses, regardless of their size or focus, to quickly acquire standards of information assets' security. From a historical point of view, large businesses were first to deal with information security because they processed a large amount of data on daily bases. Larger and richer businesses had enough resources to invest in asset security. Small and medium-sized enterprises (SMEs) thought that cyber threats target only large businesses. However, more and more attackers focus on SMEs because they do not adequately protect their sensitive data (Král, 2011). According to Ernst & Young, there are five main reasons why businesses should deal with information security (EY, 2014):

- Constant changes in the business environment,
- The ecosystem of digitally linked objects, people and data,
- Making the internet available for traditionally closed operating technologies (e.g. critical infrastructure, internet of things),
- Cloud,
- Mobile technologies and customer orientation.

Businesses are increasingly experiencing the risk of information security disruption, but many do not respond when a security incident occurs (Huo, Meng & Chen, 2015). As a result of the expansion of computer networks and the internet, businesses are more susceptible to attacks on confidential information, data, information systems (Bolek, Korcek & Beňová, 2015), ICT and employees. Protecting business information against threats is the domain of information security management, which is defined as follows:

- ISO/IEC 27001 standard defines ISMS as a system that protects confidentiality, availability and integrity of information by introducing a risk management process and providing confidence to stakeholders that the risks are sufficiently managed (STN ISO/IEC 27001, 2014),
- ESET (2014) considers ISMS to be the basis for risk management to establish, implement, operate, monitor, revise, maintain and improve information security in organizations,
- According to ENISA (2015), ISMS represents a system that achieves required qualitative characteristics of information security (confidentiality, availability, integrity) in services offered by organizations,
- Singh et al. (2013) claim that ISMS is a system of balanced intersection of technical, managerial and human aspects of information security in an organization,
- Ondrák, Sedlák & Mazálek (2013) perceive ISMS as an effective documented management system of information assets aiming to eliminate their potential loss or damage.

Based on the definitions above, we consider ISMS to be a comprehensive system within the overall organization management system that protects information from risks. By maintaining this system, the organization becomes trustworthy from the point of view of all stakeholders, such as employees, suppliers or customers. The introduction, implementation, monitoring and improvement of ISMS consists of many activities that need to be performed at regular intervals.

The availability of cheap mobile devices and the expansion of the internet have become key factors of the increasing use of the internet (Yazdanifard, Edres & Seyedi, 2011). E-business is growing in proportion to the expansion of the internet (Wu, Zhou & Yuan, 2012). Enterprises' success depends on the effective use of ICT (Prakash, Soni & Mittal, 2014). New electronic markets are emerging wherever the internet is available. E-commerce is on the rise, as evidenced by the Eurostat (2017) and countries such as China and the United States, which multiply their revenues from electronic sales of goods and services annually (Cohen, 2016). Slovakia also confirms the upward trend (Dvorský, 2016). The annual increase in the number of e-businesses and the progressive computerization of society (e-government, e-health) indicate that the development of e-business in Slovakia will continue. However, the development will not be possible unless businesses observe basic dimensions of information security (confidentiality, availability and integrity of information assets). At the time

of a large number of threats, offensive methods and techniques, the e-businesses can not afford to ignore information security. We are convinced that the right way is to apply a process approach to ISMS which guarantees adequate information security of e-business by minimizing the consequences of risks.

Access to information security in e-business is different for each business size category. From the point of view of governance and enforcement of information security, microenterprises and SMEs have a specific environment compared to large enterprises. The smaller the enterprise, the bigger differences are between them (Dekýš, 2010):

- SMEs and microenterprises have little or no security team,
- Information security management is performed by the IT department,
- Budget for security is either part of an IT budget or does not exist,
- SMEs and microenterprises have a lower range of financial, time and human resources allocated to information security,
- SMEs and microenterprises generally use open-source projects to minimize expenditures.

Unlike microenterprises and SMEs, large enterprises can more easily allocate resources to create a separate IT security unit, also because of the risk of greater consequences of security incidents. Moreover, they are more aware of the legal requirements in the field of information confidentiality and are of interest for ISMS professional consulting companies, which they are easier to cooperate with (SHREDIT, 2017). Large enterprises can focus on more sophisticated security solutions due to much larger budget than SMEs and microenterprises. Large businesses have more processes, employees, larger IT infrastructure, so they need to secure far more information assets than SMEs and microenterprises.

Research Objectives and Methodology

The main objective of the paper is to evaluate the perception of ISMS's importance in e-business on the Slovak electronic market. Successful achievement of the main goal is based on meeting the following partial objectives:

- To evaluate the survey focused on information security management in enterprises operating on the Slovak electronic market,
- To review enterprise-rated variables and analyze the variables in terms of business size,
- To evaluate relationships between the examined variables using the correlation analysis,
- Assess the dependence between information security costs and the level of information security in the researched enterprises according to the following hypothesis and based on studies by Černý (2014), Singh et al. (2013), Stehlíková & Horovčák (2012):

    - H_0: There is no statistically significant correlation ($r < 0.3$) between the costs spent on information security and the level of information security provided by the enterprises,
    - H_1: There is a statistically significant correlation ($r > 0.3$) between the costs spent on information security and the level of information security provided by the enterprises.

The objectives of the paper are achieved using statistical methods and general methods of scientific work. When examining the structure of the data set we used descriptive statistics and the Kolmogorov-Smirnov test (K-S test) to verify the normal distribution of the data. When examining dependencies between the variables in the case of normal distribution, we used Pearson correlation coefficient and, in the case of other distributions, Kendall's Tau-c and Spearman's correlation coefficient. The following table lists the variables whose values are input into data analysis.

Table 1: Research variables

ISMS – Information Security Management System	
ISMS1	Necessity of dealing with ISMS within e-business
ISMS2	Possibility to protect e-business without ISMS
ISMS3	Possibility of ISMS to improve e-business results
ISMS4	The need for ISMS in the e-business of the respondent
ISMS5	Practice of ISMS in the enterprise
ISMS6	Share of information security costs from total costs
ISMS7	Sufficiency of financial resources for information security
ISMS8	Satisfaction with the information security level in the enterprise
ISMS9	The level of information security in the enterprise

Source: Authors' own work

A data collection was carried out in the form of an electronic questionnaire distributed in Slovak e-businesses from October 2016 to January 2017. The number of respondents is 91, which we consider to be a representative sample with respect to data sensitivity and the number of e-businesses in Slovakia. This number reached 9355 in 2015 with the year-on-year increase of 1105 e-businesses in (Heureka, 2015). The survey variables are continuous and measured on a scale from 0 to 100 points. The following table shows a structure of the data set by economic activity (NACE Rev. 2).

Table 2: Structure of the data set by economic activity

Economic activity according to NACE Rev. 2	%
A – Agriculture, forestry and fishing	5.49 %
C – Manufacturing	2.20 %
F – Construction	2.20 %
G – Wholesale and retail trade; repair of motor vehicles and motorcycles	50.55 %
H – Transportation and storage	1.10 %
I – Accommodation and food service activities	1.10 %
J – Information and communication	2.20 %
K – Finance and insurance activities	1.10 %
M – Professional, scientific and technical activities	6.59 %
O – Public administration and defence; compulsory social security	1.10 %
P – Education	2.20 %
R – Arts, entertainment and recreation	2.20 %
S – Other service activities	21.98 %
∑	**100.00 %**

Source: Authors' calculations

The most surveyed enterprises come from the G section (50.5%), the S section (21.98%) and the M section (6.59%). The results confirm that most e-businesses are focused on retail or wholesale. In terms of business size, 73.63% of microenterprises, 23.08% of SMEs and 3.30% of large enterprises were involved in the survey.

Results and Discussion

The ISMS survey in businesses that trade on the Slovak electronic market has brought a number of valuable insights that reveal the current perception of importance and attitude towards ISMS. Descriptive statistics of the examined variables are listed in Table 3.

Table 3: Descriptive statistics of the ISMS variables

Variable	Min	Max	Kurtosis	Skewness	Mode	Median	M	SD
ISMS1	0	100	-0.73	-0.51	100	70	**64.89**	**30.02**
ISMS2	0	100	-1.03	0.23	50	49	**45.02**	**30.23**
ISMS3	0	100	-0.79	-0.09	50	50	**51.75**	**29.38**
ISMS4	1	100	-0.74	-0.41	100	60	**61.26**	**29.33**
ISMS5	0	100	-0.70	0.66	0	24	**30.08**	**28.59**
ISMS6	0	77	4.64	2.04	5	6	**12.63**	**15.11**
ISMS7	0	100	-1.03	0.48	–	29	**36.95**	**32.15**
ISMS8	1	100	-0.54	-0.61	50	70	**66.63**	**27.09**
ISMS9	1	100	-0.68	-0.52	80	70	**62.93**	**27.68**

Source: Authors' calculations

The variable named ISMS1 determines whether it is necessary to deal with ISMS within e-business on a scale from 0 points (definitely not) to 100 points (certainly yes). Data shows that businesses (M = 64.89, SD = 30.02) claim that ISMS should be addressed in e-business. Median represents 70 points, while up to 25% of respondents rated the variable by more than 93 points. E-businesses are aware of the importance of ISMS. Since the results of the K-S test at a significance level of $\alpha = 0.05$ confirm that the data are distributed normally ($Z = 1.16$; $p = 0.120$), we assume that with 95% reliability the interval for the mean value of ISMS1 is between 58.64 and 71.14 points.

Another variable is the possibility of protecting e-business without ISMS (ISMS2). We examined whether e-business could be protected against risks without the comprehensive ISMS, where 0 points mean "definitely not" and 100 points mean "certainly yes". The results show the indecision of business representatives in this issue (M = 45.02, SD = 30.23, Modus = 50, Median = 49), although more respondents are skewed (0.23) to lower values. Only 10 % of respondents reported more than 88 points. These respondents argue that securing e-business is certainly possible without the ISMS. The data is normally distributed (K-S test, $Z = 1.00$, $p = 0.269$), so we can determine the 95 % confidence interval for the mean value of the normal distribution (38.73, 51.32).

The ISMS3 variable studies whether the established ISMS can improve the economic performance of an e-business on a scale from 0 (definitely not) to 100 points (certainly can). In this case, the results are again indecisive (M = 51.75, SD = 29.38, Modus = 50, Median = 50). Respondents can not judge whether ISMS affects the business performance or not. The data are flatter (-0.79), slightly sloping to smaller values (-0.09) and normally distributed (K-S test, $Z = 0.86$, $p = 0.465$). The 95 % confidence interval for the mean value of the statistical population is between 45.63 and 57.87 points.

The fourth variable (ISMS4) measures the need to introduce, deploy, maintain and continually improve ISMS in an e-commerce business on the same scale as the previous variables. 50 % of the respondents rated ISMS4 more or less than 60 points. The most common value is 100 points and there is 15.38 % of such businesses. On average, the survey participants lean towards the need for perfecting the ISMS in their business (M = 61.26, SD = 29.33). 75 % of respondents reported more than 46.5 points. According to the K-S test's results at the significance level of $\alpha = 0.05$, the data are normally distributed ($Z = 0.89$; $p = 0.407$). Therefore, we can assume that the mean value is between 55.16 and 67.37 points with 95 % reliability.

The ISMS5 variable examines whether businesses establish, implement, maintain, and improve ISMS in their environment. The variable is specific because it was categorized into four intervals the respondents were familiar with. Values were divided into categories from 0 to 25 % (enterprises establish the ISMS), up to 50 % (establish and implement the ISMS), up to 75 % (establish, implement and maintain the ISMS) and up to 100 % (improve the ISMS). 0 % means that businesses do not perform any ISMS activity. Figure 1 shows the shares in the given categories.

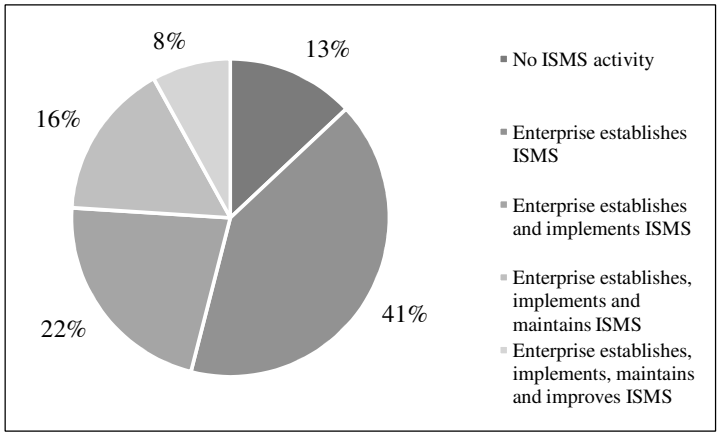

Fig. 1: Share of enterprises practicing ISMS

Source: Authors' calculations

Most enterprises are only in the initial phase of ISMS (41 %). However, up to 13 % of e-businesses do not carry out any activity in this area. Interestingly, 8 % of the researched enterprises already have the ISMS established, implemented and are improving the system. On average, e-businesses reach M = 30.08 points; SD = 28.59 points. 75 % of the values are up to 50 points. These data show that businesses do not implement and are paying little attention to the ISMS. Because the data are not distributed according to the normal distribution (K-S test, Z = 1.47, p = 0.018), the 95 % confidence interval of the mean value can not be reliably determined.

The share of information security costs from total business costs (ISMS6) measured in percentage follows. On average, enterprises invest 12.63% of total costs in information security (M = 12.63, SD = 15.11). An overview of costs in terms of business size is shown in Figure 2. SMEs invest no more than 18.86% of total costs followed by microenterprises (10.81%) and large enterprises (9.67%). We consider the cost shares of all business sizes to be surprisingly high, but the results may be distorted by a low number of respondents in the SMEs and large enterprises' categories, as well as a few high values in the data set. The most of e-businesses use 5 % of information security costs. Half of the values are less or more than 6 %. It is visible in the descriptive statistics that the data are not normally distributed. This is confirmed by the K-S test (Z = 2.49; p <0.001). According to the statistics, we can see that the relatively high mean value is affected by several high values. The mode and the median show a more realistic data layout. Therefore, we claim that the e-businesses allocate to information security around 5 % of their total costs, which we consider to be appropriate.

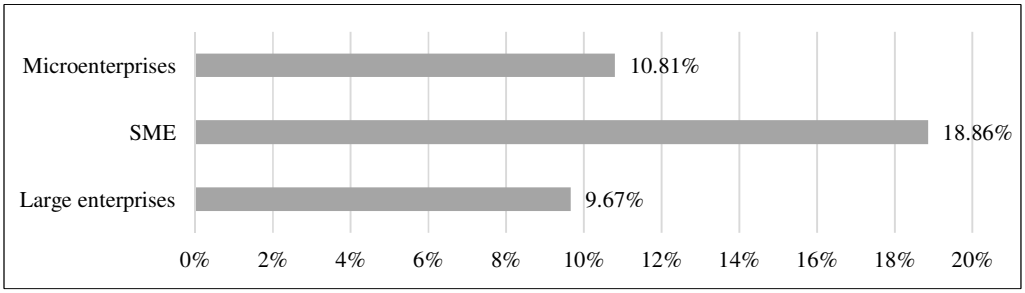

Fig. 2: Share of information security costs from total costs by business size

Source: Authors' calculations

By ISMS7 we studied, if an enterprise has enough funds for adequate protection of its information on a scale from 0 (definitely not) to 100 points (certainly yes). The mode represents 29 points. According to kurtosis, the data set contains more extreme values (-1.03), but skewness shows smaller values (0.48). On average, the respondents determined that the enterprises do not have sufficient financial resources for information security (M = 36.95, SD = 32.15). The average values by business

size are shown in Figure 3. According to assumptions, large enterprises have the most free funds, averaging 51.33 points, followed by microenterprises (37.33 points) and SMEs (33.67 points).

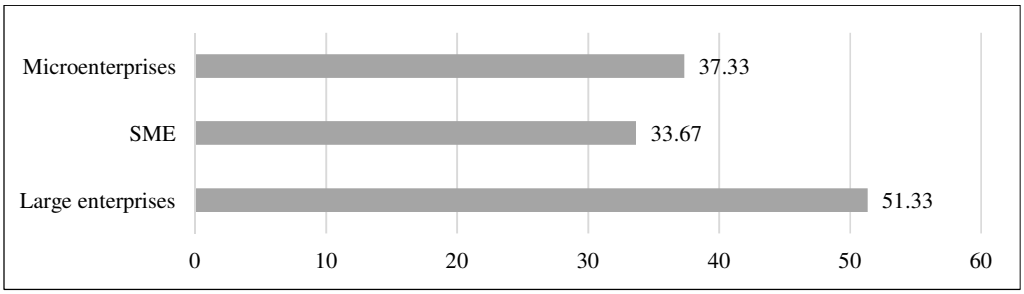

Fig. 3: The average amount of financial resources for information security measured in points
Source: Authors' calculations

In our opinion, the ideal interval for evaluating the sufficiency of financial resources is 75 points or more. However, only 19 % of the e-businesses reported such figures. Only 25 % of the enterprises have rather enought resources, more than 59 points. Up to 10 % of the respondents selected values of 0 or 1. This means that around one tenth of the e-businesses do not have enough resources to secure enterprise information. 95 % confidence interval can not be determined because the data are not normally distributed (K-S test, Z = 1.33, p = 0.043). The mode can not be calculated due to two values with the highest frequency (1 and 50).

The ISMS8 variable examines the extent to which e-businesses are satisfied with securing their information assets. The respondents assessed the variable on a scale from 0 points (definitely not satisfied) to 100 points (certainly satisfied). On average, the business representatives are rather satisfied (M = 66.63, SD = 27.09). Up to 50 % of the values are over 70 points. Kurtosis determines more flat data (-0.54) which are skewed to the right (-0.61). According to the K-S test, the data do not meet the condition of normal distribution (Z = 1.33; p = 0.043). In summary, most enterprises are rather satisfied with their level of information security.

The variable of enterprise's information security level (ISMS9) is linked to the previous variable (ISMS8) because it measures the perceived security level on a scale from 0 (minimum) to 100 points (maximum). The mean value is M = 62.93 points; SD = 27.68 points. The enterprises claim that their level is sufficient. We argue that the level should be much higher because of the current threats' danger. The information security level determined by the respondents and grouped by business size is shown in Figure 4.

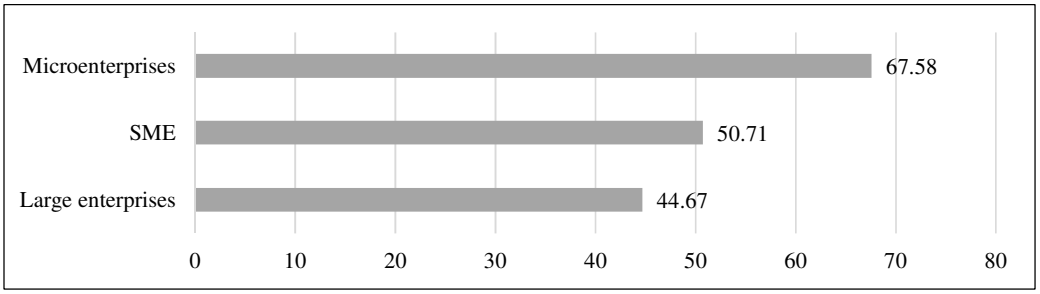

Fig. 4: The level of information security determined by enterprises
Source: Authors' calculations

Microenterprises have the highest observed information security level among other business sizes, averaging 67.58 points. SMEs follow with 50.71 points. The information security level of large enterprises is rather insufficient (44.67 points). The large enterprises are more aware of the need to protect information than businesses of other sizes and thus identify their shortcomings more. In addition, they need to secure many more areas, systems and processes than other enterprises. The

respondents most often rated the information security level at 80 points. Only 25 % of the e-businesses have the level of less than or equal to 47.50 points. The data are not normally distributed (K-S test, Z = 1.63, p = 0.006). The values of the information security level can be explained in two ways. Either the level is really sufficient and the results reflect the real situation, or the enterprises lack security awareness and education while the respondents believe that the level of information security is good enough. We refer to the second part of the claim.

Correlation Research of the Information Security Management System

In the previous section, we found that the interval variables (scales) ISMS1, ISMS2, ISMS3 and ISMS4 are normally distributed by using the K-S test. Therefore, correlations between these variables are identified by the Pearson correlation coefficient whose results are found in Table 4.

Table 4: Correlation matrix of variables with normally distributed data

		SY01	SY02	SY03	SY04
ISMS1	Pearson Correlation	–	0.24	0.39	0.42
	Sig. (2-tailed)		0.020	0.000	0.000
	N		91	91	91
ISMS2	Pearson Correlation	0.24	–	0.00	-0.24
	Sig. (2-tailed)	0.020		0.966	0.022
	N	91		91	91
ISMS3	Pearson Correlation	0.39	0.00	–	0.39
	Sig. (2-tailed)	0.000	0.966		0.000
	N	91	91		91
ISMS4	Pearson Correlation	0.42	-0.24	0.39	–
	Sig. (2-tailed)	0.000	0.022	0.000	
	N	91	91	91	

Source: Authors' calculations

The ISMS1 scale correlates with ISMS2 (r = 0.24; p = 0.020) and ISMS3 (r = 0.39; p <0.001) just weakly. The strength of these scales' interdependence is small. There is a medium correlation between ISMS1 and ISMS4 (r = 0.42; p <0.001). It means that the variables have a moderate relationship. There is no correlation between the ISMS2 and ISMS3 scales (r = 0.00, p = 0.966). This represents that the possibility of protecting e-business without ISMS and improving the economic performance of e-business through ISMS are unrelated. The scales of the ISMS2 and ISMS4 variables, r = -0.24; p = 0.022, as well as the ISMS3 and ISMS4 scales, r = 0.39; p <0.001, correlate weakly. Because the values of ISMS5, ISMS6, ISMS7, ISMS8 and ISMS9 are not normally distributed according to the K-S test results, we used the Spearman's and Kendall's Tau-c coefficients to examine the correlations. The results with higlighted values of more than weak correlations are shown in Table 5.

Table 5: Results of Spearman's correlation and Kendall's tau–c

	Statistic	ISMS 1	ISMS 2	ISMS 3	ISMS 4	ISMS 5	ISMS 6	ISMS 7	ISMS 8	ISMS 9
ISMS 5	Kendall's tau–c	0.16	0.08	0.11	0.22	–	0.31	0.30	0.05	0.18
	Spearman Correlation	0.22	0.10	0.14	0.30		**0.42**	**0.41**	0.05	0.26
ISMS 6	Kendall's tau–c	-0.06	-0.01	0.08	0.07	0.31	–	0.18	-0.09	0.06
	Spearman Correlation	-0.10	-0.01	0.11	0.11	**0.42**		0.24	-0.13	0.08
ISMS 7	Kendall's tau–c	0.05	0.15	0.01	0.12	0.30	0.18	–	0.12	0.22
	Spearman Correlation	0.09	0.21	0.02	0.16	**0.41**	0.24		0.17	0.32
ISMS 8	Kendall's tau–c	0.03	0.13	-0.04	-0.01	0.05	-0.09	0.12	–	**0.51**
	Spearman Correlation	0.04	0.18	-0.06	-0.04	0.05	-0.13	0.17		**0.68**
ISMS	Kendall's tau–c	0.14	0.12	0.15	0.07	0.18	0.06	0.22	**0.51**	–

	Statistic	ISMS 1	ISMS 2	ISMS 3	ISMS 4	ISMS 5	ISMS 6	ISMS 7	ISMS 8	ISMS 9
9	Spearman Correlation	0.20	0.18	0.24	0.11	0.26	0.08	0.32	**0.68**	

Source: Authors' calculations

According to Spearman's correlation coefficient, the ISMS5 scale correlates moderately with the scale of ISMS6, r = 0.42, and ISMS7, r = 0.41. The Kendall's Tau-c results do not confirm such strength of interdependence in both cases. The ISMS5 scale with SY06 (τ = 0.31) and ISMS7 (τ = 0.30) correlates only weakly. We are inclined to the Kendall's Tau-c results due to lower coefficient values. The level of ISMS establishment, implementation, maintenance and improvement in e-businesses is only weakly related to the costs incurred for information security and also to the perceived sufficiency of financial resources to adequately protect business information assets.

Other combinations of the scales, except for the satisfaction with the information security level in the enterprise (ISMS8) and the level of information security in the enterprise (ISMS9), are weakly correlated. The scales of ISMS8 and ISMS9 correlate moderately as evidenced by Spearman's rho (r = 0.68) and Kendall's Tau-c (τ = 0.51). The satisfaction with the information security level in the enterprise is moderately related to the level of information security in the enterprise. In general, only some of the scales have medium linear dependence (ISMS8 and ISMS9, ISMS1 and ISMS4). The correlation of other ISMS scales is only weak or possibly nonexistent (e.g. ISMS2 and ISMS3).

Testing the Hypothesis

The basis of the hypothesis is that the amount of funds spent on information security relates to the level of information security determined by e-businesses. If an enterprise spends more, it perceives higher level of information security, or from the other point of view, if the e-businesses perceive the high level of information security, they also have higher information security costs. We test the hypothesis by the correlation analysis of the share of information security costs from total costs (ISMS6) and the level of information security in the enterprise (ISMS9). Because the results of the K-S test for ISMS6 (Z = 2.49; p <0.001) and for ISMS9 (Z = 1.63; p = 0.006) prove that the data are not normally distributed, we selected Spearman's correlation coefficient and Kendall's Tau-c to measure the correlation. The results are shown in Table 6.

Table 6: Results of the interdependence of ISMS6 and ISMS9 variables

	Category	Statistic	Value	Asymp. Std. Error	Approx. T	Approx. Sig.
Symmetric measures	Ordinal by Ordinal	Kendall's tau–c	0.06	0.07	0.78	–
		Spearman Correlation	0.08	0.11	0.72	–
	N of Valid Cases	–	91	–	–	–

Source: Authors' calculations

The Spearman's correlation coefficient (r = 0.08) and the Kendall's Tau-c (τ = 0.06) are very low and close to zero, which reflects the trivial mutual linear dependence of the studied variables. Because of these results we accept the null hypothesis. The relationship between the costs spent on information security in the e-businesses and the level of information security set by the e-businesses is minimal. There is no statistically significant correlation between the variables. The minimal correlation of the variables is shown in Figure 5, where the points are randomly distributed.

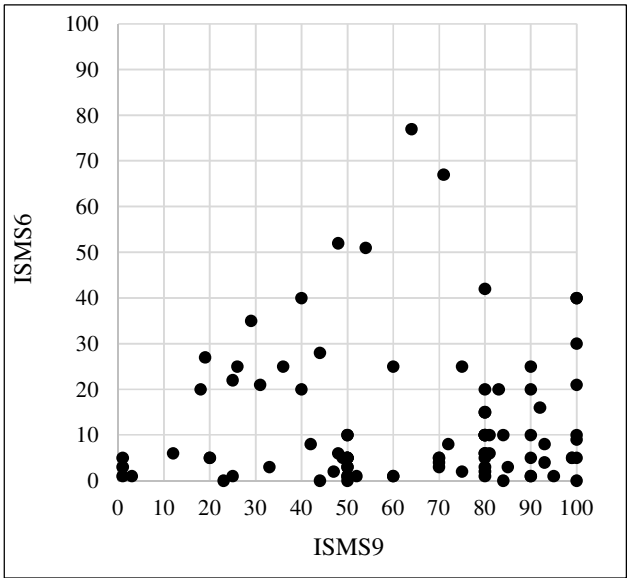

Fig. 5: Correlation diagram of ISMS6 and ISMS9 variables

Source: Authors' calculations

It is possible to explain this knowledge from the point of view of dividing security measures into technical and organizational measures. While technical measures are costly, organizational measures do not necessarily mean additional costs, although they also contribute to raising the information security level. For example, if an enterprise develops, publishes and adheres to an information security policy, which is not a technical control, it will significantly increase the perceived level of information security with little or no additional costs. Therefore, investing in information security does not affect the perceived level of information security in e-businesses.

Based on the results of the ISMS variables, we note that businesses operating e-commerces on the Slovak electronic market have only a basic overview of the information security and are prepared for information security threats at the basic level. The enterprises agree that the ISMS needs to be addressed in e-business. They are aware of the ISMS importance. They also advocate that the ISMS should be implemented in their environment. However, the e-businesses do not pay enough attention to the ISMS. Most enterprises claim that they establish the ISMS (41 %), which means that they use at least basic security measures (e.g. antivirus software, firewall, TLS protocols). On the other hand, up to 13 % of the surveyed enterprises do not perform any ISMS activity. Additionally, the e-businesses are rather satisfied with their level of information security which they consider sufficient. We are attributing such unfavorable condition to the perception of the information security level based on the application of only basic security measures and due to low security awareness. We exclude the impact of the lack of financial resources due to the nonexistent correlation between the costs spent on information security and the level of information security in the e-businesses.

Conclusion

To conclude, we found out that e-businesses are aware of the importance of ISMS and incline to the need to improve it, but they do not introduce the ISMS. E-businesses are rather satisfied with their level of information security, which they see as sufficient. We also identified that businesses only have a basic overview of information security and are prepared for information security threats only at the minimum level. Considering the hypothesis, we researched whether the information security costs out of total costs (ISMS6) and the level of enterprise information security (ISMS9) depend on each other at least at a moderate level ($r > 0.3$). Because the Spearman's correlation coefficient ($r = 0.08$) and Kendall's Tau-c ($\tau = 0.06$) are close to zero, we have accepted that a zero hypothesis is true. The linear correlation of the examined variables is trivial. There is no statistically significant

correlation between the information security costs and the information security level. Unlike Singh et al. (2013), Černý (2014), Stehlíková & Horovčák (2012), we have not confirmed the dependence between the information security costs and the information security level in e-business.

Financial Analysis of Distressed Companies in Emerging Countries: Methodological Approaches

Olga Lvova, PhD (Economics), Associate Professor, Lomonosov Moscow State University, Moscow, Russia, E-mail: Lvova@spa.msu.ru

lvova.oa@gmail.com

Abstract

The paper considers the development of methodological approaches to financial analysis of distressed companies considering certain specifics of emerging economies within framework of sustainable development of global economy. The research explains reasonability of shift from "accounting" approach to "flexible market analysis model" of distressed companies' at emerging markets and provides concrete methodological approach based on cash flow analysis, comparative interfirm analysis, comprehensive transactions investigation, concerning presence (absence) of distressed company's intention to continue activity. This approach to financial diagnostics contributes to proactive crisis management and to the transformation of insolvency model from liquidation towards restructuring of distressed business.

Keywords: financial analysis, cash flows, bankruptcy prediction, insolvency, bankruptcy

Introduction

Problems of business insolvency and bankruptcy, assessment of distressed companies' restructuring possibilities or reasonable assets appraisal during corporate liquidation are currently important for all countries. However, in emerging markets bankruptcy threat usually concerns much wider range of companies. Financial distress of companies from fast-growing economies (India, China, etc.) can be partially related with unsustainable growth rate[1] of some companies, i.e. such growth which outperforms the possibilities of funds raising. In long-established, but currently stagnating market economies some businesses suffer from lack or insufficient government support (both direct financial injections and indirect lightening of taxation and lending).

Issues of monitoring the opportunities for a business rescue, choosing corporate rehabilitation procedures, determining of market value of distressed companies have extremely high importance in emerging countries with short history of market economy (Russia, Ukraine, Belorussia, Kazakhstan, etc.). Insolvency institute in these countries does not provide appropriate solutions for above-mentioned problems due to its imperfection: positive experience of business recovery within bankruptcy procedures is practically absent (Table 1), "grey schemes" for delaying terms of proceedings and assets stripping tend to become a common practice, illegal seizures of distressed enterprises are used by means of insolvency procedure for property repartition, creditors' claims during liquidation are satisfied at the low level. For example, in Russia according to official statistics of Unified Federal Register of Bankruptcy Information (UFRBI) in 2016 the share of settled debts decreased in comparison with 2015 – from 5% to 3,2%.

Table 1: The amount of insolvency proceedings in the last ten years in Russia (number of cases)

	2006	2007	2008	2009	2010	2011	2012	2013	2014	2015
Accepted applications on insolvency (bankruptcy)	83068	30015	27032	35545	33270	27422	33226	27351	35583	41040
Financial rehabilitation	39	33	48	53	91	94	92	67	58	68
debt repaid	8	3	6	2	6	7	3	4	4	0
External administration	947	752	579	604	908	986	922	803	817	882
solvency restored	31	41	40	11	14	13	25	15	18	14
Composition	106	126	126	127	255	376	563	585	598	651

Source: Unified Federal Register of Bankruptcy Information (UFRBI).

Nevertheless, in such countries pre-conditions for shift from prevailing liquidation of distressed business towards focusing on its rehabilitation became to develop. This process should be accompanied by closer attention to analytical instruments of assessment of distressed companies' perspectives. The development of methodological approaches to financial analysis of distressed companies considering certain specifics (that is so-called "creative accounting" (Griffiths, 1986), deliberate bankruptcy with systematically repeating financial schemes of debt settlement avoidance) is an important economic and legal problem.

Hypothesis of the research is reasonability of shift from "accounting" approach to "flexible market analysis model" based on cash flow analysis, comparative interfirm analysis, comprehensive transactions investigation, concerning presence (absence) of company's intention to continue activity. Necessity to take into account of economic and political factors makes this potential methodic difficult to formalize, so it is possible to develop only methodological approaches.

Literature Review

Financial diagnostics is a critical condition of proactive crisis management. So, financial analysis of distressed companies is traditionally considered by specialists in two main aspects – predicting insolvency (proactive activity) and analysis of already insolvent firms (reactive crisis management to reveal main problems and suggest solutions).

Methods of predicting corporate distress were initially suggested by Altman (1968), then by Conan & Holder (1979), Taffler & Tisshaw (1977), Taffler (1982), Jones (1987), Zmijewski (1984), Platt (1990), Beaver (1998, 2005), etc. Many further models developed discriminant analysis approach and were based on economic statistics of certain (usually – developed) country collected during certain period of economic cycle and not always suitable to contemporary emerging markets.

There are also papers examining analysis methods in financial distress, which "is, in short, the dynamic process towards corporate failure" (Fawzi et al., 2015). It should be argued that financial distress is not equal entering to liquidation (Grice & Dugan, 2001), but is a turning point in corporate life cycle: so, financial analysis can help to reveal main problematic issues and design recovery plan.

Practice of management of already insolvent companies under bankruptcy proceedings in different jurisdictions, including emerging economies, has been studied by many national specialists (Wessels, 2006; Lowitzsch (ed), 2007; Giorgini & Vallens (ed), 2015; Lvova & Bobyleva, 2012; Lvova, 2014; Karelina & Erlikh, 2012; Lai, 2016).

In 2008 Ministry of Economics of the Russian Federation started a mutual project with European Bank of Reconstruction and Development (EBRD) on development of Federal standards of financial analysis as guidelines for insolvency administrators. This work was not completed but widely criticized for the lack of consistency, complexity of financial analysis and concrete analytical methodic not corresponding with the current level of bankruptcy institute development in Russia.

So, today scientific and practical works on financial analysis methodology for distressed companies in emerging economies are still practically absent; most of papers on bankruptcy are usually devoted to the legal framework examining whereas economic aspects of insolvency proceedings, including financial analysis issues, are undercharacterized. This determines the choice of the paper topic.

The Possibilities of a Common Methodology in Emerging Countries

In Russia financial diagnostics of distressed companies under bankruptcy proceedings is regulated by two special legal acts: "Rules of financial analysis for insolvency administrator" (approved by the Government Decision of the Russian Federation at 29 June 2003 №367) and "Temporary rules of identification of deliberate and fictitious bankruptcy by the insolvency administrator" (approved by the Government Decision of the Russian Federation at 27 December 2004 №855). These provisions did not fully meet their objectives from the moment of coming into force. During the last years their limitations, impossibility of performing main goals became more obvious due to adoption of new Federal Law "On accounting" (Law at 06 December 2011 №402-FZ), changing of financial and economic conditions in Russia and insolvency institute by itself.

Irrelevancy of these documents and their insufficiency to creditors' and court's requirements were discussed among academics and practitioners for several times at Subcommittee of crisis management of Chamber of Commerce and Industry and in scientific papers (Bobyleva, 2010). Among disadvantages of applicable rules the following are usually considered: prevailing of "accounting" type of analysis, choice of inconclusive and even incorrect ratios. In a whole, these Rules on analysis have the following limitations:

- do not orient at deep financial analysis to make relevant decisions;
- do not aim at revealing of key success factors of the company, main drivers of business recovery, do not allow to evaluate the scale of crisis, discover factors of its development;
- assessment of capability of breakeven activity does not include widespread methods of managerial control (direct-costing analysis, factor analysis, risk management);
- main attention is usually paid to current operating activity of the distressed company while financial and investment activities are not considered.

The implementation of traditional methodology of analysis and diagnostics also gives the possibilities to use creative accounting and benefit from it. For example:

- overvaluation of assets by: intentionally not writing off bad accounts receivable, gathering illiquid inventories, recognition of loans issued as «financial investments» in assets;
- artificial improving of financial results by recognition bad receivables in sales revenue enlarging financial results;
- formal filling of Cash flow statement as it usually has no sense, because tax authorities are not interested in it and banks giving loans also check this statement in a formal way.

So, it can be concluded, that a company shows "bad" ratios, when it lost the hope for recovering or if deliberate or fictitious bankruptcy took place.

The imperfection of the methodology and its creative implementation are not the only reasons for the fact that the analysis does not recognize insolvency. In emerging economies the number of bankruptcies is connected with economic conditions only partially (Figure 1). In identical economic conditions in Russia in the period of 2005–2007 the amount of insolvency proceedings differed in 2-3 times. The big number of applications in 2006 can be explained by the easy procedure of

application for the "missing debtors" bankruptcy and so-called "assetless companies". In 2007 the procedure became more complicated and the number of insolvency proceedings sharply reduced. Another example is crisis of 2008–2009: paradoxically it has not caused strong increase in bankruptcies. The amount of bankruptcies in 2008 even decreased to 90% of the 2007 level.

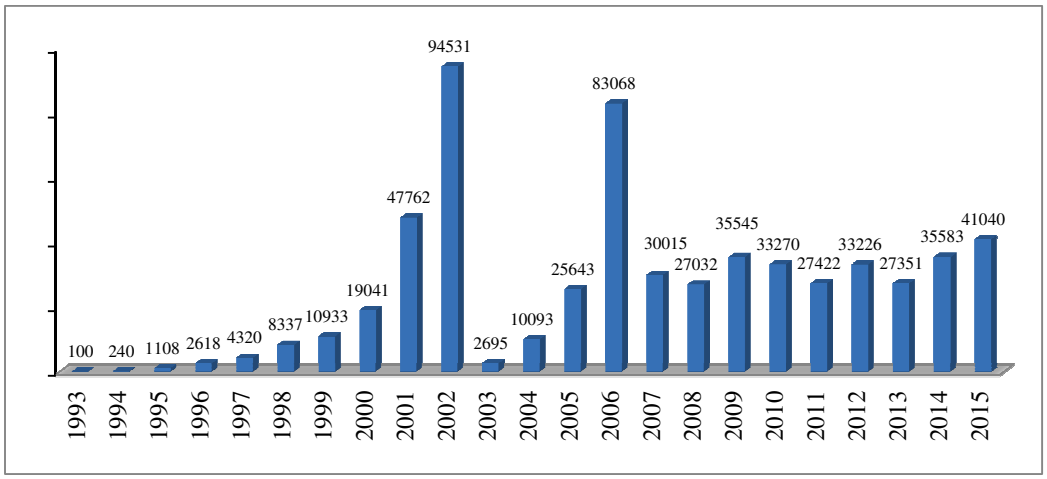

Fig 1: The amount of insolvency proceedings opened by the court in 1993-2015

The volatility of the amount of initiated cases shows, from the one hand, the immaturity of the Russian insolvency system and, from the other hand, to a certain degree can be explained by direct governmental support of "strategic" enterprises in crisis despite the financial analysis results. For example, in spite of low efficiency and "bad" ratios, according to "Anti-crisis Government Program for 2010", PJSC "AvtoVAZ" received 25 bln rubles. It gave short-term effect but in 2015 the company received net loss of 74 bln rubles, the loans were restructured with the help of government.

Another typical situation was with OJSC "Transaero Airlines". By 2015 the company has accumulated debt approximately 1,1 bln Euro which it was unable to repay and so went bankrupt. The loans have been approved because the company had "good" financial ratios for a long period before (in particular it was achieved by creative accounting – overestimation of intangible assets). The creditors took into consideration that the company was "too big to fail", had close relationships with national aviation authorities. So, they continued crediting the company while the government made the decision not to support air carrier.

These examples demonstrate that financial analysis based on certain ratios calculation can not show the real situation within the company, especially taking into account specifics of public protection of selected companies. Financial diagnostics of such companies needs special methodological approaches according to their legal status and belonging to a group of strategic ones.

In this regard, the question arises if financial ratios can be useful for bankruptcy prediction in emerging countries. As it is known, world widespread bankruptcy prediction methods can be divided on subjective (A-methods) and objective (Z-methods). A-methods are based on expert opinion, which considers both firm's goodwill, personality of director, competitiveness, etc. Z-methods include calculation of financial ratios and their linear combinations, use statistical method to assort such classifying measures variance of which between considered groups would be maximal but within these groups – minimal (multiple discriminant analysis, MDA). The most popular models are suggested by E. Altman (USA), J. Conan and M. Holder (France), R. Taffler and H. Tisshaw (England), H. Platt and M. Platt (USA), W. Beaver. These models have different number of ratios which vary significantly in dependence on subjective view of analyst and used data in the specific period of time in the certain country. It can be concluded that simple transfer of, for instance, American model at Russian conditions is unacceptable. Using of "alien" models in emerging markets is incorrect also due to the next reasons:

- ratios used in the model for advanced market economy are not always possible to find in financial reporting of companies working in emerging economy;
- calculated ratios can be incorrect due to falsification of accounts, its "creative" character, i.e. understatement of sales revenue, profit, assets;
- financial statements of companies from emerging economies imperfectly corresponds with IFRS and GAAP what makes impossible standard interpretation of financial analysis results.

There are some national bankruptcy predicting models, in particular for Russia (Kovalev & Volkova, 2000; Zaytseva, 1998; Sayfullin & Kadykov, 2003; Davydova & Belikov, 1999), but they also should be applied carefully: proposed sets of ratios seem controversial; suggested ratios gravities are poorly proved. Disadvantages of these models are objective: transitionary proportions in Russian economy do not allow to derive normative values, results of empirical studies for gravities' determining give highly volatile results.

So, one of our conclusions is that in emerging countries existing methodology of bankruptcy diagnostics and prediction for the future based on financial statements gives few information about company's present situation.

Modern "Market" Approach to Financial Analysis of Distressed Companies

Existing "accounting" approach to analysis based on financial statements, taking into account above-mentioned limitations and specific features of companies' activity in emerging economy, makes implementation of new 'market' methodological approach to analysis essential. Market model of analysis is hard to formalize because of many possible scenarios in prejudice of alignment of approaches. It has so called "cloud character", i.e. stipulates goals and tasks of analysis, its stages, methodical approaches, but leaves freedom of concrete options choice.

In the same time, the financial analysis of debtor is considered by the court as one of evidences within official bankruptcy procedure and it should give explicit conclusions about: (a) financial standing of the debtor; (b) possibility (impossibility) of conducting breakeven activity by the debtor; (c) availability (unavailability) of solvency restoration.

This approach is a basis of the Russian Federal Standard Draft of "Rules of financial and economic analysis of the debtor" which has been developing by the group of specialists since 2015 and now is at the validation phase[2] (Bobyleva, Lvova et al., 2015). Standard considers obligatory conducting of *basic* financial analysis of the debtor which can include one or two stages and parallel analysis of presence (absence) of evidences for transactions' voidance (Figure 2).

First stage is aimed at verification whether the debtor was indeed carrying out of its general business activity and (or) there was absence of intention (reasonability) to continue such activity. If the fact of main activity absence was established, the first stage is terminated. As a result, there is substantiation of further liquidation procedure.

Second stage is conducted while the fact of presence of general business activity or intention to continue was established. The result of second stage is conclusion about possibility (impossibility) of conducting breakeven activity by the debtor, availability (unavailability) of its solvency restoration, substantiation of further appropriate bankruptcy procedure opening.

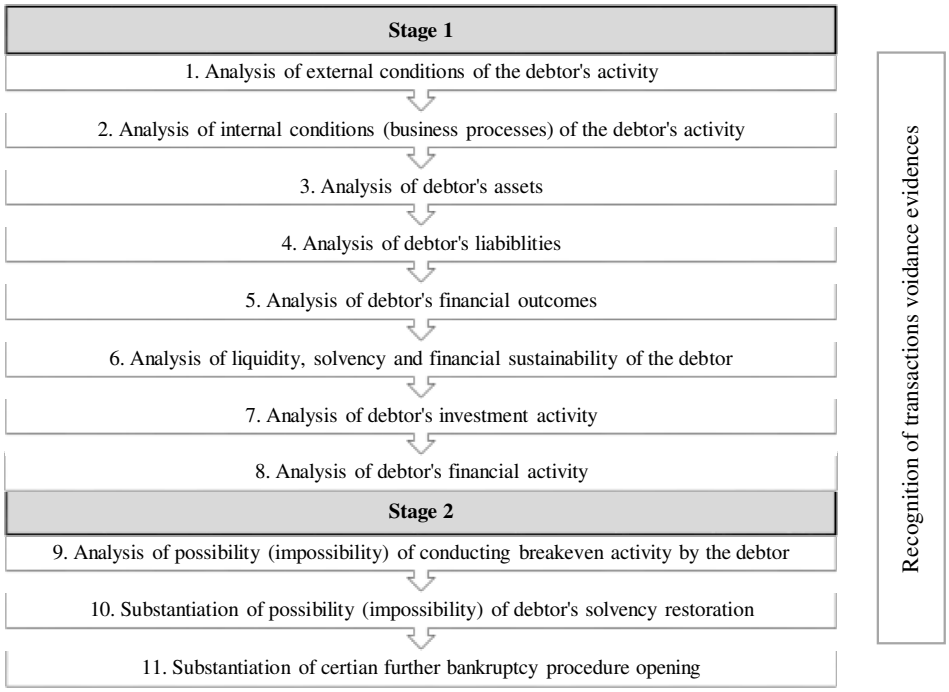

Fig. 2: Order of basic analysis of financial analysis of the debtor

Analysis of external conditions is aimed at recognition of influence of macroeconomic, regional and industrial factors at the debtor's financial standing. It should be noticed that flexibility of such model of analysis implies, that insolvency administrator considers not all but relative to debtor's business factors from Table 2.

Table 2: Analysis of external conditions of the debtor's activity

Description of factors	Tasks of analysis
1. Macroeconomic factors	
1.1. Geographic location, economic conditions of the region	To recognize the influence on debtor's activity of natural, seasonal, environmental factors, investment climate, taxation regime, specifics of region where the debtor acts
1.2. Inflation in the country and within certain region	To recognize the influence on debtor's activity of inflation level
1.3. Medium interest rates for similar scale and industry business	To compare credit conditions for debtor's business with mid-market ones
1.4. Currency rate	To learn correlation between currency rate changing and fluctuations in prices of the debtor's goods and services if it used import raw materials and other units bought for foreign currency
1.5. Other external factors related to debtor's business	To recognize the influence on debtor's activity of tariffs, stock exchange indexes, etc.
2. Specific market factors (according to debtor's business)	
2.1. Specifics of industry public regulation	To learn specific issues of government control of debtor's business industry which usually has significant importance at emerging markets
2.2. Market of debtor's commodities (services)	To determine influence of competitive environment, consumer demand and prices. Analysis should include such

	categories as debtor's consumer groups; sales volume in dependence on types of goods sold and domestic / foreign market distribution; methods of payment, debtor's market share, main competitors in relation to types of goods sold, prices dynamics, presence of substitutes
2.3. Purchase of supplies	To recognize the influence on debtor's financial standing of changing in raw materials prices, corresponding volume of deliveries (for example, price increase, reduction in requirement of raw materials, etc.)
2.4. Terms of bank credit	To analyze the influence of interest rate, credit terms, credit scoring of debtor's business by the bank

As the result of external conditions analysis, the influence on debtor's business activity of above-mentioned factors should be recognized, the main damaging factors for debtor's financial standing should be emphasized, the possibility of necessary business adaptation to these factors should be assessed. Investigation of voidable transactions can be considered as an element of deliberate bankruptcy analysis.

Characteristics of indebted company itself (block №2 within Stage 1 at Figure 2) includes analysis of internal features which should allow to propose following conclusions about:

- change in the assortment, volumes of production and sales of goods (services) and the reasons of it;
- change of costs' structure, level and reasons of it;
- reasonableness of purchasing prices at supplies, their correspondence with market prices, law and good business practices;
- correspondence of prices for goods (services) sold to market prices;
- opportunity and reasonability to save certain types of debtor's activity;
- organizational and production structure and their correspondence to main business types, goals and tasks of the debtor's activity;
- interconnections of the debtor's firm within group of companies (if applicable);
- dynamics of number of employees, payroll, incentive rewards relatively certain employees' categories, and reasons of changes in these measures;
- quality of financial accounts and statements, tax compliance;
- debtor's strategy: existence of business plans, current budgets, extent of their elaboration, implementation opportunities and possible risks.

The next step is Assets analysis (block №3 within Stage 1 at Figure 2) which should contain the following information:

- book value of all debtor's assets as at the last reporting date including explanation of main elements;
- assets classification into 4 groups: (1) assets, without which the main debtor's business activity would be impossible; (2) assets, sale of which would be problematic; (3) asset, which could be sold to cover creditors' claims, court expenses and insolvency administrator remuneration; (4) assets, which are impossible to sale;
- possible estimated market value of debtor's assets;
- value of pledged assets (book and collateral);
- transactions and actions of debtor's supervisory bodies, conducted within explored period of time, resulted in illegal disposal of debtor's assets.

Analysis of debtor's liabilities (block №4 of Stage 1) serves to discover reasons of significant change in debt to equity proportion, reveal voidable liabilities, find opportunities for due dates restructuring and suggest the conclusions about:

- constitution and structure of debtor's liabilities;
- liabilities dynamics (separately at each type of liability), reasons of their change and consequences for the debtor's activity;
- reasons of past-due debt arising and its types;
- reasonableness of liabilities and its classification;
- liabilities which come due in the next month, two months, quarter, half year, year;
- debts which can be settled by instalment;
- constitution and size of claims by creditors' classes, debt volumes and duration;
- opportunities and conditions of debt restructuring according to due dates by making agreement with certain creditors.

Financial outcomes block (№5 of Stage 1) includes the analysis of sales revenue, cost of goods sold, distribution and administrative expenses, non-operating gains and losses, gross profit, operation profit and pretax profit, net profit. After this step, analysis of liquidity, solvency and financial sustainability (block №6) follows. At these stages of analysis widespread financial ratios are still used, but, taking into account all their limitations, they are accompanied by cash flow analysis as suggested by Fawzi, Kamaluddin & Sanusi (2015). Nevertheless, this approach is also imperfect due to difficulties in relevant information obtaining.

Investment activity analysis (block №7) has attracted not enough attention till now. Nevertheless, it reveals sources of investment projects financing, examines whether it would be necessary to continue existing investment projects (or terminate them), to restore solvency and achieve breakeven activity by the debtor. Analysis of financial activity (block №8) is aimed at determining the level of credit and other financial instruments usage.

If at the Stage 1 it was found that the debtor has not both performed current activity and planned it for future, conclusion about impossibility of solvency restoration should be done. In his case the analysis is considered as enough evidence to commence liquidation procedure. If the analysis lead to opposite conclusion that the debtor has indeed performed current entrepreneur activity, the Stage 2 of analysis begins.

Breakeven activity is considered as possible (block №9 of Stage 2 at Figure 2) if future sales revenue will exceed costs, potential gains exceeding losses.

Analysis of possibility (impossibility) of debtor's solvency restoration (block №10) is based on conclusions of block 9 (possibility of breakeven activity). The tasks here are to examine each bankruptcy procedure and provision to choose suitable for debtor's solvency restoration; to calculate the value of claims to cover under rehabilitation procedures; to determine potential amount due (positive cash flow) by the debtor. If this amount due exceeds calculated value of claims, the conclusion about positive opportunity of debtor's solvency restoration within terms set by Bankruptcy Law is provided. So, if analysis in block 9 and 10 had positive results, concrete rehabilitation measures should be specified, cost-benefit and potential performance analysis should be provided, certain time limits should be set.

In parallel with general basic analysis the specific transactions analysis is to be conducted. This process is also difficult to formalize because the legal provisions of each emerging economy set different meaning and grounds of transactions voidance evidences. Methodological approach considers the following elements of such analysis:

- choosing of transactions for detailed investigation by examining of contracts content in comparison with their actual performance, materials of court and other inspections; credit contracts, etc.;
- classification of received data by voidable transactions categories: interested-party transactions; significant transactions; credit contracts, pledges, surety contracts; guarantee agreements; transactions with debtor's assets; suspicious transactions made

within main debtor's business activity; suspicious transactions at bank accounts of the debtor; inconsistent salaries payments including incentive bonuses;
- transactions from this sample are classified at ones made before bankruptcy proceeding opening (not less than 3 years before) and at others made under court procedure;
- legal grounds for transactions voidance should be formed and the juridical possibility of voidance should be assessed.

In Russia, according to the Bankruptcy Law, there are three types of voidable transactions and special indicators ("red flags") should be investigated within this type of analytical activity (Table 3).

Table 3: Recognition of transactions voidance in Russia: types of deals and "red flags"

Type of voidable transaction	"Red flags"
1. transactions with unfair counter-performance	– undervaluation or overvaluation of prices of sold (purchased) goods in comparison with market level; – inherently unprofitable for the debtor terms and (or) forms of payment for sold and purchased items; – any forms of disposal or encumbrance of debtor's assets without proportional decrease in liabilities.
2. transactions intended to causing harm to creditor's interests	– unilateral transaction made by the debtor having sighs of insolvency or insufficiency of assets; – transactions with interested parties; – other conditions of transaction (assets or liabilities within transaction have value more than 20% of book value of debtor's assets; debtor changed his address in anticipation of transaction and did not inform creditors, abolished documents or damaged assets, etc.).
3. transactions giving preference to one creditor prior to others	– transaction can lead to change in priority of lien; – usually: transactions between indebted company and banks, demanding more security of pledged immovable property.

As the result calculation of losses for creditors' claims satisfaction from suspicious transactions should be provided taking into account the proportion of decrease in value or size of debtor's assets.

Conclusion

The current study has successfully confirmed hypothesis established in the introduction: distressed companies in modern emerging economies should be analyzed by applicable "market" approach while accounting ratios have certain limitations. Implementation of suggested "flexible market analysis model" based on cash flow analysis, comparative interfirm evaluation, comprehensive transactions investigation, concerning presence (absence) of company's intention to continue business activity will allow to assess possibilities of business rescue in reasonable way.

Market model of analysis will, first of all, help to shift concentration from consequences of crisis in distressed or indebted company (i.e. negative change of assets and liabilities, losses arising, etc.) to discovery of external and internal factors of unsuccessful performance, searching of conditions to recover business.

If liquidation procedures are more appropriate for a certain debtor this methodological approach to analysis would help better appraisal of debtor's assets value, the amount of bankruptcy estate.

Though suggested model was developed for Russia, it can be adjusted for other emerging economies while basic conditions are quite common.

Endnotes

[1] Opposite to Sustainable Growth Rate (SGR). Concept of SGR was originally developed by R.C. Higgins in 1977 and implies the maximum rate at which company sales can increase without depletion financial resources. (Higgins, 1977; Platt et. al, 1995; Ross et. al, 2008).

Preferred Stocks as Instrument for Sustainable Development: Valuation Aspects

Tamara V. Teplova, Higher School of Economics – National Research University, Moscow, Russia, e-mail: tteplova@hse.ru
Pavel G. Shabalin, Higher School of Economics – National Research University, Moscow, Russia, e-mail: pgshabalin@edu.hse.ru

Abstract

Preferred stocks are used both to raise funds for investment projects and lock-in control in the company. On the one hand, the founder is able to retain control in a company using preferred stocks to select better investments projects, on the other hand he is able to finance ones with newly issued preferred stocks i.e. preferred stocks should be treated as instruments for sustainable development of a company.
However, conflicts of interests may occur between common shareholders and preferred stock owners. Accurate valuation of common and preferred stock can resolve the agency conflicts, improve financial stability of a company in the market and overcome financial crisis in the business.
The paper studies the determinants of the price difference between voting common shares and nonvoting preferred shares in the four largest preferred stock markets: Brazil, Germany, Russia and South Korea. In these countries, preferred shares are treated as equity type securities and dual-class share structure with preferred shares as inferior equity class is widely used. The paper presents determinants of the dual-class premium across the markets: control contest, inferior liquidity of preferred shares, corporate governance, company ownership structure and value of shareholder voting rights provided by each stock class estimated through option prices technique.

JEL: G13, G32

Keywords: sustainable development, corporate control, preferred shares

Introduction

The concept of sustainable development requires to take into account the interests of all groups: common shareholders, debt providers and owners of hybrid securities (preferred stocks, convertible securities). Conflicts of interests may occur between common shareholders and preferred stock owners, shareholders and bondholders due to market imperfections. One of the methods to deal with agency conflicts is the valuation methodology of different financial assets of a company which can be used to improve financial stability of a company in the market and overcome financial crisis in the business. Our paper is devoted to characteristics of preferred stock market and valuation of preferred stocks as long as explaining the price difference between common and preferred shares.

The paper studies the determinants of the price difference between voting common shares and nonvoting preferred shares in four countries: Brazil, Germany, Russia and South Korea. In these countries preferred shares are treated as equity type securities and dual-class share structure with preferred shares as inferior equity class is widely used. Those markets are the largest ones of preferred stocks as equity type securities. Preferred stocks in Russia were firstly introduced in the early 1990-s after completion of privatization process. In South Korea preference shares were used by Korean conglomerates as instrument for deleveraging in 1980-s. The history of preferred stock issuances in Germany and Brazil is longer. However, in all four markets preference stocks provide similar set of rights to shareholders.

The paper presents determinants of the dual-class premium across the markets: control contest, inferior liquidity of preferred shares, corporate governance, company ownership structure and value of shareholder voting rights provided by each stock class estimated through option prices technique.

Literature Review

Private benefits of control are not attributable to minority shareholders but to the controlling ones. Meanwhile value of voting rights owned by minority shareholders is going to increase in case of control contests among management teams. In turn the lower the difference between ownership stakes of largest and second largest shareholders the higher the probability of control contest. It implies no one shareholder owns control stake in a company. It also means that each minority vote might be decisive in contest for control. Non-voting stock in such case will be irrelevant and its value will not be affected by increase in probability of control contest. Therefore observed voting premium depends both on value of private benefits of control and probability of control contests (Rydqvist (1987), Zingales (1995), Chung and Kim, (1999)). If there is a shareholder who owns control stake in a company control contests probability ceases and voting premium decreases.

Liquidity is the second determinant that explains preference stock discount. On the one hand «bid-ask» spread is treated as a proxy for asset liquidity (Amihud and Mendelson, (1986)). On the other liquidity measure based on trading volume can be used (Amihud (2002)). Both measures are widely used in empirical studies. We use relative trading volume of common and preference shares as a proxy for liquidity differences. Liquidity effect is more pronounced in some extreme cases like one in Norway where significant impact of the liquidity of certain market segment on the voting premium was observed. In Norway foreign investors could invest only in non-voting shares, therefore non-voting shares were traded at a significant premium to the voting shares (Ødegaard (2006)).

The protection of minority shareholders depends on the efficiency of corporate governance as mentioned by La Porta et al. (2000). When shareholder rights are better protected by law, minority shareholders are willing to pay a higher price for the company shares (La Porta et al. (2002)). Thus the likelihood of expropriation of non-voting minority shareholders depends on the level of corporate governance in the company. The lower the legal protection for minority shareholders, the higher the private benefits of control (Zingales, (1994), Zingales, (1995)) and vice versa (Nenova (2003)). Legal environment determines the institutional framework for all companies in a country, while level of corporate governance in certain company may vary significantly. Companies may embed special provisions in the corporate charters to protect rights of minority shareholders better. In order to evaluate level of corporate governance several proxies can be used. A corporate governance index introduced by Gompers, Ishii, Metrick (2003) includes a range of corporate governance quality variables. In this paper we estimate corporate governance quality using ADR dummy variable and free-float variable. In order to list ADR on its shares a company has to increase the level of corporate transparency in terms of information disclosure. ADR issuance can be treated as a signal to the market participants about company aims to improve quality of corporate governance as mentioned by Matos (2017). Doidge et al. (2009) proposed the higher the level of private benefits of control in a company, the lower the propensity to cross-list its shares on a foreign exchange. There is empirical evidence that cross-listing decreases voting premium (Coffee, (1999), Doidge (2004)). Free-float proxy for corporate governance was used in paper (Wang, Xu (2004)).

A higher level of ownership concentration reduces the likelihood of control contests, so the voting premium will be lower. The presence of controlling shareholder diminishes the magnitude of control contests. The type of controlling shareholder is extremely important. According to Caprio and Croci (2008) the premium will be higher, if a family owns a significant stake in a company or controlling block of shares. Maintaining control in a company for a family is more important than for other types of shareholders. A family is more prone to expropriate minority shareholders. Similar findings on the Brazilian market regarding the influence of the family on the size of the premium were derived by Saito, Di Miceli da Silveira (2010). In line with this we test the same hypothesis using dummy variable equals one if significant stake in a company is owned by a family and zero otherwise. The premium becomes lower when change of control is unexpected, that is typical for companies where

the control stake is owned by the government. Thus, we used dummy variable equals one if ownership stake of 20% or more is owned by the government and zero otherwise.

There is no clear evidence of significance and expected sign of leverage as an explanatory variable for voting premium as mentioned in paper of Barclay and Holderness, (1989). Jensen, (1986) showed on the one hand the higher degree of leverage, the more difficult access to free cash flow for managers thus there should be inverse relation between leverage and the premium. The presence of debt disciplines the managers limiting investments in bad projects. Threat of bankruptcy and obligation to repay debt force managers to adhere shareholders' interests. On the other hand effective control of management over company assets is higher with debt thus there should be direct relation between leverage and the premium (Harris, Raviv, (1988)). The disciplining role of leverage can be changed as a result of amendments of legal environment (Kang, Kim (2006)). We also incorporate in our model ROA and natural logarithm of market capitalization as a proxy of company size. These variables can explain the probability of control contests.

The difference in shareholder rights of each stock class can explain significant portion of dual-class premium. As a rule unlike common stock, preferred shares are not granted with voting rights. However preferred stock receives voting rights when dividend payments are omitted and lose it when dividend payments are resumed. Unlike previous literature we proposed a new explanatory variable of the dual-class premium - a market value of corporate voting rights attached to a common stock. The empirical estimates of the new explanatory variable were derived from option prices using put-call parity relation based on procedure proposed by Kalay et al. (2014).

We presented main papers trying to explain price difference between common and preferred shares in Brazil, Germany, South Korea and Russia in the table below.

Table 1: Key empirical research papers on preferred stock discount in Brazil, Germany, South Korea and Russia

Country	Authors	Period	Methodology	Number of companies in the sample
Brazil	Carvalhal A., Subrahmanyam A.	1994, January - 2004, December	1. event-study; 2. panel regression (GLS)	141
	Saito R., Di Miceli A.	1995-2006	1. pooled regression; 2. FE model	87
	De Souza V.F., Fernandes M.	2003, June - 2013, July	1. RE model; 2. FE model	48
Germany	Fatemi A., Krahnen P.	1990-1993	1. pooled regression	58
South Korea	Chung H. Kee, Kim Jeong-Kuk	1992-1993	1. OLS	119
	Lee I.	2000, January - 2010, November	1. OLS	113
Russia	Muravyev A.	1997-2005	1. FE model; 2. OLS	71 in FE; 99 in OLS

Source: Authors' analysis

As it's seen from the table above research methodology used in these papers based primary on panel regressions with fixed-effect estimator. It should be noted that the determinants of the price difference between common and preferred shares mentioned in the table 2 below are not sufficiently tested in Russia, Germany and Korea. Confusing results were obtained on determinants like

ownership structure, liquidity, and the proportion of voting shares in total shares outstanding. In addition, the most recent sample period is limited by 2013.

Table 2: Frequency analysis of the studies devoted to determinants of price spread between common and preferred stocks

	Total	Russia	Brazil	Germany	Korea
Overall	7	1	3	1	2
Liquidity	6	1	3	1	1
Dividends	7	2	3	1	1
Corporate governance	6	1	5	-	-
Ownership structure	12	-	8	4	-
Shareholders rights	7	3	4	-	-
Accounting measures of performance	7	-	6	-	1
Control contests	7	3	1	1	2

Source: Authors' analysis

The impact of value of shareholder voting rights on the price difference has not yet been evaluated. Thus, a new study of the determinants of the spread is required, that allows to test the significance of the determinants in key preferred stock markets in the world.

Institutional Framework

Despite the similarity of preferred stock in Brazil, Germany, Russia and South Korea there are some unique features of preferred stock in each market.

Issuance of preferred stock in Brazil were allowed in 1976. Instead of elimination of preferred shares from the market as an asset class the reform of 2001 granted preferred shareholders with higher level of protection and benefits. Today companies in Brazil have to choose one of three privileges for preferred shareholders: a minimum dividend of 3% of the book value of the share; a higher dividend rate than for ordinary shares (higher by 10%); the right to sell shares at a price of at least 80% of the price of the controlling stake in the M&A deal (tag-along right). Preferred stock holders are granted with voting rights if dividends are not payed during three consecutive years.

There are three main features of preferred stock in Germany. First preferred stock provides small advantage in terms of dividends privileges in comparison with common stock embedded in the corporate charter. For instance, according to corporate charter of BMW preferred stock dividend is assumed by 0.02 euro higher compared to common stock dividend. Corporate charter of Volkswagen provides 0,06 euro more per preferred share compared to common stock. Second dividends on preferred stock are cumulative and there is no upper bound for preferred stock dividends. And third preferred stock holders are granted with voting rights if dividends are not payed during two consecutive years. Unlike US where only common stock are listed in Germany both stock classes are listed. The maximum share of preferred stocks as a percent of total shares outstanding is 50% by law and as a rule most companies in Germany issued exactly 50% of shares outstanding as preferred shares that is higher than in US market.

In Russia, the maximum share of preferred stocks as a percent of total shares outstanding is 25% by law. The legislation provides three approaches to calculate dividends: fixed amount, as a percent of nominal value of shares, special procedure for dividends calculation. Most Russian firms approves in its corporate charters special procedure for dividend calculation that is based on 10% of net income in accordance with Russian accounting standards divided by the number of preferred shares outstanding which is 25% of shareholder capital. Another important provision embedded in corporate charter of Russian firms provides dividends for preferred stock not lower than ones on common stocks. If calculated value of preferred stock dividends is lower than one on common stock final dividend for preferred stock should be at least as high as dividend on common stock.

In South Korea, preferred stock market developed gradually. Before 1986 the national authority allowed to issue preferred stock treated as more debt than equity type security. Dividends for preferred stock was guaranteed at the level of national key rate. Preferred stock dividend was cumulative. In 1986 preferred stocks without voting rights and dividends equal to dividends for commons stock plus 1% were introduced. These types of preferred shares are called «old preferred» and most common in the market nowadays. Due to absence of other provisions apart from higher dividends to compensate lack of voting rights these preferred shares became less popular among market participant and devalued strongly. Because of that national market authority implemented amendments into corporate law in order to better protect preferred shareholders. In October 1996 after amendments were implemented into Commercial Act companies were allowed to issue new preferred stock. Minimum threshold level of dividends for such stock must be embedded into corporate charter. New preferred shares could be converted into common stock in one-to-one ratio after definite period of time. And dividends for new preferred stock were cumulative. Despite the availability of new type preferred shares for issuance in the market old type preferred are still actively traded in the market. Moreover, most of the preferred stock in Korean market are old-type preferred. The maximum share of preferred stocks as a percent of total shares outstanding is 25% by law like in Russia.

Data and Sample Description

The main source of data is Thomson Reuters and DataStream databases. We have additionally checked ownership data in ORBIS database, provided by BUREAU VAN DIJK, as well as in the CAPITAL IQ database provided by McGraw Hill Financial agency. The sample includes companies incorporated in Brazil, Germany, Russia and South Korea and issued preference shares in exchanges of the countries. As long as preferred stocks are not granted with voting rights by rule we exclude preferred shares with voting rights («Voting Rights Per Share» is set to zero). Financial companies (banks, insurance companies) were excluded from the sample. We excluded «new preferred» type shares in Korea. «New preferred» shares have cumulative dividend payments and can be automatically converted into ordinary shares after the expiration of the time specified in the company's charter. Having such provision doesn't allow to compare market price spread of these preferred shares with the spread of market values in other countries. In order to select only «old-type» preferred shares, we relied on the special designation of shares of an old type in the KRX ISIN SYSTEM. «Old-type» preferred name includes «P» symbol while «new-type» - «PB». In Brazil, several companies issued several types of common stock (for instance, «Altus Sistema»). We excluded the class of common shares without voting rights. Some brazilin firms have several classes of preferred stocks («A» and «B» classes). In such cases we included more liquid class in the sample.

In order to estimate the basic model of dual-class premium we examine more than 200 listed firms that have both common and preferred shares throughout the period from 2007 to 2017. We exclude companies with incomplete information, as well as shares that are not traded on the exchange in the period 2007-2017.

The sample consists of 213 companies from four countries: 69 in Brazil, 19 in Germany, 49 in Russia and 76 in South Korea. As it presented in the table below most of the companies that issued both common and preferred stocks operate in utilities (half of the market in Russia), consumer cyclicals and basic materials sectors. However institutional organization of national economies has a significant impact on the distribution of companies in terms of industry breakdown. Utilities preferred stocks prevail in Brazil and Russia, while there are only one company in Germany and none in South Korea in this sector. It is also should be mentioned that technology and telecommunication companies do not usually use preferred stock.

Table 3: Industry breakdown of companies with preferred stock in Brazil, Germany, South Korea and Russia

	Brazil	Germany	Russia	South Korea
Total	69	19	49	76
Healthcare	-	3	-	6
Consumer Cyclicals	17	4	3	10
Industrials	10	6	4	15
Basic Materials	14	2	6	15
Technology	-	1	-	9
Consumer Non-Cyclicals	2	2	1	17
Utilities	21	1	24	-
Energy	2	-	7	4
Telecommunications Services	3	-	4	-

Source: Thomson Reuters, Authors' estimates

The numbers of dual-class companies with preferred stock as a share of all companies in domestic market are as follows: 19% (2%, 10% and 4%, respectively. The share of companies in the sample by market capitalization: 18%, 12%, 10% and 34%.

Number of companies newly issued preferred stock by markets is presented in the table below.

Table 4: Quantity of new preferred stock issues in Brazil, Germany, and South Korea and Russia

	Brazil	Germany	Russia	South Korea	
				Old-type	New-type
Total for the period 2007-2017	7	-	33	7	8
2007	2	-	3	3	3
2008	-	-	6	-	-
2009	-	-	2	1	-
2010	-	-	3	-	1
2011	2	-	15	1	1
2012	1	-	3	-	-
2013	-	-	-	1	1
2014	-	-	1	-	-
2015	1	-	-	-	1
2016	-	-	-	-	1
2017	1	-	-	1	-

Source: Thomson Reuters, Authors' estimates

Apart from Russia newly issued preferred stocks in Brazil, Germany and Korea are rare. To explain such anomaly, we looked at the average age of companies in the sample. As shown in the table below the oldest preferred stock issuers are incorporated in Germany. It is in line with data in previous table. No one company issued preferred stock in Germany in the sample period.

Table 5: Descriptive statistics of companies age that issued preferred stock in Brazil, Germany, South Korea and Russia

	Brazil	Germany	Russia	South Korea
Average	60	107	52	47
Median	57	105	51	49
Min	11	21	9	-
Max	145	259	166	93

Research Methodology

We use panel data regression with fixed-effect estimator as main research tool. Summary of variables used in the model are presented in the table below.

Table 6: Summary of research variables, definitions, and coefficients' signs

Variable	Meaning	Description	Expected sign
DCP	Market price spread	The difference between common and preferred stock prices, divided by preferred stock price as of the last trading day in each quarter	Explanatory variable
CTRL_FIGHT	Proxy for control contests	The difference between stake of the largest and second largest shareholder as of the last day of each quarter	-
DIV	Dividend differences	The difference between dividend on preferred share and one on common share divided by the price of preferred share	-
LIQ	Liquidity differences	Natural logarithm of trading volume ratio: preferred stock volume in numerator, common one in the denominator	-
SIZE	Company size	Natural logarithm of company market capitalization	?
ROA	Assets profitability	Earnings before interest and taxes (EBIT) divided by Total Assets	?
LEVERAGE	Leverage	Total Liabilities divided by Total Assets	?
FREE_FLOAT	Share of stocks owned by market participants	Number of free-float stocks owned by market participants divided by total shares outstanding	-
ADR	Company issued ADR on its stocks	Dummy variable ADR=1, if company issued ADR on its shares, 0 otherwise	-
GOV	Company is owned by the government	Dummy variable GOV=1, if the government owns more than 20% of voting shares, 0 otherwise	-
FAM	Company is controlled by family	Dummy variable FAM=1, if family owns more than 20% of voting shares, 0 otherwise	+
VR	Value of voting rights	Value of corporate voting rights estimated based on put-call parity relation	+

We use new valuation technique to determine corporate voting rights value on the basis of synthesizing non-voting stock using put-call parity for market prices of options. We use the most liquid options on common stocks in Brazil, Germany, Russia and South Korea (sample used for option based calculations is different from the sample used in the basic model of dual-class

premium). Synthetic common stock $\hat{S}(T)$ is constructed using market values of call option c, put option p and present value for their common strike X:

$$\hat{S}(T) = c - p + PV(X) \quad (1)$$

Accordingly, the market value of corporate vote can be described as the difference between market values of common stock S and synthetic common stock $\hat{S}(T)$:

$$Vote(T) = \frac{S-\hat{S}(T)}{S} \quad (2)$$

The holder of an option on common stock can't vote on underlying unless he or she exercises the contract. As such he or she doesn't have a right to vote at a shareholder meeting. Because of that synthetic stock doesn't vote until option has expired so the difference between the values is a measure of corporate voting rights value.

In order to implement new technique in purpose of voting rights value calculation in emerging markets we need first carefully study financial contracts specifications. For instance, most of the options traded on exchanges are American but not European. Therefore, early exercise premiums EEP_{call}^{div} and EEP_{put}^{div} due to expected dividends must be considered. Accordingly, for American style options value of corporate voting rights is estimated as follows:

$$\hat{S}(T) = c - EEP_{call}^{div} - p + EEP_{put}^{div} + PV(X) + PV(Div) \quad (3)$$

It should be taken into account increasing relation between voting rights value and time to options expiration. In order to eliminate time dependence of voting rights value we annualize data. First, we obtained implied discount factor using the equation:

$$Vote = \frac{S-\hat{S}(T)}{S} = \frac{S-S*e^{-d_y T}}{S} \quad (6)$$

where $e^{-d_y T}$ – implied discount factor.

Hence:

$$d_y = -\frac{\ln(1-Vote)}{T} \quad (7)$$

And annualized voting rights value:

$$AVote = 1 - (1 - Vote)^{\frac{365}{T}} \quad (8)$$

In order to get reliable estimates, we calculate median estimates of corporate voting rights value in each country and then use given estimates as an explanatory variable for overall dual-class premium in each country for the last 30 trading days to better fit results with current market environment.

Conclusion

Preference share market provides opportunity for companies in Brazil, Germany, Russia and South Korea to raise funds in the market and lock-in control in the company as long as such instruments are not granted with voting rights. However, preference shares in the countries are quite different from ones in other stock markets.

We explained key determinants of the dual-class premium across the markets: control contest, inferior liquidity of preferred shares, corporate governance, company ownership structure and value of shareholder voting rights provided by each stock class estimated through option prices technique.

Taking into account key determinants influenced price difference between common and preferred stocks the national authorities should implement amendments to corporate law to better protect preferred shareholders using provisions and thus boost the popularity of preferred stocks among markets participants.

The Effect of Oil Taxation on Investment Activity of Companies and Economic Growth in Russia

Alla Bobyleva, Doctor of Sciences (Economics), Professor, Lomonosov Moscow State University, Moscow, Russia, E-mail: Bobyleva@spa.msu.ru

Abstract

The results of Russian public policy in oil industry taxation are examined and serious challenges are identified: although the reforms have positive macroeconomic effect on Federal Budget revenues, growth in extraction and primary distillation, some problems still require the solution – oil industry tax burden increases, results of oil extraction at fields with high capital expenditures decrease. Today the Russian Government is put in a dilemma either strengthen long-term sustainability by implementation of strategic tax maneuver – the introduction of Excess profit tax (successfully applied abroad) and create conditions for industry development or pursue a goal of short-term filling of the Budget because of difficult economic period for Russia. Strategic tasks and the main focus of further tax regime reforming for improving the sustainability of the Russian economy are emphasized in the paper.

Keywords: oil industry tax regimes, investment opportunities of oil companies, tax maneuver, excess profits tax, tax on financial result, Russia

Introduction

Oil industry is the main income-producing sector of the Russian economy. From 2006 oil & gas revenues provide about 40-50% of Russian consolidated budget (Ministry of Finance, 2016). Any changes in this industry (including taxation) may have great multiplying economic effect not only in Russia but all over the world since Russia is one of the world leaders in oil reserves, its production and export.

Nowadays the following trends in the Russian oil industry development should be emphasized:

- despite oil extraction increase, depletion of oil fields is rising;
- the quality of new geological discoveries decreases and therefore the capital intensity of the development of complex and remote fields is growing;
- export's geography is changing: there is decline of oil & gas deliveries to Europe and growth to region of Asia/Pacific;
- new entrants appear at the international market;
- many countries shift to alternative energy sources and develop energy-saving technologies;
- taking into account the dependence of Russia on equipment's import and foreign loans, current sectoral sanctions encourage delay of some investment projects' execution;
- recession in Russian economy slows down the growth of fuel and energy domestic demand and reduces investment activity within fuel and energy complex.

All these serious challenges need an adequate response. One of the main steps within solution of oil industry problems (and, hence, problems of oil-depending Russian economy) is formation of adequate tax regime, which would allow, from the one hand, to provide completion of budget and performing of social functions by the State, and to meet needs of long-term development of this leading branch of economy – from the other.

Thus, the goal of the research is an assessment of the existing oil tax regime's performance and justification of its development key indicators to improve the sustainability of the Russian economy.

Methodology

In the research we assessed the effect of tax system on Russian budget and on the investment activities of the largest Russian and foreign oil companies in 2010-2016. The selection of companies is determined by their significant role in the oil world production and export. The study period 2010-2016 is selected due to the possibility of observing the influence of dramatic changes in oil prices in 2014.

The effect of changes in oil tax revenues for the Russian budget was evaluated in Russian currency and in dollar equivalent taking into account purchasing power parity. The analysis of the dynamics of companies' tax burden was made in the following areas:

- the resulting indicators of activities (sales, assets, EBITDA);
- the tax burden by types of taxes;
- the share of taxes in revenue;
- the tax burden per barrel of oil equivalent.

The Results of Tax System Modernization during the Last Years and Perspectives for Further Reforms

Contemporary tax regulation system has been forming from the late 2002. The important part of reforms in the beginning of 21st century was the introduction of mineral extraction tax (MET) in 2002. Then taxation reforms of 2007 (Spilimbergo, 2007), 2013-2014 and many other adjustments took place. As the result, taxation system became more transparent and close to international practice, completeness of the budget has increased together with the growth of extraction and refining activities.

As far as the effect of modern tax system on oil companies is concerned, the research shows that the share of the total tax burden in the Russian companies' revenue remains high and is much more than the largest of the foreign oil companies. For example, in 2016 the maximum percentage of taxes in the revenue was observed in "Bashneft" – 60% of total revenue, the minimum - in "LUKOIL" (19% of total revenue). Among observed foreign companies the maximum share of taxes in revenue was in "EXXON" – 20%. It is also interesting to notice that in Russian oil companies a high proportion of taxes in revenue is the consequence of high "industry" taxes (MET, export duties, excise duties). In the largest foreign oil companies the share of "industry" taxes in revenue is small – about 1-2% (except EXXON where it is about 20%).

Thus, it can be concluded that the tax regulation in the Russian oil industry is still based on gross revenues from extraction, refining and export: it allows to administer taxes in relatively effective way and to fill the budget, but it neither stimulates the development of oil companies' investment potential nor provides correlation between financial results of companies and paid taxes.

Nowadays the strategic tasks of further tax regime reforming are the following:

- establishing of stable and predictable terms of taxation;
- nature rent withdrawal without sacrificing of financial sustainability and investment attractiveness of efficient companies of fuel and energy complex;
- efficient allocation of revenues generated by fuel and energy sector between the State and business (determination of optimal tax burden);
- attraction of investments to hard-to-reach reserves' extraction, exploitation of small, depleted oil and gas fields.

An important part of tax regime strategic reform in Russia can become an introduction of widely used in developed oil producing countries supplementary charges – Excess profits tax (EPT) and Tax on financial result (Alexeev & Conrad, 2009; Lvova, 2015). These taxes implementation provides tax differentiation depending on concrete oil extraction conditions, acceptable level of net revenue in case of availability of operational profit. All tax mechanisms based on such excess profits taxes has significant advantages in comparison with prevailing using of mineral extraction tax (MET): they reduce opportunities for selective approach to taxation of certain oil projects, stimulate investments to discovery new fields since the tax does not apply until the full payback of capital expenditures. This

reform can substantially bring together conditions for development of Russian and foreign companies, increase the competitiveness of Russian producers.

In 2016 the concept of Tax on financial result was developed together by Ministry of Finance and Ministry of Energy of Russia, which implies pilot adoption of this new tax in 2018. In parallel export duty will gradually decline to balance internal and external oil prices.

Nevertheless, in contemporary Russia the shift to EPT has also weaknesses and certain threats. Our SWOT-analysis (Bobyleva, 2015) evolved the following:

- complexity of establishing new system of cost control and tax administration, providing true recording of production, investment and financial measures. In Russia it is difficult to build because of practice of "creative" accounting, transfer pricing;
- many project, price and currency risks should be assumed by the State, which can lead to decrease of budget incomes.

Conclusion

Thus, the threats of dramatic tax maneuver for Russia seem quite serious. After EPT implementation budgetary revenues can diminish, in particular, because many projects of hard-to-reach reserves' extraction will be under construction in the coming years and have relatively low profitability. In a whole, systematic approach to reformation of oil industry tax regime should consider concrete stages (road map) of such tax shift to achieve balance between the society's interests and oil companies. Long term milestones and road map should exclude the possibility of frequent and random law adjustments and give oil companies and the State an opportunity to plan for a long perspective.

Currently, the process of global shocks in oil industry continues (high volatility of prices, the reduction in demand and its geographic change, sanctions against Russia). This is the reason why this research is in progress.

Russian Foreign Energy Policy within The Conditions of Credibility Gap

Igbal Guliyev, Deputy Director, International Institute of Energy Policy and Diplomacy, Moscow State Institute of International Relations (MGIMO-University), Moscow, Russia, E-mail.: guliyev@miep-mgimo.ru

Abstract

The research motivation is based on the transformation of the external energy strategy of Russia in the conditions of sanction regime. For sure these limitations approved by world leaders made swing the domestic energy policy of the Russian Federation. The special attention is paid to the current trends in the sphere of international energy relations (with emphasis on Europe). The author investigates the new goals of Russia's new energy paradigm given unfavorable external economic conjuncture. In the article special attention is also paid to the issue of political motivation of anti-Russian sanctions directed at impeding Russia's development and its Fuel & Energy Complex, in particular. Today, against the background of the current political situation, the energy strategy of Russia is exposed to adjustment. In order to develop the theme, the author specifies current tendencies, describes the action of Moscow at international energy market and as a result gives a forecast. Russia has the important task of ensuring technological independence on the energy sector on the basis of import substitution of the equipment, broad diversification of the directions of export of energy resources, preservation of leading positions in the world market of peaceful nuclear energy, stabilization of world oil prices etc. The author concludes that the external energy strategy of Russia is important part of foreign policy strategy of the country, and it is focused on practical cooperation with all countries and is aimed at protecting interests of the state.

Keywords: international relations, cooperation, energy policy, sanctions.

Introduction

Energy interests traditionally play a huge role in Russia's international policy. Relevant tendencies of foreign relations, acute contradictions between states and transnational companies as rivals at energy markets, battle for establishing total control of transit corridors – all these factors influence Russia's foreign and domestic energy policy. Given that international relations have become the zone of confrontation, with economics and energy sector being hostages of the geopolitical games. External energy ties have to be adjusted to dynamically changing rules of international cooperation. Unfortunately, the standards of peaceful world's existence are devastating including vigorous violation of international laws, evasion of Security Council resolutions etc., that are not solving interstate tensions and contradictions.

This state of affairs is not enough for the USA administration that clearly set the goal to expand its hegemony to new capacious markets. Evidently the energy EU market is a great base for that. But there is a big problem: it is occupied by energy companies of Russia. So "the winter is coming" for the whole country. The US initiated a broad campaign against Russian threat, blocked Ukraine for secure transit deliveries to Europe, implemented sanctions against Moscow, calls for blocking advantageous for the EU project Nord Stream 2. As the main partner of the USA, Europe supported anti-Russian restrictions. US/EU companies are forbidden from participating in technology-intensive Arctic deep-water, shale, and heavy oil projects. Russian companies, however, are used to relying on foreign partners and do not yet have the capabilities for solo exploration and development in deep-water. As West Siberia - the bedrock of the Russian oil industry - continues to mature, venturing into frontier projects will be essential for maintaining stable output [1]. But the American international policy is not the subject of this article. Ultimately we are interested in Russia's energy policy in the

context of above-mentioned conditions. As a result, Russia found itself between a rock and a hard place (on the one hand – sanctions, one the other hand – low oil prices), within the condition of credibility gap. Energy sector suffered the greatest losses: embargo concerns high-technology equipment, important investment programs were squeezed, joint programs of Arctic oil and gas fields' exploitation were frozen, Russian energy giants – Gazprom, Gazpromneft, Rosneft, Transneft etc. were deprived of cheap borrowings. The sanctions against Russian energy sector, and Russian counter-sanctions in 2014-2017, are listed in Table 1.

Table 1: western sanctions against Russian energy sector, and Russian counter-sanctions in 2014-2017

Year	Country	Sanctions against Russian energy sector	Russian counter-sanctions
2014	USA	*April 11* – sanctions against Crimean company "Chernomorneftegaz" *July 16* – sanctions against: Russian energy companies ("Rosneft", Russia's largest independent gas producer "Novatec") and Feodosia oil terminal; Russian banks ("Vnesheconombank", "Gasprombank") – prohibition of debt financing for more than 90 days *September 12* – restrictions on cooperation with Russian energy companies ("Gasprom Neft", "Lukoil", "Gasprom", "Surgutneftegas", "Transneft", "Rostech")	*March 28* – mirror sanctions lists against USA, EU, Canada *August 7* – one year import restriction on certain goods from countries that imposed sanctions (list included products, raw materials and food country originaing from the United States of America, European Union countries, Canada, Australia and Norway) *August 11* – restrictions on government procurement of foreign goods of light industry
	EU	*May 12* – asset freeze of 2 Crimean companies (Chernomorneftegaz and Feodosia) *August 1* – restricted access to EU capital markets for Russian state banks ("Sberbank", "VTB", "Gasprombank", "Rosselhosbank", "Vnesheconombank"); prohibition of the export from EU of goods for a number of projects in Russian oil industry (in particular, several types of pipes and drilling tools) *September 12* – the same sanctions against others Russian enegry companies ("Rosneft", "Transneft", "Gasprom Neft"); european companies are prohibited to provide Russian partners with exploration and production services of deepwater and Arctic oil, as well as for projects of shale oil *December 20* – a large expansion of the list of goods and technologies of energy sector that can't be exported to Crimea and for the use in the Crimea (oil and gas exploration and production)	
	Canada	*April 12* – sanctions against Crimean company "Chernomorneftegaz" *April 29* – sanctions against Russian banks ("Rosenergobank", "Expobank") *July 24* – sanctions against Russian energy companies (in particular, "Vnesheconombank", "Gasprombank", "Novatec") – cessation of financing to energy companies and financial institutions from "the black list"	
	Ukraine	*May 26* – general joining to the EU sanctions against Russia *August 14* – adoption of Sanctions law that permits the termination of transit of energy resources through Ukraine	
	Albania Iceland Liechtenstein Montenegro Norway	*October 15* – general joining to the EU sanctions against Russia	
	Australia	*June 19* – sanctions against several Russian companies (including "Chernomorneftegaz") *September 1* – prohibition of export of weapons and equipment for the oil and gas sector to Russia; access of Russian state banks to the Australian capital market; investments into / trade with the Crimea	

	Japan	*August 5* – sanctions against Crimean companies "Chernomorneftegaz" and "Feodosia"	
2015	USA	*July 30* – sanctions against subsidiaries of "Vnesheconombank", "Rosneft"	Mirror extension of the sanctions lists against countries that imposed sanctions to Russia *June 24* – a one-year renewal of special economic measures against the Western countries from August 6, 2015 to August 5, 2016 *July 29* – order on waste disposal of products under embargo (enterded into force August 6, 2015) Food embargo against Albania, Montenegro, Iceland, Liechtenstein and Ukraine
	EU	*March 14* – sanctions renewal against Russian companies until September 15, 2015 *June 22* – economic sanctions renewal until January 31, 2016	
	Canada	*February 18* – sanctions against Russian oil company "Rosneft" *June 29* – sanctions against "Gasprom", "Gasprom Neft", "Surgutneftegas", "Transneft"	
	Ukraine	*December 30* – import prohibition related to all the goods originating from the Russian Federation	
2016	USA	*September 1* – sanctions against subsidiaries of "Gasprom"	*June 29* – renewal of the food embargo from August 6 2016 until December 31, 2017
	EU	*July 1* – sanctions renewal against Russian companies until January 31, 2017	
	Ukraine	*July 6* – renewal of import prohibition related to all the goods originating from the Russian Federation (until December 31, 2017)	
	Montenegro Albania Norway Liechtenstein	*October 15* – general joining to the EU sanctions against Russia	
2017	USA	*January 13* – sanctions renewal for one year *June 20* – restrictions for Sergey Nazarov, Deputy Minister of economic development of the Russian Federation *August 3* – tightening of the sanctions regime against Russia; restrictions on the transfer of American technology to exploration and production of Russian oil, for deep water, Arctic offshore and shale formations (not only for companies under sanctions, but for all oil and gas projects); restrictions on the supply of technologies and services required for the construction of pipelines and on energy companies financing from USA. Persons investing in the energy sector in Russia, can also fall into the black list. U.S. policy should among other things be to oppose the construction of the pipeline "Nord stream — 2".	*June 30* – conter-sanctions renewal until December 31, 2018

The Key Development Vectors of Modern Russian Energy Policy in the Context of Western Sanctions

In this article the author used mainly sources and domestic media in Russian language (Energy strategy, Energy companies press releases, CDU TEK, Ministry of Energy of Russian Federation) with adding statistic data from official foreign Internet editions (Cambridge Econometrics) and news agencies (Reuters, Financial Times). The article highlights experts' opinions (Bloomberg and McKinsey) on the range of relevant issues.

Research question is "What are the key development vectors of modern Russian energy policy in the context of Western sanctions?" In order to answer this question (research design), the author gives good grounds for modifying old Energy strategy of Russia, specifies current tendencies, describes the action of Moscow at international energy market and as a result gives a forecast, with using the methodologies of system and analytical approach, synthesis, review, benchmarking assessment and deduction.

Although this research was carefully prepared, the author is still aware of its limitations and shortcomings. It's impossible to take into account all factors in the multiple international energy landscape. One single action or a law can change the world energy balance, so the author has to make certain assumptions based on real facts all other things constant.

Granting geopolitical background in the world, policymakers of the Russian Federation modify the National Energy Strategy, adopted in 2009. In order to optimize goods structure of exporting energy resources and to decrease dependence of the federal budget on world oil prices, Russian government implemented "tax maneuver". It really reduces oil products export duties and increases production tax [2].

Another step of domestic changes in the National Energy Strategy is the technological one. Russia places greater focus on technological independency of Fuel & Energy Complex based on import substitution of the "illicit" equipment. In theory that should reanimate the range of Russian enterprises and stimulate economic development.

Home energy policy heavily tied to its foreign component. Russia is bound to diversify export directions of energy sources, with maintaining and reinforcing energy cooperation with its traditional partner – Europe, despite current political confrontation. Energy sphere inevitably will be the center of seeking for touch points between Russia and Europe. It is notorious that the European Union plans to decrease energy dependence on Moscow through expanding its list of energy resources suppliers and transiting to Renewable Energy Sources, innovative initiatives etc.

But we are supposed to see the results of these processes on a long-term horizon. Nowadays notwithstanding the European anti-Russian rhetoric, the figures of interstate energy cooperation show sustainable growth, with Russian oil and gas companies at the top-list of biggest energy resources suppliers [3].

The Europe's dependence on foreign oil supply (mainly including Russian companies) increased from 76% in 2000 to more than 88% in 2016 and this demand is still in growth. Russia is a main Europe's supplier of oil products with more that 30% share [4]. Rosneft and Lukoil lead the list of biggest oil exporting companies.

Natural gas is also a weak point of the EU in terms of suppliers' diversity. Russia (mainly Gazprom) remains the leader of gas deliveries to the Old World; Norway takes the second place in this field. At year-end 2016 Gazprom is reported to intensify its influence on Europe natural gas market with increasing its share in import by 2,5 % to 33,5% [4]. Despite this tendency of growth Gazprom's export monopoly is considerably challenging both legally and practically by new producers, with several producers lobbying the regime for more flexibility when it comes to the issuance of export licenses.

After the project “South stream” being frozen, Gazprom was continuing to look for appropriate alternatives, one of that has become “Turk Stream” [5]. The offshore part of the pipeline will cross the Black Sea bed. Maximal depth along the route will reach 2,200 m. The length of the offshore part will amount to 910 km.

As planned, the Turk Stream pipeline will surface on the shore of the European part of Turkey near Kıyıköy with gas delivery point at Lüleburgaz for the Turkish customers, and a border crossing between Turkey and Greece in İpsala serving as delivery point for the European customers. Construction of the Turk Stream gas pipeline was commenced on May 7, 2017 in the Black Sea near the Russian coast. On June 23, 2017, the docking of the shallow and deep-water parts of the Turk Stream gas pipeline took place and the laying of the deep-water section started [6].

Another ambitious project of Gazprom - Nord Stream 2 gas pipeline (fig 2) is suggested to extend from the Russian coast of the Gulf of Finland to the German coast at Greifswald. Many analysts believe that this project has attracted undue attention, as it is merely a commercial undertaking. Moreover, Nord Stream 2 has been found by Europe’s legal services to be consistent with existing European law. Other experts continue to express concerns about the increasing of the Gazprom’s monopoly and non-fulfilment of planned diversification of the EU energy supplies and supply routes. There is a skeptical approach among European policymakers, so the project’s proponents and opponents are unlikely to agree on a joint assessment of the project any time soon.

According to the competent American edition Bloomberg, "The United States government," the last Senate anti-Russian sanction bill says, "should prioritize the export of United States energy resources in order to create American jobs, help United States allies and partners, and strengthen United States foreign policy"[7]. It seems aimed against Nord Stream 2 that proves above-mentioned suggestions about the US intention of gaining European energy market.

The key goal of Nord Stream 2 consists in bypassing unstable Ukraine from gas transit corridor. In the past the unpleasant incidents initiated by Kiev have already expose Europe to danger of being frozen. The European Union has to choose between its own energy security and both the wish to please the United States administration and support Ukrainian authorities.

Contradictory relations with Europe make Russia look for other vectors of external energy partners. In this regard Moscow is trying to become an active participant of energy space in Asia-Pacific Region that is correlating with Russia’s international economic policy. Russia possesses necessary possibilities for “east expansion” – vast territories, favorable geographic position, enormous resource potential required by neighbors, external policy based on non-interference in internal affairs of other countries. But there are some difficulties: inveterate distrust in relations, intense competition for conquering perspective Asian markets, lack of Far East region’s infrastructure development and the necessity of its correlating with regional transport arteries. For establishing conditions of intensifying export-import relations with Asian states Moscow can participate in creating trade corridors within such projects as “Eurasian initiative” and “Silk Road Economic Belt”.

Russian atomic industry maintains leadership at the world market of peaceful nuclear development. The key projects of this sector are Busher-2 in Iran, Kudankulam in India, Tianwan Atomic Power Station (APS) in China, Ruppur in Bangladesh, Paksh-2 in Hungary, Hanhikivi in Finland and Akkuyu in Turkey [8]. Moscow is interested in expanding export geography of high-tech solutions, which are able to bring not only economic dividends but political ones too. For example, an APS built by specific technology will require further maintaining by country of origin and concrete fuel for ensuring the function security. That is all can confine the possibility of sanction and other discriminating measures.

Moscow continues consistently to pave the way for maintaining the federal budget, benefiting from oil production cuts up till March 2018. The Cartel and other non-OPEC countries have vowed to rebalance the global market after the halving of oil prices since 2014 decimated the budgets of oil-

dependent producers [9].

Prior to the agreement, Russia had also reached a new post-Soviet oil peak, surpassing expectations from abroad. The ramp-up has been partly driven by development of condensate-rich gas fields in the Urengoi area. Brownfields have also experienced better decline rate management and more investment [10].

For Russia this agreement is a victory of energy diplomacy, because this means the more or less stable oil prices, consequently a ruble's solid rate of exchange and a permanent budget revenue. While the government previously admitted that it had higher hopes for the agreement, expecting oil prices to stabilize at around USD55-60/bbl., it has no regrets in backing OPEC and believes the market situation has improved. If the deal is extended, it will be hard for participating companies in Russia to withdraw. This gives them the opportunity to focus on exploration efforts and grow their resource base while the market rebalances.

Conclusion

Russia's economy has stabilized after the dramatic drop in the price of oil in 2014 and 2015, but the future of Russia's Fuel & Energy Complex, and its precise interaction with global energy actors, are hard to predict. What is clear, given the importance of energy sector to the Russian economy and given Russia's leading role on the global oil and gas landscape, is that the fate of these industries in Russia will significantly determine the country's economic trajectory. In turn, understanding Russia's oil and gas future will be essential for an understanding of broader global energy markets.

To sum up it's necessary to underline that even in the context of credibility gap Russia is ready to hold a dialogue on the energy agenda. Moscow is modifying its energy strategy to maintain and expand external markets and in the meantime the biggest country in the world is trying to modernize economics, technically re-equip its production and increase immunity to menaces and challenges.

Legal Aspects of Corporate Management within the Pre-Bankruptcy Period in the Context of Russian Bankruptcy Legislation Reforms

Elena Pirogova, Associate Professor, National Research University Higher School of Economics, Moscow, Russia, e-mail: pirogova-el@yandex.ru
Yulia Zhukova, Associate Professor, National Research University Higher School of Economics, Moscow, Russia, e-mail: julia-jukova@yandex.ru

Abstract

The present paper is aimed at identifying legal barriers to effective organization of a corporation's crisis management within pre-bankruptcy period. At the moment, there is a lack of legal regulation of interaction between corporate management bodies in case when temporary financial difficulties can be overcome due to efficient management policy. Reformation of bankruptcy legislation reflects search for the best model of distribution of rights and obligations within a corporation at the stage of bankruptcy predication. However, the conducted study shows that the proposed model is not logical enough. The analysis of the recently introduced innovations reveals that bankruptcy legislation still does not take into account the subtleties of corporate legislation and the specifics of the position of sole executive body (or the "head of the debtor" in the terminology of the Bankruptcy Act) in the corporate management system. The authors discover insufficiently clear definition of the subjects of responsibility for late submission of bankruptcy petitions. Besides the reforms leave out of account the difference in the issues of convening an extraordinary general meeting in different types of corporations. The research covers the issues of protective mechanisms encouraging a corporation's managers to adopt proactive bailout measures.

Keywords: Crisis management, bankruptcypredication, obligation to file a bankruptcy petition, bankruptcy

Introduction

Economic unsteadiness nationwide causes the increase of incidents of financial instability at the "micro level": numerous commercial entities which used to function successfully before face a crisis period. Finding themselves on the verge of bankruptcy can be typical for many companies, even if it occurs due to an unfavorable coincidence of temporary circumstances. In such cases it is a matter of vital importance not to aggravate the situation by negative consequences of corporate conflicts. In its turn, taking into consideration the specifics of bailout measures, the absence of detailed legal regulation leads to the development of individual approaches to the standards of due behavior of the members of the management bodies, in the period when they have to take risky decisions in the interests of a corporation. Meanwhile, these decisions are not always taken under the conditions of unanimous consent. In connection with this, the present study is supposed to identify the main legal barriers to the implementation of effective antirecession policy as well as outline the prospects for optimizing the regulation of actions of a corporation's managers within the pre-bankruptcy period.

Literature Review

The notion "pre-bankruptcy period" is not regarded as a full-fledged legal term, while economic content does not correspond to the content of bankruptcy signs under «The Insolvency (Bankruptcy) Act» (hereinafter - the Bankruptcy Act). The theory of crisis management distinguishes four stages of pre-bankruptcy, from emergence of financial instability to the bankruptcy itself (Zharkovskaya et

al., 2011). Unlike economic ones, legal signs of insolvency are based on the fact of the existing unpaid debt. Only the actual inability to meet creditors' claim for a certain sum within a certain period, regardless of economic reasons, is important for initiating a bankruptcy case (Art. 2 of the Bankruptcy Act).

The heterogeneity of the concept of "pre-bankruptcy period" causes the need for complex studies at the interface between economics and law, but currently it is difficult to talk about full-fledged interaction of representatives of these sciences. Studies in the field of crisis management and financial diagnostics of enterprises are very extensive. It is important to mark out the role of academic works of the following scientists: Bobyleva A. (Bobyleva et al., 2015, Bobyleva and Lvova, 2016), Lvova O. (Lvova and Bobyleva, 2014), Zaytseva O. (Zaytseva, 1998), Goncharov M. (Goncharov, 2001), Zharkovskaya E. (Zharkovskaya et al., 2011), Korotchenkov A. (Korotchenkov, 2016), Kochetkova A. (Kochetkova and Kochetkov, 2017) etc.

Yet, taking into account instability and often inconsistency of legal regulation of the period of taking bailout measures, it should be recognized that current legal studies in this field do not cover significant aspects. However, profound regulation could favor effective implementation of the achievements of scientists in the field of crisis management. Until July 2017 there had been no development of legislation regulating the activities of the debtor as well as founders, members of management bodies, creditors, etc. during pre-bankruptcy period. Accordingly, legal studies in specified this area are not numerous.

In the area of bankruptcy prevention, it is worth to mention articles by Karelina S., Professor of the Department of Entrepreneurial Law of the Moscow State University, reflected in the section References (Karelina, 2013, 2011). Besides, significant contribution was made by the researchers of Perm University, who prepared a number of articles on legal framework of bankruptcy prevention (Golubtsov et al., 2014; Zhukova and Kondratieva, 2012).

As for studies on specifics of a corporation’s management at the pre-bankruptcy stage, interaction of management bodies and correlation of corporate and bankruptcy legislation, it is necessary to emphasize the deficiency of scientific research on these issues. The matters of corporate management during the crisis period haven’t been examined in details yet. Sufficient attention is paid to the issues of liability for committing unlawful acts on the threshold of bankruptcy. However, in view of the legislation’s rapidly changing it is still impossible to assert existence of a profound theoretical foundation.

Data and Methodology

The methodology of the presented study is based on the analysis of the current provisions of Russian bankruptcy legislation in correspondence with corporate one and the results of the latest reform of bankruptcy law, which is devoted directly to rights and responsibilities of participants in corporate relations on the threshold of bankruptcy. Furthermore we have studied materials of court practice on the issues of bringing the head of the debtor to liability for failure or untimely submission of a bankruptcy application during the last 3 years in order to identify trends in the increase of cases of using subsidiary liability mechanisms for the benefit of meeting of creditors’ claims.

Research Questions

As it has been mentioned above, the pre-bankruptcy period can be conventionally divided into two stages from the legal point of view. Although at the first is the stage "economic" signs of bankruptcy already exist, there are no formal legal signs of bankruptcy, and, therefore, the grounds for the creditor's appeal to the court. At the second stage the signs of bankruptcy appear according to Article 3 of the Bankruptcy Act. The first stage falls only under partial regulation by the Bankruptcy Act and is referred to as "bankruptcy predication". The predication of bankruptcy is interpreted as the debtor’s awareness of inability to meet the obligations that will occur in the future (Telukina, 2004: 126).

Thus, the moment when it should become obvious exactly for the debtor's head is of significant importance.

The procedure of carrying out bailout measures and their composition are not duly regulated yet. The Law only indicates the possibility of taking measures aimed at restoring the debtor's solvency (Articles 30-31 of the Bankruptcy Act). In the absence of such regulation, those responsible for the corporation's sustainability have to be guided only by the general framework of current legislation. No special regime provides benefits and / or a special procedure for taking bailout measures. Adequacy of legal regulation depends on the ability to encourage managerial actions aimed at achieving financial sustainability without unreasonable risk of qualifying such actions as misbehavior.

It is worth notifying that on July 29, 2017 the Bankruptcy Act was significantly amended, and to some extent the amendments concern the complexity of a corporation's structure as well as the division of powers between its bodies. Until then, the provisions of the Bankruptcy Act focused mainly on the debtor's CEO and his |her duties in the situation of threat or real signs of insolvency, whereas proper attention was not paid to the role of other bodies. Meanwhile, other management bodies frequently consider it necessary to avoid the initiation of bankruptcy proceedings and to use all available means to improve the situation without drawing someone's attention to it.

Results and Discussion

Formally, in the presence of any of the circumstances listed in Article 9 of the Bankruptcy Act, the CEO is authorized and simultaneously obliged to file bankruptcy petition regardless of the approval of the appropriate collegial management body. This was fixed in the Decree of the Plenum of the RF Supreme Court №29 of 15/12/2004. Moreover, the CEO is obliged to apply "*in the shortest term,* but not later than in a month from the date of occurrence of relevant circumstances" (Par. 2 of Article 9 of the Bankruptcy Act).

Until 29/07/2017 a non-appeal to the court in the presence of formal grounds entailed only the chief manager's personal responsibility. Presently the composition of those responsible for initiating the bankruptcy process has been expanded. According to clause 3.1 of Article 9 of the Act, "if the debtor's head did not apply to the arbitration court with an application of the debtor within a specified period and the grounds for the appeal were not eliminated, within ten calendar days from the expiry of this term, those who are entitled to initiate the convening of an extraordinary general meeting of shareholders of the debtor, or others controlling the debtor, are obliged to demand a meeting of the debtor's management body entitled to initiate liquidation of the debtor, in order to take a decision to appeal to the arbitration court with a bankruptcy petition. The meeting must be held in no later than ten calendar days from the day the claim for its convocation is filed. This body is obliged to take a decision to appeal to the arbitration court if the relevant circumstances are not eliminated by the date of its meeting". In its turn, the Article 61.12 now provides subsidiary liability for the failure or untimely filing of the debtor's application for all those obliged to apply to the court, as well as for those responsible for convening a meeting to make a decision on filing applications of the debtor to the arbitration court, and / or adoption of this decision.

The purpose of the research is to evaluate the potential effectiveness of these innovations for the purpose of optimizing a corporation's management during the crisis period. In fact, the most valuable amendment is joint responsibility of all those who have the opportunity to influence application to a court. The introduction of joint responsibility, undoubtedly, allows to reduce risks of the actual pressure on the CEO by the shareholders and the board of directors in order to prevent the filing of an application and the transfer of all responsibility for such failure to the CEO. Nonetheless, it should be noted that "pitfalls" still remain, so further attention will be focused on them.

The Scope of Obligated Persons

First of all, the introduced rule does not clarify the composition of those who are obligated to convene a general meeting. Those entitled to claim for convocation of an extraordinary general meeting, for example, under the Law "On Joint-Stock Companies", include a revision committee, an auditor, and shareholders possessing at least 10% of voting shares. At the very least, they should be somehow informed about the transformation of their right to claim for convocation of a general meeting into an obligation. How are they offered to learn about the circumstances referred to in Article 9 of the Act, and, moreover - about the expiry of the term of the sole executive body's obligation to apply to the court? It seems that the Bankruptcy Act in the present edition does not distinguish the body responsible for holding a general meeting, including an extraordinary one, and those entitled to apply to this body for convocation of an extraordinary general meeting. Furthermore, the Law "On Joint-Stock Companies" claims that in case when the relevant body fails to meet the requirements for convening a general meeting, those who require its convocation have the right to apply to the court with a claim for compulsory conduct of the meeting. The Bankruptcy Act does not specify whether this right transforms into obligation, and whether the 10-day period is relevant in this case. It would be more logical to point out the obligation of the relevant body to initiate an extraordinary meeting.

Thus, in a corporation where the presence of the board of directors is mandatory (i.e. public joint stock company), those responsible for non-convening or untimely convening of an extraordinary general meeting must be members of the board of directors. In the event that the decision is not adopted at the convened general meeting, according to the logic of the Act, responsibility must be born by shareholders. Speaking about a limited liability company, where, as a general rule, it is the sole executive body that is responsible for convening a general meeting, the obligation in case of violation of his own duty to file an application becomes pointless because of the coincidence of the obligated individuals in one person. Yet, if the meeting has been convened, for instance, at the request of another authorized person, but shareholders have not taken a positive decision, then, respectively, the liability extends to them.

Moment of Creation of Obligation to File a Bankruptcy Petition

A number of controversial issues is connected with the definition of the moment of "activation" of the authorized body's obligation to convene an extraordinary general meeting. The expiry date of the term of filing a petition by the CEO which is the beginning of a 10 day period for convening an extraordinary meeting, appears to be clearly undetermined. One of the reasons for this is the uncertainty of occurrence of the initial CEO's obligation to apply to the court.

It is significant to underline the unambiguity of the date of creation of the circumstances specified in Article 9 of the Bankruptcy Act, or the date when they should become obvious to the chief manager. Meanwhile, subsequent qualification of the CEO's conduct as illegal depends on the definition of this moment. The courts consider this moment as the date of summing up the results of financial and economic activities during the calendar year, or the date of the formation of the balance sheet. In addition, creditors or insolvency officers refer to the date of the court decision to collect the debt, or the date of bringing to the tax liability, in short, the dates to which the company's obligation to pay off the debts with a particular creditor is related to. Yet, the moment of creation of the obligation is not identical with the moment of acknowledgement of impossibility to execute it.

So according to the Bankruptcy Act there is no time for the sole executive body to coordinate filing of an application with other management bodies of the corporation. Any initiatives resulting into loosing of time are more likely to lead to CEO's further possible personal responsibility in the event of insufficiency of assets. Court decisions usually contain statement that the debtor's head, having been informed about the company's financial condition, could not fail to realize the need to apply to the court ('Consultant Plus', 2017). The fact of shareholders' pressure is not of legal significance. The absence of the collegial body's consent, or even the need to raise this issue and get approval are unacceptable excuses for CEO's omission.

Interlacing the corporate bodies' competences when deciding whether to file a bankruptcy petition

It appears that the legislator adheres to a somewhat contradictory logic, pointing out that the decision of a corporation's supreme management body is mandatory only in case when the sole executive body has not applied to court on his own initiative. The secondary nature of the general meeting's decision and the absence of its necessity in case of a sole decision taken by the CEO, do not fully coincide with the basic rules of corporate law, which provide for a strict separation of bodies' competence and accountability to each other. Current civil and corporate law do not stipulate cases of alternative competence of the shareholders' general meeting and the sole executive body. The issue still requires clarity whether a decision by the supreme management body is necessary or not. And in case it is necessary, it would be reasonable to begin the initiation of the bankruptcy process with the convocation of an extraordinary meeting. This sequence of order seems to be much more logical, not only in the view of correlation with the basic rules of building a management system in a corporation, but also in terms of distribution of responsibility. It is impossible to exclude the situation of putting pressure on the chief manager during the period when the latter is already legally required to apply to the court. At the same time the board of directors or shareholders may be planning to take rehabilitation measures, such as profitable bargains, negotiations with the creditor on debt restructuring, etc. As a result, the chief executive officer will still be responsible if the bankruptcy petition is filed by the creditor, since the first person who has an obligation and courts assume the CEO's initial knowledge of the company's financial condition. Besides, the sole executive body in the joint-stock company is not authorized to claim for a convocation of an extraordinary general meeting. Joint responsibility may not occur, considering the indistinctness of the moment of time when the obligation to convene an extraordinary meeting for those who are entitled to this arises. Also, members of the board of directors can formally fulfill their obligation to hold the meeting after gaining time, and, thus, relieve themselves of liability. It is also possible that the obligation to convene the meeting is fulfilled, but the required quorum simply is not gathered, with all the ensuing consequences provided for by corporate legislation. In all these cases the head of the debtor remains the only liable person.

Current legislation does not stipulate any protective mechanisms for the head of the debtor against actual pressure put by controlling shareholders, which is still a gap. It is unlikely for the CEO to take such a radical decision on behalf of the corporation regardless of the opinion of the shareholders' opinion in standard business practice. A voluntary appeal to the court does not always lead to bankruptcy, and in this case the CEO is likely to lose his / her position. Moreover, Par. 2 of Article 61.13 claims that "if the debtor's application is submitted in case of the debtor's ability to meet the creditors' claims in full, or the debtor has not taken measures to dispute the applicant's unreasonable claims or claims made by creditors in the bankruptcy case, the debtor, the debtor's head and other individuals controlling the debtor shall be liable to creditors for damages caused by committing bankruptcy proceedings or unreasonable recognition (undisputable) of creditors' claims".

Thus, at the crucial moment the head of the debtor carries both the risk of failing the company, having hurried up with the application (and, therefore, most likely, losing the position), and the risk of being brought to further liability for a possible revealed failure to fulfill the obligation of applying to court. The CEO has "shortest time" to resolve this dilemma. Under such circumstances, especially in the context of a corporate conflict, it is not surprising that the CEO's decision may turn out to be unreasonable, according to the terminology of Article 53.1 of the Civil Code of the Russian Federation, Article 71 of the Federal Law On Joint Stock Companies, the Decree of the Supreme Arbitration Court of the Russian Federation №. 62. There is no need to establish the CEO's unconscionability for qualification his / her behavior as unlawful in order to demand compensation for the company's losses caused by such a decision, or to bring him / her to subsidiary responsibility in case of bankruptcy. Unreasonableness of his / her actions is enough.

The designated risk generates the risk of mismatch of management bodies' actions in the period of bankruptcy predication. The current Bankruptcy Act does not take into account the specifics of the debtor's head's position in the corporate management system and lack of his | her competence for making some strategic decisions. Despite the amendments, the Act still requires to take corporate decisions separately, regardless of the position of other management bodies, which potentially

reduces the effectiveness of crisis management at the corporate level.

Furthermore, in accordance with the new edition of paragraph 1 of Article 30 the debtor's head as well is obliged "to take all reasonable measures to prevent the bankruptcy of the debtor in reasonable time". It seems to be illogical that this responsibility falls solely on the CEO if speaking about a corporation. The CEO's obligation to notify other bodies and shareholders has been excluded, while the obligation to immediately publish information and whereas the obligation to solely take urgent bailout measures has been enrolled. These amendments seem to be, at least, rather controversial.

Conclusions

It is supposed that, in order to optimize the interaction of a corporation's management bodies for sorting out anti-crisis issues, it is necessary to consolidate the obligation of the head to send firstly an official notification both to the members of the board of directors, if any, and to the shareholders. Perhaps, this action should be bound to the moment when the debtor obtains the right (but yet not the obligation) to file a petition. Meanwhile, considering the terms of corporate procedures, it is not entirely fair to limit the CEO's obligation by "the shortest period". If the Act establishes the possibility of taking measures to restore the corporation's solvency, there is a certain need to provide a time space within which non-appeal to court with a petition will not be qualified as unlawful omission.

The decision to apply to court with a bankruptcy petition is proposed to be made initially at the level of the supreme corporate management body. Therefore, in case of a complex corporate structure of the company, the members of the board of directors should be primarily responsible for ensuring the timely decision. It is rational to establish the CEO's obligation to officially inform the body responsible for convening a general meeting and, accordingly, to impose subsidiary liability only in the event of its non-performance. We believe that the one-month period, currently provided for to the head of the debtor to file the application could be sufficient to convene a general meeting. In accordance with the decision of this meeting the chief manager must apply to court. The requirement to convene a general meeting just after the head of the debtor misses the time term for applying to court is undoubtedly illogical, since it can be convened immediately after revealing of relevant circumstances, without violating the corporate subordination of the supreme management body and the chief executive officer.

Considering that the bailout measures are not regulated either, and these measures are implemented outside of judicial control, taking most of these measures is always followed by risk of further liability. In this connection, amendments to the Bankruptcy Act providing the obligation to take measures solely for the chief manager are not completely constructive. The obligation to act in the corporation's favor reasonably and in good faith, and therefore - to care for its financial stability, is assigned to all members of management bodies, regardless of the pre-bankruptcy period. The imposition of additional obligations requires their detailed specification, as well as giving legal significance to actions taken to fulfill this particular obligation, in order to avoid mentioned risks. Additional regulation is needed for a corporation's management at each stage of the pre-bankruptcy period. The importance of legal tools for optimizing crisis management should not be underestimated, since gaps and contradictions in the legal regulation of activities within the pre-bankruptcy period give rise to vulnerability of key participants of the crisis management process and the potential threat of the invalidity of their activities.

Mitigating Energy Poverty at Emerging Markets: Review of Policies and Institutional Frameworks

Igbal Guliyev, Deputy Director, International Institute of Energy Policy and Diplomacy, Moscow State Institute of International Relations (MGIMO-University), Moscow, Russia, e-mail: guliyev@miep-mgimo.ru

Igor Litvinyuk, Senior Analyst, Centre for Strategic Research and Geopolitics in Energy, International Institute of Energy Policy and Diplomacy, Moscow State Institute of International Relations (MGIMO-University), Moscow, Russia, e-mail: litvinyuk@miep-mgimo.ru

Abstract

This study examines institutional arrangements that are deemed necessary for planning, coordinating and implementing energy access policies and programs for emerging markets and developing economies. The article discusses modalities for energy access partnerships, and reviews various strategies to mobilize financial resources to bridge the energy access gap, based on the examples from several developing economies.
With expanding policy dialogue, knowledge sharing, relevant partners' engagement and financial resources mobilization being considered as prerequisites to ensure universal energy access, a sector-wide development approach to energy access is proposed as key element for longstanding and substantial engagement of governmental agencies and development donors. In conclusion, the authors come up with recommendations for future financing mechanisms, and discuss the role of Sustainable Development Goals as the opportunity to increase the level of technical, financial and human resources, and achieve one of its targets – universal access to modern energy services.

Keywords: energy access financing, institutional framework, international energy cooperation, sustainable development

Introduction

Sound institutional frameworks and timely, effective intergovernmental coordination are prerequisites for channeling donor funding, planning development strategies and cooperating on cross-border power trade, as well as regulating efforts towards long-term sustainable development through competent and responsive national institution, accountable for delivering results in terms of reliability, quality and timeliness. These criteria are interrelated and depend on governmental actions and policies. For instance, reliability and quality depend on actions taken to augment capacities of grid operator, potential mini-grid operators and household system installers. Reliability and quality of service provided by grid also depend on actions taken to add and maintain adequate generation capacity and maintain network.

To satisfy country-specific development priorities, national governments should effectively manage funds and resources for targeting national development goals. Prioritization and regional initiatives could resolve competition between sectors for limited public funding. A positive and open environment for dialogue and cooperation with development partner community to finance national electrification programs, as well as knowledge exchange to help governments carry out sector reforms will strengthen institutions and improve sector performance and efficiency.

Strengthening institutional capacity involves:

- Reviewing the mandates of relevant government sectors to identify their constraints, as well as technical and financial capacities;

- Streamlining the government sectors to promote cooperation and coordination;
- Promoting collaboration between governments in planning and implementing;
- Ensuring appropriate legislative frameworks;
- Establishing appropriate regulatory framework; developing legal and institutional framework; and
- Formulating policy frameworks.

Literature Review

Engaging relevant stakeholders to build partnerships is critical, as suggested by various assessments by international organizations and development agencies, – as there are multiple roles to play and each stakeholder must be responsible for the tasks for which they have a comparative advantage. Existence of different stakeholders with clear roles and mechanisms for interaction and coordination across the value chain is key factor in building partnerships. It has been repeatedly underscored that leveraging business as much as possible to increase energy access (EA) should be a priority, as this allows it to be directed towards reaching the "last mile".

Stakeholders' Engagement

Governments play a central role in planning, regulating, measuring, policymaking and implementation, but the private sector or public institutions also balance the costs and revenues at affordable levels and ensure long-term operation of systems. For example, ESCOs in Fiji are allowed to adjust tariffs to ensure that reliable performance is viable on a site-by-site basis and to ensure that adequate financial incentives are in place for expansion of supply in rural areas.

Participation of local communities, investors and consumers in design and delivery of energy services is essential. A success factor identified in the Vietnamese rural electrification effort has been the building of effective partnerships among the state utility, local authorities and communities, specifically through sharing of costs and responsibilities. In some cases, introduction of new actors or networks such as cooperatives and associations further intensifies cooperation and initiates coherence with the larger community in the area. Building partnerships with communities ensures provision of appropriate energy services, promotes community ownership and responsibility, increases contributions of labor, time and other resources, and encourages participation in decision-making, planning and implementation. It is also critical for daily operation and maintenance. Engaging local stakeholders can make it possible to reach poor, difficult-to-reach communities with modern energy and offer opportunities for scale-up. A growing number of entrepreneurs are demonstrating – often at a relatively small but rising scale – that profitable ventures can be built in low-income markets. Local small and medium-sized enterprises (SMEs), social enterprises, non-governmental organizations (NGOs) and conglomerates are succeeding in selling modern lighting and cooking devices, off-grid electrification and, to a smaller degree, grid extension services to the poor.

Institutional development of Alternative Energy Promotion Centre (AEPC), established in Nepal in 1996 with the objective of developing and promoting renewable/alternative energy technologies, may illustrate this. Working with external development partners and domestic stakeholders, AEPC has emerged as capable and strong governmental institution for rural energy development. Initially, AEPC worked with donors on institutional development and programme implementation. The Energy Sector Assistance Programme, funded by the Danish and Norwegian governments, the Rural Energy Development Programme, funded through UNDP and the World Bank, and the Renewable Energy Programme, funded by the European Union, built up the institutional capacity of AEPC to manage sizable energy programs. After implementation of a few projects, the Government of Nepal and development partners entrusted AEPC to manage the National Rural and Renewable Energy Programme, a $170 million multi-donor-funded programme for promotion and expansion of rural energy services in remote areas.

Nowadays, AEPC supports project developers (communities, households, manufacturers, installers and distributors) in preparing bankable projects. AEPC has succeeded in establishing the Central

Rural Energy Fund as a financial institution to select banks to administer subsidies and facilitate soft credit to developers for rural and renewable energy promotion. AEPC pre-selects subsidy applications and is responsible for technical verification before submitting to the handling bank for financial verification and payment in accordance with the government's Subsidy Policy and Delivery Mechanism. Currently, AEPC is working to develop its development plan to respond to increasing demand for expanding energy services.

AEPC has earned recognition as an apex body for renewable energy technologies promotion. As a result of AEPC's efforts, nearly 3.5 million households in Nepal have benefited from various kinds of energy technologies: it has contributed to around 30MW of electricity generation through micro-hydro systems, and installation of 700,000 solar home systems and 350,000 biogas systems. Moreover, these programs have been successfully registered as Clean Development Mechanism (CDM) projects that generate revenues from carbon trading. At a broader level, Nepal has developed good policy and institutional frameworks, introducing the Rural Energy Policy 2006, Renewable Energy Subsidy Policy 2013 and Renewable Energy Subsidy Delivery Mechanism 2013, which describe technical standards for various technologies. The Government of Nepal is prioritizing renewable energy sector and attracting more external development partners to scale up renewable energy technologies in various locations.

Strategies to Mobilize Financing

Due to high initial investments and low returns associated with EA investments, governments have either directly financed EA efforts or used regulatory instruments and incentive frameworks to encourage EA investments by energy utilities. International development agencies, as well as philanthropic and impact financing, have all contributed in varying degrees to increasing EA.

Government resources, even augmented by loans, carbon finance and development assistance, will not be enough to provide such high levels of investment and there is a role for private finance to play. To engage the private sector, countries need:

- Strong financing institutions and ecosystems that can develop and implement EA projects;
- National finance architecture, consisting of national development banks, commercial banks, capital markets and structures to lower the risks of investments; and
- Progressive policy and regulatory frameworks that encourage private sector participation and investment.

The role of the private sector in EA has been generally limited to electricity generation through independent power producers or as equipment manufacturers and suppliers. The sector has been less involved in transmission and distribution verticals of electricity sector, yet being useful in making distribution infrastructure investments in areas with high concentrations of consumers, where the return on investments is likely to be better. This is challenging, however, for electrifying peri-urban and rural locations, where the concentration of households and commercial/industrial consumers is likely to be lower, and electricity demand levels are low, leading to low return on investment prospects and discouraged participation of the private sector. The government's role is to provide incentive frameworks, such as performance-based subsidies that encourage private sector electricity distribution companies to invest in electricity distribution infrastructure to provide EA to that segment of customers for which there is no clear business case.

Existing Mechanisms for Public Sector Financing

The major initiatives in EA have been supported through public finance from governments, often targeted at large-scale electrification and transition to LPG. Governments have historically used their budgets to support rural electrification, but progress has been slow. Public finance through government budgets is often the only financing option available for EA. The experiences in China and Indonesia, for example, show that EA can be achieved using a mission mode supported by public finance at scale. However, public finance may not be sufficient for addressing the EA challenge.

Domestic borrowing has played an important role in the energy sector; infrastructure bonds issued by governments and public bonds issued by institutions such as the Renewable Energy Certificate (REC) in India have been used to finance rural electrification. These bonds often have a long tenure and low returns but also low risks. Some of the bonds were tax-free. Such incentives have resulted in high investment interest – the 20-year $100 million bond with a return of 7%, issued by REC in 2015, was oversubscribed by 400%. However, domestic borrowing to finance EA has been limited to countries where bond markets and regulatory frameworks are established.

External borrowing from development agencies offering concessional and large-scale financing has been one of the key financing sources for EA. Multilateral financial institutions have been major financiers for EA. In least-developed countries (LDCs) and Small Island developing states (SIDS) in particular, where availability of local finance is limited and of low creditworthiness, special funds provide long-term, low-interest finance. Bilateral development agencies also provide financial resources but are often conditional, with the source of equipment and services limited to country providing external finance.

Development assistance initiatives through multilateral development agencies, bilateral development agencies, NGOs, etc. has also supported EA in the form of grants and technical assistance. Some of the development assistance focuses on policy and capacity-building aspects that enable environment for promoting EA and build human and institutional capacity. Others support projects and programs through which electrical or thermal EA was provided to communities. For example, Global Environmental Facility (GEF) has financed the incremental costs (additional costs for pursuing a low-carbon EA technology or approach compared to the baseline business-as-usual approach) for a number of EA projects that supported renewable energy-based EA. Also, Climate Investment Fund finances low-carbon development and climate change adaptation initiatives, offering resources to support renewable energy-based EA projects. In particular, the Scaling up Renewable Energy Programme (SREP) currently supports renewable energy investments in countries such as Maldives, Nepal, Solomon Islands and Vanuatu in the Asia-Pacific region, with plans to support other low-income countries. However, due to limited availability of resources, development projects and programs have mostly concentrated on piloting and demonstrating specific technologies, models and approaches.

Climate finance has played a significant role in supporting EA initiatives through renewable energy development. Through CDM, many countries received revenue from Certified Emission Reductions (CERs) to improve financial viability of a number of EA projects before 2012, the final year of the first commitment period of Kyoto Protocol. The Programme of Activities was instrumental in bundling small projects together to obtain financing from sale of CERs. A voluntary carbon finance market exists to offset emission reductions at institutional and individual levels through Verified Emission Reductions (VERs); however, the combined demand for CERs and VERs is currently at a low level, which limits the ability of carbon market to influence EA efforts.

Existing Mechanisms for Private Sector Financing

The private sector role has been limited primarily to manufacture and supply of systems and equipment for energy services. However, a number of initiatives have encouraged the sector to go beyond this role. Governments and development agencies have employed a number of mechanisms to attract private finance for EA, such as subsidies, tax incentives, soft loans, guarantees, etc.

Yet it is stated that more than four-fold increase from the current annual investments in EA will be needed to achieve universal EA targets under Sustainable Development Goal 7, which would require major changes in current finance architecture. The emphasis of EA financing so far has been primarily on electrification and not enough investments are being made in non-solid fuel access for thermal energy use, and progress on this has lagged behind. The level of investment in EA to non-solid fuel remains the biggest financing challenge, as this investment needs to increase by a factor of 44. A major bottleneck for financing non-solid fuel is that the current business models and financing

mostly focus on supporting cooking and space heating devices at a smaller scale than large-scale service or fuel sales-based models.

A number of developing countries have low credit ratings, limiting the ability of their governments to raise resources that are low-cost and long-term, which affects investments available for EA. Absence of local finance ecosystem that includes microfinance institutions, rural and agricultural development banks, and local debt and equity markets, constrains the ability of both public and private sectors to raise local finance for infrastructure investments. Both are particularly challenging for SIDS and LDCs.

The role of private sector and the leverage of private finance for EA investments have been limited. The private sector and public-private partnerships (PPPs) have been leveraged in electricity generation as independent power producers (IPPs) but not significantly in electrification and non-solid fuel access. Capability for developing and structuring EA projects that can attract direct private finance or PPPs will be important to reach financial resource mobilization requirements to achieve universal EA. While a number of innovations have been attempted to engage private sector investments in EA, these haven't been scaled up or replicated to significant levels.

A number of lessons may be observed from existing experience in financing EA. Domestic public finance and government subsidies are the major sources of EA finance investments in the region, followed by external borrowing assistance from MDBs, development assistance and climate finance. Public finance through subsidies and grants is limited by government budgets and not sustainable in the long term. External financial sources such as loans, development aid and climate finance have played an important role in demonstrating technologies and business and financial models and in providing policy support.

Given wide range of government and public sector capabilities, local financial institutions, private sector capabilities and local finance ecosystems, the type of resource mobilization models required in countries is likely to vary. The role of private sector needs to increase significantly; however, low returns from such investments and absence of a progressive policy and incentive framework have constrained the role played by private sector. Its participation and finance in EA can be increased through lowering risks for these investments and improving financial returns and capital recovery. Risk transfer instruments such as guarantee funds, as well as mechanisms such as incentives, soft loans, etc. to improve the investment prospects have been used and hold promise. Under the right conditions, PPPs could play an increased and highly significant role in enhancing EA. There appears to be a need to look beyond existing structures, business models and financing mechanisms to scale up finance for achieving universal EA by 2030. Alternative and innovative financing mechanisms may offer possibilities.

Alternative and Innovative Financing Mechanisms

A number of alternative and innovative approaches are being tried out to finance and implement EA initiatives, some of which may offer potential for application to scale up EA finance. Some of these are discussed below.

Crowd funding

Crowdfunding uses contributions from a large number of people. It has been in existence for a considerable period of time, but in the past few years, Internet platforms have been used to expand reach, increase transparency and reduce transaction costs. Depending on project details and finance demand, investors commit to providing equity or loans. When the financing target is met, the funds are made available to the promoter for the project to be implemented. Upon successful completion of the project or initiative, the promoter pays returns to the equity investors or pays back the loans with interest. It is estimated that the volume of global crowdfunding in 2015 was $16 billion, of which the share for renewable energy was $170 million, supporting more than 300 projects.

Increasingly, crowdfunding platforms are also supporting clean energy and EA issues. Many of such platforms are based in Europe and the United States, such as Trillion Fund, Abundance, Village Power, Solar Schools, etc., which mainly fund energy projects in the countries where they are located. However, there are sites like SunFunder, which focus on off-grid solar for renewable energy and have raised $7 million of investment in 58 loans supporting 368,000 people. The $700 million invested in Kiva microloans, which support microloans in developing countries, also offers green loans that include solar lighting and home systems and clean cook stoves. The financial regulatory frameworks for crowdfunding are emerging.

While the crowdfunding platforms are growing as an alternative means of finance for projects and initiatives, which may not be supported by commercial banks, crowdfunding share of EA projects so far has been quite small. However, crowdfunding of EA projects and initiatives could be a significant prospect for the future. Small-scale financiers could use such platforms to support EA projects in their countries. Private sector entrepreneurs and public sector agencies will determine the role of crowdfunding and, if integrated into policy and institutional frameworks for EA, crowdfunding could provide significant supplementary resources to support universal EA.

Carbon finance

Carbon finance in the form of CER and VER revenues did support a number of EA projects. But given the current low demand and low price scenario after 2012, few projects are being supported by carbon finance. The outlook for carbon markets is unclear, although the Paris Agreement has established a new market-based mechanism that will come into effect after 2020. This new mechanism may create demand for Internationally Transferred Mitigation Outcomes. The impact of the proposed mechanism will depend on demand and rules that will be developed but, in the short term, voluntary carbon market for VERs may provide some limited finance for EA projects.

Paris Agreement aims at limiting increase of global average temperature to well below 2°C above pre-industrial levels. It is committed to mobilizing $100 billion/year to support climate change mitigation and adaptation in developing countries by 2020, with a bigger resource mobilization goal by 2025. Carbon finance has already mobilized over $10.5 billion for strategic priority areas including energy. The funding can be accessed by organizations through a “direct access” route and by private sector through Private Sector Facility. It also uses a range of financial instruments – grants, loans, equity and guarantees – to support climate change projects in developing countries. Electricity access and non-solid fuel access initiatives using renewable energy and low-carbon energy sources such as LPG have the potential to benefit at scale. The emergence of carbon finance could be of importance to LDCs and SIDS, as there will not be a cap on resources that are allocated to smaller countries. However, accessing large-scale resources for EA will require mobilization of strong national institutions including private sector and ability to structure and develop a pipeline of projects.

Green Bonds

Green bonds are debt instruments for raising financial resources from the markets for “green” projects. Bonds have traditionally been used by both public and private entities to finance infrastructure projects, including EA projects. Green bonds constitute a new global effort to establish a labeling system by a number of organizations such as Climate Bonds Standard and Ceres Green Bond Principles, as well as national regulators such as China Central Bank’s green bond guidelines. It is estimated that only 11% of bonds that could be classified as “green” are actually labeled and the major locations where bonds are green-labeled are in Europe and North America. Multilateral development banks have issued green bonds, as have private companies, commercial banks and municipalities.

Green bonds represent a small segment of global bond market: “green” projects being supported by proceeds of green bonds totaling $65.9 billion include energy, buildings and industry, transport, water and waste management. However, there are no obvious financial advantages to be gained by

labeling a bond "green," although it may attract environmentally conscious investors. Existing green bonds targeting renewable energy investments are consistent with the global trend. It is possible that proceeds of green bonds issued by World Bank, ADB, KfW, etc. are supporting EA projects. Indeed, it is possible to label local currency and foreign currency-denominated bonds that target renewable energy-based EA projects as green bonds. If such green bonds result in additional foreign or local currency resources and increase the scale of resources mobilized, they could augment the financial resources needed for universal EA. Green bonds are more relevant in countries that are creditworthy and have strong financial ecosystem and are more challenging in LDCs and SIDS, although it is possible for bilateral development agencies to use green bonds from the European and North American markets to support EA projects in Asia-Pacific's LDCs and SIDS. A similar approach is applicable to bilateral development agencies from countries such as Australia, Japan and Korea, which may use domestic or internationally issued green bonds to support EA investments in other countries including LDCs and SIDS.

Another mechanism to finance and implement EA initiatives is Pro-Poor Public-Private Partnership (5P) Model approach, championed by Economic and Social Commission for Asia and the Pacific (ESCAP). It is an innovative approach for widening access to energy services for rural development. Drawing on the logic of traditional PPPs, the 5P approach aims at mobilizing private sector financing to develop rural energy utilities that are technically sustainable and ultimately financially self-sustaining. In this regard, 5P lies between profit-oriented PPPs and socially oriented grant-based projects. The 5P model differs from a traditional public-private partnership in three ways:

1. It is participatory and involves a broad number of stakeholders;
2. While profit is not disregarded, the core of the 5P approach is rural development through livelihood enhancement of the rural poor;
3. 5P is inherently cooperative rather than competitive.

Rural communities are not viewed solely as consumers of energy utility, but also as partners, through utility co-ownership and management. These partnerships are characterized by sharing investment, responsibilities, risks and rewards among partners. The role of the public sector is to facilitate these partnerships through enabling policy frameworks.

However, rural energy projects are still perceived as high-risk investments, typically with high up-front costs and low rates of return. To diminish the perceived risks in rural energy, 5P attempts to redefine the roles of energy project stakeholders, focusing on community participation and management, ownership and enterprise development. Beyond the private sector, community mobilizers, NGOs and civil society, among others, can be engaged to assist the project stakeholders in understanding the potential income-generating activities gained from productive energy use and to support livelihood development and sustainability of the energy utility.

Community-based management of rural energy utilities is not a novel concept. However, lack of appropriate training for operation and maintenance, along with minimal monitoring, has often led to long-term equipment failure, particularly in micro-hydro plants. The risk of long-term utility failure creates a large disincentive for rural energy investment. The 5P approach attempts to alleviate this risk, by engaging the private sector beyond the role of investor, as a key stakeholder in the project. A private sector stakeholder has incentive to ensure the long-term operation of the energy utility in order not to jeopardize the potential revenue generated.

Discussion

In most countries public finance alone would be insufficient to achieve universal EA by 2030, as required by SDG 7, and there is a need to leverage private finance using appropriate structures including PPPs. Governments need to establish progressive policy and regulatory frameworks to engage private sector and international finance and raise the level of resources in order to achieve the target. Integration of SDG 7 and use of Sustainable Energy for All (SE4All) tools could enable governments to attract development finance to support national plans in EA.

There is a need to improve governance, regulation and management of the electricity sector in order to increase the level of financing available to achieve universal EA by 2030. Investments in expanding existing electrical grids will likely involve governments and energy utilities playing a central role. Providing electricity access to meet Tier 1 of the Multi-Tier Framework requirements of 12Wh/day may only require relatively low levels of resources providing electricity access; however, Tier 2 requirements of 200Wh/day and higher would require much higher levels of resources. A critical factor in the financing of grid-based electrification would be the creditworthiness of the electric utilities. Many of the electricity utilities, which are often vertically integrated, are financially and operationally inefficient. Many utilities operate like government departments, often at a loss or with low return on their investments owing to low levels of bill collection and high levels of losses. The high levels of losses for utilities result from a combination of technical losses due to poor quality equipment and unchecked pilferage and theft of electricity at the distribution network level. Another reason for operational losses for energy utilities is that electricity tariffs do not reflect the cost of supply and investments. In order to ensure that electricity tariffs are cost-reflective, electric utilities are financially sustainable and the interests of all other stakeholders are balanced, there must also be an independent electricity regulator. Adequate capacity of government and regulatory agencies is important to ensure that policy and regulatory frameworks ensure financial viability of electricity utilities, thereby enhancing the creditworthiness of the utilities and associated stakeholders.

More effort is needed to develop business models and financing structures for a transition to non-solid fuels for thermal energy. The financing challenge is likely to be significant in this effort due to limited government policies and the absence of models and track records in this area.

Conclusion

SDGs provide a significant opportunity to increase the level of technical, financial and human resources for achieving EA, as well as an opportunity for development assistance agencies to increase their investments in EA projects. It is therefore important to put policies in place that ensure national efforts towards EA by governments and private sector are aligned with SDGs, and try to leverage development assistance. This is particularly relevant for LDCs and SIDS. Countries may also utilize various tools available under the SE4All framework, such as Rapid Assessment and Gap Analysis, development of country action agendas and development of investment proposals. Preparations using the SE4All tools could help countries take advantage of international and development assistance to achieve universal EA.

SDG 7 also calls for enhanced international cooperation on clean energy research and technologies that offer an opportunity for countries to collaborate. This presents an opportunity to collaborate in the area of financing mechanisms and business models for EA. International organizations and development agencies could play a facilitating role in such international cooperation efforts.

Capstone - Experience with Experiential Learning Project Course at Institute of Business Management (IoBM)

Marium Mateen Khan, Lecturer, Marketing Department, Institute of Business Management, Karachi Pakistan, marium.mateen@iobm.edu.pk

Mohammad Ekhlaque Ahmed, Assistant Professor, Marketing Department, Institute of Business Management, Karachi Pakistan, ekhlaque.ahmed@iobm.edu.pk

Abstract

The case study aims to highlight the importance, process and framework of the Capstone Project Course (Experiential Learning) that has been initiated by Institute of Business Management (IoBM). The case provides detailed analysis of how the Project is executed by the students under the guidance of the Faculty and industry supervisors assigned to each group of students. The project entails various methods to monitor the performance of the task at hand and the students input and efforts in the duration of both Capstone 1 and Capstone 2 Projects (3 credit hours each). This initiative taken by the university highlights the different aspects of experiential learning processes and how it benefits the academia as well as the company in the industry. It is a cost free project carried out by students to enhance their learning and exposure into the corporate sector first hand. This kind of projects from multiple disciplinarians has proven to be a milestone for the students and the University in the learning with concrete outcomes for the industry as a whole.

Keywords: Capstone Assessment, Experiential Learning, Capstone Circular, Capstone Pathway

Introduction

The word Capstone is used for a final achievement which is built upon the past works and encircles those past works. Capstone projects are often included in engineering curricula in order to integrate functional, operational and other multidisciplinary areas. Capstone projects are also used to inculcate professional skills amongst the students, which are difficult to impart in a traditional form of lecture based class or a course (Ward, 2013).

According to (Ward, 2013) Capstone projects serve as a medium that facilitates students in transitioning from academic phase to a professional life. Such projects have a direct effect on university's ranking and reputation in the industry and its students' employability. Hence, it is worthwhile to introduce and continue such experiential learning projects at university level.

Capstone projects are designed in a way that encompasses all the areas and aspects of an undergraduate student's experience through the application of student's skills and breadth of knowledge learned throughout the undergraduate program. The aim behind these projects is to develop the students and their skills for their professional career. Capstone projects aim to develop a student's skills which include; multi-disciplinary team-work, application of theory, data interpretation, problem solving, design, communication skills, and ethics. Generally, these objectives are specified in the outcomes of the program and for university's assessment for accreditation (Ward, 2013).

Successful and effective capstone projects are of immense value to the employers, as they rely on these projects to equip the graduates with knowledge, skills and experience to bring success to their respective organizations. Hence, it is important to enlist the elements that contribute towards the success and effectiveness of a capstone project (Ward, 2013). (Howe and Wilbarger, 2005) documented such

elements for engineering capstone projects, which include; duration, faculty involvement, organizational structure, funding sources, project sourcing and industry sponsorship. These elements can be used by other universities belonging to other domains around the world.

Capstone Business Curricula

Mintzberg, (2004) asserted that the professors who teach MBAs overemphasize the sciences of management while ignoring its art. Mintzberg, (2004) argues that after graduation MBA students have inflated views about their ability and competence to be successful. He emphasizes that for effective management many essential skills can only be learned through the personal experience and suggested major changes in the management education which will encompass more experience based learning before a student graduates and transitions to a professional life.

Kolb & Fry, (1974) developed an experiential learning model based on four elements; concrete experience, observation and reflection, formation of abstract concepts, and testing in new situations. They argued that the learning cycle can begin at any one of the four points. Thus, the model should be envisioned as a continuous spiral.

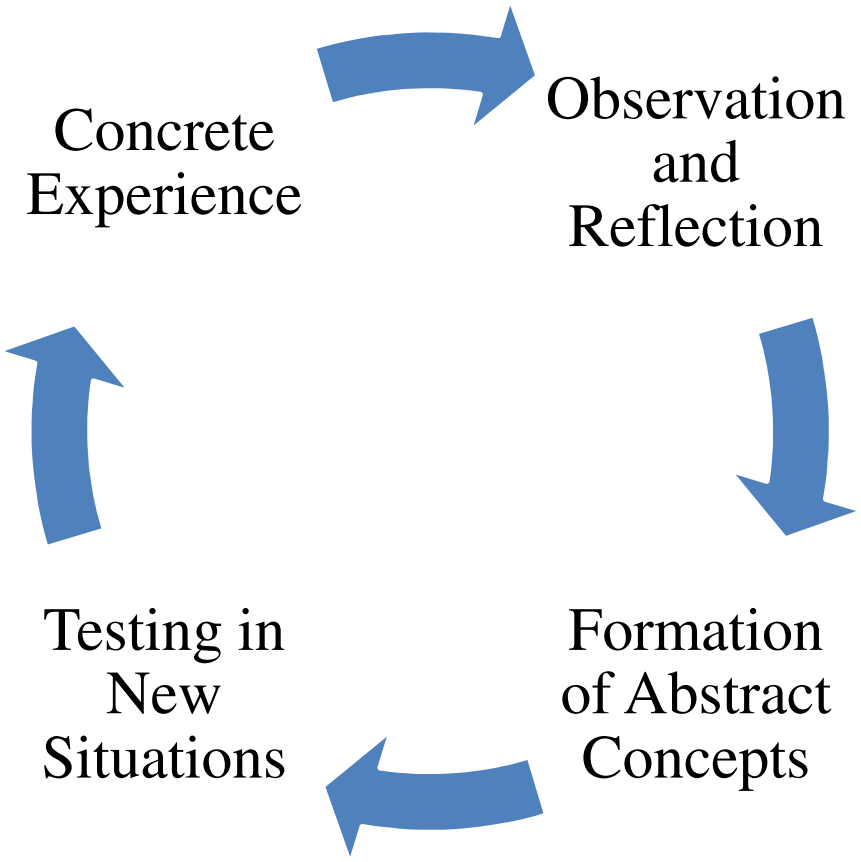

Figure 1: Kolb & Fry, 1975

In the model given in Figure 1 two important aspects can be seen; use of concrete experience for testing ideas and the use of feedback in order to change theories and practices Kolb, (1984). The model emphasizes that experience plays a vital role in learning Smith, (2001). Some of the critics have argued that the model given by Kolb is too simplistic. However, Tennant, (2006) stated that the framework provides an excellent guideline for planning of teaching and learning activities.

Incorporating Job Shadowing into a Business Course

According to McCarthy and McCarthy, (2006) in order to follow the experiential model, business programs should begin with job shadowing. However, Paris and Mason, (1995) defined job shadowing as an option to gain a work experience where students learn about a job by walking through the work day as a shadow of a competent worker. Job shadowing is a work experience that is temporary, unpaid exposure to the workplace in an occupational and functional area of interest for the student. Students get to witness firsthand work environment, employability and occupational skills in practice, the value of professional training and potential career options. Job shadowing is designed to increase career awareness, help in modelling student behavior through examples and reinforce in the student the link between classroom learning and work requirements. Almost any and every workplace is a potential job shadowing site.

Capstone Project Course at Institute of Business Management (IoBM) - Methodology

The objective of Capstone Project Course at IoBM is to provide the students of MBA program an opportunity to work on real world issue and connecting it with the conceptual framework using the most modern management tools. The project engages the students with real world complexities and helps them enhance their competencies and skill related to strategic thinking, communication, managing information and choosing among alternatives.

Projects on corporate issues involving multiple functional areas e.g., marketing, finance, supply chain, operations etc. are provided by the industry experts and the students carry out those projects. The level of efforts required by each project is at least 900 man-hours for each group comprising of 5 students. Each student groups is assigned a faculty supervisor that becomes a liaison between the academia and the industry and to support and guide the students throughout the project.

After the project has been completed a presentation is given to the top management of the firm from which the project came from. During the presentation students provide their insights to the top management along with their recommendations. In many firms those suggestions and recommendations have already been implemented or are in the process of being implemented. The evaluation of the work done by the students is not just in the hands of the faculty supervisor but also by the industry expert.

Initial Capstone Pathways

The Capstone project consists of two initial pathways that is provided to the students i.e. Firstly an Organization oriented Projects, wherein the company from various industries are approached to identify the cross functional issue for the students to study, analyze and recommend alternative solutions through guidance. The second Pathway includes an industry Research Projects where students are involved in the identification and selection of a significant industry topic with practical applications in multiple organizations. These industry researches revolve around the dimensions of the progress made in Pakistan and through facilitations by Faculties, the data gathered would conclude consolidated results.

The project is monitored through different methods which include documents and Forms to be filled on a regular basis or the number of times the students visit the corporations. Some of the documents entail

Capstone Logging forms, Capstone checklists and Capstone Project Plan on how it would be executed with the prescribed timeline. This helps in record keeping of the project for both the Organization and the University **(See Annexure 1).**

Steps for Initiation of a Capstone Project

In order to receive a project from a company following steps are carried out:

1) Sending of invitation for capstone project to a company **(Annexure 1)**
2) Receiving a feedback from the company about the project
3) Arranging a meeting with the top management of the company
4) Acquiring project from the company; company fills the registration form **(Annexure 2)**
5) Registration of students for Capstone project course
6) Formation of student groups for the project (3-5 members, depending on the project)
7) Allocation of projects to the student groups based on their specialization (subject majors)
8) Providing a faculty supervisor to each group to act as a monitor and liaison
9) First meeting of the student group with the company/industry supervisor who will be monitoring the project progress
10) In the first meeting briefing is given about what the company expects from the students and what is desired by the end of the project is required. The company provides the list of deliverables and deadlines to the students
11) Students start working on the allocated tasks, and weekly updates are provided to the company. Students are constantly in touch with the company and make changes as per the feedback of the company **(Annexure 3)**
12) After all the deliverables are completed a final presentation is made by the students on the analysis of their findings. The presentation is first delivered to the Capstone project lead and the Dean. After approval from both after changes if required, the presentation is given to the top management of the company that gave the project
13) After the completion of many projects the findings and recommendations are implemented by the companies
14) Many companies gave more projects after the completion of the first project. Some companies extended the project to second phase as well
15) Students of the projects were also provided with a job offer by some of the companies

Assessment and Grades

Capstone Projects are executed through three hour per week sessions with the assigned supervisors at a scheduled time and day of the week. Attendance of these sessions are recorded which help students to discuss their weekly progress of the project at hand. These sessions may also include lectures, peer reviews, student presentations and ono-to-one clinics with academic staff. The combinations of these sessions conclude with a refined problem which may need further exploration and establishment. The analysis of the data and a well-argued based report is presented which addresses the company specific/ industry related problems. At the end of the semester, a grade is assigned to the student with regard to their performance in the project in both Capstone 1 and Capstone 2.

Details on the assessment as rubrics is provided and discussed by the Faculty Supervisor at the beginning of the course to give students information before commencing the project. Each group will establish a portfolio that would contain all the project artifacts related to the entire duration of the project consisting of (but not limited to) proposal, plans, interim progress reports, notes on each individual item referred in secondary research, scheduling and notes of all primary research activities such as pictures, screenshots, transcripts, sketches of incremental development of ideas, and preliminary results and other analyses.

Grades are given by the faculty (60%), Head of department (20%) and industry supervisor (20%). Assessment forms used in this regard are given in **Annexure 5**.

Capstone project course was started in summer of 2015 at IoBM. In the first semester IoBM received 9 projects from different companies belonging to different industries. Students were able to carry out all 9 projects successfully. In the next semester (Fall 2015), IoBM received 19 projects in total. Some companies gave more than one project during this semester, while some companies extended their projects for second phase by the IoBM students. From then onwards IoBM has done over 100 projects with more than 50 national and international companies (**See Annexure 6 for List of Sample Projects**).

Corporate Feedback

The industry supervisors were a part of the projects given by their companies and played the counterpart role of the faculty supervisor in monitoring of the project progress throughout the project. After the projects were finished at the end of each semester industry experts highly appreciated the work done by the student groups for their respective companies. The recommendations made by the students were also implemented in some of the companies and some companies even offered jobs to the students. The detailed feedback of the industry experts is present in **Annexure 8.**

Student Feedback

After the first semester students requested the expansion of Capstone projects on more functional and operational basis along with the availability of projects for each major specialization area of the students (Marketing, Human Resource, Finance, Supply chain). On the basis of this feedback more projects were acquired falling in different functional and operational aspects and areas of specialization. Detailed feedback of the students is present in **Annexure 9**.

Conclusion

Currently IoBM is not charging anything from the companies for the research services being provided by its MBA students. The experience of capstone project course benefits not just the students but also the company through the provision of new and unbiased market insights gathered by the students on behalf of the company. The students deliver in-depth analysis and recommendation for company's decision making on the designated task. At the same time Capstone Project provides an opportunity to the students to engage with real world complexities, enhance individual competencies and develop lasting skills most importantly in thinking and analysis, communication, managing information and decision making. This also helps the students to review current understanding and assess alternate approaches to the identified problem applying theoretical and conceptual framework (well researched) and demonstrating a capacity for evaluation and critical thinking. IoBM has started to receive consultancy projects from different companies because of Capstone project course. Furthermore, IoBM is planning to open a consultancy center for the graduates and companies to collaborate.

Final Year MBA Capstone Project on an Industry Issue

Dear Sir/Madam,

CBM's MBA program is focused on developing a real life understanding of problems and issues of industry and organizations in Pakistan through experiential learning projects. The final year project of the MBA students provides them with an intensive real life exposure of studying and resolving an issue or problem faced by an industry organization. Your organization can benefit from the deployment of one or more of our student groups for a project requiring research, fieldwork, analysis and alternatives.

IoBM invites you to engage one or more of our student groups to conduct an in-depth analysis of an issue that your company would like to investigate and present their findings and recommendations. Please note that the final year MBA Capstone Project is spread over two semesters with an expected student effort of 1500 man-hours. Each project will be assigned to a student group who will complete project under the close supervision of IoBM Faculty.

This experience will benefit the company through the provision of new and unbiased market insights gathered by the students on behalf of the company. The students will also deliver in-depth analysis and

recommendation for company's decision making on the designated task. At the same time Capstone Project provides an opportunity to the students to engage with real world complexities, enhance individual competencies and develop lasting skills most importantly in thinking and analysis, communication, managing information and decision making. This will also help them to review current understanding and assess alternate approaches to the identified problem applying theoretical and conceptual framework (well researched) and demonstrating a capacity for evaluation and critical thinking. . Please also note that information obtained during the completion of each project will be treated as highly confidential.

We are currently in the process of registering new Capstone projects for the coming semester (Spring 2017), which will commence from January 2017. For this purpose we would like to invite your organization to provide us with a project. We hope that this proposal will be of immense interest to you. We are enclosing a Project Proposal form which may be filled from your side and sent to us as soon as possible.

The list of projects done so far by the students of IoBM with their project details is attached. During the period from summer 2015 till date (Fall 2016) the students of IoBM have completed over 100 projects with around 60 national and international companies.

Should you need any further information on this subject, please feel free to contact our Capstone Project Coordinator, Ms. LMN, (lmn@institute.com Cell# xxxx-xxxxxxx).

Sincerely yours,
EFG (Lead Capstone Projects, OPQ institute)

Capstone Presentation Assessment Scoring Sheet (Group Grading)

Date: _____

Group Project Name: _____ Evaluator Name: _____

Evaluator Affiliation: ☐Project Supervisor ☐IoBM Expert Panel ☐Project Client ☐External Expert

Term: ☐SPRING ☐SUMMER ☐FALL Year: - _____

☐ Capstone I ☐ Capstone II

Directions:	1) Mark assessed level. 2) Sum the total for each section (I, II..) in the **Score** column 3) Add all scores to get **Total Score**. ***Awarded score will be calculated out of 25 for final grade.***				
1	**Communication Skills**	Fails to Meet Criterion	Meets Criterion	Exceeds Criterion	**Score**
	I. Speaking				
	A. Team spoke clearly and distinctly throughout	1	2	3	
	B. Team spoke with confidence and with appropriate tempo	1	2	3	
	II. Delivery				
	A. All team members remained attentive and engaged with the audience, even when not presenting	1	2	3	
	B. Delivery medium chosen was appropriate and effective	1	2	3	
	C. Team listened effectively to adequately address questions	1	2	3	
2	**Content**				
	III. Organization / Preparation				
	A. Introduction effectively communicated presentation goals	1	2	3	
	B. Topic was well focused & appropriate	1	2	3	
	C. Project deliverables were clearly explained	1	2	3	
	D. Conclusion summarized ideas well	1	2	3	
	IV. Project Deliverables				
	A. Project work addressed the business problem at hand	1	2	3	
	B. Project deliverables account for the time spent on the project	1	2	3	
	C. Project delivered value to the client organization	1	2	3	
	D. Evidence of research and fieldwork available and well documented	1	2	3	
	E. Evidence of research and fieldwork available and well documented	1	2	3	
	F. Overall Performance of Team	1	2	3	
	Total Score

Guidelines

The scales measure the behaviours and abilities that all capstone students are expected to progressively attain and refine through the capstone projects

Problem Solving. Ability to analyze problems or procedures, evaluate alternatives, and select best course of action			
① ②	③ ④ ⑤	⑥ ⑦	Not Observed
Developing Performance Can make routine decisions but needs ongoing guidance and checking	**Good Performance** Can be relied upon to make good decisions, requires limited guidance	**Superior Performance** Independently manages complex tasks and makes good decisions for work without guidance	

1. Interest in Work. The degree to which the student pursues goals with commitment and takes pride in accomplishments.			
① ②	③ ④ ⑤	⑥ ⑦	Not Observed
Developing Performance Shows little enthusiasm for assigned work, infrequently requests additional tasks	**Good Performance** Enthusiastic about their assignments/work, agreeable to new responsibilities, asks for new tasks	**Superior Performance** Displays enthusiasm for work that is beyond their job requirements; proactively seeks new tasks and responsibilities	
2. Ability to Learn. The extent to which the student becomes proficient with job duties and work processes.			
① ②	③ ④ ⑤	⑥ ⑦	Not Observed
Developing Performance Sometimes slow to become proficient at new tasks or work processes	**Good Performance** Quick to become proficient at new tasks	**Superior Performance** Exceeds expectations in the complexity and difficulty of work they are able to successfully complete	
3. Quality of Work. The ability of the student to set high standards for own personal performance; strive for quality work; put forth extra effort to ensure quality work (includes oral and written communication).			
① ②	③ ④ ⑤	⑥ ⑦	Not Observed
Developing Performance Work does not meet expectations, has more than the expected number of errors	**Good Performance** Work is usually very thorough and well done, few errors	**Superior Performance** Work is always very thorough and of excellent quality, few if any errors	
4. Quantity of Work. The volume of work produced by the student, along with his or her speed and consistency of output.			

① ②	③ ④ ⑤	⑥ ⑦	Not Observed
Developing Performance Does not always complete work within time limits	**Good Performance** Completes the majority of work within specified deadlines	**Superior Performance** Consistently completes work ahead of schedule; seeks additional tasks	
5. Problem Solving. Ability to analyze problems or procedures, evaluate alternatives, and select best course of action			
① ②	③ ④ ⑤	⑥ ⑦	Not Observed
Developing Performance Can make routine decisions but needs ongoing guidance and checking	**Good Performance** Can be relied upon to make good decisions, requires limited guidance	**Superior Performance** Independently manages complex tasks and makes good decisions for work without guidance	
6. Teamwork. The degree to which the student works well in a team setting			
① ②	③ ④ ⑤	⑥ ⑦	Not Observed
Developing Performance Can make routine decisions but needs ongoing guidance and checking	**Good Performance** Can be relied upon to make good decisions, requires limited guidance	**Superior Performance** Independently manages complex tasks and makes good decisions for work without guidance	
7. Response to Supervision. The manner in which the student responds to direction and constructive criticism			
① ②	③ ④ ⑤	⑥ ⑦	Not Observed
Developing Performance Sometimes disregards direction and feedback from supervisor	**Good Performance** Integrates feedback from supervisor into their work to improve productivity & efficiency	**Superior Performance** Takes the initiative to follow through on all feedback from supervisor and to continuously improve	
8. **Resourcefulness.** The student's ability to develop innovative solutions and display flexibility in unusual circumstances.			
① ②	③ ④ ⑤	⑥ ⑦	Not Observed
Developing Performance Unsure how to approach new or stressful situations; has difficulty adjusting to changing priorities	**Good Performance** Responds appropriately to new or stressful situations; can adjust to changing priorities and	**Superior Performance** Generates effective resolutions to new or stressful situations; readily adjusts to changing	

and circumstances	circumstances with guidance	priorities and circumstances

Project Supervisor's Comments – Please comment on student's overall performance:

Evaluation Discussed With Student: ☐YES ☐NO
☐NOT APPLICABLE

Do you want to supervise the student in Capstone II? ☐YES ☐NO
☐NOT APPLICABLE

Supervisor's Evaluation 30% (Individual Score)	Weekly Progress Report 25% (Individual Score)	Panel's Evaluation 25% (Group Score)	Client's Evaluation 20% (Group Score)

Company Evaluation of Work Report (To be filled by Industry Supervisor Only)

Company Name: _____ Evaluator Name: _____

IoBM Supervisor Name: _____ Date: _____

Term: ☐SPRING ☐SUMMER ☐FALL Year: - _____

☐ Capstone I ☐ Capstone II

As a requirement of the Capstone Project programs, students have been tasked with working towards solutions for your identified business needs. During this process, students are required to coordinate and provide you with periodic work reports. Work Reports are marked by both the Industry Supervisor (YOU) and the IoBM nominated Project Supervisor. To receive credit for the report, a student must receive acceptable or higher from both markers. Providing appropriate feedback on the subject matter of the report can be difficult for the university evaluator since the content is normally related to the work environment. Therefore, we request your assistance in this area.

Your input is greatly appreciated!

Quality of Subject Matter	Poor	Average	Good	Outstanding
Team's Work Ethic & Commitment to the Project				
Command on Technical Aspects of the Project				
Team's Ability to Add Value to the Organization				
Overall Feedback				

Industry Supervisor's Comments – Please comment on group's overall performance:

Do you want to continue with IoBM's Capstone Program? ☐YES ☐NO
☐NOT SURE

Overall Marks Awarded to Group: ____/20

Annexure 6
Sample Capstone Project List

Capstone Projects Summer-2015			
S.No	**Company Name**	**Department**	**Project Description**
1	Dalda Foods (1)	Marketing	Brand Strategy Development
2	Dalda Foods (2)	Marketing	Gap identification and Downstream Innovation
3	Abbott Pakistan	Marketing	Model transformation from Product to Category Communication
4	Pharmevo	Supply Chain	Improving Supply Chain/Channel Integration
5	Engro	HRM	Public welfare development project to hire disabled people.
6	Hashwani Group	HRM	Process mapping of different activities of different depts. and preparing SOPs and JDs.
7	Leopards Courier Pakistan	HRM	Issues with Job satisfaction of Senior Managers and how to improve it.
8	CDC	Finance	Reasons for low investor base in capital markets of Pakistan.
9	GSK	Supply Chain	Supply chain SOP for inventory and ware housing.
10	GETZ Pharma	Marketing	Develop strategies for successful penetration for health care market for existing OTC products.
11	TCS E-Com (Pvt.) Ltd	HRM	Recommendation of best HR practices being followed by local and international companies.
12	Express News	Media Industry Research	To identify the net reach of the Channel.
13	Ehtesham Packages (1)	Marketing	Feasibility report for a reel to reel Label Printing machine with online additional option.
14	Pharma Industry	Supply Chain	Issue of local production of raw materials for pharmaceutical industry.
15	Qindeel Academy	Process Improvement	To develop a donor-social action plan, and develop awareness campaigns.
16	HBL	Finance/Audit	To evaluate/gauge the effects of traditional audit practices in Banking Industry.
17	Alpha container industries Pvt. Ltd	Process Improvement	Suggestions for proper placement of workforce.
18	Engro Foods Limited	Marketing	New channels' identification and Market proposition for new product.
19	Lucky Cement	Supply chain	Suggestions for the appropriate disposal of coal ash.
20	JS BANK	Finance	Impact of JS Group on Economy of Pakistan.

Industry Experts' Comments

Nutralake Healthcare

It is a wonderful experience to work with final year MBA students of IoBM. I think it is a win-win situation and more productive for the students. The project makes the students aware of real situation handling in life project with the company. I really appreciate the excellent efforts.

Abbott Laboratories Pakistan Limited

The group performed well against the set guidelines whereas the delivery was also observed timely. Despite being lacked on some research aspects, they covered the shortfall in a quick succession hence their performance in the last duration of the project timeline was exemplary.

Their field work commitment considering the difficult timing w.r.t. pharmaceutical sector needs to be commended especially the females in the group as they demonstrated the conformance to the appointments and also to the interviewing principles at par with their male colleagues.

Lastly their presentation as a group was also very well appreciated at Abbott's desks where they not transported the real and unedited insights but also showed their citizenship towards the company as a group.

Wavetec – Vendi

The group showed good commitment to the project, I would be interested in working with them for phase 2 and implementing some of their suggestion during part 1 to judge the results in a more practical environment

Digitz Pvt. Ltd

The group worked really hard in getting all the research done, full marks on that. Another noticeable thing was that they took initiatives when needed. However, their submission was not on time and the project was delayed. But all in all, it was a good effort made.

Dalda Foods (Pvt.) Ltd

The quality of research work put up by the students is commendable. We were able to cull insights from the data shared, which will serve as a part of key inputs for our business. Great job! Great effort!

Online Distributions

The team did a tremendous job. They have submitted a comprehensive report with well-defined each and every aspect of the work given. We are planning to float this SOP through them to our partners.

PharmEvo (Private) Limited

We acknowledge the efforts of students in delivering the task assigned to them, and interacting with different group of people to analyze the causes of given state of problem and then suggesting practical solutions.

Overall the students were able to develop and suggest a plan to reduce lead time involved in delivery of Pharmaceutical products.

We wish them best of luck in their future endeavors.

Premier Agencies

We acknowledge and appreciate the efforts of students in exhibiting the professional knowledge over the task provided to them. Overall Student's group was able to develop an insight for potential categories and the linkages between consumer buying patterns.

We wish them good luck for their project and corporate career.

Zong

Overall good effort by the group, they took the time to learn industry dynamics before conducting the research. Data collected by the students was comprehensive and useful for the brand

Engro Tarang

They have done hard work, they know their stuff, they have talked to the people to gain insights. Iam liking what I am seeing so far done by them. I like some of the recommendations made by the students and I am looking forwards towards implementing them at Engro.

Engro PWD

The students owned the project since the start. They went in explored the areas and found far beyond what I had expected from them. The things they have highlighted are now being worked on. I wish all the student a best of luck for the future.

UBL

The IoBM students have done a tremendous job. The insights revealed in this phase were theoretical, now in the next phase we expect them to go on the practical side of the key areas highlighted.

Hashwani Group

I showed the Org Charts and Performance Appraisal documents you developed for us to the Director HR and she really liked your work and wishes me to convey her commendations. I am happy that employees at all level cooperated a lot and you handled the meetings meticulously.

We look forward to your project presentation and recommendations. It was a pleasure working with you in Capstone: 1 and are happy to continue the project to Capstone 2. The TORs you have sent look good and we look forward to doing more work with you.

China Overseas Port Holding Company

On behalf of COPHC Management. We highly appreciate the great amount of efforts put in by IOBM dedicated faculty and knowledge yearning students. Experiential Learning philosophy, initiated by IOBM, is undoubtedly a very effective mean of transferring knowledge and experience to students. We take pride in collaborating with IOBM in executing this mission.

We really appreciate the amount of hard work and research work that IOBM students have demonstrated during their CAPSTONE.

We certainly welcome more such project and want to be part of IOBM agenda of shaping Business Education for future generation!

Premier Agencies

I'm very much satisfied with the efforts of students. They all have been wonderful students and a great team. I wish I had you all again in Capstone 2 for my projects!

I was surprised and delighted to see students handle the challenges of conducting surveys with the sales reps in even remote areas and present their in-depth analysis. I am particularly impressed by the integration of the Blue Ocean Strategy concepts in your analysis which has been very interesting and very informative.

Dabur Pakistan

The group should add more value in terms of Research & way forward to launch Fem in Pakistan.

Annexure 9

Student Feedback

Positive points	Points need to be Worked on
Was Capstone Project Course helpful for you and in what manner?	
Ability to learn a lot of new things which could only be learned while on job	Should be done in BBA as it will be more beneficial to students aspiring for a career. .
Broadened the learning horizons. Also learned how to process ideas and communicate effectively	More projects of Marketing, HR and Supply chain and lack of projects on Financial areas
A complete learning by experience, provided vast knowledge of the field and practical world experience	Capstone project field work was a hassle for working students.
Which other skills were developed through Capstone Project Course?	
Stress management skills as we have to handle a lot of pressure in this project. Along with improvement in self-confidence, communication and analytical skills	Project-job incompatibility
How has the experience influenced your critical thinking and problem solving skills/abilities?	
Both skills have greatly improved along with time management and coming up with alternative solutions	An employed student like me finds it very difficult to balance capstone, job and MBA altogether
Please share a specific example of how your experience impacted, if at all, your transition to workplace and how this specific example impacted your career?	
I am getting diverse experience and I am now more confident and have enhanced analytical skills. I was able to arrange training sessions on my own after this experience. Also helped in transition to new work place	Even though capstone project helped in certain areas I still think it's a burden on students who are working and have to meet deadlines of capstone project too
How can the mentoring sessions be improved?	
Our mentor was extremely helpful during the project. He has been a great luminary. He assisted us, guided us and motivated throughout. I really enjoyed being mentored by him	Work should be acknowledged when it's done right. Timings of interaction for capstone should be made feasible for students specially those who work

Digital Strategy of Telecommunications Development: Concept and Implementation Phases

Andrey Polyanin, Central Russian Institute of Management, Branch of RANEPA, Orel, Russian Federation, polyanin.andrei@yandex.ru

Tatyana Golovina, Central Russian Institute of Management, Branch of RANEPA, Orel, Russian Federation, golovina_t78@mail.ru

Yulia Vertakova, Southwest State University, Kursk, Russian Federation, vertakova7@ya.ru

Abstract.

Prime objective of Russia modern information society development in the conditions of digital economy establishment is mainstreaming of information and communication technologies, particularly massive adoption of technologies BigData. This information society development objective determines priorities in modern information technologies application in the Russian Federation. Particularly this problem is vital for telecommunication branch, where it is necessary to develop and implement digital development strategy. Foreign countries that already financing digital technologies obtain essential advantages and possess competitive advantages in the world market that is significant in the globalization conditions.

Formation of principally new digital strategy of communication development will present new digital platform on practical realization of digital solutions in this sphere and provide increase of competitive performance of all economy branches absolutely and improving population life quality.

The necessity of development of scientific-methodological approaches to the definition of digital strategy concept in the sphere of telecommunications is provided with integrative and globalizational processes, which dictate the necessity to search modern methods, tools and technologies of innovations promotion.

Keywords: digital economy, telecommunications, development strategy, technologies BigData.

Introduction.

Modern development of global space is impossible to imagine without development of information and communication technologies, the Internet of things and thus, development of telecommunications in the conditions of digital economy formation. This problem is of interdisciplinary character, because to solve it is necessary to attract knowledge of informatics, electronics, sociology, economy and all complex of special management forms (strategic, finance, innovative, investment, etc.). Scientific works of the following scientists and professional associations: Don Tapscott (Tapscott D., 1999), Gates B. (Gates B., 2001), Kupriyanovsky V. (Kupriyanovsky V.P., 2016), Dobrynin A. (Dobrynin A.P., 2016), Boston Consulting Group (Boston Consulting Group, 2011), Boston Consulting Group (Boston Consulting Group, 2015), Boston Consulting Group (Boston Consulting Group, 2016), International Bank for Reconstruction and Development (International Bank for Reconstruction and Development, 2016) made particular contribution to the research of information society, formation of new technological paradigm, electronic business models, digital technologies

implementation and digitalization development. However in existing publications and scientific research results the digital economy development problem is examined mainly in general without specific character of methodology formation of development management of digitalization processes in some economic spheres. They don't pay adequate attention to digital strategy of telecommunications development and its implementation phases.

Now Russia implements information branch development strategy up to 2025, but, unfortunately in this strategy there is no word mentioned about digital economy, digital methods and digital solutions. Foreign countries at present realize digital conversions in all branches of national economy to increase their Global Competitiveness Index and formation of Industry 4.0 (realization of the fourth industrial revolution), which covers complete digitalization of business-processes.

In 2016 January, 1 the President of the Russian Federation Putin Vladimir Vladimirovich in his message appealed to: «I suggest starting large-scale system program of economy development of new technological generation so called digital economy». This suggestion was taken up by the Government of the Russian Federation and in February 2017 started the work over development of general strategy of digital economy implementation in Russia.

There is one more problem, which is the absence of clear definition of «digital economy» on the legislative level in Russia.

Research objective is to ground the digital strategy of telecommunications development and its implementation phases to transfer Russia economy to a totally new level of technological development and increase global competitive ability.

Main research results. The authors proved that telecommunications branch is grounding for formation of the platform including digital ecosystem, accelerates the pace of its development. At the moment, telecommunications endure sufficient global changes.

We present in figure 1 global tendencies of telecommunications development in the conditions of digital economy development.

Russia market of mobile communication differs greatly from other economy branches, because it consists of foreign and Russian companies, and the state penetration is not so deep. Notably Russian stockholders possess more than ¾ of the market.

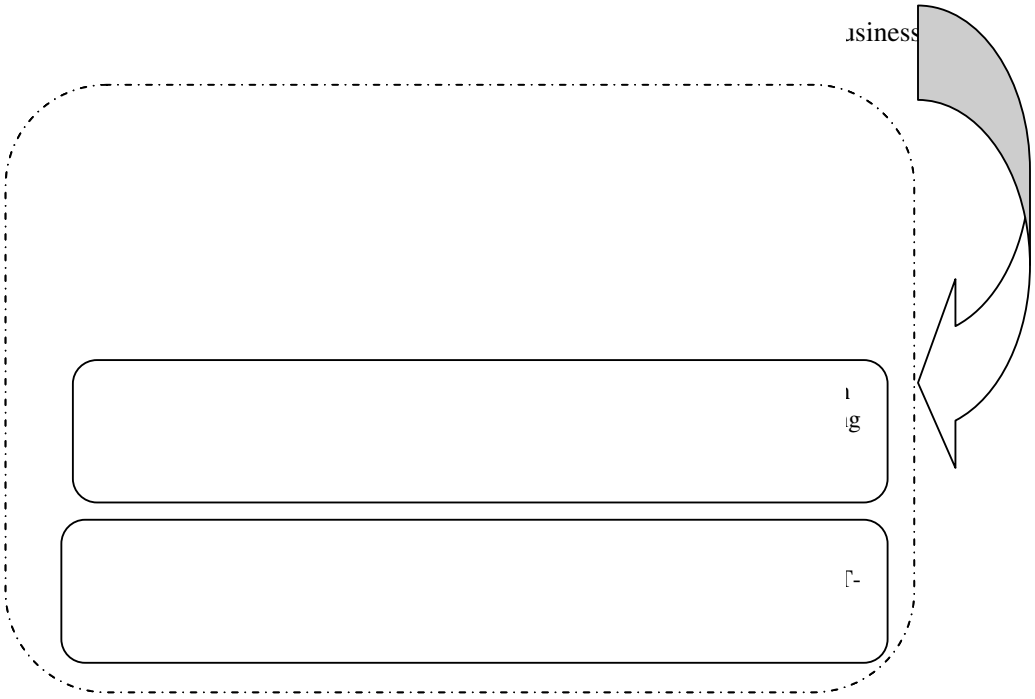

Fig 1. Global tendencies of telecommunications development in the conditions of digital economy development (compiled by the authors)

We present in figure 2 the structure of the Russian market of mobile communication in 2016.

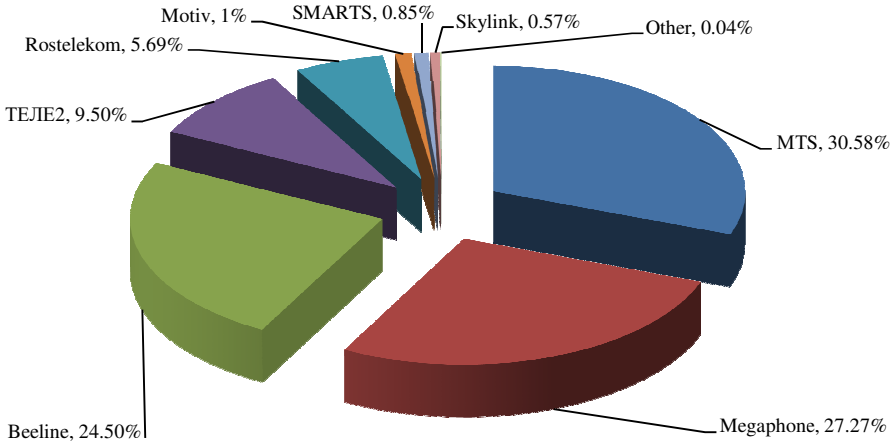

Fig 2. Structure of the Russian market of mobile communication in 2016 [The BostonConsultingGroup, 2016]
Amount of telecommunications market in 2016 is 1,6 bln. rub.

We resent in figure 3 structure of the telecommunications market of Russia in figure 2 (2016).

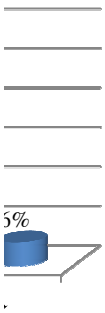

Fig 3. Structure of the telecommunications market of Russia in 2016 [The BostonConsultingGroup, 2016]

The market structure analysis displays that the maximum share at the telecommunication market in Russia is occupied by mobile communication. Let us analyze the telecommunications market segment.

Nowadays the main tendency is geometrical increase of mobile communication subscriber number in Russia. Thus, for 2015 mobile communication subscriber number has increased by 627,11%. We present in figure 4 the corresponding tendency of mobile communication subscriber number in Russia change for 2009-2015 (bln. people).

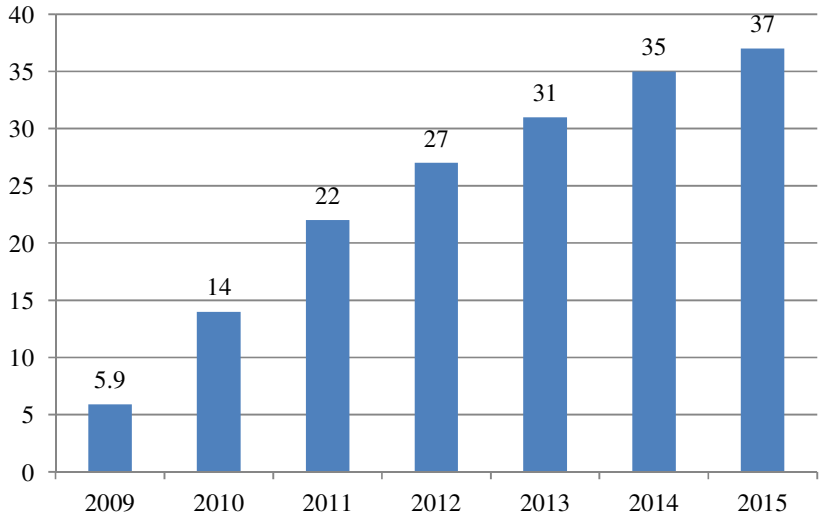

Fig 4. Tendency of change of the number of mobile communication subscriber in Russia for 2009-2015 (bln. people) [The BostonConsultingGroup, 2016]

At present, the tendency of growth and fast development of informedia not only at the Russia market but also especially at the world market is observed. Thus, in comparison with 2012 market volume has increased by 4,8% in 2015.

In 2015 the software market is in the order of four hundred billion dollars of the USA. It is more than 4,3% — growth, marked in 2012. IDC expects that this middle-positive script will be saved for the next following years [Ahmad N., 2016].

Software market (SW) is developing according to five trends: mobility, «clouds», social networks, processing of big data and fast solution adaptationи. Cumulative turnover of top-100 of the world IT-companies has decreased by 1% (in comparison with 2012) up to $693 bln. in the fourth quarter of 2015.

Turnover decrease for all 2015 also corresponds to 1%. Meanwhile, considering two last years, sales volume in 2015 was more about by 3% in comparison with 2014.

IDC divides common software market into three main segments: applications, software tool, system and infrared software.

Among these three segments the market of system software was nearly 23% from consolidated revenues in 2015 and became the most growing, from 5,6% growth indicator in comparison with 2014.

Software tool segment growth mostly was conditioned with improvement of indictors on directions: «Management of structured data» (+ 7,3%) and «Software for analysis and data transfer» (+ 6,0%). Besides, companies began to pay more attention to analytics and «big data» (Big Data), that is why popularization of solutions of type «Analytic platforms» and «Software for data bases management» [Dobrynin A. P., 2016; Inc. Copyright, 2013] has become one of the basic market trends.

In application segment which is 50% from total revenues, the growth in 2015 was 5,5% in comparison with the preceding. The market growth of corporative and content-applications was 10%.

Corporative application market motto has become outspreading of corporative social networks and applications for teamwork. Content application market motto has become search and content analytics, the market that has increased by 13,2% in comparison with the previous year. Trend on big data analytics influenced significantly on the market development [Taylor E., 2016].

In segment «System and infrared software», which was in 2015 27% from total revenue and grew up by 5,5% in comparison with 2012, secondary segment «System software» grew up by 8% in connection with Windows 8 output, and also with spreading of virtualization and cloud technologies.

At the same time today at the Russian market, the solutions on US-communications that can not compete with key market players production are not presented.

Meanwhile Russian companies have potential for development of already existing complex solutions on telecommunications networks design and their functional extension.

Positive forecasts and high growth paces of the world market VoIP and UC-solutions allows speaking about vitality of complex solution development, uniting all accessible mode communications [International Bank for Reconstruction and Development, 2016].

With market development it is possible to observe appearance of C niche segments (UC-solutions on increase of improvement of operational efficiency of employees, solutions integrated with business applications, etc), which can occupy new products from Russian designers.

The following business strategies at the information sphere enterprises are realized in international companies [Avdeeva I.L., 2013]:

– growth strategy;

– franchising strategy;

– emerges and acquisition strategy;

– foundation of joint venture strategy.

We do strategic analysis of telecommunications market on the ground of five competitive forces analysis of Michael Porter's model (figure 5).

To develop general strategy of telecommunications market development is necessary to do SWOT-market analysis.

Particularly it is necessary to estimate the effect and degree: «strong points – possibilities», «strong points-threats», «weak points – possibilities», «weak points – threats».

We present in figure 6 the results of SWOT-telecommunications market analysis.

The carried out strategic analysis of telecommunications branch proves the necessity to work out digital strategy of its development.

Digital strategy is a strategy of implementation of new technologies for transferring organizations of telecommunications sphere and their services to a new level of efficiency and customer focus. All the services must be digital by default, easy to apply and advisably personalized. Digital strategy should be clear, but at the same time flexible. It should help to coordinate the activity between subdivisions, connecting points to organize more effective approach to application of digital platforms.

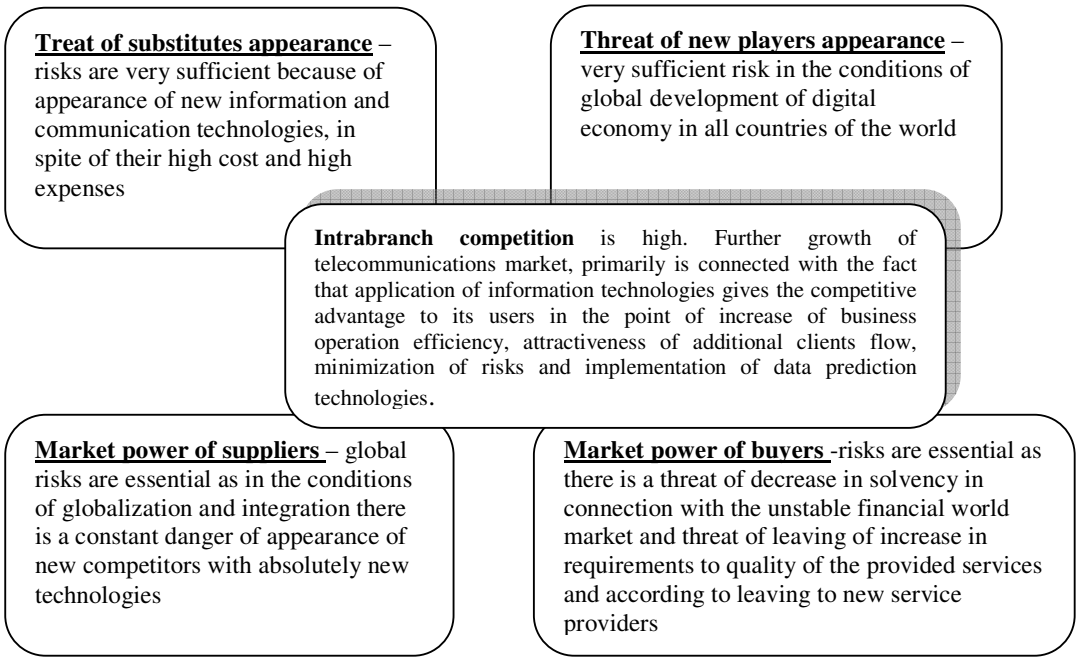

Fig 5. Strategic analysis of telecommunications market on the ground of five competitive forces analysis of Michael Porter's model (compiled by the authors)

Promising trend of realization of digital strategy of telecommunications development is creation of platform on the ground of concept BigData. Technology BigData implies processing of structured and unstructured data of big amounts to obtain useful and intelligible for business entities results.

STRONG POINTS - POSSIBILITIES	STRONG POINTS - THREATS
–segment Big Data in Russia is at the phase of formation, but the demand for these technologies is increasing from year to year; – absence of big data analysis experience, it decreases considerably analytics in the telecommunications area. Suggested strategy**: Growth strategy**	– unstable development of the world finance market creates barriers of telecommunications market entry; – absence of implementation experience of technologies Big Data results in decrease of information potential of the suggested projects in the telecommunications area. Suggested strategy: **Emerges and acquisition strategy**
WEAK POINTS - POSSIBILITIES	**WEAK POINTS - THREATS**
– low paying capacity of consumers results in recession in demands for services; – understudied modern informational technologies decrease the pace of branch organization development. Suggested strategy: **Strategy of inner growth of branch enterprises**	–low percent of investment in connection with high risks and the world economy; – absence of strategic view in branch development results in slow growth of Suggested strategy: **Strategy of limitation of strategic development**

Fig 6. Results of SWOT-analysis of telecommunications market (compiled by the authors)

This technology can be useful for solution of the following tasks: market situation forecasting, marketing and solutions optimization, effective clients segmenting, goods and servicing improving, making more sufficient managerial decisions on the base of BigData analysis, optimization of investment portfolio, increase in labor productivity, effective logistics, condition monitoring of fixed capital.

We present in figure 7 components and directions of development of technology BigDataв of the modern economy.

In this new phase of Big Data development, such technologies as DSSD, Apache Spark and GemFire will be so important as Hadoop.

The underlined components give platform BigData possibility to do creative and effective analysis of all available data in preparation of managerial solutions in the conditions of digital strategy formation. Herewith it is necessary to stress that the components can be included as structured and unstructured and thread specific data.

The formation process of platform BigData is quite difficult because since difficult problems are solved using vast almost monumental data arrays. Herewith preferred directions, used for implementation big data, usually developed with considering application flexibility. They are not commercial products; they have lower level of support and servicing. They are not created as ready solutions of definite problems. Exactly because of their flexibility reason, they can be difficult and complicated in expansion.

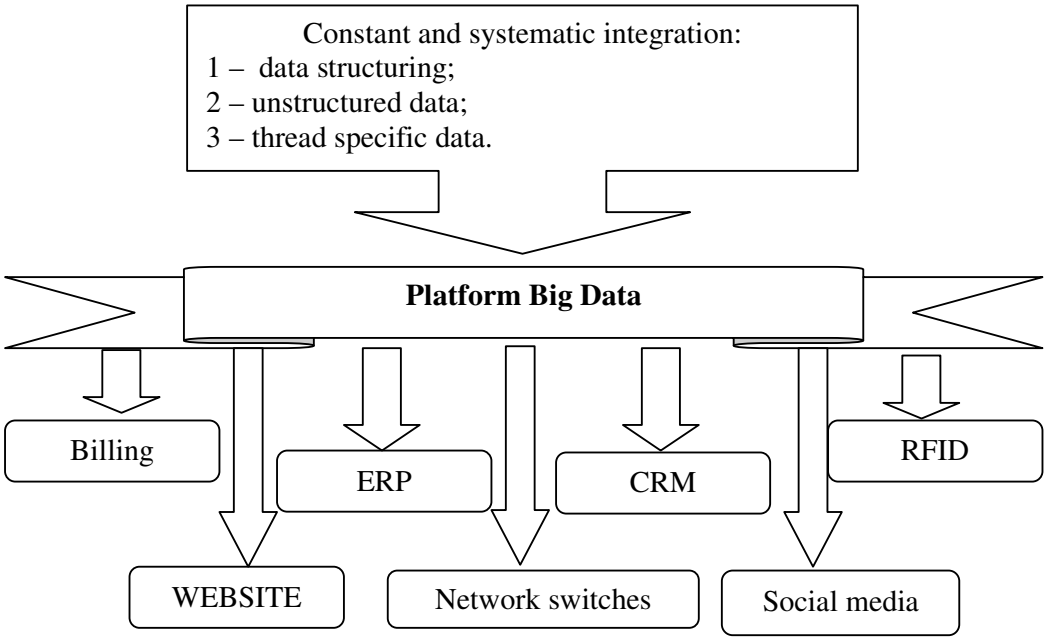

Fig 7. Components and directions of technology development BigData (compiled by the authors)

Development of platform BigData suggests simultaneously new and common ways of data application aiming at influencing on events, when they occur. This gives new opportunities for telecommunications in wide scales.

In order to translate analytics in memory into reality two events must take place. At first, supporting technologies should get the necessary development to provide adequate memory to allocate massive data assembly. More than that, it is necessary to think about how efficiently data should be moved between large objective archives and systems fulfilling analyses in memory. These two elements operate in principally different modes, and it is necessary to create special conditions for IT groups, to transfer the data back and force with necessary rate and transparent to users. Works are carried out; new object archives, special flesh arrays for rack mount and also special technologies that can unite them into one system. Initiatives with open code will play important role in search the answer to this challenge.

Secondly, massive computing environments in memory require stability and dynamics of data. The problem is in the following, providing data persistence, any of their defects become stable. As a result, in 2016 storage systems for environments doing data processing in memory start to appear. They will provide services of deduplication, snapshots, tired storage, randomizing, replication, and possibility to determine the last state when data were true, and system operated correctly. These functions will be extremely important as far as transfer to analytics in real time, when more safe technologies of data processing in memory will become commercial.

Thus, the formation phases of digital strategy of telecommunication development is:

1 – development of technology of processing and data transfer;

2 – active implement unto the world industry concept 4.0;

3 – intellectual systems rapid development;

4 – data management and formation of new direction «data management»;

5 – «clever» changers and constant controlling data integration ;

6 – data integration.

This direction realization requires development of methodology of management system of digital telecommunications strategy. Its realization mechanisms should be organizational, legal and finance constituents:

- creation of necessary infrastructure for development of progressive digital technologies in telecommunications, including system of examination, developing promotion, information application, etc.;

- creation of innovative partnership of scientific, industrial enterprises, higher educational establishments to form complex approach to digital strategy realization;

- creation of attractive investment conditions for increasing innovative activity, including development of public-private partnership mechanisms;

- improvement of managerial improvement of innovative projects in the sphere of digital technologies, based on implementation at all levels of process project management with personalization of responsibility throughout project portfolio to its decomposed elements;

- selection and promotion of competitive digital and pervasive technologies, business stimulation, implementing innovations, by means of creation of industrial parks and branch centers of technologies, which will provide attraction of investments, development and support of telecommunications;

- development of standards directed to widening of digital technologies application in telecommunications.

Digital technologies projecting should be based on detailed approach to pre-project processes and phases of Research and Advanced Development.

The authors suggest procedure of estimation of viability of digital technology choice on the functional model ground, which is based on cognitive analyses method and expert estimation of digital strategy realization problem.

Digital technology quality is determined with quality of data management, of used resources and implemented mechanisms.

Dependences estimation due to the specificity of digital technologies suggests application of expert estimation, particularly to estimate data management quality, information and communication resources.

Quality change of one of the indicators of digital technology results directly or indirectly to quality change of other processes, including digitalization process via the feedback system.

In this connection, to estimate the influence of dynamics of digital technology quality on the separate processes condition or digital strategy realization quality is rational to use special technology of distribution of technological processes in communications.

Conclusions.

It is proved that viable mechanisms of telecommunications digitalization are considered as essential feature of digital economy organization in Russia, consisting in transfer into new technological level at the sake of information and telecommunication technologies implementation on all stages of creation of value-added chain.

Organizational managerial approaches to development of digital technologies should have strategic character; determine directions of digital economy development and main approaches to its implementation phases.

The suggested phases take into consideration challenges and emerging opportunities for telecommunications in the digital economy era.

The primary phase of digital strategy implementation should become maintaining of interaction processes among all digitalization participants, business allows structures to unite potential possibilities, harmonize technological interests, and decrease the innovative risk level. As a result, it will provide increase of their innovative activity and creation of advanced base for further telecommunication development.

The investigated digitalization processes are in the ground of development of digital strategy concept of telecommunications development that provides selection of parties forming science and industrial base of digital business in the given sphere, digital technologies promotion, finance, information and consultative support. The central point of digital strategy of development is a client and his quickly changing demands.

The research result is possibility of practical application of strategy and mechanisms of its phase-by-phase implementation for further development and active implementation of digital telecommunications by means of creation of scientific and research and experience and practical knowledge base through powerful sector of research and development activities.

Directions for future research.

Formation of digital strategy of telecommunications development particularly and economy in general is a complex issue on transfer to a new technological level at the account of implementation of information and telecommunication technologies at all stages of value-added chain. In this connection, the further scrupulous investigations and development should be:

1. Development of methodic approaches to management of economy development digital strategy.

2. Formation of integration mechanisms of Russia and its leading digital segments into digital economy space of states-members of Eurasian Economic Union by means of attraction of state-private partnership and concession on Eurasian digital assets development.

3. Solution of problems of activity regulation in Russia of global digital companies and regulatory framework creation for labor market functioning in the conditions of digital economy.

In this connection, it is necessary to have methodic approaches to risk management, connected with employee displacement and personnel adaptation to new work conditions.

4. Further research is necessary to devote to questions of creation and realization of educational programs and innovative projects with application of e-learning technologies for elite specialists education, those who possess engineering interdisciplinary approach to innovative tasks solution in the conditions of digital economy development.

Abstract

Information and data security have become the biggest concern for almost all organizations. At the same time, new security challenges emerge constantly as networks become more highly distributed and virtualization architectures are adopted. Big data analytics promises to deliver opportunities for prevention and detection of advanced cyberattacks using internal and external big security data. The increase of these streamed and stored data together with the development of distributed analytical systems has led to rapid increase in demand for big data analytics integration in in the field of cybersecurity. Therefore, this paper attempted to discuss these practices. A literature review was conducted and the most suitable components were identified with the aim to propose a conceptual model, which should help to combat cybersecurity threats involving big data analytics in the Hadoop ecosystem. By implementing this model, organizations may be able to detect threats, create more defense mechanisms, and improve security of their infrastructure.

Keywords: Cybersecurity, big data analytics, Hadoop ecosystem, conceptual model.

Introduction

The exponential growth in Information and Communication Technologies (ICT) has caused major changes to society over the past decades. ICT systems have become almost obligatory in all kinds of sectors. However, as the ICT revolution unfolds, it will indeed bring benefits, but it will also bring risks and challenges (World Economic Forum, 2015). Over the few past years, cybercrimes have increased rapidly with cybercriminals continuously exploring new ways to circumvent security solutions to get illegal access to ICT systems and networks. Therefore, threats to ICT systems are on the rise, and the type and frequency of cyberattacks are increasingly more sophisticated (Aradau and Blanke, 2015; Donaldson et al., 2015; Mahmood and Afzal, 2013). These attacks could be from hackers, viruses or internal employees, and it is very clear now that this would lead to lose a large amount of money, time and other resources (Rabai et al., 2013). Most times, cybercriminals would modify the existing malware signatures to exploit the flaws exist in the new technologies (Jang-Jaccard and Nepal, 2014). Leuprecht et al. (2016) argued that these solutions to the rapidly growing problems associated with cybersecurity and new ICT require a more balanced understanding.

As a result, various security monitoring systems are being employed to protect the network and resources from the cyberattacks (Mahmood and Afzal, 2013). The big network datasets that are generated in this process by security monitoring systems need an efficient design for integrating and processing them at a faster rate using various parallel and distributed computing platforms (Aradau and Blanke, 2015; Donaldson et al., 2015; Marchal et al., 2014; Kambatla et al., 2014). To address these issues, large scale security monitoring is recognized as a promising technology, which can enhance the security of networks in characterizing, monitoring, detecting, and mitigating cyber threats in a timely manner. It aims to provide critical information on the network activities for decision making processes, protect against infiltration and manipulation of data, ensure network resilience, and defend against cyber threats (Donaldson et al., 2015; Marchal et al., 2014; Yu et al., 2013).

According to Chen et al. (2016), at first, it is challenging to quantify the impact of threats as they may come from various sources. Second, it is difficult to detect threats because the detection system has to inspect various data sources, which are always in large-scale with different formats and semantics. Monitoring different applications and detecting threats can be characterized as high volume data streams and real-time processing requirements. Rahman and Esmailpour (2016) stated that the volume of data and the amount of corresponding traffic are increasing at such a high velocity that the architecture of traditional data centers is no longer sufficient to handle the network traffic. Therefore, the efficient storing and processing of such big data to ensure security and efficient operations become a challenging and urgent issue (Aradau and Blanke, 2015; Chen et al., 2016; Jang-Jaccard and Nepal, 2014; Rahman and Esmailpour, 2016).

New big data technologies such as the Hadoop ecosystem, stream pattern mining, complex-event processing, and NoSQL databases are enabling the analysis of large-scale, heterogeneous datasets at unprecedented scales and speeds (Alguliyev and Imamverdiyev, 2014; Mazumder, 2016; Storey and Song, 2017)). Hadoop is actually not a single technology but an ecosystem of a number of components (or frameworks) most of which are part of the projects developed by open source communities under Apache Software Foundations. The components in Hadoop ecosystem are in various states of maturity and are continuously evolving. Most of the components of the ecosystem, which are widely used today, are part of Apache top-level-projects, where as many are brewing as Apache Incubator Projects (Mazumder, 2016; Storey and Song, 2017).

Big security data can be stored in a dedicated repository which can also combine and analyze real-time data together with historical data (Cárdenas et al., 2013; Mahmood and Afzal, 2013). Big data analytics then aims to obtain beneficial information from large-scale and complicated data (Lněnička, 2015). The related technologies allow extending traditional information security systems by facilitating the storage, maintenance, and analysis of security data to detect known patterns to stay ahead of malicious activities or intruders (Terzi et al., 2015). Therefore, the main aim of this paper is to propose a conceptual model to combat cybersecurity threats involving big data analytics in the Hadoop ecosystem.

The rest of this paper is organized as follows: Section 2 describes the research methodology and methods. Section 3 is focused on the theoretical background. A conceptual model and its components are proposed and described in Section 4. It is followed by the discussion and future research. The final section presents the major conclusions.

Methodology and Methods

Efficiently storing and processing large-scale big security data is a challenging issue. Also, as big data are typically processed in a distributed manner over a set of nodes, being distributed considerably increases the potential threats to the system and increasing the complexity of security measures needed to combat those threats. For this purpose, the main aim of this paper is to propose a solution for organizations

dealing with cybersecurity threats, which will involve big data analytics in the Hadoop ecosystem. In contrast to Yu et al. (2013), this solution explores all the options offered by the Hadoop ecosystem and related platforms. It should help efficiently collect, integrate, transmit, store, and retrieve security-related big data. The Hadoop ecosystem was chosen because of the fact that the big data analytics movement was primarily started and still primarily fueled by the open source platforms, tools, and services and also because of the more experience and the public domain information available around them.

The literature reviewed was selected based on its novelty and discussion of important topics related to big data analytics and cybersecurity, in order to serve the purpose of this research. Methods of decomposition, aggregation, and criteria comparison were used. The ecosystem perspective applied then provided a framework within which most other aspects represented by big data analytics can be incorporated. In this regard, the role of conceptual modeling for big data analytics was accepted as defined by Storey and Song (2017).

Literature Review

Cyber security and its key aspects

Cybersecurity refers to the technologies, processes and methodologies designed to protect computers, networks and data from unauthorized access, vulnerabilities, and attacks. The goals of cybersecurity are: 1) securely obtain and share information for accurate decision-making, 2) find and deal with vulnerabilities within applications, 3) prevent unauthorized access, and 4) protect confidential information. The cybersecurity process involves following a coherent set of best practices to protect all assets of value within a particular organization (Shoemaker and Conklin, 2012). Cyber defenses then must focus on protecting the confidentiality, integrity, and availability of data and the ICT systems that process those (Donaldson et al., 2015).

Current Intrusion Detection Systems (IDSs) analyze several protocols and data and events observed by them are correlated by Security Information and Event Management (SIEM) in order to detect intrusions. One shortcoming is that current solutions realizing in-depth packet analysis are not scalable and adaptable to big network producing high quantity of data (Marchal et al., 2014). In the last few years, IDSs have tried to leverage cloud-based approaches to optimize their detection capabilities. Cloud-based approaches allow for the collection of information from a very large pool of users and data analysis at a central point (Virvilis et al., 2014). This recent trend towards using clouds introduces similar vulnerabilities. If organizational data are stored in a cloud, their transfer from organizational systems to the cloud creates a potentially vulnerable channel. A failure of cloud providers' systems or an injunction served on them for an unrelated matter may also prevent continuing access to these data (Leuprecht et al., 2016; Storey and Song, 2017). This issue was addressed by Rabai et al. (2013) who explored a user-centered measure of cybersecurity, and demonstrated how this measure can be used to analyze cloud computing as a business model. They offered a quantitative model of security measurement that enables cloud service providers and cloud subscribers to quantify the risks they take with the security of their assets.

Big Data Analytics Technologies and Systems

The continuity of big data technologies is exemplified by such concepts as parallel, distributed, grid computing and, most recently, cloud computing. These architectures maximize storage, networking, and computing power for data-intensive applications. This progress was enabled by framework innovations in cluster computer systems, which consist of many nodes, each having their own processors and storage, all connected by high-speed networks (Kambatla et al., 2014; Liu, 2013; Lněnička, 2015). Big data analytics is in active use in several fields and, in recent years, has attracted the interest of the security community for its ability to analyze and correlate security-related data from a wide range of data sources across significant time periods and at unprecedented scale (Cárdenas et al., 2013; Terzi et al., 2015; Virvilis et

al., 2014). It plays an important role in detecting advanced threats and insider threats. Monitoring systems can potentially minimize false alarms by providing big data analytics and improving threat detection (Virvilis et al., 2014).

In this regard, big data analytics can be used to assist systems in collecting internal data by merging with relevant external data to detect known patterns to stay ahead of malicious activities or intruders (Kambatla et al., 2014; Marchal et al., 2014). Many big data platforms, tools, service, and also techniques have emerged that can handle the volume, velocity, and variety of machine-generated and network-related data (Lněnička, 2015). Hence, these big data systems are being part of a cyber defense strategy for every organization to meet the needs of complex and large-scale big data analytics (Jang-Jaccard and Nepal, 2014; Mahmood and Afzal, 2013). The anomaly detection, intrusion detection, fraud detection, advanced persistent threats (APT) detection, and forensics from big data has been accomplished by examining the logs, system events, network traffic, website traffic, SIEM alerts, cyberattack patterns, business processes, and other information sources (Jang-Jaccard and Nepal, 2014; Mahmood and Afzal, 2013; Terzi et al, 2015).

Surveys, studies and related components of the ecosystem

Surveys such as that conducted by Mahmood and Afzal (2013) presented the application of big data analytics techniques to cybersecurity. Authors stated that big data provide the following unique features for cybersecurity: a more agile decision-making approach for networks managers with surveillance and monitoring of real-time network streams; dynamic detection of both known and previously unknown suspicious/malicious behavior, usage, access pattern, transaction or network traffic flow in real-time; and appropriate big data hardware and software to cope up with the aforementioned requirements. Alguliyev and Imamverdiyev (2014) addressed these challenges to realize the true potential of big data analytics for cybersecurity: privacy-preserving big data applications, APT detection by big data analytics, high-performance cryptography, big datasets for security research, data provenance problem, security visualization, and skilled personnel. Ten et al. (2010) conducted a comprehensive survey on cybersecurity of critical infrastructures and proposed a supervisory control and data acquisition security framework with the following four major components: 1) real-time monitoring, 2) anomaly detection, 3) impact analysis, and 4) mitigation strategies. In addition, they developed an attack-tree-based methodology for impact analysis, which is based on power system control networks.

Another study conducted by Virvilis et al. (2014) described the importance of offline analysis along with the real-time data in threat detection. Although analyzing the offline data causes a delay in the attack detection, it is equally important to consider the time the attackers spend in reaching their objective. Jang-Jaccard and Nepal (2014) then discussed new attack patterns in emerging technologies such as social media, cloud computing, smartphone technology, and critical infrastructure to understand how malware utilizes the unique characteristics to proliferate itself. In this regard, the cyber system forms the backbone of a nation's critical infrastructures, which means that a major security incident on cyber systems could have significant impacts on the reliable and safe operations of the physical systems that rely on it (Ten et al., 2010).

A cloud computing based architecture for conducting cybersecurity situation awareness was proposed by Yu et al. (2013). Particularly, they leveraged the cloud infrastructure with a cost-effective data storage and investigate efficient stream processing techniques to reduce operational delays. By using the parallel computing techniques, they also discussed a parallel cloud based threat detection, which integrates both signature-based detection and anomaly-based detection. Similarly, Chen et al. (2016) proposed a cloud computing based network monitoring and threat detection system to make critical infrastructure systems secure. It consisted of three main components: monitoring agents, cloud infrastructure, and an operation center. They used both Hadoop and Spark to speed up data processing by separating and processing data streams concurrently. Marchal et al. (2014) proposed a solution to cope with the tremendous amount of

data to analyze for security monitoring perspectives. The application domain of such a system is mainly network intrusion detection and prevention, but can be used as well for forensic analysis. Data correlation schemes are proposed and their performance is evaluated against several well-known big data framework including Hadoop and Spark.

Development and Description of the Proposed Model

As demonstrated in the literature review, the exponential growth of data has created opportunities for world-wide web-based information sharing, but also led to the proliferation of cyberattacks (Yu et al., 2013). As a result, the challenge these days is less about defending access to the network and the devices on it, and more about big data analytics and preventing access to them (Aradau and Blanke, 2015). Furthermore, there is an increasing number of end user devices distributed in the organization network and a large amount of data stream collected from different applications, operating systems, and network equipment for the cybersecurity analysis (Yu et al., 2013). However, traditional security solutions are not capable anymore of encompassing the real-time big data network streams using traditions tools and techniques for long-term and large-scale analytics (Cárdenas et al., 2013; Mahmood and Afzal, 2013).

In this regard, to conduct the cybersecurity situation awareness, a large volume of data streams from monitored devices needs to be efficiently stored and processed in real-time (Yu et al., 2013). The Hadoop framework and other big data platforms are now commoditizing the deployment of large-scale, reliable clusters and are enabling new opportunities to process and analyze big security data (Cárdenas et al., 2013). One big problem of Hadoop is that it wasn't built with security in mind. It was developed solely to address massive data storage and faster processing (Spivey and Echeverria, 2015). There has been research on the development of fully distributed IDSs to address the limitations of central and hierarchical systems; however, only small-scale implementations have been realized (Virvilis et al., 2014). Therefore, these issues was considered and solved in a new conceptual model.

A cybersecurity analytics model using distributed infrastructure is depicted in Figure 1. It consists of three main components: big security data sources, data collection and transport, and distributed infrastructure including security layer for authentication and authorization. It follows the concept mentioned by Cárdenas et al. (2013) and Mahmood and Afzal (2013), where big security data can be stored in a dedicated repository, which can combine and analyze real-time data together with historical and external data.

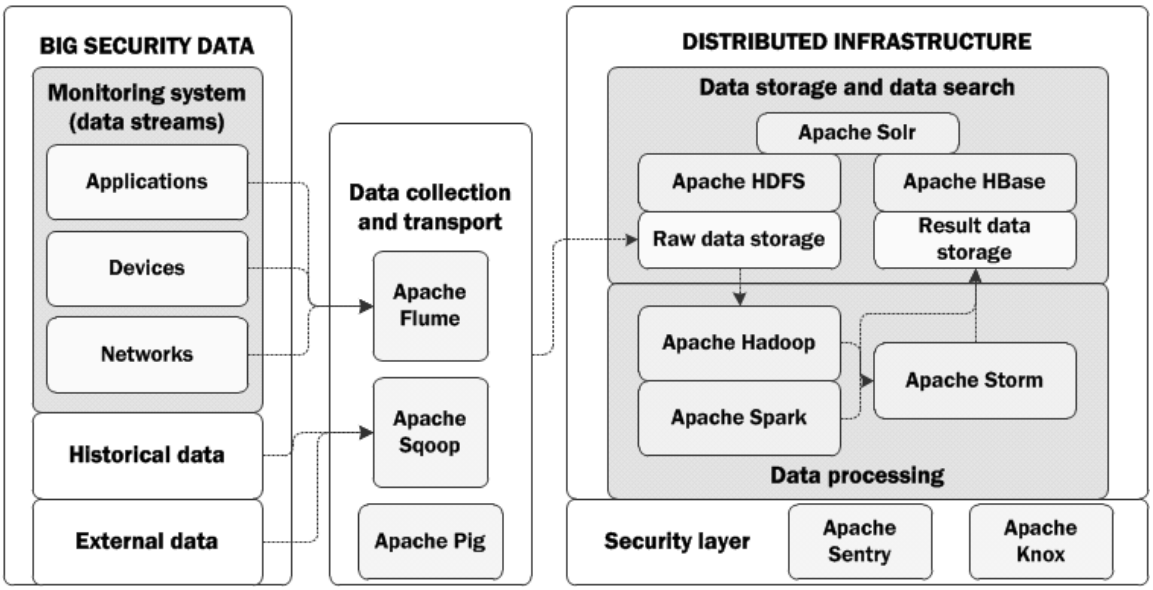

Fig. 1: Cyber security analytics model using distributed infrastructure with the Hadoop ecosystem

Data collection and transport component was proposed with the use of Apache Flume, a distributed, reliable, and available service for efficiently collecting, aggregating, and moving large amounts of log data, and Apache Sqoop, a tool designed for efficiently transferring bulk data between Hadoop and structured datastores such as relational databases. Apache Pig is a platform for analyzing large data sets that consists of a high-level language for expressing data analysis programs, coupled with infrastructure for evaluating these programs.

A distributed infrastructure was leveraged to develop a cost-effective storage. Distributed architecture may be implemented using cloud computing. With a large number of servers in a data center, a cloud infrastructure is a distributed system, which provides large data storage space and high computation facilities. The real-time monitored stream of data can be fed and stored in the storage server waiting for threat analysis and detection (Chen et al., 2016). For this purpose, as presented in Patrikakis et al. (2013), the OpenStack solution can be used, because, in contrast to VMware cloud and Microsoft's Hyper-V, it is free of charge, is also able to supports high availability of resources, as well as scalability and interoperability.

To conduct the cyber threats, the monitoring and threat information needs to be effectively collected and transmitted to the cloud for security analysis. Apache Hadoop and Spark-based data processing was used to improve data storage efficiency, speed up access to data, increase the efficiency of threat monitoring and detection, and eliminate operational delays concurrently. Since Spark has its own cluster management computation, it uses Hadoop for storage purpose only. Otherwise, instead of Apache Hadoop, Apache Storm was used as a free and open-source distributed real-time computation system. Storm makes it easy to reliably process unbounded streams of data, doing for real-time processing what Hadoop did for batch processing (Mazumder, 2016). Apache Hadoop File System (HDFS) was used as a raw data storage and Apache HBase was used a result data storage, where can be the results easily retrieved and used for detection and visualization purposes. Apache Solr is the open source platform for searches of data stored in HDFS in Hadoop.

Taken these components together, big security data can now be stored in a dedicated storage, which can

not only accommodate internal or external data but also combine and analyze real-time data together with historical data. As stated by Kambatla et al. (2014), since these analyses typically operate in closed systems (i.e. much of the data, infrastructure, and analyses are performed within the same security domain), issues of privacy and security in analyses are easier to handle. Therefore, a security layer with Apache Sentry and Apache Knox was proposed. Apache Sentry is a granular, role-based authorization module for Hadoop. Sentry provides the ability to control and enforce precise levels of privileges on data for authenticated users and applications on a Hadoop cluster. Sentry currently works out of the box with Apache Hive, Apache Solr, Impala, and HDFS (limited to Hive table data). The Apache Knox Gateway is a system that provides a single point of authentication and access for Hadoop components. Apache Sentry is then designed to be a pluggable authorization engine. It allows to define authorization rules to validate a user or application's access requests for Hadoop resources. Sentry is highly modular and can support authorization for a wide variety of data models in Hadoop.

Discussion and Future Research

Big data technologies are complex and evolving. They are needed to address many issues related to web, mobile, social, cloud, and big data analytics, as these continue to mature. Hadoop ecosystems are also evolving. However, despite the hype, Hadoop has had a rather slow acceptance rate. Spark, however, is rapidly dominating real-time parallel processing (Storey and Song, 2017). The proposed model took this into account and although the solution used both these platforms, Spark was preferred. On the other hand, there are also other big data analytics platforms, tools, and services that can be deployed, see Lněnička (2015) or Lnenicka and Komarkova (2015). Clarke (2016) stated that although the big data literature, academic as well as professional, has a very strong focus on opportunities, far less attention has been paid to the threats that arise from repurposing data, consolidating data from multiple sources, applying analytical tools to the resulting collections, drawing inferences, and acting on them. Therefore, the conceptual model considered the existence of historical as well as external data through their lifecycle phases ensuring that the whole process is designed to combat cybersecurity threats.

Aradau and Blanke (2015) also claimed that while critical scholars have drawn attention to the social, political, and legal challenges to these practices, the debates in computer and information science have received less analytical attention, hence, they developed a critical intervention into the public controversies concerning data-driven security and digital surveillance. A key component to arriving at a robust security architecture for a distributed system is to understand the threats that are likely to be present, and to be able to categorize them to better understand what security mechanisms need to be in place to help mitigate those threats (Spivey and Echeverria, 2015).

Future research will be focused on the implementation of this model. The main purpose will be to show the practical applicability of the components defined in the new model solution. There have been several MapReduce and Hadoop based algorithms implemented to monitor network traffic such as Lee and Lee (2013), Liu et al. (2014) or Narang et al. (2014).

Conclusion

Big data analytics for cybersecurity is an emerging area that requires extensive new research. The comprehensive literature survey reported in this paper has identified the lack of research in some areas. A new conceptual model offering high storage capacity, flexible deployment, more computation resources, and less expensive infrastructure investment was proposed to deal with the cybersecurity threats involving big data analytics in the Hadoop ecosystem. Finally, the issue of cybersecurity in the emerging big data technology space needs to be supplemented by the understanding of how kinds of data are produced through their lifecycle. The proposed threat monitoring and detection model can effectively collect, store, and process big security data in real-time as data streams as well as historical data.

Abstract

The key for conducting reliable ex-ante and ex-post governmental policy analysis relies on the accessibility to relevant and accurate databases, which becomes a must for the government institutions in order to take informed decisions and assess the impact of the past macro-economic policies. Thus, in this paper we develop a solution for dealing with these issues by adopting a comprehensive set of identity management maintenance steps, including data governance, data migration and unified reporting mechanisms. Because analysis cross-government database system is such a resource intensive task, continuous data maintenance identity management is a must. This is achieved via program governance specific activities that should not change when there are changes at political level. The data maintenance process should be continuous and should have the objective of insuring that the links between relevant systems are kept. Moreover, having a good identity management practice gives the benefit of offering personalized government services to the population.

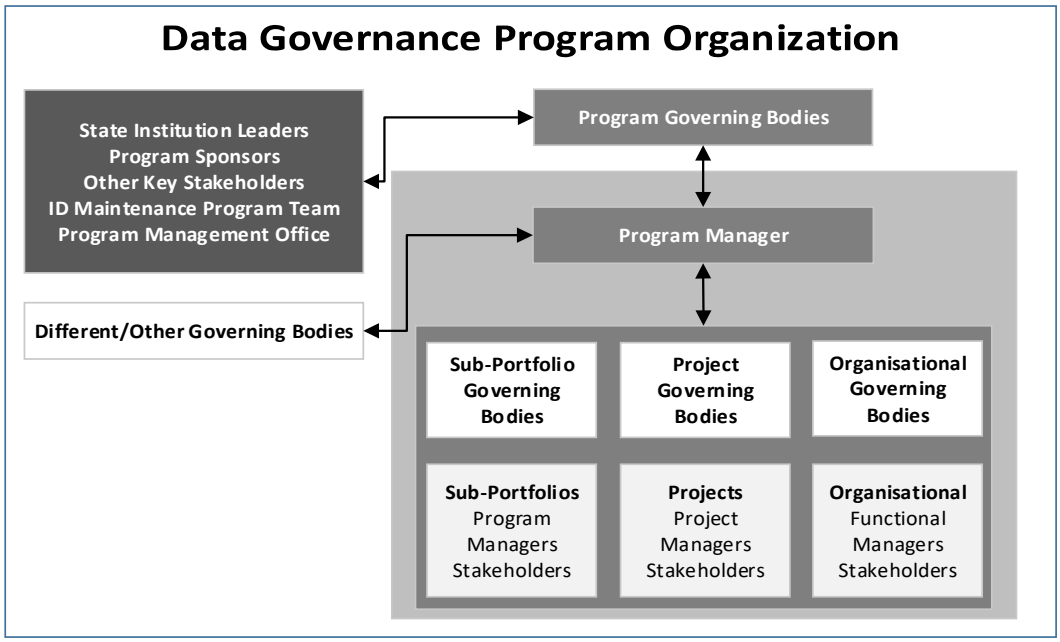
Keywords: *identity management, maintenance, data governance program, government policy*

Introduction

One for the main objectives of all governments is taking measures in reducing unemployment and making sure that most of the available workforce in the country is engaged in taxable activities. In order to achieve those objectives there is a constant need for relevant and accurate data that will enable the government institutions to both take informed decisions and to measure the impact of the past macro-economic policies.

However, when it comes to informed decision making, especially inside state owned agencies, there is often the issue of having to deal with databases and systems that are either incompatible, unsynchronized, un-linked or all of the above taken together. Moreover, there is a known reticence between agencies to collaborate with each other for various reasons. The fact that most of the state institutions have their own budgets and autonomy to implement the IT systems they see fit, without having to synchronize with other possible involved parties (like other ministries or congruent agencies that are having activities in intersecting or same fields) only complicates the matter at a macroeconomic policy level (see, among others, Roman and Popescu, 2015; Pirciog et al., 2015; Militaru, 2015, Avram et al., 2013).

This is why, the main purpose of this paper consists in presenting a solution for dealing with these issues by adopting a *comprehensive set of identity management maintenance steps, including data governance,*



data migration and unified reporting mechanisms so that the decision makers can, in fact, have some sort of reliable datasets about the population and the impact of ex-ante and ex-post measures taken.

The proposed comprehensive set of identity management maintenance steps will be presented further below, by considering the logical data flow from recurrent and continuous data governance activities to data management practices and reporting mechanisms. Thus, the structure of the paper is the following: section 2 is dedicated to the cross-project (nation-wide program) data governance flow, while the data migration / transformation flow will be presented in section 3. Section 4 describes the reporting and data analysis process, while the last section concludes.

The Data Governance Flow

The reason that it always comes to data program wide governance practices is the fact that state IT systems are usually very vast and will be in a constant state of change. This means that if one needs to have a good overview over individual identities (companies, persons, employees, etc.) with data spread across multiple IT systems, one needs to make sure that this data is always aligned as per agreed principles.

So as to meet governmental strategic and operational goals in the field of maintenance of identity (ID) management, the government agencies should implement nation-wide data governance programs. This higher function should be established so as to provide control over high level data management tasks. At program level, the governance functions and processes are very distinct from the usual functional management activities (e.g. projects taken at the individual level, non-project work related activities and eventual subprograms) (see fig. 1).

Source: authors' adaptation from PMI (2016). *Governance of Portfolios, Programs and Projects: A Practice Guide,* Newtown Square, PA: Project Management Institute

Fig. 1: Data Governance Program Organization

Data governance at program level should focus on decision making guidelines for general ID management tasks so that it can deliver the value needed to meet national strategic and operational goals – like lowering the unemployment rate by a targeted margin. This is very important at the macro-economic level, as the results can be in turn used not only to estimate and measure but also for publicity and image purposes in future election campaign activities.

As defined by the PMI (2013) a program is "a group of related projects, subprograms and program activities that are managed in a coordinated way to obtain benefits not available from managing them individually. Data governance programs comprise various components, primarily subprograms and individual projects within the program. Non-project components or program activities are needed to manage the program itself such as training, operations, and maintenance."

The "program governance" refers to the sum of the elements that comprise the governance activity, each having functions, processes and sub-programs (including implementation projects). The governance function means, basically, grouping processes related to each other and across governance domains in order to support the portfolios, the programs and the projects that the government wants to implement.

All of these functions are structured as control, integration, oversight and decision making activities.
The reason why the data governance activity is to be taken into account is that one needs some sort of overseeing body to manage cross-organizational identity data (in our specific case a program will always be meant to obtain a unified view over data related to entire classes active populations). In this way there is always a degree of control over what is happening at cross platform level and integration between databases and systems remains feasible over long periods of time.

The Data Migration / Transformation Flow

In the process of maintenance identity management over a multitude of very large, national, state-wide systems, the normalization is a very complex process with exponential business complications. This is due to the fact that different state agencies implement systems that best serve their particular interests (like social security, medical insurance, active teaching systems and requalification programs, military drafting, census specific databases, electronic voting counters, etc.) One can imagine that usually the data dimensions will never be easily comparable between those systems.

In the following sub-section we will present a general case study using as an example data migration and transformation practices with SAP legacy specific systems from multiple sources into one new unified destination.

The 6 Step Approach for Data Normalization and Migration

The data migration in complex identity management projects will usually follow several steps that are most of the time repeating themselves. All data is usually stored into a common dedicated destination source (called form here on data warehouse DWH). Depending on the complexity of the task and the government objective, several other, intermediary steps can be added in-between. The list below describes the steps taken during the program in order to finalize the data migration process and reaching a unified data modelling and reporting process. Each step will be further on described in some high detail level.

- Data Readiness Evaluation
- Data Normalization
- Data Extraction
- Validating Techniques
- Data Transformation and Loading Process

- *Data Readiness Evaluation*

During the data preparation phase, there are a number of tasks that need to be done before real data migration takes place, activities like installation and configuration of the specific data normalization tools (in SAP case the Data Services tools), creation of the data migration design templates, SDS standards, and also the determination of the data objects in scope (for example all data related to income measurement). This has been captured in the data migration object list. Furthermore, in this phase the high level data migration and cleansing approach have to be clearly stated and delivered.

Installation and configuration of the SDS tools will be the data warehouse (DWH) responsible. The DWH team will be responsible for data templates and the finalizing of the data object list and the data migration along with the cleansing approach.

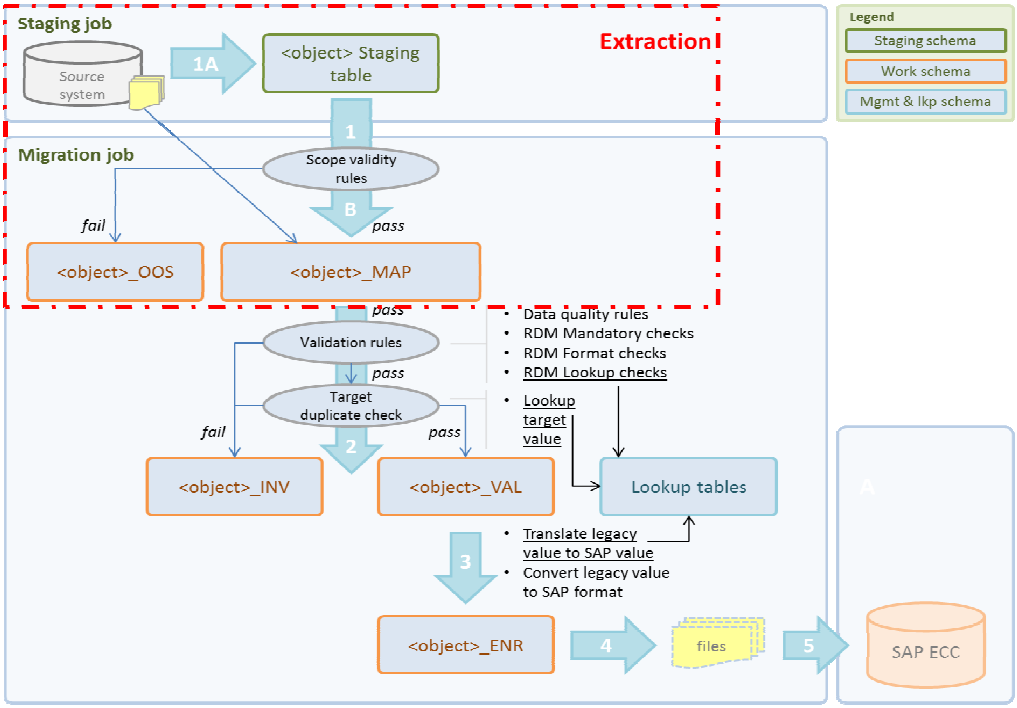
Table 1: Correspondence between activities, deliverables and responsible parties

Activity	***Deliverable***	***Party Responsible***
Create Functional Design	Functional Design Documentation	DWH owner
Create ETL document	ETL documentation	DWH owner/Implementation Program Team
Create Mapping Document	Data Mapping Documentation	DWH owner
Build data structure and content not available in the original systems	New data structures created	Implementation team

Source: authors own contribution

➢ *Data Normalization*

Data normalization is a repetitive task that will be done in close cooperation with the all related governmental agencies that have source data. The actual normalization should fall under the program implementer's activities. The DWH team will supervise the data cleaning process and even be involved in the program's governance.



Before the start of the data accuracy related tests the presumption is that the newly data placed in the DWH is 100% clean. Therefore verifications and normalization of data process is iterative until the data is accepted as being fully cleaned so it can be used for Identity Management analysis. In some countries, where data access can be done only by the government agencies themselves Identity Management and Maintenance is not even relevant since the population will never access these source systems and do interrogations or ask for online services according to their level (like printing the tax return forms, or asking for online reports on their personal financial statements and at-level taxation levels).

➢ *Data Extraction (from source systems) and Validating Techniques*

Usually there are 2 sub-steps to be considered at this level:

Step 1 (in the picture presented below) is the extraction of relevant (raw) data from the source systems and store them in the staging tables in DWH. In this first step there is no specific logic, however, the data will be taken over from the source system in a 1:1 ratio. When the data gets extracted from the source system there is a **Step 2** in the extraction process where all the validation will take place and the data will be stored in two kinds of tables:

1) _ERR tables containing data from the staging tables that does not comply with the validity rules
2) _MAP tables containing data from the staging tables that passed the validity rules and can now be used for reporting and analysis.

Source: authors own contribution

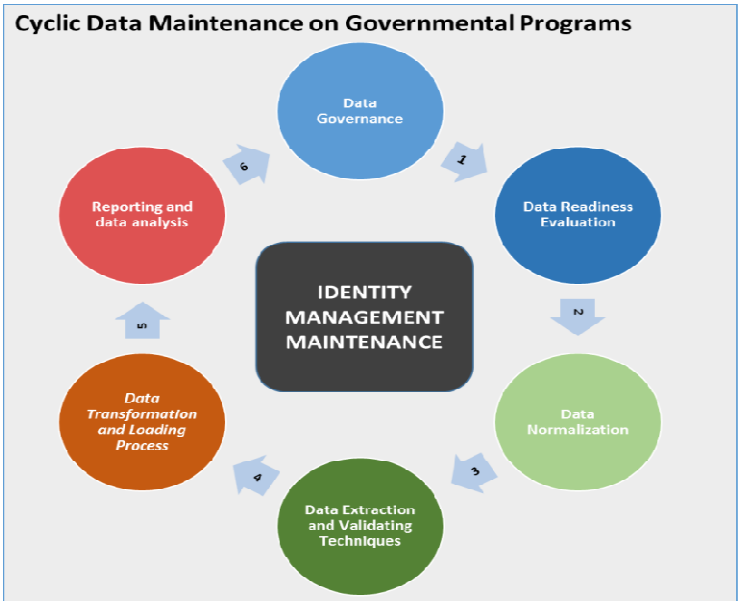
Fig. 2 : Extraction process from multiple source systems

➢ *Data Transformation and Loading Process*

The data transformation represents data enrichment, normalization and aggregation. It is a crucial step that will basically bring the data from several sources to a level that can be used in analysis, reporting and decision making. It is described in fig. 2 being associated with steps 4 and 5.

Reporting and Data Analysis

Having now all the Identity data with all the needed attributes linked to it, deep analysis activities can be performed by state institutes regarding aspects and patterns observed on the active population. Nationwide measures can be now taken using extensive unified reporting mechanisms that will try to help in the decision making process, implementation of combating poverty (see Avram and Militaru, 2016) and income inequalities (see Popescu and Militaru, 2017), coaching and educational initiatives across entire classes of individuals (Roman and Popescu, 2015) and so on.



There is however an aspect that is often neglected and this is the *reporting process of the maintenance of ID management itself*, not the reporting on the impact and results of the governmental measures. With having controls implemented over the data, we propose a fully cyclic view that will close the circle and restart the entire process over and over. Of course that over the years, the data requirements will change, while more and more information will be needed to be linked to an identity.

This means that with every cycle, during the governance phase, additional analysis and decisions need to be considered so as to meet the newly formulated requirements and challenges. This is achieved by implanting general metrics that will give an indication on how and what needs to be done and will show the current situation in regards to the entire set of data.

The scope of the article is not to go into detail over how data status is to be reported on but as a program management recommendation we can give the following fields where special attention needs to be given:

- **Time needed to both get and analyze the data** – For each system an allocated time needs to be put forward. This should include data analysis, transformation and loading.
- **Data cost** – This includes monetary values of both man-hours and other resources needed to get the needed data sets but also hardware and software costs, legal fees and so on.
- **Data quality (DQ)** – On this we propose that a comprehensive set of metrics need to be taken into consideration that will reflect correctly the DQ status during all phases of the program
- **Actions Needed** – This included not only the decisions taken but also the time by which then need to be implemented, the responsible parties, the controlling entities and a detailed step-by-step description that will lead to the materialization of the objectives

We propose that these points can be followed by using a combination of good practices and specialized tools like SAS and SAP reporting tools (see, for instance, Eslinger, 2016).

Fig. 3: The Data Maintenance Cycle

Conclusions

Because analysis cross-government database system is such a resource intensive task, continuous data maintenance identity management is a must. This is achieved via program governance specific activities that should not change when there are changes at political level. The data maintenance process should be

continuous and should have the objective of keeping the links between systems (unified keys, data transformation rules, relevant reports) always relevant.

Moreover, if this is achieved, then personalized government services to the population can be offered since reaching and maintaining data unification cross systems will enable the population to log into the state systems from exposed interfaces and use their private IDs to perform various tasks like paying taxes online, filing complaints over the internet, checking tax situation from their mobile telephones, etc. Moreover, all these activities can be linked to specific persons, along with their other relevant data and based on these electronic identities, the government can take active measures, implement various programs, verify the results, launch internet campaigns and, in the end, help their citizens by taking informed decisions.

Abstract

This research plays a role to comprehend the attitude and behavior of Pakistani consumers towards online grocery shopping. It helps to identify factors (Product/service quality, Product guarantee, Convenience, Product/service cost, Product varieties, Perceived risk, Social norms and Website design) that can influence customers to switch to online grocery shopping and adopt online shopping as their prime mode of purchase. Findings indicate that high perceived risk is the most important and significant factor as compared to all other factors. Consumers who are less familiar with technological devices, find it difficult to trust today's technology, which includes, domestic housewives. Whereas young generation is relatively excited about the emerging medium. Purposive and snowball sampling techniques were used collect the data using questionnaires. The results show that lack of variety and overpriced products also appeared to be the major factor when choosing online grocery as the prime source of shopping. This research not only finds out the existing online shopping trends and perception of people towards online grocery but also provides an insight into the future scope of online grocery shopping in Pakistan.

Keywords: Online grocery, Karachi, Pakistan, future scope of online shopping, attitude and behavior, online grocery awareness

Introduction

Internet plays an important role in connecting to information and people. It has significantly helped shortening the distance between people and their prospects, hence given birth to online services and ventures. Online shopping is trending in the world giving increased output every year. Virtual marketplaces are catering to all kinds of consumer needs be the needs be tangible or intangible, standardized or general and durable or perishable (Datamonitor, 2010). Computer appliances, books and accessories lead the market share for online shopping being the standardized goods. Whereas products like groceries are still struggling to attain popularity among online consumers (Grewal, Iyer, Levy, & Michael, 2004).

Grocery products are the edible commodities that are bought from supermarkets on the continuous basis, usually at regular intervals of time. Traditionally, groceries are bought in set-up where the consumer can

inspect the product before buying (Klein, 1998). The sense of touch, smell and sight directly effects buying decision of consumer. Also, the marketplaces are not limited to the perishable products but also accommodate durable eatables (such as canned and packet food) and non-food goods such as household appliances (Schuster & Sporn, 1998). Hence, grocery shopping becomes an actual expedition where physical activity is undertaken and strong senses help determine the choice.

Online grocery shopping looks promising when compared to other products available online but it faces rather different challenges of its own for its buyer as well as sellers. Benefit of doubt increases where a buyer takes sensory attributes involved in the traditional process. Also, delivery/transportation of fragile items become a delicate problem. In some cases, the buyer is just not interested to leave their deep-rooted shopping habits and switch to new ones; regardless of how much of their time and money is saved. It is crucial to explain the variables that influence buyers towards the purchase of grocery products online (Liao & Cheung, 2001).

It is important to note that online shopping takes more than just the desire to act. Although it does not involve traveling, carrying heavy weight or work-hour restriction, the presence of certain resources is mandatory that make the transaction possible (Chu, Arce-Urriza, Cebollada-Calvo, & Chintagunta, 2010). Thus it is important for buyers to be well equipped and aware of the technicalities of online shopping so that their experience is without any hindrance (Shim et al., 2001). Individuality of each potential customer also plays an important role in defining sales. A person with more internet exposure will tend to shop more than the person who has less experience with internet (Frambach, Roest, & Krishnan, 2007).

There is a lot of potential for online grocery trade as Generation Y and their predecessors use technology frequently to save time and seek convenience as compared to the previous generations who are accustomed to buying groceries from brick and mortar stores. The grocery shoppers of new age are identified as better educated and risk taking individuals who try new things and opt for easier solution to problems. From the research related to internet usage of people, findings conclude that complex decision making of consumers is based on social cognition of individuals.

This research aims to identify the factors that are important to increase the adoption of online grocery, what consumers want from a grocery store and what are their current attitudes towards the concept. Furthermore, the research aims to identify the pain points of consumers that need to be catered in order to increase the adaptability of online grocery shopping.

E-commerce has greatly evolved over the past few years, creating differentiation between the leaders and laggards in most industries. The worldwide expansion of the internet has resulted in the transformation of the e-commerce market. E-commerce statistics state that 40 percent of worldwide internet users have bought products or goods online via desktop, mobile phone, tablet or other online devices (Statistica, 2014). As per Express tribune, (2014), the e-commerce industry is booming throughout the Asian region, with India leading the e-commerce websites. Pakistan, although a late entrant to the world of e-commerce, has recorded a massive rise in online shopping trends and other e-commerce businesses. Pakistan's e-commerce market is expected to surpass $1 billion in five years. Currently valued at over $60 million, the country's e-commerce sector is doubling in size every year i.e. it is growing at a compound annual growth rate (CAGR) of over 100%.

The market share of online grocery in Pakistan is around $25 million (Arshad, 2015). Pakistan's e-commerce market is expected to reach over US$600 million by 2017 (Ahmad, 2015). To further facilitate the adoption of online grocery, analysis of consumer needs and their behavior is crucial. The study layouts consumer perception and readiness towards online grocery shopping. It further highlights the pain points that are need to be eradicated in order to increase the rate of acceptance of this new medium.

Literature Review

Researchers have worked a lot on online grocery, how consumer adopts a new buying behavior and what compels them to change their behavior. One such research group is Hartman. According to Hartman, (2015), the attempt of selling grocery online in 1990's appeared to be failure but, now online shopping is taking over the shift. Unquestionably, consumers are now more interested in buying packaged goods that can be stored for days. This is also aiding the online grocery trend. The increasing scope of digital has got many brick and mortar stores worried for their digital presence as new digital players are taking away their consumer share of wallet and is making presence in the consumer mind. Many stores are now planning to enter into the digital era and create their presence online (Hartman Group, Forbes, 2015).

Hartman group, (2015) is of an opinion that, Brick & Mortar stores will not completely get off the market but few shoppers are getting over the conventional notion of doing grocery. Important point to ponder over is the idea that, will online grocery shopping become acceptable and provide share of wallet from good number of consumer? Hartman Group, (2015) report states that online grocery shopping helps early adopters save around 39% of their time, 36% of money and around 27% fuel.

In order to widen the scope online grocery need to focus on under stated areas:

- Target Households: young urbans and families
- Meet Underserved Needs: highlighting convenience
- Look for Cultural Hooks: try to get monthly subscriptions etc.

Online grocery shopping helps buyers eliminate the activity of physically visiting the stores, providing convenience to get things delivered on a single click, no standing in long lines and no carrying of heavy bags. They also reduce unnecessary shopping habits and picking extra items while shopping in a store. It will quickly grab the attention of consumers who are procrastinators and are not fond of visiting the stores. While people who visit physical stores in terms of outing and for fun will still prefer brick and mortar stores. Unless, they find some super quick delivery or discounts or coupons or other order processing conveniences. However, considering the food culture it is evident that digital food will make its place and technology will help earn greater shares. (Hartman Group, Forbes, 2015).

Nielson group investigated five factors to know about online grocery shopping, which are:

1. Consumers love online grocery shopping but it will take them time to get comfortable with it. The supply side needs to make shopping experience easy by making user friendly interface of the web or app. It must be easy to navigate and provide time saving and efficient delivery service.
2. Online store should provide maximum number of listings and product options to choose from as it is different to buy online than offline. The e-store should have good number of packages and categories available.
3. Consumer perception and behavior while buying online is affected in various ways. It is important to provide an easy to use platform. Greater variety would help buyer choose and make comparisons.
4. Online shopping has greater transparency, price visibility, extensive distribution and customization available.
5. It is important to build proper marketing strategy to align your store with the best marketing strategies to increase interactions and link customers with your brand. Create excite, bring innovative ideas and build relationship on social media platforms along with spreading awareness.

Court, Elzinga, Mulder and Vetvik, (2009) researched about the process consumer goes through while making a decision. According to them, marketing has one goal**,** and it is to reach consumers at the moments that most influence their decisions. Marketing has always sought those moments, or touch points, when consumers are open to influence. For years, touch points have been understood through the metaphor of a "funnel" consumers

start with a number of potential brands in mind (the wide end of the funnel), marketing is then directed at them as they methodically reduce that number and move through the funnel, and at the end they emerge with the one brand they choose to purchase.

In modern times, the funnel concept fails to capture all the touch points and key buying factors resulting from the explosion of product choices and digital channels, coupled with the emergence of an increasingly well connected and well-informed consumer. The situation calls for a more sophisticated approach which is less linear and more complicated than the funnel suggests to help marketers navigate in these complex times. The new approach is called *consumer decision journey.* This concept is applicable to any geographic market that has different kinds of media, Internet access, and wide product choice, including big cities in emerging markets (Court, Elzinga, Mulder and Vetvik, 2009).

This approach was developed by examining the purchase decisions of almost 20,000 consumers across five industries and three continents. The research showed that the proliferation of media and products requires marketers to find new ways to get their brands included in the initial consideration set that consumers develop as they begin their decision journey. It was also found that because of the shift away from one-way communication—from marketers to consumers—towards a two-way communication, marketers need a more systematic way to satisfy customer demands and manage word-of-mouth. In addition, the research identified two different types of customer loyalty, challenging companies to reinvigorate their loyalty programs and the way they manage the customer experience. Moreover, the research reinforced the general belief in the importance not only of aligning all elements of marketing—strategy, spending, channel management, and message—with the journey that consumers undertake when they make purchasing decisions but also of integrating those elements across the organization. When marketers understand this journey and direct their spending and messaging to the moments of maximum influence, they stand a much greater chance of reaching consumers in the right place at the right time with the right message (Court, Elzinga, Mulder and Vetvik, 2009).

The new model by Court, Elzinga, Mulder and Vetvik, (2009) suggests that the decision-making process is a more circular journey, with four primary phases representing potential battlegrounds where marketers can win or lose: initial consideration; active evaluation, or the process of researching potential purchases; closure, when consumers buy brands; and post purchase, when consumers experience them. The qualitative part of the research, consumers told us that the fragmenting of media and the proliferation of products have actually made them reduce the number of brands they consider at the outset. Faced with a plethora of choices and communications, consumers tend to fall back on the limited set of brands that have made it through the wilderness of messages. Brand awareness matters: brands in the initial-consideration set can be up to three times more likely to be purchased eventually than brands that aren't in it.

In today's decision journey, consumer-driven marketing is increasingly important as customers seize control of the process and actively "pull" information helpful to them. The research found that two-thirds of the touch points during the active-evaluation phase involve consumer-driven marketing activities, such as Internet reviews and word-of-mouth recommendations from friends and family, as well as in-store interactions and recollections of past experiences. A third of the touch points involve company-driven marketing. Traditional marketing remains important, but the change in the way consumers make decisions means that marketers must move aggressively beyond purely push-style communication and learn to influence consumer-driven touch points, such as word-of-mouth and Internet information sites. When consumers reach a decision at the moment of purchase, the marketer's work has just begun: the post purchase experience shapes their opinion for every subsequent decision in the category, so the journey is an ongoing cycle (Court, Elzinga, Mulder and Vetvik, 2009).

As mentioned earlier, the research also identified two kinds of loyalties. Of consumers who profess loyalty to a brand, some are active loyalists, who not only stick with it but also recommend it. Others are passive loyalists who, whether from laziness or confusion caused by the dizzying array of choices, stay with a brand without being committed to it. Despite their claims of allegiance, passive consumers are open to messages from competitors who give them a reason to switch. All marketers should make expanding the base of active loyalists a priority, and to

do so they must focus their spending on the new touch points. That will require entirely new marketing efforts, not just investments in Internet sites and efforts to drive word-of-mouth or a renewed commitment to customer satisfaction (Court, Elzinga, Mulder and Vetvik, 2009).

Developing a deep knowledge of how consumers make decisions is the first step. For most marketers, the difficult part is focusing strategies and spending on the most influential touch points. In some cases, the marketing effort's direction must change, perhaps from focusing brand advertising on the initial-consideration phase to developing Internet properties that help consumers gain a better understanding of the brand when they actively evaluate it. Other marketers may need to retool their loyalty programs by focusing on active rather than passive loyalists or to spend money on in-store activities or word-of-mouth programs. The increasing complexity of the consumer decision journey will force virtually all companies to adopt new ways of measuring consumer attitudes, brand performance, and the effectiveness of marketing expenditures across the whole process.

Four kinds of activities can help marketers address the new realities of the consumer decision journey.

- Prioritize objectives and spending
- Tailor messaging
- Invest in consumer-driven marketing
- Win the in-store battle

In many companies, different parts of the organization undertake specific customer-facing activities—including informational Web sites, PR, and loyalty programs. A number of executives are responsible for each element, and they don't coordinate their work or even communicate. These activities must be integrated and given appropriate leadership.

But the full scope of the consumer decision journey goes beyond the traditional role of CMOs, who in many companies focus on brand building, advertisements, and perhaps market research. These responsibilities aren't going away. What's now required of CMOs is a broader role that realigns marketing with the current realities of consumer decision making, intensifies efforts to shape the public profiles of companies, and builds new marketing capabilities.
Marketers have long been aware of profound changes in the way consumers research and buy products. Yet a failure to change the focus of marketing to match that evolution has undermined the core goal of reaching customers at the moments that most influence their purchases.

Hansen conducted a research on to investigate whether consumers who have adopted online grocery buying perceive this way of shopping differently from other online consumers. The study investigated whether already established online grocery buyers can be discriminated from other internet users or not? For this purpose data were collected from an online (web-based) survey of US consumers using self-administered questionnaires.

Hansen, (2005) elucidated 3 types of innovation a) discontinuous innovation b) dynamically continuous innovation c) continuous innovation. Online buying represents a discontinuous innovation as it includes technological advances as well as changes in consumer behavior. In order to understand the diffusion of such innovations, how such innovation is adopted is crucial to understand.

Rogers suggests five factors that increase the rate of acceptance and diffusion of innovations:

1. **Communicability** is the ease with which the innovation can be observed or communicated among potential adopters.
2. **Triability or divisibility** refers to the possibility of trying the innovation without huge investments
3. **Complexity** refers to the potential adopter's perceived complexity of the innovation or of using the innovation.

4. **Compatibility** is the degree to which the innovation is consistent with existing values and past behavior.
5. **Relative advantage** is the degree to which consumers perceive the innovation as superior to existing alternatives.

In addition to this, **perceived internet grocery buying risk** should also complement stated 5 factors by Rogers. To investigate the ability of these factors to discriminate between various types of consumer adoption behavior three online consumer segments were considered.

a. **Segment 1:** non-adopters of online shopping
b. **Segment 2:** online shopping adopters (excluding groceries)
c. **Segment 3:** online shopping adopters and online grocery-shopping adopters

Analysis of the research suggests that consumers who have adopted online grocery buying attach higher compatibility, higher relative advantage, more positive social norms, and lower complexity to online grocery shopping when compared with consumers who have never bought anything on the internet yet and consumers who have purchased goods/services on the internet but not groceries. The results also suggested that household income per year is higher among online grocery adopters than among non-adopters (Hansen, 2005).

Hansen, (2005) suggested that online grocery retailers should adapt themselves to the daily life of consumers. Consumers should not be expected to compromise their existing shopping needs and habits in order to carry out online grocery shopping. Online retailers should also make sure that online grocery shopping is easy to understand. They should market the relative advantages of online grocery shopping (possibilities for saving time and money) to the entire household.

Conceptual Framework

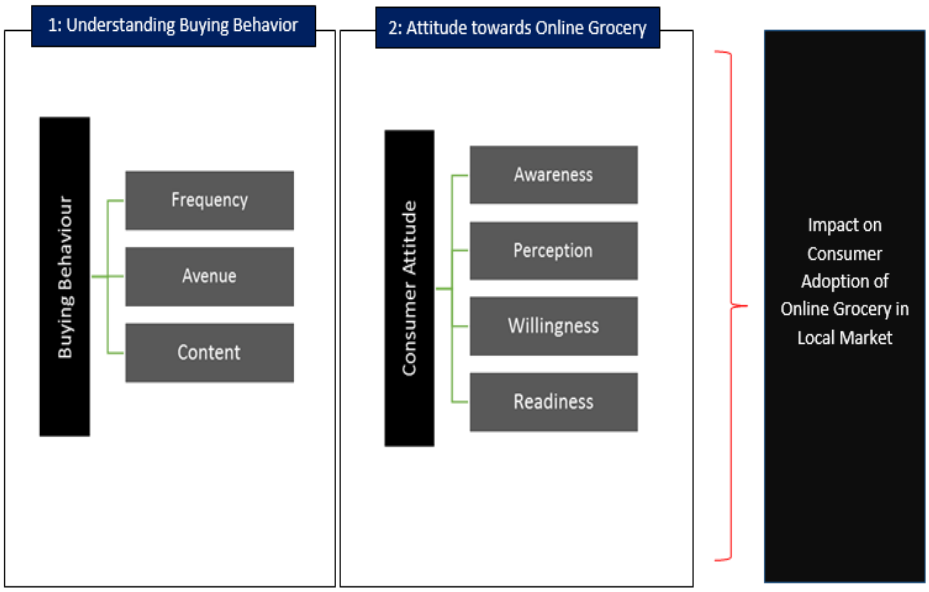

Figure 1 : Conceptual Framework - Online Grocery Shopping

The conceptual framework, studies the impact that the pre-established buying behaviors have over the attitude towards online grocery buying. Both; the buying behaviors of grocery shopping and the attitude towards grocery shopping; are further analyzed through few factors which are discussed in the following section:

The conceptual framework initially studies generic buying behavior of a consumer towards buying grocery. The intention is to analyze whether the current buying behaviors of local consumers are deeply rooted or not? In an actual market setting, the factors and behaviors associated with buying grocery are immense. However, in order to narrow down our research to focus on few significant behaviors we intend to study three main factors associated with buying grocery, which are as follow;

- **Frequency:** Frequency refers to the number of visits done to a grocery shop in a said time period. For instance - daily visits, weekly visits, bi-monthly visits or monthly visits.

- **Avenue:** Avenue refers to the situational context of a grocery store. We intend to study what a consumer prefers in terms of size and location of the store. Is a local consumer satisfied going to a small general store to buy groceries, situated at the end of his street? Or does he prefer to visit super stores and does not mind taking out his car for that?

- **Content:** Content refers to the things that make on a consumer's grocery lists and are purchased on a regular basis.

- As mentioned above, the conceptual framework intends to gauge the extent to which the buying behaviors towards grocery shopping are rooted in our local consumers. The higher the frequency, the higher the acceptance towards different grocery avenues and higher the list of items purchased – would translate into deeply rooted buying behaviors which are hard to overcome since they come naturally to consumers.

The given state of buying behavior and the established extent of its strength has a direct impact on a consumer's attitude towards online grocery, which is the second part of our conceptual framework. The four primary factors which can be studied in order to gauge the consumer attitude towards online grocery are as follow;

- **Awareness:** Are the local consumers even aware of such a concept of buying groceries online?
- **Perception:** How do the local consumers perceive online grocery?
- **Willingness:** Are the local consumers willing to try online grocery?
- **Readiness:** On what readiness stage are the local consumers on in terms of online grocery buying? (Buying Readiness Stages: Awareness, Interest, Desire and Action)

Attitude towards online grocery buying can be said positive if the aforementioned four factors are high/positive. Which means for an attitude to be positive a local consumer should have acceptable levels of awareness, positive perception, and positive willingness and should be at least interested in doing groceries online.

Since the concept of online grocery is of novel nature in local market - thus, online grocery model can only be adopted by local consumers if attitude towards online grocery is positive and it does not adversely interplay with the pre-established grocery buying behaviors (Ali et al., 2017).

Methodology

The purpose of the study is to identify the factors that have an impact on adoption of online grocery as their prime shopping mode and to know the behavior of Pakistani consumers towards online grocery shopping. The research targets the sample population of consumers drawn from Karachi who have or do not have any previous experience of online grocery shopping.

Sample size for the study was 90 individuals and it employed purposive and snowball sampling techniques to get data from the respondents who were best suited for the research at hand. Data was collected primarily using questionnaire technique. The research questionnaire caters to five section of questions designed to know different aspects of consumer behavior. Section one includes questions related to demographic profile of respondents such as gender, age, relationship status, education etc. Section two consists of questions that relate to general online shopping and awareness of online grocery and grocery stores in Pakistan. Section three focuses on questions regarding their perception towards online grocery, their willingness to buy and the factors that refrains them to buy online grocery. Section four consist of Likert scale questions to assists in knowing the opinion of people regarding online grocery shopping, their preferences and value proposition they are looking for. Sections five consist of questions that gauge consumer readiness towards online grocery shopping.

We distributed our questionnaire to respondents who are aged 18 years or above. The questionnaires were further divided into 3 target markets.

A) Domestic household consumers
B) Professionals

In process of our research we identified a new target market and included it as part of our research i.e. lives alone, Students and young professionals who live alone in Karachi.

Research Questions

1. What is the current understanding of online grocery in Pakistan?
2. What is the general attitude of consumer towards online grocery?
3. What factors are important to increase the adoption of online grocery?
4. What value a consumer wants an online grocery store to offer?

Hypotheses

H_1: Local consumers are not aware of online grocery shopping in local market

H_2: Local consumers don't have positive perception towards online grocery shopping in local market

H3: Local consumers are not willing to experience online grocery shopping in local market

H_4: Local consumers are not ready to adopt online grocery shopping in local market

Analysis and Discussion

The internet phenomenon is providing a new mode to do business in Pakistan. With E-commerce expected to become a $1 Billion industry by 2020 (Tribune, 2015), the future outlook is bright with immense potential in all areas for this yet untapped market of 200 Million people of Pakistan. This massive transformation is leading a behavioral change in consumers as to how they shop for products and services across the board ranging from grocery items to automobiles. The focus of this paper will be on grocery products.

On our fact finding journey, we further conducted a thorough research and survey analyses pertaining to the Pakistani market. The idea was to understand the different consumer perspectives as to how they view the online grocery model in Pakistan. For the purpose of simplicity we have categorized the respondents into three groups which are as follows:

1) **Domestics:** This segment is comprised of the local households of Karachi including both men and women. Traditionally women in domestics lead all the major purchase decisions for their households and have deep rooted cultural preferences as to what and where to buy from. It is a planned purchase for them, which occurs on a monthly basis, mostly at super markets and large retailers. Although they share the same touch point as professional women but are slightly more complex in their selection of products. An important aspect is their lack of awareness for the online model coupled with their ability to access computers and doubts about online buying of goods. For them, understanding of the model and addressing their fears is the first step towards their road to online shopping. Simple questions ranging from the time taken to deliver goods to the quality of the products supplied need to be promoted through well advocated channels. Furthermore the responses also uncovered that the use of single products in the initial phase to encourage trials.

2) **Professionals:** These respondents were women belonging to the age bracket of 20-29. For them grocery shopping is an experience which they enjoy; particularly if it involves going to the supermarkets like Naheed or Aghas. They make informed and planned purchase decisions unlike the live alone. For them, variety is important and becomes an important factor in choosing the shopping venue as well. Despite low awareness to the online model, 53% of the respondents favored towards giving the online model a try. This reflects that the segment does have a potential but needs to be pitched across the right touch points. Again, to tap this segment we need to align the product simultaneously on convenience and variety which will in turn be a determinant of how

price sensitive they (professionals) become to that offering. But one obstacle identified in the responses was the physical inspection of the product, the answer to which lies in '360 degree' display of products on the webpage along with clear photography to make the products vivid and more observable to the users. Factors like quick delivery, promotional offers and discounts coupled with authentic brand portfolio is what they are looking for. However despite the odds, the working women are willing to pay 5-8% premium if they are able to get the right product at the right moment. Bundle offers from multiple brands under one roof, can again come in handy to attract such visitors over the website.

3) **Live Alones:** As the name suggests, this class of respondents are people who are living single-handedly for education or job purposes in Karachi. With more than 70% being male and falling in the age bracket of 20-29, they have a high preference for home cooked meals and are the decision maker when it comes to grocery buying. Normally the 'live alones' don't have a planned purchasing pattern but they do make weekly purchases based on their need. Although only 20% of the respondents were familiar with the online model for grocery but willingness to try was higher, making them a viable target to pursue. Being a highly price sensitive audience and significant preference for convenience, bundle offers is the ideal way to attract 'live alones' for online grocery shopping. By capitalizing on the need for convenience and properly positioning the offers to their budget, the 'live alones' can serve to be regular and loyal customers. The focus should be on how flexible the model can be for them in a time saving manner.

Strategic Findings

- Young people falling in the age group of 20-29 years of age are more likely to purchase online, while their older counterparts are less prone to shop for groceries online
- 72% respondents purchased groceries on monthly basis, while only 19% purchased on weekly basis and only 9% purchased on fortnightly basis
- 59% respondents did not feel the need to purchase anything after they had purchased for the entire month, while 41% did feel that there still was the need to shop for certain things even after their monthly purchase was done
- Only 10% respondents were used to purchase groceries online while 61% respondents said that they would try online grocery shopping in the near future. However, 75% respondents purchased groceries from the supermarkets (Figure - 3)
- When asked about the factors that influence purchase of groceries online, the respondents stated that online grocery shopping provided convenience of sitting at home or office and order the needed things without any hassle, while prices and variety were the second and third most important factor that influenced online purchase of groceries (Figure - 4). The respondents further elaborated that while purchasing online they were able to compare the rates and number and type of variants available on other online grocery shopping platforms which gave them an assurance that the purchase they were doing was worth their money
- The respondents stated that they avoid online grocery shopping because it lacks the element of physical examination by the buyer, and the chances of forgery is also present along with the possibility of security risk that the buyer's personal and financial information might be misused (Figure - 5)

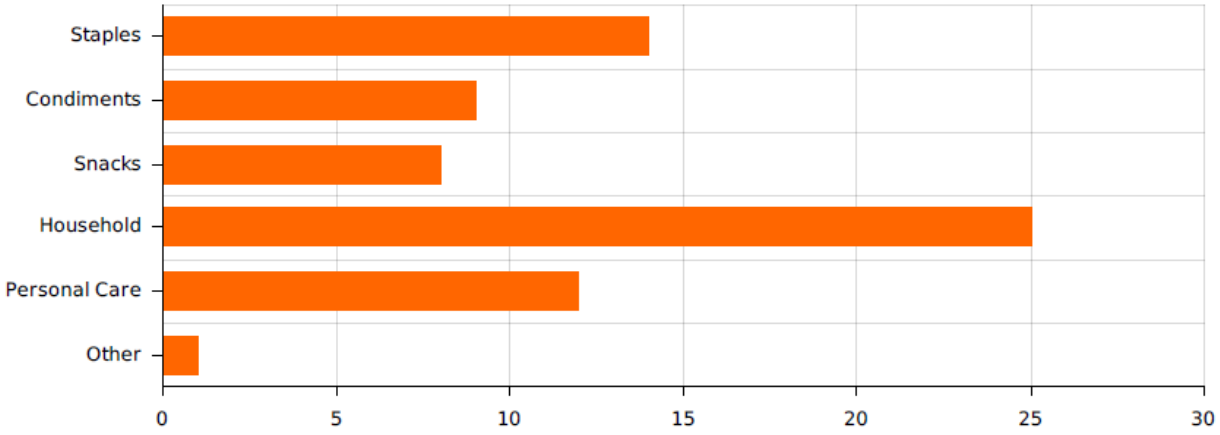

Figure 2: Purchase Items mostly bought in Groceries

Figure 3 : Typical Mediums of Shopping

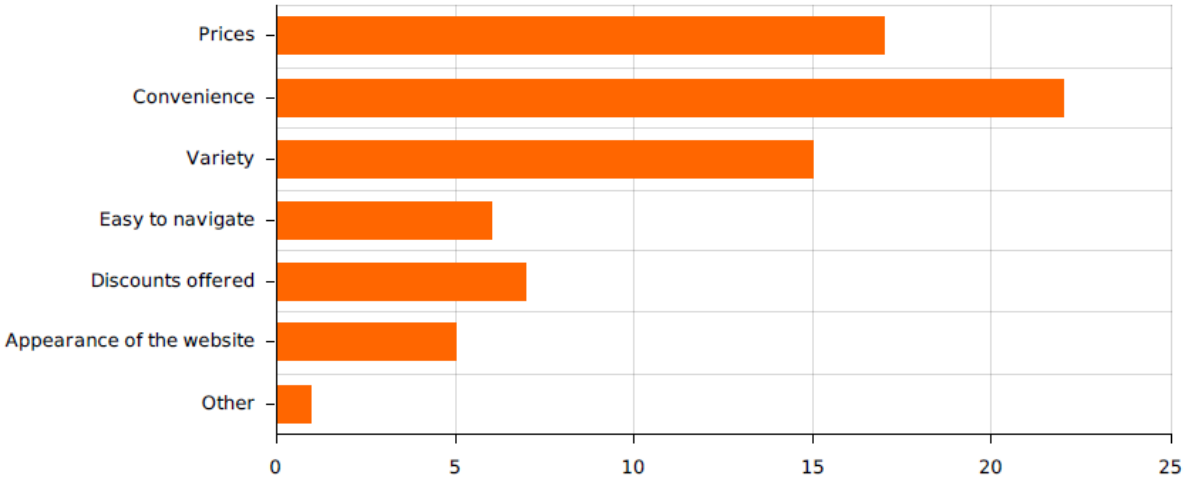

Figure 4: Factors Influencing Online Grocery Shopping

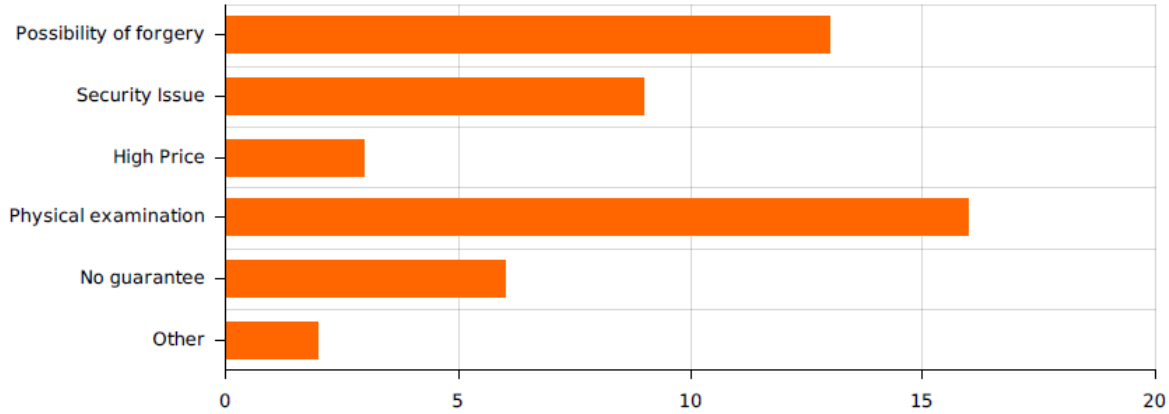

Figure 5 : Reasons for Avoiding Online Grocery Shopping

Conclusion and Recommendations

From the above analyses, it is clear that there is a long road to fully penetrate the market. Our analyses identified that there is a significant image problem for the online model, coherent across the three segments of respondents. Buying from retailers is a norm and disruption of any norm is not easy and nor is it always welcomed. Instead of positioning it as an alternative, we need to position the online grocery as something which can go hand in hand with the traditional model. The idea is to slowly encompass the user to accept the new way of shopping. Equally important is the fact as to how to create awareness amongst people. At the start we need to focus on users who will be the core drivers of growth for this industry like the live alone or professionals who actually can feel the need for this model.

The next step is to how relevant the offerings are to the audience. As correctly pointed out in the survey, respondents were unclear as to what products can they actually buy over the internet. This shows that there exist a gap in communication which need to be filled comprehensively so that the consumer expectations can be set at the right level. Equally important is the availability to house multiple brands.

Consumer have deep associations with brands and would want to buy only their favorite brands. This brand power can be used to encourage those consumers to shop online, who face shortage of authentic brands.

Last but the least is the intrinsic aspect of shopping. Pakistan is experiencing a dynamic shift from general trade to modern trade. By every passing time, bigger retailers are opening up like Naheed etc., which indicates the new trend pertaining to the shopping experience. To cultivate a similar response we need to offer the consumers something equal in value. This value can vary across the three segments we have identified above. Each segment has its own needs and preferences and the best way is to have a step by step approach.

Integrated Assessment of Socio-Economic Differentiation: Cross-Country Comparison

Abstract

Severe structural maladjustments conditioned by the process of globalization, the effects of sanctions and the migration policy as well as a high degree of territorial differentiation throughout the world's economic space have become the essential features of the present-day global economy. Inequalities in the development of territories, the inconsistency of national and regional economies within the global socio-economic space, the common practice of setting strategic priorities without due consideration of the effects of globalization result in further growth of the spatial disparities in the levels of socio-economic maturity and living standards. Those factors and trends also lead to slack in the global economy in general and loss in competitiveness for national economies. It is obvious, that the dynamics of a number of indicators which would be representative of the quality of economic space requires thorough analysis. It would also provide a possibility to conduct a valid measurement of the degree of the differentiation among territories in the aspects of their socio-economic development and the standards of living and consider the ways of its regulation. The present research work engages some theoretical and empirical methods, the techniques of analysis and synthesis as well as the methods of mathematical modeling in economics for the basic socio-economic indicators of the development of territories.

Keywords: differentiation, inequality, socio-economic development, economic space, composite indicator, state regulation.

Introduction

Currently, the spatial transformations of Russian economy essentially involve systemic changes in the administrative and territorial structure of the country. Alongside with the processes of integration within the national economic space under way, there is an evident aggravation of the contradictions in the inter-budget relations and a growing economic disparity among the regions as well as a worsening downward course of interregional expansion and monopolization. As a consequence, a number of political and economic risks arise, which deteriorates the investment climate due to growing uncertainty in business. The enforcement of interregional competition for the funds available for investment, human resources, technologies and institutional assets is conflicting in nature; therefore, it requires careful scientific analysis as part of the study of the integration mechanism which engages all the entities within the national economic space.

At present, the main problem we face while assessing the level of socio-economic development of a region and the degree of differentiation among the regions is to select sets of primary indicators which would be representative of particular aspects in regional economic and social activities. Both Russian and foreign literature proposes various approaches to forming sets of valid primary indicators describing the degree of spatial differentiation.

A number of Russian and foreign economic scientists have addressed the issues of identification, measurement and regulation of disparities in the development of territories; in particular, foreign experience of state regulation of territorial differentiation is considered in the research works by A. Pigou, D. Bell, D. Miller, A. Swift, J. Poterba, S. Slesnick, D. Cutler, L. Katz, B. Meyer, D Sallivan, G. Becker, N. Thomes, Caporale, G.M. and Spagnolo, N. (Caporale & Spagnolo, 2012), Chen, J.-H. and Chen, Y. (Chen & Chen, 2015), Gehringer, A. (Gehringer, 2014) and some other authors.

Results and Discussion

The effects of interregional socio-economic differentiation are ambivalent, which is presented in Table 1.

Table 1: the effects of territorial economic differentiation on socio-economic development of a region

Favorable effects	Unfavorable effects
1. interregional economic inequality boosts most complete fulfillment of the potential of a particular region; 2. provides the possibility to enter into competition within the global economic system; 3. gives rise to highly developed regions with a great proportion of advanced industries and enterprises which become drivers to the growth of the country's economy and provide resources to support the lagging territories; 4. gives rise to clusters, areas of advanced development and special economic zones.	1. wide wealth disparity among the population; 2. growing maladjustments in the structure of the national economy; 3. emergence of struggling regions with a relatively low level of real incomes of the people, high unemployment, weak investment activity of the economic entities, insufficient fiscal capacity because of a low rate of self-sustainability of the region, etc. 4. redistribution of the federal financial resources (which are rather limited) to support the lagging regions.

The source: prepared by the author

The Russian Federation is the world's largest country in area (Table 2), so, as a consequence, territorial socio-economic differentiation has existed throughout history.

*as of 2016; ** as of 2015 and 2016

Socio-economic development of any country depends on the standards and the quality of living. The problems related to the performance of the economic system as well as to providing the adequate standards of living for all remain acute. Those challenges we have been facing are conditioned by a dramatic degree of differentiation throughout the global economic system in the context of territorial development. At that, in most countries the mobility of resources and technologies is pretty low (Vertakova et al., 2016).

Thus, the dynamics of the key indicators which are representative of the living standards in a number of countries requires careful analysis. Besides, the factors of the differentiation among the countries in the context of the standard of living as well as the main mechanisms which would facilitate the development of an effective social policy are to be considered. The literature presents various quantitative and qualitative approaches to measure the inequalities in living standards; most of them rest upon the indicators proposed by UN we will focus on in this study.

The Gini coefficient (or a normalized Gini index) represents the degree of inequality in the actual distribution of the cumulative income (or consumption) of the nation's population. It may vary from zero to one (or 0% to 100%); the higher the value, the more severe the inequality of income and wealth is.

However the use of Gini coefficient as a measure of actual income inequality has some limitations. Its strengths and weak points are presented in Figure 1.

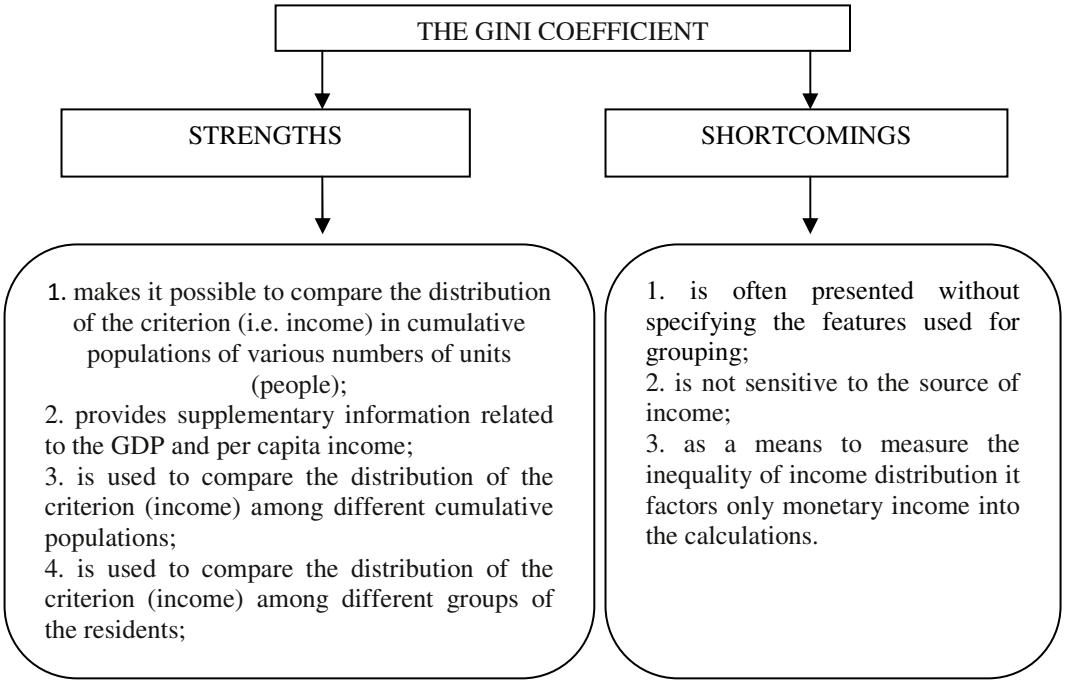

Fig. 1 The Gini coefficient

The ranking of the countries according to the values of the index of income concentration (the Gini coefficient) in dynamics over years 2000, 2005 and the period of 2010-2015 is presented in Table 3.

The data analysis shows that since 2011 the 1-st position in the ranking of the countries has been occupied by the South African Republic, where the Gini coefficient was 63,1% in 2011 (63,4% in 2015). However, compared to year 2013, when the coefficient value reached its maximum of 65%, it tends to decline. In 2015 Brazil, Chile, Mexico, Bolivia, Macedonia, Nigeria, the Philippines, Israel, Angola became the top ten leading countries. Russia was ranked 14 (41,3%), standing down China (42,1%), but

outstripping the USA (41,1%). For Russia, the coefficient value also tends to decline, although slightly, compared to 2010 when it reached 42,1%.

The source: prepared by the authors according to the data provided by Russian Federal State Statistics Service

Among the socio-economic indicators the Human Development Index (HDI), which is commonly viewed as an index of "potential human development" (PHDI), is deemed particularly representative of the actual level of socio-economic development of a country (or a region). It is a composite statistic which reports not only mere economic advancement, but also the social environment for human life and development. It is often used as a synonym for "human well-being" or "quality of living".

The value of the Human Development Index varies from 0 to 1; the closer the value is to one, the higher is the level of human development; consequently, the shorter is the way for the country (or region) to make in order to achieve certain desirable targets.

The dynamics of Human Development Index for different countries over the period of 2010-2015 is presented in Table 4.

The source: prepared by the authors according to the data from UN Development Program

The analysis of the statistics presented above provides the following evidence:

Since 2010 the 1-st position is occupied by Norway with the HDI of 0,938 (0,944 in 2015). In 2015 Australia, Switzerland, Denmark, Netherlands, Germany, Ireland, USA, Canada and New Zealand became the top ten leading countries. Russia was ranked 50-th.

According the annual rating of the human development potential the countries are roughly distributed into four main groups. For 2015 they were rated as follows:

- the countries with a very high HDI value, where it varies from 0,944 (Norway – 1-st position) to 0,802 (Montenegro - 49-th position);

- the countries with a high HDI value, where it varies from 0,798 (the Republic of Belarus ranked 50-th) to 0,702 (Samoa ranked 105-th). Among those are Russia (which shares the 50-th position with Belarus) and some countries – member states of the former USSR, such as Kazakhstan (ranked 56-th) with HDI of 0,788; Georgia (ranked 76-th) with HDI of 0,754; Azerbaijan (ranked 78-th) with HDI of 0,751; Ukraine (81-th) with HDI of 0,747; Armenia (85-th) with HDI of 0,733. China with HDI of 0,727 (ranked 90-th) is also included into this group;

- the countries with a medium HDI value, where it varies from 0,698 (Botswana ranked 106-th) to 0,555 (Cambodia, 144-th), Moldova (ranked 107-th, with HDI of 0,693), Turkmenistan (109-th, with HDI of 0,688), Uzbekistan (114-th, with HDI of 0,675), Kirgizstan (120-th, with HDI of 0,655), Tajikistan (129-th, with HDI of 0,624);

- the countries with a low HDI value, where it varies from 0,548 in Kenia (145-th) to 0,348 in Niger (188-th).

Among all the member states of the former USSR only Baltic countries entered the first group of the states with a very high level of potential human development: Estonia ranked 30-th with its HDI of 0,861, Lithuania (37-th position, HDI of 0,839) and Latvia (46-th position, HDI of 0,819).

According to 2015 statistics Russia kept ahead of the field among other BRICS members, the group of the largest countries with high-growth economies, whereas Brazil was rated 75-th, China – 90-th, SAR – 116-th and India – 130-th.

The five so-called failed states of Africa south of the Sahara (Burundi, the Republic of Chad, Eritrea, the Central African Republic and Niger) tail the list. Despite a partial turn to the better which has been observed over the recent years, the life expectancy in those countries remains extremely low (40 to 50 years), the socio-economic environment is greatly unfavorable, the literacy rate is unsatisfactory (no more than 30% of the population are able to read and write), and the income per capita is estimated less than 1000 USD a year.

The rates of violence, murder, discrimination and civil conflicts do not always report of the actual rate of crime in a particular country, basically because crime is not always associated with direct danger to life. However, the related statistics is assembled (on the basis of the data contributed by the users) and reported annually at free access on www.numbeo.com, which provides the world's largest database.

Table 5 presents the statistics which report of the rates of crime and safety in different countries over the period 2012-2016.

As shown in Table 5, Venezuela had the highest crime rate in 2012 (84,74%) and in 2016 (84,44%). In 2014 Afghanistan (82,51%) came up to the 1-st position, and in 2015 South Sudan (85,32%) headed the list. The reported safety rates in those countries were the lowest. Besides, in 2016 South Sudan, SAR, Papua New Guinea, Honduras, Nigeria, Trinidad and Tobago, Salvador, Brazil, Kenia made "the top ten" among the countries which had extremely high crime rates. In 2016 Russia was ranked the 50-th among the 117 countries (the crime rate of 47,31%). However, Table 5 provides evidence to the fact that the rate of crime in Russia became lower from year to year.

Table 5: crime and safety statistics by country over the period of 2010-2016

2012				2013

The source: prepared by the authors (as reported by Numbeo.com)

This encouraging trend is conditioned by the economic advancement, growing employment and education rates and increased professionalism of the law enforcement authorities.

As reported on Numbeo.com, the following countries have the lowest crime rate: Taiwan (21,21%), Hong Kong (20,85%), Japan (19,34%), Singapore (15,81%), South Korea (14,31%).

A large extent of spatial economic and social differences determines a state policy which would work towards consistent lowering of the territorial differentiation within the country. The state intervention in the regional development is regulated by the Constitution and by special laws. State regulation of the economy is implemented through all the state institutions.

We have carried out careful analysis of a number of scientific studies as well as program, normative and legal documents which provided a basis for classifying the main standard instruments of the regional policy towards reducing the degree of socio-economic differentiation and defining the scope of their possible application (Table 6).

Table 6: classification of the instruments of the regional policy towards reducing the spatial differentiation among the regions

Instruments	Scope of possible application
Budget transfer	Redistribution of funds (budget revenues) between budgets of different levels (both vertically and horizontally) by means of inter-budget transfers
Territory administration	Amalgamation, aggregation or disaggregation of territorial administrative units; integration of border areas
Investment	Creation of favorable market environment to encourage investments in the lagging regions
Innovative	Development of new industrial enterprises on the basis of the regional innovation programs
Claster	Development of the priority clusters and growth areas in the lagging regions to foster their economic advancement
Free economic areas	Allocation and organization of free economic zones in the lagging regions by reference to its specifics
Infrastructure	Exploitation of the unemployed comparative infrastructural advantages of the region
Resource	Exploitation of the spare "idle" resources and the resource-based competitive advantages of the region
Institutional	Improvement of the regional business climate
Fiscal	Employment of the fiscal mechanisms for the purposes of regulation and reauthorization as to revenue budgeting between the Centre and sub-federal entities

The source: prepared by the authors

The analysis of the main commonly used instruments to reduce the degree of territorial socio-economic differentiation exposed the interdependence of those instruments and the above-mentioned types of spatial differentiation as well as appropriateness of their classification according to the scope of their possible application in current terms.

Transfer payments as the instrument of the state regulation remains most widely used in this country. A great number of studies and statistical surveys show that the commonly applied way to support regional budgets and close the budget deficits by means of manual redistribution of funds from the self-sustainable regions to the lagging ones has significantly negative effects on both the donor and the recipient.

Conclusions

The potential possibilities for fiscal instruments of the state regulation of the national economic system (in particular, of the socio-economic development of the regions) were considered by a great number of Russian and foreign economic scientists, beginning with the founders of theoretical economics.

State regulation of spatial differentiation with a purpose to improve the living standards and well-being of the population of the regions should be premised on the following principles:

- the reduction of the disparities in the socio-economic development among the regions should be intended to ensure the economic advancement in every particular region;

- the state should provide support not only to the lagging regions, but also should create a favorable environment for raising the standards of living in other regions;

- interregional redistribution of the resources should be intended to improve the standards of living in the regions;

- both short-term and long-term national economic security interests have priority over the regional interests.

Thus, we can highlight the following basic lines of the state regulation as a policy intended to reduce the disparities in the economic and social development of the regions:

1. state investment in the real sector of the economy and the infrastructure of the regions with a purpose to boost their economic growth;

2. encouragement of the national large businesses to invest into regions;

3. maintaining the equilibrium of the labor markets;

4. carrying out a redistributional policy intended to smooth out the income inequalities among different regions by means of social-oriented transfers and investments in the human capital.

The Main Approaches to the Implementation of Technical Re-Equipment of the Industrial Enterprises during Realization of State Economic Policy

Yulia Vertakova, Southwest State University, Kursk, Russia, vertakova7@ya.ru

Tatyana Babich, Southwest State University, Kursk, Russia, tanybabich@mail.ru

Abstract

Each country needs an effective government economic policy to achieve the strategic goals of economic and social development. The most important task of state economic policy is to ensure growth of living standards of the population. One of the tools to achieve this goal is to increase the efficiency of industrial production. The purpose of the study is justification of approaches to the implementation of technical re-equipment of industrial enterprises. These approaches allow forming the mechanism of realization of technical upgrading in the implementation of the directions of state economic policy. The methodological basis is the key methodologies and approaches presented in the works of foreign and domestic scholars in the study of technical re-equipment of industrial enterprises. The study also used statistical methods and comparative analysis of countries by level of development. The result of this study is the proposed implementation mechanism of technical re-equipment of the industrial enterprises in the implementation of directions of the state economic policy and the formation of the state support measures in its application. Also established seven basic approaches to the implementation of technical re-equipment, which allow us to achieve operating, economic and social efficiency. In General, this process may promote technological upgrading of industries. Practical significance of the research is that the authors formulated the conclusions and recommendations can be applied in industrial enterprises for a more qualitative assessment of economic efficiency of projects of technical re-equipment.

Keywords: State economic policy, economic growth, modernization, approaches to the implementation of technical re-equipment

Introduction

The current economic situation is quite complicated. But it creates the conditions for various types of human activity. Directions and tasks that can solve the economy depend on its construction and organization.

In modern conditions the government plays an important role for the functioning of any economic system. It performs certain functions in the sphere of economy through the implementation of public policy.

One of the directions of realization of the state economic policy of any country is the implementation of innovative technological development. Moreover, this trend has a global reach. This is due to the necessity of transition to new sixth technological way. According to experts its formation is predicted to 2020, and by 2040 it will enter into a phase of maturity. For comparison, in the US 5% of the productive forces belong to the sixth phase and about 60% to fifth. In Russia the majority of the productive forces is in the fourth technological way, and about 10% in the fifth. Therefore, the development of industry and the transition to new sixth technological order are the main directions of state economic policy of Russia.

To implement these measures, the following goals and priorities of Russia's scientific and technical development are proposed: industrial modernization, energy efficiency improvement, import substitution.

Moreover, the modernization of industry is based, among other things, on the technical re-equipment of enterprises. This circumstance led to the actualization of research related to the development and improvement of tools and methods for managing this process, aimed at increasing the economic efficiency of development.

It should be noted that the studies of voiced problems in different periods of development are devoted to works both foreign (H. Grubel, Krugman Paul R. , etc.), and domestic researchers (AG Semenko, V.A Plotnikov, O.Yu. Mamedov, etc.). But, despite a large number of scientific publications on the problems under consideration, there remain questions that need to be solved. Such problems include: justification of approaches to the implementation of technical re-equipment of industrial enterprises and ways of state support of this process. In this regard, the development of scientific and practical recommendations in this field of research is of practical importance for effective economic development.

Results and Discussion

Any state economic policy (GEO) should have specific goals, priorities and draw on a strategy that can ensure their achievement.

The objectives of economic policy can be quantitative (for example, GDP growth of 3%, a decrease in inflation by 2%, etc.) and qualitative (improving living standards, access to education, etc.), as well as short-, medium- and long-term.

Table 1 presents the results of the comparative analysis of Russia and selected countries of the world in achieving some applied goals of implementing the state economic policy for 2016.

Table 1: Ranks of selected countries of the world to achieve some targets for the implementation of the GEO in 2016

Country	GDP per capita (thousand dollars), 2016.	Rank by GDP per capita	Unemployment rate, 2016.	Rank by unemployment rate	Inflation rate, 2016	Rank by inflation rate	Industrial production growth (%), 2016.	Rank on industrial production growth
Russia	26100	8	8,2	7	7,2	10	0,7	10
Belarus	17500	10	0,7	1	14	13	-3	13
Germany	48200	2	4,3	4	0,4	5	1,5	7-8
India	6700	13	8,4	8	5,6	9	7,4	1
Poland	27700	7	9,6	10	-0,8	1	4,2	4
United Kingdom	42500	3	5,1	6	0,5	6	0,3	12
USA	57300	1	4,7	5	1,3	7	2,1	5
Turkey	21100	9	9,8	12	8	11	4,5	3
Ukraine	8200	12	10	13	13,5	12	2	6
France	42400	4	9,7	11	0,3	4	1	9
Chine	15400	11	4,2	3	2,3	8	6,1	2
Japan	38900	5	3,2	2	-0,1	2	0,5	11
European Union (EU)	37800	6	9,5	9	0,1	3	1,5	7-8

The source: Calculated by the authors on the basis of data [https://gks.ru] and [https://total-rating.ru]

According to Table 1 of the countries represented, the United States ranks first in terms of GDP per capita, at the last - India. Russia in this indicator takes 8th place, the EU - at 6th place, China - at 11th.

It is known that it is possible to achieve full employment at the level of natural unemployment from 1.5 to 4%. In 2016, only Japan was able to reach this interval. In the remaining countries under consideration (except for Belarus), the unemployment rate is higher: Russia is on the 7th place (8.2%), the USA - by 5 (4.7%), China - by 3 (4.2%), the European Union - by 9 (9.5%).

In 2016 there was a decrease in the level of inflation in Poland and Japan. In general, a slight increase in inflation was in the EU (3rd place), in France (4th place). The United States in this indicator was on the 7th place, Russia by 10, China by 8. Belarus is on last place.

The maximum growth in industrial production was observed in India (7.4%), the lowest in Belarus (-3%). Russia in the growth of industrial production from the countries in question was in 10th place in 2016, the USA - by 5, the EU and Germany occupied 7 and 8 places (with the same level), China - by 2.

In general, in order to increase the effectiveness of achieving the above-mentioned goals of the GEO, Russia needs a transition to an innovative and technological development path. This requires modernization of the country's economy. So you can talk about the modernization of individual enterprises, but then it is customary to use the term "technical re-equipment".

The main problems hampering the innovative development in Russia are: the gradual loss of high-tech industries, the raw material orientation of development, the substantial physical and moral wear of fixed assets that do not meet modern requirements, especially in the face of growing competition in world markets for goods and services, and so on.

The features of Russian industry, including the raw material orientation of the economy, influenced the structure of the state fixed assets as a whole. As a result, the value of fixed assets in the extractive industry has increased from 2008 to the value of fixed assets in the manufacturing industry.

It should be noted that the material and technical base of the Russian economy is characterized by a low level of labor productivity (in 2015 the index was only 96.8% compared to the previous year), the introduction of resource-saving technologies and information systems, although this problem was repeatedly considered at the level leadership of the country [9]. One of the main reasons for this trend is the non-temporary structure of fixed assets).

In Russia, the high level of wear and age of machines and technological equipment remains. According to Rosstat, the average age of equipment is on average 20 years. The share of equipment older than 15 years exceeds 40%, and many enterprises use machines older than 30 years. The pace of renewal of engineering, determining the pace of development of the entire economy of the country, is 2 times lower than in industry as a whole.

As for innovation activity at industrial enterprises in Russia, its level remains low after falling several times during the crisis period. Also, the mechanisms of pro-movement in the production of promising developments are inefficiently applied. These problems have been repeatedly understood at different levels of management, since machine-building is the basis for the innovative development of the entire economy, its technical re-equipment and reconstruction. So, Russia ranks 31st in the world in the number of filed patent applications, 30th in terms of R & D expenditures (they make up 1.1% of GDP), which is much lower than the analogous indicators of the leading countries of the world [2].

Thus, one of the main factors of raising the labor productivity of the country's economy with a view to ensuring its sustainable development is the growth of the technological level of industry, which can not be achieved without large-scale technical re-equipment of industrial enterprises.

Technical re-equipment is a complex form of renewal of basic production assets, which involves a qualitative change in the enterprise, leading to socio-economic results.

Analyzing the types and methods of technical updating, as well as the approach proposed in [5], we have formed the main approaches to the implementation of technical re-equipment in industrial enterprises (Table 2). The peculiarity of these approaches is: first, a strategy is chosen for the development of the enterprise, which sets the target benchmark that the enterprise strives to achieve when implementing technical re-equipment; then a selection criterion is selected for selecting the appropriate approach.

Table 2: The main approaches to the implementation of the technical re-equipment of an industrial enterprise

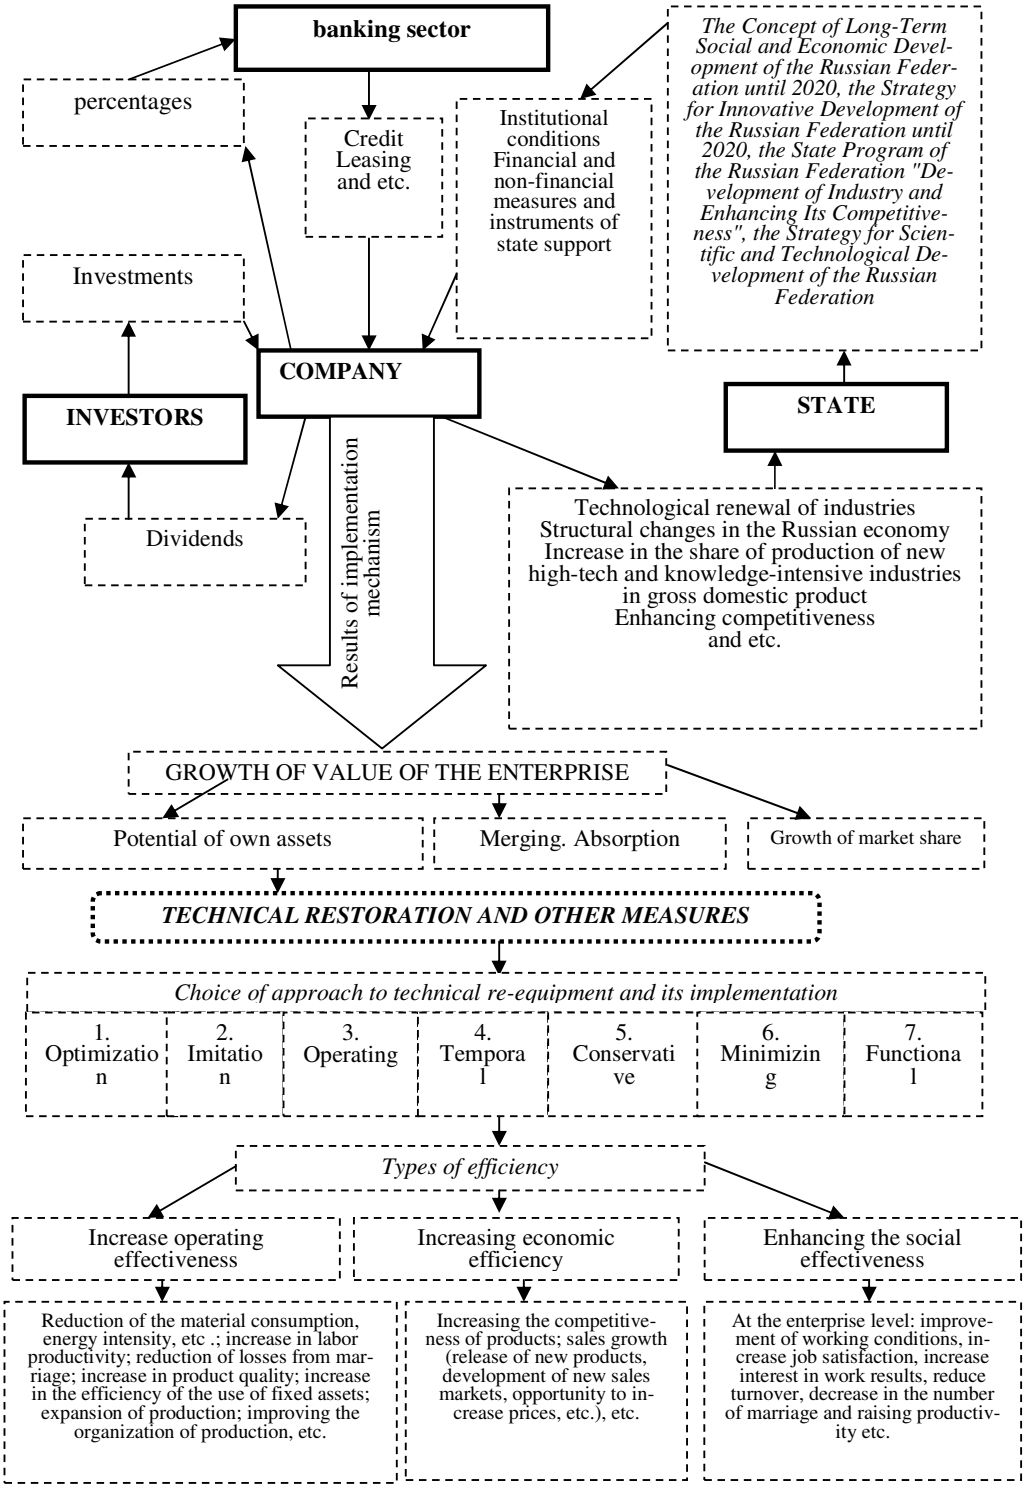
Approach	Development strategy	Target milestone	Content	Selection criteria
Optimization	Increasing the competitiveness of an enterprise while optimizing costs	Optimality of development	Replacement of equipment using the optimization criterion "price-performance-quality"	Multi-criteria choice of a variant of technical re-equipment "price-performance-quality"
Imitation	Strategy – follow the leader	Orientation on the main competitor	Technical update is carried out at the level of the main competitors	Technological level of the main competitor
Operational	Cost minimization strategy	Operating costs	Selection of the most simple operational equipment	Minimum operating costs
Temporary	Maintaining a stable current functioning	Replacement of equipment as soon as possible	Purchase of equipment in stock at the supplier's premises	Speed of technical re-equipment
Conservative	Maintaining the technological level of production at the existing level	Replacement of equipment without resistance to changes	It acquires something that is familiar and does not change technology	Minimum costs for implementation and maintenance
Minimizing	Cost minimization strategy	Minimum costs	Choosing the cheapest equipment	Minimal costs
Functional	Innovative development	Growth of enterprise competitiveness and innovative development	Selection of the most modern equipment	Growth of enterprise value

The source: compiled by the authors

The most effective way, which gives the most efficiency, is the functional approach, however, in practice, currently the percentage of its use in industrial enterprises is limited to 3%, while the other business entities prefer the other approaches mentioned above, which do not fully reflect the social-economic essence of technical re-equipment.

Formed approaches make it possible to justify the mechanism of technical re-equipment at an industrial enterprise, the logic of which is presented in Fig. 1.

According to the proposed mechanism, the participants in the technical re-equipment process are: the state, the banking sector, investors and the industrial enterprise.



banking sector

7. Functional
Types of efficiency
Increase operating effectiveness
Increasing economic efficiency
Enhancing the social effectiveness
Reduction of the material consumption, energy intensity, etc .; increase in labor productivity; reduction of losses from marriage; increase in product quality; increase in the efficiency of the use of fixed assets; expansion of production; improving the organization of production, etc.
Increasing the competitiveness of products; sales growth (release of new products, development of new sales markets, opportunity to increase prices, etc.), etc.
At the enterprise level: improvement of working conditions, increase job satisfaction, increase interest in work results, reduce turnover, decrease in the number of marriage and raising productivity etc.

Figure 1. Structure of the technical implementation mechanism rearmament at an industrial enterprise *(compiled by the authors)*

The state on the basis of certain normative documents realizing the direction of state economic policy (for example, the Concept of Long-Term Social and Economic Development of the Russian Federation until 2020, the Strategy for Innovative Development of the Russian Federation until 2020, the State Program of the Russian Federation "Industry Development and Increase its competitiveness, the Strategy of scientific and technological development of the Russian Federation from 2016, etc.), creates institutional conditions, and applies certain measures of state support (financial and non-financial) incentives for enterprises to carry out technical re-equipment.

The main instruments of support at present can be the measures proposed by the Ministry of Industry and Trade of Russia [6]:

1) financial measures and instruments (subsidizing interest rates, project financing, supporting R & D, subsidizing pilot lots of equipment, supporting regional programs, techno-parks and clusters, encouraging leasing, supporting export lending, partial reimbursement for engineering costs, manufacturing and export, financing development institutions);

2) non-financial measures and instruments (special investment contracts, exhibitions, fairs, conferences, promotion on foreign markets, protection of interests of Russian producers abroad, regulation of state purchases of industrial products, support of project consortia, development of engineering centers, standardization and technical regulation).

Enterprises for the implementation of the mechanism may attract borrowed funds. To do this, they can develop business plans (or a feasibility study for the project), which they can then send to the banking sector in order to obtain loans, leasing, etc., as well as investors. As a result, the enterprise, having implemented the technical re-equipment, can increase the value of its business, as it has been repeatedly proved that the growth of own assets directly increases the cost of the enterprise itself.

To realize technical re-equipment, the industrial enterprise chooses the approach to its implementation, proposed in Table 1. Depending on the results of this choice, it can receive a certain efficiency. The greatest result is given by the functional approach, in the implementation of which the enterprise can improve the operational, economic and social efficiency.

Conclusion

1. It is established that the world development trends dictate the implementation of innovation and technological development as one of the directions for implementing the state economic policy of any country.

2. To ensure the creation of modern production technologies, technical re-equipment of industrial enterprises is necessary.

3. Technical re-equipment of industrial enterprises is a sequential, purposeful and cyclically repeating process that ensures the renewal of equipment and technologies, the mastery of production of modern technological level products on the basis of a new way of thinking of labor resources, predetermined by retraining, retraining and re-training personnel for the purpose of working with new technology and production technologies.

4. Authors based on the rationale for the enterprise development strategy setting the targets for its development proposed approaches to the implementation of technical re-equipment of industrial enterprises (optimization, simulation, operational, temporary, conservative, minimizing, and functional). It was found that the most preferable is the functional approach, which is aimed at increasing the competitiveness of the enterprise and its innovative development, mediated by the choice of the most modern equipment, the value of the enterprise, which ultimately provides broad functionality, increased energy efficiency, efficiency, etc.

5. The proposed approaches allowed to substantiate the structure of the mechanism of technical re-equipment of industrial enterprises, realizing which the business entity can achieve operational, economic and social efficiency.

Abstract

Investment activity from the state or private investors is a necessary condition for the innovative development of economic systems. The purpose of the study is to develop approaches to the procedure for multi-criteria selection and coordination of interests of interested economic entities in the selection of innovative investment projects. The result of the study is the development of a mechanism that provides methodological support for the adoption of managerial decisions at the federal and regional levels. And also it is shown that innovative and investment projects aimed at financing promising areas of activity will allow not only to ensure the production of new types of products, but also create conditions for the development of the organization in the long term.

Keywords: strategic innovation, industry, territory, investment projects.

Introduction

Orientation only for export of raw materials, trade and development of the service sector will not allow Russia to achieve a high financial and economic situation in the modern world. To do this, it is necessary, first of all, a stable industry, focused on the production of high-tech products. In the Strategy for Innovative Development of the Russian Federation for the period up to 2020, it is pointed out that Russia is setting ambitious but achievable long-term development goals that are to ensure a high level of the population's well-being and to consolidate the geopolitical role of the country as one of the leaders. The only possible way to achieve these goals is the transition of the economy to an innovative socially-oriented development model (Vertakova et al, 2015).

Many scholars have studied the innovation-investment aspects of the economy, including Hadas Schwartz-Chassidima, Joachim Meyerb, Yisrael Parmeta, Efrat Rogatkaa, Ohad Amzalega, Phaal R (Phaal, Paterson, Probert, 1998), (Schwartz-Chassidim, Meyer, Parmet, Rogatka, Amzaleg, 2014).

With insufficient level of institutional environment effectiveness, lack of financing, underestimation of the role of investments in the process of production functioning, it is possible to encounter a situation where all competitive advantages of the enterprise (or even the industry as a whole) will be lost. In its turn, innovative activity is understood as a set of measures to create fundamentally new or new consumer properties of products, to create and develop new or modernize existing production methods (technologies), to distribute and use the corresponding products, to apply innovations (innovations) that ensure cost savings or creating conditions for it (Zagodarchuk, Plotnikov, 2014), (Kozin, Yakovlev, 2016).

Similar projects, in view of their special significance for the country's economy, are usually carried out within the framework of state innovation policy.

Results and Discussion

The world practice of development and implementation of the state strategy of innovative development of the national economy and development of production in the sphere of modern high-tech products and competitive technologies testifies to the formation by all developed and successfully developing countries of a list of priority areas of science and technology and industries where, with the maximum possible participation of national science and industry, Training and preparation of own personnel of specialists and workers, long-term programs and major innovative projects and programs.

In turn, Russia has not yet developed enough mechanisms for state regulation and control over the implementation of state programs and innovative projects to create conditions for attracting investments, for measures to preserve competitiveness and the development of domestic science and industry to create primarily in their country, new jobs with a high level of wages. A specific feature of the Russian economic structure is that Russian large enterprises are developing against the backdrop of weak development of small and medium-sized businesses. In Russia, small businesses are mainly engaged in trade and intermediary activities (Kotlyarov, 2016).

Over the past 25 years, the domestic industry has accumulated a whole range of systemic problems that affect its further innovative development. We shall name and characterize the main ones.

1. The financial situation of many industrial enterprises and scientific organizations remains complex. 2. The general wear and tear of machines and equipment in many branches of industry is 48.7%. At the same time, the average age of equipment in the active part of fixed assets is 11.2 years (Burkov et al, 2002).

The aging equipment leads to a decrease in the quality of the products. 3. Completely lost the production of a number of components. 4. Another serious problem of the domestic industrial sphere is the human factor. Today, the average age of workers in production (the so-called "blue collar") is 55 years. These negative trends in recent years have caused a disruption in the process of the reproduction of knowledge - there is no one to transfer experience accumulated by veterans. 5. As practice has shown, innovation-active enterprises introduce mainly product innovations aimed at expanding the range, improving the quality of products, using more efficient components and materials. At the same time, new production methods, the so-called technological innovations, which, along with the release of new products, reduce material costs in production, are not introduced everywhere.

At the first stage, a database is being created, into which the existing innovation investment projects and programs should be included, the implementation of which is planned by economic entities located in the region or planning to implement its project on this territory.

At the second stage, the projects are ranked according to the descending or increasing of some criterion (for example, the repayment time of the loan, the amount of tax revenues to the budget for the planning period, economic or social efficiency, etc.). The evaluation of projects is carried out by experts who have knowledge and experience in the relevant field of activity. This allows choosing the most promising innovation and investment projects, the implementation of which will help improve the state of innovation infrastructure, promote the innovative development of the region and enhance the intellectual potential of the population. Local authorities should select the most effective projects by all criteria, which will allow selecting those projects that will receive state guarantees. Financing can be organized with partial attraction of means of subjects of economic relations within the framework of public-private partnership. Particularly relevant is the use of this approach in the context of the policy of import substitution (Kozin, Yakovlev, 2016). In case there are many criteria for evaluating the project, it is possible to conduct several stages of selection.

It should be noted that there are probably two types of procedure for ranking innovation-investment projects. The first is when projects are evaluated according to several criteria (economic effect from their implementation, social and other types of effects) that are interrelated. In this case, increasing the value of one of them increases the values of the others. The ranking process is simplified and has the form of a one-source agreement on the interests of economic operators. The second kind is that when an improvement in the value of one criterion leads to its deterioration by another criterion.

The presence in the database of a significant number of options determines the need to reduce them. For this purpose, first, options are selected that satisfy the existing constraints. Then among them there remain variants corresponding to restrictions, but having different degree of conformity to the given criteria. The analysis of compliance with criteria allows for the third stage to negotiate the values and leave one option (or a small number). The final decision must be taken by the official (body) planning the project's implementation.

The procedure for reducing the number of options for innovative investment projects used within the framework of the proposed mechanism requires detailed elaboration. Decision-making should be carried out using a scientific approach.

Let a priori given constraints: L - the total costs and {Li} - the minimum values of the estimates by the criteria (for convenience, we will assume that the advantages of subjects of economic relations are reflected in the desire to increase project estimates by all criteria). In this case, the variant (some set of projects) will be acceptable if it is characterized by total costs not exceeding R, and estimates by all criteria, not less than the corresponding minimum values {Li}. To generate a set of acceptable variants, you can use the procedure for building a network in which the branching of the "tree" of options corresponds to adding or removing one of the projects from the set of realized ones, and the criteria for cutting off unnecessary options is either exceeding the maximum possible amount of expenditure, or reducing the estimate for at least one of the Criteria to the minimum allowable.

For the selection of the most effective projects, the economic and social effects that can be obtained as a result of their implementation should be assessed. Based on the results of processing the completed questionnaires available in databases, the arithmetic mean of the two types of effects is calculated.

The expert group, using the appropriate criteria (Table 1), scores the expected effect (in our case, a five-point scale will be used) from the implementation of innovation and investment projects aimed at achieving the strategic objectives of the industry in the region. We confine ourselves to two types of effects - economic and social, each of which will contain four indicators. In practice, depending on regional specifics; the state of innovation infrastructure, the level of industrial development, the goals to be realized in the strategic development of the region, and other factors [3, 5], indicators, as well as the effects, can be much larger. The number of possible innovation-investment projects available in the database is also unlimited.

In practice, there is a relatively high predictive efficiency of the use of capital in the implementation of innovative investment projects, characteristic of some territories (regions) of the Russian Federation. To a large extent, it can be caused by a well-developed system of control measures by the regional authorities, as well as by placing funds in highly liquid projects that do not require long payback periods.

Consider the option in which funding will require three projects. They can be implemented either simultaneously, or two of them, or one. It all depends on budget constraints. The initial data for carrying out the necessary calculations are presented in Table. 2.

Table 1: criteria of expert evaluation of the effectiveness of innovation and investment projects (option for reporting data for project A)

Accepted indicator	Evaluation Criterion	Score
1	2	3
1. Economic effect of project A		
1.1. Increase the filling of regional and local budgets	B_b	4
1.2. Receiving additional benefits through the commercialization of intellectual property	D_k	3
1.3. Development of infrastructure for innovative support of enterprises for providing information, consulting, marketing, financial and other services	R_{in}	5
1.4. Growth of volumes of realization of the national science-intensive products and high technologies	R_n	2
2. The social effect of project A		
2.1. Increase in the number of jobs in production using modern technologies	M_r	3
2.2. The possibility of introducing the results of intellectual work	W_{it}	4
2.3. The possibility of using the results of project implementation by the population	V_n	2
2.4. Raising the standard of living of the population to standards adopted in developed countries	U_l	4

Table 2: initial data on the implementation of innovative investment projects (option for reporting data for projects A, B and C), taking into account Received economic and social effect (assessed in points)

Effect type	Project and costs required For its implementation, thousand rubles.		
	A	B	C
	2000	1500	3300
1	2	3	4
Economic effect (E_e)	14	11	15
Social effect (E_s)	13	8	10

Source: calculations carried out by the authors

Variants of project support, as well as the value of expenditures and estimates by criteria are given in Table. 3. In total, eight possible combinations of the implementation of the projects were obtained. Let's pretend that L = 3500 rub. In this case, variants 6, 7 and 8 are excluded from the total aggregate, the total implementation cost of which exceeds the established limit on the amount of financing. The first option, in which none of the possible projects is implemented, with zero value of all indicators from the settlement table is also subsequently excluded. However, in practice this situation is quite possible due to lack of funding.

Table 3: grouping of all variants of innovative and investment projects

№ п/п	Project			Expenses, Thousand Rubles	The resulting types of effects (Estimated in points)		$\sum E_i$
	A	B	C		E_e	E_s	
1	2	3	4	5	6	7	8
1				0	0	0	0
2	+			2000	14	13	27
3		+		1500	11	8	19
4			+	3300	15	10	25
5	+	+		3500	25	21	46
6	+		+	5300	29	23	52
7		+	+	3800	26	18	44
8	+	+	+	6800	30	31	61

Source: calculations carried out by the authors.

The application of the rule of the Pareto-dominant variants allows to exclude from the whole set of variants that do not enter into 20% with a maximum sum by two criteria. To exclude 80% of the projects, it is proposed to rank the sum for the two effects (economic and social) and exclude projects, for this sum, referring to the 0-80% interval. Applying the Pareto rule to a certain set allows you to exclude 80% of the options that will not provide the maximum effect.

The application of the Pareto rule to a set of possible options makes it possible to select only those projects whose implementation efficiency should exceed 80%. In our example, the only variant of the grouping that satisfies the restrictions on the amount of expenses and the corresponding conditions of the Pareto rule is the first option, which provides for the implementation of project A (Table 4).

The example of the calculations carried out within the framework of the proposed mechanism for the implementation of innovative investment projects aimed at achieving the strategic objectives of industrial development in the region demonstrates that in the multi-criteria problem that is being solved, the final decision is very sensitive to the choice of the priority system that determines the procedure for multi-criteria selection.

When deciding whether to support projects, it is necessary to harmonize the interests of stakeholders who have the ability to influence the final decision and advocate an increase in estimates based on certain criteria. The procedure for reconciling interests can be described by solving the task of motivational management.

Table 4: grouping of selected options for implementation of innovative investment projects based on the application of the Pareto principle

№ п/п	Project			Expenses, Thosand/Rubles.	The resulting types of effects (Estimated in points)		$\sum E_i$
	A	B	C		E_e	E_s	
1	2	3	4	5	6	7	8
1	+			**2000**	**14**	**13**	**27**
2		+		1500	11	8	19
3			+	3300	15	10	25
4	+	+		3500	25	21	46

Source: calculations carried out by the authors

Consider a system consisting of n subjects evaluating m options for supporting projects. The utility of the *i-th* entity from the implementation of variant *j* is *hij, i = 1¯, n, j = 1, m*. We fix the two variants *j* and *k*, we define the "gain" of the i-th subject from the "transition" from the implementation of variant j to the variant *k*:

$$\Delta_i(i,k) = h_{ij} - h_{ik}, i \in I = \{1,2,\dots,n\}, \quad (1)$$

At the same time Δ_*i (i, k)* is the total gain of all subjects from this transition:

$$\Delta(i,k) = H_0(j) - H_0(k), \quad (2)$$

Where

$$H_0(j) = \sum_{i=2}^{n} h_{ij}. \quad (3)$$

The function $H_0(j)$ can be the objective function of a "system" with *n* subjects. It is consistent with the Pareto rule in the following sense: if the variant *j* Pareto prevails variant *k* (in terms of utility level for the subjects, and not the number of points obtained as a result of multi-criteria selection), then $H_0(j) > H_0(k)$.

The governance model under consideration requires the introduction of a governing body, for example, regional authorities. Motivation management corresponds to the introduction of the incentive system$\{\sigma_{ij}\}$, on the basis of which the objective function of the *i-th* subject acquires the following form:

$$f_i(j) = h_{ij} - \sigma_{ij}, \ i \in I. \quad (4)$$

The interaction of the subjects turns out to be dependent on the matrix$\sigma = \|\sigma_{ij}\|$. Let's assume that the budgetary constraint C for the total amount of funding appears in the motivation management task under consideration.

First, we examine the coordination of interests of subjects in the absence of a budget constraint $(C = +\infty)$. We fix two arbitrary variants *j* and *k*.

According to the results obtained in [2, 12], the use of the incentive system by local authorities allows making sound management decisions

$$\sigma_{(.)} = \begin{cases} \Delta_i(j,k) - \delta_i, i = k \\ \sigma_i^H, i \neq k \end{cases}, \quad (5)$$

Where i = k support by the *i-th* economic entity of the *k-th* variant $\sigma_i^H = max$;

h_{ij}- Strategy of discouraging the economic entity for evasion *k-th* option; $\delta_i > 0 > 1$ Is an arbitrarily small positive constant, which forces us to support variant *k*.

In formula (5), the first mode corresponds to the transfer of utility, and the second mode is the disincentive for individual deviations. If the utility transfers correspond to an internal constraint that is,

closed in the set of subjects then the transfer amount must be negative. If regional authorities need to attract external funds or use their own funds in the amount of $C \geq 0$, the budget constraint is transformed.

$$\sum_{i=1}^{m} \sigma_i (j,k) = \Delta(j,k) = H_0(j) - H_0(k) \geq -C. \quad (6)$$

Thus, on the one hand, in the framework of a closed set of subjects (for $C = 0$), expression (6) is a condition for the positive balance of transfers, and on the other, as noted above, this is a sufficient Pareto condition, the dominance of variant *k* over variant *j*.

To consider the role of the budget constraint, it is expedient to fix an arbitrary variant of *k0* and to determine the set of options that can be supported by subjects of economic relations (taking into account balanced motivational management by local authorities) as an alternative to option *k0*:

$$P(k_0, C) = \{j\Delta(k_0, j) \leq C\}. \quad (7)$$

A set of P (C) options that can be supported as alternatives to any other options:

$$P(C) = \bigcap_{k_0} P(k_0, C) = \{j|H_o(j) \geq max(H_0(i) - C)\}. \quad (8)$$

When regional incentive systems are used by the regional authorities (4) any point of the set (8) is Pareto significant. In addition, the rating of Pareto variants is determined. Given a budget constraint L, any variant of the set (8) can be realized.

Implementation of the presented mechanism in practice in the current circumstances requires the involvement of significant administrative and financial resources. This circumstance determines the high role of the state in the implementation of innovation and investment projects aimed at achieving the strategic objectives of the development of industry in the region.

Conclusions

Summing up, we can draw the following conclusions:

To ensure sustainable economic growth in Russia, it is necessary to implement an effective state policy on key areas for ensuring national security and innovative and investment development of all major sectors of the country's national economy;

On the effectiveness of the selected mechanisms and tools for selecting and implementing innovative investment projects aimed at achieving the strategic objectives of the industry in the region, socio-economic development of Russia depends, including on the competitiveness of the main types of domestic products, goods and services, on raising the standard of living of the population, quality of education, science, high-tech industry, health and culture. First of all, it is necessary to ensure the priority development of industries that are of particularly important strategic importance for Russia and its regions - points of growth aimed at achieving a powerful synergetic effect;

A transparent mechanism should be established to monitor the activities carried out within the framework of real state support of priority innovation and investment projects for the renewal of technologies and funds of the processing industries of the country's economy in order to ensure the production of competitive products for Russia's domestic market in Russia.

Acknowledgments

This paper is an output of the science project of the government task of Ministry of education and science of the Russian Federation № 26.3546.2017/PCH "Development fundamentals of analysis and prediction of structural and dynamic parameters of the regional economy are based on the integration of the Russian and world experience of management of territorial development and modern scientific doctrines".

Characterization of Software Development Methodologies in the Telecommunication Industry of South Africa

Olebogeng Helen Nojila, North West University, Private Bag X2046, Mmabatho, 2745, South Africa, olebogenghellennojila@gmail.com
Nehemiah Mavetera, North West University, Private Bag X2046, Mmabatho, 2745, South Africa, Nehemiah.mavetera@nwu.ac.za
Chipo Getrude Mavetera, North West University, Private Bag X2046, Mmabatho, 2745, South Africa, Chipo.mavetera@nwu.ac.za

Abstract

In South Africa, there are numerous telecommunication service providers which include; Vodacom, Cell C, MTN and Telkom. These companies provide wireless, mobile and cable telecommunication services (SA Info 2015 and Deloite 2014). In order for this services to be provided, software services as part of infrastructure are needed. Software development is therefore a requirement and software development methodologies (SDMs) must be in place to enable this. The telecommunication industry however, does not have a well-documented list of the SDMs that are used to fashion these software products.

This study investigated the software development methodologies used in the telecommunication industry of South Africa. A qualitative-interpretive approach and a case study method were used to find software development methodologies used in different companies. Four leading telecommunication companies were identified and using semi-structured interview techniques, a total of eight case data were collected from these companies. Then a cross analysis method was utilized to identify similar patterns among the findings.

The results indicated that software development life cycle and agile methodologies are used in the telecommunication industry. However, in their formalized (espoused) state, these software development methodologies do not fully address the telecommunication requirements, therefore they tailor them into methods-in-action(methods-in-use) to best suit their needs. The results also indicated scanty knowledge of SDMs from some telecommunication companies.

Keywords:Telecommunication, software development methodologies, telecommunication companies, software development, information technology.

Introduction

Telecommunication industry contributes significantly to the gross domestic product (GDP) in South Africa (SAI 2015). The industry offers services and products that connects the world (Mazengera 2009 and The Editors 2012). As such, quality technologies which include mainly their software need to be developed for better management and delivering their expected services (Lemétayer 2010). It is therefore imperative to assess the use of software development methodologies (SDMs) that maybe in use to guide their software development tasks.

Though SDMs maybe generally used, every software development project brings new views to software development which can either be weaknesses or strengths (Jeff 2012; Preeti et.al 2014 and Deepak et al. 2010). This suggests that there is no single methodology solution that addresseses the development of different software solutions. (Preeti et.al 2014 and Deepak & Pooja 2010).

The telecommunication industry is complex in nature and has its own specific requirements that are not always properly handled by current information technology techniques (Plunkett Research 2015; Patel 2002; Jared 2013 and SAI 2015). The imminent compexity of programming and new softaware developments bring extra challenges for information technology practitioners to sustain the management requirements as well as organisational technical needs (Haigh 2010 and Jared 2013).

Numerous SDMs have genrally been created to aid software development, therefore it is necessary to align certain SDMs to specific software projects (Preeti et.al 2014). The telecommunication industry has numerous software solutions that need to be implemented, however there is a lot of uncertainity as to which SDMs are suitable for each project (Jared 2013; Deloite 2014 and TE 2012). Pressman (2007) and Preeti et.al (2014) suggest that not employing SDMs in software development is bound to result in project failure.

In line with challenge of assessing suitable SDMs for the telecommunication industry the researcher identified research objectives as follows;

- to investigate SDMs used in telecommunication industry
- to identify the SDMs used in the telecommunication industry;
- to specify requirements for SDMs suitable for the telecommunication industry and
- to justify the significance of SDMs in the software development process

Literature Review

Description of Software Development Methodology

According to Centers for medicine & medicate services (2008) software development methodologies refers to a framework that is used to structure, plan, and control the process of developing an information system. Avison & Fitzgerald (2006) state that software development methodologies are a general collection of procedures, tools and techniques, and documentation which assist developers to structurally develop a software. According to Huisman & Livari (2006) refer to software development methodologies as a combination of a systems development approach, a systems development process model, a systems development method and a systems development technique. Over the years, numerous authors have provided different definitions for software development methodologies, however there are comparable elements within the definitions that are mutual. These include; philosophy, procedure, method, tools and techniques. For the purpose of this study SDMs are regarded as a structural procedure to develop software solutions with the use of a paradigm, approach, methodology, methods, tools and techniques, and also support telecommunication software solutions requirements which are; reliability flexibility, security and adaptability.

The Software Crisis

The instigation of SDMs followed after software crisis which took place in the 1960s (Fitzgerald,1996). The concept “software crisis” referred to software projects which did not meet user’s requirements, were above budget and or were not finished within the estimated time (Fitzgerald 1996). As a result most information technology practitioners proposed the use of formalized methodologies to minimize the negative outcome of software crisis (Fitzgerald 1996). The creation of SDMs came as a solution to guide software developers through the software development process (Malik & Siew 2009 and Preeti & Saru 2014). The use of SDMs in an organization is perceived by many information technology practitioners as a good tool to reduce project failure (Klimeš & Procháska 2006; Preeti et.al 2014; Avison & Finformation technologyzgerald 2008; Yahya et al. 2002 and Saini,Saini & Gupta 2009).

Justifying the use of SDMs

To date, software development methodologies have been adopted as the main tool that drive software development (Fitzgerald 1996 and Preeti & Saru 2014). Avison & Fitzgerald (2006) and Preeti et.al (2014) emphasise that software development methodologies are of essence for almost all software development endeavors. It is for these reasons that the anticipation of software development failure still prevails in cases where SDMs are not employed (Avison & Fitzgerald 2006 and Preeti et.al 2014). It common however that some organizations still do not implement the use of software development methodologies to develop software solutions, yet they still produce successful project.

Benefits Of Software Development Methodologies

The use of SDMs in software development has shown great improvement in the end product (Mihailescu & Mihailescu 2009; Griffin & Brandyberry 2008; Huisman & Livari 2006; Yahya, Yahya, Yusof & Omar, 2002 and Masrek, et al. 2008). When software development methodologies are put into practice they make the development process manageable and easy to control (Jeff 2012 and Yahya, et al. 2002). Continuous use of SDMs ensure that there is sufficient communcation among all the stakeholdrs involved in the software devlopment project, more specifically, communication between developers and users (Futrel, Shafer & Shafer 2002; Mihailescu et.al 2009 and Preeti et.al 2014).The use of SDMs also ensures standardization of the development process (Jeff 2012; Avison & Fitzgerald 2008 and Futrell et.al 2002). This is achieved through the nature of SDMs structure which have predefined guidelines (Leem & Kim 2002 and Meso, Madey, Troutt, & Liegle 2006).

Challenges Of Software Development Methodologies

Some companies still do not employ the use of SDMs for reasons such as them being time consuming and costly (Wetherbe 2001; Pieterse 2006 and Griffin & Brandyberry 2008). Other organisations are concerned that SDMs do not capture the unique nature of every project (De Vries 2004; Avison & Fitzgerald 2002; Yahya, et al. 2002 and Fitzgerald & Russo 2002). The use of SDMs have not been fully accepted in the business world. This is so because sometimes information technology practitioners find it hard to encourage their use, especially in cases where there is lack of evidence of their success (Griffin & Brandyberry 2008; Mihailescu et.al 2009; Siau & Tan 2005). Research also highlight that SDMs do not take much consideration of the human aspects during the development process, but rather focus more on the technical aspects, this in turn results in unsatisfied users (Yardley 2002).

Telecommunication companies in South Africa

Major telecommunication companies that operate in South Africa include MTN, VODACOM and Cell C. These were targeted for data collection through interviews. These companies also operate internationally, however this research was only foused on factors that affect the local branches in Sourth Africa. In South Africa telecommunication is one a major business that grows at an exponetial rate, ranging from mobile telephony, broadband connectivity, wireless and satellite communication (SAI 2015), South Africa has the most developed telecommunication infrastructure in network in Africa (SAI 2015).

Sdms Specifically For Telecommunication Industry

Some of the prominent researchers on SDMs specifically for telecommunication industry identified in this research are Mansurov (2000) & Modatel (2003). The telecommunication industry is one of a kind industry with its own unique software challenges (Deloite 2014). The nature of this industry is that it is unpredictable and fast paced in terms of advancements of software development. It is therefore

encouraged that there should be use of SDMs that specifically address the telecommunication industry software development challenges. These SDMs should be reliable, flexible, secure and adaptable (Jared 2013). Some SDMs were identified in this study that specifically address software development challenges for the telecommunication. These SDMs involve the breakdown of the software development projects into controllable tasks, define outputs throughout the development process and they function in the science paradigm. The identified SDMs include, Model Driven Methodology (MODA-TEL), Mansurov's Accelerated Development Methodology and Mobile D

Research Methodology and Design

Theoretical foundation

The theoretical foundation for this research is based on the Actor Network Theory (ANT). ANT in summary considers human and non-human actors as they interrelate to form a network to achieve a specific goal. This study looked at how targeted actors for this study contributed to the development of software solutions. Figure 1 below illustrates a network of actors in the telecommunication industry.

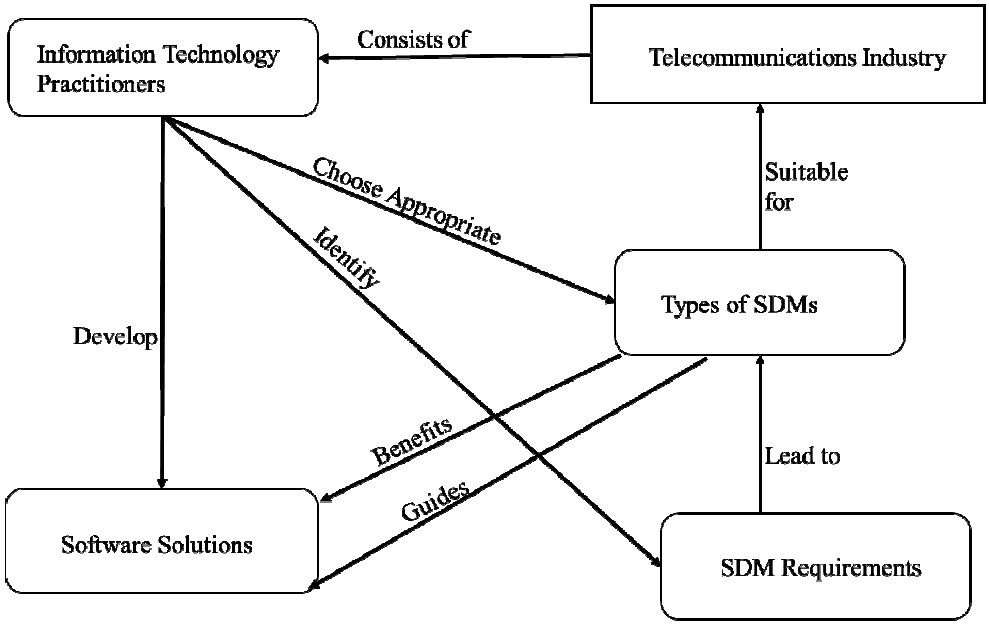

Figure 1: Theoretical foundation of the study: Based on the actor network theory

Figure 1 above depicts the theoretical foundation based on the ANT and displays the relationships among the actors of the telecommunications industry for this study. This depiction assisted the researcher with formulating the research questions.

Research Paradigm

According to the foundation as depicted in figure 1, this study was suitably interpretive in nature because it targeted the views of information technology pravtitioners in the telecommunication industry. This meant that the results of the study were therefore subjective. However, but engaging the interpretive

research paradigm allowed the researcher to comprehend and interpret the use of SDMs in the telecommunication industry with less bias (Collinson 2012; Anderson 2013; Douglas 2015 and Thushara 2014).

Research Approach

The researcher managed to attain comprehensive interpretations which also qualified the study as a qualitative research (Goran 2012;Snape & Spencer 2003; Van Wyk 2012 and Occupy Theory 2014). The telecommunication industry software development processes are not very easy to grasp, therefore the conveniences of the qualitative approach assisted the researcher to attain a clear understanding of the environment in an attempt to generalize the results and help to sustain contextual focus (Goran 2012 ; Mason 2002 ; Van Wyk 2012 and OC 2014).

Research Design

Data Collection strategy – Case Study

A case study strategy was preferred as the appropriate approach that provided a structured way to collect data, examine it, attain results and compile a report (Hancock 2002; Rowley 2001 and Van Wyk 2012). The researcher had no control or influence in the telecommunication industry, the case study strategy served as an appropriate approach for an outside individual to get data in a non-interfering way (Van Wyk 2012).

Data Collection method - Interviews

To acquire the desired information on SDMs in the telecommunication industry, it was vital that the researcher personally get involved with participants by interviewing them. This assisted the researcher to understand the participants' perception, experiences, roles and responsibilities in the environment (Van Wyk 2012). Through the interviews, the researcher attained multiple viewpoints from information technology practitioners in the targeted telecommunication companies. Semi-structured interviews were used to collect deep and expressive data from the respondents.

Interview appointments were scheduled in advance between the researcher and individual interviewees and electronic copies of the interview questions were e-mail in advance to allow them to prepare for the interview sessions. The researcher attended each session with paper based interview questions to guide the interview process. Interview discussions were captured on a digital recorder with the approval of participants. Each interview session lasted for about 30 minutes on average.

Sampling

Target population: The targeted participants for this study were information technology practitioners that are involved in software development such as programmers and software designers and analysts in the telecommunication industry.

Sampling method: The focused and purposeful sampling techniques was used because it does not involve choosing participants randomly but targets experts in a particular field (Patton 2002; Hancock, et al. 2007 and Van Wyk 2012).

Sample: A sample of four major telecommunication companies in South Africa namely Vodacom, Cell C, MTN and Telkom was chosen to make up four cases for this study. From these four cases, eight (8) interviews were done, where there were two (2) interviewees form each case.

Data Analysis

A cross case analysis was done as a form of data analysis in order to assist the researcher to identify the similarities and differences among the cases (Denscombe 2003 and Freed 2001 & Lamnek 1995). Through cross case analysis, associations among variables and features of phenomena studied were also identified (McGuiggan & Lee 2008). This method of analysis was preferred because it is inexpensive, fairly quick and is the best tool that can explain the real life relations that a survey cannot (McGuiggan & Lee 2008). To assist the researcher with interpretation coding was used to identify each case for example**,** cases A B C and D and each interviewee was coded according to their case code for example, A1, A2 and so on.

Ethical Consideration

Even though the targeted cases were mentioned in this study, an anonymity agreement was done between the researcher and the targeted cases. The researcher therefore cannot align the codes to the actual case as identified by name to respect the agreement.

Research results and findings

To address the problem statement and the objectives of the study, the results focused on the following measured aspects:

- Software development methodologies currently applied in the organization:
  - Three out of the four cases studied (A, B and C) reported that they are using SDMs and in all three case the software development life cycle SDLC was the main methodology.
  - All four cases (A, B, C and D) reported that they are using agile SDMs including scrum and lean methodology, but the first three cases (A, B and C) are using them to a lesser extend as compared to the fourth case (D).
- Software development methodologies satisfaction:
  - Case A and C indicated that they are less satisfied with the use of the SDLC as a software development methodology as it has proven overtime to result in many software projects failing through delays and exorbitant costs.
  - Case B emphasized that the SDLC sometimes result in successful software development solutions provided that the processes is followed prescribed.
  - Case C and D reported that they are satisfied with the SCRUM and mean methodologies in terms of cost. They added that SCRUM help them understand their team members much better, provides them with proper priority management, mitigating priority inversions, transparency and correct deadline estimations.
  - All four cases (A, B, C and D) are satisfied and prefer the use of agile methodologies because these methodology is more reactive and flexible.
- Software development methodologies effectiveness:
  - the results from all four cases indicated that SDMs are effective in a manner that they provides team members with a sense of accountability, provides a better communication channel and ensures that software solutions are delivered on time, within budget and meet user's needs.
  - SDMs are efficient in providing better software development management, proper costing, verification and quality control. Software development methodologies ensure information technology governance, software governance and company governance.
- Software development methodologies modification:

- Results from three cases (A, B and C) indicated that they are not flexible to choose and follow agile methodologies at will, they only adapt their use whenever the need arises.
- All four cases agreed that when they employ the use of agile methodologies, they do not always necessarily use them as prescribed, they make adjustments to them as necessary.
- In all four cases results show that SDMs do not always suit every environment nor do they suit every project, therefore making changes is part of successful implementation of most SDMs.
- Cases (A, B and C) outlined that combining of the software development life cycle and agile methodologies has proven to be working for them sometimes. They scale down the process of the SDLC into smaller processes so that they can apply aspects of agile methodologies especially for small projects.

- Criteria to choose methodology:
  - All four cases reported that they choose the SDMs based on project requirements, team size, project size and whether the team accept the methodology.
- Willingness to adopt a methodology:
  - All four cases agreed that they are willing to accept the use of SDMs provided they addresses their daily struggles and makes it easier or better for them to tackle software development.
  - Case D however emphasized that is reluctant to adopt any more SDMs as their current ones meets the bare minimum requirement in their environment. They mentioned that adopting new SDMs is costly and time consuming.
- Software solution project success rate:
  - All four cases reported that they have experienced more project success than failure. This means that most projects were completed within stipulated time frame, budget and meet users requirements

Table 1 below presents the tabular view of the results as highlighted in section 5 above and as discussed in section 6 below.

Table 1: Tabular presentation of research results

	Experience with SDMs	SDMs Being Used	Perception with regards to use of SDMs	Readiness to adopt new SDMs	Criteria for telecommunications industry SDMs	Challenges with using SDMs
A1	5 Years	SDLC, Agile RUP, Agile SCRUM, modified agile steps	less satisfied with the use of the SDLC - prefer the use of agile methodology	willing to adopt the use of new SDMs	- based on project requirements	only allowed to adapt their use whenever the need arises
A2	3 Years	SDLC, XP, , Agile RUP, Agile SCRUM, modified agile steps	SDMs are effective, provide sense of accountability, better communication - software delivery on time, within budget and meet user's needs.	willing to adopt the use of new SDMs	flexible, adaptable, reliable and save time	costly and consume a lot of their time
B1	9 Years	SDLC, XP, RAD, JAD, modified agile steps	prefer the use of agile methodology	willing to adopt the use of new SDMs	flexibility and adaptability	SDMs do not always suit every environment nor do they suit every project
B2	7 Years	SDLC, XP, RAD, JAD, modified agile steps	- better software development management, - proper costing, verification and quality control - ensure software governance	willing to adopt the use of new SDMs	proper structure, verification, correction	need more time and training team members
C1	11 Years	SDLC, modified agile steps	less satisfied with the use of the SDLC	willing to adopt the use of new SDMs	quality control, accountability, quick delivery,	many information technology practitioners are less informed about SDMs
C2	5 Years	SDLC, modified agile steps	satisfied with the SCRUM and other lean methodologies	willing to adopt the use of new SDMs	measure performance and manage team members	the telecommunication industry has to adjust SDMs to better accommodate their needs
D1	15 Years	SDLC Agile RUP, Agile SCRUM, XP, derive steps	have experienced more project success than failure	reluctant adopt the use of new SDMs	proper planning, proper requirements analysis, and avoids scope creep	original SDMs are in some cases inadequate for some software projects
D2	13 Years	SDLC Agile RUP, Agile SCRUM, XP, derive steps	Absence and improper use of SDMs has resulted in high rates of software solution projects failing	reluctant adopt the use of new SDMs	make their job much simpler and controllable	SDMs increase the time frame of the development process

Results Discussions According To Research Objectives Literature and Questions

Objectives

Objective 1: to identify the software development methodologies used in the telecommunication industry

From the results acquired, it was apparent that SDLC and agile methodologies are prominent in the telecommunication industry. The SDLC is the main corporate SDM while agile methodologies are implemented internally for mostly smaller software development projects. The integration of the SDLC and agile methodologies is also practiced to attain best results. In some cases alteration of the SDLC is done. Literature has identified SDMs that are explicitly intended for the telecommunication industry, nonetheless according to the data collected, none of these SDMs are implemented in the telecommunication industry.

Objective 2: To Specify Requirements For A Sdms Suitable For The Telecommunication Industry

The results obtained indicated that it is imperative that SDMs in the telecommunication industry should be flexible, adaptable, reliable and save time to ensure better management and successful implementation of these software development methodologies.

Objective 3: to justify the significance of SDMs in the software development process

The lack of or incorrect use of SDMs has caused many software projects to fail. Presently used SDMs in the telecommunication industry has proven to be constructive and works accordingly. Nonetheless alteration possibly will be desirable since not all software development project are alike and requests different implementation processes.

Literature

Advantages of Software Development Methodologies in the Telecommunication Industry

The results indicated that the use of SDMs in the telecommunication industry is important and that the use SDMs is primary, for mitigating risks and ensuring that software project are produced within time, budget and meet users' needs. Existing SDMs have proven to be helpful as employed in the telecommunication industry.

Disadvantages of Software Development Methodologies in the Telecommunication Industry

The lack of or wrong use of SDMs has triggered software development failure in many instances. Results indicated that the use of SDMs is costly and consume a lot of their time. Since the telecommunication industry is fast paced following prescribed steps within methodologies is not practical. This will lead to tailoring of methodologies, which will need more time and training team members on the insights of the new tailored method. Tailoring the method may also require an expert who will diligently review the methodology to certify its efficiency and reliability.

The findings in line with research questions

Do telecommunication companies use SDMs during software development?

In summary the answer to this question is yes. However it is also imperative to note that many information technology practitioners are less informed about SDMs. Majority of information technology practitioners who holds a significant experience are well knowledgeable about the SDMs in theory, appreciate their role in the organization and can relate SDMs and the development process.

What SDMs are used currently in the telecommunication industry?

The SDLC and agile methodologies are the mostly used SDMs in the telecommunication industry. Agile is preferred for its qualities such as flexibility and adaptability in software development. SDLC is a primary corporate SDM in the telecommunication industry.

To what extent are SDMs followed in telecommunication industry?

In some cases the telecommunication industry has to adjust SDMs to better accommodate their needs. This is because the original state of the methodology may be inappropriate for the particular software project they have to do. The mixture of SDLC along with agile methodology has been tested and tried and works accordingly in the telecommunication industry.

What are the views of information technology practitioners about SDMs in the telecommunication industry?

The SDLC is not preferred in the telecommunication industry. It increases time frame to the development process, since rework on an enormous projects is continually necessary. The SDLC has also been confirmed over time that it is not well-matched in the telecommunication industry and has failed repeatedly. Agile methodologies are the appropriate SDMs for telecommunication industry. The use of SDMs in the development process has presented benefits such as proper structure, verification, corrections, quality control, accountability, quick delivery, measure performance and manage team members. Absence and improper use of SDMs has resulted in high rates of software solution projects failing. This is since the absence of SDMs leads to poor planning and poor requirements analysis, ultimately leads to scope creep and eventually to project failing.

Every single methodology has its welfares and may result in software development project success if implemented correctly or altered to suite the situation. Nonetheless adequate knowledge and attitude of team members plays an important role for a software development project success.

SDMs would be more advantageous in a fine structured environment in which each information technology practitioner has his/her own tasks and responsibilities. This is since SDMs are designed in a way that a team member is assigned his/her own responsibilities and tasks. This is an intimidating task if a single team member has presumed the task and responsibilities of more than two information technology practitioners. Information technology practitioners are prepared to welcome and accept SDMs, provided it will make their job much simpler and controllable. Results also stated that the environment the information technology practitioners are working in is unbalanced and dynamic, so the ideal methodology should be time conscious, reactive easy to understand and follow.

What is the criteria used by telecommunication companies to choose the SDMs for each software development project?

The project size is one aspect they take into consideration when it comes to selecting a proper SDMs to use once developing software solution. The SDLC is chosen when dealing with a huge project. Agile methodologies are chosen when dealing with a smaller projects. Another aspect they look at is the team size, they usually go agile root if the team size is small otherwise they use the SDLC root with larger teams. Another criteria is business requirements where if they are dealing with numerous and complex requirements they go agile. If the requirements are less complicated and only include an unimportant number of people then they use agile methodologies.

Conclusion and Recommendations

Conclusions

From the results acquired, this research can conclude to confirm that SDMs are practical in the telecommunication industry. Agile methodologies and the SDLC are used to support software development project. This results stipulate that SDMs are applicable and suitable in the telecommunication industry. However there is still a lot of issues to be ironed out regarding the implementation of SDMs since some information technology practitioners are not well up to speed with their use. SDMs may need to be refined looking at the special needs of the telecommunication industry, this will make easy implementation when developing software solution. It could be that there will be less modification needed with every project undertaken. In this case team members may warm up to the use of SDMs as it will be easy to understand and follow, without consuming a lot of their time during the development process.

Recommendations

Recommendation 1: The use of a proper organizational structure

The results indicated that the respondents are working in a more unstructured environment in which one person can assume the responsibilities of three people. This in turn result in confusion and low quality of work. Therefore this research recommend that the telecommunications industry review their organizational structure. A proper organizational structure will improve decision making, employee performance customer service and help streamline operations (Osmond 2016).

Recommendation 2: Awareness and training

Many respondents indicated that they are aware of SDMs in general. However many could not describe precisely how its application can be beneficial to their company. Many SDMs have been recommended and permitted, though they have not explored their contents to evaluate which one will work finest for them. Therefore this research recommends that management send their employees for proper training such as short courses on software development methodologies. This will results in better job performance.

Recommendation 3: Using a responsive methodology

All companies interviewed are using software development life cycle, nevertheless this methodology has caused some of their projects to fail. Taking into consideration the unstable nature of the telecommunication industry, the best appropriate method in this instance ought to be more responsive to

cater for the frequently changing user requirements. A responsive methodology is one that adjusts to change as it happens, forecasts future changes and provides possible answers for future occurrences.

Recommendation 4: Explore SDMs designed for the telecommunication industry

Literature has identified software development methodologies that were specifically designed for the telecommunication industry. During the interview sessions, none of the respondents mentioned any of these methods, this proves that they are unaware of them and they chose to use general software development methodologies. This study however recommends that the telecommunication companies look into these software development methodologies and explore them, as they were designed considering the complex nature of the telecommunication industry

Abstract

At present, it is urgent to develop various directions of regional business differentiation in order to maintain the effectiveness of its functioning. A franchise is an effective method that allows small businesses to improve their reputation and standing in the shortest possible time, and larger companies to capture additional market share. The objective of this article is to analyze Russian and foreign experience of franchise development and to identify its main types, as well as to study the opportunities of regional business differentiation and development of the territories implementing different types of franchises. The study has been carried out applying scientific methods of analysis and synthesis as well as economic and mathematical methods. The work reveals the challenges and outlines the prospects for franchise development as one of the most progressive and effective forms of business doing. An empirical research has been conducted by means of investigating European countries, the USA and Japan. The article emphasizes that franchise companies are mostly small businesses, however, currently, franchise technology is also being implemented by relatively large enterprises.

Keywords: franchise, business differencation, economic development, regions.

Introduction

When studying the importance of franchise for business development, it can be said that it is obvious to expect an increase in interest in this specific type of business doing in the future, which will be a foundation for the development of different countries' territories. The orientation towards the development of franchise companies is one of the directions of supporting any country's economy which will make it possible to increase the effectiveness of the conducted policy, to create conditions for the regional competitiveness and economic growth. The study of the opportunities of implementing franchise as a tool for business development is widely covered in scientific researches (E. Calderon-Monge (Calderon-Monge, 2017), I. Pastor-Sanz (Pastor-Sanz, 2017), P. Huerta-Zavala (Huerta-Zavala,2017), S. C. Michael (Michael,2014), E. Crawford-Spencer(Crawford-Spencer,2015), C. Atwell (Atwell,2015), etc.).

A franchise is important since its implementation creates conditions for business rapid development in the existing market and at the same time solidifies business positions. This area of research is relevant due to the fact that in the present period of economic development, a franchise is assessed as a progressive and effective type of doing business which allows introducing new ideas quickly into business processes and building business models, as well as developing the territories.

Results and Discussion

At the first stage of our study, we have analyzed the foreign experience of franchise organizing and the level of its development in the countries which are the leaders of the world economy.
Let us consider the franchises present on the market today. Thus, according to RBC (RosBusinessConsulting Holding (Russia), the most expensive franchises are the ones listed in Table 1.

Table 1: top most expensive franchises

Brand	Type of activity	Investments
Hilton Worldwide	Hotel company	from 400 mln rub
Chaihona N 1 (Чайхона №1)	Chain of restaurants	from 120 mln.rub
Fun City, Fun Kids, Fun Jump	Family Fun Parks Chain	60-100 mln.rub
IL Patio	Chain of restaurants	from 33 mln. rub
Camp David	Men's clothing trade	15-22 mln. rub
Elki-palki (Елки-палки)	Fast food chain	from 18 mln.rub
Wyndham Hotel Group	Hotel company	-
Wendham Grand	Luxury 5 stars plus	$ 225,000-275,000
Ramada	Category Business 4 stars plus	$ 70,000-90,000
RamadaEncore	Category Budget 3 stars plus	$ 55,000

The source: Data available on the websites [https://www.entrepreneur.com/franchise500] and [http://www.franchise.org] were used when compiling the table.

The main share of franchises falls on the USA, since this country considers franchising as one of the priority forms of international activities and supports the franchisors' entering foreign markets. In 2015, IFA (International Franchise Association) published a report which indicates that there were 781,794 franchise enterprises in the United States in 2015. The leaders among the franchises in the US were indicated in the IFA's Top 500 European Franchises - Ranking (Table 2).

Table 2: the US top franchises

Rank	Franchise	Number of branches	Year of company's foundation	Country	Type
1	*7-Eleven*	*53,119*	*1927*	*USA*	Food products: 24-hour shops
2	*Subway*	*43,926*	*1965*	*USA*	Fast Food
3	*McDonald's*	*36,258*	*1955*	*USA*	Fast Food
5	*KFC*	*18,875*	*1930*	*USA*	Fast Food
6	*Pizza Hut*	*14,967*	*1958*	*USA*	Restaurants
7	*Burger King*	*14,000*	*1954*	*USA*	Fast Food
9	Jani-King	12,000	1969	*USA*	Hygiene
10	Jan Pro	11,676	1991	*USA*	Hygiene

The source: Data available on the websites [https://www.entrepreneur.com/franchise500] and [http://www.franchise.org] were used when compiling the table.

Thus, the majority of franchise companies are food and catering-oriented, i.e., cover agricultural production. According to IFA, in the structure of the US franchises, the largest share was accounted for

by fast food chain restaurants (38 %), followed by real estate services (16 %), restaurant chains (13 %) and food (12 %) (Fig. 1)

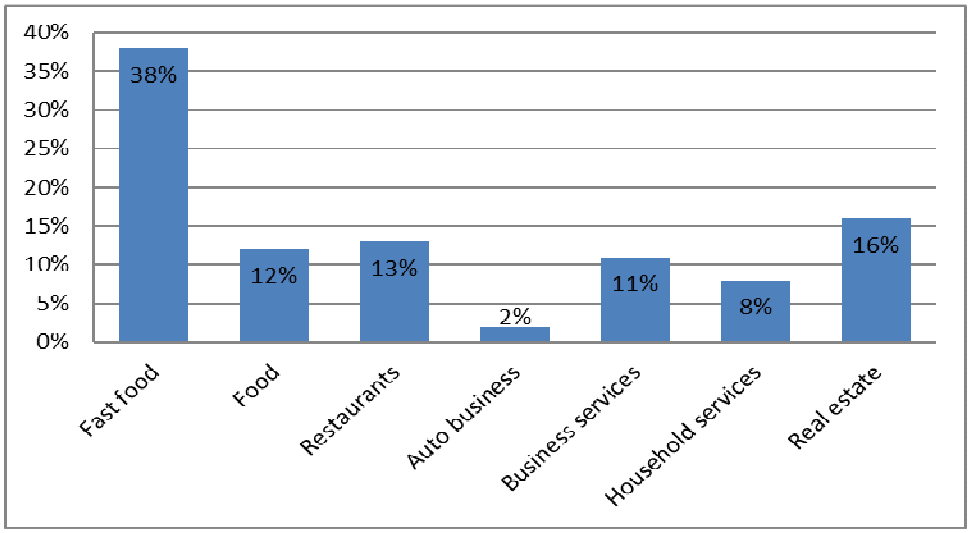

Fig. 1 The US Franchise Structure

The source: Data available on the IFA website [International Franchise Association, http:// www.franchise.org] were used when building the diagram

Since food franchises are the leading ones, this area will always be attractive for investments. In 2015, in the US, the economic performance of food-oriented franchises (fast-service restaurants, full-service restaurants and retail food) was about 341 billion dollars.

The studies conducted by AFA (American Franchise Association) showed that after two years only 15 % of newly established enterprises remain on the market, while the share of successful franchise enterprises is much higher – 85 %. The sales volume in the US franchise system is about $ 1 trillion a year; it should be noted that 40 % of retail sales fall on the share of franchise system[1].

The European Franchise Federation (EFF) assessed about 8,500 different franchise brands and 2,500 US brands functioning in the EU [Etro, 2011]. Top 500 franchises in Europe show that, although US brands are still very popular, many franchises established in European countries also became major brands across the continent and beyond[2]. Examples of the most successful European franchises are given in Table 3.

[1] Data are available on the website of American Franchise Association http://americanfranchiseassociation.com/

[2] Data available on the website of The European Franchise Federation http://www.eff-franchise.com/ were used

Table 3: the most successful European franchises

Rank	Franchise	Number of branches	Year of company's foundation	Country	Type
1	Spar	12,314	1932	the Netherlands	24-hour shops
2	Bata	6,700	1894	The Czech Republic	Retail Stores: Clothing and Footwear
3	Benetton Group	6,000	1965	Italy	Retail Stores: Clothing and Footwear
4	LCF Clubs	5,000	1985	the United Kingdom	Education: Children
5	Etam	4,200	1916	France	Retail Stores: Clothing and Footwear

8	Swarovski	2,350	1895	Austria	Retail Stores - Jewelry
9	*Telepizza*	*1,234*	*1988*	Spain	Fast Food
10	Yves Rocher	1,600	1959	France	Beauty and Cosmetics

The source: Data available on the website of The European Franchise Federation [EFF- http://www.eff-franchise.com], as well as the website [http://www.franchisedirect.com] were used when compiling the table

Currently, franchising has a wide distribution. In France, Germany, and the UK, service-oriented franchise is very common. The analyzed countries are characterized by high growth rates in the turnover of retail trade and services. These activities are currently prevalent in the franchising market of Central and South-Eastern Europe and are the most dynamic and potentially 'broad' ones for further development.

We examined the Japanese experience of developing this form of entrepreneurship as an example of Asian franchise. Japan is a country with a well-developed economy. It ranks third in the world ranking after the US and China. It happened due to the technogenic development of the economy; among the franchisors, Japan is one of the leading countries in the world. It is worth noting the country's government's active attitude to the problem, since it is franchising that is the main contributor in the formation of the national economic policy. Japanese franchising contributes to the creation of a large number of new jobs, responds quickly enough to changing consumers' demands, and constantly offers new types of goods and services. Japan is one of the few countries where franchising procedure is not accompanied by compulsory licensing and strict statutory compliance Wright O., McAuley A., (Wright, McAuley, 2012).

The IFA Top 500 European Franchises Ranking includes only three Japanese franchises (Table 4).

Table 4: top Japanese franchises

Rank	Franchise	Number of branches	Year of company's foundation	Country	Type
1	Kumon Inst. of Education Co. Ltd.	25,384	1954	Japan	Education: Children
2	Yamaha	4,900	1954	Japan	Education: Children
3	*Beard Papa's*	*366*	*1999*	Japan	*Bakery shop*

The source: Data available on the website of The International Franchise Association [http://www.franchise.org] as well as the website [http://www.franchisedirect.com] were used when compiling the table.

JFA (Japan Franchise Association) discloses the structure of Japanese franchises. According to these data, in Japan, the most developed franchises are trade-oriented and food-oriented ones take the second place.

Each country also has its own specificity of franchise implementing, which is related to certain factors, for example, a demand for certain goods and services among the population and the trend of development of a certain economic branch.

Thus, it is the USA that has the most effective backgrounds for franchise development, including those related to the catering sector. The International Franchise Association also creates certain regulations which a company shall comply with when buying and/or selling a franchise.

In Russia, franchising is being developed in different areas. Trade-oriented franchises have the leading position – their share exceeds 50 %. In recent years, public catering and fast food franchise companies are actively developing. The Russian market is characterized by a regional distribution of franchises. After a company enters large cities, it begins its active introduction and promotion in the regions, which allows developing a franchise more dynamically.

Currently, there are about 500 franchise companies and almost 20,000 franchisees in Russia. Most of the franchise companies involve food and restaurant business, retail clothing and footwear; service industry is also widely represented among franchise companies. The share of foreign franchises in Russian market is approximately 40 % (Pizza Hut, KFC, Baskin Robbins, Burger King, Subway, as well as retail Terranova, Mango and others).

In our country, those industries in which profit margin is higher are preferred. Thus, Russian franchisors enter the sectors of public catering, trade and business services. Analysts also talk about high potential for franchise development in Russia. The professional Golden Brand 2015 Franchise Ranking includes several Russian franchises which are presented in Table 5.

Table 5: the most successful Russian franchises

№	Brand	Price
1	Invitro	from 850,000 rub
2	33 Penguins	*690,000* rub
3	TONUS CLUB	from 2,200,000 rub
4	Rosinter Restaurants Holding	from *2,000,000* rub
5	*Shokoladnica*	from *4,000,000* rub
6	Samsonite	from 3,500,000 rub
7	*CoffeeShop Company*	from *4,000,000* rub
8	*Harat's pub*	from *9,000,000* rub
9	Tochka Krasoty	from 1,500,000 rub
10	*Coffee Like*	from *500,000* rub

The source: Data available on the website of Golden Brand [http://reyting-franshiz.buybrand.ru/rating/] were used when compiling the table.

Thus, more than 40 % of world trade turnover is carried out through franchising networks of franchisee enterprises. In market economy, a developed trading network is a strategic competitive advantage. The franchise business model is effective in Russia. It is actively developing in the conditions of a high level of franchisee enterprises' 'survival'. According to the forecasts of the Russian Franchise Association, there will be about 400,000 points of sales of goods and services managed by franchisees by 2025 in Russia. Currently, in Russia there are about 40,000 points of franchises.

However, it is necessary to create appropriate conditions for franchise development. It is necessary to establish legal foundation to regulate the activities of franchise firms, in particular, when implementing protectionism policies in the agricultural sector. This measures will exclude informal relations in the franchise functioning and thereby increase its effectiveness. It is advisable to develop state government program to support small businesses and franchise development system.

Let us analyze the process of economic benefits, for the territories where franchise activities are expanding, using multi-factor econometric models.

The following factors were selected for the multi-factor function Y (GRP per capita, rub / person): X1 is the level of franchise development on the territory, X2 is the investment component.

On the basis of the technological table, the paired correlation coefficients were calculated and, taking into account the obtained data, a regression model was constructed.

$$Y = -54 + 2{,}2x_1 + 2{,}7x_2$$

The model was checked for adequacy according to Fisher's F-criterion; the parameters were checked according to Student's t-test; the obtained results showed that as a whole the model is adequate and all regression coefficients are significant.

Partial elasticity coefficients show how much the analyzed indicator changes on average with 1 % change of each factor for a fixed position of other factors: E1 = 5.1 %, E2 = 9.2 %. Thus, with an increase in the level of franchise development by 1 % on a territory, the economic benefit will grow by an average of 5.1 %, when the investment component will grow by 9.2 %, respectively, which indicates the effectiveness of implementing such a development tool as franchise entrepreneurship.

Conclusions

In an emerging market economy conditions, franchising is the fastest way to build a business using practical standards and the easiest way to make a profit in the short term. For large, well-known companies, franchising is a way to expand business; from the point of view of entrepreneurs it is an opportunity to become the owner of a profitable business under the 'all-inclusive' scheme. It is necessary, in particular, to pay attention to the development of public catering-oriented franchise entrepreneurship and to suggest that foreign companies involve Russian suppliers of raw materials, which is especially important in the context of sanctions.

Currently, in Russia there are about 500 franchise companies and almost 20,000 franchisees. Franchising is developing in different areas in Russia. The leaders are trade-oriented franchises (the share exceeds 50 %), food and restaurant businesses, whereas the share of foreign franchises in the Russian market is about 40 %. However, it is necessary to pay attention to the fact that the main share of franchises falls on the USA. The Russian Franchise Association predicts that in 2016-2017 the market will not slow down the growth rates and state companies will be included in the development of the franchise market.

Acknowledgments

The study was carried out with the support of the Russian Foundation for Basic Research No. 17-02-50127 "Management of the differentiation of the regions' economic space in the period of the formation of neoindustrialism in Russia".

Abstract

The article reflects the importance of technology development, reengineering of business processes in a competitive environment of global and domestic levels. Thus explains the selection of the optimal simulation environment for Russian enterprises. The author proposes an effective methodology for conducting reengineering of business processes of the enterprise, which allows you to build an effective development strategy. The paper discusses the main causes of the need for re-engineering business processes in large business enterprises.

Keywords: business process, modeling business processes, strategy, process approach,reengineering, strategic management.

Introduction

The process approach has received active development in the field of quality management regulations developed by the International organization for standardization ISO. A business process is a set of interrelated activities that convert inputs into outputs, i.e. input resources into production Komissarova M.A. (Komissarova, 2011). The idea is to present any activity in your organization, or directly the organization of the process is regarded as an axiom. It was formulated by E. Deming, the founder of quality management Deming, E. (Deming, 2011). At the moment we have enough evidence that the process approach enhances the quality and effectiveness of governance. It can be used to achieve significant cost reduction by establishing and optimizing business processes of an enterprise, it is not necessary to resort to reduction of business.

The activities of each company has the chain of processes from marketing and planning to sales and after-sales service. It is possible to allocate following features of business processes Kozlova A.A. (Kozlova, 2011):

- the owner of process – the official who is responsible for the progress and results of the process;
- resources allocated to a process can include equipment, staff, facilities, environment, transport, communications, materials, Finance, documentation, etc.;
- process parameters are the characteristics by which the owner of the process and the top management can judge the effectiveness of process execution and the achievement of planned results;
- the customer is a consumer of the results of the process, the degree of satisfaction which is an evaluation of the effectiveness of the process;
- inputs process input items (raw materials, products, equipment, information or service), which moves the execution of the project are converted into outputs of the project;
- outputs of the process are the products, information or service for which the process;
- a network of processes of an organization is an Association of interrelated and conflicting processes of an enterprise into a single system.

Each business process can be broken into additional sub-processes. All the processes of the organization can be divided into major and minor. The main processes lie in the path of the products in the form of marketing information, design and material of the object. Subsidiary have no direct relationship to production, they serve to ensure the normal functioning of the main processes, such as preparation, training and certification of personnel, document management process, assurance process.

Process approach – access to the productive idea of domestic suppliers and consumers, as real activity, added value is not carried out the individual elements of the functional hierarchy and permeates the enterprise as a set of processes. The main advantages of bottom-approach is to focus on the end result, the interest of each Executive in improving the quality not only of the final product, but its work, responsiveness to external and internal changes, streamlining the exchange of information between the functional units, the implementation of quality control in the process instead of quality control Cheremnykh, O.S. (Cheremnykh, 2015).

Compare the main features of traditional and process approaches in table 1.

Table 1: Comparison of the functional approach to management with the process

Sign	Approach	
	Functional	**Process**
The content of the approach	Enterprise management is based on the separation of structural units having a set of specific functions	The management of the enterprise is represented as a set of processes that convert the inputs and outputs of the carrying value to the consumer
Organizational structure of management	Vertical hierarchical structure	Horizontal system the definition of responsibility for each business process
Object	The division, organizational structure	Business process
The aim of the production processes	To maximize coordination between departments, based on a functional division of labor	Maximum satisfaction to internal customers
The efficiency of decision-making	The decision is directly with the problem in the production	Coordinating the timely adoption of decisions
Social policy	Training of workers in the framework of the official and functional activities	Continuous training and promotion of personnel, improvement of professional skill and competence in the field of quality
Dignity	Conflict-free decision-making process, which excludes the interdependence of decision-makers	Orientation on the final result, high efficiency, flexibility in responding to external and internal changes, quality control of process instead of product, motivation, efficiency, democratic system of government
Disadvantages	The lack of interest in the outcome, complicated the exchange of information between departments, leading to increased overheads and timing decisions, authoritarian management	The relationship of decision-makers

In the implementation of the process approach performers have greater powers, increasing their role, autonomy and, therefore, impact and satisfaction with work. The leaders are exempt from current operational issues and focus on solving the strategic, systemic issues.

Thus, the transition from functional to process management is the first stage of reorganization. For the introduction of process management will require a radical transformation. Conversion data in the literature is called reengineering.

Reengineering business processes is a strategy of business management that focuses on analyzing and designing work and business processes of the organization. It aims to help the company review its current operations in order to significantly improve customer service, reduce operating costs, enhance the competitiveness of enterprises Harmon, P. (Harmon, 2015).

Its the beginning of the re-engineering of business processes takes in 1990 when Michael hammer, a former Professor of computer science at the Massachusetts Institute of technology, published the article "Reengineering: don't automate – obliterate", which stated that the main task of managers is to reduce activities that do not add value, instead of implementing technology for their automation. This statement hints at focusing managers on the wrong issues, namely that information technology has been used primarily for automating existing processes, instead to recognize these processes obsolete. In his subsequent writings Hummer has defined reengineering as the fundamental rethinking and radical redesign of business processes to achieve significant improvements in key for modern business performance indicators as cost, quality, level of service and efficiency Hammer, M. (Hammer, 2011).

Since 1995, actively began to publish works criticizing the idea of reengineering, a wave which as a result began to fade Robson, M. (Robson, M., 2014). Since then, considering business processes as a starting point for the analysis and reorganization of business processes is a standard part of the methodology of reengineering, but is less radical than earlier proposals. Recently, the concept of managing business processes have received major attention in the corporate world, as it is actively stimulated by the desire to increase the efficiency of the process and supported by information technology. Therefore, the study and application of modern model of reengineering of business processes is an integral part of strategic planning the top management of the enterprises in the current economic environment Bardakov, A.A. (Bardakov, 2016).

Reengineering based on the concept of discontinuous thinking identifying outdated rules and fundamental assumptions underlying the work, and a definitive break with them Petukhov, V.I. (Petukhov, 2017).

There are two ways of applying the reengineering of business processes:

1. Systematic – the current process is understood, documented and analyzed to systematically create new and better processes. This type of reengineering is based on the rules of the ESIA (to destroy, to simplify, to unify, automate).

2. Reengineering from scratch – the existing process is fully utilized, and a new one is created from scratch by a fundamental rethinking of the previous one. This method reduces the risk of repeating old mistakes, but the neglect of the concepts of the previous process can lead to the neglect of knowledge and experience accumulated in the organization Zlatkin A.A. (Zlatkin, 2016).

There are standard methods and techniques applied when redesigning business process reengineering.

1. Horizontal compression of the process — merging multiple working procedures in one operation. The technique allows to reduce the number of errors and reduce the number of employees elimination of their consequences, to improve the controllability of the production with clearly distributed responsibilities among employees.

2. Vertical compression of processes — providing the artists the right to make independent decisions. The increase in the role of every employee in the company reduces delays, reduces the cost of products and services, accelerates the reaction to customer requests, etc.

3. The steps of each process in the natural order — the use, along with a linear ordering of the works parallel to their conduct, leads to a reduction in time and cost.

4. The execution of processes in various options — the process starts with testing procedures, which aim to determine which option to implement is most appropriate in a given production situation.

5. The implementation of each work where it is most appropriate — the distribution of work between departments, eliminating unnecessary integration.

6. The decrease in the number of inspections minimizing the number of approvals by reducing external points of contact and, as a consequence, the Erasure of distinctions between the functional units.

7. Authorized Manager provides a single point of contact — if the process is complex and integration is not possible, then "authorized" the Manager answers a customer's questions and solves his problems, has access to all the IP used in the process, and to all the performers.

8. The predominance of a mixed centralized-decentralized approach — the use of modern information technologies enables the company to act at the level of Autonomous units, saving them the possibility of using centralized data.

Results and Discussion

The application of reengineering business processes at the present stage is impossible without information and communication technologies.

In the last few years gaining popularity of software products for modeling business processes, designed to facilitate reengineering. Their primary purpose is the rendering of technological and managerial chains of actions, events, and functions Zlatkin A.A. (Zlatkin A.A., 2016).

The most popular software products in this group:
— ARIS Toolset;
— BPWin;
— Business Studio.

Software products of this type allow for the analysis, documentation and improvement of business processes to model action processes, determine their order, and the necessary resources. With their help you can build charts of different level and purpose. Various charts that are created in such software products reflect an overall view of the process, its relationship with the external environment, necessary resources, results, relations between processes, system components, define the sequence of operations that allow us to calculate costs, the cost of production, identify the most costly processes.

The choice of optimum tool environment of modeling business processes of the enterprise will be implemented among the six software products:

- Business Studio;
- Business engineer (Bitek);
- ORG-Master Pro;
- Bizagi BPM Modeler;
- IBM WebSphere Business Modeler.

Business Studio — business modeling allowing to build an effective organization Business Studio: business modelling (Business Studio: business modelling).
Main objectives:

- formalization of strategy and control of its achievement;
- design and optimization of business processes;
- design of the organizational structure and staffing;
- generation and dissemination among staff of regulatory documentation;
- implementation of the quality management system in accordance with ISO standards;
- the formation of Technical tasks and support the implementation of information systems.

The system allows you to design business processes using IDEF0 diagrams, IDEF3, DFD, and import the finished chart in Microsoft Visio.

Business engineer is a professional tool for the modeling of the enterprise activities and the development of regulatory documents Business engineering technologies (Business engineering technologies).

The system supports the full cycle of designing: from strategy development, key performance indicators and business processes, ending with the analysis and optimization of the organizational structure, improve the efficiency of personnel, projects, building a system of quality management, Finance and the enterprise information system.

Software product allows you to develop a business model and to form the basis of analytical reports and regulatory documentation in various areas: strategy, business processes, personnel, etc.

ORG-MASTER allows to develop a system of goals and indicators, business processes, financial, informational, organizational structure and so on Business Engineering Group (Business Engineering Group). When designing the data can be presented in a hierarchical directories, projections (reflecting the relationship between books), diagrams. For business processes supported by the development of diagrams in notations IDEF, Cross Functional Flowchart, EPC (Event-Driven Process Chain). It is possible to build organizational charts and diagrams, own the type of.

The developed diagrams can be analyzed using cost analysis, resource loading can be calculated the average execution time. The system supports the possibility of collecting and monitoring key performance indicators.

Bizagi is the BPM system developed by the same company, and is aimed at the modeling, execution, automation and analysis of business processes Business Studio: business modelling (Business Studio: business modelling) Bizagi (Bizagi). The Bizagi system includes 3 modules for full customization processes:

 Modeler is a full — featured modeling processes in BPMN notation;

 Studio is the development environment business processes;

 Engine — runtime processes that are available to users in any browser on any device.

The system supports the BPMN notation, which allows you to design business processes using diagrams that have some differences from the DFD. The last time such a notation is gaining in popularity.

IBM WebSphere Business Modeler is a software tool aimed at modeling, simulating and analyzing business processes. In addition to this IBM WebSphere Business Modeler allows you to create a list of KPIs, link them to elements of the business process and by simulating the model to predict their values IBM (IBM). Thus, monitored the achievement of strategic and tactical goals of the company.

Software product allows to describe business processes with BPMN diagrams. Information about the organization can accumulate in the form of structured directories between directories can be established relationship.

ARIS Business performance Edition supports the full cycle of business processes: from the description of the strategy to controlling.

A software module products ARIS Design Platform (ARIS Business Architect, ARIS Business Designer, ARIS Business Publisher and other) allow you to simulate, optimize and publish business processes. Supported design diagrams of the business processes in such popular notations like IDEF, Basic Flowchart, Cross Functional Flowchart, EPC, BPMN, BPEL ARIS COMMUNITY (ARIS COMMUNITY). You can also create your own chart types.

Supported simulation. Conducted cost analysis, analysis of resource loading, analysis for the presence of information gaps in the process, the semantic analysis of process, analysis of the processes supported by information systems, report on critical points in the process.

In order to select the optimal, we need to evaluate the above system and compare with required for the work criteria.

The evaluation of the position of each tool environment of modeling business processes, we have carried out among domestic and foreign software products. For this, we analyzed data on sold licenses for the products of domestic and foreign companies over the past 5 years. The results are presented in table 2.

Table 2: Number of sold licenses for software products for 2012-2016, PCs

Product	The number of sold licenses, PCs
Business Studio	300
Biznes-ingener	118
ORG-Master Pro	239
Bizagi BPM Modeler	148
IBM WebSphere Business Modeler	512
ARIS Business Performance Edition	485

Next, we divided the data modelling system business process functionality with the help of expert assessments. The results are presented in table 3.

Table 3: Evaluation of systems modeling of business processes functionality

The name of the system	Functional capacity evaluation on a five point scale (1 – least functional to 5 most functional)
Business Studio	4
Biznes-ingener	5
ORG-Master Pro	4
Bizagi BPM Modeler	4
IBM WebSphere Business Modeler	5
ARIS Business Performance Edition	5

Based on the obtained data we developed a matrix to determine the leading system in terms of sales and functionality for later selection of software products (figure 1).

Based on the obtained matrix, we conclude that leaders are Business Studio, IBM WebSphere Business Modeler, ARIS Business Performance Edition. Other systems are the closest pursuers of the leaders, which suggests that all ON some similar functionality, they are different only in popularity among customers.

The next step will carry out the selection of one system for further work with the business processes of JSC KEAZ using the method Churchmen-Ackoff. This will form the criteria which must be met by the simulation system business processes:

1. easy to install on your PC;
2. menu in Russian;
3. the convenience of the interface;
4. the low price of the license;
5. the availability of technical support;
6. integration with Microsoft Visio;
7. ease of implementation the simulation;
8. the possibility of conducting a functional cost analysis and build a strategic map.

Next, we examined 2 strategies: choosing a foreign system of modelling business processes (A), the choice of the domestic software product (In).

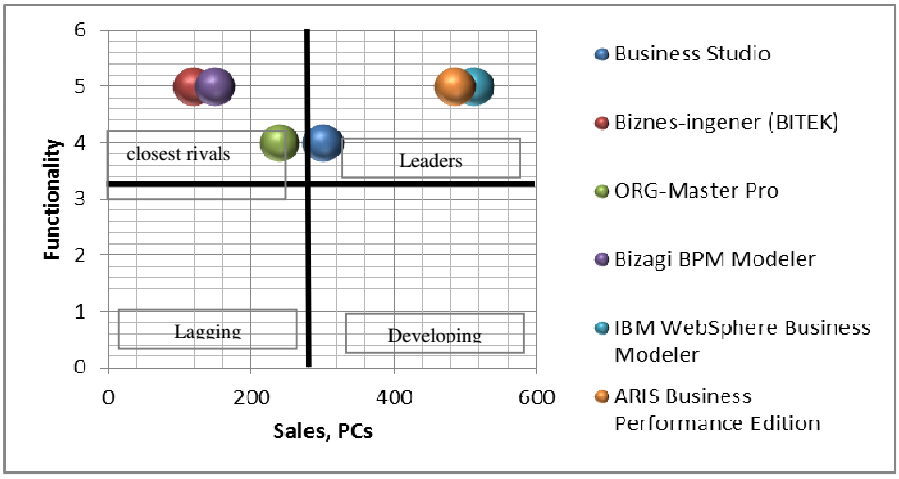

Fig. 1 Matrix for determining leadership among systems modeling of business processes

The source: compiled by the authors

The generated ranking of criteria by importance is presented in table 4.

Table 4: Ranking of criteria by importance

Goal	Rank
1.Easy to install on the PC	2
2.Menu in Russian	1
3.The convenience of the interface	4
4.Low price license	5
5.Technical assistance will be available	6
6.Integration with Microsoft Visio	7
7.Ease of implementation the simulation	8
8.The possibility of conducting a functional cost analysis and build a strategy map	3

Produce comparison purposes in table 5.

Table 5: Comparison purposes

Comparison purposes	The total value

V6< V1+V2+V3+V4+V5+ V8	7
V5< V1+V2+V3+V4+V8	6
V4< V1+V2+V3+V8	5
V3< V1+V2+V8	4
V8< V1+V2	3
V1< V2	2
V2	1
	36

We will assess the policies against each and the achievement of the 8 goals in table 6.

Table 6:Evaluation of strategies

Strategy / Goal	A	B
V1	0,8	0,6
V2	0,8	0,5
V3	0,1	0,8
V4	0,1	0,9
V5	0,1	0,9
V6	0,1	0,9
V7	0,1	0,7
V8	0,4	0,7

Let us calculate the utility of the strategies:
ПА=0,8*0,06+0,8*0,03+0,1*0,11+0,1*0,14+0,1*0,17+0,1*0,19+0,1*0,22+0,4*0,08=0,187;
ПВ=0,6*0,06+0,5*0,03+0,8*0,11+0,9*0,14+0,9*0,17+0,9*0,19+0,7*0,22+0,7*0,08=0,799;

Thus, we can conclude that for realization of Russian projects in reengineering, it is advisable to choose a strategy – choosing a domestic software product, as an indicator of its efficiency is much higher than the figure of strategy And choice of foreign systems of modeling business processes.
From the above matrix to determine the leadership systems of modeling business processes, we find that the only domestic software product that fall into the category of leaders is Business Studio 4.0.

Conclusions

Despite the fact that the technology of reengineering of business processes has been used for over 20 years, Russian companies are currently not developed sufficiently universal method of reengineering, taking into account the peculiarities of their functioning. Therefore, we propose the following algorithm of a phased description of the preparation and further implementation of the reengineering of key business processes of industrial enterprise (figure 2).

The proposed method consists of two major parts: determining the re-engineering and direct implementation of the reengineering of key business processes Vertakova, Y., Klevtsov, S. and Klevtsova, M. (Vertakova, Y., Klevtsov, S. and Klevtsova, M., 2015).

In the first block describes the business direction of the enterprise and major groups of business processes. Using the BCG matrix is necessary for reengineering. Next, using the model of a hammer is to assess the maturity of process management in the organization.

In the second block describes the model of key business processes "as is" and assessed for stability using Shewhart charts, is functional-cost analysis. Based on the data used for modelling business processes "as it should be," determined by the ideal values and on their basis we construct a matrix of gaps. At the last stage are eliminated gaps between the performance of models on an "as is" and "as should be".

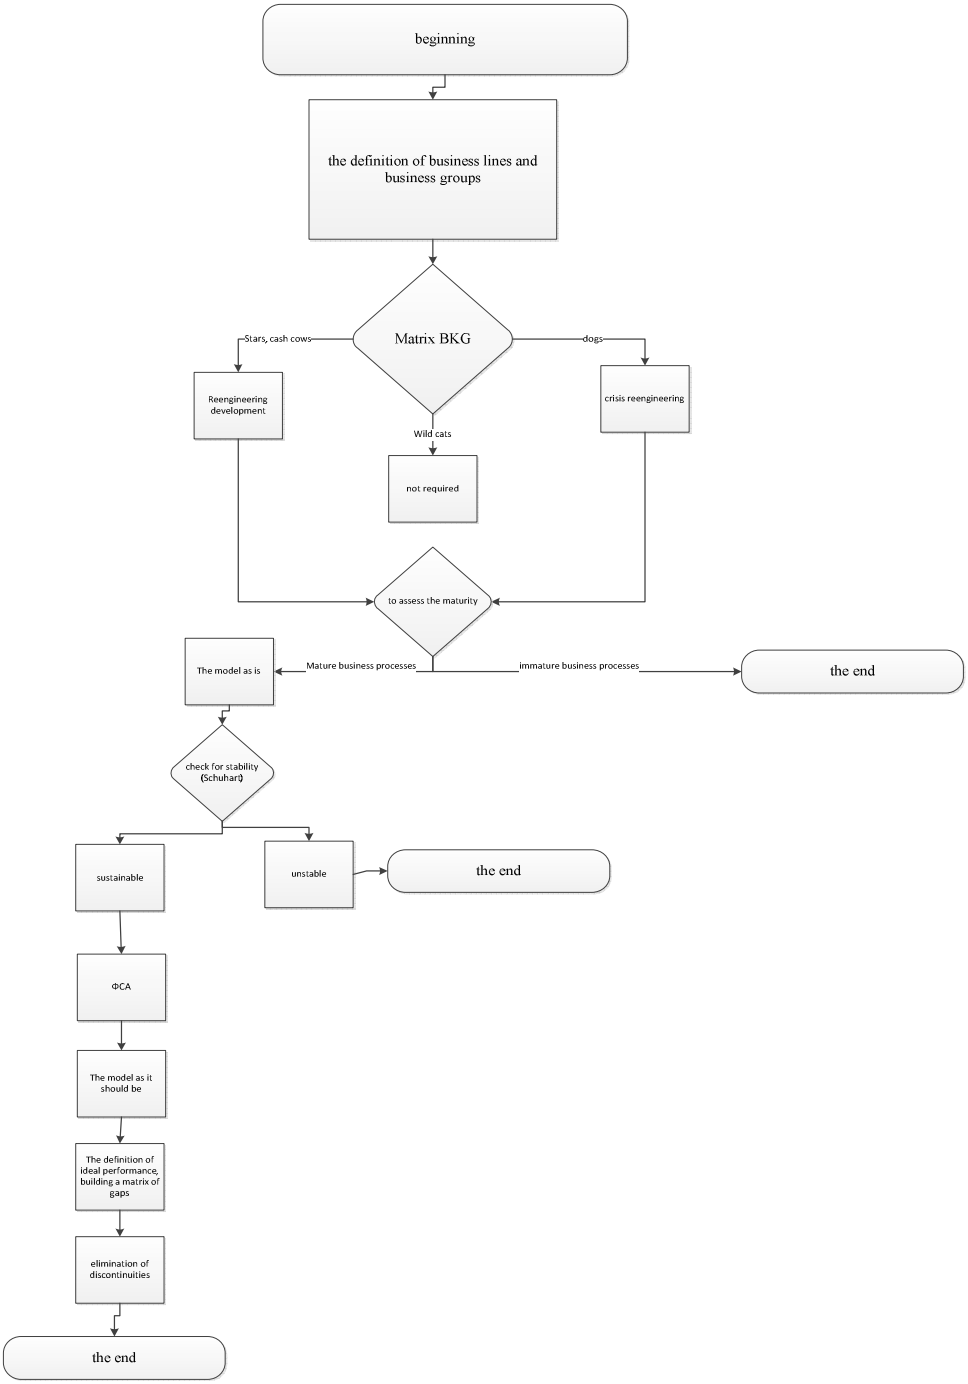

Fig. 2 Stages of the methodology for reengineering business processes

The source: compiled by the authors

Using this technique, an industrial enterprise can carry out the reengineering of business processes independently, without the involvement of external consultants, which significantly saves time and financial resources for the reengineering of the business processes of the organization.

Acknowledgments

This paper is an output of the science project of the government task of Ministry of education and science of the Russian Federation № 26.3546.2017/PCH "Development fundamentals of analysis and prediction of structural and dynamic parameters of the regional economy are based on the integration of the Russian and world experience of management of territorial development and modern scientific doctrines".

Abstract

The article deals with current issues associated with the choice of instruments of economic mobilization and revitalizing sustainable economic growth. Public – private partnership for transport sector is one of the best ways to organize and control relations between the state and business, create and upgrade public infrastructure. The authors noted that one of the most controversial issues remains the problem of increasing the activity models of public – private partnerships as an alternative tool for the development of transport infrastructure. The analysis of the transport infrastructure of Russia and other countries of the world. On the basis of factor analysis a classification of the subjects of the Russian Federation by the level in the sphere of PPP. Presents the results of the rating of the Russian Federation and other countries the level of development of public – private partnerships. The possibility of implementation of infrastructure projects using the public – private partnership.

Key word: transportation infrastructure, economy development, public-private partnership, sustainable development.

Introduction

The problem of the development and implementation of different forms of public-private partnership (PPP) is important today because currently the mechanisms of PPP are a basic tool allowing implementing long-term and large-scale projects aimed at socio-economic development both at the federal and regional levels since the trend of budget spending cuts, including spending on transportation infrastructure projects, is forecast. There are many examples of successful PPP projects implementation. Currently, PPP is a well-proved mechanism to attract additional resources to the region for its development, in particular, for the development of transportation infrastructure.

Prospects and problems of interaction between business and government entities, forms and mechanisms of public-private partnership implementation, including sustainable development of regions were investigated in the works (L. Saringer (Saringer, 2004), B. Akitoby, R Hemming, G. Schwartz (Akitoby, Hemming, Schwartz, 2007), Yu. V. Vertakova, V. A. Plotnikov, (Vertakova, Plotnikov, 2012), E. Engel, R. Fischer, A. Galetovic (Engel, Fischer, Galetovic, 2014) O. Shilkina, (Shilkina, 2015), etc.).

Despite the growing interest in this subject area, many of the problems of interaction between state bodies and business entities are not fully disclosed, in particular, the issues regarding the regulatory and financing support of the authorities for PPP projects are not thoroughly examined. The same can be said about the issues relating to the system of public administration in the sphere of public-private partnership at the federal level.

In order to create conditions facilitating investments from extra-budgetary funds for more efficient use of the mechanisms of public-private partnership it is necessary to solve a number of tasks:

- To improve methodological and regulatory framework in the sphere of PPP, which will contribute to the growth of the number of models and forms of public-private partnership at the federal and regional levels;

- To improve financial mechanisms and instruments for implementing PPP projects to achieve maximum effectiveness of PPP mechanisms application;
- To create an effective support system for private partners and concessionaires;
- To form an comprehensive system of state-private partnership management.

Due to the unstable economic situation in the world and, in particular, in Russia, the basic prerequisites for the development of transportation infrastructure are to a greater extent related to the implementation of PPP mechanisms. Implementation of different forms of public-private partnership will attract additional extra-budgetary investments in that region, which has traditionally been the area of public investments.

Results and Discussion

The most pressing problem affecting the development of transportation infrastructure in Russia is driving conditions of public road network at inter-municipal and regional levels which is currently unsatisfactory; more than 50% of the roads do not meet modern road standards and regulations; there is also underfunding for roadworks in the conditions of growing traffic density.

In Russia, there are a great number of settlements which have no all year-round connection with public road network by means of hard surface roads. These roads provide not only connection with the major economic centres but also form their development potential. One of the main factors for the socio-economic development is the fact that most of these roads are far from the major rural settlement systems, which increases negative demographic processes in rural areas and, in this regard, hinders considerably the development of rural areas, causing reduced agricultural production, population outflow, extinction of villages, and towns. The current system has also led to the degradation of the system of intra-settlement roads and roads in populated areas, especially in linear settlement systems. Technical conditions of most roads can only be assessed as satisfactory; almost all regional roads require renovation and upgrading.

The main current problem of the implementation of the measures aimed at the development and modernization of transportation system is limited amount of planned investments and lack of infrastructure facilities.

The formation of the mechanisms of interaction between the state and the private sector can help solve this problem. The state and private entities should combine their efforts to reform the transportation infrastructure.

Implementation of infrastructure projects applying PPP mechanisms ensures economic growth, investment attraction, new jobs creation, which will lead to sustained growth of income per capita and the regional budget increase.

Currently, more than 1,300 PPP projects are being developed and implemented in Russia. They include:

- 15 federal projects; - 191 regional projects;- more than 1,100 municipal projects.

With regard to PPP projects in the area of transportation infrastructure, the following trends are observed (Fig. 1):

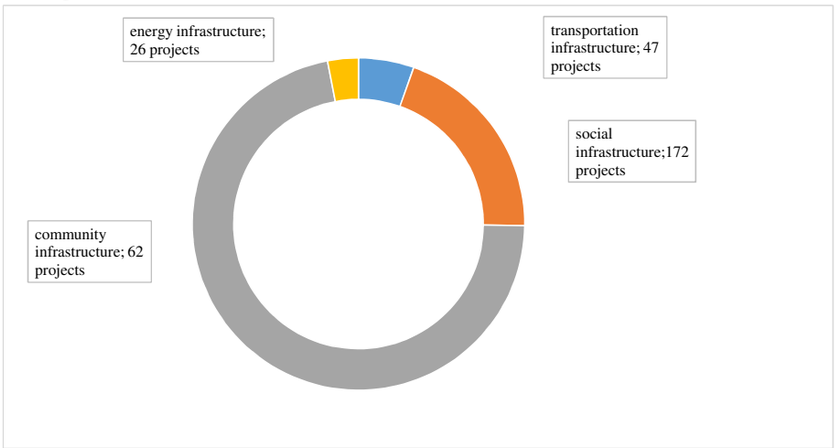

Fig. 1 Number of PPP projects in different infrastructure areas after project close stage

The source: developed by the author using data of the Ministry of economic development and trade of the Russian Federation; Federal State Statistics Service data presented on it's website (http://www.gks.ru/bgd/regl/b12_01/IssWWW.exe/Stg/d12/3-5.htm

Currently, 47 PPP projects in the transportation infrastructure sector have passed commercial close stage and are being implemented in Russia; this is equivalent to only 5% of all the projects. Municipal and regional authorities adopt experience of structuring PPP federal projects in the sphere of motor-roads. The demand for motor-road infrastructure modernization is still very high. The first projects started in the sectors of railway and public road transportation. In Russia, these are the most important PPP projects[10].

The value of the criterion "The level of public-private partnership development in the Russian Federation (RF)" is determined based on the evaluation of its component factors values:

1. Development of the institutional environment;
2. Development of regulatory basis of the RF subjects in the sphere of PPP;
3. Experience in PPP projects implementation in the RF regions.

Accordingly, the calculation of the integrated index (The level of PPP development in the RF subjects) is as follows:

$$Rj = \alpha \times Lj + \beta \times Nj + \gamma \times Ej$$

Where *j* is the ordinal number of the RF subject; *α, β, γ* are the values which determine the significance of the component factors, when $\alpha = 0{,}03$, $\beta = 0{,}03$, $\gamma = 0{,}04$; *Lj* is the value of the factor "Development of the institutional environment of the RF subject in the PPP sphere".

According to this technique, the RF subjects are divided into 5 groups according to the level of development (Table 1).

Table 1: classification of the level of PPP development in the RF subjects

No of the group	The level of PPP development in the RF subjects	
1	leaders by the level of PPP development	60-75%,
2	regions with a high level of PPP development	45-60%,
3	regions with an intermediate level of PPP development	35-45%,
4	regions with a low level of PPP development	25-35%,
5	regions with a very low level of PPP development	0-25%.

The source: developed by the author using data of the Ministry of economic development and trade of the Russian Federation Federal State Statistics Service [http://www.gks.ru].

As mentioned above, currently, more than 1,300 projects are at different stages of implementation in Russia. The cumulative private investment is 640, 3 bln rubles.

It should be noted that the ratio of private investment in infrastructure in PPP projects to the nominal RF GDP is less than 1%. In comparison to other countries with a similar volume and structure of investment in infrastructure according to PPP principles, the percentage ratio of private investment to nominal GDP volume is much higher (Fig. 2).

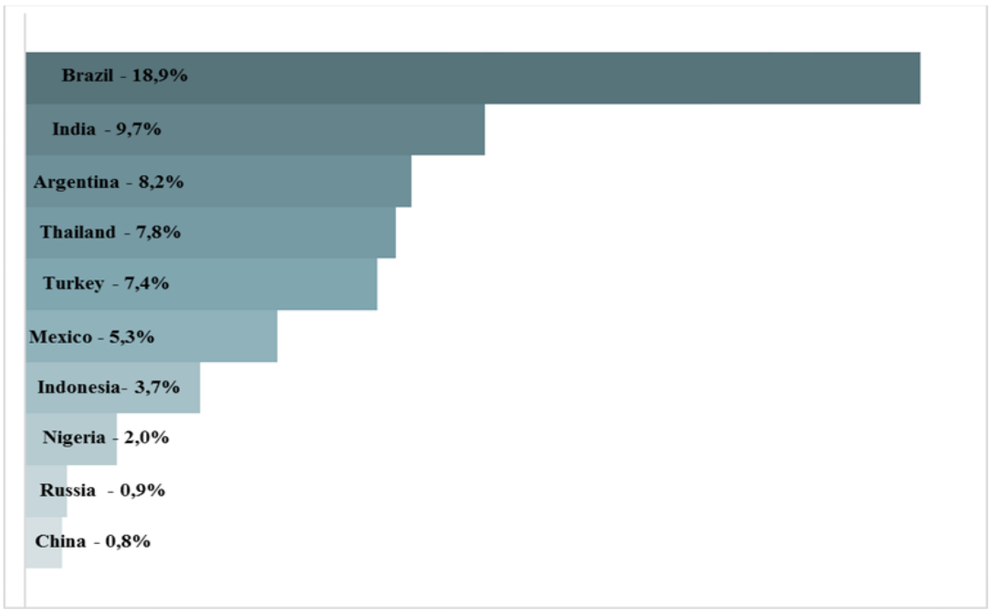

Fig. 2 The ratio of private investment in PPP projects to nominal GDP

The source: developed by the author using the data from the unified information system of public-private partnership in the Russian Federation, World Bank, Federal State Statisticse. [http://www.pppi.ru].

According to expert assessments, if this ratio is at the level of 4 - 5%, then it can be said that the process of attracting infrastructure investments into Russian economy on the basis of public-private partnership is balanced.

Conclusions

Summing up we can say the following:

- the most common investment projects with different forms of PPP in Russia are social, communal and transportation infrastructures. The practice of implementing PPP mechanisms is worked out mostly in relation to motor-roads;
- along with other infrastructure industries, transportation provides the basic social living environment being an important instrument for achieving social, economic and foreign policy goals;
- sustainable development of transportation system is a guarantee of the unity of economic space, free product and services handling, competition and freedom of economic activities, ensuring the integrity of Russia and its national security, improving the environment and living standards in the country;
- the world practice shows that successful collaboration of private sector and the state in the field of transportation infrastructure development indicates the viability and effectiveness of PPP mechanisms. In such work, the activities of regional authorities and the state as a whole are predominant. They determine the mechanisms of attracting private capital, methods of responsibilities and risks distribution, and, above all, the regulatory framework;
- public-private partnership, is certainly one of the most effective mechanisms of interaction between the state and business entities, which allows implementing large-scale and long-term projects aimed at developing the economy of the country.

This paper has been prepared within the project APVV 15-0765 "Inequalities and Economic growth" and VEGA 1/0431/16 "Economic growth and social and environmental impacts".

Abstract

Last decades have featured a lasting interest in economic development and its determinants by both economic theorists and empirical researchers. Besides economic factors as capital formation, natural resources, conditions in foreign trade or economic system, some socio-economic characteristics of the society such as human resources, quality of institutions, economic freedom or inequality come up to act as determinants of economic development. Multidimensionality of the assessment can present a practical problem especially in case of the multitude of cross-correlated measures. In this study we explore performance of the principal component analysis procedure in dimensionality reduction in the framework of non-parametrical DEA models employed to evaluate economic freedom of 178 countries of the world. Benchmarked against the full dimensional model, the results prove a fairly good performance of DEA-PCA technique.

Keywords: economic freedom, data envelopment analysis, principal component analysis

1. Introduction

Last decades have featured a lasting interest in economic development and its determinants by both economic theorists and empirical researchers. Leaving aside economic factors as capital formation, natural resources, conditions in foreign trade or economic system, some socio-economic characteristics of the society come up to act as determinants of economic development. Human resources or general education have been explored by a vast number of studies on human capital starting back in 90s by Romer, Barro and others. Technical know-how and technological change have been subject to as many analyses employing growth accounting based on the Solow model. Institutions have been analysed profoundly in quantitative studies of Acemoglu and Robinson, specific problems of media voter are dealt with in Alesina and Rodrick or Persson and Tabellini´s works.

Inequality and economic growth has been an issue from Adam Smith´s times. The modern data based approach initiated by Kuznets culminated in a hype brought about by Piketty´s *Capital in the 21st century*.

Lastly, economic freedom as a determinant of growth has deserved much attention since the studies of 90s.

Friedman associates higher levels of economic freedom with political freedom and prosperity. In an empirical approach it is Berggren (2003), Sturm et al. (2002), Gwartney et al. (2004), and most recently Akin (2014) who came up with the evidence of the impact of economic freedom on growth.

In Figure 1 one can see the positive correlation between the level of economic freedom and economic performance.

Generally, any attempt to quantify the impact of factors on economic growth, whether it is a regression, semiparametric or non-parametric model, starts by identifying key variables. In the considered area, fortunately or not, there is a large quantity of proposed measures available from a multitude of data sources[1] which poses a question of choosing or constructing an optimal measure.

Narrowing down the scope of the research, this study focuses on the economic freedom exploring a particular non-parametric way of measuring which is best represented by Data Envelopment analysis (DEA) modelling. DEA is a nonparametric method used to assess the performance of profit and non-profit organizations. It assumes that the input and output variables are known a priori. In each environment, there exists a huge number of input and output variables, and all the variables will serve as either input or output variable. If there are a large number of input and output variables the discriminatory power of the model reduces. To overcome this difficulty one may need to reduce the input and output variables using appropriate scientific methods.

[1] The renowned *Stiglitz Report* (Fitoussi et al, 2009) lists a multitude of welfare indicators.

Zhu (1998) suggests that principal component analysis as a complementary approach is applied to 'output to input' ratios. The idea of combining DEA and PCA methodologies to achieve dimension reduction was developed independently by Ueda and Hoshiai (1997) and Adler and Golany (2001, 2002). In these papers it is suggested that the variables can be divided into groups, based on their logical composition with respect to the production process, and then replaced with principal components representing each group separately.

In multivariate data analysis the problem of data dimensionality is of great importance. There are many techniques aimed at the reduction of the number variables used. The most common include (a) factor analysis, (b) principal component analysis (PCA), (c) variable reduction procedure based on a partial covariance (VR) or quite recently (d) efficiency contribution measure (ECM).

Factor analysis is heavily employed in regression models featuring a massive body of empirical literature. PCA has been employed in a number of areas ranging from .. to face recognition. Ueda – Hoshiai (1997) and Adler – Golany (2002) were first to employ PCA in DEA economic analysis.

VR procedure of Jenkins – Anderson (2003) presents a systematic statistical method for deciding which of the original correlated variables can be omitted with least loss of information, and which should be retained. Results reveal that even omitting highly correlated variables could have a massive impact on computed efficiency measures. Adler (2010) demonstrates that PCA - DEA provides a more powerful tool than VR with consistently more accurate results.

ECM approach proposed by Pastor et al. (2002) is based on testing the marginal contribution of each variable to the efficiency estimation based on the pair of specifications – total model and reduced model. ECM differs from VR in the role of DEA. While VR makes the variable selection using a statistical test, ECM involves DEA estimation.

We chose to employ PCA and explore statistical properties of the results benchmarked against the full dimensional DEA model constituting a measure of economic freedom. Hereafter we proceed by the description of SBM DEA model and principal component routine. In Section 3 data and results of statistical tests of seven DEA models with varying number of variables and proportion of the original variance accounted for are presented and finally Section 4 concludes and outlines the further research.

2. Measuring economic freedom

Standard measures of economic freedom typically present indexes composed as a weighted sum of subindicators describing various aspects of economic freedom such as.. The weights are set ex ante and represent certain authors´ beliefs as for the importance of the respective subindicators with regard to the total score. In this study we elaborate on the alternative way offered by data envelopment analysis (DEA) modeling. The weights would be implicitly ascribed individually in the optimization procedure.

2.1 SBM model of efficiency

Let economic subjects (which could be any economic subject transforming inputs into outputs) under examination be called DMUs (Decision Making Units) which reflects their independent economic behavior. It is assumed to have DMUs transforming m inputs into s outputs. Inputs and outputs are organized in the matrices **X** and **Y** respectively, element x_{ij} meaning amount of input i used by DMU j, and the similar way in the output matrix **Y**.

The *slacks-based* model (SBM) proposed by Tone (2001) is one of the powerful DEA developments to capture all sources of inefficiency of the DMU. The objective function ρ is meant to represent score of efficiency and features two important properties: unit invariance and monotonicity.

A function $\rho = \dfrac{1-\frac{1}{m}\sum_{i=1}^{m} s_i^- / x_{i0}}{1+\frac{1}{s}\sum_{r=1}^{s} s_r^+ / y_{r0}}$ meets the requirements of the both, moreover, it can be derived that $0 < \rho \leq 1$ which makes it easy to interpret values as efficiency scores between 0 and 100%.

From the computational viewpoint, evaluation of efficiency takes the form of a fractional program:

$\min\limits_{\boldsymbol{\lambda},\mathbf{s}^+,\mathbf{s}^-}$	$\rho = \dfrac{1-\frac{1}{m}\sum_{i=1}^{m} s_i^- / x_{i0}}{1+\frac{1}{s}\sum_{r=1}^{s} s_r^+ / y_{r0}}$		(2.1)
s.t.	$\mathbf{x_0} = X\boldsymbol{\lambda} + \mathbf{s}^-$		(2.2)
	$\mathbf{y_0} = Y\boldsymbol{\lambda} - \mathbf{s}^+$		
	$\boldsymbol{\lambda} \geq 0$, $\mathbf{s}^- \geq 0$, $\mathbf{s}^+ \geq 0$.		(2.3)

Following Tone (2001) one can arrive at a linear program

min	$\tau = t - \frac{1}{m}\sum_{i=1}^{m} S_i^- / x_{i0}$		(2.4)
s.t.	$t\mathbf{x_0} = X\boldsymbol{\Lambda} + \mathbf{S}^-$		
	$t\mathbf{y_0} = Y\boldsymbol{\Lambda} - \mathbf{S}^+$		
	$\boldsymbol{\Lambda} \geq 0$, $\mathbf{S}^- \geq 0$, $\mathbf{S}^+ \geq 0$, $t > 0$		

The dual linear program associated with (2.4) is

$\max\limits_{\xi,\mathbf{v},\mathbf{u}}$	ξ		(2.5)
s.t.	$\xi + \mathbf{v}\mathbf{x_0} - \mathbf{u}\mathbf{y_0} = 1$		(2.6)
	$-\mathbf{v}X + \mathbf{u}Y \leq \mathbf{0}$ $\mathbf{v} \geq \frac{1}{m}[1/\mathbf{x_0}]$		
	$\mathbf{u} \geq \frac{\xi}{s}[1/\mathbf{y_0}]$		

After solving linear programs formulated by (2.4) or (2.5) – (2.6), one can go back to original variables $\mathbf{s}^{0+}$, $\mathbf{s}^{0-}$, $\boldsymbol{\lambda}$ as optimal solutions of (2.1) – (2.3) and determine ρ_0 for DMU_0 under evaluation. Efficient DMUs will have values of ρ equal unit representing the *best practice* performance. The rest of DMUs are

thus inefficient scoring $\rho < 1$. For inefficient units, the models can also indicate a *peer group* of reference units whose performance is most easily achievable for the ones lagging behind. To give the model output orientation, input slacks in (2.1) are omitted. We denote the model SBM-O:

min	$\rho = \dfrac{1}{1+\frac{1}{s}\sum_{r=1}^{s} s_r^+ / y_{r0}}$		(2.7)
s.t.	$\mathbf{x_0} = \mathbf{X\lambda} + \mathbf{s}^-$		
	$\mathbf{y_0} = \mathbf{Y\lambda} - \mathbf{s}^+$		
	$\boldsymbol{\lambda} \geq 0,\ \mathbf{s}^- \geq 0,\ \mathbf{s}^+ \geq 0$		

2.2 Principal component analysis

Principal component analysis is a widely used method for reducing dimensionality of the data. Sticking to notation from the previous sections inputs and outputs from matrices **X** and **Y** would be replaced with a smaller set of new variables – principal components (PCs). PCs are determined by the following procedure:

$PC_r = \sum_{k=1}^{m} l_{kr}\mathbf{Y}_i,\ \text{ s.t. } \text{var}(PC_r) \rightarrow \max,\ \sum_{k=1}^{m} l_{kr}^2 = 1$	(2.8)

Clearly, PCs are uncorrelated linear combinations of the original data. There is at most as many principal components as the number of original variables (r= 1, 2, ..., s in case of outputs). Pursuing the goal of reducing dimensionality it is sensible to pick the least possible number of PCs while retaining maximum of the information. The researcher can state should beforehand how much of the variance in original variable should PCs account for.

3. DEA-PCA measures of economic freedom

3.1 Data and modelling

As described above, we apply DEA model to subindices of economic freedom of 178 countries of the world. The indices would enter the model in the role of outputs. Abstracting from any efforts or cost of achieving a certain level of economic freedom, we set input to unit for each country and run an output oriented model. Thus we arrive at a composite indicator resembling standard index of economic freedom. The difference consists in ascribing the optimal weight to each category so as to maximize the total score which is ensured by the program (2.1). We adopt twelve dimensions of economic freedom from Heritage Foundation (2017) as outputs in the matrix **Y**.

We measure economic freedom based on 12 quantitative and qualitative factors, grouped into four broad categories, or pillars, of economic freedom:

Heritage Foundation

- Rule of Law (property rights, government integrity, judicial effectiveness)
- Government Size (government spending, tax burden, fiscal health)
- Regulatory Efficiency (business freedom, labor freedom, monetary freedom)
- Open Markets (trade freedom, investment freedom, financial freedom)

Each of the twelve economic freedoms within these categories is graded on a scale of 0 to 100. A country's overall score is derived by averaging these twelve economic freedoms, with equal weight being given to each.

3.2 Full dimensional model

A comprehensive full dimensional model *ef12* is computed using optimization (2.7). Calculations involved determining scores for each of 178 countries in the dataset. The results comprise values of slack variables, values of dual variables determining efficiency frontier and the set of efficient countries. This can be complementarily established by filtering out countries with unit efficiency scores.

While it is not the focus of this study to bring recommendations for decision makers (though the ultimate DEA models´ purpose is exactly that) we report efficient DMUs (countries) from the *ef12* model in Table A2 in Appendix without any other values of variables involved in computations barely listing efficient countries. Other variables will be subject to the correlation analysis and do not present an interest of their own. Variables used and specification type are stated in Table 2.

3.3 Principal components and DEA

PCA was conducted following the routine of (2.8). In practical application, a covariance matrix **C** of the demeaned original variables was produced. Then eigenvectors and corresponding eigenvalues are computed and sorted in a descending order.

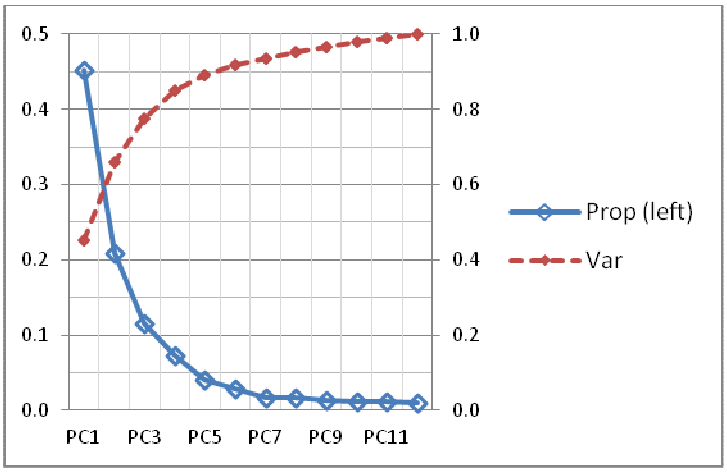

Fig. 2: Variance explained by principal components

Source: Authors´ calculations

Now it is possible to express the original data in terms of the chosen number principal components at the cost of the corresponding loss of variance of the raw data explained. In Figure 2 one can see a portion of the total variance explained by individual PCs (proportion) along with the cumulative variance. Based on the results depicted in Figure 1 we chose to explore first six principal components accounting for 90% of the total variance in the data and halving the initial number of variables.

In Table 2 models are listed along with the variables employed. All models are output oriented with constant return to scale assumption.

Table 2: Overview of the variables and models

model	type	variables						
		output						input
ef12	SBM-O-C	12 sub-indicators						1
pc1	SBM-O-C	PC1						1
pc2	SBM-O-C	PC1	PC2					1
pc3	SBM-O-C	PC1	PC2	PC3				1
pc4	SBM-O-C	PC1	PC2	PC3	PC4			1
pc5	SBM-O-C	PC1	PC2	PC3	PC4	PC5		1
pc6	SBM-O-C	PC1	PC2	PC3	PC4	PC5	PC6	1

Source: Authors´ calculations

Solving each model involves conducting 178 optimizations of the (2.7). Variables for the model *ef12* are described in the Section 3.1.

3.3 Statistical testing

Having obtained a single composite index (efficiency score) from a comprehensive ef12 model and DEA scores from reduced PCA models, the question of substitutability can be attempted to answer. First we are interested in the degree of correlation between the scores from individual models. Efficiency scores are stored as variables *sef12* (the full SBM model) and *spc1* through *spc6* models. In Table 2 correlation matrix of these variables is provided.

Table 3: Correlation matrix – scores from models

sef12	*spc1*	*spc2*	*spc3*	*spc4*	*spc5*	*spc6*	
1	0,33	0,16	0,32	0,31	0,26	0,19	*sef12*
	1	0,46	0,44	0,41	0,32	0,25	*spc1*
		1	0,85	0,78	0,65	0,51	*spc2*
			1	0,88	0,68	0,56	*spc3*
				1	0,79	0,66	*spc4*
					1	0,85	*spc5*
						1	*spc6*

Source: Authors´ calculations

From the correlation matrices it is not possible to determine whether the dependence between the variables is statistically significant. To test for that we therefore generate two series of differences between both the score and the rank from *ef12* and *pc* model. Running a regression of the differences on a constant (with a heteroskedasticity robust errors) makes clear whether the differences are of a systematic nature or not and which direction they tend.

Table 4: Correlation matrix - ranks

ref12	*rpc1*	*rpc2*	*rpc3*	*rpc4*	*rpc5*	*rpc6*	
1	0,63	0,09	0,33	0,32	0,30	0,24	*ref12*
	1	0,43	0,46	0,44	0,45	0,29	*rpc1*
		1	0,81	0,77	0,65	0,48	*rpc2*
			1	0,84	0,63	0,49	*rpc3*
				1	0,78	0,63	*rpc4*
					1	0,85	*rpc5*
						1	*rpc6*

Source: Authors´ calculations

Table 5: Differences between scores and ranks

	const	p-value			const	p-value
sd1	0,441	1,35E-52	***	rd1	-3,742	2,84E-01
sd2	0,064	5,10E-03	***	rd2	-3,657	5,05E-01
sd3	-0,136	4,08E-10	***	rd3	-3,433	4,67E-01
sd4	-0,179	1,71E-15	***	rd4	-3,230	4,99E-01
sd5	-0,275	3,33E-28	***	rd5	-2,320	6,35E-01
sd6	0,340	3,04E-36	***	rd6	-1,129	8,28E-01

Source: Authors´ calculations

Table 5 displays the results – constants from the regression and the corresponding *p*-values. It is obvious that differences in scores are systematic being positively tilted for models *pc1*, *pc2* and *pc6*. For *pc3* through *pc5* the bias appears to be significantly negative. Taking a look at the ranks reveals negative difference across all PC models, this underestimation of the full range model is not statistically significant.

4. Conclusions and further research

As institutional quality presents a proved basis for economic performance, we probed alternative method of assessing European institutions within the set of EU and OECD countries by employing SBM model and shrinking the set of variables employing PCA method. The discriminatory power of the DEA seems not to have suffered in a considerable way.

Getting more convincing results would require employing methods for identifying and possibly omitting outlying data for which a number of procedures is suggested in DEA literature. After that additional non-parametric testing could be conducted involving e.g. Mann-Whitney Rank Sum test. Some routines such

as Wilcoxon test (whether the difference between two observations has a mean signed rank of 0) are more robust against outliers and heavy tail distributions.

Some authors, e.g. Banker, Simar and Wilson or Pastor et al. propose statistical tests for measuring the relevance of inputs or outputs. as well as tests to consider potentially aggregating inputs or outputs intead of reducing dimensionality of the whole bulk of variables.

Abstract

Final year project (FYP) is of critical importance, as students have to achieve this last milestone to finish their degree. This paper presents the students' experiences with final year projects in the Faculty of Computing and Information Technology, Rabigh (FCITR). On the basis of its findings, a prototype is developed using the open source technology to manage projects and guide the students.

Keywords: graduation project, information systems, student guidance, project archiving.

Introduction

Capstone based FYP is a mandatory part of graduation in many curriculums in undergraduate programs of Information System (IS), Information Technology (IT) and Computer Science (CS). In this project, an integrated approach is followed to train students to manage software development by utilizing the knowledge achieved during the earlier semesters.

FYP project is an integral part of graduation in FCITR. Fifth-year students can register for the project only after completing their mandatory credit hours. It is a two-semester long activity in which the students (in a group of at least two) complete a project under the supervision of one of the faculty members. In the first semester, students form a group, choose a topic of their interest either proposed by students or by the supervisor, and work on introduction, literature survey, analysis and design of the selected project. In the second semester, the focus is on the implementation and testing. At the end, the completed project is presented for evaluation. A number of reports and forms are needed to be submitted during these two semesters within the given time frames.

Some studies have identified students' difficulties in completing their FYPs and the needs of developing such tools that can help to monitor and manage graduation projects (Bouvki, 2007; Leung et. al, 2015). The web-based FYP management system by Leung et. al. (2015) supports three types of users: the program organizers, supervisors and group members. Their system consists of five modules: project allocation module, the communication module, project management module, file sharing and repository module, and also submission and grading module. The FYP management systems by Clement and Bounds (2014) include tools to connect students with potential supervisors before the project allocation starts, while also include submission and collection of assignments, which are among the common functions in a Content Management System (CMS). Bakar et. al (2011) also reported their development and user experience of FYP management system at Universiti Kebangsaan Malaysia. Their system

consists of three major modules: user profile, project monitoring and appointment setting modules. The HKU CS Project Management System (2013) is a project management system developed in at the University of Hong Kong, Department of Computer Science. The system can show project information, news, schedules and project allocation.

Background of the Project

Currently in FCITR all the work is being done manually. Many problems are adherent to hand operated or manual systems such as loss of information, prone to errors, waste of time etc. Secondly, there is no digital archive of completed projects. With every passing year, as the number of graduates is increasing, this way of managing project reports is becoming more difficult. There is no way to check which topics have already been chosen. Searching for some particular report is also very difficult. Although the course management system is available to provide the courses add and drop procedure but it doesn't suit well to FYP's requirements.

Users & System Development

The Questionnaire

We prepared a questionnaire for collecting information regarding the preparation of the graduation projects of the students. For this purpose, a few questions were designed and were uploaded on the Google questionnaire system and there was a participation of 62 students. 95.2% of the respondents stated that they are in the graduation year. 80.6% of the students indicated that they have difficulty in communicating with their supervisors. 83.9% of the students wished to use various internet means to communicate with their supervisors, whereas the other 24.2% prefer personal communication with their supervisors. 83.9% indicated that they have difficulty in understanding the steps of the project. Only 19.4% indicated to seek resort from their supervisors in case of difficulty in understanding the project steps, meanwhile the others preferred to seek help from previous students' experience. The results also indicate that 91.9% read previous students' projects and 95.2% feel that it is a good idea to create a website for archiving students projects in the faculty. The respondents also agree that creating a website is a good idea since it will provide students a platform to benefit from the previous projects and ideas. Using these ideas, we wish to build a system, which will provide instant access to students and faculty to benefit from the experiences of the past students in minimum possible time besides providing access to all previous project reports instantly.

Review on Current Systems

We did a review on two systems namely, 1) the University of Leeds, School of Computing Undergraduate Projects Archive, and 2) the City University of Hong Kong, College of Science and Engineering.

The University of Leeds website displays titles of the projects with links to electronic copies of project reports [6]. The City University of Hong Kong, College of Science and Engineering [4] website consists of several sections, including a section for guidance and section to archive the student projects. It also includes video links to projects with subject areas and objectives for each project.

Based on the above reviews of related works and user requirements, we had outlined the criteria for the proposed system as in Table 1. It shows the main similarities and differences between our project and related work. Hence the benefits of the proposed systems are as follows:

1. Provides possibility to communicate with the supervisor of the project
2. Provides archives of previous projects
3. Provides schedule to students
4. Provides student guide in the form of templates and guidelines
5. Providing list of important external link

Table 1: Comparison between the proposed website and related work

	Related work					Our Website
Criterion			Queen's University Archives	University of Leeds	College of Science and Engineering	Senior Project Archiving and Student Guidance System For FCITR
Design		Language	English	English	English	English
		Browsers (Mozilla Firefox, Internet Explorer, Chrome)	✓	✓	✓	✓
Function	Student	Register to the Website	X	X	X	✓
		Guidance	X	X	X	✓
		Communicate with supervisor	X	X	X	✓
		Browse/Search the previous projects	✓	✓	✓	✓
	Supervisor	Register to the Website	X	X	X	✓
		Communicate with student	X	X	X	✓
		Communicate with administrator	✓	✓	✓	✓

Technology

Open Source technology was adopted for the development of the prototype. Our project use XAMPP, which is developed by Apache Friends and includes a server, database and interpreter. The fact that XAMPP is an open source cross-platform web server package makes it easy to test and deploy your web server on any operating system. It was also chosen because it includes all the features that are needed for web server setup. Other web and design tools used include Macromedia Dreamweaver, Macromedia Flash and Macromedia Photoshop.

Logical Data Model

Database design is the process of producing a detailed data model of a database. This logical data model contains all the needed logical and physical design choices and physical storage parameters needed to generate a design in a Data Definition Language. The design is used to identify relationship between the modules or tables. The term database design can be used to describe many different parts of the design of

an overall database web site. Figure 1 is referring for the database design that we used in our web based information system.

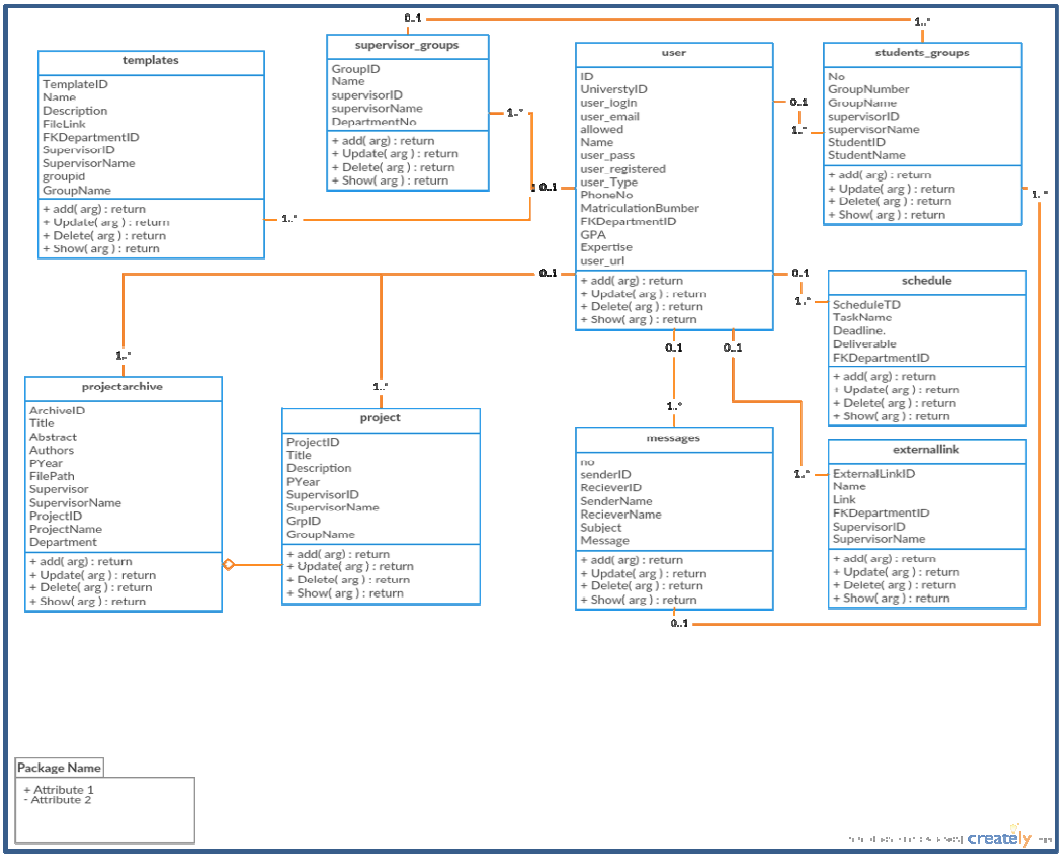

Fig. 1: Logical data model for GP Organize System

Results

Some interfaces of the developed prototype are presented in this section. Figure 2 shows the home page. After logging in, a different dashboard is presented to three types of users: student, supervisor and administrator.

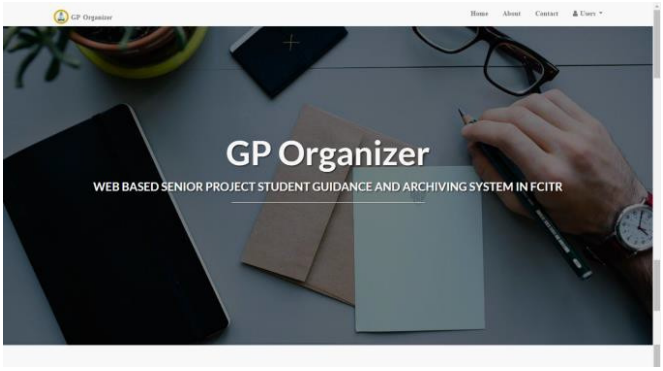

Fig. 2: The prototype's home page

A new group can be created using the screen shown in Figure 3.

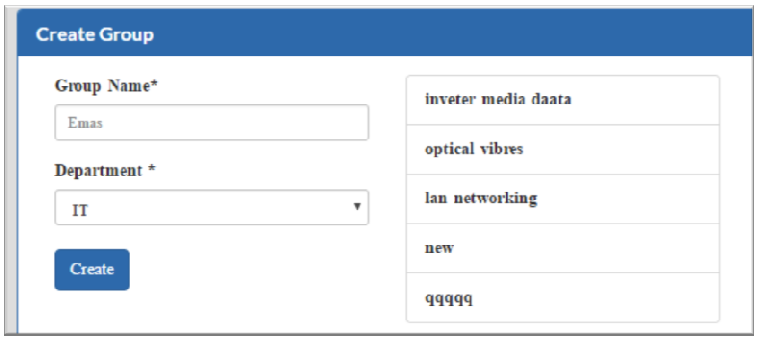

Fig. 3: Create group window

After creating groups, the available final year students are added to the group as shown in Figure 4. The supervisor can add a new project and one group can be assigned to each project as shown in Figure 5.

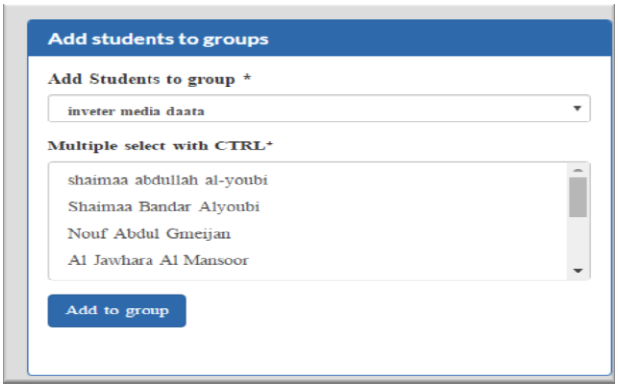

Fig.4: Screen for Adding Students to Groups

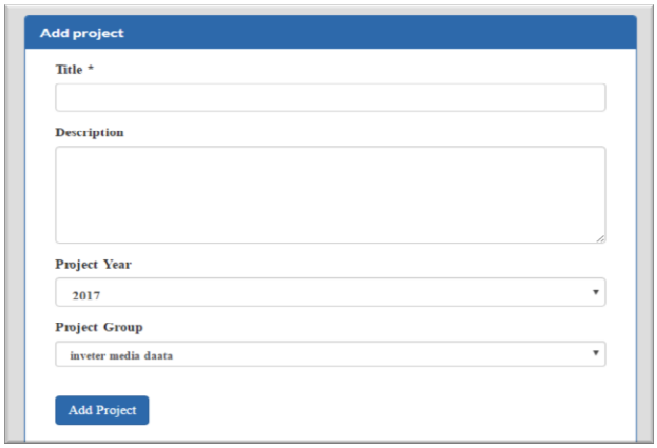

Fig. 5: Screen for Assigning a Project to a Group

On completion, project can be added to archive a shown in Figure 6.

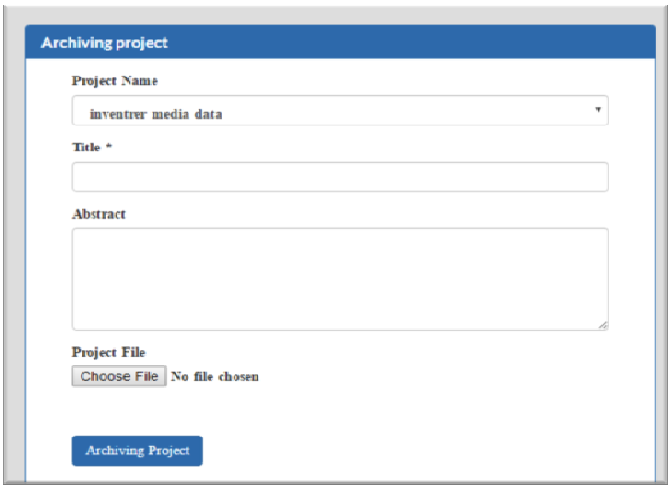

Fig .6: Window for Archiving a Project

Student and supervisor can communicate with each other. Figure 7 shows how students can send message to the supervisor.

Supervisor can add guidance for students in the form of documents, for example like templates or links to external resources which students can refer to as reference. This window can be found as in Figure 8.

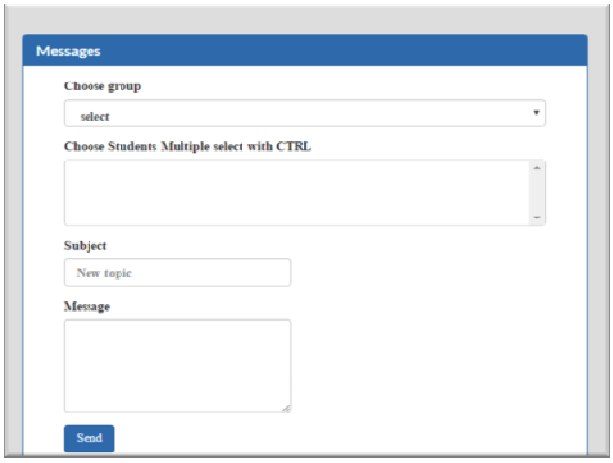

Fig. 7: Send Message to Students window

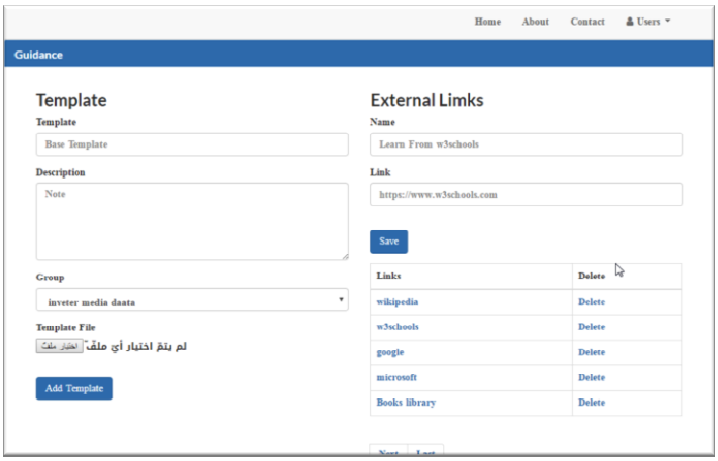

Fig. 8: Screen for Adding Guidance for Students

To add a new milestone in the schedule, information like task name, deliverables, end date, and for which department is added as shown in Figure 9.

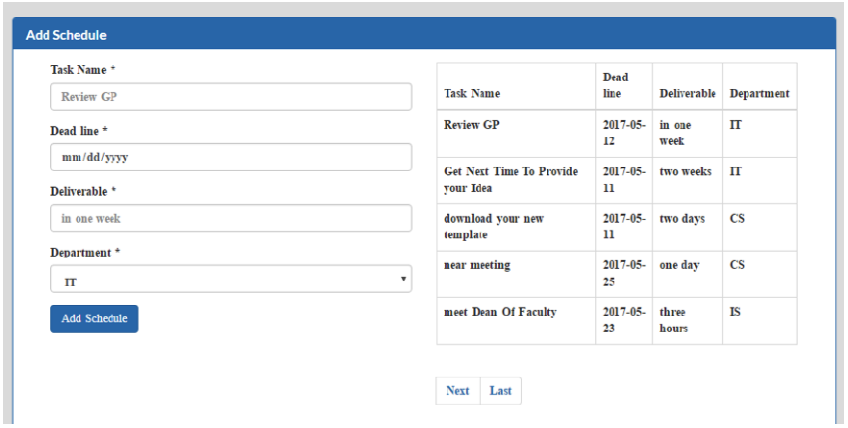

Fig. 9: Screen for Adding Project Milestone for Students

Another way of giving guidance to student is provided on one screen where templates and different documents can be downloaded. Students can access external links provided and can also view the milestones as shown in Figure 10.

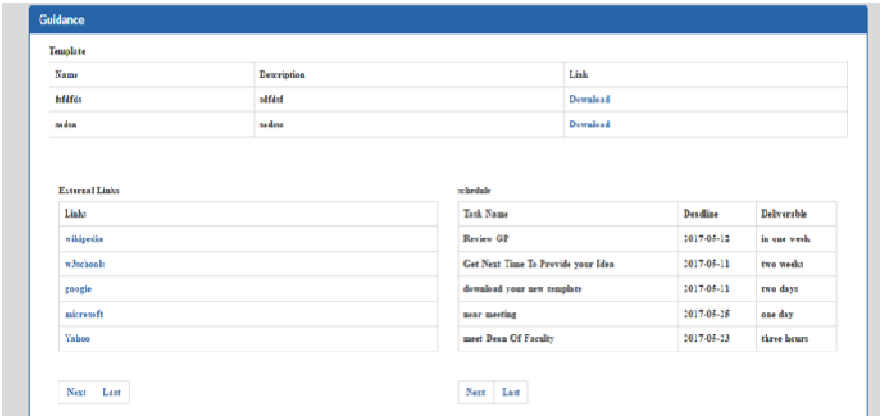

Fig .10: Screen for Giving Guidance Students

FYP archive as showed in Figure 11 gives lists of all the available projects along with their details and possibility to download the report.

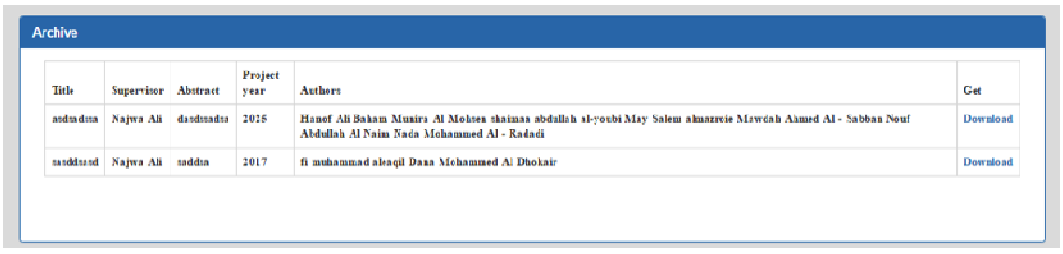

Fig. 11: Window for List of Previous Projects

Figure 12 shows the overview presented to administrator. It includes information about number of students, faculty numbers, and groups, reports in archive, schedule and guidance details.

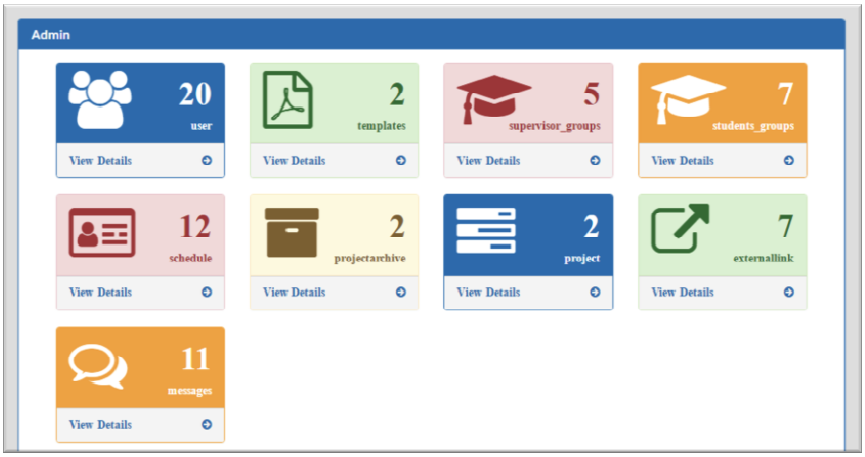

Fig. 12: Overview for Administration Window

The usability and user acceptance tests were conducted and 3 students from final year participated in these tests. Results indicated the positive feedback.

Conclusion

The project has achieved the goals and objectives that were initially set out and defined. In this section, we present lessons learnt from the project and future enhancement areas for the prototype. Lesson 1: The web based developed system provide the one point access to all the project related information. This system helps the students to understand the FYP project requirements by browsing the previous year projects and by accessing important guidelines, templates and milestones. On project completion, supervisor can move it to archive. Providing the messaging options also facilitates students' communication with the supervisor. This system helps student and supervisor to organize and manage their senior projects. Lesson 2: Requirement elicitation is a complex process. This is evident as several methods (i.e. interviews, brain storming, survey, use-cases and prototyping) has been used. The prototype approach has been used for requirement specification of future system development. Lesson 3: Open Source technology provides a quick alternative in an environment where high costs are primary impediments.

We propose three future enhancement areas for the prototype:. Enhancement 1: The system focuses on student guidance and previous projects archiving. It may extend to monitor the students by checking the assigned tasks to which percentage it is completed. Enhancement 2: Another enhancement that can be made is adding the functionality of chat. Enhancement 3: A number of questionnaires are filled in during the project by students and supervisors. On the basis of those and task completion information, grading module can also be developed.

The Study Project on Employees Creativity Effect on Innovation in a Manufacturing Company

MSc Eng. Kamila Tomczak-Horyń, Opole University of Technology, Opole, Poland, k.tomczak-horyn@po.opole.pl, r.knosala@po.opole.pl
Prof. Dr Hab. Eng. Ryszard Knosala, Opole University of Technology, Opole, Poland, r.knosala@po.opole.pl

Abstract

The article describes the importance of employee creativity in a company. The perspectives of research on creativity and the determinants of creative production space are presented. So far, no methodology has been developed to measure the creativity of workers in manufacturing enterprises and to assess the innovations introduced. For this purpose, appropriate tools and methods have been developed. The article presents the methods and tools used in assessing the innovativeness of a company and the level of innovation introduced. Also authoring tools to support the creativity of workers in production companies are described: A questionnaire of creative attitude and Sheet for work sample evaluation. The field of impact assessment of the creativity of the employees on the development of innovative solutions in the company was also presented.

Keywords: creativity, innovations, innovator, company.

Introduction

Creativity plays an important role in entrepreneurial processes. It is a factor stimulating the development of the company. Combined with the knowledge and social competences, it leads to innovation (Luecke, 2003). The innovation is a task for every employee, not just for the research and development department. It is important only to create a safe space for innovation. It fosters self-expression, experimentation, risk-taking, and admitting mistakes without the fear of punishment (Dyer, Gregersen, Christensen, 2011). Creativity should be used in all aspects of company's operations, as each of them can affect its effectiveness (Kosieradzka, 2013).

Currently, there are no tools supporting an identification of internal factors responsible for innovation and creativity in the company. This state of affairs has contributed to the development of a concept of the study on employees' creativity effect on product and/or process innovations in a company. The study will be conducted on small, medium and large innovative manufacturing companies. The first step in the study is the selection of companies by analyzing their level of innovation. Then, product and/or process innovation in the company is subject to an evaluation. The final step in the study is an evaluation of the predisposition to the creative thinking of the innovators. A number of tools described in this article have been developed to carry out the study.

1. Prospects of the study on creativity

Creativity can be analyzed from different perspectives. The popular classification is the "four P" model, i.e., the study on creativity through the prism of person, process, product and place. The first aspect concerns an identification of the creative potential of the examined person. The following tools are most commonly used for this purpose (Karwowski, 2009b):

- creativity tests allowing to determine the level of fluidity, flexibility and originality of thinking,
- techniques focused on self-description (personality questionnaires),
- interview and observation of the examined person.

In the case of creative process analysis, it is desirable to describe and understand what happens when a creative work arises. According to Necka (1995) the creative process takes place when a new and valuable result is obtained, and it is characterized by novelty and value. Analysis of the process of ideas creation is an important source of information about the examined person. Experimental tasks, most often related to problem solving, are a significant issue in the creative process examination. They seek to determine what factors are important during the creation process, and then manipulate them to verify their effect. The role of attention, stimulation and the influence of positive or negative emotions is emphasized, then they are manipulated and their effect on activity effectiveness is determined (Karwowski, 2009b).

Another approach is an analysis of the product (creative product), which also provides a lot of information about the creative capabilities of the innovator. In this case, the importance of the study should be attributed to experts' evaluation and content analysis (Karwowski, 2009b).

The last perspective of creativeness analysis concerns the study of its over-individual dimension, i.e., the analysis of "the climate in the workplace". Task of Amabile (1996) the work environment significantly affects the search for ideas and their implementation. In this aspect, it is examined whether the company and the physical place of work favor creativity and innovation. The studies in this area are conducted using questionnaires or observations (0).

2. Space for creativity in the company

Creativity requires an environment focused on an innovative development. Creative employees should be provided with an environment that will support their activities and lead to the implementation of a rationalized solution (Kosieradzka, 2013). An important element affecting innovations is the working environment and the climate in the company. An atmosphere favoring creativity concerns the characteristics of the environment, which may be a stimulant or inhibitor of creative activity. Employee-to-employee contacts and open discussions contribute to the emergence of creative ideas. They are possible due to the elimination of barriers requiring a hierarchical shift to a flattened one, where the teamwork is preferred.

There are three important approaches that develop the concepts of climate for creativity: the G. Ekvall concept developed by S.G. Isaksen and K. Lauer (Karwowski, 2009a), the view by T.M. Amabile (1996, 1997) and the concept of M. West (2002).

G. Ekvall is the author of the first questionnaire for the measurement of workplace atmosphere. According to G. Ekvall, the "climate for creativity" is a factor that supports the production and introduction of new products and solutions. It supports the development and assimilation of new, different proposals. This approach recognizes the climate as one of the variables affecting the ability of the company for modernization to continuous development. According to the author of the concept, significant elements forming the creative climate include: challenge, openness and confidence, time for ideas realization, supporting the ideas, debate and taking the risks. G. Ekvall's approach coincides with the concept of T.M. Amabile (1996, 1997). It is based on the belief that creativity within the company is affected by:

- ability to create innovation at the managerial level;
- motivation of the company to carry out activities characterized by novelty;
- resources including people, materials and time.

Such an approach was the basis for creating a tool in the form of questionnaire for the measurement of creativity climate in organizations. The questionnaire covers eight scales. In a research study by Amabile (1996, 1997) the factors that encourage creativity include the following:

- motivating for creative activity by the organization,
- encouraging the creativity by the supervisor,
- support from co-workers,
- autonomy and freedom,
- sufficient resources,

- challenging work.

Two scales describing inhibitors of creative activity, such as pressure resulting from burdens and organizational difficulties blocking and disrupting the creativity, were also included in the questionnaire.

The last approach developed by M. West (2002) refers to a climate that fosters innovation in the organization. According to the author of the concept, four elements affect the creative atmosphere: security, innovation support, clear goals, and task orientation.

3. Procedure of the study on an effect of innovators' creativity on innovation development in the company

Examination of an effect of innovators' creativity on the development of innovation in the company is conducted according to the adopted scheme (Figure 1). In a research study by Tomczak-Horyń, Knosala (2016) the first step in the study is an analysis of the level of company's innovation. It is based on a questionnaire survey and an interview with the decision maker in the company. The next step is an analysis of the documentation concerning process and/or product innovation introduced in the company. The author or authors of the innovation will be selected and evaluated at this stage. The last step is an examination of innovators' creativity. It includes an assessment of their creative attitude and evaluation of work sample.

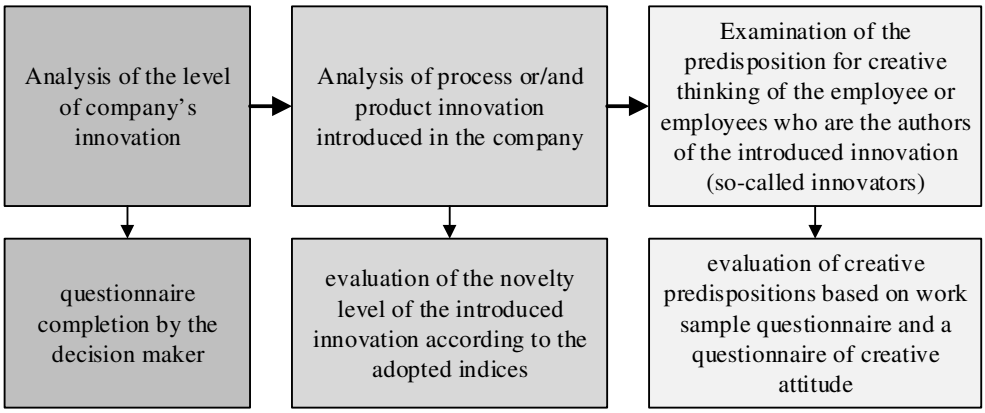

Fig. 1: Procedure of the study on an effect of innovators' creativity on innovation development in the company

Source: own elaboration

4. Methods and tools used in an evaluation of company's innovation and the level of innovation introduced

Appropriate methods and tools were used at particular stages of the study in the company (Fig. 2).

Evaluation of company's innovation

The analysis of the companies participating in the study will be based on semi-structured interview. It contains elements of structured interview, which is conducted on the basis of an individual interview with the respondent and contains specific questions. Additional questions not included in the questionnaire may appear during the interview, which may be important for the development of the study (Blandford, 2013).

In a research study by Tomczak-Horyń, Knosala (2016) a questionnaire survey is a tool used to help to evaluate the company's innovation. The questions in the questionnaire concern an evaluation of company's development identifying the economic situation, employment, investments, or employees

involvement in innovations creation. Further questions concern, inter alia, kind of innovations introduced by the company in the years 2013-2016 and the plans for the implementation of innovative processes in the years 2017-2019.

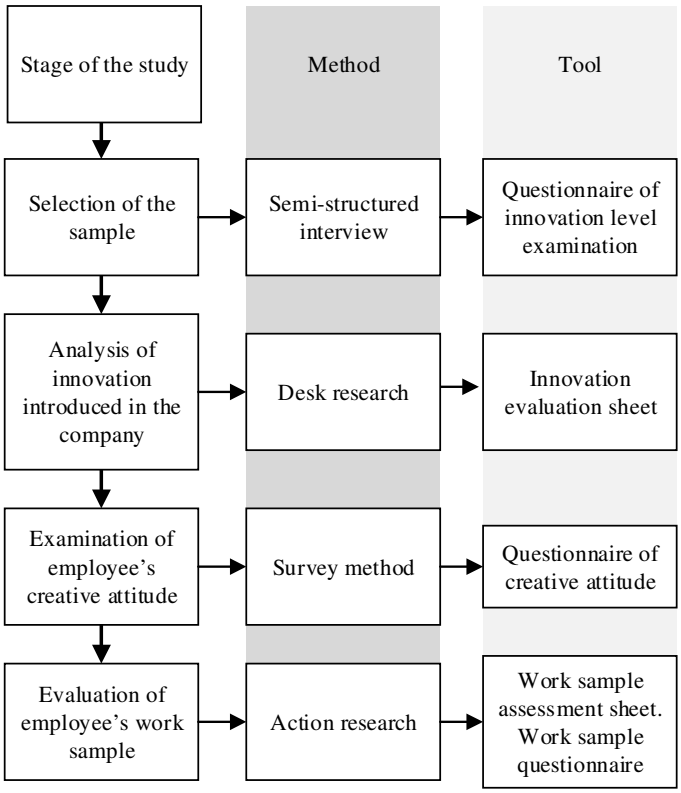

Fig. 2: Scheme of the study considering the methods and tools applied
Source: own elaboration

Evaluation of the level of innovation introduced

Determination of the level of company's innovation is followed by an analysis of the existing data on the innovation introduced. The analysis will involve an examination of the level of innovation. Innovation assessment sheet is a tool used to support the evaluation. It includes the indicators such as:

1. The degree of novelty in terms of the company - level of innovation introduced in the company scale.
2. The degree of novelty in terms of the market - level of novelty of innovation introduced in the market scale.
3. The time of introduced innovation operation - number of months of innovation using.
4. The scope of innovation - scope of innovation introduced in the company.
5. Innovation universality - areas of the company that have benefited after innovation was introduced.

The first indicator concerns the analysis of innovation within the company. It enables the division of innovation into three solutions: solution not used in the enterprise so far, solution that is a significant change in the already existing solution in the company, and a micro-solution.

The second indicator refers to the level of novelty on the market scale. This indicator adopted a commonly used classification, distinguishing incremental and radical innovations. Incremental innovations are improvements that consist in refining of the existing forms or reconfiguring them to

serve new purposes. In turn, radical innovations involve the introduction of completely new, unused solutions (Knosala, 2017).

Next indicator refers to the determination of the time of solution operation. If the idea has been implemented and works for some time then it can be assumed that it is effective. Based on the initial assumptions, the high effectiveness of introduced innovation was assumed to be its application over nine months (Knosala, Boratyńska – Sala A, Jurczyk – Bunkowska, Moczała, 2013).

The indicator concerning innovation scope informs about the number of workstations in which innovation can be applied. A high level of this indicator is reached with the solution implemented on 4 and more posts.

The last indicator concerns the universality of innovation and is measured by determination of the number of areas in the company that could be improved due to the innovation. These could be, for example, parallel improvements in OSH, logistics and manufacturing.
The indicator of innovation range and universality refers to the evaluation of process innovation.

5. Design of questionnaires used in the study of innovators' predispositions for creative thinking

In a research study by Tomczak-Horyń, Knosala (2016) the last stage of the study in the company is an examination of innovators' predispositions for creative thinking. This examination concerns the determination of the creative attitude and an evaluation of the work sample. A questionnaire of creative attitude is a tool supporting an evaluation of the creative attitude of the innovator. This is a self-assessment questionnaire. It consists of 18 statements concerning the employee's behavior in the situation of improvement and operation in the company. The examined person determines to what extent agrees with the statement on the basis of a 5 point scale. A maximum of 72 points can be obtained in the evaluation of the creative attitude. If an employee earns the sten score of 9 - 10 position, it means that he or she is characterized by a very high creative attitude. The sten score below 4 means a low creative attitude (Tab. 1). A questionnaire of creative attitude is described in Tomczak – Horyń, Knosala, 2014, 2016.

The second area of creativity evaluation is an assessment of the work sample using action research (AR) method (Coughlan, Coghlan, 2002). According to K. Lewin, AR's precursor, the method is based on the performance of the subsequent steps on a spiral basis: assumption - action - evaluation. Correct application of this method comes down to an identification of the problem and gathering facts allowing to solve it. The subject of AR interest are practical issues related to the direct problems of the group.

The method is performed in a natural environment using a qualitative view, such as a record of events and behaviors as well as observations (Tomczak-Horyń, Knosala, 2017b).

The tools supporting the evaluation include: work sample questionnaire and work sample assessment sheet. The work sample questionnaire contains six tasks concerning open-ended problems or task situations.

Table 1: Scale sten type for the creative attitude questionnaire (Tomczak-Horyń, Knosala, 2014)

Sten	Score		Creative attitude
	from	to	level
10	69	72	very tall
9	66	68	
8	63	65	tall
7	60	62	
6	56	59	average
5	53	55	
4	50	52	low
3	47	49	
2	43	46	
1	0	42	

Their purpose is to reveal the employee's ability for divergent thinking. Divergent thinking plays an important role in problems solving. It involves "breaking away" from the previously known ways of perceiving and acting. The open-ended tasks are the prerequisites for divergent processes. Divergent thinking skills are responsible for performing the tasks and solving the problems with more than one correct solution (Nęcka, 1995). In order to diversify the tasks, four versions of the questionnaire were developed: A, B, C and D. They contain different problem situations to solve, however, measuring the same abilities. An example of questionnaire construction is described in Tomczak – Horyń, Knosala, 2017b. Solution of the task is evaluated according to 4 indicators:

- Fluency of thinking – ease of making solutions to the problems;
- Flexibility of thinking – ability to change direction of thinking;
- Originality – ability to produce ingenious, unusual and distant answers;
- Elaboration – ability to complement the overall outline of plans, as well as concepts.

A comment on the assignment of points with respect to specified indicator was included in the work sample evaluation sheet (Tab. 2).

Table 2: Sheet for work sample evaluation (Tomczak – Horyń, Knosala, 2017a, 2017b)

Sheet for work sample evaluation		
Name and surname of the candidate		Problem number .....
No.	**EVALUATION OF PROBLEM SOLVING**	**Number of points**
1	**Thinking fluidity – number of solutions created in a given time period** *Determine the number of problem solutions (1 solution = 5 points)*	
2	**Thinking flexibility – diversity of solutions** *Determine the number of categories the solution/solutions of problems can be included to (1 category = 1 point)*	
3	**Originality – statistical rarity of responses** *Determine the level of problem solution/solutions originality (value of degree = number of points)*	
4	**Elaboration – details of solution/solutions** *Determine the level of problem solution/solutions elaboration (value of degree = number of points)*	
I	**SUM OF POINTS** *(sum from 1 to 4)*	

The value of the degree of originality and elaboration index is evaluated on the basis of the adopted scale (Tab. 3).

Table 3: The value of the degree (Tomczak – Horyń, Knosala, 2017a, 2017b)

The value of the degree	The name of the degree
1	very low
2	low
3	average
4	high
5	very high

The initial point scale was accepted in the evaluation of the employee's work sample (Tab. 4). The employee can earn more than 15 points. The maximum value of points that can be obtained depends on the number of problem solutions and the number of categories to which the problem solution can be addressed.

Table 4: Point scale evaluation work samples (Tomczak – Horyń, Knosala, 2017a, 2017b)

Results	Sample work evaluation
49 – higher up	very high
38 – 48	high
27 – 37	average
16 – 26	low
15– under	very low

6. The area of the study on employees' creativity effect on innovation development in the company

The study on determination of employees' creativity effect on the development of innovation in the company is still ongoing. Companies participating in the study will be selected in terms of innovation level, size, as well as type of innovations introduced. The selection of companies will be focused on different case studies, so that at least six different case study combinations would be obtained. The subject of the study will be three types of companies in terms of their size and two types when regards the innovations introduced. Small, medium and large innovative manufacturing companies will be subject to the study. Product and/or process innovations introduced in the company will be analyzed (Figure 3). The next stage of the study will involve the selection of the authors of innovation and an evaluation of their predispositions for creative thinking. The study concerns the measurement of fluid creation which is related to creativity.

So far, the study was conducted in two large manufacturing companies. The first examined company is specialized in the production of exclusive and stylish wooden furniture. The second case study is the company from food sector. The company specializes in the production of baby food and infant food as well as adult food products used in medical nutrition. The study demonstrated that both companies are undoubtedly innovative. The companies systematically introduce all four types of innovation: product, organizational, process and marketing. In both companies, the innovations were created in teams and concern product innovations. A coffee table with compartment on a tripod was introduced in the company from the furniture industry. The developed product is an innovative solution not used in the company before. In terms of the market, it is incremental innovation. This is an improvement of the existing forms or their reconfiguration aimed to serve new purposes. The

product is on sale for a year. The technology and equipment that is in the company's resources were used in its manufacturing.

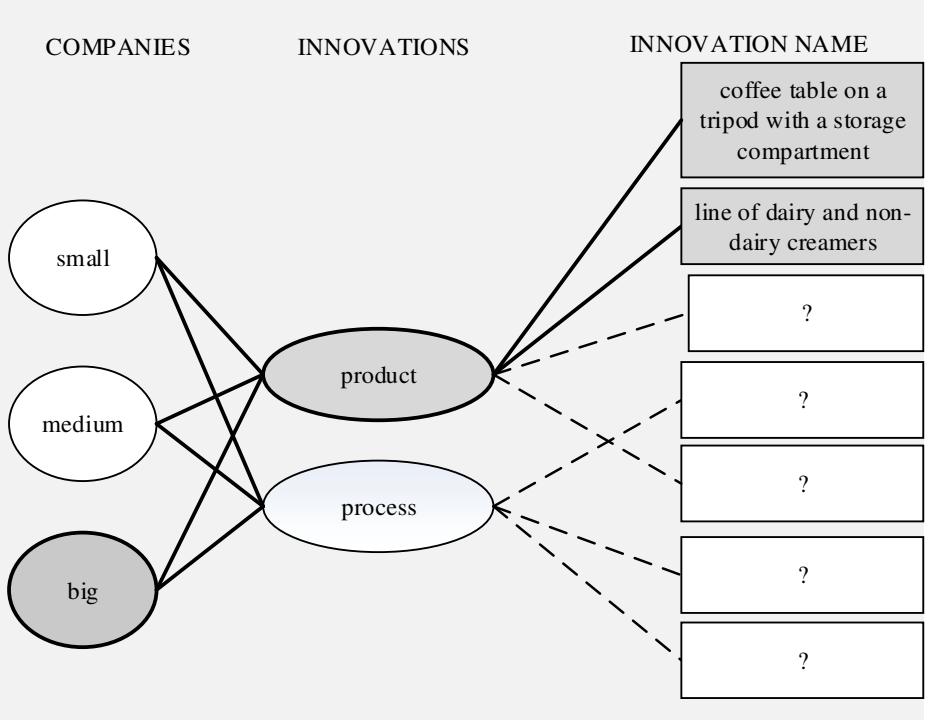

Fig. 3: Types of planned research

Source: own elaboration

A line of porridges with or without milk was introduced in the company from the food sector. The innovation is a significant change in the company's already existing solution. In terms of market, this is an incremental innovation. The product is on sale in the market over the year.

The final stage of the study was the assessment of innovators' predispositions for creative thinking. Work sample questionnaire and creative attitude questionnaire were used for this purpose. At this stage of the study it is still too early to present and draw conclusions in this regard. Proper evaluation of employees' creativity effect on the development of innovation can only be made after the obtaining of intended research sample.

7. Summary

The employees' creativity is a key competency nowadays. This contributed to the research works on employees creativity in manufacturing companies. This article presents the concept of the study on innovators' creativity effect on the development of innovation introduced in the company. The tools used in the evaluation of company's innovativeness, the level of innovation introduced and innovators' predispositions for creative thinking were described. The study using the tools described in the article was conducted in a large manufacturing company in the furniture industry and in a large food production company. The study will be carried out in companies until a differentiated research sample is obtained. The results will allow to evaluate an effect of innovators' creativity on the innovation introduced in the company.

Abstract

Modern information society features knowledge both as a key element of basic activities, and a framework factor of contemporary civilization. Therefore, paramount importance for estimating the efficiency of public institutions belongs to the knowledge management defined as the process of creating, sharing, using and managing the knowledge and information of an organization (Girard, J.P. Girard J.L. (2015). The system of education, particularly, higher education institutions play a central role in the development of knowledge management theory and practice in contemporary society. In its turn, the system proper also benefits greatly from the capitalization of knowledge and raising the efficiency of using the intellectual capital. One of the most important imperatives of the modern educational system is the continuity of the educational process, which necessitates creating the optimal system of higher school and secondary school interaction. This seems especially true for pedagogical education. The article is aimed at providing theoretical background of the innovative approach to organizing interaction of universities and schools, at characterizing the key principles of the interaction. The article contains comments for the definite examples of the pedagogical cluster as an instrument of the interaction between universities and schools with a view to raising the efficiency of using the intellectual capital at different levels of educational system.

Keywords: higher education, teacher education, cluster model, knowledge management, integration.

The key figure in the knowledge management system of an educational organization is a teacher, a personality possessing a complex of information, communication and social competences in information, communication, and a high level of accomplishment as well as the aspiration for improving the level of his / her pedagogical excellence with the help of implementing new technologies.

The professional tasks solved by the teacher in his/ her professional activity are a major factor of influence on the contents of teacher's instruction. The category of the teacher's professionalism includes not only a complex of knowledge and skills which present an important prerequisite for the efficiency in teaching activity (Isaeva, 2003), but also vital personal qualities alongside with experience. Modern educational environment requires a teacher to have such qualities as research skills, skills of projecting educational processes and solving pedagogical tasks, as well as the skill of planning classes in accordance with various goals.

The demands that the teacher's personality should meet in within the framework of perfecting the knowledge management comprise the following personal qualities: empathic orientation, humanitarian orientation, ability to win the children's trust, pedagogical optimism, sociability, sense of humour, creativity, emotionality, tactfulness, volitional professional powers, organizational skills,

capability of volitional impact and logic argumentation, the skill of setting and solving tasks, basic knowledge in pedagogy, psychology, sociology, multimedia teaching technologies, ability and skill of transforming the scientific material into the material of a school subject, managing the technical facilities, ability to apply and develop the system of efficient teaching methods.

Of high importance in the teacher's professionalism is his/ her education at the university. Making the education productive in accordance with the modern level of intellectual capital management and oriented to the demands of the modern labour market requires increasing efficiency in cooperation between university and school.

It should be noted that this cooperation is being implemented due to the principle of theory and practice interconnection, though the analysis of the real situation has revealed a number of problems.

The problem of cooperation between universities and schools begins with defining goals: the university's aim is to enroll the applicants with a high level of knowledge while the school views the university's mission at this stage in organizing the preparation of the senior students for entering a higher education institution (only for the process of entering, not for the training). Thus, the school is oriented to the short-term result – the percentage of prospective students. Meanwhile, the school students' personal and professional self-regulation generally remains their own and their parents' task. This occurs because of the absence of integration of educational programmes of basic and higher education and is especially visible at the level of basic education.

The second pedagogical discrepancy is connected with the school students' low motivation. Generally, university professors work with senior school students. They are least connected with primary school, which greatly restricts the potential of the universities' positive educational impact on school instruction. Despite the efforts undertaken at a senior level, the problems originating from primary and secondary school remain.

The third problem is linked to the school's not realizing the necessity of academic supervision from outside. The school administration aims at a definite practical result, therefore, they turn to science only in extreme situations: e.g. for working out the concept of the school's development, while preparing documents for the due licensure or attestation, etc.

The fourth problem concerns the best graduates of pedagogical institutes who do not intend to work in the field and graduate only for getting good humanitarian education.

Currently, there are several traditional models of creating interaction between basic and higher education. These include organization of profile (magnet) grades and school students' pre-university instruction. Still, the drawback of most of these models is their being one-sided as the school acts as a customer while the university as a contractor. After its leavers' enrollment, the school being no longer responsible for education results does not feel the need for further cooperation with university. At the same time, the university (especially a pedagogical one) requires establishing and expanding networks with schools as basic and experimental grounds. Thus, the basis for interaction between school and university should be the equal cooperation of all the parties united by the process of solving the commonly-set tasks (not only the preparation for university). In the process, the efforts of each subject harmoniously correspond to the interests and needs of others, which results in achieving the most efficient use of intellectual resources possessed by the educational system.

Quite actual today is the concept of professional and developmental teaching which has an integrative character (Zeer, 2010). The students in an educational programme of a pedagogical higher education institution should possess the knowledge of pedagogy and psychology; they should know the modern school, kindergarten, college, they should be able to be administrators and researchers. In other words, a student should more or less fully realize the activity acquired in course of tuition. A future teacher should get not only an operational experience in performing special functions in profession, but also get a social and practical experience. It will help him/ her to get integrated in the practice and

corporate environment of an educational institution and smoothly go through the social on-the-job adaptation, to reveal his/ her own creative and intellectual potential.

The core of the teacher's professional training is the idea of combining learning with practice. We regard the integration of professional pedagogical education and school internship, as said above, as a process of unification (inter-penetration and mutual enrichment) of theory and practice aimed at formation of the student's readiness for professional activity.

Integration is a peculiar reaction to the processes of separation of the unity taking place in all spheres of being and learning. The restoration of the unity occurs through transformation of the synthesis constituents and their acquiring new qualities. Degree and intensity of these transformations are mostly determined by inner capabilities of integration components as well as goal-settings defining the limits of functioning and development (Chapaev, 2007).

Organization of the efficient interaction between university and school can be based on ~~the application of~~ the cluster approach to the development of education. This approach allows for enhancing the processes of knowledge management on a more complex and integrated basis, which contributes to raising its efficiency. The pedagogical cluster as an innovative model can solve the problem of cooperation between university and school as it features the educational, methodological and research work with teachers, academic advising, scientific and methodological backing of the educational process, testing the modern educational technologies, preparation of the school-leavers for entering a higher education institution, raising the teachers' and students' scientific consciousness, providing the school's educational process with new programmes and guidelines, improving the teachers' professional skills, carrying out research into problems of education, organizing scientific and methodological seminars for teachers, providing support in holding conferences and pedagogical councils, inclusion into work with parents, etc.

The development of cluster-based education began in Europe in the 1990-s as a result of extrapolation of cluster theory and development offered by M. Porter (The Competitive Advantage of Nations, 1990; On Competition, 1998) who analyzed the experience of the Massachusetts educational cluster led by Massachusetts and Harvard Universities in comparison to other states (first of all, California) and overseas examples.

The term cluster origins from information technologies and is used to define a unity of several homogeneous elements which may be regarded as independent units possessing certain properties. This term is traditionally used in economics (Porter, 1980) but recently it has been used in Russian pedagogy which is explained by the need to unite professional forces for solving the issue of training teachers in accordance with the demands of educational organizations.

In pedagogical education a cluster is a unity of spatially located institutions and organizations interacting on the basis of agreements and participating in realization of scientific, educational and innovative goals of training specialists in education (Sokolova, 2014).

According to the researchers, the basic cluster properties include:

- specialization (the objects comprising the cluster function in one common market and use similar processes);
- plurality of participants (the clusters unite various enterprises acting in the market);
- life cycle (in its development a cluster passes stages of a life cycle – creating, development, maturity and decline);
- innovation (for maintaining the cluster's high competitive ability it requires the speeding of the innovation process) (Lapygin).

Considering the university's role in the development of modern theory and practice of cluster approach, it is possible to single out an educational cluster as a type presenting a system of modern interaction in the form of social partnership and dialogue.

Educational cluster is a unity of interconnected institutions of professional education joined on a discipline-specific principle by partnerships with enterprises from the corresponding sphere. The main functions of the educational cluster are as follows: the economic function (creating the sphere of efficient services timely meeting the needs of the sphere's needs); the social function (creating guarantees for graduates of professional institutions), the marketing function (advertising advanced educational technologies, organization of career guidance), the legal function (providing for working out the legal basis of the partnership, for the subject position of all social partners), the pedagogical function (joint projecting of the educational activity in the sphere of the specialist's instruction, providing for the content and technological part of the social partnership among all the educational cluster participants).

The case of an educational cluster is a pedagogical cluster whose main distinctive features are creating conditions for training the specialist with different levels of professional education, integration of education and science, the increased prestige of teaching as a profession).

The model of a pedagogical cluster can be presented a s a unity comprising organizational, managerial, technological and content-related levels allowing for distinctly picturing a targeted process of social partnership development, for defining the correspondence of the goal to the final result. The specificity of the pedagogical cluster is a unity of the content-related, procession and resultant aspects of implementing social partnership in the system of pedagogical education with the view of increasing the quality of professional school graduates preparation.

The analysis of cluster development experience has shown that the CIS-states environment has various types of clusters: according to activity direction (competence-oriented, scientifically-innovative, innovative-educational, socio-cultural); according to the level of organization (regional, republican, municipal, institutional, international); according to the areas of education, etc. The clusters of various types and levels of organization are regarded not as colliding, but rather as complementary.

As distinct from the traditional system, the cluster model allows for creating an innovative educational paradigm to develop along the following magistral directions: instructing qualified staff, generating new knowledge and technologies, the system of industrial and technological support, managing innovative activity, investing into socially important and technologically-intensive projects, promoting the intellectual property assets in the market.

As a number of regions (including the Penza region) are marked by a considerable disbalance between directions and the scope of training specialists in universities in the region and the economy's demands there, the cluster model is aimed at providing for training staff for the developing economic spheres linked to the innovative projects. First, it enables the students to choose the priority areas of instruction according to the current and prospective demands of the region. Second, it leads to minimizing problems with the graduates' employment. Third, a higher education institution (as a cluster innovative core) is provided by the qualified faculty. Fourth, through the process of the cluster model implementation defined are the problems of scientific research actual for the region together with the ways of their solutions. Thus, the organized interaction helps to look differently at the possibilities of the formed and potential connections of schools with different structures: higher education institutions, secondary education institutions, scientific and research organizations, public and commercial organizations as well as realize socially important projects.

Initially, we present the experience of creating pedagogical clusters on the territory of the Russian Federation. Indicative is the experience of Orsk humanitarian and technological institute (a branch) of Orenburg state university (the city of Orenburg) in creating the innovative and educational cluster which provides the students with the opportunity to continually emerge into the sphere of their future professional activity, allows for studying and generating the best practices, for fast testing of the scientific achievements, for upgrading the organization and contents of the professional instruction. In Moscow a university and school cluster is working on an experimental basis. It consists of 33 complexes comprising 220 school and kindergartens. The teachers work according to the new

paradigm of activity education. Tatarstan has recognized the cluster approach as efficient instrument of the republic's economy since 2007-2008. In March of 2006 the Cabinet of Ministers of Tatarstan approved the Concept of Formation of National Clusters. There has been recently worked out the Strategy of Development and Placement of the Productive Forces in the Tatarstan Republic until 2030 on the basis of the cluster approach. The social and pedagogical cluster is an instrument of creating an open pedagogical education of the future as seen by K. Minin Nizhny Novgorod pedagogical university. The infrastructure of the Ulyanovsk region is created on the Programme of Development of Innovative Processes in Pre-School, Secondary Education and Professional Education Organizations and Organizations of Additional Education of the Ulyanovsk Region with the independent regional educational cluster. The Programme has been realized since 1994 with the aim of providing conditions for innovative development of the system of pre-school, secondary school, basic, additional and professional education of the Ulyanovsk region. In the Archangel region a pedagogical cluster will start working in 2017 uniting the efforts of all the educational organizations in the spheres of higher, secondary professional, additional and basic education.

The Penza region has all prerequisites for realization of the project on creating a pedagogical cluster as a new educational network environment: professional institutions interested in cooperation, a higher education institution with the qualified staff realizing the tasks of professional integration of the University educational complex (Penza State University). V.G. Belinsky pedagogical institute of Penza State University is oriented to the cluster approach in staff training. Currently the cluster includes V.G. Belinsky pedagogical institute of Penza State University, the Ministry of Education of the Penza Region, the City Department of Education, and ten secondary schools.

The inclusion of educational institutions into the pedagogical cluster takes place of the principles of territorial proximity, mutual cooperation, joint usage of the facilities and resources. Designing the models of interaction between V.G. Belinsky pedagogical institute and secondary education institutions was based on the following principles of the cooperation:

– the principle of openness realized in the institutions' ability to choose the way of their development;

– the principle of adaptability providing for harmonious relationship inside the interacting teams, connections of educational institutions with social environment;

– the principle of consistency forming the ability of an educational institution to build its own educational trajectory inside and outside the institution;

– the principle of availability oriented to the nearest perspectives of the institution's development and wide access to education for students and their parents;

– the principle of cultural conformity contributing to the institution's maximum use of its environment, society and region;

– the principle of cooperation expressed in creating beneficial conditions for the self-realization and development of the intellectually gifted children and teenagers, for the dialogue in interaction.

The aims of the pedagogical cluster in the system of regional education are as follows: improvement of the quality of training teachers who would be socially and professionally mobile and competitive in the labour market; provision of the innovative character of educational, research and experimental activity of higher education institutions, enterprises and organizations in the region; integration of education, science and industry; development of the educational, material, methodological and industrial base of the institutions involved in the activities of the scientific and educational cluster.

The pedagogical cluster allows for solving the following tasks:

1) Modernization of the educational process and improvement of the educational process management (changing the organizational structure of the educational system; redistribution of the duties among its elements; formation of the new institutions of the educational system offering a wide range of educational programmes and services; transformation to the open education).

2) Improvements in the quality of students' training at all levels of instruction. Development of staff potential (implementation of new technologies; opening new profiles of instruction on the

employers' demand; designing and modernization of study plans and curricula (including the school ones) adjusted to the university's requirements; designing the joint study plans for higher education providing for continuous education for experienced and young teachers; creating conditions for close interaction of the faculty with secondary education organizations inside the cluster; attracting the necessary number of the pedagogical staff of the corresponding qualification; professional retraining of teachers.

3) Modernization of the scientific and research process and creating a methodological and material base (creating a coordination centre with a view to organizing the efficient cooperation of research staff of higher educational institutions in accordance with the potential employers' interests). The cluster will provide participation of students, professors and teachers in research work on education problems, as well as the process of getting practical skills which will improve the quality of teachers' training and simplify on-the-job adaptation. Moreover, the laboratory and technical facilities will be brought in line with the modern requirement of IT-development in education.

The pedagogical cluster based in Pedagogical Institute of Penza State University realizes the following models of interaction among organizations:

1. Information and cognitive social activity concentrated on expanding the students' knowledge about the world and about self a subject of all-civilization process of school and out-of-school activity. This model supposes the functioning of organization services: additional courses, clubs, lecture-centers, research-to-practice conferences, counselling, excursions to the Interactive museum of entertaining sciences where the guidance is done by the students of the Faculty of Physico-Mathematical and Natural Sciences.

2. The problem-related, analytical or discussion activity supposes development of social activity aimed at conceptualization and analyzing reality which includes training, workshops, problem seminars, round tables, research and project activity.

3. Social and role model comprises social activity and is committed to the senior students' pre-professional training (contests, Olympiads, conferences, project activity, subject-oriented summer physic-mathematical camp, the school of a young psychologist, etc.).

4. Play activity is targeted at various types of extracurricular work.

The main directions of developing interaction are learning and teaching (comprising working out and approbation of manuals, study guides for students and school teachers, managing academic activity in various subjects, developing contacts of school teachers with university professors with a view to exchanging experience and counseling), and research and methodological cooperation. The latter features such forms as joint round table talks on most important issues of the cooperation, methodological seminars at university departments with school teachers' participation, organization of annual student research-to-practice conferences with school students' participation, reviewing school students' research and project works by university professors, involving school teachers into participation in university conferences, organizing subject olympiads and contests for school students at university, additional courses and clubs for school students organized at university, methodological support provided by university staff with working out academic programmes, working out and publication of joint paper collections, study guides, monographs with generalizations of cooperation between the faculty and school methodologists and on results of scientific research, supervising school students' research activity, providing university facilities for school students' use (a possibility to use the university library), involving faculty into organization of regional and all-Russia contests.

Supervising the school students' research activity includes: revealing and instructing the students with enhances abilities for research work, using a system of variable tasks aimed at developing logic and creative thinking in the study process, joint instruction of school students on basic research skills (choosing a theme, goal-setting, analyzing sources, research part, scientific style, presenting results).

In this aspect the research activity contributes to the teacher's professional development, to the improvement of his/ her creative potential, as participating in research work leads to maintaining a certain status in an educational institution, research activity helps the teacher to get rid of outdated views and become more flexible in different situations.

The third direction features staff cooperation in the process of teachers' professional retraining by means of organized courses of professional development. In our university there is a centre of additional pedagogical education offering various programmes: professional development, specialists' retraining aimed at improving their professional knowledge, perfecting management skills.

Of greater importance is interaction in the sphere of career guidance preparing students for professional self-determination. There come Welcome days at university, meetings with teachers, school students and their parents on application process and regulations, presentation of the university in the form of videos and handouts, inviting school students to university events (talent contests, KVN, etc.).

The cluster form of the organization allows for creating a common innovative product and preparation of the highly-qualified staff possessing the necessary professional competences. Continuos communication of the prospective teacher with prospective students contributes to the young teacher's professional adaptation to the school environment. As a result, the school administration gets a well-trained specialist.

Nevertheless, the school realities and analysis of social and pedagogical research shows that even with the high level of readiness for pedagogical activity, the pedagogical institute graduate's personal and professional adaptation may be quite slow and complicated. The problems that a young specialist faces at the school can be grouped as follows: 1. Professional problems connected with a wide range of activity and the necessity to feel confident in the school environment; 2. Organization problems connected with managing own professional activity; 3. The problems of integration in the teaching staff, establishing interaction and understanding with colleagues and administration; 4. Emotional problems connected with acquiring a new social role.

Apart from that, the introduction of new educational standards at the school leads to additional difficulties in a beginner's professional adaptation. Thus, he/ she turns out in a situation of vagueness on the way to integration into the new educational environment which makes professional adaptation more complicated. We see the solution to the problem in managing psychological and pedagogical support to the young teachers' adaptation provided by our 'School of a young teacher' organized within the cluster's framework. This kind of cluster work comprises a complex of measures improving the qualifications of a young teacher up to the level on which he/ she would be able to model own professional activity according the the Federal Standard requirements.

'The School of a young teacher' maintains the following directions of activity:

1) diagnostic monitoring reflecting the teacher's personal development in three aspects: a) professional (studying pedagogical experience, the teacher's theoretical and methodological training, analysing the efficiency of the lesson according to the Federal Standard requirements, evaluating the level of professional maladaptation; b) behavioural (analyzing the emotional and volitional sphere of a personality, studying professional motivation); c) personal (studying self-assessment, underlying risk for psycho-emotional burnout).

2) seminars in modules given by university methodologists as well as by most advanced school teachers with a highest qualification category: psychological and pedagogical foundations of educational activity, modern teaching technologies, creative self-development pedagogy, a teacher's methodological competence, a modern teacher's image.

3) training programme (organized by university psychologists) aimed at facilitating successful social and psychological adaptation of young teachers, support with establishing an emotional contact with colleagues, creating an atmosphere of collaboration in a group of teachers,

building self-confidence, taking group decisions, practicing different types of interpersonal perception, building a teacher's awareness of own personal needs and positive change of his/ her attitude towards self and others.

A teacher's professional development becomes more successful with expanding the possibilities of his/ her self-realization in professional sphere. Becoming a professional is impossible without the skilful organization of the university educational environment which is a major factor of building a future teacher's professional competence. Required for this are the following conditions:

– the content of the subjects under study should be practice-oriented and close to reality;
– the forms and methods of activity should be clear, logically grounded and easily applied in the school reality;
– the student-teacher relationship should be build on the principles of democracy and developmental teaching;
– there should be material and technical facilities for organizing students' modern educational activity and development.

The work of base practice grounds, holding scientific and research conferences, organization of research laboratories, holding joint seminars of students, professors and school teachers will allow for creating such environment.

The efficiency of the pedagogical cluster as an instrument of school and university cooperation depends on the following factors:
– improving the work on the model "School – University – School", attracting new participants from the innovation organizations of Penza city, varying the forms of interaction inside the cluster;
– providing methodological support for young teachers (School of a Young Teacher, organizing seminars and conferences for the teachers of the Penza region);
– creating conditions in the pedagogical higher education institution for students' preparation for successful professional activity;
– maintaining the students' professional formation in the university through their creativity potential development;
– establishing relationship between the faculty and the students on the principles of mutual respect and cooperation;
– developing students' self-administration within the university;
– getting students involved into socially important projects;
– building students' social activism.

The inquiry held for the teachers from the schools included in the pedagogical cluster showed a rather level of their awareness of the essence and importance of school and university integration. Most teachers noted that the cooperation between a higher and a secondary school expands the common educational space and improves the quality of education, which is beneficial for all the participants. The university gets a real idea of the modern school students' level of knowledge and can contribute to its promotion thus getting applicants and students with good background. In this turn, the school is interested in raising its prestige and status in the educational market. The teachers can get their professional development supplementing it with new forms of activity and new kinds of knowledge. The students will get the education meeting the up-to-date requirements and standards as well as the skills of research activity. The parents will have an opportunity to learn about the requirements for university education and see if their children's professional choice was right.

Therefore, understanding the essence of and practical realization of the cluster approach create the necessary prerequisites for discovering new resources and possibilities of development of educational system improving the quality and competitiveness of education. The organized interaction allows for creating a practice-oriented educational environment which raises the competitive ability of all the cluster participants, maintains the training of highly-qualified specialists within the optimal terms and provides means for building individual educational trajectories of professional self-realization. As

seen from the experience of foreign states, different regions of Russia and also the practice of Penza State University, cluster approach can increase the efficiency of the educational axis "School-College-University-Education Authorities"; provides for the full and all-round use of the human assets which is key to the educational environment; enhances the development of not only the intellectual but also social and cultural constituents of the educational organization and brings the knowledge management in education to the new level.

Morocco

Abstract

Attractiveness is an important element in the development of a territory because it helps put it in front of the competitive scene territories, and it makes such a product to be sold to develop. It is seen, in fact, as imperative for all countries. This is facilitated in particular by adopting a territorial marketing strategy that allows you to highlight its strengths and promotes development through the provision of territorial marketing actions.
It appears to us then, the existence of a relationship between the practice of territorial marketing and regional development. Therefore we will try to demonstrate this relationship by focusing on the contribution of the tourism sector in the region Tanger Tetouan.

Keywords: marketing territorial, regional development, tourism, region Tangier Tetouan.

Introduction

In the wake of the English-speaking countries and Northern Europe, territorial marketing is now in fashion. Due to the increasing mobility of production factors, the increase in free trade agreements, but also the increasing number of offers offered to international investors, tourists and organizers of professional events, cities, regions or countries with an intensification of international competition. Similarly, existing and potential customers have increasingly personalized requirements.

What to do in such a context to defend and enhance its attractiveness? How can we attract more activities, promote territorial competences or retain our industries and jobs? What is certain is that generalist messages no longer carry. To assert itself as "a key place" at the heart of world trade,the territories must identify their elements of differentiation in relation to their competitors, whether in terms of price or specific qualities. To improve the competitive position of their territories, local officials are wondering about the ways and means of evolving their territorial offers to be more competitive.

Faced with these questions, territorial marketing offers decision makers a global approach that makes it possible to highlight the attractiveness factors of cities, intermunicipalities, departments or regions.

That said, a highly attractive territory clearly represents significant comparative advantages: job offer, investment ... and this is where the notion of development makes sense.

Previously, development was targeted by national strategies for a country as a whole, or by sectoral development strategies that target the development of each sector or industry independently of other sectors. Today, however, it has been shown that the most effective way of addressing the development problem relates to the use of an upside-down approach, from the inside to the outside, which means that Development must be triggered from regional levels and not from national levels.

Tourism not only facilitates job creation, it also plays an important role in creating equality in the distribution of wealth between regions. It reduces the funding period for new infrastructure and helps protect historical monuments that represent resources for tourism. (Morena, 2004) "Tourism is a means of individual and collective fulfillment, insofar as it fosters mutual understanding and respect between peoples and societies. Traveling for reasons of religion, health, studies and cultural or linguistic exchanges are particularly beneficial forms of tourism that deserve to be encouraged, as well as nature tourism or ecotourism "(Morena, 2004).

The choice of the city is not arbitrary. Indeed, the city of Tangier constitutes a center of concentration of most Moroccan or foreign investments and presents a fertile ground of development. The city sparks the common interest of both the state and investors in order to take advantage of its resources in several aspects.

Our study allows us to:

- Highlight the territorial marketing tools that will enable the territory to improve its attractiveness.

- To clarify the concept of regional development that is used but not in an appropriate way.

- Show how companies participate in the regional development of the Tangier-Tetouan region.

Territorial marketing and regional development: literature review

Territorial Marketing Literature Review

Definitions of territorial marketing are abundant, especially by specialized authors and researchers. These definitions range from the most restrictive, limiting the role of territorial marketing, to broad definitions that attribute to marketing territorial role in the economic development of a territory, a city or a region. Definitions include:

- Territorial marketing is an approach aimed at attracting companies to a territory, facilitating business activity and promoting a territorial image favorable to endogenous development.

- The marketing of a city can be defined as its individual or collective actions to attract new activities on its territory, favor the development of companies operating locally and globally promote a favorable image.

- Territorial marketing represents the art of positioning a village, a city, a region, a metropolis on the vase world market.

However, referring to one of the authors, namely the sociologist Michel Wieviorka, the term "territorial marketing" appeared in 1975 and since then has evolved both theoretically and practically This is related to the major concerns of space, or more precisely territories, at that time. It is not only a matter of promoting or selling the territory, but of caring for and developing its natural qualities and the potential of the regions.

Beginning in the 1980s, territorial marketing was much more associated with urban development, but it is important to emphasize in this connection that the true meaning of this neologism is conceived only through the first book by Ashworth and H. Voogd (1990) entitled "Selling the city: Marketing approaches in public sector planning" (Mendes, 2006).

Importance, practices and tools of territorial marketing:

Territorial marketing has a very important contribution to the economic development of a territory. It is a tool that attracts and retains various targets, including tourists and businesses. The latter constitute a real investment in the territory in question ,this contribute to the improvement of its quality of life and to the creation of a sense of belonging for all the players in the territory. This is how we can affirm that territorial marketing is a very important means of local development and that is expressed in a communication and a dissemination of the values of the territory.

As we have seen, the territories now use the same reasoning as companies. They even use the same tools, the same methods to differente themselves from their competitors. The challenge of the territory is to "constitute local excellence in the face of competition"

For this there are many tools like:

Knowledge tools: statistics, surveys, SWOT analysis, PESTEL analysis, etc.

➢ Management tools: strategic marketing (segmentation / targeting / positioning), marketing-mix, evaluation.

➢ Tools for action: promotion, mobilization of local actors, development, improvement of the local offer ...

However, the "copy / paste" of this practice is not systematic and should not be systematic since it leads to a certain efficiency and standardization of territorial marketing.

Regional Development and the Tourism Sector

Regional Development Literature Review

Until the 1960s, development was seen as a set of quantitative mutations and measurable progressions of products and average incomes - progress generally achieved through increasing industrialization of the economy. For a given population, this would mean access to a certain level of wealth and material well-being, estimated in terms, for example, of GNP, GDP, or per capita income. These indicators situate countries on the scale of development.

Development, as we define it here, is both economic and social. It refers to all the technical, social, demographic and cultural transformations accompanying the growth of production. It can be associated with the idea of economic and social progress, which reflects the improvement of the standard of living and the level of education, which are considered essential for the well-being of the population.

Tourism, a promising sector for the regional development of Morocco

Tourism is now regarded as the world leader in the economic sector, with a contribution of more than 10% to world GDP. In 1963, the UN Tourism Conference defined the tourist as "a temporary visitor staying at least 24 hours in the country visited, whatever the reasons for his stay" (Pasqualini & Jacquot, 1989 quoted in Dupont, 2002). In 1994, the United Nations extended the definition of tourism to include "all the activities deployed by persons on their journeys and stays in places outside their usual environments for a consecutive period Shall not exceed one year for leisure, business or other reasons not related to gainful employment in the place visited "(UNWTO, 1994).

Tourism not only facilitates job creation, it also plays an important role in creating equality in the distribution of wealth between regions. It reduces the funding period for new infrastructure and helps protect historical monuments that represent resources for tourism. "Tourism is a means of individual and collective fulfillment, insofar as it fosters mutual understanding and respect between people and societies. Traveling for reasons of religion, health, studies and cultural or linguistic exchanges are

particularly beneficial forms of tourism that deserve to be encouraged, as well as nature tourism or ecotourism.

The development of tourist destinations is strongly affected by globalization; Tourism is "an industry built around the concept of the nation-state, where each destination has its institutions, political, economic and social / cultural capital. Yet they are all competing with each other for the wealth and status that tourism can create. " Tourism competition is not limited to destinations offering identical or similar services, but can be extended to destinations offering completely different tourist offers.

Tourism is a sector that has not only an important role in the economic sphere for the creation of wealth and improvement of the quality of life of the populations of the tourist destinations; It also helps to bring people and communities in contact and to cross cultures and civilizations. It therefore has an important role to play, that of "facilitating dialogue between cultures".

From an economic point of view, tourism is the sector that produces the highest incomes, as soon as possible and with the least investment. Given the fact that many poor countries and regions in the world do not have sufficient resources to develop industrial economies, tourism becomes a relevant and rapid solution to improve living conditions and reduce poverty.

In the final analysis, the sustained development of the tourism sector is accompanied by the emergence of a new generation of national operators that contribute to the modernization and competitiveness of the sector: tourist investment funds, developers and developers of integrated stations , Operators, low cost airlines, receiving agencies ...

In turn, international tourism operators, hotel managers, tour operators and airlines, are numerous to set up in Morocco, helping to strengthen the know-how, accessibility and visibility of the sector on the international scene.

Contribution of the Territorial Marketing of the Tourism Sector to the Regional Development of the Region Tangier Tétouan

Research Methodology

The epistemological posture of our research is based on positivism, a paradigm that allowed us to explain an existing reality, the choice of the positivism paradigm goes in the sense that we try to explain the link between territorial marketing practices and regional development. The principle of causality is at the heart of our positivist paradigm, because it consists in the assertion that any event or phenomenon can be explained by a causal link . To explain this reality, we must therefore discover the simple reasons by which the facts observed are related to the causes that explain them. The path of our research is rather confirmatory than exploratory, it is a matter of confirming assumptions.

Structure of the guide interview

In order to make the analysis even more relevant, it was agreed to carry out a qualitative study of the organizations likely to contribute to the regional development of the Tangier-Tetouan region,but also 30 tourist companies including 17 hotel chains and 5 travel agencies, the remainder being divided between the rental agencies and the associations organizing events.
The aim is therefore to explore the strategy of local authorities and to see to what extent they adopt the appropriate strategy of territorial marketing.
It is in fact a direct interview with the various regional officials of the tourism sector in the region Tangier Tétouan. Indeed, we have chosen the organizations with the most authority and impact on decision-making in the sector as well as those directly attached to the Ministry of Tourism. We have therefore chosen SMIT: the Moroccan tourism engineering company, the CRT: the regional tourism council and finally the Tangier Tourism Delegation.

I: general presentation: This sheet is a collection of the data of the actors responding to our questionnaire. It gives us an overview of the characteristics of the actor allowing us to operate a

certain classification for the purposes of analysis. The organization presents its objective, its vision and its missions, this allows us to analyze the contribution of the structure in the promotion of the region and the encouragement of investments.

II: Tangier Tétouan: This field allows us to have a global view of the region Tangier Tétouan, that is to say the infrastructures of the region as well as the situation of tourism.

III: Elements relating to territorial marketing: a vision of territorial marketing by the actors. Through this third sheet, we look for the existence of a territorial marketing strategy within our field of investigation. To this end, we have structured this form around the key elements of territorial marketing, in particular the apprehension of the actors involved in territorial promotion and development activities, the attractive or repulsive factors for the actors as well as the issues related to decision-making and The brand image of the study territory.
The focus is therefore on territorial marketing practices within the organization as well as incentives for investment.

IV: Elements related to regional development: This component is devoted to the measurement of the contribution of tourist enterprises to regional development.

During these interviews, the difficulties that we encountered were mainly in contact with those responsible who were not at all available because of the tourism foundations that took place during the same period.
In spite of this, we have been able to draw a significant amount of information about the territorial marketing practices of each of them as well as their vision of regional development and to what extent one can influence the other.

Discussion of Results and Recommendations

Analysis of semi-directive interviews

In order to complete our study, we have agreed to conduct semi-structured interviews with the heads of tourism development organizations in the Tangier-Tétouan region. To do this, it was necessary to draft an interview guide to guide the discussion to the most relevant elements of the analysis.
For all the officials questioned, the main objective is to promote the destination of the region Tangier Tétouan. Indeed the 3 institutions surveyed consider that the destination Tangier Tetouan presents significant assets likely to make pillar of the sector of tourism in Morocco.

Indeed for all those surveyed, the destination Tangier Tetouan has important potentialities and unavoidable assets such as the sea fronts for the development of the seaside tourism, the spaces clothe for the tourism of nature as well as the cultural tourism with the monuments and The ancient medinas.

The situation in the sector is relatively satisfactory in view of the revival of the destination in the Vision 2020 plan and the budgets allocated for the renewal of monuments and the establishment of new attraction policies.

Based on the discussion we had with the various managers, we found that they do not have a specific territorial marketing policy because of their focus on product policy by neglecting other marketing elements that could promote The development of the region.

The results of our global analysis showed that the majority of actors attached high importance to regional development projects. This is confirmed, in particular, at the regional level by the fact that the actors consider that development projects are very important. This importance is reflected in the role played by the actors in the regional development process.

Moreover, they are proposing incentives for investors and especially for tourism that stops once the project is completed, there are no post-investment satisfaction monitoring and control measures.

This case causes an obstacle especially for the organization of events or all the work begins before and after the event.
As for territorial communication, it is a variable taken seriously by all the officials interviewed, but the latter is limited to traditional channels not sufficient to highlight the destination Tangier Tetouan.
Concerning the last component constituting the regional development, the answer of the responsible ones leads to confusion. Indeed, the notion of regional development already is not quite clear to them. Regional development is limited to economic development only and does not take into account other important variables.

However, they believe that territorial marketing contributes to the regional development of the Tangier-Tetouan region through job creation and regional wealth and the strengthening of regional budgets

Recommendations for the Implementation of a Territorial Marketing Strategy to Strengthen Regional Development

Through the analysis previously elaborated, we found that the organizations specialized in promoting the tourism sector in the region do not have a territorial marketing policy or strategy adapted to the Tangier-Tetouan region. This is why the proposal to adapt the operational marketing tools to the territorial marketing of the city is important for the development of the Region.

In an operational marketing approach, the territory is perceived as a "product" having a price and being the subject of a communication policy. It will therefore be necessary to adapt the mix marketing tools to the specificities of territorial marketing.
We propose a reflexion access on the 4P adapted to the specificities of the region Tangier Tetouan namely:

-***Product policy***:If the place of investment can be considered as a product, this product can not be considered as any product. Indeed, unlike other goods or services whose contour or components are easily identifiable, the "product region" requires a greater reflection.
Like any product policy, whose main goal is customer satisfaction, the region product must be defined according to the perception of the investor, who is not only looking for a location, but also access to new opportunities.
The product region is therefore perceived in terms of improving the competitive position that the investor is likely to achieve through a new location.
Product policy can therefore be defined as the set of actions that serve to provide as complete a range of services and sites as possible to meet all demands. Product offerings include the following steps:

- ✓ Analysis of the motivations and needs of investors in order to know the characteristics of the demand.
- ✓ The rigorous analysis of the resources present in a territory and the specific capacities of the latter, with its strengths and weaknesses.
- ✓ The choice of a positioning for the territory.
- ✓ The exploitation of the factors of the attractiveness existing within the territory.
- ✓ The adaptation or creation of new factors of attractiveness, which will make it possible to have an offer tailored to the needs of investors.
- ✓ -The diversification of the tourist offer will allow investors to better understand the territory.

-The distribution policy: Distributing products means bringing them to the right place, in sufficient quantity, with the right choice, at the right time, and with the services necessary for their sale, consumption and, where appropriate, their maintenance.
However, in the context of territorial marketing, the distribution policy aims to facilitate access to the city by improving transport networks. The road network, the rail network, ports and airports are being

renovated to meet the needs of the industry and to forecast the economic and demographic evolution of the city.

***-Price policy*. :** The price policy in territorial marketing is materialized by the creation of different incentives for the decision to set up the company so that the latter comes to settle in one territory rather than another.

Incentives are an extremely widespread instrument of attraction policy. This instrument has the advantage of being more easily manipulated by the host territories than the other elements are likely to influence the decision to implant.

According to the study done by our care we found that the main difficulty encountered by tourism companies is fiscal and financial difficulties, however we will propose some proposals likely to help companies to face this problem among these solutions we propose :

- ✓ TAX INCENTIVES: As Tax holidays or temporary tax exemptions, Tax credits and deductions for investment, Accelerated depreciation, Aid to companies in difficulty ....
- ✓ FINANCIAL INCENTIVES: Loans, advances and interest subsidies, Loan guarantees and guarantees, land grants ....

-The communication policy: In order to face the different problems of territorial marketing, territorial communication is one of the most important elements in solving and taking into account all the difficulties facing territorial marketing. It is therefore of great importance for the realization of development projects.

It facilitates exchanges between stakeholders (communities, NGOs, regional authorities, community groups, etc.) with the aim of tackling common problems of development and achieving common objectives for Community action.

Investing in territorial communication is important, if not decisive, in the development of the Tangier-Tetouan region by enhancing the Tangier Tetouan destination by using the various communication media that can have a significant impact on investors.

Conclusion

We are witnessing an area in which marketing is involved in regional development and where it guarantees the best way to approach investors, to influence their localization decisions and to convince them to come and settle in the territory, which is an advantage Shared for both parties:

- Companies benefit from the advantages offered by the territory in qualitative and quantitative terms.
- The territory benefits from the advantages linked to the installation of companies, in terms of employment, financial resources, image, ...

The contribution of territorial marketing to regional development is one that seems to be understood and taken into account by the developed countries. The link between these two aspects, which could be implemented, in our case thus marks a great importance in the development of a region. However, this does not fully agree with the Tangier Tetouan region.

At the end of this study, we can only be aware of its incomplete nature. It is clear that it still needs to be improved and expanded and that it suffers from several shortcomings, but we still believe that it has shown how marketing can be considered as a tool for territorial development.

Nowadays, economic development is an imperative for local and regional authorities, which have become responsible, at least in part, for this development must influence the main factor of this development, namely: the enterprise.

Indeed, regional development requires the establishment and presence of companies, they create jobs for the inhabitants and finance the communities through the taxes they pay.

In the Tangier-Tetouan region, more than elsewhere, territories need companies to invest in them, create jobs, pay wages and taxes, create supply and demand. Unfortunately, territorial marketing is far from being A tool for regional development, to the extent that no application is made. It is not even envisaged, as a tool favoring the installation and maintenance of businesses within the territory.

The Significance of Small Businesses in the Township Economy: A South African Perspective

Caswell M. Maloka and Mduduzi S. Dlamini

Small Enterprise Development Agency

South Africa

cmaloka@seda.org.za or mdlamini@seda.org.za

Abstract

The purpose of this paper is to examine the significance of small businesses in the township economy in the post-apartheid South Africa. The majority of townships in South Africa are confronted with numerous challenges that affect the expansion of entrepreneurship activity and establishment of small businesses. These challenges date back from the past policies of spatial arrangements and exclusion of black businesses in the development agenda of the then apartheid government. Townships in South Africa are largely characterized by the lack of resources and infrastructure crucial for business development, high levels of unemployment, poverty and inequality. The development and support of small businesses in the townships is viewed as a panacea for the aforementioned challenges. Studies have demonstrated that there is a latent potential for township businesses to contribute meaningfully to the country's economic growth given the availability of adequate business development support. The democratic South Africa has since experienced the introduction of a number of government driven initiatives and programmes designed to stimulate entrepreneurship and promote small businesses. However, these initiatives appear to be fragmented and not coordinated with diminutive focus given to small businesses in the townships in particular. This paper argues that, in order for government to curtail the ever growing rates of unemployment, poverty and inequality in the country, role players in the small business development ecosystem including the Small Enterprise Development Agency (Seda), should start working intractably close with each other to leverage resources directed to small business development. The study used the literature review to demonstrate the purpose and support the argument as indicated above.

Keywords*:* Entrepreneurship, Small business, Township Economy, Unemployment, Poverty

Introduction

According to the recent data released by Statistics South Africa (Stats SA), the official unemployment rate in the country stands at 27.7% with more than half of the population living in poverty (StatsSA, 2017). The majority of the unemployed and people living in poverty conditions reside in townships and rural areas. Entrepreneurship and establishment of small businesses in the townships are therefore seen as a fundamental solutions through which these challenges can be addressed (Charman, 2017; Lekhanya, 2015; Chili, 2015). The substantial and meaningful involvement of people living in townships into the mainstream economy through their own businesses is therefore crucial (Lekhanya, 2015). Entrepreneurship and small businesses are viewed as the vital drivers for job creation and poverty alleviation, with 90% of jobs expected to be created in the small business sector by 2030 (National Development Plan, 2012). In recent years townships have seen an emergence of entrepreneurship activities and small enterprises due to the abolishment of legislations of the then apartheid regime that prohibited and discouraged black people to participate in the mainstream economy. The Department of Small Business Development (DSBD) in its strategic plans, recognises the importance of township small, medium and micro enterprises (SMMEs) and their contribution to economic growth, employment creation and poverty alleviation. Therefore, the department has prioritised the implementation of the National Informal Business Upliftment Strategy

(NIBUS), which focus on enhancing the competitiveness of a majority of township businesses. The government is privy to the challenges facing small businesses and cooperatives within the township economy. This paper therefore seek to examine the significance of small business in the township economy in the post-apartheid South Africa using the literature review. The article is structured into seven sections. It provides the historic overview of townships, a description of the township economy as well as the characteristics of small enterprises in these area so as to provide context to this paper. Furthermore, it unpacks the significance of small businesses in the township economy and outline how government can strategically intervene to assist these businesses.

Historic Overview of South African Townships

The literature review points to the origins of townships in South Africa back from the past policies of racial segregation and apartheid government (Jürgens, Donaldson, Rule & Bähr, 2013). The term 'Township' is usually described as previously underdeveloped areas in the country designed for black population living in the outskirts of the urban centres (Charman, 2016; Matli & Jordaan, 2016). These areas were deliberately designed to provide a pool of cheap labour constituted by black people from rural areas working in industries, mining and domestic work in the urban areas (Jürgens *et al*, 2013). Therefore, the formation of townships was to enable black population easy access to and from work. They are characterised by overpopulation, high levels of poverty, unemployment, low levels of household income, poor infrastructure and commercial investment (Chili, 2015; Jürgens *et al,* 2013). The apartheid spatial planning system provided limited investment in all forms in these areas including shelter and education (Charman, 2017). Hence, black people were constrained access to capital, education, basic and social privileges (World Bank, 2014). The limited access to such opportunities obliterated the fabric that small enterprises could be established by black people in the townships (Gauteng Township Revitalisation Strategy, 2014/19; World Bank, 2014). The inheritance from these past policies affected the growth of the SMME sector in the townships and demoralised those that ventured into business by denying them of any support. These perpetuated the growing levels of unemployment and poverty as a result of growing population in these areas (Jürgens *et al,* 2013). These authors argue that the above - mentioned issues are remnants of the apartheid government and have continued in the democratic government. Nevertheless, townships have seen a gradual increase in the levels of entrepreneurship and number of small businesses; and remain home for many people in the country. According to Matli & Jordaan, (2016), South Africa has made sizeable improvement in the living standards of townships.

Understanding the Township Economy

During the apartheid administration, the township economy in South Africa functioned in isolation from the mainstream economy. However, post the democratic dispensation, the process of integration took place (Jürgens *et al*, 2013; Charman, 2017). The term township economy represents the micro-economic and related activities occurring within the townships (World Bank, 2014). It is further defined in the Gauteng Township Revitalisation Strategy (2014/19) as enterprises and markets operating within the townships. The majority of these enterprises are characterised by high levels of informality with narrow access to markets. Hence, the concept is usually associated with the informal economy (Ligthelm, 2003). Township enterprises are understood to have been established in order to meet primarily the need of the people residing in the townships (Charman, 2017). However, a large amount of the product offered by these enterprises are not produced within the townships, but in their nearest towns or cities. Worryingly, a majority of people living in the townships spent greater part of their income on goods and services outside of these areas (McGaffin, Napier and Sebina, 2015). Evidently, Thulo (2015) indicates that 25% of the money generated within the township is spent there. The township economy is largely dominated by low income households which define the buying power and the skill profile of individuals living in the townships. The household income in most of the townships is usually generated from labour obtainable in the nearest cities and towns in form of wages and salaries or through engaging in a wide variety of small-scale economic activities (McGaffin *et al*, 2015). Currently, there is no established national report which gives accurate data on the impact of the township economy. However, its contribution to economic growth and job creation is widely acknowledged by many. According to the study conducted by the World Bank (2014), South Africa's townships contribute up to R100 billion to the overall economy. Therefore, a

concerted effort need to be directed to the township economy in order to unlock its full potential, important for job creation and economic growth.

Typical Characteristic of Small Enterprises in the Township Economy

Small businesses in South African township economy are involved in a wide variety of economic activities (Matli & Jordaan, 2016). Township SMMEs are largely survivalists and micro-enterprises and mostly informal (Charman, 2017). Survivalist enterprises are described as a set of SMMEs mostly involved in activities carried out by unemployed people who are unable to find permanent jobs (Tustin, 2003). These kind of enterprises does not employ anyone and generate insignificant income with little investment in capital and skills training. Their productivity level is very low as a greater number of these enterprises are involved in service and retail activities (Chili, 2016; Charman, 2017). On the other hand, micro- enterprises mainly involve the owner and several family members. Micro-enterprises employ more than four regular workers (Charman, 2017). Entrepreneurs from township areas have basic business skills. Though a majority of these enterprises lack formality, they given appropriate support they have the potential to develop and become formal structured enterprises (Dockel 2005). Most of the township enterprises are considered to be necessity driven as opposed to opportunity driven. Examples of such enterprises include amongst others spaza shops, hair salons, car washes, back room property rentals, street vending, shabeens, minibus taxis, stokvels and mechanical services (Chili, 2016). Dockel (2005) argue that survivalist and micro enterprises tend to increase when the economy decline and decrease as the economy grow. Therefore, these businesses serve as a safeguard that provide a means of survival during economic difficulties. SMMES play most important role in the township economy since they represent between 70% and 80% of all black owned business activities in South Africa. Geographically, township small businesses can generally be found on the streets and inside (multi-storey) buildings. Some are operated from residential yards, converted garages, houses, disused factories and old office blocks. They are highly visible at traffic lights, road junctions, mini-bus taxi ranks, alongside the road, and in markets.

The Significance of Small Businesses in the Township Economy

Small enterprises continue to play a significant role towards contributing to economic growth, employment, poverty alleviation and inequality in South Africa (Marnewick, 2014; Lekhanya, 2015). This is despite being faced by numerous challenges such as fear of crime, lack of access to electricity, shortage of space and serviced business sites, high transport costs, access to finance, regulatory burdens etc. (Ligthelm, 2003; McGaffin *et al*, 2015). According to the Bureau of Economic Research (BER) SMME quarterly update report commissioned by Seda, there are currently 2.23 million business which account to 65% of the total employment in South Africa (BER, 2017). The majority of these enterprise operated in the informal sector (67%) while 29% are represented in the formal sector. This suggest that the majority of small businesses are found in the townships as these enterprise are usually characterised by informality. Fundamentally, small businesses are the drivers of employment creation to offset the impact of poverty that is rampant within township societies. Small businesses operating in South Africa offer goods and services that satisfy the needs of households living in these areas. They are vital for creating social stability and vibrant productive township economy. The significant role played by small business in the township is further recognised by government of South Africa as echoed in documents such as the National informal Business Upliftment Strategy and the Gauteng Township Revitalisation Strategy.

Government Policies and Strategies Geared towards Township Small businesses in South Africa

Township businesses in South Africa have pertinent strengths and weaknesses that require specific policy responses in order to enhance their efficiencies and competitiveness. The South African government is increasingly expected to create an enabling environment that should foster business development and growth in these areas. Through its agencies and various departments at national, provincial and local levels, the government has put in place mechanisms in order to provide support on small business development. However, the government has not fully adopted an integrated

approach implementing these strategies other role players. Fostering public and private partnerships and small business networks has been identified as critical in order to unlock fully the potential of small businesses and township enterprises in particular. It is therefore important to critically examine government policies and strategies directed towards facilitating establishment and improving business in the townships at the national government. Government policies and strategies directed to supporting township businesses are premised on the 1995 "White Paper on national strategy on the development and promotion of small business in South Africa". In 2014, the South African government showed its commitment on intensifying small business development in the country and established the Department of Small Business Development (DSBD). The DSBD was mandated to drive an integrated approach to the development and promotion of small businesses and cooperatives; through a focus on the economic and legislative drivers to contribute to radical economic transformation. The department fulfil its mandate through the two implementation agencies namely Seda and Small enterprise finance agency (Sefa). These entities respectively in partnership with various stakeholders provide non-financial and financial business development support services and programmes to entrepreneurs and small businesses in South Africa. A number of most prominent policies and strategies have been implemented over time as efforts by the government to increase the impact of the role played by township small businesses. These include amongst others:

National Small Business Amendment Act (2004)

Fundamentally, the National Small Business Amendment act led to the establishment of the Small Enterprise development Agency (Seda) which play a significant role on providing non-financial resources, capacity building services, products and services to all entrepreneurs and existing small businesses nationally. The Act promotes integrated approach to small business development. Seda to some extent has made major strides in ensuring that business development support is extended in all the provinces including township areas and is expected to intensify support to township businesses in line with the DSBD strategy. The Act mandates the Agency to facilitate, develop, coordinate and foster partnerships across all spheres of government, the private sector and relevant stakeholders that may assist it in achieving the set objectives. Township businesses remains a priority to receive business development support in order to unlock their potential to compete locally and internationally.

Broad Based Black Economic Empowerment (BBBEE) Act and Preferential Procurement Policy Framework Act

These pieces of legislation were primarily introduced to facilitate support to a majority of black owned enterprises (previously disadvantaged groups) to become actively involved in the economy and to aid small business owners particularly with access to market. In 2013, the South African government published the revised BBBEE codes of good practice that seeks to strengthen and grow successful black owned enterprises. According to the Department of Trade and Industry (DTI, 2013), in the revised codes of good practice all companies, except Exempted Micro Enterprises (EMEs) are required to comply with the five elements of the BBBEE scorecard, namely: ownership, Management Control, Skills Development, Enterprise and Supplier Development. While it is expected that corporates, State owned enterprises and big businesses will step up and adopt enterprise and supplier development to benefit small businesses particularly black owned businesses particularly in townships, it appear as if the impact of these Acts are yet to be fully realised . Critics have pointed out that these Acts benefit a minority and has done little to promote entrepreneurship and support to small businesses. However, it is expected that programmes such as the Supplier Development Programme implemented by Seda and its partners, should make a meaningful impact towards enhancing the capacity and competitiveness of township small enterprises in order to participate in the various supply chain opportunities available.

National Informal Business Upliftment Strategy

As earlier pointed out that Township small businesses are largely informal survivalists and this has an implication on the type of business development support received from both the government and private sector. From the public sector there is the National Informal Business Upliftment Strategy

which is driven by the DSBD targeted to informal businesses. It provide support to local chambers/business associations and Municipal Local Economic Development offices to deliver and facilitate to implementation of SMME development programmes focusing on informal businesses in townships (DSBD, 2015). Small businesses owned by women, youth and people living with disabilities in township areas and rural areas are the designated preferred groups for this strategy. Most importantly, the strategy take cognizance that informal business transactions cut across various economic sectors even though it prioritizes five economic sectors for intervention namely: retail, manufacturing, services, construction and maintenance which are predominant in township SMMEs. However, provinces or local municipalities are at liberty to prioritise sectors based on economic conditions prevalent in each particular region. In each of the identified sectors, the strategy facilitates for provision of a range of interventions which include: skills development (technical, business skills, computer skills etc.), marketing and branding (marketing material, brochures, signage etc.), product improvements (standards, quality etc.), technology support, machinery and equipment, basic compliance (business registrations, licensing, accreditation etc.). These interventions are demand driven and depend on assessments conducted on these businesses. However, the government is continuously experiencing some resistance from a significant number of informal enterprises who are not so keen to formalise their businesses. In instances where these businesses formally register their businesses, trends indicate that they do not continuously comply with legislative requirements leading to deregistration and ultimate closure due to penalty costs that they accumulate over time. NIBUS need to be fully adopted and be applied across the township economy in order to realise the benefits of small businesses.

Approaches for Entrepreneurship and Small Businesses Development in Townships

There is a mounting pressure for the South African government through DSBD and its agencies to upscale a meaningful small business development support directed towards township business as figures of unemployment soar and poverty threatens the socio-economic fabric in these societies. While the expected impact may not be immediate as desired by the masses, the government has an opportunity to join forces with other stakeholders from the SMME development ecosystem and work together to create a conducive environment for small businesses development in township areas. Some of the proposed approaches to make a meaningful impact to township entrepreneurship and small business growth include the following:

Establishment of Township Business Hubs

A study conducted by Seda to analyse state, needs, opportunities and challenges of small business in the township economy (2016), indicated that it is essential to establish township business hubs in order to advance a coordinated business development support to small businesses. These hubs aim to stimulate entrepreneurship and township economies and will greatly benefit small businesses in terms of business skills development fundamental to exploiting income generating opportunities. In this regard, Seda is expected to play a coordination role and partner with relevant stakeholders to establish these hubs in order to provide relevant business infrastructure (shared facilities e.g. Internet, training rooms boardrooms etc.) as well as, business development support services (e.g. administrative support, training in business development and management etc.). Most importantly, this approach require the involvement of the private sector, government and local municipalities to work together to ensure active participation of township SMMEs in the economy.

Basic Entrepreneurial Skills Development

Given that townships suffer high levels of unemployment, and as indicated by statistics that majority the unemployed is the youth, which is often forced to venture into starting some form of businesses (necessity driven) as means to survival. As a result, these businesses are without skills and contribute to the increase in number of informal businesses established in these areas. However, Informal businesses remain vital for livelihood in townships and in order to make these enterprises more sustainable and to create additional jobs; skills development is fundamental in the township economy. The Basic Entrepreneurship Skills Development programme (BESD) is a German and South African

government's initiative financed by the South African Department of Higher Education and implemented by the Department of Small Business Development with Seda. This initiative seeks to transfer basic business skills to small business owners. The implementing approach is embedded on coaching which facilitate learning and support to emerging entrepreneurs. Youth from communities are offered basic entrepreneurial skills development, network linkages with the public and private organizations. The BESD increase the sustainability of micro enterprises, improve the prospects of income generation and job creation in townships. The impact of this programme will fully be evident in the townships once its implementation is intensified across the country.

Entrepreneurship in Schools

Entrepreneurship programme or activities in schools, particularly those in townships is very significant for encouraging entrepreneurial mind-set and attitude of learners at the early stage of development. Having entrepreneurship programme entrenched and implemented throughout the entire educational system, focusing on entrepreneurial skills and not necessarily on subjects, from primary school all the way through to tertiary level, and even beyond is vital for the growth of township small businesses. Seda has since introduced the entrepreneurship in schools programme which aim to ensure that learners are equipped with entrepreneurial skills needed to start and grow businesses. This initiative is most appropriate and could be a solution to the ever-growing youth unemployment in particular, graduates and school leavers who find it difficult to find jobs when they finish their studies in township areas. Youth equipped with entrepreneurship skills lead to more creative population starting productive and innovative enterprises in townships. Government is expected to continue with establishing linkages between Universities, Technical and Vocational Education and Training (TVET) colleges and businesses as partners in order to enhance innovation and facilitate business growth. Fundamentally, internships in the area of entrepreneurship are identified as key in order to link entrepreneurial training to enterprise development.

Township Small Business Expos

The township small business Expo serve as an important platform of empowering and developing the booming township economy. The Small Business Expo is devoted to the development of small enterprises in the townships, providing an invaluable platform to market their businesses and interact with prominent business leaders and representatives from a number of corporate companies. It is the ideal platform to stimulate business growth and motivate both current and aspiring entrepreneurs. The direct engagement with small businesses and entrepreneurs exclusively active in townships great brand awareness, loyalty, sales and disseminate information on procurement opportunities.

Conclusion and Recommendations

The contribution of small businesses in South Africa is widely recognised by many including government and the private sector. While entrepreneurship levels are low and high business failure rates is predominant in townships, these businesses have the potential to become power houses and significant players in economic development. Therefore, there is a need for an integrated approach towards small business development support directed to township entrepreneurs and SMMEs implemented by all relevant stakeholders. It is vital to establish value adding strategic and implementing partnerships in order to advance fully enterprise development in townships. A focused, clear vision and coordinated approach is key to channel and leverage on resources for SMME support in townships. There is a no one size fits all approach towards SMME support, however, the commitment from all role players is vital to unlock the potential of township businesses as they are significant in the South African economy.

The Challenges and Opportunities of the Sharing Economy: The Case of a Developing Economy

Léonel Matar,
Université Saint-Joseph, Faculty of Management, Beirut, Lebanon, leonel.matar@usj.edu.lb

Georges Aoun,
Université Saint-Joseph, Faculty of Management, Beirut, Lebanon,
gaoun@usj.edu.lb

Abstract

Globalization, new technology and the standardization of the way of thinking in developed, emerging and developing countries give the sharing economy a huge opportunity all over the world. The economy of sharing is spreading in all domains and activities. Many economic sectors are facing challenges and competition from a new business model and new ideas based on digital platforms and spreading rapidly across all societies. The volume of this economy is increasing yearly and the defenders of the sharing praise the benefits of this phenomenon. The debate is open about the reality and the consequences of an economy evaluated to several billions of dollars and will be able to disrupt the life of millions of persons globally. In our paper, we analyze the sharing today and tomorrow, the benefits and the challenges of this economy. We explore the human implications, the assumption of sharing on the job market and on the nature of work today and in the near future. Our methodology is based on a literature review of the subject and on an analysis, using three conceptual models considered the most appropriate regarding the sharing economy: The Diffusion of Innovation Theory (DOI, Rogers), the Creative destruction (Schumpeter) and the Social exchange theory (Homans and Blau). We conduct a survey on university students in order to identify, analyze and study their motivations concerning the sharing.

Keywords: Sharing Economy, Digital Platform, New Technology, Globalization

1 Introduction

The collaborative economy changes the pattern of production and consumption of goods and services. New technologies through digital platforms disrupt the links between supply and demand. All sectors are concerned through exchange relations based on mutual trust. In addition to presenting this new economic model, our paper seeks to study the motivations of graduate and undergraduate business students concerning the concept of sharing.

Collaborative and / or sharing economy is spreading at a high speed across all northern countries, affecting all industries. This trend is no longer limited to rich and developed countries, but it is also spreading in the countries of the South, of course, following different paths. The new consumer logic, the financial crises, the proliferation of Internet and the weight of social networks open the way to new ideas for the sharing and consumption of all kinds of products and services.

Our paper aims to analyze the functioning and the new trends of this economy, which arouse interests and fears. The over-valuation of what is owned should generate new revenues for individuals bypassing most of the time the traditional exchange system. Collaborative economy is affecting several market sectors. Born among grassroots to be essentially collaborative and sharing, it gradually became a big business. The wave of collaborative economy also affects the Arab countries and Lebanon. In this article, we will study the evolution of this trend in Lebanon.

2 The Sharing Economy Yesterday and Today

2.1 Can we define the sharing economy?

Few literature and researches of collaborative economy are available. The modern foundations go back to 1978 in the writings of Marcus Felson and Joe L. Spaeth who wanted to bring answers, solutions and alternatives to the stakes of unrestrained consumption with consequences on economic, financial, social and environmental levels.The definitions of collaborative economy are varied and multifaceted, but they all come together. An economic and consumption model essentially based on the exchange, sharing, rental of goods and services[1] that favors the use rather than the ownership (Botsman, 2014). Sharing is considered as a phenomenon that connects consumers with each other in order to consume. Indeed, the new technologies through the digital platforms have come to increase the links and the contact of the people who wish to exchange all kinds of products and services. There are several words that designate this new form of consumption: "economy of sharing", "peer-to-peer economy", "collaborative consumption", "collaborative economy". The purpose of all these denominations often follows the same logic, in this case exchange and sharing, but there are differences concerning types, modalities, vocations and exchange systems.

The main characteristics of the collaborative economy are:
1- Merchant or non-market transactions between suppliers and users
2- Suppliers are individuals, professionals and non-professionals
3- The link between transactions is a digital device (platform)

2.2 The new forms of consumption

2.2.1 Collaborative economy

An economy built on the networking of people and communities with connected centralized institutions with the aim of: Transforming the way we can produce (linking inventors with companies, ex: Quirky),

Consume (optimization of the use of products through efficient models of redistribution and shared access ex: Zipcar, Airbnb, Lyft),

Subscribe to financial services (direct relationship between individuals or companies for non-intermediated loans, ex: Kickstarter, Pave),

Learning (connecting teachers and students throughout the world, democratization of teaching ex: Coursera, Skillshare)

2.2.2 Collaborative Consumption

An economic model based on the sharing, exchange, trade or rental of products and services favoring the usage rather than the ownership. This model reinvents not only what we consume, but also the way we consume. We can cite three models: the collaborative lifestyle with the exchange of the use of products and services (Zipcar, Airbnb, Lyft), the redistribution of unused or underused products (ebay) and a system of products and services, rental of clothes (Run the Runway).

2.2.3 The economy of sharing

An economic model based on the sharing of underutilized assets against monetary and non-monetary benefits. It is largely focused between individuals (Airbnb, couchsurfing, lyft, Getaround,…).

2.2.4 Peer-to-Peer Economy

The peer-to-peer economy facilitates the sharing and direct exchange of products, it is a service based on peer trust. (Airbnb, couchsurfing, lyft, UberX, Kitchsurfing, Etsy). Most of the digital platforms of the collaborative economy have emerged in the United States, the sharing economy has now spread all over the world, it has become a global phenomenon, thanks to the expansion of new technologies and platforms to other countries, as well as new ideas for consumption. Platforms are proliferating in many countries, where cities are increasingly "sharing" centers of practice. Paris, for example, has become the center of the sharing economy in Europe. Colombia, the most Anglo-Saxon country in Latin America, has become a hub for Latin America. In Asia, Seoul, which is a smart city, is considered as a very important sharing center. Last year, the Ecuadorian government launched Buen Conocer, an initiative to reinvent the economic system based on the principles of open sharing networks, open production, and an economy of common goods. Even the Arab world has started to share economies through a multiple platforms and actions that bring citizens closer to each other. According to a global online survey conducted by Nielsen, 68% of consumers are willing to share or rent their personal belongings in exchange communities or for monetary income.

3 A New Economic Model or a New Economic Theory

3.1 A new exchange model

Power is moving from centralized institutions and organizations to individual and community networks. The distribution of products and services is no longer the sole monopoly of companies, the power of distribution has radically changed. From the status of the passive consumer of the 20th century, today's consumer has become at the same time creator, collaborator, financier, producer, supplier and inventor. Collaborative economy gives a new dimension to the uses of assets, it allows valorizing a sleeping wealth and the resources underused, it creates a link between what one possesses and what the others want to use. Efficiency and trust are the basis of this economy.

Collaborative economy makes our society more horizontal and less hierarchical; peer-to-peer relationships promotes individual and collective emancipation; the transaction may seem less formal, even if sharing and information are the basis of exchange. The institutionalization of exchanges done through the intermediary of the digital platform (the website) which serves as a store or a retailer and which ensures the link for the transaction. Its virtual concept characterizes the transaction because the two parties do not know each other and then it is achieved either by the connection between the supplier and the applicant or by a meeting to exchange the good or the product, or by sending the coordinates to conclude the transaction.

The digital platforms considered the driving force of the collaborative economy must face today a supply that is becoming more professional and more demanding, their roles are:

- define the relationship between suppliers and applicants

- linking effective triangular (platform-supplier and applicant)

3.2 Old theories, New Model

3.2.1 The Diffusion of Innovation Theory: a Customer and User Analysis

The sharing economy may be analyzed in the context of the Diffusion of Innovation Theory (Rogers, 1962), because the product or the service offered to consumer, client or user is done in a new manner. Even if the finality of the consumption and the usage of the product or the service is, the same. The concept of innovation is defined as any object, idea, technology, or practice that is new. The diffusion of innovation accomplished through communication to explain how, over time, an idea or a product gains

momentum and spreads to a specific population or social system. The Diffusion of Innovation (DOI) Theory is to be applied in the case of the users or clients more than regarding offerors of the product or the service. According to DOI Theory, we can distinguish five established adopted categories: innovators, early adopters, early majority, late majority and laggards.

DOI analyses five factors that enhance and influence the adoption of innovation or new idea.

Relative Advantage - The innovation should be considered as better than the idea, service, or product it replaces.

Compatibility - The innovation must be adequate and compatible with values and demands and of the future adopters.

Complexity - The innovation should be easy to use and understandable.

Triability – The adopter likes to be sure that the new idea is already tried and experienced before adopting it.

Observability - The adopter wants serious results from the innovation in order to accept it.

The major firms of the sharing economy have gone through all the stages. Airbnb, Uber, Lyft, Blablacar, etc… experienced all these steps differently. The success (or the failure) can be analyzed through this theory because the sharing concept was considered when launched as an innovation using new channels of distribution, buying and selling products, programs and services. These offers already existed but the way of promoting and distributing is very new. Digital platforms are the fruit of technology. Rogers considers technology and innovation as synonyms, *"A technology is a design for instrumental action that reduces the uncertainty in the cause-effect relationships involved in achieving a desired outcome"*. Because all the firms of the sharing economy are essentially based on the technology and cannot work or function without a digital platform, the product or the service offered needs a high value of technology and reliability in order to be considered as new innovation. As such, the product or service is not a real innovation; the context of its diffusion gives a new futuristic aspect.

3.2.2 The Creative Destruction: Corporate and Job Challenges

Capitalism must reinvent itself all the time; otherwise, it could never ensure sustainability. The sharing economy disrupts many sectors and jeopardizes the job of millions of workers all over the world. A growing number of workers in the developing, developed and emerging economies begins to worry about the future (Sundararajan, 2016). Because we are in the globalization era, the fast spreading of this concept affects simultaneously companies and workers in developed, developing and emerging countries. The destruction of jobs is accompanying the evolution of this economy. The Creative destruction (Schumpeter, 1942) can be totally applied today to the sharing economy. The innovation of products, services and process will automatically endanger and eliminate many sectors. The collaborative economy is accused of creating precarious jobs, without social protection and escaping labor market regulations in the countries where it operates. Indeed, we may wonder whether it is really the vocation of this new economic model to create jobs or only to maximize profitability by inventing a new form of work. These criticisms and misunderstandings are merely a reflection of the change that globalization and new technologies bring to the conception of work. The labor market changes, today we are seeing a transformation of the economic system and capitalism, which primarily affects workers and employees. It is legal and legitimate to fear a new vision of work that threatens the existing order.

3.3.3 The Social Exchange Theory: Trust and Sharing

The trust is a key element behind exchange and sharing. We witness a trust on two levels: the digital platform and the providers of the product or services (Airbnb, Uber, Zipcar, ….). Our open world, globalization and technology facilitate the interaction and the trust between people and strangers; we are bypassing big corporations and traditional institutions to realize exchange. Trust is shifting away from governments and big institutions into the hands of all of the population, technology and the work wide web are enabling trust between people (Botsman). The sharing economy is opening a new trust era, the main challenge today is more about trust than technology, and the individual social exchange imposes to all of us to trust each other because our personal reputation can be positively or negatively affected. The shift in trust from institutions to individuals represents the new way of exchanging and doing business and will transform many economic sectors in the near future all over the world.

4 Survey

A survey conducted on 117 university students gave us several elements about the awareness and the perception of the sharing economy.

The main answers were as follows:

- More than 7 out of 10 of the respondents know what does the sharing economy means. This answer reveals that the awareness is high but in the same time, we can consider it as not sufficient because the majority of the university students are supposed to know this economy. The reason is the non-generalization of the phenomenon in a developing or emerging economy such as Lebanon.

- The answers concerning the knowledge of four name of branded sharing economy platforms tell us that Uber is the most well-known, the vast majority of respondents already heard about, followed respectively by Airbnb (53%), Blablacar (33%) and Couchsurfing (4%). Many reasons lay behind these answers. If 97% are aware of Uber, it is because of the presence in the media of this company, the availability of these services in most big cities all over the world and sometimes because of the controversy of these platforms. Airbnb comes in second place because it is less mediatized compared to Uber and with less worldwide problems. Blablacar, which is less present in the world than the two others platforms. As a European service and because the habit of carpooling is not so developed media, Blablacar even if it is the leader in its field, remains less well known globally than Uber and Airbnb. Couchsurfing that is the real sharing is ignored by respondents because no large organizational structure manage their operations and because the aim of the service is strictly free of charges so less incentive for offers.

- The potential of the sharing is promising, two third of the respondents plan to use these services in the future. It means that the trend is very strong especially among young persons because the majority accepts this concept.

- Trust is crucial when it comes to the sharing economy. Three out of 4 of the respondents consider trust as the main concern for this service followed. Trust remains an important criterion because the core of this economy is exchange with strangers.

- Three out of 4 estimate that these services have a future. The high rate of answers considering the sharing economy as promising reveal that people really believe in this new economic and business.

5 Conclusion

The sharing of physical objects, services and spaces will increase in the next few years. Sharing becomes today an important part of our life. This concept is rapidly spreading all over the world. People in developed, emerging and developing economies are exploring and working on new idea. In order to use goods, services and spaces more collaboratively. The economy of sharing is accompanied by the birth of a new language and vocabulary such as access, social values, exchanges, user, borrowers, lenders and contributors. This new economy disrupts the life of millions of persons across the world but, at the same time, it opens new horizons and creates opportunities for all of us. The future of the collaborative economy in emerging countries is not different from that of others markets. Four variables might influence the use of platforms by consumers: use of technology, trusting strangers, saving the service fees and looking for environment protection; these variables could be related to the age and the gender of the users. The result of this research will highlight the diffusion of innovation for services based on the sharing economy in third world country and inform the actual service providers in sectors affected by the sharing economy about the risks they will face in the near future. Entrepreneurs that might exploit this new phenomenon will benefit from this new type of business while those working in the old system will be affected and penalized if they will not adapt to this new and challenging reality. The use of platforms may seem different at times, but goals tend to meet. It is natural that the slow adoption of this type of exchange, the lack of confidence and the desire for possession, still limit the adoption of this new economy by emerging countries. Millennials born with the new technologies will welcome this type of exchange. Indeed, we note through the part in which we speak about the birth, the evolution, the challenges and the promises of the economy of sharing, a growing enthusiasm of the population.

Abstract

The involvements of women in business particularly in small and medium enterprises (SMEs) have received global attention including Malaysia. Despite the important role of women entrepreneurs to the economic development, participation of Malaysian women in SMEs is unequivocally rated low. In order to bridge the gap there is need for radical application of creativity in their business operations. Hence, the aim of this paper is to review the need for innovation management practice among women entrepreneurs of SMEs in Malaysia. Through review of relevant literature, the concept of innovation management in business has been explicitly discussed as well as the underpinning theories. Appraisal of the innovation management was explored through data mining in order to build a sustainable framework with a view to accelerating performance in women-owned businesses. This paper is expected to serve as a template for existing and upcoming women SMEs in Malaysia towards better entrepreneurial innovation and performance which by extension would boost GDP of the Malaysian economy.

Keywords: Innovation management, women entrepreneur, SMEs, Malaysia

Introduction

Small and medium enterprises (SMEs) have been variously acknowledged as a major source of global economic growth and employment of the entire nation. Hence, SMEs need to be managed in more effective in various aspects of their business management .Considering the need for innovation management practice of the SMEs, it is a known fact that global economic woes are expected incidents of business life which often manifest in the form of economic recession. Such is expected to pose serious threat to the survival of SMEs due to their scale, hence, in such turbulent times; effective management strategies in form of innovations will provide relief against devastating consequences of such economic downturn. Apart from this, the performance of any SMEs can be generally measured by the quantum of efforts placed on research and development (R & D) in the area of innovation management practice. Furthermore, literature has shown that the success of SMEs requires an efficient management capability of selling its goods and services and in this regard SMEs will depend on high level of effective and practicable innovations that are expected to lead to performance improvement and strength recession, recovery and peak periods of business cycles. Additionally, for SMEs to respond fast to product demand differentiations resulting from market demands in the present global industrial world there is need for a potent innovation management practice (Apak & Atay, 2014; Al-Ansari, *et. al.,* 2014; Kalay & Lynn, 2016).

More importantly, in this recent global change, innovation management is becoming one of the key drivers for change and competitive advantage within industry. Accordingly, SMEs as business concerns are required to respond rapidly to these emerging changes. This will enable it to fulfill customers' expectation and demands rapidly. Going by the nature of high involvement of women in the SMEs, there is the need to adequately explore and employ innovation management practice in order to meet the numerous challenges and expectations facing efficient delivery.

In Malaysia, the involvement of women entrepreneurs in SMEs still remained lower over the period of years. As at 2015 the percentage distribution of SMEs by ownership status between men and women showed that men-owned SMEs is in the region of 80.3% while the women-owned SMEs stood at 19.7% (Department of Statistics, Malaysia & SME Corp., Malaysia, 2015). From the same source, it was revealed that measuring the use of ICT among women SMEs only 27% have the knowledge and usage ICT which is expected to form the backbone of innovation in the area of knowledge management. Also, the statistics revealed that out of the various sectors of enterprises of SMEs women were seen flourishing in services with 91.7%; manufacturing – 7% and less than 1% in other prominent sectors like agriculture, construction, mining and quarrying among others. This is an indication that women entrepreneurs still need more to tap from innovation management practice so as to gain the capacity of competing with their male counterparts. Nevertheless, it is an understatement that women business owners contribute to the overall employment and are productive in generating good revenue (Nel, *et. al*., 2010) but it is the efficient application of the innovation management practice that will explore and exploit these potentials.As a result, the Malaysian Government has been concerned with creating and developing quality, resilient, and successful entrepreneurships which are competitive in all the potential growth sectors of the economy, and to cultivate an enterprising culture among Malaysian women.Therefore, the purpose of the paper is to identify the main drivers of innovation management practice and propose a framework that will be suitable for the improvement and better innovation practices and performance of women SMEs in Malaysia.

Women Entrepreneurs

Women entrepreneurs have been acknowledged to play critical roles for bringing their ideas and capabilities towards successful achievement of the SMEs development (Alam, *et. al*., 2012, Rani &Hashim, 2017). There are diverse definitions of women entrepreneur which depend on the context of its role. In the Malaysian context, women in business can be classified in the census under the employment classification of employer, self-employed and own-account workers (Jamilah, 1992). Based on United Nations Economic and Social Commission for Asia and the Pacific (UNESCAP) discussion paper, women in business generally fall into micro, small and medium enterprises (MSMEs), either as managers or as owners from an employer's angle (Teoh& Chong, 2008).

Some of the characteristics of women entrepreneurship as enunciated by Teoh and Chong (2008) include: women-owned businesses are no more likely to fail than man-owned; differences in initial capital and goals explain the power performance in growth and survival of women-owned businesses; women entrepreneur discussion is considered important since it is part of ongoing effort to alleviate poverty in developing countries in relation to the sustainable development goals; and the response from women entrepreneur is still considered relatively low because of low level of education, lack of capital, cultural and religious constraints (Teoh& Chong, 2008).

The performance of women entrepreneurs in their businesses has become an important area of recent policy and academic debate. Comparatively, little rigorous and in-depth research, however, has been undertaken on the issues of gender and business performance, especially in Malaysia (Alam, *et. al*, 2012). Performance is the act of doing something successfully using knowledge as distinguished from merely possessing it. However, performance seems to be conceptualized, operationalized and measured in

different ways (Srinivasan, *et. al*.2002), thus making cross-comparison difficult. Among the most frequently used operationalization are survival, growth in employees and profitability. In fact, the potential benefits inherent in women entrepreneurial outfit, women entrepreneur still face systematic barriers in the conduct of business in some part of the world (Alam, et. al, 2012; Roomi& Parrott, 2008). Also women-owned businesses are found to be more likely to fail (Bekele & Worku, 2008). Furthermore, researchers have been reporting that women entrepreneurs growth rate is comparatively low than that of their male peers (Enhai, 2011). In addition, women are likely to be pushed or pulled in the realm of entrepreneurship whereas there is a need to change the push into the pull factors (Zlatkov, 2015). Besides, there is a need to introduce and equip women entrepreneurs with women entrepreneurial orientation and required competitiveness (Mahmood&Hanafi, 2013). All these essentially call for workable innovation capabilities in order to ease off the aforementioned barriers. In fact the phenomenon of women entrepreneurship is still standing silently in the queue waiting for its turn to be acknowledged fully (Teoh & Chong, 2008, Rani & Hashim, 2017).As a result of the common constraints associated with women entrepreneurship globally and in Malaysia especially, there have been several calls for innovation management practice (IMP) as a veritable concept to enable them tap the prospects towards better performance of women SMEs. Literature has identified some of the drivers of IMP to include knowledge management, usage of ICT, capital, education, training and counseling, networks, government support, managerial skills and social security and freedom to mention a few. All these issues had constituted the main thrust of this proposed research.

Theory of Innovation Management in Women-Owned Enterprises

The new theory of innovation management that adequately explains and supports substantial value creation from radical innovation should be subjected to three fundamental criteria and tests; (1) it should comprehensively explain the history of radical and incremental innovations; (ii) successfully applied and described in many case studies over decades by real industrial businesses; and (iii) describe how value creation is driven by both tangible capital and intangible capital based on the new capabilities of people and organizations, new business models and new industry structures that form dominant design (Miller (2015) any.However, in this paper two classical theories are considered appropriate; the sociological theories and feminist concept in Business.

Theory of Social Structures on Women's Entrepreneurship

Sociological theories argue that social structures (workplace, family, and organized social life) affect women's access to entrepreneurial opportunities and may influence performance (Aldrich, 1989). Occupational segregation, underrepresentation in upper level management positions, and expectations about family roles may restrict women to certain industrial sectors, as well as affect motivations and goals for their business ventures (Aldrich, 1989). The extent to which women entrepreneurs face structural barriers in these areas will arguably have an impact on the performance of their ventures.

The degree to which these structural dimensions affect women entrepreneurs depends greatly on the country context. In particular, the perceived acceptability of women's participation in entrepreneurship varies from country to country, relative to the expectations and cultural norms for women in a given society. This indeed has been attributed as one of the major barriers to women SME performance in Malaysia (Tambunan, 2009; Ming-Yen & Siong-Choy, 2007). Research also reveals that women starting new ventures are frequently hindered by the lack of business information, advice, and access to networks and business support systems (Allen & Truman, 1993). Essentially, these differences in social structure across developed and developing countries suggest variation in individual factors affecting performance of women-owned businesses (Lerner, Brush & Hisrich, 1997). In the United States an early study conducted by Kalleberg and Leicht (1991) found that women's businesses were no more likely to fail and were just as successful as men's, which was contrary to conventional wisdom regarding women's

inferiority in entrepreneurship. It is however good to note that as a result research, global economic competition and government support and dynamism, women from negatively affected countries are increasingly accepted as equal in their entrepreneurial endeavors, making it easier for their business to grow and succeed. In order to bridge the gap thereby promoting performance acceleration, the need for innovation management practice (Lerner, Brush & Hisrich, 1997).

Feminist Concept and Analysis in Business

The feminist theory aims to bring about social change as women are seen to be very important in the structuring of society, even though women historically have been identified as disadvantaged, a situation that needs to be abolished (Calás & Smircich, 2009; Mbwilo, 2015). By producing knowledge, social change can occur, including entrepreneurship change. Feminist theory helps us to look at entrepreneurship as a social change through a feminist analytical lens and see that it brings a significant impact in economic activities. Calas *et al*. (2009) argue that women have emerged from a male- dictated structuring of society, which had to occur, and among the needed changes are the removing of the barriers to entry to public life for women and also appreciating different practices as positive inputs to society. They suggest that a female centered structure of the society is the only means to oppose patriarchal structuring. Looking through a feminist theoretical lens will enable entrepreneurship dynamics to be further noticed and seen.

Feminist studies have been conducted by numerous scholars worldwide, in different disciplines. As a strand of the modern feminist approach, the women in development (WID) approach was introduced, so as to highlight women's contribution to income generating activities (Rathgeber, 1990). Although,it was later found that only the symptoms were being dealt with instead of the core of the problem. According to Cornwall et al. (2007) "women are the poorest of poor" in Africa, although most of the work is done by women, including agricultural work, household work and all family responsibility and reproductive work. Women are being seen as just a mere picture which is there to portray a story; they are being viewed as hopeless, inactive and excluded free from development and their unsung qualities and contributions to development needs to be observed (Cornwall, 2001).Stanley (1990) argues that the peasant character has not been given enough space and gratitude, and this leads to ignoring women. "The failure to acknowledge women's roles, activities and rituals has resulted in a definite informational bias"(Stanley & Wise, 1990). Moreover it is argued that " At the root, feminist inquiry is built on the common cause of highlighting women's voices in the name of challenging patriarchy and eradicating women's oppression in the home and beyond"(Daly and Stubbs, 2007). In the late 1970s the gender concept grew up and become very important. Researchers tried to see how to conceptualize the social constructions of masculinity and femininity by applying biological perspectives to social relations between women and men (Mbilinyi, 1992).

According to Cala *et al.* (2009), analysts' attention was drawn to gender relations not because of the sex of participants as individual actors, but due to the material production of their social life and cultural production. This made gendering entrepreneurship through premises restructuring highly visible in mainstream entrepreneurship. Mbughuni (1994) states that significant attention has to be paid to gender in order to see it as a locus of discrimination, a factor like age, geographical location (rural or urban), ethnic group, and global location which distinguishes the circumstances and barriers facing different women. According to Walker (1995) gender relations in indigenous societies in Africa are characterized by misappropriation of women's hard work by men. Women being part of a male dominated society makes it very difficult for them to freely grow and operate their businesses; this makes women vulnerable and weak and as a result hinders them from making independent decisions.

Principles and Importance of Innovation Management

Innovation has long been argued to be the engine of growth regardless of the condition of the larger economy. Innovation indeed has been a topic for discussion and debate for hundreds of years (Miller, 2015).

Drucker (2015) defines innovation as "the act that endows resources with a new capacity to create wealth". He (2015) refers sources of innovation as "windows" of opportunity because each window is a distinct opportunity for innovation, but one can see certain aspects of other opportunities for innovation by looking through a single window. Drucker (2015) identified four windows within the firm – the unexpected event, incongruities, process need, changes in market structure and three windows outside the firm –demographies, changes in perception, and new knowledge. He suggested one way to recognize opportunities for innovation as applying the ones that are most relevant for use at a point in time and that each opportunity is capable of being relevant at any given time.

Considering the relevance of innovation management in any business Miller (2015) described that radical innovation is required for sustained, adequate rates of economic growth driven by improvements in productivity, quality and cost in industries such as health care, education, construction and energy. Hence, corporation must be able to adapt and evolve if only the wish to survive (Trott, 2008). Also, This is attributed to the fact why today the idea of innovation is widely accepted. It has become part of our culture – so much that it verges on becoming a cliché. But even though the term is already embedded in our language, to what extent do we fully understand the concept? Also, to what extent is this understanding shared. For instance, a scientist's view of innovation may be very different from that of an accountant or an entrepreneur even in the same organization. All these are some of the issues that prompted the choice of this research.

Drucker (2015) asserted that systematic innovation must be integral to the process of management in all organizations. In systematic innovation, there is need to adopt specific practices regarding organization, staffing and rewards for innovative activity. The new should not be forced to carry the overhead burden that is carried by the mature until the new matures and become capable of carrying these changes. This often requires physical separation of the new from the old within the organization structure. Furthermore, resource allocation should be done in accordance with the resources of people and money that an innovative project can effectively use at a given point in time. On the other hand, if a project is approaching breakthrough, the maximum among of resources it can effectively absorb should be applied. Essentially, innovations require a clear market focus as well.In applying the concept of innovation in entrepreneurial skills all the aforementioned principles must be carefully studied and followed in order to achieve best performance and by extension high profit. Against all, this change comes the increased need for entrepreneurs to be vigilant because unless we stay ahead of change we may become victims of change (Trott, 2008). The earlier changes are discerned, the earlier the opportunities they create can be converted into innovations and converting opportunities into successful innovations, the better but requires good management practices.Expatiating on entrepreneurial management

Innovation Management Drivers among Women SMES in Malaysia

In Malaysia, the importance of entrepreneurial ventures in the economic development of the nation is indisputable. Chee (1990) reports that entrepreneurial ventures tend to employ more workers per unit of capital, help increase total savings in the economy, have a favorable impact on regional development, serve as training grounds for developing the skills of industrial workers and entrepreneurs, and play an important complementary role to large firms in the economy. Tan (1990) adds that they help to sustain economic growth and stabilize the economy in periods of recession. They are also very significant contributors to the economic strength of the nation considering the

direct output of goods and services as well as the role in supplying requisite inputs to other enterprises and government undertakings. There are number of factors that become driver for innovation management for women entrepreneurs. The four divers (Figure 1) include; information technology, research and development collaboration; human capital development; and product and market strategy.

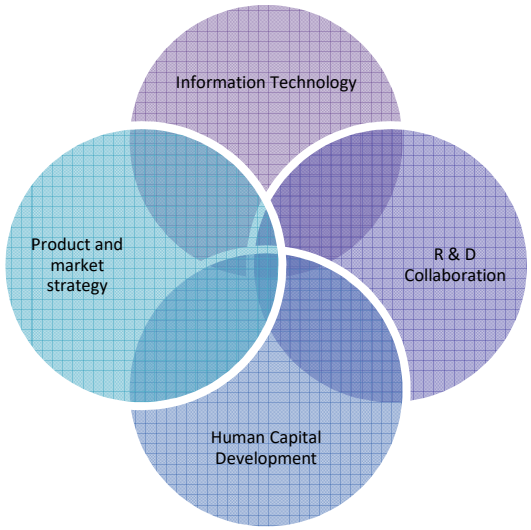

Figure 1: Four driver for innovation management

Information Technology

There is a growing understanding of how businesses should operate using IT to achieve optimal effectiveness. Implementation of IT projects, especially large IT projects, is synonymous with management of changes in an organization, be it for altering the work culture or gaining competitive advantage. When formulating effective change management strategies to support the introduction of IT, it may be useful to integrate and use concepts and practices drawn from disciplines such as traditional project management, organizational/product innovation, and change management theory and practices (Kuruppuarachchi, *et. al.* 2002). The complex interaction between the use of information technology (IT) and its changing organizational setting requires organizations to address how investments in IT/information systems should be evaluated (Patel & Irani, 1999). Since IT has a strategic significance in an information-rich economy in reducing cost, upgrading quality, improving customer service, and enhancing integration with vendors to increase the economic power of the firm(Ndubisi & Jantan, 2003; Jantan & Kannan, 1997), the Malaysian Government is bent on motivating women entrepreneurs in particular and all Malaysians in general to adopt and use IT.

In Malaysia, the increased use of information technology is the result of several factors. The mass production of computer parts has pushed the price of these products down to a very affordable level. This decline in cost has the effect of allowing even smaller firms and homes to utilize new technologies for their daily needs. Moreover, the abolition of a 10 percent sales tax on computers, software and accessories in Malaysia has helped consumers not only to possess a computer but also

increase the marketing of computers in the nation (Ndubisi & Kahraman, 2005). Since ICTs possess the unique capability to improve processes not just by transferring information efficiently but also by making it available in time to users, the Malaysian government has increasingly strived to make technology more and more affordable to entrepreneurs, especially women entrepreneurs, whose contributions to the growth of the Malaysian economy have consistently been publicly acknowledged by the government.

The relationship between technological skill and enterprise development, particularly in relation to entrepreneurship, is crucial. Peacock (1997) reports that the share of women business owners that have established a homepage for their business has tripled since last year: 23 percent now have a homepage, compared to 16 percent of male business owners; 47 percent of women business owners currently subscribe to an online service, compared to 41 percent of male business owners; 51 percent of women business owners frequently use the internet to communicate or send e-mail, compared to 40 percent of male business owners; 22 percent of women report frequent usage of the internet to conduct research, compared to 14 percent of male business owners; and 9 percent of women business owners compared to 3 percent of male business owners use the internet to review business opportunities or make bids on contracts. The research of Ndubisi&Kahraman, (2005) was aimed to investigate the extent and pattern of information and communication technology (ICT) usage by women entrepreneurs in Malaysia, as well as the impact of personal traits on usage show that slightly above 50 percent of the respondents are using seven out of the eight varieties of systems presented. Notwithstanding the effort made sofar to make IT accessible to the entrepreneurs, research has established the fact that IT knowledge among women entrepreneurs in Malaysia is still comparatively very low

Research and Development (R&D) Collaboration

Innovation is essential for an organization's growth to sustain competitive positioning and to strengthen it (Lin & Lin, 2016). At the same time, businesses are forced to find partners to benefit from innovation given rapidly changing global market conditions and increased competition (Horibe, 2003). Thus, the openness in the innovation process is becoming more prominent recently as evidenced in various academic literature (Patra& Krishna, 2015). Intensive competition in domestic markets gives a reason for firms to expand their technology into new markets overseas (Lee &Jeong, 2010). However, the uncertainty in the global marketplace has caused a fundamental change in firms' innovation strategies (Lee &Jeong, 2010; Kang, 2012). To mitigate this confusion and secure global markets, collaborative innovation has become commonplace in organizations, and needs to be studied (Lee &Jeong, 2010).

Globalization could be done simply if firms collaborated with buyers and/or distributors regardless of their size (Horibe, 2003) Furthermore, different modes of network relationships have different effects on their performance (Lin & Lin, 2016). International collaboration raises important questions regarding the relationship between R&D and innovation (Ebersberger&Herstad, 2013). Among the challenges hindering the Women SMEs from Malaysia to compete in the international markets are the low level of technological capabilities, lack of skilled human capital, and low level of research and development (R&D) (Muhammad Khalique *et al*. 2011).

Business enterprises that derive their ongoing competitiveness from innovation, both by cultivating in-house capabilities and through collaboration with experts in universities and research institutions locally and internationally are fundamental to innovation system performance and the productivity of an economy. Malaysia already compares favorably in some respects, as one of the few developing economies where the business enterprise sector is the main performer and funder of R&D. However, there is a continued need to strengthen the innovation capabilities of Malaysian businesses, especially the smaller firms, which are less prone to undertaking R&D or innovation. The establishment of the proposed

national Research Management Agency (RMA) with responsibility for the implementation and evaluation of competitive R&D grant schemes would also support the simplification and streamlining of the governance framework (Asada, Nixon &Keon, 2017). Malaysian women entrepreneurs can boost their business horizon locally and internationally through R & D collaboration in modern marketing and Technological advancement.

Human Capital Development

The human capital is one of the most important factors supporting the survival of microenterprises. The success of the enterprise depends on the relevant preparation, knowledge and education of the owner as well as the employees (Ptak-Chmielewska, 2017).Arribas& Vila (2007) introduced also the definition of accumulated human capital, which is used for summing up human capital of the owners (more than one person). They proved that enterprises owning such accumulated human capital live longer and have higher chances for success, which is also determined by better financial condition of the enterprise. Initial capital is distributed on more people so is better secured form individual failures of one of the owners.

Becker (1993) defined human capital as: studies concerning actions influencing future income material and non-material by increase of human resources, those actions are defined as investment in human capital. Those actions are: education, professional training, medical care, seeking information about prices and income. Those actions are dedicated to increasing the abilities, knowledge, and health in the goal of increasing income. Human capital is a part of the enterprise but is connected with a worker and is worker's property. Investment in human capital increases the potential of return ratio. The most important in investment in human capital is education and professional training. People with higher education level have more possibilities and chances on thelabor market. It is important to compare the costs and income from education. It is visible in case of women education. Education and training increases the worker's abilities and efficiency also in managerial abilities (Becker, 1993).

In a knowledge-based economy intellectual capital appears as the most important and critical resources for organization to thrive in a competitive environment. According to Ding & Li (2010), in a knowledge-based economy the intellectual capital is gradually replacing the physical assets in modern enterprises. It is indispensable for modern and high tech enterprises to pay full concentration not only in products innovation, marketing channels, market and services, but also they need to improve the research and development ability on market and product, and pay attention to the gardening and management of the enterprise intellectual capital (Leitner, 2011). Shaari*et al.*, (2010) and Bataineh&Zoabi (2011) argued that intellectual capital is a very important factor for the success of organizations to take competitive advantage. Human capital development is one of the surviving drivers of innovation management for women entrepreneurs in Malaysia.

Product-Marketing strategy

The growth of any enterprise is considered dependent on the product marketing strategy (Brindley, 2005). Cliff (1998) submits that it is usually an uphill task for women to adapt to changes in the market environment than men and he treated this as one of the potent barriers limiting the growth of women entrepreneurs. This also cut across new product development. For women-in-business in Malaysia to strive and ensuring steady growth, there is need to treat product marketing strategy as an innovation management tool.

Government Role in Women Entrepreneur

It is no gainsaying that government of Malaysia like other developed economies is making appreciable effort in promoting and enhancing vibrant women entrepreneurial ventures through different ways which

include provision of enabling environment, loan facilities, subsidies, training and motivation among others (Tambunan, 2009; Oly Ndubisi, & Kahraman 2005). Nevertheless, studies abound demanding more from government in order to raise the standard of women entrepreneur higher for it to compete with its counterparts in Europe, United Kingdom and U.S.A among others.

Oly Ndubisi, & Kahraman (2005) emphasized on the importance of information technology and communication (ICT) to women entrepreneurs but also pointed out the low level of their knowledge and application of ICT in their day-to-day business activities. They however, as a matter of urgency called on the Malaysia government to roll out programmed that would not only make computer accessible but as well organize training grounds for them. Ismail, et.al. (2012) corroborated this point but included it as one of motivational factors on women entrepreneurship venturing in Malaysia which government could be relevant. Also included as ways by which government could promote women entrepreneur are adequate provision of affordable credit facilities, research and development through training and adequate knowledge management (Ismail, et.al.2012; Tambunan, 2009).

Furthermore, Sarker & Palit (2014) in a proposed framework on the factors contributing to success of women entrepreneur emphasized that government could be relevant in the areas of access to technology, training and motivation, social security and freedom; financial assistance and easy regulations, family support and quality assurance. Supporting this proposition Teoh and Chong (2014) lamented absence of enabling laws especially those ones related to child care subsidies and temporary assistance for needy family (TANF) programmed to support women entrepreneurs in Malaysia. The study identified this as a critical issue for women entrepreneurs particularly single mothers with low income and who run micro-business, as they are seen to be the ones in need of most help and support. The study cited example of Singapore where self-employed parents have the privilege and are entitled to six days per year of child care leave and/or infant care leave until the year the child turns seven years old. Malaysian government has the responsibility of enacting such enabling laws for the purpose of encouraging women in business.

In conclusion, it is timely that the society changes its mindset not only to reduce the gender gaps but also to acknowledge the role of women entrepreneurs (Sandberg, 2013). Sandberg (2013) believes that equal opportunity is not equal unless everyone receives the encouragement that makes seizing those opportunities possible. Hence, support and encouragement from stakeholders especially government are requires because women entrepreneurs encounter many barriers than men to become successful. The awareness should be enhanced to empower women entrepreneurs in the world economy and to be recognized in the coming future (Bruch, 2012).

Proposed Framework for Innovation Management Practice among Malaysian Women Entrepreneurs

Based on the literature this paper has identified four important drivers of innovation management (Information technology, research and development collaboration, human capital development, and product marketing strategy). As they relate to women SMEs in Malaysia, it is worth-noting that most studies have not incorporated the role of government in the implementation of innovation management practice which is treated as an academic research gap. Hence, it is the intention of this study to add that there is need to consider the mediating role of the Malaysian government in the application of innovation in women SMEs. This has brought about the proposition of the innovation management framework as shown in **Figure 2**. The empirical aspect of the framework is to be treated in the future research. But the main thrust of the framework would be to determine the mediating role of the Malaysian government in the relationship between the innovation management drivers and women SMEs Performance.

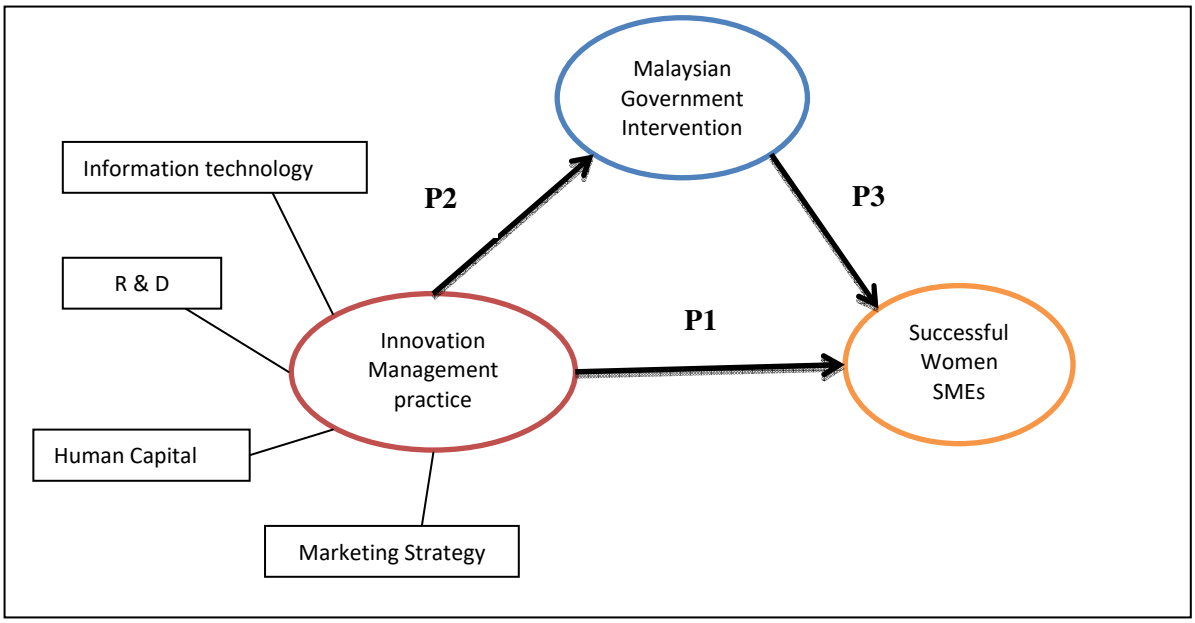

Figure 2: Proposed research assessment framework for innovation management among Malaysian Women SMEs

Marketing strategy

The increasing growth of its business by marketing and selling products of an organization taking place in new markets is closely related to the marketing strategy the organization chooses. These new markets may appear to be market segments or new geographical areas as well (Ansoff, 1957).Finding new potential market for its existing product would always be the main objective for any organization that takes the option of market development. The strategies would include identifying users in different markets with similar needs to the existing customers and also determining new customers who would use the product available in a different way. Alpha, 1957 stated that finding new geographical markets is one method of achieving this.

Information Technology

Nguyen, 2005 mentioned that there are several studies related to women entrepreneurs as one element that would make why women stay away from the corporate sector with the intention to become entrepreneurs, (Brown, 1997; Chandralekha et al, 1995; Gundry et al,2002;. Helmi, 1997; Hamilton, 1993; Stoner et al, 1990; Winn, 2005), with the adoption of information technology among women entrepreneurs' (Ndubisi and Kahraman, 2006). Meanwhile according to Schultz, 1959; Becker, 1964; Mincer, 1974, as to Human Capital; Human capital theory maintains that knowledge provides individuals with the increase in their cognitive abilities which leads to more productive and efficient potential activities.

Human capital

In addition, the businesses owners' business planning and managerial capability can only be implemented if women entrepreneurs possess human resources, capable and equipped with skills to conduct production

duties. Thus, recruiting suitable staff, providing sufficient motivation and training, building good relations with the stakeholders and monitoring workers' performance are important criteria in successful entrepreneurs.

Research and Development

A low level of education and exposure could prevent motivated entrepreneurial movement in their surroundings. Certain substructure components give the impression to make considerable impact on the entrepreneurial environment. These components include the existence of universities and research and development programs, a well-educated and technically skilled labor force and modern transport and communication facilities that provide easy access to suppliers and customers (Bruno & Tyebjee, 1982; Gartner, 1985).

Conclusion

In line with the objective of this study, the search into the related literature has revealed four (4) key innovation management drivers that will drive women-owned business towards high productivity. These identified drivers include information technology, research and development collaboration, human capital development and product marketing strategy. This study believes that women entrepreneurship in Malaysia stands the chance of competing favorably well with its counterparts globally if these drivers could be tenaciously applied. Also the study generates hypothesis that government has a mediating role to play in ensuring a positive and working relationship between innovation management practice and successful women SMEs.It is however expedient to mention that the workability of innovation is not automatic but requires radical and purposeful implementation. Nada, *et al* (2012) identified some causes of failure of innovation in business concerns to include poor goal definition, poor action alignment, poor allocation of team and resources, poor feedback of results, poor performance monitoring and poor collaboration between customers and suppliers as well as inaccurate interpretation of request from customers. This calls for holistic application of the concept.

In conclusion, the relevance of innovation management practice in ensuring physical and economic growth in women entrepreneurship in Malaysia cannot be over emphasized as empirical studies abounds to support this assertion. This study is expected to serve as a template for existing and upcoming women SMEs in Malaysia towards better entrepreneurial performance which by extension would boost GDP of the Malaysian economy.

Acknowledgement

FINFLEX-CBMC: A Cost-Benefit Model Addressed to Solution Architectures Considering Uncertainty

Yeimi Peña, Universidad de Los Andes, Systems and Computing Engineering Department, Bogotá, Colombia, and yy.pena29@uniandes.edu.co
Eduardo Miranda, Carnegie Mellon University, Software Engineering Master's Program, Pittsburgh, PA, USA 15213, and mirandae@andrew.cmu.edu
Dario Correal, Universidad de Los Andes, Systems and Computing Engineering Department, Bogotá, Colombia, and dcorreal@uniandes.edu.co

Abstract

Solution architectures support the design of technology solutions that are critical for responding to companies' requirements. These architectures require that financial analysis that considers details of variables of alternatives and components. However, since most current financial models address overall IT investments, it is difficult to calculate the detailed and precise financial indicators required for solution architectures. Consequently, financial variables can be omitted, and financial indicators can have imprecise values. With this in mind, our study presents FINFLEX-CBMC, a cost-benefit model specifically for solution architectures. Adoption of the Design Science Research paradigm for definition and evaluation of FINFLEX-CBMC allows it to offer specific indicators related to alternatives and components which can reduce the risk omitting of variables while increasing flexibility for comparing alternatives and provision of support for technology investment decisions.

Keywords: Cost-benefit model, solution architectures, uncertainty, and solution components.

1. Introduction

Solution architectures are essential for companies to enable value generation and increase the efficiency of processes related to design and implementation of technology solutions [1]. As Fig. 1 shows, a technology solution's design considers solution architectures from which are derived one or more alternatives that represent different options for the technology solution [2]. An alternative has a set of solution components that represent technology functionalities such as information systems [1], [3], which in turn can have particular variables such as benefits and costs associated with them and that must be considered to calculate the alternative's financial indicators using cost-benefit models [2], [4], [5]. Financial indicators are indispensable for determining the feasibility of the technology solution, analyzing its possible risks, and for justifying any investment [5], [6]. These financial indicators must consider uncertainties derived from unpredictable events such as changes in requirements to identify positive or adverse consequences of IT investments [2], [6].

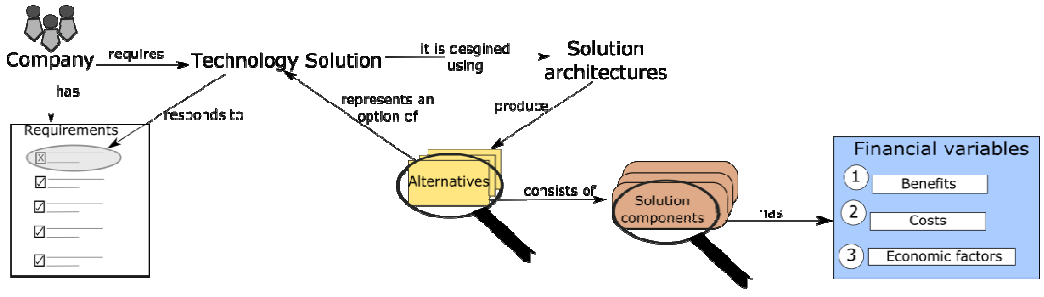

Fig. 1. Solution architecture approach

Once alternatives are defined, a company has the crucial task of selecting the one that is most convenient for implementing the technology solution [2]. To choose an alternative, companies commonly compare the alternatives' financial indicators [2], [4]. Although comparison of alternatives is valuable, it is important to consider the financial indicators at the component level because they include particular financial variables, economic factors, and unpredictable events [2] that support analyses such as comparison of the profitability between components of various alternative solutions [2].

Although there is an extensive literature about cost-benefit models addressed to technology solutions [7]–[9], most of these models are directed at overall IT investments and have a high level of granularity[i] [3], [10] that limits the detailed cost-benefit analysis required for solution architectures. Consequently, financial indicators may not accurately indicate valuation due to the omission of specific variables [3], [10], it may be difficult to identify financial indicators at the component level which could limit comparisons of components [2], and uncertainty at the component level could impact financial indicators. This study defines FINFLEX-CBMC, a cost-benefit model that supports financial analysis of alternatives and solution components in solution architectures while considering uncertainty. To define and evaluate FINFLEX-CBMC, we adopted the Design Science Research paradigm [11]. The results from evaluation of FINFLEX-CBMC indicate that it supports financial analysis of solution architectures and their alternatives and components, offers detailed data considering the uncertainty of financial variables, and supports the comparison between and among components and alternatives.

This paper is structured as follows. Section 2 describes the theoretical background. Section 3 presents related work and the objective of this research. Section 4 describes the research methodology. Section 5 describes FINFLEX-CBMC. Section 6 presents the evaluation of FINFLEX-CBMC, and Section 7 presents a discussion, future work, and conclusions from this research.

2. Theoretical Background

This section briefly describes the conceptual framework of FINFLEX-CBMC.

2.1. Financial variables

A solution component can incur specific costs [5], support materialization of different expected benefits [5], be associated with specific economic factors such as taxes and depreciation [4], and be impacted by unpredictable events that imply different uncertainties [6]. Due to these conditions, we can identify the following financial variables at the component level [2].

a. *Initial Investment* consists of acquisition costs of assets required for a component at time zero [5].
b. *Benefits* are consequences of an action that improve or promote the comfort of a company [5] and which are represented as quantified monetary profit in this study [2].
c. *Costs* consist of the purchase or rental price of a service or asset implied in a solution component [5], [12] and are represented as a quantified monetary value in this study [2].
d. *Economic factors* are relevant market and economic data that can influence the value of an IT investment [2], [5]. This study includes taxes, the inflation rate, depreciation, and salvage or rescue value.

2.2. Unpredictable events

Unpredictable events such changes in providers and new technologies [13] create uncertainty levels that must be considered in the variables of the cost-benefit analysis to determine whether the consequences for a company will be positive or adverse [2], [6]. An unpredictable event (ue) is defined in consideration of the features proposed by Vélez [13] and Neufville [6]: type (economic,

technical or regulatory), level of impact (low, medium, high), and variability (low, medium, high). To measure the uncertainty derived from the ue, we adopted the activities proposed in the Applied Information Economics model (AIE) [10], [14][ii] and the definitions of Vélez [13].

- Estimating the ranges (*low, more probable, very probable)* of the *cost and benefit* variables using expert criteria, subjective probability technique, or historical data [13], [14].
- Quantifying the uncertainty using probability distributions [9], [14]**.**
- Calculating the error of estimation using Monte Carlo Simulation. This technique depends on the number of samples: the greater the number of samples, the more accurate the estimate will be [14], [15]. If the number of simulations increases, the probability of failure has a lower error in accordance with research done at the University of Missouri [15]. Considering that, we use Equation 1 to calculate the error of estimation considering the number of samples N, the probability of failure p_f, and the quartile of standard normal distributions $u_{1-\alpha/2}$.

$$\varepsilon\% = 100u_{1-\alpha/2}\sqrt{\frac{(1-p_f^T)}{Np_f^T}}$$

Equation 1: calculation of the error of estimation applied to Monte Carlo samples [15]

- Measuring the uncertainty supported by Monte Carlo simulations [14].

2.3. Other factors

To perform the cost-benefit analysis, the life cycle of a solution component must be considered and therefore costs and benefits must be forecast [2], [12]. The life cycle comprises activities from conception (t_c) until retirement (t_d) where duration of the lifecycle is given by $t_d - t_c$ (Fig. 2) [12].

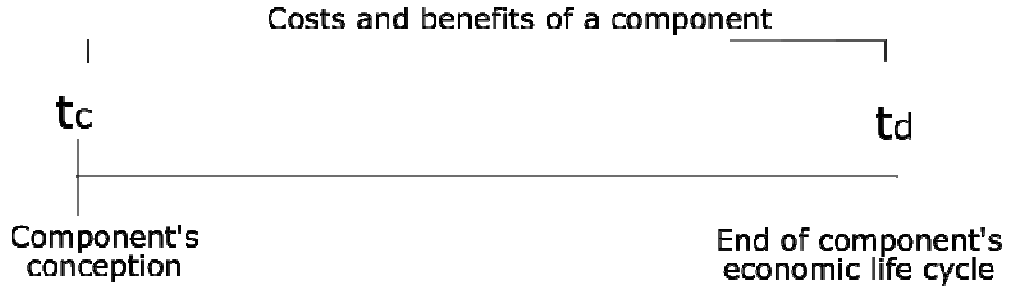

Fig. 2: Component life cycles

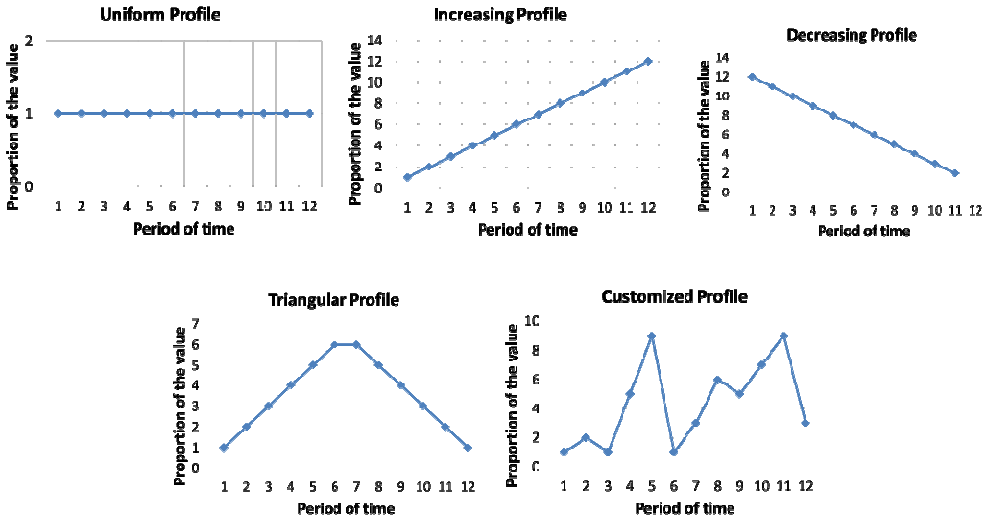

Fig. 3: Examples of profiles

To determine the cash flows that describe both output flows, the money that a company spends, and input flows, money that a company receives, during the component's life cycle, we use the five profiles illustrated with examples in Fig. 3.

2.4. Methods of Cost-benefit Analysis

Cost-benefit analysis assesses the effectiveness of budgeted investment as well as the efficiency and profitability of a technology solution[4], [2]. Cost-benefit analysis is very frequently used to analyze technology solutions [3], [6] and is supported by various methods [4], [6], [16]. FINFLEX-CBMC uses the *Expected Net Present Value* (ENPV) method [6], [16] which is an extension *Net Present Value* (NPV) method [4]. NPV (Equation 2) analyzes costs and benefits through accumulation and discounting of cash flows associated with a particular investment [4].

$$NPV\ (i) = -II + \sum_{p=0}^{n} \frac{Cf_p}{(1+i)^p}$$

Equation 2: NPV [4]

Where

Cf_p= cash flow during the period p

$-II$= initial investment

i = discount rate and refers to the opportunity cost for making a specific investment [4]

p = number of periods

ENPV is used for high-risk projects with unknown levels of uncertainty [6], and NPV is usually employed on short or certain projects [6]. While NPV is based on a single forecast of values, ENPV is based on a weighted average according to the probabilities of each of the specific NPVs. ENPV uses a variable discount rate that reflects the risks of an investment at different points of the time. Finally, unlike NPV which results in a single value [17], ENPV considers a set of NPVs to identify a range of profitability. Therefore, ENPV can consider a greater range of values with greater precision of results [6], [16]. We selected ENPV considering the specific characteristics of solution

architectures: high-risk investments, long-term returns on investments, high uncertainty levels, and changeable technology environments [13].

3. Related Work

In this subsection, we briefly describe the cost-benefit models we identified, comparisons between and among them, and the objective of this research.

3.1.Description of the cost-benefit models identified

A cost-benefit model is a mathematical representation that comprises one or several equations that are used to analyze how a business reacts to different economic situations and to calculate the outcomes of financial decisions before investments are made [4]. We identified the following cost-benefit models in the literature:

Total Value of Opportunity (TVO) is a quantitative and qualitative methodology that seeks to determine the business value of an IT investment [7], [9]. TVO supports its cost-benefit analysis on Total Cost of Ownership (TCO) [10] and supports its uncertainty analysis on the Black-Scholes Option Pricing Model [7], [9].

The *Cost-benefit Analysis Method (CBAM)* has a quantitative approach that guides stakeholders to identify costs and benefits associated with software architecture decisions that result in a system's quality attributes [8].

Total Economic Impact (TEI) is a model that aims to identify cost supported on TCO, determine the benefit related to the business value and strategic contribution, and analyze uncertainty considering the Black-Scholes model [9], [10].

Rapid Economic Justification (REJ) provides a pragmatic expression of the economic justification for an IT investment considering the alignment among its associated costs, benefits, and risks [10].

An Integrated Real Options Framework for Model-based Identification and Valuation of Options under Uncertainty [16] by Mikaelian presents an integrated real options framework (IRF) for holistic analysis of enterprise architecture projects [16]. IRF allows the evaluation of enterprise architecture alternatives through modeling of uncertainty, flexibility, benefits, and costs.

A method for valuing Architecture based Business Transformation and measuring the value of Solutions Architecture by Slot [17] presents a method to quantify the values of enterprise architecture that is financially based on business transformation [17]. The method considers costs, benefits, and management of uncertainty based on real options [17].

3.2.Problems and Objective

Table 1 compares the cost-benefit models identified.

Table 1: Comparison of cost-benefit models

	COST-BENEFIT MODELS						
	TVO [7]	CBAM [8]	TEI [10], [9]	REJ [11]	SLOT [17]	Mikaelian [16]	**FINFLEX-CBMC**
Scope	Overall IT investments	Software architectures	Overall IT investments	Overall IT investments	Enterprise Architecture	Enterprise Architecture	**Solution Architecture**
Uncertainty Measurement	Black-Scholes Option Pricing Model	Not explicit	Black-Scholes Option Pricing Model	Not explicit	Black-Scholes Option Pricing Model	Binomial lattice valuation and the Monte Carlo simulation method	**Definitions of AEI and Monte Carlo Simulations**
Granularity	High Level	High Level	High Level	High Level	Medium Level	Medium Level	**Low Level**

According to the findings presented in

Table 1, we identified the following problems:

1. Scope. Some of the models are directed to IT overall investments which could restrict the level of detail of the financial analysis of solution architectures needed for considering alternatives and solution components. The models directed toward enterprise architectures have a high level of abstraction and strategic scope that differ from the low level of abstraction of solution architectures and their technological scope.

2. Uncertainty Measurement. To measure uncertainty, some models employ the Black-Scholes Option Pricing Model. According to Hubbard, the Black-Scholes formula is not very clear about how to calculate the price of an option because there is high uncertainty in projections of option prices over time [14] while the risk rate is a constant value unlike the variable rates of a solution architecture.

3. Granularity. Four models have high granularity levels that translate to general financial indicators at the level of IT investments.

Although previous studies offer significant contributions, there is clear evidence that a specific cost-benefit model for analyzing solution architectures had not yet been developed. To respond to these shortcomings, this study aims to *define a cost-benefit model addressed to solution architectures that supports financial analysis of alternatives and solution components considering uncertainty.* To achieve our objective, we designed and evaluated FINFLEX-CBMC supported on design science research methodology.

4. Research Method for Developing and Evaluating FINFLEX-CBMC

We adopted the Design Science Research (DSR) paradigm [11] because it aims to build and evaluate artifacts that solve business needs [11]. Our research is valuable to academia and industry because cost-benefit models are valid DSR artifacts [18]. FINFLEX-CBMC is supported by the current body of knowledge [7][8] [9], [10] [17] and was designed considering the methodology proposed by Avon [19]. We followed the DSR evaluation patterns proposed by Sonnenberg and Brocke [18], and we adapted those patterns to FINFLEX-CBMC as shown in Fig. 4. The use of patterns allowed us to demonstrate, design and evaluate FINFLEX-CBMC. We explain below the three evaluation activities used for FINFLEX-CBMC.

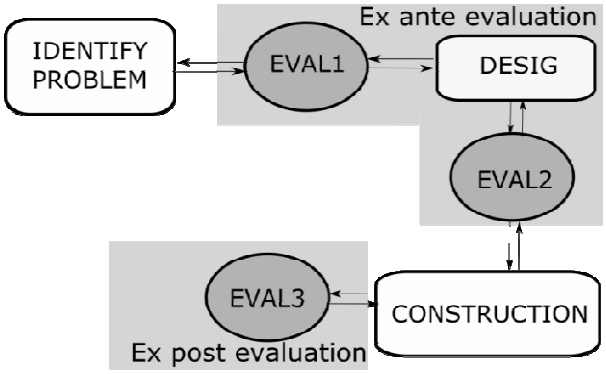

Fig. 4: DSR assesment patterns used for FINFLEX-CBMC. Adapted from [18]

1. **Identifying problem and objectives of FINFLEX-CBMC**. The first evaluation (EVAL1) justified the research problem and supported its contribution to both industry and literature. EVAL1 was completed in Sections **Error! Reference source not found.**, 2, and 3.

2. **Designing FINFLEX-CBMC**. The second evaluation (EVAL2) justified the design of FINFLEX-CBMC [18]. We designed FINFLEX-CBMC by adopting definitions from financial model of design proposed by Avon [19]. We considered the following assumptions in the design of FINFLEX-CBMC [19]:
    a. Alternatives and their components respond to the business or technology requirements that inspired them.
    b. Alternatives and their components are technically equivalents and have been technically analyzed by a company.
    c. Financial variables and economic factors of a solution component have been identified and estimated through methods previously selected by estimators.

3. **Constructing FINFLEX-CBMC**. The third evaluation (EVAL3) justified the utility of FINFLEX-CBMC (Section 6). To execute EVAL3, we first defined the cost-benefit model

(Sections 5). Then, we created a prototype of FINFLEX-CBMC to capture the required data, perform the cost-benefit analysis and present the results (Section 6).

5. FINFLEX-CBMC: A Cost-benefit Model addressed to Solution Architectures considering Uncertainty

To describe FINFLEX-CBMC, we used the generic process presented in Fig. 5. It includes the essential activities required for calculating the financial indicators of an alternative and its solution components.

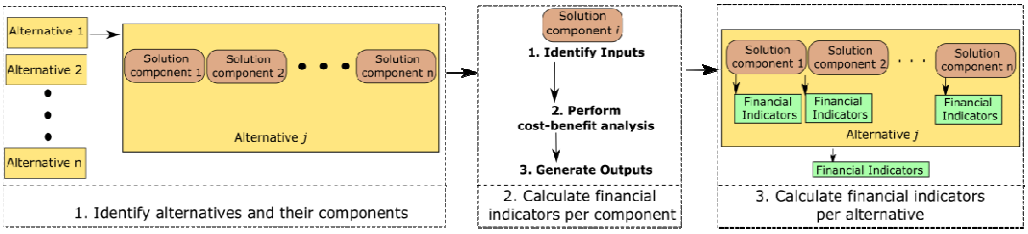

Fig. 5: Generic Process of FINFLEX-CBMC

5.1.Identifying the alternatives and their components

This activity defines the solution architecture alternatives of a technology solution and identifies the solution components of an alternative.

5.2.Calculating the financial indicators by component

The process considers the activities explained below in order to calculate the financial indicators of a component.

5.2.1. Identifying inputs

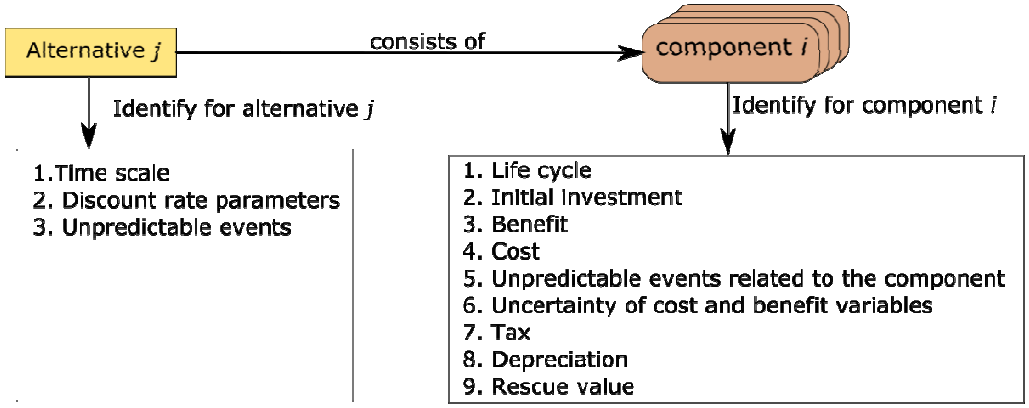

Fig. 6: Inputs required for FINFLEX-CBMC

As Fig. 6 presents, inputs have two sources: alternatives and components. The alternative's inputs are used to perform the cost-benefit analysis for all of the alternative's components while the component's inputs are particular to each component.

Input identification considers two steps:

Step 1) **Identifying inputs of alternative *j***

a. **Timescale.** Select the time scale (monthly, bi-annual, or yearly) to analyze the alternative [2].
b. **Discount rate parameters.** Identify the risk-free rate $(\mathrm{i_r})$ and the inflation rate (i_f) to calculate the discount rate .
c. **Unpredictable events**. Determine the unpredictable events $\{ue_1, ue_2, \dots, ue_n\}$ that impact the alternative [2] considering the features explained in Section 2.2.

Step 2) **Identifying inputs of component *i***

a. **Lifecycle.** Determine t_d and t_c (Section 2.3).
b. **Initial investment (II).** Identify the II (Section 2.1).
c. **Benefit.** Determine the benefit (Section 2.1) and its profile (Section 2.3).
d. **Cost.** Identify the cost (Section 2.1) and its profile (Section 2.3).
e. **Unpredictable events related to the component.** Identify the particular unpredictable events that impact a component *i* [2] using the mapping presented in
f.
g. Table **2**.

Table 2: Mapping between alternative's unpredictable events and components

	Unpredictable event (ue_j)	Component (c_i)
$Alternative_j$	ue_1	$r(ue_1, c_1)$
	…	…
	ue_n	$r(ue_1, c_n)$

Where

c_i i =1, 2, … , n are the components of A_j.
ue_j j = 1, 2, …, n are the unpredictable events of A_j.
$r(ue_j, c_i)$, represents the relationship between the components and unpredictable events.

h. **The uncertainty of costs and benefits.** Determine the range and probability distribution (Section 2.2) of costs and benefits, considering the unpredictable events related to the component *i* [2].
i. **Tax** *(Tx).* If a component *i* includes tax, it is necessary to identify its monetary values or percentages ($\{(tx_1), (tx_2), \dots, (tx_n)\}$) for the component's lifecycle.
j. **Depreciation** *(D).* If a component *i* includes the depreciation, it is necessary to identify its monetary values ($\{(d_1), (d_2), \dots, (d_n)\}$) for the component's lifecycle.
k. **Rescue value** *(Rv).* If a component has a rescue value, it should be identified as a monetary value.

5.2.2. Performance of cost-benefit analysis

To perform the cost-benefit analysis of a component, FINFLEX-CBMC executes the following activities:

1. **Calculating the number of periods** (*P*)**.** FINFLEX-CBMC calculates the number of periods ($\{p1, p2, \dots, pn\}\ where\ p1 \leq tc\ and\ pn \leq td.$) using the time scale and the life cycle.

2. **Calculating the discount rate** (i). FINFLEX-CBMC calculates i per year with inflation (i_n) using Equation 3, or i per year without inflation (i_r) using Equation 4. Once i is calculated, FINFLEX-CBMC calculates its proportion considering the timescale. As a result, i is calculated for each period $\{(i_1), (i_2) \dots (i_n)\}$.

$$\mathrm{i}_n = (1 + \mathrm{i}_r) * (1 + i_f) - 1$$

Equation 3: Nominal discount rate [4]

$$\mathrm{i}_r = \frac{(1 + \mathrm{i}_n)}{(1 + i_f)} - 1$$

Equation 4: Real discount rate [4]

3. **Calculating ENPV.** FINFLEX-CBMC calculates ENVP on the basis of 200,000iii NPVs. For each NPV, FINFLEX-CBMC performed the activities presented in Fig. 7 and explained below

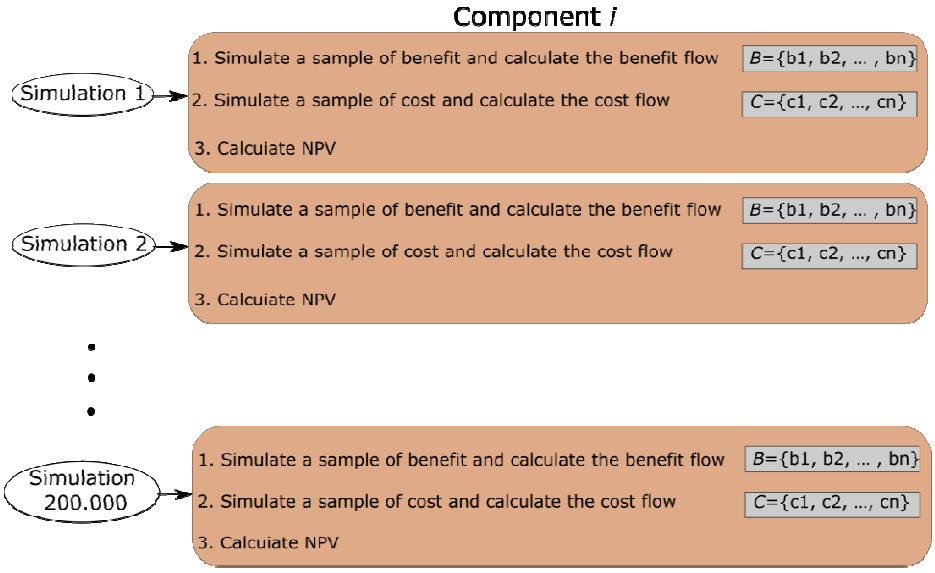

Fig. 7: ENPV calculation using Monte Carlo simulations

1. **Simulation of a random sample of benefits** through Monte Carlo simulations based on the ranges and probability distribution [14]. Then, FINFLEX-CBMC calculates the benefit flow ($\{b_1, b_2 \dots b_n\}$) of the sample considering the selected profile and the number of periods.

2. **Simulation of a random sample of costs** through Monte Carlo simulations based on the ranges and probability distribution [14]. Then, FINFLEX-CBMC calculates the cost flow ($\{c_1, c_2 \dots c_n\}$) of the sample considering the selected profile and the number of periods

3. **Calculating NPV**. FINFLEX-CBMC calculates the NPV using the approach proposed by Brealey et al. [4] (Fig. 8) on the basis of the information provided and calculated (*II, cost flow, benefit flow, D, Tx, Rv, and* i).

Period (P)	p_0	p_1	p_2	p_3	...	p_n
Initial Investment (II)	II					
Cost flow (C)		c_1	c_2	c_3	...	c_n
Benefit flow (B)		b_1	b_2	b_3	...	b_n
Depreciation (D)		d_1	d_2	d_3	...	d_n
Pretax profit(PTx)		pP_1	pP_2	pP_3	...	pP_n
Taxes (Tx)		tx_1	tx_2	tx_3	...	tx_n
Net Profit (Np)		np_1	np_2	np_3	...	np_n
Rescue Value (Rv)						Rv
Cash Flows (Cf)		cf_1	cf_2	cf_3	...	cf_n
Discount Rate (i)		i_1	i_2	i_3	...	i_n
NVP	$					

Fig. 8:Approach to calculation of NPV [4]

Utility before taxes is calculated as:

$$Pretax\ profit\ (PTx) = b_j - c_j - d_j$$

$Where\ j =$ 1,2,…,n is the period in which variables are considered.

Next, the *net profit* is calculated as:

$$Net\ profit(Np) = pP_j - tx_j$$

Then, the *cash flows* are calculated as:

$$Cash\ Flow(Cf) = np_j + Rv_j + d_j - II$$

Finally, the NPV is calculated as:

$$NPV\ (i) = -II + \sum_j \frac{Cfj}{(1+i_j)^j}$$

Once the 200,000 simulations have been run by FINFLEX-CBMC, the ENPV is represented as shown in the example illustrated in Fig. 9.

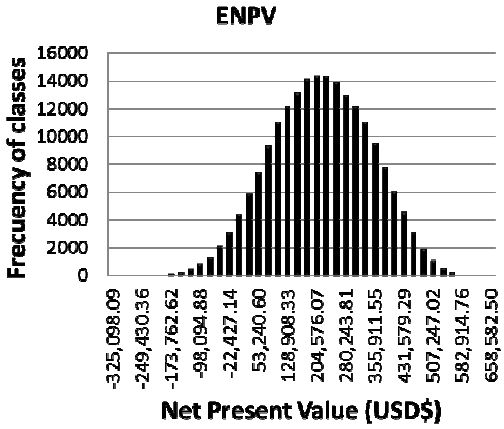

Fig. 9: Example of ENPV

5.2.3. Generating outputs

FINFLEX-CBMC generates the following financial indicators for any component i:

1. ENPV.
2. Benefit flow and cost flow as shown in Fig. 10. The benefit and cost flows are identified by calculating the mean (μ) and standard deviation (σ) of the simulated variables for each period.
3. Cash flow.

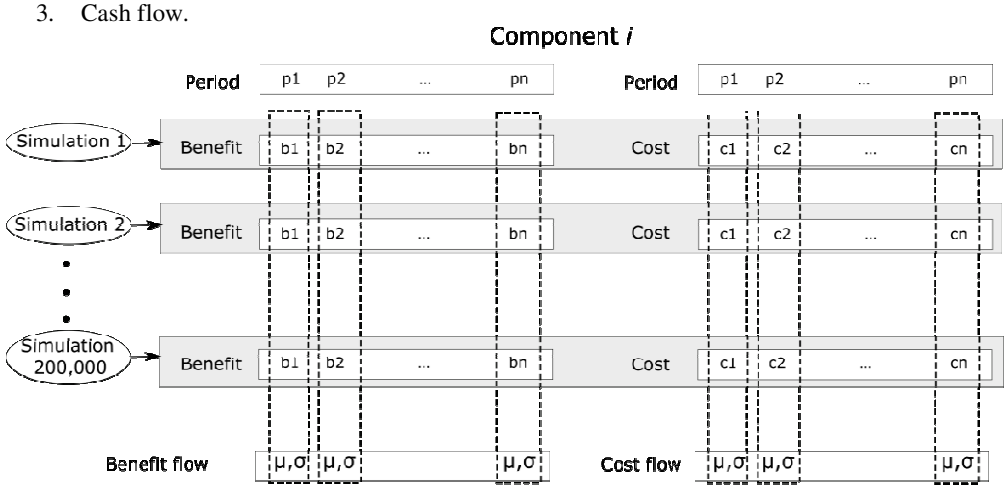

Fig. 10: Calculation of the cost and benefit flows of a component

5.3.Calculating the financial indicators for each alternative

FINFLEX-CBMC calculates the following financial indicators for each alternative:

1. Profitability of an alternative

$$Profitability\ of\ Aj = \sum_{i=1}^{n} \mu(ENPV_{component\ i})$$

2. Cost flow of an alternative

$$Cost\ of\ Aj\ (p) = \sum_{i=1}^{n} Cost(component\ i)_p$$

$Where\ p = 1,2,\ldots,n$ is the period in which the cost is considered.

3. Benefit flow of an alternative

$$Benefit\ of\ Aj\ (p) = \sum_{i=1}^{n} Benefit(component\ i)_p$$

$Where\ p = 1,2,\ldots,n$ is the period in which the benefit is considered.

Fig. 11 presents the results of the financial indicators at the component and alternative levels as calculated by FINFLEX-CBMC. This result supports the comparison between components and alternatives and provides detailed data to support investment decisions.

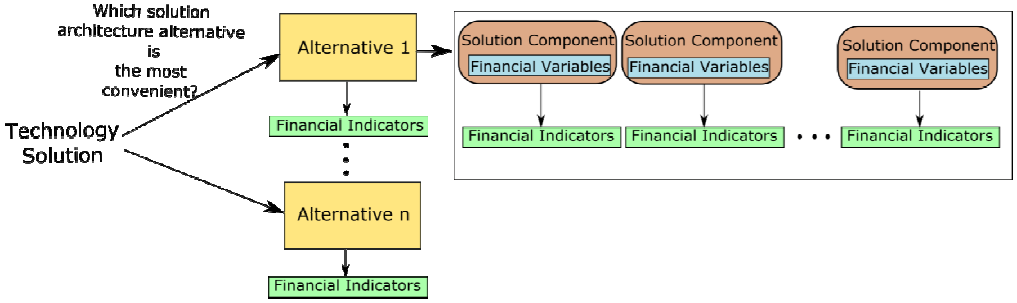

Fig. 11: Financial indicators at alternative and component levels

Finally, as
Fig. 12 shows, the design of alternatives is commonly an iterative process in which the first iteration has a high level of granularity and the last iteration has a low level of granularity. FINFLEX-CBMC can be used independently of the alternative's granularity.

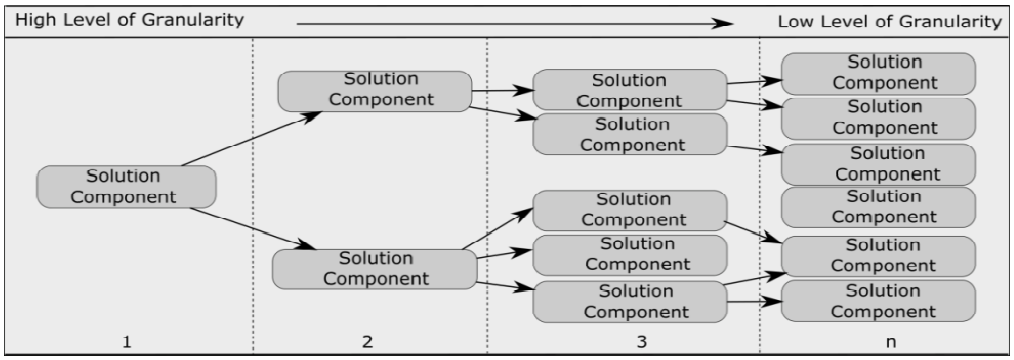

Fig. 12: Level of Granularity of alternatives

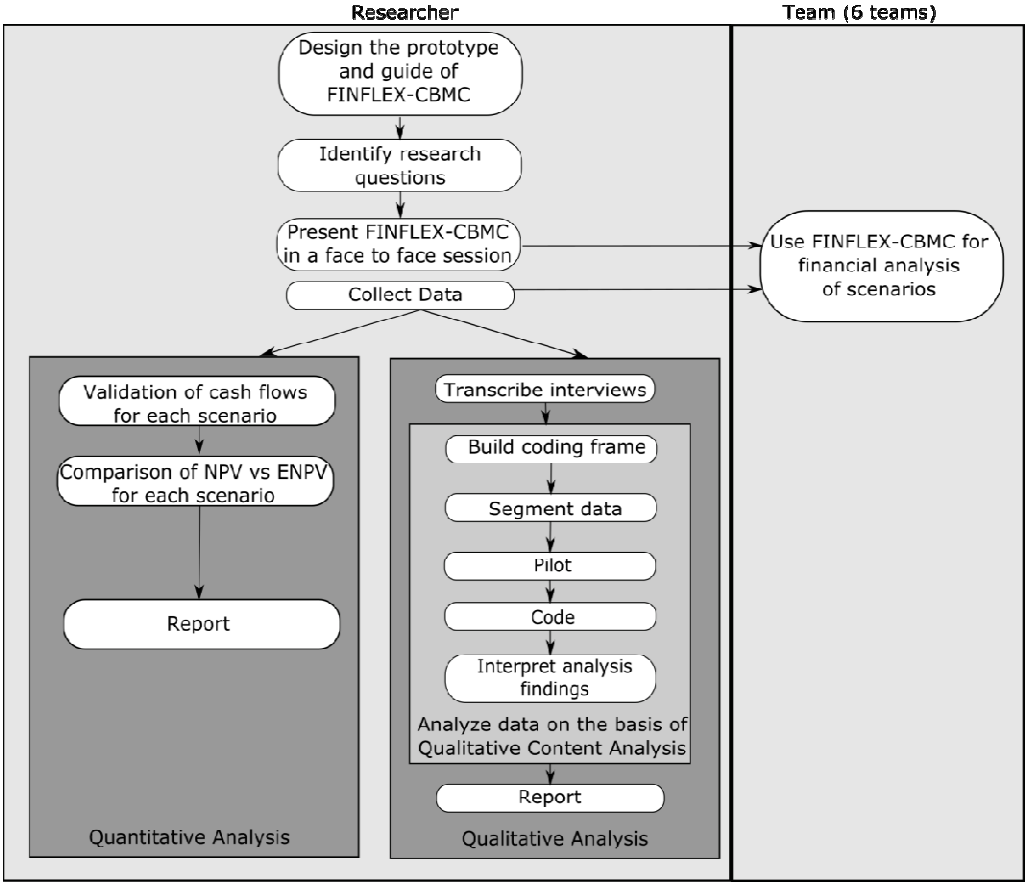
6. Evaluation of FINFLEX-CBMC

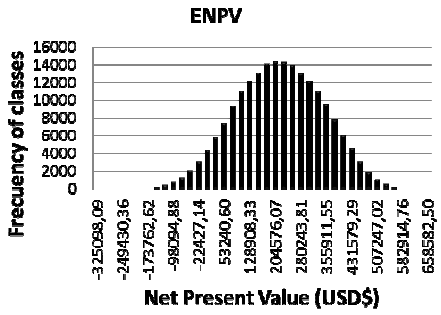
FINFLEX-CBMC was evaluated to justify its utility based on the *scenarios* method [11]. This method was selected because we evaluated FINFLEX-CBMC on the basis of six scenarios that were performed by 32 IT professionals distributed into six teams. EVAL3 was conducted between August

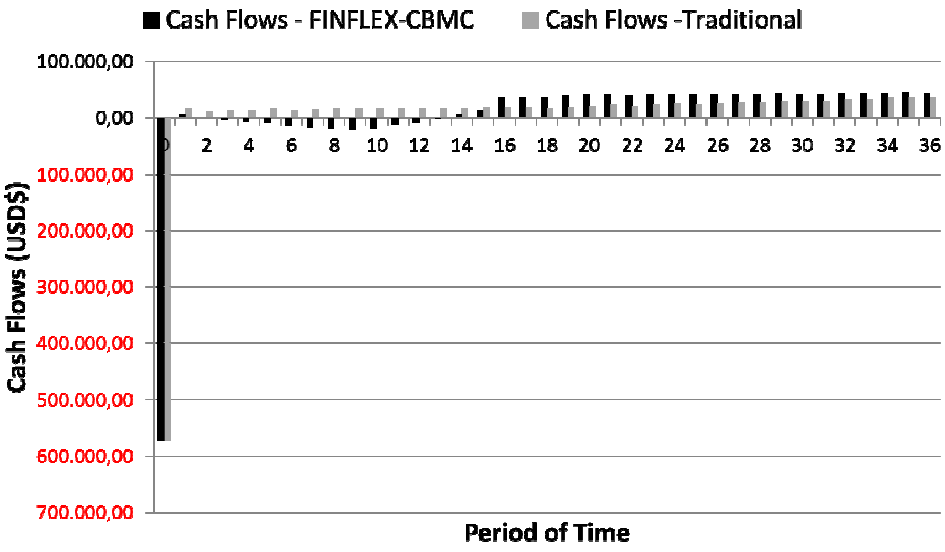
2016 and December 2016 as part of the Solution Architecture course offered by the master's degree in Architecture of Information Technology of Los Andes University (https://sistemas.uniandes.edu.co/en/mati-en). Each scenario represented between one and three solution architecture alternatives that responded to the requirements of a hypothetical company called CCT. CCT offers technology services based on Business Process Outsourcing within Colombia and internationally. CCT currently has difficulty managing customer data related to information traceability and consolidation. Consequent high levels of customer dissatisfaction have increased risks of losing customers and sales opportunities. **Error! Reference source not found.** presents an example of one alternative defined by one of the teams.

The evaluation methodology is presented in **Error! Reference source not found.** Due to space limitation, we have only briefly described the quantitative analysis. As Fig. 13 shows, we first designed a prototype and a guide for FINFLEX-CBMC. Then, we identified research questions to determine how FINFLEX-CBMC supports financial analysis of solution architectures. Next, we presented the prototype and the guide to the six teams in a face-to-face session. Subsequently, the teams evaluated their alternatives using FINFLEX-CBMC. Finally, we collected and analyzed the instances of the prototype with scenarios defined by the teams (A total of 12 solution architecture alternatives because some of the teams only defined one alternative for each scenario).

The objective of the quantitative analysis was to compare traditional financial indicators with the financial indicators generated by FINFLEX-CBMC. Specifically, we compared NPV and ENPV and the cash flows of these approaches. Table 3 presents the results of the financial indicators of one example for three alternatives that had a *high level of granularity*. For this reason, each alternative was analyzed as a unique component.







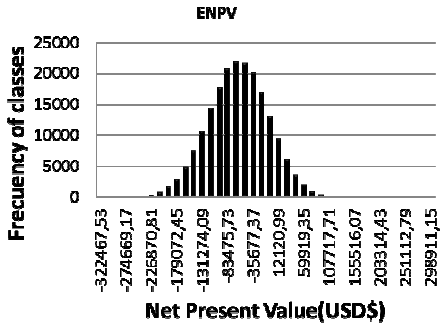


Fig. 13: Methodology for evaluating FINFLEX-CBMC

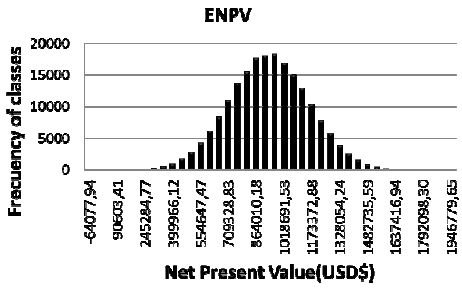
Table 3: Scenarios considered in quantitative analysis

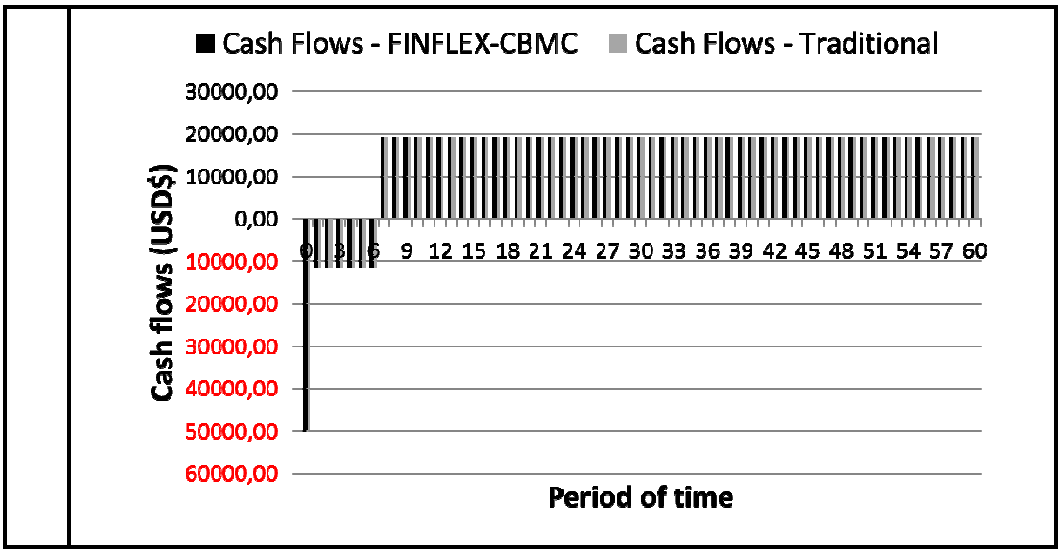
	Traditional financial indicators	FINFLEX-CBMC indicators	
Scenario 1	NPV = $ 41,630.50		Minimum value -$ 325.098,09 Q1 (Percentile 0,10) $ 111.043,94 Q2 (Mean (μ)) $ 204.023,31 Standard Deviation (σ) $ 130.437,38 Q3 (Percentile 0,75) $ 297.598,84 Q4 (Percentile 0,95) $ 373.493,98 Maximum value $ 658.582,50
			

Scenario 2

NPV = -$59,037.19



Minimum value	-$ 322.467,53
Q1 (Percentile 0,10)	-$ 109.695,32
Q2 (Mean (μ))	-$ 70.840,66
Standard Deviation (σ)	$ 82.910,88
Q3 (Percentile 0,75)	-$ 32.724,75
Q4 (Percentile 0,95)	$ 1.106,30
Maximum value	$ 298.911,15



Scenario 3

NPV = $583,349.34

Minimum value	-$ 64.077,94
Q1 (Percentile 0,10)	$ 757.945,97
Q2 (Mean (μ))	$ 908.891,76
Standard Deviation (σ)	$ 223.938,40
Q3 (Percentile 0,75)	$ 1.060.613,36
Q4 (Percentile 0,95)	$ 1.196.270,64
Maximum value	$ 1.946.779,65

It can be seen from the results that, while the NPV offers a unique value for identification of the profitability of a solution, the ENPV is a rich source of data for analyzing risks and possibilities of profitability.

For example, in scenario 1, the NPV is $ 41,630.50 which could be a good basis for making a decision since it is positive. However, the NPV's value is lower than the mean (μ) of ENPV which is $204,031.30 and, since the standard deviation (σ) of ENPV is $130,437.38, profitability is likely to be nearly 50% higher than that indicated by NPV alone. ENPV can give experts more information for each percentile plus the standard deviation measures possible risks of an investment. It is also interesting to analyze the minimum and maximum profits of a solution. For example in scenario 2, the minimum profit is -$322.467, the maximum profit is $298.911, and the average profit is -$70.840. In this scenario, experts can identify the maximum and minimum possible profits as well as the risks thereby providing more robust information to support investment decisions.

The scenarios reveal some differences regarding cash flows between the traditional NPV and the ENPV which could affect identification of outflows and inflows that in turn could result in notable differences regarding investment in a particular solution. The ENPV's cash flows are the results of simulations which may provide more certainty to the analysis.

Finally, on the basis of the results of the quantitative evaluation, we concluded that FINFLEX-CBMC offers more detailed and richer financial indicators than does the traditional NPV for making investment decisions regarding solution architectures.

7. Discussion and Future Work

This paper has presented FINFLEX-CBMC, a cost-benefit model that calculates financial indicators of solution architectures on the basis of their components and alternatives. FINFLEX-CBMC contributes to the determination of unpredictable events and measurement of uncertainties to determine positive and adverse events related to an investment. FINFLEX-CBMC has a number of advantages:

- It calculates financial indicators at two levels of detail for solution architectures: alternatives and components.

- It permits comparison of financial indicators for components and alternatives and measures uncertainty associated with financial variables which can increase the accuracy of the indicators calculated.

- It consolidates financial variables and financial indicators related to solution architectures. FINFLEX-CBMC's flexibility allows performance of sensitivity analysis on the basis of the variation of the financial variables, and it supports risk analysis of IT investments on the basis of ENPV and its metrics.

Although FINFLEX-CBMC provides a complete set of calculations and supports a cost-benefit analysis of solution architectures, it does have some limitations. These include the amount of data required for the use of FINFLEX-CBMC, the performance of the FINFLEX-CBM's prototype, and absence of the experience of the architects in the interpretation of financial indicators of stochastic models like FINFLEX-CBMC. Consequently, results could be omitted or misunderstood by an interdisciplinary team.

We are considering the following activities to continue the development of FINFLEX-CBMC:

1. Implementation of the prototype on another platform that improves performance and user experience.

2. Definition of a methodology to support FINFLEX-CBMC that will offset the absence of experience interpreting financial indicators. We propose to include detailed examples and descriptions to identify the utility of the financial indicators.

3. Validation of FINFLEX-CBMC with case studies to provide more details and use of the model in real cases.

4. Analysis of historical data to support FINFLEX-CBMC and to reduce the complexity of the analysis.

Acknowledgements

The authors of this paper would like to thank the group of professionals of the Master's Degree of Architecture of Information Technologies at Los Andes University for participating in the evaluation of FINFLEX-CBMC. Their comments and scenarios have helped us identify the advantages and disadvantages of our financial model, as well as pointing towards future research to improve our work.

Abstract

This research is aimed to explain the influence of business strategy, top management support (TMS) on the effective of management accounting information system (MAIS) and its impact on corporate performance. The research methodology used quantitative approach while the statistical method used SEM-PLS. Questionnaires and interviews had been done to 240 managers from 60 state owned companies in Indonesia. Result had shown that business strategy did not have any influence on the quality of management accounting information system. Top management support on the other hand, had influences on the quality of management accounting information, in addition the quality of management accounting information system had influences on the performance of the organization.

Keywords: Business Strategy, Top Management Support, Quality of Management Accounting Information System , Corporate Performance

Introduction

Since 1980s' corporate performance and all the efforts to realize it has become an interesting topic, (McAdam & Braine, 2002). One determining factor is the availability of management accounting information system that will provide accounting information which is needed to help managers in making decisions related to strategic planning and even long term goal planning, in allocating resources, controlling and doing evaluation, (Atrill & McLeny, 2009). This thing is in accordance to the statement from Fawcet et.al (1997), that accounting information systems have to be able to provide all of the information related to financial measures and other measures that can escalate long term performance.

There are still a lot of problems related to the performance of state owned company management in Indonesia. This thing is supported by the evidence from an audit on state owned companies which were done by *Badan Pemeriksa Keuangan Republik Indonesia* (BPK RI) between the period of 2014 and 2016 as follows: the company managed ineconomically over the last three years (2014-2016) with the value of ineconomis in 2016 amount to 1,378,950.28 Milion IDR increased 208 % compared on 2014. In addition, the company is also managed inefficiently or a waste of amount 11.652,169 Milion IDR on 2016. This condition indicates a decline in management performance over the last three years.

Literature Reviews

Business Strategy

Business strategy is one way that was taken by companies to set up corporate's purpose and goals for a long term while also planning on some activities which have to be done and making the allocations

of some resources needed to reach the goals (Robin & Judge, 2013). Kourdy (2003) stated that a business strategy is ideas which affect planning, decision making, and strategic analysis that eventually result in competitive results. Considine et.al (2010) stated that business strategy is how the organization makes an agreement with competitors and sets products which can be sold to the market and arranges distribution method of these products.

From the accounting perspectives, strategic mangement is activities taken by top management related to corporate's performance determination and accomplishment for a long term, (Wheelen & Hunger, 2012). According to Campbell et.al (2002), business strategy is the basis of target determination and corporate's long term goals and the applications on many actions and the resource allocations which are appropriate to reach the goals of the company.

Business strategy in this research is actions taken by management in realizing the goals of the company in a long term and implemented in the setting of company's vision and missions and also company's goals to put the company in the condition of competitive advantage.

O'Brein & Marakas (2011) classified the standard of business strategy in five dimensions which are Cost leadership strategy, Differentiation Strategy, Innovation Strategy, Growth strategy, Alliance strategy. Laudon & Laudon (2014) defined six dimensions of business strategy as follows: very good activities, new products, best service and latest business models, intimacy with customers and suppliers, increasing the decision making process, competitive advantage, business survival. In this research, business strategy was measured in qualified operational dimensions, market orientation and competitive advantage.

Top Management Support

TMS is a series of actions which appear from managers behaviour (Young and Jordan, 2008), and is also support given by managers or leaders to share knowledge about company's activities (Rahab et.al, 2011). in contrast, Kandelousi et.al, (2011) claimed that TMS can be seen in many forms for examples helping team members in problem solving, showing commitment in working and encouraging staffs and awareness in giving financial support, allocating human resources and other physical resources and also refer to project leader delegation and teams which have the power to the success of the project accomplishment. The urgent thing at the moment is top management support on the implementation of Management Accounting System, (Mulyani,2009).

Xu (2015) defined TMS as how far top managers in a company understand and support the implementation of information system. Gunasekaran and Ngai (2004) on the other hand, stated that TMS is moral support such as financial support and technical support in the information and technology to get input on management value. According to Ragu and Nathan (2004), TMS is support from management by facilitating various management operationals and the activities of strategic information technology.

In this research, TMS is defined as the awareness from top managers in providing many resources in the implementation of Management Accounting Information System to personify organization performance.

Linying, (2008) said there are two indicators to measure TMS, which are financal support and required resources, support in the form of promoting changes in accordance with company's goals. Whereas Young & Jordan (2008) used different indicators to measure TMS which are allocating time to system development which is equal to the benefits and cost that will be gained later, reviewing plans, evaluating result, and facilitating management problems by integrating Information Comunication Technology (ICT) and company's business.

In this research, TMS is measured by some indicators: resource provision, involvement in reaching the goals of the organization and the allocation of work performance incentive base.

Management Accounting Information System

Systems are a series of sub systems, components or elements which work towards the same goals to produce the expected outcome, (Mulyani, 2016). MAIS is a procedure that produces information to internal users such as managers, executives and employees/workers, (Hansen and Mowen, 2007).

Heidman (2008) said that MAIS is a formal system giving information from internal circles to the decision making. According to Belkauoi (2002), MAIS is a system that produces and spreads information which is relevant for internal decision making. The components of accounting information system consist of user, procedure, data, software, information technology and internal control (Mulyani, 2009). In accounting information system, the quality of given information is important for the success of the system which is applied in the organization as accounting standard procedures (Xu, 2009).

In this research, MAIS is defined as a process of data collection, measurement, and financial data storing which then be distributed to many sectors for decision making in the improvement of the organization performance.

The effective of MAIS can be seen from the ability of this system in producing information which has wide scope, the ability to accomplish particular work at one time and responsive to customer's complaint, (Bentley & Whitten, 2007). Delone & McLean (2003) gave dimension indicators adaptability, availability, reliability, response time and usability. Stair & Raynold (2012) measured the effectivity of MAIS with different dimensions, which are flexible, efficient, accessible, timely. In this research, the effective of MAIS is measured with usability, accessibility and timely dimensions.

Corporate Performance

Kurt & Van (2004) defined performance as a value which is made by an organization using productive assets compared to expected values by the share holders. In addition, Kurt & Van (2004) traditionally stated that corporate performance is defined in financial standard. This is a major regulation set by the authorities and auditors to reveal certain financial information. How far financial details should be revealed depends on the type of the companies whether they are private or state owned ones, on the size of the companies, or on whether they are registerred or not in stock exchange. The standard of financial performance can be devided into two major types: (1) standard based on accounting data; and (2) standard based on market which comes from market share value.

Performance is the standard of productivity using output and input, which are all the things and services including resources that are used to reach goals of the organization, and because of that the effort of improving productivity is improving performance , (Manzoni & Sardar, 2009). In addition, Peter & Savoi, (2000) also stated that performance has to do with organization efficiency. Efficiency is not only a parameter of performance but also a tool to accomplish the goals of the organization through diversity and standardization. Furthermore, Peter & Savoi (2000), claimed that performance also corresponds to result and outcome which can be realised by an organization.

In this research, corporate performance is defined as the ability to utilize all the resources owned by an organization in achieving goals in the concept of value for money which means effective, efficient, and economical by focusing on the ability to compete and regular improvement.

Tajuddin & Ahmad (2013) claimed that the parameter of traditional performance may be sufficient in the context of common industry, but may not be when it is in a more specific public sector one. In public sector, organization performance is generally seen from non-financial aspect. Output and outcome measures are highly relevant, and there are some other parties with interest and accountability relations. Then, public sector institutions adopt or adapt various plannings and technical analysis from industries in order to improve the ability to run the business. Lusthaus *et. al* (2002) measured the organization performance in some dimension: effectivity, efficiency, financial viablility. In this research, organization performance is measured from effectivity, efficiency and economical dimensions.

Theoretical Framework and Hypothetical Development

The Influence of Business Strategy on the Effective of Management Accounting Information System.

Some factors which influence the effectivity of information system are information technology, business strategy and the culture of the organization, (Romney & Steinbart, 2015). Because business strategy is a broad framework then the relation to MAIS is highly strong, (Gottschalk, 2006), in addition it cannot be denied that business strategy and the effectivity of MAIS are highly related one to another , (Laudon & Laudon, 2014).

A research linked to business strategies done by Lee & Miller (1996) concluded that business strategies significantly influence the design of accounting information system. Mulyani & Arum (2016) also stated the same, that a business strategy which was made by a competent management has a positive influence on the effectivity of MAIS. In addition, Chong & Chong (1997) showed a finding that a business strategy influences the design of MAIS. Based on theoritical analysis and previous research, can be sum up that a business strategy positively influences the effectivite of MAIS.

The Influence Of Top Management Support On The Effective Of Management Accounting Information System

MAIS will run effectively if top management gives full support in the form of either resource provision or involvement along the implementation, (Kimbal et.al, 2008). When top management gives full support either resource or finance then the application of the management accounting information system, ERP will run well, (Princely, 2008). TMS on the effectivity of MAIS can also be seen in many management activities and financial support, (Linying, 2008).

The result of research conducted by Mulyani et.al (2016) found out that TMS has a positive influence on MAIS which is implemented in an intelligent business system. Thong et.al (1993) concluded that TMS has a positive influence on the effective of MAIS. Gunasekaran & Ngai (2004) also found out that support and involvement from top management have influenced the success of information sytem in the Supply Chain Managaement. Daud & Triki, (2013) claimed that TMS has an influence on accounting information system. Young & Jordan (2008) concluded in their research that TMS has a significant influence on the application of MAIS. Based on theoritical analysis and previous research can be concluded that that TMS has a positive influence on the effective of MAIS.

The Impact of Management Accounting Information System Effective on Corporate Performance

An information system which can be implemented in RFID combined with management policy in applying JIT, TQM can significantly increase corporate performance, (Pamela et.al, 2014). A company with well managed information system ranging from input process and output for operational activities to financial record can rise corporate performance because each part can respond every need and problem immediately (Bacha,2012).

Mulyani et.al (2016) found that accounting information system has a strong influence on improving corporate performance, this is also proven by the fact that a higher performance accomplishment when a company is more interactive in applying management accounting information system, eventhough generally showing that management accounting information system has shown a positive infleunce on perofrmance , (Agbejule, 2011). In an environment with a high unpredictability, a broad scope of MAIS can give information that will increase the performance of the organization, (Chong, 2004). This finding is also supported by Cheng, (2012), where broadscope MAIS shows a positive influence in performance. The higher the broadscope with information directly used by management,

the higher the corporate performance is. Based on theoritical analysis and previous research can be concluded that the effective of MAIS shows a positive influence in corporate performance.

Based on theoritical frame that analyse the influence of Business Strategy, TMS, Effecvite of MAIS and Corporate Performance, it is illustrated in the graph of framework as follows:

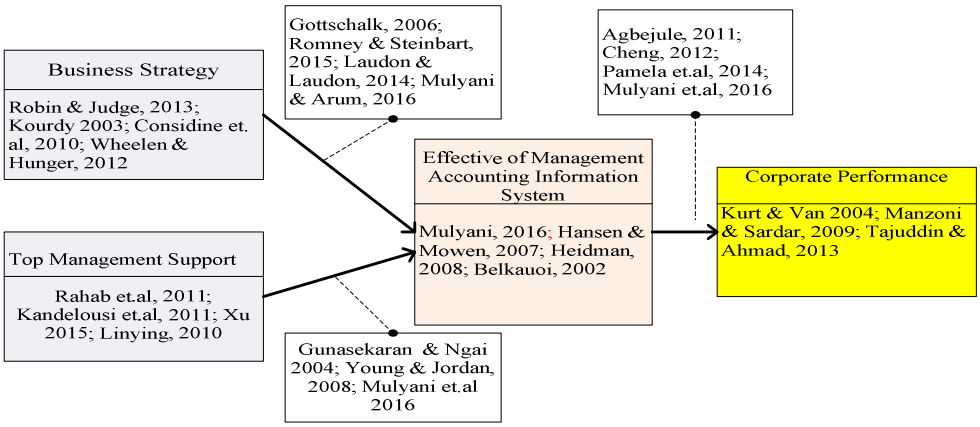

Figure 1 : Theoritical Framework

Based on research framework, hypothesis in the research are as follows:

Hypothesis 1 : A business strategy has an influence in the effective of management accounting information system.
Hypothesis 2 : Top management support has an influence in the effective of management accounting information system.
Hypothesis 3 :The effective of management accounting information system has an influence on corporate performance

Research Methodology

Population in this research was state owned companies (BUMN) running in both banking and non banking business in Lampung, Indonesia with total of 71 companies and 60 sample companies with purposive random sampling method. Selection of state owned companies because these companies operate not only focus to profit oriented but also consider the welfare factor of society. This characteristic is different from the profit oriented private company. To get a result showing a real condition then questionnaires were spread out and a direct interview was also conducted to a total of 240 middle level managers. The data were analysed using Structural Equational Model (SEM) with Partial Least Square (PLS) approach. This research used 95% confidence level, or α 5% so that t table 1,96 was generated as a parameter to accept or reject the hypothesis.

Result and Discussion

Prior to the hypothesis testing, to check the questionnaire accuracy as an intsrument to measure the proper variable then validity and reliability tests have to be made which are shown in table 1

Table 1: Validiy and Reliability Test

	Loading Factor	AVE	R Square		Loading Factor	AVE	R Square		Loading Factor	AVE	R Square		Loading Factor	AVE	R Square
X1		0.64780		X2		0.55551		Y		0.38395	0.79416	Z		0.47720	0.83883
X1.1		0.79354	0.79676	X2.1		0.83939	0.76842	Y1		0.87802	0.64915	Z1		0.66853	0.76514
x.1.1.1	0.911			X2.1.1	0.924			Y1.1	0.939			Z1.1	0.862		
X1.1.2	0.892			X2.1.2	0.908			Y.1.2	0.956			Z1.2	0.717		
X1.1.3	0.869			X2.2		0.75672	0.84419	Y2		0.69671	0.82923	Z1.3	0.865		
X1.2	0.906	0.85517	0.82074	X2.2.1	0.877			Y2.1	0.712			Z2		0.66432	0.64399
X1.2.1	0.932			X2.2.2	0.863			Y2.2	0.941			Z2.1	0.793		
X1.2.2	0.918			X2.3		0.74556	0.52802	Y3		0.79114	0.86810	Z2.2	0.836		
X1.3	0.868	0.79567	0.78365	X2.3.1	0.928			Y3.1	0.841			Z3		0.57686	0.83360
X1.3.1	0.900			X2.3.1	0.793			Y3.2	0.936			Z3.1	0.807		
X1.3.2	0.844											Z3.2	0.771		
												Z3.3	0.816		

Based on table 1, it is known that loading factor value for each indicator is 0,5 higher which means all the seen indicators in every single question is valid as a parameter and all indicators have R^2 value above 0,5 that indicates all indicators have good reliability levels. The result of hypothesis testing is presented in figure 2

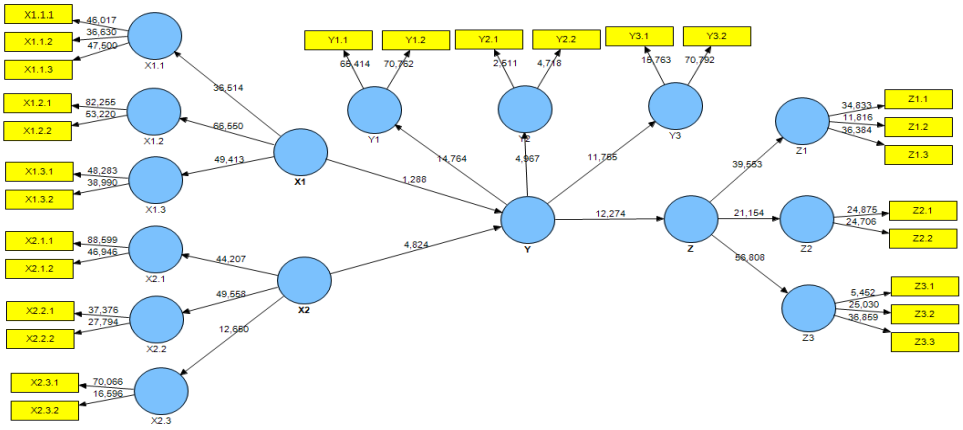

Figure 2: Hypothesis Testing Result

The Influence of Business Strategy in the Management Accounting Information System Effective

Based on the result of hypothesis testing in figure 5.1, coefficiency value of business strategy in the effective of MAIS is 1,288 lower than t count 1,96, thus the first hypothesis is turned down.
The business strategy applied in state owned companies (BUMN) have no impact on the effective of MAIS. This is because most of the policies in state owned companies (BUMN) in many districts area are regulated by the head office without considerring the real situation in the district area such as product, price and quality competition. The answers from the respondents also show that companies which still have not shown qualified business (14%), companies which are not market oriented (19%), not doing product diversification (22%), companies which cannot make product diversification (20%). This indicates that the strategy and policy applied are top-down, thus making the state owned companies in the district areas only run the system made by head office so that the branch offices only focus on operational of the company. This result cannot support the previous one done by Mulyani *et. al* (2016), Chong & Chong (1997).

The Impact of Top Management Support in the Effective of Management Accounting Information System

The direction of TMS to MAIS shows that there is an influence of TMS to MAIS, with coefficiency of 4,824. A positive value shows that every 1 unit rise of TMS can increase the quality of MAIS as much as 4,824.

Coefficiency of 4,824 higher than t table (1,96) proves that TMS has an influence in MAIS so that hypothesis 2 that states TMS has an influence in the effective of MAIS is acceptable. This thing is seen from the reality that in a tight business competition top management realise the importance of information system as a tool to win the competition. The proof of this TMS is attention and commitment to system development and the application of MAIS that is integrated in every part and the provision of required resources for the success of MAIS. The answers from the respondents also show a high commitment from management to implement a new information system (35%) and top management is willing to give fund for improving and maintaining information system (83%). This result supports the previous research done by Thong et.al (1993), Chong & Chong (1997), Gunasekaran & Ngai (2004), Ragu et.al (2004), Young & Jourdan (2008), Daud & Triki (2013).

The Influence of Management Accounting Information System Effective In Corporate Performance

Coefficiency of 12,74 shows that effective of MAIS has a significant influence in the corporate performance (t count value : 12,74 higher than t table : 1,96) thus hypothesis 3 is accepted. The condition from the field shows that all of the state owned companies have implemented integrated MAIS and can be accessed online so that every division needing information to support accomplishing the work and even decision making can be done in realtime. This condition enables all the managers to make a fast decision making and cut bureaucracy chain thus making the corporate performance increase.

Conclusion

Based on the result of the research it can be concluded that a business strategy does not have any influence on the effective of MAIS which is mainly due to the top down system implemented by the head office in all strategies in the companies. TMS has a positive influence on the effective of MAIS that is seen by a high commitment from top mangement to make improvement and maintenance of the available information system in the company. The effective of MAIS has a positive influence on the performance of the company. Many strategical decisions made by management are generally based on the information generated by the system implemented in the company.

Previous studies tested business strategy, TMS, MAIS and corporate performance in private companies, while this research was conducted on state-owned companies with non profit oriented objectives. Differences in the characteristics of the unit of analysis will affect the results of the study.

This research is still limited to state-owned enterprises in the field of banking and non banking finance while the type of state-owned enterprises in Indonesia is very diverse. Subsequent research can examine all state-owned enterprises using cluster systems to classify the types of companies or combine private companies and state owned enterprise.

Abstract

This study aims at investigating the influence that absorptive capability has on competitive advantage of Portuguese textile small and medium enterprises (SMEs). Therefore, a quantitative methodological approach was used, conducting a descriptive, exploratory and transversal empirical study, having applied a questionnaire to a sample of Portuguese exporting firms. The research results suggest that absorptive capability enhances competitive advantage in the analysed SMEs, through the acquisition (cost leadership and differentiation), assimilation (cost leadership), transformation (cost leadership) and exploitation (cost leadership and differentiation). Therefore, the findings sustain the necessity to invest in absorptive capability, which contributes to the firms' competitive advantage in foreign markets.

Keywords: absorptive capabilities, competitive advantage, SMEs.

Introduction

Small and medium-size enterprises (SMEs) are increasingly confronted by challenges and opportunities in international markets. Together with large corporations, smaller firms are among the key players in international trade. Smaller firms that belong to traditional (low-tech and labor-intensive) industries can find here opportunity for growth or challenge their survival. In fact, they are particularly vunerable to global competition, particularly from players located in low-labor-cost economies. In order to achieve competitiveness in this context, smaller firms need to develop unique, firm-specific assets (Zucchella & Siano, 2014).

Firm survival is lowest when firms are small; thus, the development of effective strategies is critical for the continuity of business (Thornhill & Amit, 2003). According to the extant literature, increasing business competitive position, particularly SMEs, is of pivotal importance for the development and renewal of national economies (O'Cass & Sok, 2014). At present, although SMEs are recognised as important contributors to modern economies, our understanding of how they thrive in an increasingly competitive environment and achieve growth is limited (Anderson & Eshima, 2013). Thus, it is urgent to understand the drivers of SME performance.

The competitive environment has long been considered one of the critical contingencies in strategic management. In essence, dynamism and complexity reflect the degree of uncertainty facing an organization and munificence signals a firm's dependence on those environments for resources (Lumpkin & Dess, 2001).

Another body of literature in the field of strategic management has focused on dynamic capabilities (see Barreto, 2010). The firms' success depends not only on its' resources and capabilities, but also the ability to adapt itself to the industry contingencies and markets in which operates. Firms may possess resources but must display dynamic capabilities otherwise shareholder value will be destroyed (Bowman & Ambrosini, 2003). It is in this context that emerges the Dynamic Capabilities View (DCV) (Amit & Schoemaker, 1993; Teece et al., 1997) to support the adjustment to environmental change. DCV is not divergent but rather an important stream of RBV to gain competitive advantage in increasingly demanding environments (Ambrosini & Bowman, 2009; Barreto, 2010; Eisenhardt & Martin, 2000; Wang & Ahmed, 2007). Monteiro, Soares and Rua (2017) defend that in versatile markets, firms' capabilities should be dynamic and managers must display the ability to ensure consistency between business environment and strategy in order to continuously renew skills.

Our study is responsive to the call of Sousa, Martínez-López and Coelho (2008) which suggests that, in the context of international markets, firms' survival and expansion, and consequent economic growth of many countries, is strongly dependent on a better understanding of the determinants that influence competitive advantage. In fact, the factors that set off SME growth (including exporting) are still in need of research (Stouraitis, Harris, Harun & Kyritsis, 2017). So, the purpose of this paper is to broad the boundaries of entrepreneurship and strategic management literature and test the following hypotheses — *does absorptive capabilities positively influence small business competitive advantage?*

Theoretical Framework

Absorptive capabilities

In modern business environment with high turbulence, knowledge has been designated as a dominant source of competitive advantage. In order to survive certain pressures, companies need to recognize, assimilate and apply new external knowledge for commercial purposes (Jansen, Van Den Bosch & Volberda, 2005). This ability, known as absorptive capability (ACAP) (Cohen & Levinthal, 1990), emerges as an underlying theme in the organizational strategy research (Jansen et al., 2005).

Cohen and Levinthal (1990) presented a definition of ACAP most widely cited by academic research, as the firm's ability to identify, assimilate and exploit new knowledge. Thus, this ability access and use new external knowledge, regarded as an intangible asset, is critical to success and depends mainly on prior knowledge level, since it is this knowledge that will facilitate the identification and processing of new one. This prior knowledge not only includes the basic capabilities, such as shared language, but also recent technological and scientific data or learning skills. By analysing this definition is found that absorptive capability of knowledge only three dimensions: the ability to acquire external knowledge; the ability to assimilate it inside; and the ability to apply it.

Zahra and George (2002) divided ACAP in Potential Absorptive Capability (PACAP) and Realized Absorptive Capability (RACAP). PACAP reflects the firms' ability to acquire and assimilate knowledge that is vital for their activities. Knowledge identification, acquisition and assimilation is related to routines and processes that permit to analyse, process, interpret and understand external information. RACAP includes knowledge transformation and exploitation, where transformation is the ability to develop routines that facilitate the integration of newly acquired knowledge in existing one. Knowledge exploitation are routines which enhance existing skills or create new ones by incorporating acquired and transformed knowledge internally.

In order to cope and enhance each ACAP dimension, Jansen et al. (2005) argue that firms need to develop organizational mechanisms which enable them to synthesize and apply newly acquired knowledge. Thus, there are coordination mechanisms that increase the exchange of knowledge between sectors and hierarchies, like multitasking teams, participation in decision-making and job rotation. These mechanisms bring together different sources of expertise and increase lateral interaction between functional areas. System mechanisms are behaviour programs that reduce

established deviations, such as routines and formalization. Socialization mechanisms create a broad and tacit understanding of appropriate rules of action, contributing to a common code of communication.

However, a challenging point for managing the firm's ACAP is that many firms fail to: a) consistently acquire and disseminate the collected information from sphere of front-line units (e.g. marketing and sales managers), b) transform or integrate this knowledge into the general market intelligence, or c) successfully apply the intelligence to increase their competitive position and/or customer value preposition, which in turn will enhance superior performance (Rakthin, Calantone & Wang, 2016)

Competitive Advantage

The different way managers interpret the same external environment leads to distinct policies formulation and differentiated actions, which, together, is reflected in organizational performance (e.g. Lumpkin & Dess, 1996; Zahra, 1993).

The increased intensity of business competition has forced firms to adopt a non-traditional management techniques and tools. Maintaining competitive advantage is a dynamic and infinite activity (Hung, Yang & Lien, 2010).

How firms achieve and sustain competitive advantage? This is the fundamental question in the field of strategic management (Teece et al., 1997). Porter (1985) considers simply a matter of creating value for customers and doing it better than competition.

Porter's model to classify firm strategies remains the most commonly supported and acknowledged framework in strategic management literature (Allen, Helms, Takeda, White & White, 2006). Porter proposed four competitive strategies: broad cost leadership, broad differentiation, cost focus and differentiation focus. While cost leadership or differentiation is defined as dominant competitive strategies, focus is not a standalone strategy and "is not sufficient for above-average performance' (Porter, 1985, p. 15). Consequently, there is a tendency in the literature to recognise two main sources of competitive advantage: a) cost leadership – reaching lower costs than competitors and b) differentiation – creating more value for customers than the average firm (Lechner & Gudmundsson, 2014). Furthermore, and according to Porter, the two logics of differentiation and cost leadership are incompatible.

Hence, we can reduce the study of competitive strategy to differentiation and cost leadership, especially if the competitive strategy is related to other strategic elements of firm's behaviour. Differentiation means to fulfil customers' needs in a unique way, based on speed, customer service and flexibility, which is consistent with innovative approaches and characteristics of entrepreneurial firms. Cost leadership requires substantial financial resources (to invest in tangible assets), is based on process innovation, learning curve benefits, economies of scale and standardization, and seems to be less appropriate for small firms, given the resource constraints (Lechner & Gudmundsson, 2014).

Sustainable competitive advantage represents firm's competitive maintenance on the long run, whose performance is above average, resisting the dynamic evolution of competition, consumers and industry (e.g. Amit & Schoemaker, 1993; Peteraf, 1993; Porter, 1985).

Hypotheses Derivation

Teece *et al*. (1997, p. 516) defined dynamic capabilities as the "firm's ability to integrate, build, and reconfigure internal and external competences to address rapidly changing environments". Dynamic capabilities thus reflect firms' ability to achieve new and innovative forms of competitive advantage.

ACAP is a dynamic capability found in organizational processes that enables firms to reconfigure their core resources, react to environmental dynamics and build competitive advantage (Zahra & George, 2002).

H1a: Acquisition's absorptive capabilities are positively associated with cost leadership.

H1b: Acquisition's absorptive capabilities are positively associated with differentiation.

H2a: Assimilation's absorptive capabilities are positively associated with cost leadership.

H2b: Assimilation's absorptive capabilities are positively associated with differentiation.

H3a: Transformation's absorptive capabilities are positively associated with cost leadership.

H3b: Transformation's absorptive capabilities are positively associated with differentiation.

H4a: Exploitation's absorptive capabilities are positively associated with cost leadership.

H4b: Exploitation's absorptive capabilities are positively associated with differentiation.

Methodology

Sample and Data Collection

The population of this empirical study has been drawn from Portuguese textile industry firms. Questionnaires were used as primary data sources and were carried out over the period of February 16 to April 30, 2016. The identification of companies was done through the Portugal's Textile Association (Associação Têxtil de Portugal) database (ATP, 2014). So, in this study we use a non-probabilistic and convenient sampling.

A total of 247 complete and validated questionnaires accounting for 25% per cent of the population were obtained. This response rate is considered quite satisfactory, given that the average of top management survey response rates are in the range of 15%-20% (Menon & Bharadwaj, 1999).

Statistical Analysis

We used PLS-SEM path modelling to test our hypothesis, specifically the software SmartPLS 3.0 (Hair, Hult, Ringle, & Sarstedt, 2013; Sarstedt, Ringle, Smith, Reams, & Hair, 2014). We believe that the PLS-SEM path modelling is best suited to estimate our research model since: 1) this study focuses on prediction and explanation of contructs variance (in our case 2, with 5 dimensions); 2) our research model has a complex structure; 3) the relationship between entrepreneurial orientation and competitive advantage (via cost or differentiation); 4) this study uses first and second-order reflective constructs; and 5) the sample (n=247) is somewhat small.

Measures

This study uses well-validated scales from previous studies to operationalize the key constructs and adapted them to the particular context of our empirical setting.

Independent variables – According to Zahra and George (2002), ACAP construct is divided in *Potencial Absorptive capabilities* (PACAP) e *Realized Absorptive capabilities* (RACAP). To mesure this construct we use Jansen et al. (2005) scale..

Dependent variable - Competitive strategy was measured through two dimensions, differentiation and cost leadership, using Morgan et al. (2004) scale.

Results

The structural equation model is a multiple regression analysis, with reflective indicators that are presented as an image of the unobserved theoretical construct, representing observed variables or measures, with the objective of strengthening the relationship of influence between the constructs (Marôco, 2010). The simple correlation between these indicators with their construct must have a value equal to or higher than 0.707 so that the shared variance between the construct and their indicators is higher than the error variance (Carmines & Zeller, 1979).

Partial Least Squares (PLS) is a technique that best fits predictive applications (exploratory analysis) and theory development when it is not soundly established (Roldán and Cepeda, 2014). This technique, on one hand, maximize the explained variance of the dependent variables (latent or observed, or both) and estimate structural models with small samples (Chin & Newsted, 1999; Reinartz, Haenlein & Henseler, 2009). On the other hand, it estimates reflective and formative measurement models without identification problems (Chin, 2010). PLS appear to be a preferable option for researchers with samples below 250 observations (247 in this study) (Reinartz et al., 2009).

In order to verify the reliability of overall variables we estimated the stability and internal consistency through Cronbach's alpha (α). Generally, an instrument or test is classified with appropriate reliability when α is higher or equal to 0.70 (Nunally, 1978; Chin, 2010). The result of 0.937 achieved for all variables is considered excellent, confirming the sample's internal consistency (Pestana & Gageiro, 2000). Table 1 show all constructs largely achieved the required level.

Table 1: Cronbach's Alpha of multidimensional variables

	Cronbach's Alpha	***p* values**
ACAQ	0,776	0,000
ACAS	0,847	0,000
ACEX	0,897	0,000
ACTR	0,872	0,000
COST	0,900	0,000
DIF	0,940	0,000

We also use the composite reliability coefficient to assess construct validity (Chin, 1998). This coefficient reflects construct adequacy for a level higher than 0.6 using confirmatory factor analysis (Gefen & Straub, 2005), as in our case. Table 2 illustrates that the studied constructs (all multidimensional) highly exceeded the minimum required for a good fit.

Table 2: Composite reliability coefficient of multidimensional variables

	Composite reliability	***p* values**
ACAQ	0,839	0,000
ACAS	0,906	0,000
ACEX	0,921	0,000
ACTR	0,903	0,000
COST	0,930	0,000
DIF	0,950	0,000

For validity assessment, two subtypes are usually examined: convergent and discriminant validity. Convergent validity implies that a set of indicators represents one and the same underlying construct (Henseler et al., 2009). Fornell and Larcker (1981) suggest using the *Average Variance Extracted* (AVE) criterion and that an AVE value of at least 0.5 indicates sufficient convergent validity. Next table demonstrates that only entrepreneurial orientation is below the minimum required.

Table 3: Convergent validity

	AVE	***p* values**
ACAQ	0,471	0,000
ACAS	0,763	0,000
ACEX	0,661	0,000
ACTR	0,612	0,000
COST	0,770	0,000
DIF	0,705	0,000

Discriminant validity is the degree to which any single construct is different from the other constructs in the model. To have discriminant validity a construct must exhibit weak correlations with other latent variables that measure different phenomena. There are two measures of discriminant validity in PLS. The Fornell–Larcker criterion (1981) recommends that the AVE should be greater than the variance between a given construct and the other with which it shares the model. The second criterion suggests that the loading of each indicator is expected to be greater than all of its cross-loadings (Henseler et al., 2009).

We can observe the explanatory power of each variable in the model. Entrepreneurial orientation is the only purely explanatory variable and reputational resources and absorptive capacity of knowledge exploitation the explained variables. Chin (1998) distinguishes the explanatory power from moderate to substantial. Table 4 expresses the good results in terms of discriminant validity of the research model, confirming that constructs do differ significantly.

Table 4: Discriminant validity

Fornell-Larcker Criterion	**ACAQ**	**ACAS**	**ACEX**	**ACTR**	**COST**	**DIF**
ACAQ	0,686					
ACAS	0,337	0,873				
ACEX	0,381	0,645	0,813			
ACTR	0,421	0,644	0,851	0,782		
COST	0,396	0,390	0,277	0,153	0,877	
DIF	0,421	0,343	0,458	0,489	0,335	0,840

In order to determine the significance of the studied relationships and the confidence intervals of the path coefficients, we used bootstrapping technique. The weighted coefficients indicate the relative strength of each exogenous construct. According to Hair Jr., Hult, Ringle and Sarstedt (2014), relationships between constructs, with structural coefficients higher than 0.2, are considered robust. From table 5, we thus conclude that the original model does not present non-significant paths.

Table 5: Model's *Path Coefficients*

	Original Sample (O)	Sample Mean (M)	Standard Deviation (STDEV)	T Statistics (|O/STDEV|)	P Values	2.5%	97.5%
ACAQ -> COST	0,361	0,361	0,053	6,858	0,000	0,260	0,455
ACAQ -> DIF	0,258	0,259	0,058	4,462	0,000	0,130	0,375
ACAS -> COST	0,398	0,394	0,080	4,971	0,000	0,217	0,535
ACAS -> DIF	-0,002	-0,006	0,085	0,024	0,981	-0,165	0,147
ACEX -> COST	0,361	0,355	0,136	2,653	0,008	0,093	0,607
ACEX -> DIF	0,131	0,148	0,104	1,259	0,209	-0,058	0,352
ACTR -> COST	-0,562	-0,550	0,109	5,173	0,000	-0,766	-0,339
ACTR -> DIF	0,270	0,264	0,089	3,032	0,003	0,094	0,444

Figure 1 presents the final research structural model with the effects and explained variance of latent variables.

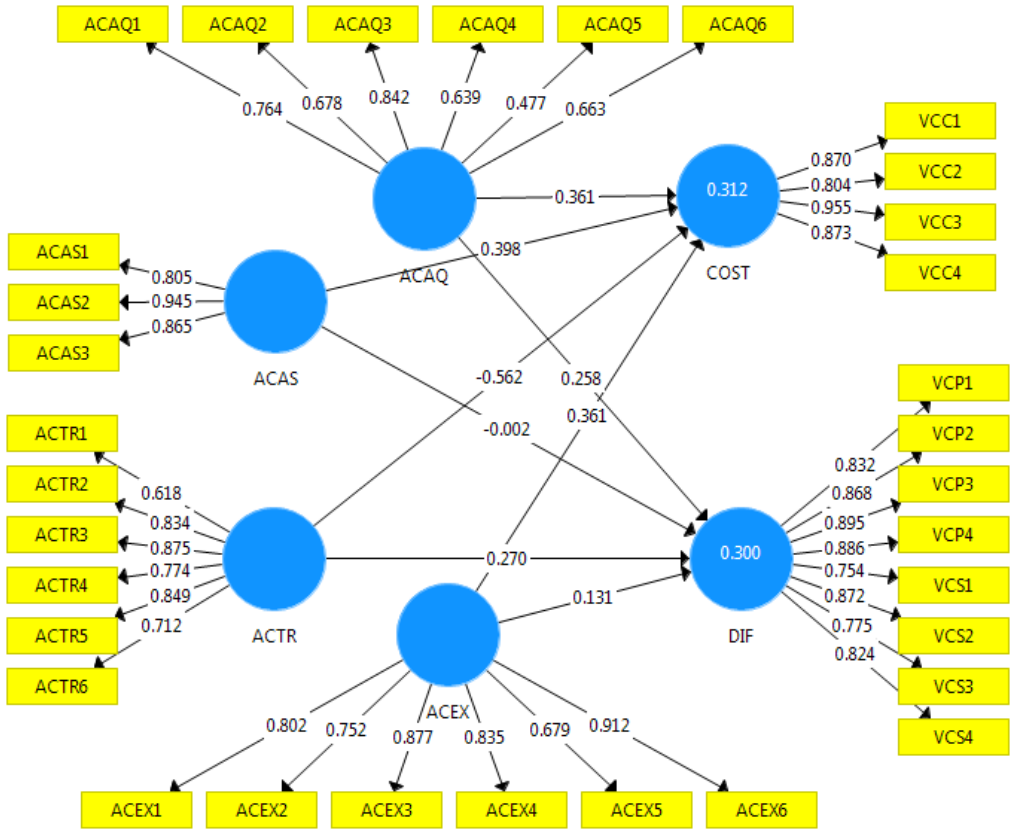

Figure 1: Research structural model

Key: ACAQ - Acquisition's absorptive capabilities; ACAS - Assimilation's absorptive capabilities; ACTR - Transformation's absorptive capabilities; ACEX - Exploitation's absorptive capabilities; VCC – Competitive advantage *cost leadership*; VCC – Competitive advantage *differentiation*.

Results from Table 5 indicate that the development, growth or investment by the management in this type of capabilities will not affect the strategy definition, but rather stimulate the development of international activities. So, H1a, H1b, H2a, H3a, H4a and H4b were supported in our model, and H2b and H3b non supported.

Discussion and conclusions

This paper seeks to contribute to the development of the literature on factors that influence small firms competitive advantage through a robust empirical study. The central context of this research is on SMEs, which constitute the vast majority of firms in Portugal, as in most word economies.

Absorptive capability has a positive and significant impact on competitive advantage (H1a, H1b, H2a, H3a, H4a and H4b supported). Teece and colleagues (1997) argue that, through dynamic capabilities, firms are able to develop, integrate, reconfigure and adapt their resources and capabilities to umpredictable markets and achieve competitive advantage. In this study it is demonstrated that our SMEs do not include dynamic (absorptive) capabilities in the formulation of their competitive strategy, as suggested Zahra and George (2002). Hence, H2b and H3b were not supported.

Small traditional firms represent a very important part of the economic system in many European countries. Their significant contribution to the gross domestic product (GDP), national exports, and job creation, makes them an important policy target (Zucchella & Siano, 2014). In fact, and according to Portugal's Textile and Apparel Association (ATP), this industry in 2016 accounted for 20% of industrial employment, 9% of GDP and 10% of Portuguese industrial exports.

We can only speculate that the Portuguese textile industry faces considerable challenges, not only regarding the economic crisis in international markets, which restricts access to resources, but also concerning consumption patterns. Furthermore, international competitiveness does not allow SMEs to develop a competitive strategy based on differentiation, changing thus their business model paradigm. Indeed, mature industries are characterized by increased competition and price deflation due to overcapacity (Parrish, Cassill, & Oxenham, 2006). As reported by the ATP (2014), globalization pressures, such as textile trade liberalization, have considerably affected the industry. The textile sector is being subjected to strong pressures in a fast-changing business environment due to market volatility and strong competition world-wide. The key success factors of the industry are related primarily with cost (labor, energy, transport), but also with geographical location (flexibility, responsiveness, proximity service), knowledge (know-how, experience, technical expertise, research and development, networking) and recognition (tradition, brands, quality). Therefore, we acknowledge that the sector is developing strong differentiation factors. Firms in these mature markets must look for ways to stay competitive and develop strategies that enables them to differentiate themselves from other firms.

Theoretical and Practical Implications

Our study is responsive to the call of Sousa et al. (2008) which suggests that, in international market context, firms' survival and expansion, and consequent economic growth of many countries, is strongly dependent on a better understanding of the strategic determinants that influence competitive advantage.

Moreover, our study confirms the important complementarity of intangible resources and dynamic capabilities, thus not diverging from RBV and DCV (e.g. Ambrosini & Bowman, 2009; Barreto, 2010; Eisenhardt & Martin, 2000; Wang & Ahmed, 2007).

We also highlight the contribution of this study to the theory of strategic management. It is known that strategy includes deliberate and emergent initiatives adopted by management, comprising resource and capabilities used to improve business performance (Nag, Hambrick, & Chen, 2007). In order to remain competitive, firms must assess which strategic determinants give them an advantage

over their competitors. The findings are a contribution to clarify the influence of entrepreneurial orientation, intangible resources and absorptive capabilities in small firms export performance.

Addicionally, our findings provide guidance to business practitioners, since they indicate that entrepreneurial orientation, intangible resources and absorptive capabilities are predictors of competitive strategies and performance. The research has also shown the positive influences of generic strategies on firm performance. So, for small firm managers, competitive strategy does matters and the development of one type of competitive advantage, alongside with firm's resources, is a major performance driver.

Firms are a bundle of resources and capabilities (Peteraf, 1993), it is essential to understand and identify which resources are relevant to gain competitive advantage and superior performance. Business owners must be able to systematically analyse the changes that arise in their target market(s) and to incorporate this knowledge into their processes, to identify the present and future needs and market trends, anticipate changes in demand and seek new business opportunities.

By building on the literature entrepreneurship and strategic management, this study aims to support the strategic development of business management policies designed to increase firms' performance in foreign markets and add value to the current context of change.

Research Limitations

While this research provides valuable insights into SMEs in the textile industry, the study is not without its limitations. First, the state of the economy might have affected our results. The low scores of willingness to take risks might be influenced by the current context of economic crisis. In fact, in a turbulent market, risk-taking is negatively associated to SME performance (Kraus et al., 2012) and is in fact related to firm failure (Lechner & Gudmundsson, 2014). Second, it would have been interesting to control our analysis. The fact that the research does not consider the effect of control variables such as age, location and target market of the respondents can be seen as a limitation. Third we used an online study to collect our data. While electronic data collection methods are becoming more common, strategies to encourage a greater response rate are lacking compared to other survey implementation methods. Finally, the fact that the sampling is non probabilistic and convenience is a limitation. Therefore we advise prudence in the generalization of results.

Future Lines of Research

Firstly, this study has been based on a mature sector, as is the textile sector in Portugal. The results obtained should be understood in this context. For this reason, new research could be done in more modern industries to test again the proposed relations. Second, given the irregular nature of business growth, a snapshot survey may not be able to capture strategy and performance variations over long periods of time. As such, further studies with a longitudinal perspective would be of added value to investigate why these differences persist. In other words, to find how and why some small exporters become highly successful while others, in the same industry, struggle to raise their export strengths.

Abstract

Good Financial reporting quality of the government sector is required so as to achieve accountability objectives. Accountability is an important issue in New Public Management (NPM). Society demands a good governance government. Good quality of government financial reporting increases public accountability. This paper study how the government accountant competence, the implementation of internal controls and the application of information technology affect the quality of financial reporting and its impact on public accountability. The study was conducted in regional governments of West Java in Indonesia using survey. The results show that there were significant influences of government accountant competence, implementation of internal control and information technology on quality of financial reporting. Further, financial reporting quality also has a significant effect on public accountability.

Keywords*:* Financial Reporting Quality, Public Accountability, Competence, Internal Control, Information technology

Introduction

The development of government accounting is expected to be a solution to meet the demands of transparency of government performance in terms of accountability. Accountability is a relevant concept describing the performance of the public sector. Quality information is very important for the public sector in providing accountability of all its activities to all stakeholders. The concept of NPM (New Public Management) is a concept that is now experiencing many developments into several concepts of public accountability (Mardiasmo, 2009).

Government financial reporting is still experiencing problems. The first semester report of 2014 BPK RI (Indonesia Financial Supervisory Body) revealed from 415 audits for Local Government Financial Statements, 64% The financial statements still obtain qualified audit opinion. Bisri (2013) found weaknesses of the Internal Control System in Indonesia and non-compliance with legislation in the audit of ministry finance reports/ in the management of fixed assets and social assistance. Pamungkas (2014) revealed from 40 findings on the financial statements of 2013, 12 findings of them are internal control issues. The same problem also occurs in ministries and other government institutions in processing financial reporting due to the quality of human resources (Boediono, 2014). Others are caused by inefficiency and ineffective use of information technology (Sampurna, 2015). Another problem arising in government is the issue of public accountability (Miftah, 2016).

Public Accountability in Indonesia is a problem that still faces obstacles. Achievements at the echelon I level government officers are still low as the implementation of AKIP (Performance Accountability for Government Agencies) is not yet obligatory (Afriyadi, 2017). Another problem is the weakness of the law enforcement regarding the punishment in finance and administration violation (Afriyadi, 2017).

Several problems are causes by inappropriateness placement of human resources that manage government finance, internal control issues and also inefficient use of information technology and the existence of public accountability problems. Government accounting and financial reporting aims to protect and manage public money and discharge accountability. Financial reporting is the best index of accountability (Eivani et.al., 2012). Accountability is also an instrument for control activities, especially in achieving results on public services. In this regards, a performance evaluation is required to determine the extent to which the outcomes are achieved and the means used to achieve them. Thus, it is expected that good financial reporting quality can increase public accountability.

The purpose of this study is to examine empirical evidence of the influence of Competence of Government Accountants to the Quality of Financial Reporting, the effect of Implementation of Internal Control on the Quality of Financial Reporting, the effect of Information Technology System Implementation on the Quality of Financial Reporting and the effect of Quality of Financial Reporting on Public Accountability. Previous study was conducted in smaller region, so this study is conducted in larger region in order to strengthen the results.

The results of this study is expected to be one of the solution to the government regarding the government financial reporting problems; government should optimize accountant personnel; Government should be able to improve internal control and information technology used. The results of the study are also expected to be a source of further research reference to the issue of financial reporting quality in government sector.

Literature Review

Competence

Competence is a personal characteristic, motive, behavior, skill, or knowledge that is proven to drive superior job performance (McClelland, 1973). Competence include individual competence (individual knowledge, skills and abilities); and organizational competence (collective character at the organizational level). As a contemporary organization with the latest technology, organizations are more involved in sustainable development that demands to improve individual competence and organizational competence (Dias *et. al*, 2012).

A competence is an underlying characteristic of individuals that is causally related to criterion-referenced effective and/ or superior performance in a job or situation (Spencer and Spencer, 1993).) Characteristics of competence consist of motives, traits, self concept, knowledge, and skills (Spencer and Spencer, 1993). Competence is measured by the following dimensions: (A). Knowledge consisting of: (1) Knowledge of government accounting and financial reporting process and (2) Knowledge of technical financial reporting; (B). Skills consisting of: (3) Skills, (4) Managerial Skills, (5) Technical Skills, and (6) Social Skills.

Internal Control

Internal control is defined as an integral process of actions and activities carried out continuously by the management and all employees to provide reasonable assurance on the achievement of organizational goals through effective and efficient activities, reliability of financial reporting, security of state assets, and compliance with laws and regulations. invitation (Government Act, no 60/2008). In Indonesia, SPIP (The Government Internal Control System) is an internal control system that is run comprehensively within the central and regional governments.

According to the COSO (Committee of Sponsoring Organization), internal control defined as control that (1) Effected by an entity's board of directors, management, and other personnel; and (2) Designed to provide reasonable assurance regarding the achievement of objectives relating to operations, reporting and compliance. In this study in accordance with the COSO Framework for External Financial Reporting Purposes, internal control is measured by: (1) the Control Environment Dimension; (2) Information and Communication Dimensions; (3) Monitoring dimension.

Information Technology

Technology is part of the Information Systems. Information systems collects, processes, stores and distributes information for a specific purpose or objectives (Turban & Volonino, 2012). The function of the Information System consists of: (1) Input; (2) Process; (3) Output and (4) feedback. Information Technology is the "technology" part of Information Systems (Turban, Volonino, 2012). According to Bodnar and Hopwood (2012), Information System terminology includes the use of Information Technology, which consists of computers, and other technologies used to process information. Examples of some of the technologies used in Accounting Information Systems are bar codes, scanning devices, communications protocols, and others.

Information Technology has evolved from focusing only on data processing and regular reports in the 1970s, to support increasingly to business processes, maintaining customer relationships and suppliers (Turban & Volonino, 2012). Technology would have an impact on (a) how the information in the financial statements is used or consumed; (b) how information is communicated and (c) allowing users to search data through larger and more complex processes (Wood, 2015).

Some types of digital technology used in government accounting in Indonesia are (a) Cloud Computing: is a software application with data storage services in different locations; (b) Big Data: is the storage of more information (c) Social Computing: the social interaction based on information technology; (d) Virtual & Augmented Reality: Modeling, simulation, virtual reality and modeling of interactions between means and people; (e) Cybersecurity: With the widespread use of digital technology, it is necessary to consider also the security issues; (f) Mobile: Mobile digital technology gives us the speed of communication between several parties in the world. (g) Payment System: Internet-based software for payment systems; (h) Educational: Digital technology widely used in education; (i) Artificial Intelligence & Robotics: This technology includes the automation of routine and repetitive work; (j) Digital Delivery Services: The use of digital technology has the potential to change the efficiency and customer satisfaction (Afandi and Hoesada, 2016).

In this study the measurement of variables Information technology using dimensions: (1) Platform Information Technology; (2) Utilization of Information Technology by the organization and (3) Resource Setup in Information Technology.

Financial Reporting

The corporate financial reporting is a system of communication between the management and the user-groups of the financial statements (stakeholders); in order to report the results of the corporate enterprise and also to demonstrate the credibility, accountability and reliability of its working (Saeed, 1990). The purpose of financial reporting is to make decisions in the capacity of capital as well as debt providers (Kieso *et al*., 2016).

In this study, financial reporting is related to qualitative of characteristic: (a) Relevance; (b) Faithfull Representation; (c) Comparability; (d) Timeliness and (e) Understandability.

Public Accountability

Accountability is usually defined as a social relationship in which an actor feels an obligation to explain and justify his conduct to some significant other Bovens (2004). Democracy will only be a written rule only if those in power can not be held publicly accountable for their actions and omissions, for their decisions, their policies, and their expenses (Bovens, 2004). Hupe & Hill (2007) discusses the accountability linkages with the "street level" bureaucrats. At the level of bureaucrats who directly deal with the community, then accountability includes accountability to the community.
Since the early 1970s, public attitudes and awareness toward the public accountability in many Western societies have changed significantly (Coy *et. al*, 2001). Accountability is a social practice to pursue a particular goal, which is determined by distinctive relationships and procedures (Ranson, 2003). Accountability participates in community activities by shaping the nature of its members through perceiving, judging, imagining, and acting (Ranson, 2003). According to Coy *et. al* (2001) accountability

refers to the right to know about the conditions and performance of an organization under the responsibility of a party. Accountability and the right to access information are an important way to control abuse of power (Coy *et. al*, 2001).

(Forrer *et. al*, 2010) discusses PPPs (Public-Private Partnerships), the models for distributing services and public goods. PPPs model is expected to overcome some problems that interact with private but accountable. Public Accountability in this study is measured by dimensions (1) Strategic Planning and (2) Activity Performance Indicators.

Theoretical Framework and Hypotheses Development

Effect of Competence on Quality of Financial Reporting

Accountants who are competent and have good characteristics can certainly process financial accounting and good quality of financial reporting. Bodnar & Hopwood (2012) emphasizes the importance of user knowledge and expertise on accounting information systems. Nurhayati and Mulyani (2015) found that competence affects the success of an accounting information system. Therefore, it is assumed that there is influence of government accountant competence on financial reporting quality. Accountant Competence is an important aspect in conducting the duty. Eginiwin and Dike (2014) study that competence as one of the aspect that influence the quality of financial reporting. Abbott *et. al* (2016) also found that accountant competence affect the financial reporting quality.

The Influence of Internal Control on the Quality of Financial Reporting

Stone (2014) found that internal controls help management to protect the company's assets from loss and embezzlement as well as to maintain the accuracy of the company's financial data. The Company is required to develop internal controls in order to provide reasonable assurance that the financial statements have been fairly presented (Arrens *et. al*, 2016).

Internal control will provide a degree of confidence in relation to the reliability of financial information which improve the quality of corporate financial information (Stone, 2014). Mulyani & Arum (2016) also found a significant influence between internal control over the quality of accounting information.Doyle (2007) study the relationship of internal control and accrual level of the company. Companies with serious control problems are usually smaller in size, younger, and financially weaker. Donelson *et. al* (2016) examines how weak internal controls can increase the risk of financial reporting fraud by top managers.

The Effect of Information Technology (IT) Implementation on Quality of Financial Reporting

John (2013) examines the effect of Information Technology on financial reporting found that Information Technology is very important in ensuring the credibility of the company's financial statements. Accounting Information System produce the financial reporting with support of Information Technology. The success of Accounting Information System will lead to good (information) Financial Reporting quality (Fitriati & Mulyani, 2015). Information technology makes financial reporting more accurate, useful and better quality (Imeokparia, 2013). Information Technology increases relevance and reduces reliability of accounting information Salehi & Torabi (2012). Grant *et. al* (2008) found that weak Information Technology in controlling its control affects financial reporting.
Devaraj & Kohli (2003) found that the influence of IT is the actual usage of technology. Technology may affect (a) how information in the financial statements is used or consumed; (b) how information is communicated and (c) allows users to search data through larger and more complex processes (Wood, 2015) Chan (2004) found out that the nature and characteristics of the use of information technology in enterprise information systems will affect the company's internal control over financial reporting.

The Effect of Quality of Financial Reporting on Public Accountability

Historically, the concept of accountability is closely related to accounting. In fact, it literally comes from bookkeeping (Bovens, 2004). Accountability currently comes in many shapes and sizes. It has moved beyond the origin of bookkeeping and has become a symbol for good governance, both in society and in the private sector (Bovens, 2004).

Goddard (2005) studied the relationship between accounting, governance and accountability in local government in the UK. He found that accounting practices such as audits, financial reporting, NPM practices and governance processes are considered much more important in providing contribution to accountability and governance. Torres (2004) conducted a study by looking at how governance accounting from a cash base to an accrual basis can improve transparency, accountability and reliability that exist in financial reporting. Carlin (2005) also discusses how accrual-based government financial reporting can improve public accountability. In his study Carlin (2005) states that the presence of financial reporting movements has affected public accountability systems in several countries such as New Zealand, Australia and the UK.

Government financial reporting is created to help communities see the accountability of the government and assist decision-making (Patton, 1992). In the commercial sector, company information related to decision-making is a tool to improve the accountability of public transnational corporations (Koenig, 2004).

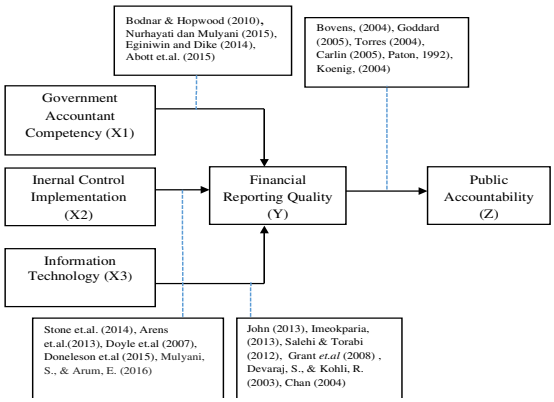

Fig. 1: Framework of Research Theory

Based on Research Framework, hypothesis in the research are as follows:

Hypothesis 1 : Accountant Competence positively affect the Quality of Financial Reporting.
Hypothesis 2 : Internal Control positively affect the Quality of Financial Reporting.
Hypothesis 3: Implementation Information Technology positively affect the Quality of Financial Reporting
Hypothesis 4: Quality of Financial Reporting positively affect to the Public Accountability.

Research Methodology

The statistical tools used to prove the hypothesis in this research is structural equation modeling (SEM) based on component or variance, known as Partial Least Square (PLS). The PLS is used because the relationship between variables is not yet based on strong theories and the number of samples are not too large. The population of the study is local cities and districts government in Indonesia. The study was conducted in regional government of West Java Province, Indonesia. West Java Province has second biggest regional income in Indonesia after the Special Capital Region, Jakarta.

The unit analysis is the cities or districts under province region, with 120 questionnaires (4 questionnaires for each districts, taken on average) distributed to accounting department personnel in 30 cities and districts in regional government using Summated Rating Method with five points Likert scale of agree to

disagree. The analysis uses the validity and reliability test data to ensure the data can be further processed. To test the Fit Model of Structural Equation Modeling (SEM) with Partial Least Square (PLS) it uses 2 assessment steps from a research model: (1) the measurement model (Outer model) and (2) the structural model (inner model) of the model studied.

Results and Discussion

The results of validity testing of User Competence (X1), Implementation of Internal Control (X2), Application of Information Technology (X3), Quality of Financial Reporting (Y) and Public Accountability (Z) obtained value *r* above 0.30 which means everything valid so that used in this research. Reliability test results show Cronbach's Alpha value of each variable above 0.70, so it can be concluded that each indicator used to measure the five variables consistent or reliable to be used as a measuring variables examined.

There are two substructure in SEM model obtained from research data and calculated using SEM approach of Partial Least Square (PLS) that is (1) structural equation model for influence of User Competence, Implementation of Internal Control and Application of Information Technology to Quality of Financial Reporting as follows: : $\eta_1 = 0.371\xi_1 + 0.388\ \xi_2 + 0.289\ \xi_3 + 0.246$; And (2) The structural equation model for the effect of Financial Reporting Quality on the Implementation of Public Accountability as follows: $\eta_2 = 0.678\eta_1 + 0.540$. Figure 5.1 is a summarized results of the path model SEM.

After analyzing the measurement model of each variable and the accuracy of the structural model, the significance test is conducted for partial influence of the exogenous variable (independent variable) to the endogenous variable (dependent variable) in accordance with the existing hypothesis. To test the proposed hypothesis, we can see the t-statistic value. The limit to reject and accept the proposed hypothesis is that if the value of t is in the range of values -1.96 to 1.96 then the hypothesis will be rejected or accept the null hypothesis (H_0).

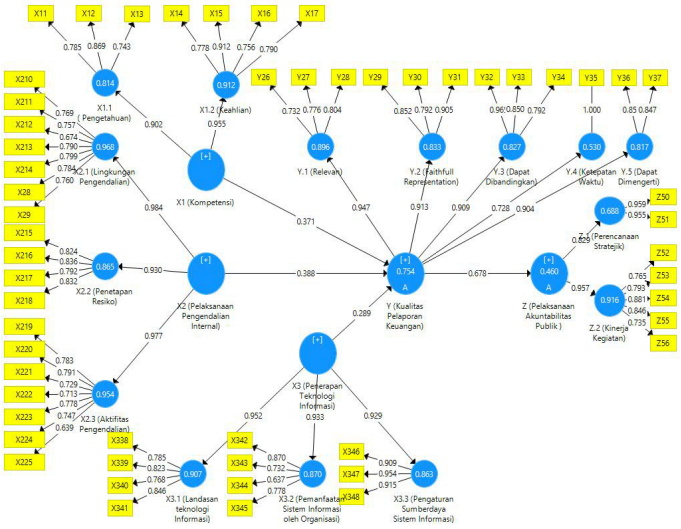

Fig 2: The SEM path model diagram with Partial Least Square (PLS)

Effect of Competence on Quality of Financial Reporting

The following test results show the significance of the hypothesis through statistical hypothesis as follows:

Ho.$\gamma 1 = 0$: Competency has no effect on Quality of Financial Reporting
Ha.$\gamma 1 \neq 0$: Competence affects positively to the Quality of Financial Reporting

Table 1: Significance Tests of the Effect of Competence on Quality of Financial Reporting

Path Coeficient	t_{ccount}	$t_{critical}$	P-value	Conclusion
0.371	2.657	1.96	0.013	Significant

Source: PLS Calculation Result

The results of the first hypothesis test show that the relationship between Competence with Financial Reporting Quality is shown by the value of path coefficient of 0.371 with a t-count of 2.657 and p-value of 0.013. The value of t-statistics obtained is greater than t-critical (1.960) and the significance (p-value) is less than 0.05. This result means that the Competence affects the Quality of Financial Reporting which means according to the first hypothesis (hypothesis 1 accepted). The magnitude of direct influence of Competence to Financial Reporting Quality is (0.371 × 0.371 × 100%) = 13.8%.

The results of the first hypothesis testing show that the relationship of competence of government accountants significantly influence the quality of financial reporting. Thus it can be said that the standard requirement of competent accountant is having sufficient knowledge and expertise in implementing the financial reporting process so that the results obtained are also qualified financial reporting.

Effect of Implementation of Internal Control on Quality of Financial Reporting

The following test results show the significance of the hypothesis through statistical hypothesis as follows:
Ho.$\gamma 2 = 0$: Implementation of Internal Control has no effect on the Quality of Financial Reporting
Ha.$\gamma 2 \neq 0$: Implementation of Internal Control affects positively to the Quality of Financial Reporting

Table 2: Significance Test of the Effect of Implementation of Internal Control on the Quality of Financial Reporting

Path Coeficient	t_{ccount}	$t_{critical}$	P-value	Conclusion
0.388	2.542	1.96	0.016	Significant

Source: PLS Calculation Result

The results of the first hypothesis test show that the relationship between variable Implementation of Internal Control with Quality of Financial Reporting is shown by coefficient value of 0.388 with t-count 2.542 and p-value equal to 0.016. The value of t-statistics obtained is greater than t-critical (1.960) and the significance (p-value) is less than 0.05. This result means that the Implementation of Internal Control affects the Quality of Financial Reporting and it supports the second hypothesis (hypothesis 2 accepted). The magnitude of the direct influence of the Implementation of Internal Control on the Quality of Financial Reporting: (0.388 × 0.388 × 100%) = 15.0%.

The results of the second hypothesis testing shows that the relationship of internal control implementation variables significantly influence the quality of financial reporting. This result also supports the second research hypothesis where the implementation of internal controls, in which the control environment determines risks and the activities of control, has an effect on the quality of financial reporting.

Effect of Information Technology on the Quality of Financial Reporting

The following test results show the significance of the hypothesis through statistical hypothesis as follows:
Ho.$\gamma 3 = 0$: Implementation of information technology has no effect on Quality of Financial Reporting
Ha.$\gamma 3 \neq 0$: The application of information technology affects positively to the Quality of Financial Reporting

Table 3: Significance Test of the Influence of Information Technology Application to Quality of Financial Reporting

Path Coeficient	t_{ccount}	$t_{critical}$	P-value	Conclusion

0.289	2.097	1.96	0.045	Significant

Source: PLS Calculation Result

The results of the first hypothesis test show that the relationship between variable information technology with Quality of Financial Reporting is shown by coefficient value of 0.289 with t-count of 2.097 and p-value of 0.045. The value of t-statistics obtained is greater than t-critical (1.960) and the significance (p-value) is less than 0.05. This result means that the application of information technology affects the quality of financial reporting which means in accordance with the third hypothesis (hypothesis 3 accepted). The direct influence Application of information technology to the quality of Financial Reporting is equal (0.289 × 0.289 × 100%) = 8.4%.

The results testing of the third hypothesis shows that the relationship of variable implementation of Information System Technology significantly influence the quality of financial reporting. These results also support the alleged or third research hypothesis in which the implementation of Information Systems Technology, has an effect to the quality of financial reporting.

Effect of Quality of Financial Reporting on of Public Accountability

The following test results show the significance of the hypothesis through statistical hypothesis as follows:
Ho.β_2 = 0: The quality of Financial Reporting has no effect on the Implementation of Public Accountability
Ha.$\beta_{21} \neq$ 0: The quality of Financial Reporting affects positively to the Implementation of Public Accountability

Table 4: Significance Test of the Effect of Quality of Financial Reporting on the Implementation of Public Accountability

Path Coeficient	t_{ccount}	$t_{critical}$	P-value	Conclusion
0.678	6.533	1.6	0.000	Significant

Source: PLS Calculation Result

The results of the first hypothesis test show that the relationship between variable of the quality of Financial Reporting with the Implementation of Public Accountability is indicated by the value of path coefficient of 0.678 with a t-count of 6.533 and p-value of 0.000. The value of t-statistics obtained is greater than t-critical (1.960) and the significance (p-value) is less than 0.05. This result means that the Quality of Financial Reporting influences the Implementation of Significant Public Accountability in accordance with the fourth hypothesis (hypothesis 4 accepted).

The magnitude of the influence of the Quality of Financial Reporting on the Implementation of Public Accountability is equal to (0.678 × 0.678 × 100%) = 46.0%. This means that the Quality of Financial Reporting gives 67.8% influence on the Implementation of Public Accountability. Fourth hypothesis test result shows that the correlation of variable of Quality of Financial Reporting has significant influence to Public Accountability. These results also support the fourth research hypothesis that is the implementation of Quality of Financial Reporting has an effect to Public Accountability.

Conclusion

The results show that it is necessary to pay attention to the accountant's competence, the implementation of internal control and adequate information technology as factors that can improve the quality of government financial reporting in Indonesia. A reliable government accountant can reduce the risk of financial misstatement; adequate internal control may reduce the risk of irregularities in financial reporting process in Government Offices. The information technology will support financial reporting process. The government needs to pay attention to this factors to improve the quality of financial reporting. Good financial reporting quality will increase public accountability and increases public trust.

The limitation of the study is that this study is only limited to the West Java Province, it is expected that further research can be upgraded to all areas in Indonesia as a whole to be able to strengthen the results of research. Other limitation is the study does not explore the problem qualitatively, so the future research is expected to be more explorative in finding out the real and problem concerning the government financial reporting and come up with the actual solutions.

The Role of the EU and EMU Membership in FDI Inflow to the Slovak Republic

Ing. Ľubomír Darmo, PhD., University of Economics in Bratislava, Bratislava, Slovakia,
lubomir.darmo@euba.sk

Abstract

The foreign companies produce the major part of the Slovak output. These were established as a result of the inflow of the foreign direct investment. The Slovak Republic has received many investments since the year 2000 in the form of privatization and greenfield investments. Gravity model, comes out from the Newton´s physics, provides information about determinants on foreign direct investment respectively international trade. The membership in the free trade area (as the European Union) and the use of common currency (as the European Monetary Union) is considered to be one of these determinants. Is the EU and the EMU membership really significant determinant influencing the flows of foreign direct investment? Several empirical papers deal with this question and assess the role of the EMU in inflow of foreign direct investment by the use of the gravity model. The paper analyses bilateral inflows of foreign direct investment to the Slovak Republic in the period 2000 – 2012. Mainly, it assesses the role of membership in the EU and using common European currency in influencing investment flows into the Slovak Republic. Nowadays, when "two-speed" EU is discussed, not only membership in the EU, but also adopting common currency is interrogative.

Keywords: gravity model, foreign direct investment, European Monetary Union.

Introduction

The Slovak Republic has entered the European Union (EU) in 2004 together with other transforming countries. The enlargement of the EU by 10 countries is the largest enlargement of the European Union in the history. Some of these countries have consecutive also adopted common currency Euro and became members of the European Monetary Union (EMU). The Slovak Republic has adopted Euro in 2009. The expectation were in increasing international trade, growth of the inflow of foreign direct investment (FDI) and thus increasing the Slovak gross domestic product (GDP), as well as the potential product. Another advantage has lied in no need to exchange foreign currencies what should increase the trade and tourism. Maybe for that reason, Slovak nationals were inclined for the Euro adoption. All along, the Slovak Republic has continued in the transformation process and has privatized many state-owned companies. At the same time, many greenfield investments were allocating within the Slovak Republic. General assumption on the FDI considers the membership in the EU and the EMU as the factors influencing its flows positively. On the other side, stable economic and political environment might attract FDI inflows regardless to the membership in some free trade areas or monetary union. For example, the highest FDI inflow to the Slovak Republic was in 2006, when the Slovak Republic was using own Slovak currency. Contrariwise, The Slovak Republic has adopted Euro in the time of global financial crisis and related sharp decline in FDI flows. Fundamental determinants of FDI inflow are the size of the economy (GDP, economic growth, potential output), potential demand (domestic or foreign), geographical location of country (access foreign market – export oriented production), legal system (mainly law enforcement), labour (unemployment, education or wages) and level of infrastructure. Another factors such as investment incentives, the EU and the EMU membership are considered as complementary and would not attract investments if the fundamental determinants were not satisfactory. Further analysis will be focused on the role of the EU and the EMU membership in influencing FDI inflow to the Slovak Republic. We

will assess these determinants by the use of gravity model including the EU and the EMU membership as variables into the econometric analysis.

Literature Review

The introduction and adoption of common currency affects the economy in two ways. Starting with the disadvantage, it means the abandoned the sovereign monetary policy by the particular country. As a result, country is not able to influence the monetary policy and country lost one of its economy policies. On the other way, the advantage of using the common currency is the decrease in transaction cost and decrease in the risk of exchange rate movements, which leads to the growth of international trade. However, Rose (2000) argues that exchange rates in the Europe were relatively stable also before the Euro introduction and had only small volatility, respectively many measures would be taken to moderate volatility. Monetary union makes impossible countries to compete in market competition as the economic performance of particular country in relation to economy of another country is expressed in the exchange rate, thus in the price of two currencies. However, such competition has stronger effect on the international trade and investment flows as the stable exchange rates with any volatility. For that reason, there must be another advantages for the common currency to be used within the Europe (if considering the EMU).

International relations between particular countries have several channels. The most important is the channel of investment flows, mainly FDI that is assumed to have positive and long-term effect on the host economy. Therefore, a high attention is devoted to the European Monetary Union in analysis of FDI inflow.

Empirical study by Rose uses gravity model, firstly used by Walter Isard in 1954 (Isard at al., 1998). This model analyses the size, respectively the volume of international trade between countries in relation to the factors influencing the trade. The easiest form of the model is as follows:

$$F_{ij} = G * (M_i * M_j)/D_{ij} \quad [1]$$

where: i and j is index for countries, F represents the trade flows between countries i and j, M is the GDP of countries, D is the distance between countries i and j a G is a constant. This simple equation shows that the volume of bilateral trade relates only to the GDP of countries and its distance. Several researchers have adjusted and extend or enlarged the equation about more variables more reflecting the fundamentals of trade between countries.

Rose (2000) uses the extended gravity model. He shows that the membership in monetary union and the volatility of exchange rate really influence the volume of bilateral trade. The enlarged equation has the following form:

$$lnX_{ijt} = \beta_0 + \beta_1 \ln\left(Y_i Y_j\right)_t + \beta_2 \ln\left(Y_i Y_j / Pop_i Pop_j\right)_t + \beta_3 lnD_{ij} + \beta_4 Cont_{ij} + \beta_5 Lang_{ij} + \beta_6 FTA_{ijt} + \beta_7 ComNat_{ij} + \beta_8 ComCol_{ij} + \beta_9 Colony_{ij} + \gamma CU_{ijt} + \delta V\left(e_{ij}\right)_t + \varepsilon_{ijt} \quad [2]$$

where:

- i and j is index for country and t is time,
- X_{ij} is the bilateral trade between countries i and j,
- Y represents real GDP,
- Pop is population,

- D_{ij} is distance between countries i and j,
- $Cont_{ij}$ is dummy that obtain value 1, if countries i and j have the common border and 0 otherwise,
- $Lang_{ij}$ is dummy with value 1, if countries i and j have common language and 0 if not,
- FTA_{ij} is dummy with value 1, if countries i and j belongs to the same regional free trade area and 0 otherwise,
- $ComNat_{ij}$ is dummy that obtain value 1, if countries are part of the same nation, 0 otherwise,
- $ComCol_{ij}$ is dummy with value 1, if countries i and je were after 1945 a colony of the same colonizer country, 0 otherwise,
- $Colony_{ij}$ is dummy with value 1, if the country i has colonized country j or j has colonialized i, 0 otherwise,
- CU_{ijt} is dummy representing the use of common currency, it obtain value 1, if countries i and j use the same currency in time t and it is 0 otherwise,
- $V(e_{ij})t$ is volatility of nominal exchange rates of countries i and j in time t,
- β je vector of exogenous variables,
- ε_{ij} represents error term and other factors.

An important role in the equation has parameters γ and δ. γ represents the effect of monetary union on the bilateral trade. δ reflects to the relation between the exchange rate volatility and bilateral trade. Model includes various variables that have logical justification. Higher level of GDP or higher GDP per capita and the size of the economy positively affect the level of international trade. Contrariwise, distance between countries decreases the level of international trade. These variables are statistically significant and have direction as assumed. Other variables (common border, common language and trade agreements) are also significant and increase the level of trade between countries. The paper has 33,903 bilateral trade observations for 5 years – 1970, 1975, 1980, 1985 and 1990. Among them, in 330 cases have countries use the common currency. Mostly, these countries are small and relatively poor countries. For that reason, extrapolation of the results for the EMU would not be suitable due to the dissimilarity of observed countries and those belonging to the EMU (Rose, 2000). Results of Rose paper are follows. Countries using the common currency have triple higher trade as countries using different currencies. Exchange rate volatility was low, respectively there was an effort to decrease it at zero level. Considering such situation, the international trade between countries would increase by common currency by 12 or 13%. Thus, the introduction of common currency has higher impact on the international trade than the zero exchange rate volatility.

In previous text, the model assessing the bilateral trade between countries was introduced. Now, we are going to deal with the FDI flows. FDI inflow and FDI outflow are important part of the capital movement affecting host, respectively home economies. We already know that membership in monetary union positively relates to international trade. How the common currency affects FDI flows? Paper by Aristotelous and Fountas (2012) deals with this question. They decided to analyse FDI flows instead of the international trade because the increase of the FDI in Eurozone was 469.9% in period 1990 – 2006, while it was only 184.3% when talking to the growth of international trade. They has formed the following equation:

$$FDI_{it} = \beta_0 + \beta_1 GDP_{it} + \beta_2 GDPGR_{it} + \beta_3 RER_{it} + \beta_4 VOL_{it} + \beta_5 DIST_i + \beta_6 EU_{it} + \beta_7 EMU_{it} + e_{it} \quad [3]$$

Endogenous variable is FDI_{it} that represents the overall FDI inflow to the country i in time t. i is index for a country and t represent time period. Exogenous variables are:

- GDP_{it} is the real GDP (output) of country i in time t,
- $GDPGR_{it}$ is the GDP growth,

- RER_{it} is the real exchange rate expressed as the currency basket of trade partners with shares given by the volume of trade,
- VOL_{it} is the change in volatility of exchange rate, it is the standard deviation of exchange rate expressed on monthly base,
- $DIST_i$ is the distance between the capital city of host country from Frankfurt as the financial centre of the EU,
- EU_{it} is dummy variable that obtain value 1, if is country the EU member and 0 otherwise,
- EMU_{it} is dummy relating to the membership in EMU respectively using common currency, it has value 1, if is country the EMU member and 0 otherwise,
- e_{it} is error term and other factors relating to the volume of FDI inflows.

The use of exogenous variables and their assumed relation (direction) to the FDI inflow is the same as in Rose model of international trade. The goal of such expressed model is by the use of regression analysis assess the role of coefficient β_7 (economic and statistical significance). Authors assumes the positive relation of the EMU and FDI inflow, so β7 would have plus sign. To achieve the goal, data from 22 OECD countries for period 1973 – 2006 is used. The time period includes the Breton-Wood monetary system of fixed exchange rates as well as the Kingston monetary system with introducing floating exchange rates (Aristotelous and Fountas, 2012). Paper gives following results. GDP has positive and statistically significant effect on the FDI inflow. The same result is for the real exchange rate and volatility. Distance and FDI inflow relates negatively and this relation is statistically significant. To the contrary, the EU membership has only small impact on the FDI inflow. Variable, they have the highest concern, the EMU membership is significant and positively affects the FDI inflow.

Another paper that deals with the FDI inflow is the paper by Folfas (2011). He focuses on the FDI inflow within the EU27 and the role of taxation in particular economies. Regression equation of his view is:

$$lnFDI_{ijt} = \alpha_0 + \alpha_1 lnGDP_{it} + \alpha_2 GDP_{jt} + \alpha_3 lnD_{ij} + \xi Z_{ijt} + c_{ij} + \eta_{ijt} \quad [4]$$

where:

- i, j a t represents indexes for host economy, home economy and time,
- FDI_{ijt} is the FDI inflow to host economy i from home economy j in time t,
- $GDP_{i(j)t}$ is the GDP of host (home) economy in time t,
- D_{ij} is the distance between economic centres of host and home economy,
- Z_{ijt} represents another variables determining bilateral FDI inflow,
- c_{ij} represents specific effects related to the allocation of investment,
- $ɲ_{ijt}$ is the error term and random variables influencing FDI inflow.

Further on, author add to equation several variables. Among them also dummies we are the most interested such as membership in the EU, use of common currency Euro or entrance of particular countries to the EU at the same time. Another variables in model are corporate tax and dummy variable offshore financial centre. The result shows that the flows of FDI are higher between larger economies. However, in comparison with gravity model analysing international trade, coefficients are lower. The explanation of such situation lays in presently discussed phenomenon of disinvestments and high fluctuation of FDI inflow caused by unrepeatable situations (privatization, huge investment projects, mergers and acquisitions). The three variables relating to the European integration are statistically insignificant. So, the characteristics of particular countries (as the GDP) are more relevant for the decision of investors as the membership in integration area. Naturally, problem might be in use of dummy variables that do not give a true picture of constantly changing processes of integration. Variable corporate tax is statistically significant. In case of its homogeneity, the flows of FDI between countries are decreasing, but the flows with offshore centres are more intensive. Author consider offshore centres

are Cyprus, Luxembourg and Malta. To conclude, corporate tax is an important factor of country sovereignty within the integration area.

The last paper by Ledyaeva and Linden (2006) applies gravity to Russian regions. The endogenous variable is the number of companies from Belarus, Kazakhstan, Ukraine, Germany, United Kingdom and Finland allocated in 76 Russian regions. Equation of the model is as follows:

$$Y_{ij} = b_1 + b_2 GRP_j + b_3 GDP_i + b_4 DIST_{ij} + b_5 AGGL_j + b_6 NR_j + b_7 DV_j + b_8 Moscow + b_9 SKA_j + u_{ij} \quad [5]$$

where:

- b represents coefficients of the equations,
- Y_{ij} is the number of the foreign companies in host Russian region (j) from foreign (investment home) country (i) in 2002,
- GRP_j is gross regional product,
- GDP_i is the GDP of foreign country,
- $DIST_{ij}$ is distance between the capital city of foreign country and capital of particular region,
- $AGGL_j$ is agglomeration effect – the ratio of GRP to the size of a region,
- NR_j represents natural sources expressed as the ratio of mining industry to the overall industry in particular region,
- DV_j is dummy variable measuring the rate of uncertainty that potential investors are facing, it obtain the value of 1 for Belarus, Kazakhstan and Ukraine and value 0 for other countries, this variable might be also explained as the cultural proximity, and common language of these post-Soviet countries with Russia,
- Moscow is dummy with value 1 for Moscow and its regions and 0 for other regions, this variable relates to the advantages of the Moscow position as the capital city of Russian Federation,
- SKA_j is the education, it is the ratio of graduate population to total population in region,
- u_{ij} is the error term.

All variables in analysis, except for NR_j, have have confirmed the assumed relation to the endogenous variable and are statistically significant. Authors have found that the most of the FDI inflow to the Russia is market seeking. It implies the FDI dependency on the GRP of particular region. So, the GRP, as well as the GDP of investment home economy has positive impact on the FDI inflow. The same are acting variables agglomeration effect, common language and culture (DV_j), Moscow and education. To the contrary, the distance has negative effect on the FDI inflow.

Data and Methodology

To assess the role of the EU and the EMU membership in influencing the FDI inflow to the Slovak Republic, the gravity model is used. The main idea of gravity model is to capture variables influencing FDI inflow positively and those that have negative effect. It is assumed that FDI inflow is positively influenced by GDP, respectively the size of an economy and negatively by distance between countries. These prime variables are added with another variables, very often reflecting the interest of authors or the regional conditions (integration area, country, region, etc.). Our goal is to assess the role of the EU and the EMU membership in influencing the FDI inflow to the Slovak Republic.

We use gravity model with added variables indicating membership in the EU and the EMU. The data period is 2000 – 2012 as we are constricted by the availability of data on bilateral FDI inflows. The panel data is used. The cross section units are 20 countries that have allocated in the Slovak Republic the most

investments during the research period. These investments represent 98.14% of all foreign direct investments. The list of countries with their shares of FDI inflow to the Slovak Republic on total FDI inflow is given in Table 1.

Table 1: The list of countries

Country	Share of FDI inflow from a particular country on total FDI inflow
Argentina	0.39 %
Austria	11.22 %
Belgium	0.84 %
Canada	0.36 %
Cyprus	6.74 %
Czech Republic	9.69 %
Denmark	1.14 %
France	8.10 %
Germany	20.52 %
Hungary	3.06 %
Italy	11.35 %
Korea, Republic of	7.18 %
Liechtenstein	0.76 %
Luxembourg	4.04 %
Netherlands	8.66 %
Spain	0.81 %
Sweden	1.20 %
Switzerland	1.00 %
United Kingdom	0.42 %
United States	0.65 %

Source: author, OECD.Stat

Endogenous variable of the equation is bilateral FDI inflow from foreign (investment home) country to the Slovak Republic (host country). The exogenous variables are GDP of the Slovak Republic, GDP of the foreign countries, distance between the Slovak Republic and home country of investments and four dummies relating to the integration processes within the Europe. First dummy represents the membership in the EU. In this case, it obtain the value of 1 and it is 0 otherwise. Second dummy represent the membership in the EMU and using common currency Euro. Third and fourth dummies are going even deeper to the integration processes. These are EU_pair and EMU_pair. The dummies have the value 1 if both countries (partners) in country pair belong to the EU, respectively to the EMU in the same time. In other words, they represents a common membership in the EU or the EMU. The Data source is OECD and World Bank. The description of data used is given in Table 2. The descriptive statistics of data is summarized in Table 3.

Table 2: The characteristics of variables

Variable	Description	Source
$FDI_{SVK,j,t}$	bilateral inflow of foreign direct investment from foreign (investment home) country j to the Slovak Republic (host country); million USD, current prices	OECD.Stat, OECD
$GDP_{SVK,t}$	gross domestic product of the Slovak	World Development

	Republic; million USD, constant 2010 prices	Indicators, World Bank
$GDP_{j,t}$	gross domestic product of the foreign (investment home) country – origin of investment, million USD, constant 2010 prices	World Development Indicators, World Bank
$DIST_{SVK,j}$	distance between capital city of the Slovak Republic and capital city of foreign (investment home) country; kilometres	European Commission distance calculator for Erasmus programmes *

For further analysis, we have check used series for the stationarity by using Levin, Lin and Chu test of common unit root and the Im, Pesaran and Shin test of the unit root for each unit, i.e, per country. Stationarity have been tested for the $FDI_{SVK,j,t}$, $GDP_{SVK,t}$, and $GDP_{j,t}$. FDI inflow is stationary at level. The Slovak GDP and GDP of investments home countries are stationary at first difference. The result of tests is given in Table 4. Purposely, we do not make log transformation of data. If we do that, we would lose data on FDI (observations) with negative and zero values. It is the reason, why we give preference to first difference. We have not test $DIST_{SVK,j}$ due to this variable is the same for country-pair and does not change in time.

Table 4: Result of panel unit root tests

	$FDI_{SVK,j,t}$		$d_GDP_{SVK,t}$		$d_GDP_{j,t}$	
Method	statistic	prob.	statistic	prob.	statistic	prob

Source: author, EViews

Because of the first difference form of $GDP_{SVK,t}$, and $GDP_{j,t}$, which are stationary, we use them to formulate the equation. The equation we apply is as follows:

$$FDI_{SVK,j,t} = \beta_0 + \beta_1 \mathrm{d_GDP}_{SVK,t} + \beta_2 \mathrm{d_GDP}_{j,t} + \beta_3 DIST_{SVK,j} + \beta_4 EU_{SVK,t} +$$

$$\beta_5 EU_pair_{SVK,j,t} + \beta_6 EMU_{SVK,t} + \beta_7 EMU_pair_{SVK,j,t} + \varepsilon_{ijt} \quad [6]$$

Firstly, we will run the regression with the use all variables. If some of the variables are going to be statistically insignificant, we will omit them from the equation and run it again. After then, we will be able to decide, if the membership in the EU and the EMU has relation to the FDI inflow to the Slovak Republic.

Results

As obvious from the literature review, we assume the positive relation between FDI inflow and the Slovak GDP, as well as foreign country GDP. The Slovak GDP measures the size of the economy and thus also the potential demand. For that reason, a higher GDP induces a larger FDI inflow. Similarly, the higher the investments home economy, the more opportunities of home companies to invest the "unused" domestic sources abroad. To the contrary, a negative relation is assumed in variable distance. However, due to the very easy and fast movement of capital, the distance would not play any role. This is the difference between analysis of FDI inflow and international trade, where in the distance means additional cost of trading (e.g. transportation cost). We assume the positive effect of all four dummies on the FDI inflow. The membership in the EU and the EMU would increase the FDI inflow as the membership might be considered as the proxy for fiscal and monetary stability. The EU_pair and EMU_pair dummies would also be positive. These variables just heighten the effect of the EU and the EMU membership and are focused on assessing the common membership of countries in the EU and the EMU.

We have run regression by using all exogenous variables. The result shows that only variables $d_GDP_{SVK,t}$ and $EMU_pair_{SVK,j,t}$ are statistically significant. The Slovak GDP is influencing the FDI inflow positively. However, the common membership in the EMU has negative sign and is significant only at 10% level. (Table 5, Model 1). We assume that this negative sign is associated with the decrease in FDI inflow after financial crisis of 2007/2008, right when the Slovak Republic has adopted Euro in 2009 and has joined to the large group of countries using common currency. Almost half of these countries belongs to our sample. The relation between the decreasing FDI inflow after the financial crisis and the adoption of Euro by the Slovak Republic so might be wrongly considered as the negative. Other variables in the Model 1 are insignificant. For that reason, we have omit them form the equation. We presume that by omitting variables, EMU_pair lose its "very poor" significance due to significant $GDP_{SVK,t}$ will capture it. This assumption is confirmed when omitting all insignificant variables from Model 1. Result in Model 2 (Table 5, Model 2) shows that only variable measuring the economic performance of the Slovak Republic is statistically significant in attracting the FDI inflow from foreign countries. It means that only GDP of host country is determinant of bilateral FDI inflow. Variables expressing the membership and effect of the EU and the EMU membership have not significant relation to FDI inflow. We might conclude that entering the EU and adopting the common currency Euro has not impact on the bilateral FDI inflow to the Slovak Republic. Only determinant influencing the inflow is the size and potential of the economy expressed by the real GDP.

Table 5: The relation of exogenous variables to FDI inflow to the Slovak Republic

Conclusion

The membership in the integration area or the use of common currency might induce the impression of its positive impact on the FDI inflow. However, the fundamental determinant influencing the FDI inflow is the GDP of a host country, respectively its growth. The GDP represents the size and the performance of the economy, where the investment has to be allocated. The development of the GDP is often an indicator of the economy "health". The GDP growth in a long run means the improvement of the macroeconomic variables and is associated with the economic and usually also with political stability. Contrariwise, the decrease in the GDP is regarded as potential crisis and instability. For that reason, investors are concern about this factor as the main determinant of their decision making process. The membership of a country in the EU or the EMU is not a fundamental FDI inflow determinant. Membership in the EU and the EMU is considered as the guarantee or security of fiscal, and monetary stability, as well as political stability. In present environment of uncertainty of future development of common currency Euro and the future of the European Union itself, the membership in the EU and the EMU does not play significant role in FDI inflow. In other words, the FDI inflow to the Slovak Republic does not relate to the EU and the EMU membership and is affected only by the Slovak GDP. We might conclude that the using of common currency and the membership in the European Union does not automatically increase the FDI inflow. As the result of the analysis shows, the membership of the Slovak Republic in the European Union and the European Monetary Union, as well as the membership of the country of investment at the same time in this integration areas does not induce the FDI inflow to the Slovak Republic. The only significant determinant relating to the FDI inflow so consist of the Slovak GDP as the measure of its economic performance.

Online Marketing as Part of the Internationalization Strategy An Analysis over Website Communication

Lidia Alexa, "Gheorghe Asachi" Technical University of Iași, Iași, Romania, lidia.alexa@tuiasi.ro

Silvia Avasilcăi, "Gheorghe Asachi" Technical University of Iași, Iași, Romania, silvia.avasilcai@gmail.com

Abstract

The profound changes in the higher education global environment had a significant impact over Romanian universities and so, internationalization gained a lot of importance on the political agenda as one of the strategic goals included in the 2014-2020 overall higher education strategy.
In this context, the article aims to analyze the internationalization process from a marketing perspective, by investigating the use of website communication by Romanian public universities in order to promote their educational offer and to increase the number of inbound international students.
The research methodology involved an in-depth analysis of 49 public universities' online strategies, by embedding their websites accessibility, design and interactivity, organization of content, SEO (Search Engine Optimization) results, as well as their specific content strategy in presenting their educational offer based on a list of specific terms considered relevant by prospective students in search of study abroad programs.
In the next stage of the study, the results were further analyzed against the ones obtained from applying the same evaluation on the websites of the top 10 universities ranked in the Webometrics Ranking of World Universities, in order to obtain a comparative imageUse the word "Abstract" as the title for the abstract section. The abstract should be no more than 250 words. It should capture research motivation, research Design/methodology, and main findings and implications. The abstract should provide an excellent summary of the paper.

Keywords: content analysis, higher education internationalization, online marketing strategy, university website.

Internationalization Context, Opportunity and Evolution

The concept of internationalization of higher education institutions has gained a lot of attention in the academia and so there is a vast literature discussing the conceptualization, the characteristics, the advantages and challenges of internationalization for universities and students alike. Kehm and Teichler (2007), after screening a broad range of publications on issues relating to internationalization in higher education, identified seven broad themes that have dominated the research conducted on this specific topic, namely, mobility of students and academic staff, mutual influences of higher education systems on each other, internationalization of the substance of teaching, learning, and research, institutional strategies of internationalization, knowledge transfer, cooperation and competition, national and supranational policies as regarding the international dimension of higher education.

Our research is focused mainly on two elements, specifically: mobility of students, more particularly, incoming students in Romanian universities and institutional strategies of internationalization conducted by Romanian public universities.

The study is significant due to the paradigm shift imposed by the need to align all higher education institutions strategies according to the internationalization practices and trends (Vardhan, 2015).

The impact of this paradigm shift is relevant, because, for a very long time, Romanian Higher Education Institutions have been focused solely on providing educational services to those who could meet their prescribed admission criteria and were operating in a supply-side market, which meant that their marketing efforts were limited to a number of unidirectional promotional actions. This strategy proved to be successful due to the high number of prospective students and the relatively limited number of competitors.

The decreasing number of domestic students and the increased global competition for educational services forced Romanian public universities to rethink their general strategy and to tailor their marketing efforts in order to better suit the student-customer information and communication needs. In order to do this, universities need to become more market oriented and this is by no means, an easy task, as there is a constant debate regarding the commercialization of higher education.

In this specific context, internationalization became a public policy priority also because the global number of international students rose by more than 75% since 2000, reaching 3.43 million in 2010 and is projected to reach 8 million by 2025 (WorldBank, 2011).

In terms of statistics and data accuracy, Rumbley (2012), states that the data regarding the international mobility of students are unclear and inaccurate for many reasons that range from the complexity of the phenomenon to the actual process of collecting data and so throughout the research we relayed on the Eurostat Learning mobility statistics, as shown in figures no. 1 and 2 The lack of specific statistical data for each of the Romanian universities included in the study is one of the research's limitations.

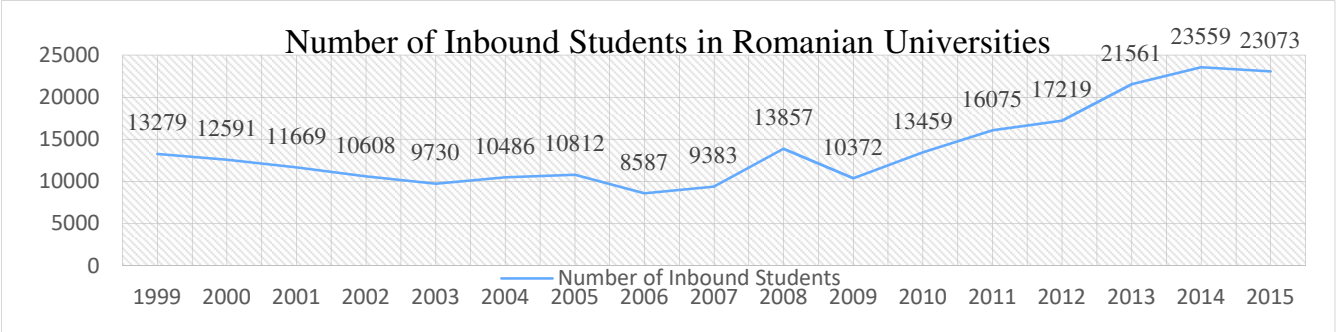

Fig. 1: The number of inbound students in Romanian Universities

The Eurostat Learning mobility statistics showed that starting with 2009 the number of students from abroad enrolled in higher education institutions in Romania has been in constant increase, with a peak of 23,559 students in 2014, out of which 8,521 in Bachelor programs, 14,534 in Master programs and 504 in Doctoral programs; however, these numbers represent less than 3% of the overall number of tertiary education graduates in 2014.

In terms of field of study, the data for 2014 showed that 42.48% of the students from abroad are studying in the" health and welfare" fields, 18.2% are in the "social sciences, business and law fields", 13.37% are in the "agriculture and veterinary fields" and 12.27% are in the "engineering, manufacturing and construction" fields.

At the same time, the inbound mobility rate has been steadily increasing as well as showing in figure 2.

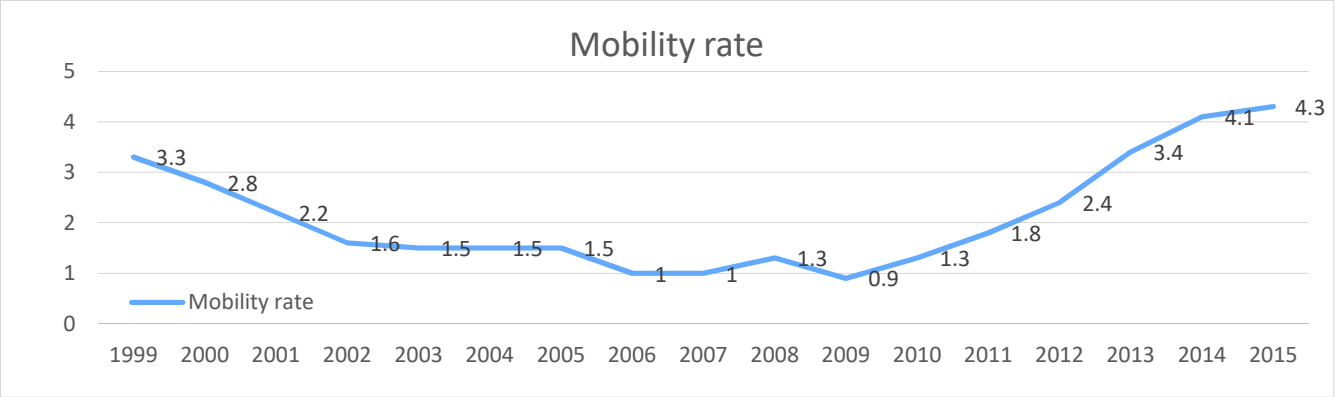

Fig. 2: Mobility rate

Although, Romanian higher education institutions are autonomous, they must comply with strict quality requirements in terms of the number of foreign students they can enroll; and while in most cases, universities indicated that they have specific targets for incoming and outgoing students, these targets did not seem to be officially adopted by the institutions since they did not present any official document (Deca L. et al, 2015).
An analysis previously conducted (Deca L. et al, 2015) highlighted that although universities would like to increase the number of incoming foreign students, the vast majority do not have a coherent strategy in place that could include advertising the institution's academic programmers, foreign language/joint degrees programs or communicating its unique selling points.

As previously stated, some of the reasons for the limited number of foreign students enrolled in Romanian universities is the lack of visibility of the English language programs and the insufficient use of online marketing instruments.

Universities Websites as Marketing Tools in the Internationalization Process

In any high involvement online purchase, such as the decision to pursue a study abroad program, providing detailed and up-to-date information and building trust with the prospective clients is essential. Urban et al. (2000) state that trust is built in a three-stage, cumulative process that establishes (1) trust in the Internet and the specific Web site, (2) trust in the information displayed and (3) trust in delivery fulfillment and service.

In order to achieve this, universities have to better understand the consumer behavior and specific information needs and expectations and act online and offline accordingly.

From a marketing perspective, websites can be seen as promotional outlets set in place in order to achieve a business or organizational goal (Apperson, 2015) and in Bishop's (2013) opinion when it comes to researching study abroad programs, the university websites often act as the first reference point. She explains that study abroad websites cater to prospective applicants by using verbal and visual imagery to engage student populations. Because websites tend to be the first choice for getting information about study abroad and hence are a crucial promotional instrument, it is important to observe and analyze the way universities are exploiting website communications in order to attract international students.

Some website scholars explain that all website communication has an ultimate goal: to "achieve positive response action from every visitor" (Sharp, 2001) and this could refer to a visitor remaining on the website for an optimum period of time, downloading content from the site, forwarding content to another person, purchasing an item, subscribing for more information, or returning to the website at a later time. From a higher education marketing perspective, when it comes to websites addressed to potential international students, the main goal should be to engage visitors so they would use the website for further direct inquiries, to apply to a study abroad program, or to share the information with other people interested in the study abroad process (Apperson, 2015).

In Quinn's (2013) opinion the university website is "the ultimate brand statement" and the homepage is a key component in the student experience that has a determining role in his further decisions and that is why it needs to be intuitive and uncluttered.

The need for a consistent and coordinated online marketing effort is confirmed by the results of the the *2014 E-Expectations Report - The Online Preferences of College-Bound High School Seniors and Their Parents* (2014) which revealed that 62% of students prefer web-based resources for learning about colleges; 40% of the respondents declared that they use a mobile device nearly all the time for web browsing while 71% said that they have looked at a college website on a mobile device.

Students and parents both rated college websites as the most influential resource for college search, with 77% of seniors and 69% of parents listing them as influential. More than half (53 %) of students listed the email as the second most influential resource, while 42 % of parents listed college planning sites as their second choice, just ahead of email (40 %).

The report also showed that when students access a university website, they look for: academic program listings (over 40%), cost (over 30%), scholarships (over 30%), financial aid (over 30%), academic program details (over 20%), housing details (over 20%), enrollment/admissions information (over 15%), and student life information (over 10%).

Another study, the 2015 mba.com *Prospective Students Survey Report* (2015) listed the school websites as the most important marketing channel and information sources prospective students use to decide on schools or programs with a Reach (percentage of prospective students who consult the source) of 83%, an Influence (percentage of prospective students who ranked the source as extremely or very influential to their decision making process) of 53% and an Impact Score (calculated response of reach and influence scaled to 100) of 100.

According to an EUROSTUDENT report (2016) students who are in the planning phase to study abroad rated the "lack of information provided by the home institution" as the second-largest obstacle to enrollment abroad (28 %).

Two other relevant elements are revealed by a research conducted by Gomes and Murphy (2003) and refer firstly, to the fact that half of the students involved in the study used search engines to locate an institutions website, which means that universities need to invest constantly in SEO (Search Engine Optimization) and secondly, 1 out of 3 students emailed the university for further details and 4 out of 5 students declared that the institution's email response influenced their choice for enrollment.

Material and Methods

Though not uncharted academic territory, the study abroad experience and the higher education internationalization process is almost never examined from a digital communication perspective, focusing on the way universities describe, promote and "sell" not only their academic services but the general international experience.

In an effort to address this particular issue, this research involved a two stage in-depth analysis over Romanian public universities online marketing strategies, regarding international students, namely the presentation websites. The first stage of the analysis focused on evaluating, with an automatic website evaluation tool, the English version of the websites of 41 public universities (6 of the public universities didn't have an English version and 2 were blocked for an external analysis with automated tools) in terms of Search Engine Optimization, Content, Design, Performance and Accessibility. This phase of the website evaluation process relayed on automated tools, namely www.site-analyzer.com. The first 10 universities ranked in Webometrics Ranking of World Universities were also analyzed using the same automated tool for comparison reasons.

Considering the purpose of the evaluation, which is to clarify the extent of online correlation with other institutions/countries or to know the ranking of a website and how much traffic it attracted (Zahran et. al 2014) the research team opted for using automatic website evaluation tools, because according to the literature, automatic website evaluation tools are fast, consistent, produce unbiased results, and obviate the shortage of experts and inconsistent results between them (Ataloglou and Economides, 2009; Dingli and Mifsud, 2011; Dominic et al., 2010, Zahran et. al). Also, these tools can offer an initial overview of the status of a website (Olsen et al., 2009). However, automation of website testing is an evolving method that cannot be considered efficient (Al Juboori et al., 2011) on its own and should not replace human evaluators, but assist them (Berntzen & Olsen, 2009; Brajnik, 2008; Dingli & Mifsud, 2011). Noruzi (2006) considers that the webometric method is an imperfect tool to measure the quality of websites while Ivory and Chevalier (2002) believe that automation is a useful complement to standard evaluation techniques.

The fact of the matter is that manual evaluations provide more details than automatic tests, which cannot capture the whole picture, so considering all the above, the second stage of the analysis focused on the content considered as essential in the decision making process of students researching study abroad programs (academic program listings, cost, scholarships, financial aid, academic program details, housing details, enrollment/admissions information and student life information).

When applied to Web-based content, the changing content can be problematic (Kim & Kuljis, 2010). However, some researchers claim that it can be overcome by rapid data collection (McMillan, 2000) and downloading websites (Koehler, 1999) and so the content analysis was conducted over a 4 week period.

The Context Unit of the analysis was the homepage and the Coding Unit was based on the eight content categories that students listed as important in their quest for information when choosing an abroad study program (academic program listings, cost, scholarships, financial aid, academic program details, housing details, enrollment/admissions information and student life information).

Data Analysis and Results

Website performance analysis

According **to** Webometrics Ranking of World Universities, which uses a ranking system based on a composite indicator that takes into account both the volume of the Web contents (number of web pages and files) and the visibility and impact of these web publications according to the number of external inlinks (site citations) they received **in 2016,** only 3 Romanian universities ranked in the first 1000 universities: "Babes-Bolyai" University Cluj-Napoca (787), University of Bucharest (860) and "Alexandru Ioan Cuza" University Iasi (879).

A previous research conducted on Romanian universities websites (Alexa et. al, 2012) revealed that 75% of all public universities had an English version of their website, while the current analysis showed that: 88% of all public universities had an English version of their website, the increased number showing a higher interest toward internationalization. Out of the 6 universities that didn't have an English version 2 had specific sections in their website for Erasmus students in English, but were not included in the analysis.
